Legislative Bodies wherein the Hon. Speaker and the Legislature Secretariat staffi will be discussed and it is entirely left to you, Sir. . ."

MR. SPEAKER:—"Four hours for this Demand and so the whole day will be taken up."

*THE HON. SRI B. GOPALA REDDI:—"There is a little constitutional change that has come over under this Demand. Previously under the Government of India Act, the Speaker's salary and the Deputy Speaker's salary were voted and not charged and the Ministers' salaries were charged previously, but now under the present Constitution of India, Ministers' salaries have become voted and your salaries have become charged. So, that is the constitutional change. Perhaps, in consonance with the position of the Speaker, his salary should be a charge on the revenues of the State and not voted as the salaries of Ministers. Previously the position was otherwise. I think, it is a welcome change and, as I said, it is in consonance with your exalted position. So, Sir, I move the Demand."

MR. SPEAKER:—"Motion moved—

'That Government be granted a sum not exceeding Rs. 55,10,300 under Demand IX—Heads of States, Ministers and Headquarters Staff.'"

JANAB M. MUHAMMAD ISMAIL:—"Mr. Speaker, Sir, I move—

'That the allotment of Rs. 55,10,300 for Heads of States, Ministers and Headquarters staff be reduced by Rs. 100 to discuss the failure of the Government to place a definite

The awkward age

—so it used to be called. We now think the Teens have a grace of their own and we encourage their new interest in appearances. Footwear is still a problem because the Teens are still growing. Clarks, who take the Teens seriously, make good-to-look-at shoes with a little extra space at the toe for growth. These shoes are made in several widths to each size, the right width decided by means of Clarks special footgauge which measures for girth as well as for length and breadth. A well-fitted Clarks shoe keeps smart and, even more important, it keeps growing feet straight and strong.

Protein deficiency

Some new facts about amino acids

EVERY physician is familiar with the problem of delayed convalescence associated with loss of weight. Recent medical research into the metabolism of protein after illness, injury or shock, throws a new light on a vexed problem.

Some ten amino acids are known to be essential in the diet. They must be ingested, for they cannot be made in the body. In this they resemble most vitamins, but unlike vitamins, they cannot be stored. By building tracer elements into synthetic essential amino acids, it has been possible to show that these substances are immediately built into protein tissues. From this it follows that tissue protein is constantly being broken down and built up anew.

The acute stage of illness or injury is marked by a vastly increased urinary nitrogen excretion. This catabolic phase, as it is called, is believed to be due to protein-raiding on the part of the patient in order to provide an increase of the essential amino acids needed for repair. After a short initial period, it is known that a high intake of first-class protein in the diet is capable of reversing the negative nitrogen balance.

Where there is loss of weight, there is frequently loss of appetite also. The ideal protein diet, therefore, is one which will tempt the palate and which will throw no undue strain on the digestive processes.

The particular advantages of Brand's Essence in the above conditions are:—

1. **It is soluble animal protein of high biological value.**
2. **It promotes gastric secretion.**
3. **It is extremely palatable.**
4. **As it can be taken as a jelly or a liquid, it is easy to ingest, digest and absorb.**

HIGHLY SATISFACTORY RESULTS
follow the adoption of
SALTS PATENT COLOSTOMY BELT

Since we first introduced this Belt we have supplied many hundreds, and the results have been highly satisfactory. Outstanding advantages are: (1) Receiver is detachable and sterilizable by boiling; (2) Bag easily removed without removal of belt; (3) Bag easily emptied and washed; (4) No crevices or metal fittings to hold faeces; (5) Smell reduced to a minimum; (6) Less bulk than the old style. Bags are easily and economically replaced. Further details and Measure/Order forms available to professional people on request.

Appointments at London address: 1, STANLEY HOUSE, 103, Marylebone High Street, London, W.1 Tel.: Welbeck 3034

Guarantee
We guarantee Aseptic Belts to remain free from defects in workmanship or material for a period of three years from the date of supply. Should any defect develop during this period, we undertake to repair or replace the Belt free of charge.

TUBERCULOSIS SERVICE IN SCOTLAND

REPORT OF A SUBCOMMITTEE* APPOINTED JOINTLY BY THE CENTRAL CONSULTANTS AND SPECIALISTS COMMITTEE OF SCOTLAND AND THE TUBERCULOSIS SOCIETY OF SCOTLAND

In June, 1949, the Central Consultants and Specialists Committee in Scotland and the Tuberculosis Society of Scotland set up a Joint Subcommittee to report on the effect of the National Health Service on the Tuberculosis Service, with special reference to specialists within that service. The Subcommittee has drawn up a report of the highest importance, not only to Scotland but to the rest of Great Britain. It is here reproduced in full.

Introduction

We have interpreted our remit as requiring us to consider the trend of development of the tuberculosis service, and, in association with this, the number of hospital beds which would be required for an optimum service, and the staff establishment which would be necessary to operate such an optimum service. We have given consideration to the training appropriate for specialists in this service and the relationship of these specialists to the medical officer of health. Our conclusions are contained in Part I of this report.

At an early stage in our deliberations we found our discussions constantly turning to the problems inherent in the present serious situation in the management and control of tuberculosis in Scotland. We accordingly prolonged our discussions in the hope of offering some suggestions on how this crisis might be overcome. These suggestions are contained in Part II of this report.

PART I

Historical

The clinico-pathological studies of the great hospital clinicians of the nineteenth century contributed very greatly to our knowledge and understanding of many diseases, among them the dreaded phthisis. These studies and Robert Koch's crucial discovery of the tubercle bacillus in 1882 established beyond all doubt the infectious character of the disease. Its importance as a problem in public health was thus starkly presented. This discovery, the prevalence of the disease, its deadliness, and its tragic social consequences all combined to throw out a challenge which was soon taken up by able and imaginative doctors. Methods of treatment were revolutionized and the value of the sanatorium regime of rest, fresh air, and good diet became quickly established. At first the influence of climate was misunderstood and exaggerated. It was Sir Robert Philip who placed the sanatorium in its proper perspective by associating it, as he did in Edinburgh between 1887 and the end of the century, with a properly devised dispensary and domiciliary service. Philip's concepts have guided the subsequent development of the organized tuberculosis services of this country, of which he is acknowledged to have been the founder.

It has been the customary pattern of the evolution of social services in our country that once an enterprise has been successfully set on foot by the voluntary efforts of its pioneers it is taken over for development by public authority. The tuberculosis service was no exception, and in 1912 it became the responsibility of the major local authorities. From then until 1948 the great bulk of sufferers from pulmonary tuberculosis were treated in institutions administered and staffed by these authorities. So far as the medical staff were concerned this had one unfortunate consequence, in that it tended to keep separate those who worked in dispensaries and those who worked in sanatoria or hospitals. In general, whilst the former aimed at becoming medical officers of health, the professional goal of the latter was a physician-superintendentship. This dichotomy was a defect, undesirable in the interests both of the individual patients and of the service. It arose chiefly in the service of the larger local authorities, who, however, by 1948 had gone far towards remedying it by staff integration.

There has been an important development within the tuberculosis field during the past two decades which has a significant bearing on any consideration of staffing problems within the service. During this period there has occurred a remarkable change in the therapeutic outlook, a steadily increasing use of active surgical procedures, and, more recently, the introduction of antibiotics and other forms of chemotherapy to supplement the old conservative

*The following were appointed by the Central Consultants and Specialists Committee of Scotland: Dr. J. G. M. Hamilton, Edinburgh (chairman); Dr. G. J. Cleland, Mauchline; Dr. I. Simson Hall, Edinburgh; Dr. A. Lyall, Aberdeen; Mr. T. Murray Newton, Glasgow; Dr. A. Smith, East Kilbride. The following were appointed by the Tuberculosis Society of Scotland: Professor Charles Cameron, Edinburgh (resigned); Dr. C. W. Clayson, Lochmaben; Dr. D. G. McIntosh, Dundee; Dr. A. Maclean, Glasgow; Dr. W. A. Murray, Drem. Dr. D. Bell, Aberdeen, and Dr. G. J. Summers, Edinburgh, were co-opted. Dr. E. R. C. Walker acted as the secretary of the subcommittee.

The subcommittee invited to assist them at particular meetings Dr. W. G. Clark, M.O.H. City of Edinburgh, and Miss M. O. Robinson, Chief Nursing Officer, Department of Health for Scotland, who are, of course, not responsible for the opinions expressed in the report.

sanatorium regime. A consequence of this change has been that the tuberculosis specialist is becoming more closely associated with the practices and methods of the general hospital. Indeed, it might almost be said that a cycle is being completed, and that tuberculosis, after a long period of relative segregation, is returning to the wide fold of general medicine.

Organization and Administration

The administration of the major part of the tuberculosis service has now become a function of the regional hospital boards. We agree that this change is desirable, for we feel that the initial diagnosis, in-patient or out-patient treatment, and aftercare of a person suffering from tuberculosis constitute a single clinical problem manifestly coming within the province of the hospital and specialist service under the regional hospital boards. We feel that division of function as between hospital and dispensary could not improve the working of the service, and indeed could only hamper its efficiency. We therefore return to the original conception of Philip of a combined hospital and dispensary unit served by a single medical staff. It seems most desirable that doctors working in this service should utilize and enhance their experience and skill by practice in out-patient diagnostic and therapeutic work, in the treatment of in-patients within the hospitals or sanatoria, and in diagnostic, therapeutic, follow-up, and preventive work in the homes of the people. On grounds of general principle we also feel that those who conduct the ancillary services of mass radiography and B.C.G. vaccination should have direct association with and interest in the other aspects of the service; they should not be condemned to long periods of repetitive routine without the stimulus of varied work. Such integration is no new concept. In Glasgow, for example, development had already proceeded far along these lines before the introduction of the National Health Service. It is our contention that the medical measures required for the control of tuberculous infection in the population at large are so intimately bound up with the care of persons suffering from the disease that they should be an integral part of the tuberculosis service administered by the regional hospital boards. We conceive that, apart from their statutory duties with reference to notifications and the Tuberculosis Register, the functions of the local health authorities through the medical officers of health should be concerned with provisions of a social and environmental character.

The following paragraphs summarize the general policy which we advocate concerning this aspect of the service:

(*a*) There should be close collaboration between the tuberculosis physician and the medical officer of health for the exchange of information and the integration of their separate functions.

(*b*) For the purposes of prevention of the spread of tuberculous infection and of the care and aftercare of the tuberculous patient the regional hospital board should provide the services of medical personnel and the local health authority should provide the services of health visitors, who, however, so far as their clinical work is concerned should be under the control of the senior tuberculosis physician.

(*c*) The work of diagnosis and treatment and of aftercare and prevention are in the modern view so closely related that no useful purpose would be served by requiring the tuberculosis physician and his staff to spend prescribed portions of their time in the service of the regional hospital board on the one hand and the local health authority on the other.

(*d*) The regional hospital board's staff should be responsible for domiciliary consultations at the request of general practitioners; for prescribing specialized domiciliary treatment, in the carrying out of which they should co-operate with general practitioners and health visitors; for the dispensary diagnostic service; for hospital treatment; for clinical aftercare; for the examination of contacts; and, so far as practicable, for the isolation of infection.

(*e*) The medical officer of health should be responsible, on behalf of the local health authority, for the provision of suitable accommodation (houses, shelters, etc.); beds, bedding, and nursing equipment; extra nourishment and clothing; domestic help; the boarding out of children from infected households; the establishment and management of preventoria. In all these matters he should have the advice of the tuberculosis physician.

(*f*) The part played by almoners and social welfare workers in rehabilitation and economic welfare is important. If these workers remain in the employment of the local health authority arrangements should be made whereby they work under the tuberculosis physician so that the latter may keep the medical officer of health informed of the medical aspects of the rehabilitation of individual patients.

(*g*) Mass radiography is a case-finding procedure. It should be regarded as a means leading to early treatment and thus to the prevention of the spread of tuberculous infection. The provision of a mass radiography service should therefore be the responsibility of the regional hospital board, whose officers should constitute the medical staff of the mass radiography units. At the same time much of the detailed administrative work required in the operation of a mass radiography service could be best carried out by the medical officer of health.

Development of the Tuberculosis Service into a Chest Service

There has been a noticeable but natural trend over the past two or three decades for the tuberculosis specialist to concern himself with pulmonary diseases other than tuberculosis. This appears to us to have come about through the introduction and development of such modern techniques as radiology, bronchoscopy, thoracic surgery, and chemotherapy. Furthermore, many tuberculosis specialists have deliberately changed the descriptive titles of their clinics and of themselves in an attempt to overcome the stigma associated with tuberculous disease so as to encourage patients to obtain specialist advice at an early stage. In this way there have arisen the "chest clinic" and the "chest physician." However, this development of the tuberculosis service into a specialist service for all respiratory diseases has been handicapped by the fact that many tuberculosis officers have in the past received a training which has been inadequate to qualify them for the specialist handling of non-tuberculous pulmonary diseases. In the past, tuberculosis officers entered the service of local authorities and, as we have pointed out, in many instances aimed at promotion, not to clinical posts as superintendents of sanatoria but to administrative posts as medical officers of health. It was therefore necessary for the young man in this field to take the Diploma in Public Health and, since his time was limited, to eschew the higher general medical qualifications, such as the M.R.C.P. Nevertheless, many energetic tuberculosis officers, with inclinations strongly developed towards clinical medicine rather than towards administrative work, have by experience and through their own initiative made themselves expert in respiratory diseases other than tuberculosis.

The tuberculosis service should be encouraged to develop into a full chest service working in close relationship with the general hospital and specialist service. At the same time those who are and will continue to be heavily involved in the diagnosis and care of patients suffering from tuberculous disease of the lung, which indeed must remain their predominant concern, will have special knowledge of the protean manifestations of tuberculous infection. Accordingly they should still be associated with the care of patients suffering from non-pulmonary tuberculous diseases, though there is obviously need for the services of appropriate "anatomical" specialists in the diagnosis and treatment of these diseases.

We therefore propose the following definition of the scope of the future chest service: (*a*) The diagnosis and treatment of tuberculous and other diseases of the chest.* (*b*) Co-operation with the appropriate specialists in the diagnosis and treatment of other forms of tuberculosis. (*c*) The aftercare of persons who have suffered from tuberculous disease. (*d*) The prevention of the spread of tuberculous infection. (*e*) Research and training.

Training

If the tuberculosis service is to develop into an adequate chest service the training of its officers must be altered and improved. The time has now come when the portal of entry into the specialty should be through general medicine and the M.R.C.P. rather than through the public health departments and the D.P.H. We feel that the tuberculosis or chest specialist ought to be thoroughly grounded in general medicine before taking up training in the specialty. With this idea in mind, and having made reference to the reports of the committees of the Royal College of Physicians of London on the training of various specialists, we offer the following recommendations regarding the period and nature of the training of chest physicians:

1st and 2nd years after graduation: Either (*a*) Two years in house-officer posts (of which one post must be in general medical wards); or (*b*) one year in house-officer posts (of which one post must be in general medical wards) and one year in general practice. The posts other than those in general medical wards might usefully be, *inter alia*, in infectious diseases hospitals or sanatoria.

3rd year—Junior registrar
4th year—Registrar
5th year—Registrar
} General Medicine. Obtains M.R.C.P.

6th year
7th year
8th year
} Senior registrar appointments within the chest service.

During the senior registrar period the aspirant should be encouraged to broaden his experience by travelling and by undertaking research work, or by working in non-clinical departments, such as those of anatomy or physiology. During this period he might with advantage acquire the Certificate in Public Health, but we see no particular advantage to be gained by his undertaking the longer and more elaborate course for the Diploma in Public Health.

It is very desirable in our view that the trainee specialist should not spend his early registrar years within the specialty. These years should be spent in the broader field of general medicine, and more closely specialized work should be taken up only after this period of general training has been completed—namely, at the senior registrar stage, or at least not earlier than the fifth year after graduation. It has been argued that this would leave the chest service deprived of junior men for doing routine hospital and dispensary work. However, the routine work referred to is in fact fundamentally important for the training of the chest specialist, and no senior registrar should feel demeaned by having to do such work after he has entered upon the training for his specialty.

*In accordance with the accepted view in this country the term "diseases of the chest" does not include conditions within the sphere of cardiology.

At the same time sanatoria and tuberculosis hospitals, like any others, require junior men of house-officer grade. While these have been difficult to recruit in the past and continue to be difficult to recruit, the requirement of a resident or intern post between graduation and registration proposed in the Medical Bill presently before Parliament should, when in force, provide a source of recruitment from which sanatoria and tuberculosis hospitals will benefit in the same way as general hospitals. It is contrary to his best interests for a young practitioner to declare his intention to enter this specialty by taking a house post in a tuberculosis hospital. A house post in such a hospital should be regarded as analogous to a house post in any other hospital and as providing the same type of experience.

Bed-requirements and Establishments

As noted above, it is our view that the tuberculosis service should be organized in units designed to include both the hospital and the dispensary aspects of the service, and served by a single integrated staff. Such a form of organization having been postulated, it was necessary to consider first the optimum size of population to be served by such a unit, and thereafter the composition of the proposed unit. After examining the position throughout Scotland, it seemed to us that the city of Dundee (population approximately 200,000) provided a suitably compact example which, in relation to both incidence of and deaths from tuberculosis, lay somewhere between the best and the worst. There was further justification for taking this as a model unit, for we were assured that for a concentrated population of this size a single tuberculosis dispensary (chest clinic) would be convenient for the needs of the community. In more sparsely populated districts it is evident that for a similar number of persons a greater number of dispensaries might well be needed to suit the convenience of both patients and staff. It seemed to us, in addition, that this unit of population could be reproduced singly or in multiples in the hospital regions of Scotland.

Estimates of the staff required for operating such a combined hospital-dispensary unit must naturally depend upon the amount of work to be carried out in the dispensary and the number of beds required for the treatment of patients suffering from tuberculosis amongst a population of this size. Various attempts have been made to estimate the optimum bed provision for tuberculosis. The Hospital Surveyors (1945), for example, used the formula of two-and-a-half times the number of deaths from pulmonary tuberculosis in 1938. The adoption of 1938 as the datum line was determined by the fact that this was the last year for which fully reliable figures were available to the surveyors. Since figures are now available for several post-war years, we tested the results of this method of estimation by applying various factors to the deaths in a variety of years both before and after the war. In addition, we obtained from physicians in the regions personal estimates of the regional bed-requirements. Some of the various figures so obtained are set out in the Appendix. It will be seen that no one of these formulae accurately matches all the estimates given by the physicians. The explanation of this divergence we consider to lie in the fact that these formulae could not wholly reflect such local differences as concentration or dispersion of population and the proportional incidence of pulmonary and non-pulmonary tuberculosis. Consequently, while we recognized that a general formula might have its value in deciding an overall policy, yet in respect of the problem under discussion the personal estimates of responsible physicians appeared more suitable.

On this basis we have estimated that for a population of 200,000 the appropriate bed-requirements would lie between 250 and 350.

Based on these figures, both of population and of bed-requirements, and after discussion of the working of such a combined hospital–dispensary unit at the present time, our recommendations are that the following would be an appropriate senior medical staff establishment (expressed in terms of whole-time officers) : three medical officers of trained rank, three senior registrars.

In our opinion the number of medical officers just suggested would be sufficient to undertake hospital, dispensary, and domiciliary attendances, mass radiography, and B.C.G. vaccination, and still leave a margin to permit of appropriate annual leave. It was never in our minds that the particular duties of each member of such a staff should be laid down in any hard-and-fast manner. The senior tuberculosis physician would naturally allocate the duties of the various members of his staff, but we should hope that he would usually find it possible to give the opportunity to all members of his staff to take part in the various activities of the unit. While we recognize that the training of many tuberculosis officers transferred from local authorities to regional hospital boards did not correspond with that which we recommend for the future, we urge the necessity for using the services of all such transferred officers within the integrated staffs we advocate.

We must emphasize at this point our recognition that regional differences in the incidence of tuberculosis, the density of population, and the concentration of hospital or other provisions might be sufficiently great as to render necessary considerable variations in the proposed establishment. It may be appropriate in some areas that one large hospital provides all or nearly all the required beds for a population served by several dispensaries. This might permit of some degree of concentration of staff. Conversely, in extensive and more sparsely populated areas a larger staff might be required to serve a larger number of dispensaries and smaller hospitals.

On the basis of the establishment discussed above, the staff requirements in the five Scottish regions would be as shown in the following Table, which also shows the staff requirements which were independently estimated by tuberculosis physicians in the regions :

Region	Physicians' Estimate	6 Staff per 200,000
Western	89	89
South-eastern	32	32
Eastern	14	12
North-eastern	11	14
Northern	7	6
Total for Scotland	153	153

House-officers

In addition to the staff proposed above it will be necessary for the tuberculosis hospitals and sanatoria to have an appropriate complement of house-officers whose duties should be confined to work in these hospitals. In the larger sanatoria an establishment of one house-officer to approximately 100 beds would be appropriate. It is evident, however, that many of the tuberculosis beds will be in hospitals of smaller size or in wards within general or fever hospitals. Wherever in such circumstances there is a concentration of 60 or more tuberculosis beds the establishment should provide for one house-officer. In the case of still smaller hospitals the services of one or more house-officers might be shared between several hospitals.

Clerical Staff

In the operation of any tuberculosis service there is bound to be a considerable volume of clerical work. We consider that the skill and time of the medical staff should not be dissipated in work which could be done satisfactorily by secretaries and clerks. Therefore, for each notional hospital–dispensary unit we recommend that there should be as a minimum : one secretary, two shorthand-typists, and one filing-clerk, exclusive of the staff required for the particular duties of the mass radiography unit.

Residential Accommodation

Since we envisage the employment of a not inconsiderable number of registrars of senior grade, many of whom may be married, we find it necessary to recommend that immediate steps be taken to increase the residential accommodation for men in this category employed at tuberculosis hospitals and sanatoria. We think that the recruitment of a sufficient number of senior registrars may be difficult under the conditions of accommodation obtaining just now at sanatoria, and because of the critical shortage of houses generally.

PART II

"Crisis Expansion"

During the months which have passed since we were appointed public attention has been increasingly drawn to the disturbing facts of the present tuberculosis situation in Scotland. As is now widely known, the salient point in this situation is that, whereas in England and Wales both the death rate and incidence rate, which rose during the second as during the first world war, have reverted almost to pre-war levels, in Scotland they have not done so. On the contrary, although there may be evidence of a commencing decline in the death rate, the notification figures continue to rise. It is of course recognized that these figures may not be a true index of incidence, since they may in part be explained by improved case finding through mass radiography, examination of contacts, and other means. Nevertheless, the stark fact remains that provision for known cases is tragically insufficient. It is now a common experience for doctors to be unable to arrange for patients suffering from tuberculosis the institutional care they know to be necessary. The important therapeutic advances of recent years make this situation the more distressing for all concerned.

We realize that the responsible authorities are fully aware of all this, have given much anxious thought to the problems which have arisen, and have instituted measures designed to solve them. Nevertheless, we feel bound to record the strong impression left after many hours spent in discussing and considering the present state of affairs, and the steps taken to meet it, that there is lacking any general appreciation of the urgency of the problem and of the need for a real emergency drive to deal with it. Not until it is tackled in a spirit of crusade will the fight be won. A slow building up of first-class sanatorium accommodation is not, in our view, what is called for. There are obvious and cogent reasons why any rapid development of this kind is out of the question. Even if it were not so, it is doubtful wisdom to make long-term and expensive

After this, return of function is encouraged by exercises, but it is not advisable to apply grease massage to the grafts until they are more consolidated—for example, three to four weeks after grafting.

Homogenous Skin-grafting

Contrary to reports, I do not believe that a successful take of skin from one person to another is possible. Medawar has shown in his experiments that such a take does not occur and that homogenous grafts are shed after three to six weeks. Homogenous skin is applied only in sheets, because in patches this skin promotes heavy formation of antibodies.

However, there are cases in which homogenous skin-grafting serves a purpose, albeit temporarily. Consider a child with widespread burns of 40% or more body surface. The trunk, thighs, and legs may be involved so that there is little or no unburned skin to provide grafts. Such a child will be gravely ill with toxaemia, anaemia, and fluid loss even when the sloughs have been removed or encouraged to separate. Provided the child survived, spontaneous healing would occur over many months, producing thin unstable epithelium over broad areas, with dense thick scarring in the flexures, which in turn would produce contractures, deformities, and loss of function. The early application of skin in sheets from another person would provide the "best dressing" for the burn areas, after separation of sloughs. It would reduce the toxaemia and tide the child over a critical period of three to six weeks. During this time some of the less badly burned areas would have time to heal and thus provide the patient with his own skin for grafting, if only a little at a time, until full skin cover was attained. Such temporary homogenous skin cover would qualify as a life-saving measure.

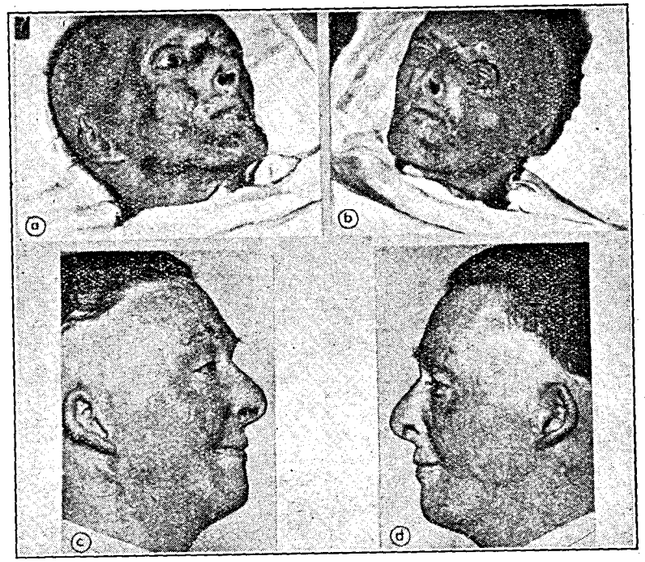

FIG. 2.—Recent burns; face. *(a, b)* Appearance in toxaemia. Ectropion of all eyelids; loss of nose-tip and parts of ears; loss of skin of forehead and cheek; *(c, d)* End result. Treatment prolonged, with intervals out of hospital. Postage-stamp grafts to forehead and cheeks still remain. Thiersch grafts to eyelids and lips. Hairy Wolfe grafts to eyebrows. Left upper arm flap to nose. Small tubed flaps from neck to margins of pinnae.

Splinting.—Areas that have been skin-grafted should be immobilized. Plaster-of-Paris gutters are most satisfactory to immobilize joints above and below the lesion.

Donor Sites.—Where possible, thighs and upper arms are chosen first. It must be stressed that as much skin as is necessary and possible should be taken from one limb before going on to another. For example, use one thigh to its utmost and keep the other thigh untouched in reserve to provide definitive skin cover. A donor site once used to provide Thiersch grafts can be used again four to six weeks later.

Application of Skin Grafts

Priority Areas.—Full-thickness skin loss of trunk and parts of limbs between joints is straightforward in that skin cover is the only issue. However, in those cases of widespread burns involving face and hands, in addition to other areas, there is a need to consider covering certain areas before others, particularly if there is likely to be shortage of available skin (Fig. 2). For example, ectropion of the eyelids should be dealt with first, in order to allow the lids normally to cover the cornea. Finger-joints and limb flexures come next in importance, and, finally, broad areas, such as trunk, thighs, forehead, cheeks, and lips. The burned hand at all times must be placed in the position of function (grasping a tennis-ball)—the best position for ankylosis, should ankylosis occur. This position is maintained by splinting while skin grafts are being applied and until they have taken.

Full-thickness Skin Grafts and Skin Flaps.—There is no indication, in my opinion, for the use of Wolfe grafts or skin flaps in the primary skin cover of burns. A Wolfe graft is a free graft of whole skin thickness. This leaves a defect which usually requires a Thiersch graft to cover it. Furthermore, a Wolfe graft is a more difficult graft to handle successfully than a Thiersch graft even under ideal conditions, and from a practical viewpoint it is not good surgery to put a Wolfe graft on to a granulating area in a burned patient and to hope for success. The use of skin flaps is best left to a later date, when healing and restoration of function have been obtained by using Thiersch grafts as described earlier.

Causes of Failure of Skin Cover in Burns.—(1) The application of a sheet of skin graft to a granulating area has less chance of success than covering with "postage stamps." (2) Placing grafts on unhealthy or too heavily infected granulations will lead to loss of some or all the grafts. The β-haemolytic streptococcus and *Pseudomonas pyocyanea* are potent sources of failure when present in heavy concentration. Adequate pre-operative pressure dressings on the granulations, with antiseptics or the appropriate chemotherapy, are necessary to obtain flat healthy granulations. (3) Imperfect pressure dressings to the grafts and incomplete fixation of the dressing will allow movement of the dressing on the graft and the collection of exudate under and around the grafts, with failure. Absent and poor splinting to the grafted limb may produce the same unsatisfactory results. (4) Rough removal of dressings on the fourth, sixth, and eighth days—that is, by tearing off grafts which had in fact taken. (5) Poor general condition of the burned patient will lead to partial or total failure of grafts. Mr. R. P. Osborne in his paper has indicated general and local preparation of the burned patient.

Methods of Cutting Skin Grafts.—There are various knives in use. To obtain small grafts the ordinary cut-throat razor may serve. On the other hand, those in frequent practice prefer the Blair knife, the Humby and Marks–Blair knives, which have an adjustable roller along the edge of the blade, or the dermatome. The various knives are most suitable on plane surfaces—for example, the sides of the thighs—but on the abdomen or back suction boxes are usually required, to produce a plane surface. The dermatome can be used on any surface, as the sticky drum picks up the skin and presents it to the knife edge. Knives and drums have their separate followers.

Refrigeration of Grafts.—Sheets of skin wrapped in tulle gras and placed in sealed sterile bottles in an ordinary refrigerator can be preserved for several weeks and then successfully used. This has been described by Jerome Webster (1944) and by D. N. Matthews (1945). The procedure is particularly effective in the treatment of moderately burned children, in that when the first cleansing of the burned area is undertaken under anaesthesia the grafts can be cut and refrigerated, to be used during the succeeding two to three weeks as the granulating areas permit, without the necessity of further anaesthetics. Combined with envelope therapy, the number of anaesthetics for a particular case can be reduced to two or even one.

A point is now reached in the treatment of the burned patient where, following the application of skin in squares, early healing is a fact. Consistent with the extent of the burn, the earlier the healing, the better the chance of return of function. The physiotherapist comes into the picture about three weeks from the date of grafting, with appropriate exercises to the limbs, gentle grease massage, and wax baths to the grafts.

Sequelae

Despite all this, certain sequelae may and do arise: (1) irritation in and around the grafts; (2) contractures; (3) keloid scarring.

Irritation in and Around the Grafts.—This is often relieved by antihistamine drugs internally and calamine lotion and antihistamine creams locally.

Contractures.—Particularly in the flexures, there may arise bands of scar tissue limiting joint movements. There may be some response to grease massage and to night-splinting, but marked degrees of contracture are on occasion inevitable. In these cases the only immediate consolation is that without skin-grafting it would have been much worse. Reference will be made to such cases later.

Keloid Scarring

Quite apart from burns, many people develop keloid scars where the skin has been traumatized. Frequently keloid will occur in the area between the mouth and lower neck, and also on the front of the chest, and yet not elsewhere (Fig. 3). On the other hand, some few patients show marked keloid everywhere on the body. In those cases in which keloid occurs it has followed suture of a skin wound under tension. It is a frequent complication in burned patients, and in my experience appears about one to two months after healing. The keloid scars may continue to increase for several months, and then show fading over a period of years.

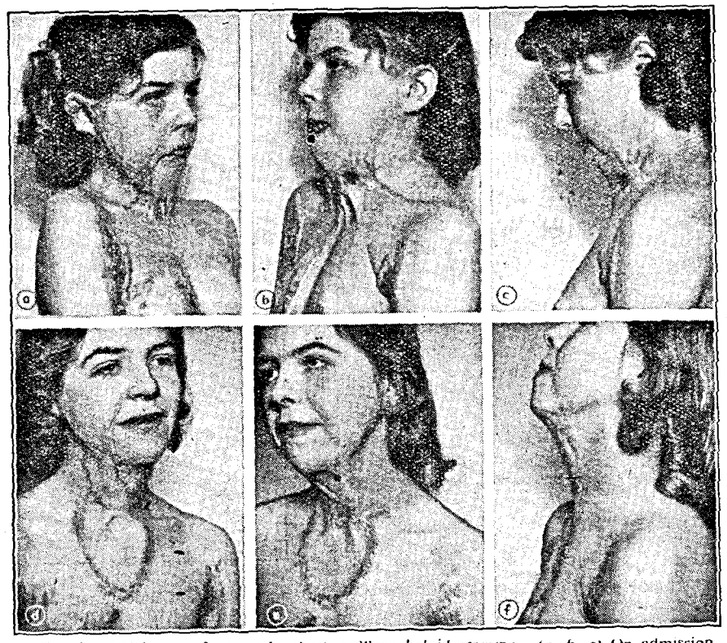

FIG. 3.—Old burns; face, neck, chest, axillae; keloid scarring. (*a, b, c*) On admission, scar contracture of neck and axillae; dense keloid. *X*-ray therapy. (*d, e, f*) After transfer of abdominal tubed flaps to neck in stages. Recurrence of keloid scarring.

Recent and rapid keloid formation is red, raised, hot and tender on pressure, and irritates to a marked degree. Old and slowly forming keloid scarring is hard and pale. Keloid scars and hypertrophic scars differ histologically only in the accumulation of scar tissue. Keloid scarring will recur after excision of a keloid scar and suture, at the margins of skin grafts and flaps, and in the donor site of a skin graft. There is no known cause for the occurrence and recurrence of keloid scars, and there is no consistent difference histologically between keloid scars, hypertrophic scars, and ordinary scar tissue. The tendency to keloid scar formation in a patient is said to diminish after the early twenties.

It is a practical point to review all cases of recently healed burns one to two months after healing, in order to check the occurrence of keloid.

Treatment of keloid scarring is sought, therefore, for pain, irritation, deformity, and disfigurement. Pain and irritation in the early keloid are treated by moderate doses of *x* rays or radium, and relief occurs over two to three months. The irradiation must be superficial and limited to the skin area involved. The dosage is that which produces a faint erythematous reaction in the skin, and this is a matter for the judgment of the skilled radiotherapist. *X* rays or surface radium may be used, and where low-voltage therapy apparatus is available the technical superiority of *x* rays over radium is unquestionable.

provision to meet what should and could be only a short-term need. The answer, we believe, does not lie in this direction but in what we have come to describe as a "crisis expansion" on the lines of the Emergency Medical Service so rapidly provided at the outbreak of the last war. The highest priority should be given to all measures which may be expected favourably to influence the situation. We regard it as essential that, while proper and due economy should be exercised in the carrying out of such measures, financial stringency should not be allowed either to weigh against their institution or to handicap their efficacy. For a nation which in the foreseeable future will require the greatest possible proportion of fit workers to allow this to happen would be to be penny wise and pound foolish.

The outstanding problem, though by no means the only important one, is the rapid provision of more functioning hospital beds for tuberculosis, and the greatest single obstacle to achieving this is recognized to be the shortage of nursing staff.

Bed Accommodation

According to such information as we were able to obtain in the autumn of 1949, the total number of hospital beds in Scotland then available for the accommodation of patients suffering from all forms of tuberculosis was approximately 6,000, but of these some 500 could not be used owing to lack of nurses. As shown in the Appendix, the total number of beds required according to the physicians' estimates for the hospital treatment of all types of tuberculosis is 7,605. It was further estimated by these physicians that of these beds approximately one-seventh would be required for the treatment of non-pulmonary tuberculosis. The estimated requirement for pulmonary tuberculosis is, therefore, approximately 6,500 beds. By the deduction of a similar proportion for non-pulmonary tuberculosis the number of beds available for pulmonary tuberculosis in the autumn of 1949 was 5,150. From these figures we concluded that some 1,350 additional beds would meet the present need.

We have endeavoured to obtain information about the number of beds at present available in infectious diseases hospitals. It has not proved possible to obtain completely reliable returns, but from such information as we did obtain we are satisfied that the total number is very considerable. On the average only about one-third of the beds in infectious diseases hospitals are occupied at any one time by patients suffering from infectious diseases other than tuberculosis. After setting aside a further one-third for emergency purposes it should, in our view, be possible to make available the remainder of the beds in these hospitals for the purpose of the crisis expansion we have in mind, provided the problems of improvisation, organization, and staffing can be solved. We fully appreciate that some technical difficulties would have to be overcome. For example, the present open-ward system obtaining in the great majority of these hospitals makes it necessary to assign whole wards to the treatment of different types of infectious disease. Under this system whole wards may stand empty or be occupied by only a few patients for quite long periods of time. The solution to this problem we believe to lie in the reconstruction, makeshift or permanent, of at least a proportion of these wards into cubicle wards. If this were done on the appropriate scale it should be possible to provide for the treatment of tuberculosis the necessary 1,350 beds over and above those already in use in infectious diseases hospitals for the care of tuberculous patients.

Whilst we believe that this would be the most satisfactory way of meeting the need, it might be found impracticable for one reason or another to provide in this way all the beds required. Should this prove to be the case the most careful consideration should be given to the possibility of using wards in general hospitals. The regional hospital boards and their medical education committees may feel that the larger teaching hospitals should be excluded from any scheme of this kind, but it should be possible to find a considerable amount of accommodation in other general hospitals.

To sum up, we are convinced that there are available in Scotland hospital beds to the number required for a crisis expansion.

Shortage of Nursing Staff

There are three categories of staff required—namely, trained nurses, student nurses, and part-trained personnel. In the first and third categories the nurses may be in part-time employment. Any rapid critical expansion must rely on the services of nurses from all three, and particularly on extensive use of part-time and part-trained nurses. Indeed, such expansion as has occurred during the past few years has been achieved largely by this system of "dilution" rather than by any substantial increase in the number of young women entering tuberculosis nursing as a career. In some hospitals part-time nurses and untrained personnel form 50% or more of the staff, but there is naturally a number of factors which limit the extent to which this system can be used, apart from the obvious one of the total number of such persons available. One limiting factor, for example, is the number of trained nurses with the necessary qualifications and experience to fill the senior charge posts.

The efforts which have been made to recruit nurses for sanatorium work seem to have been directed almost entirely towards the student nurse, the part-time nurse, and the part-trained auxiliary. It seems to have been assumed that the trained nucleus of the service was relatively static and only to be increased by increments from those completing their training in the ordinary way. Even given a highly satisfactory recruitment of student nurses this could only mean a relatively slow expansion once the initial dilution had been achieved. With a recruitment scarcely above replacement level it is evident that little increase is to be looked for except through a significant recruitment from outside to the senior ranks within the service.

It is to this means of expansion that attention should now be directed. We believe that a successful recruiting campaign might well prove to be the key to the solution of the expansion problem. Moreover, it offers in this field the advantages of a short-term scheme to deal with a short-term emergency, which we have already pointed out in connexion with the finding of beds. Utilizing the same degree of dilution by part-time nurses and part-trained personnel as has been referred to above, we estimate that the recruitment of approximately 150 trained nurses would permit of the opening of the 1,350 beds which we have reckoned to be necessary. We are aware that the possibilities of recruitment of part-time and part-trained nurses vary in different parts of the country, but we cannot imagine that the supply has been nationally exhausted. In our view the new beds which might be made available in this way need not be proportionately distributed all over the country; it would have a marked effect on the national problem even if they were wholly confined to one region.

Recruitment of Trained Nurses

We consider that an important, possibly the principal, source of recruitment of this trained senior staff will be found among the group of nurses who, having completed their training, are now in their parent hospitals as junior sisters or staff nurses, often more or less "marking time" while awaiting promotion to full charge posts. The opportunity of a responsible charge post in the tuberculosis service, supplemented by the stimulating prospect of playing a part in a task of urgent national importance, might well attract trained nurses already in such employment in general hospitals. We consider that the matrons of general hospitals should be invited to co-operate whole-heartedly in bringing the needs of the tuberculosis service to the attention of nurses in the categories we have described. It is only with the energetic and interested support of the senior administrators in the general nursing service that a recruiting campaign of this kind can be expected to succeed.

We have felt that many nurses are repelled from work in sanatoria in the mistaken belief that little clinical interest attaches to such work. Modern advances in the treatment of pulmonary tuberculosis have been such that the speed of turnover at sanatoria has increased and a much greater proportion of patients suffering from this disease are susceptible to active medical and surgical treatment, with real prospects of alleviation or cure. While it cannot be denied that the average stay in hospital of patients suffering from tuberculosis is much longer than that of patients in general hospital wards, nevertheless these modern therapeutic advances have changed the atmosphere in sanatoria so that it is now comparable to that obtaining in active general hospitals.

We are strongly of the opinion that an essential part of any recruiting campaign which aims to attract the trained nurse must include appropriate lectures, by tuberculosis physicians and senior tuberculosis nurses, designed to give a true picture of a nurse's life and work in a modern sanatorium. A campaign with this object must attempt to remove the doubts which still exist in the minds of women concerning the risks of contracting tuberculous disease while working in tuberculosis hospitals and sanatoria. The necessary assurance can confidently be given, for it is generally considered that these risks are in point of fact smaller in well-run sanatoria than they are in general hospitals, which, by virtue of the pressure of present circumstances, are often obliged to admit and care for cases of open tuberculosis under hygienic conditions far below those demanded by sanatoria.

We are aware that in the past the conditions in which nurses lived and worked in some tuberculosis institutions have been bad by any standard, as indeed they have been in many other hospitals. The existence of these "black spots" must have influenced the attitude of matrons and others responsible for the welfare of nurses and thus acted as a serious deterrent to the recruitment of nurses. While we cannot claim that the living and working conditions of nurses in every sanatorium have yet reached the optimum standard, nevertheless it is undoubtedly true that a good standard has been reached in the great majority. This fact should be brought energetically to the notice of nurses in general.

Recruitment of Student Nurses

We have been informed that there is a surplus of applicants for many training schools. We understand that in many instances such applicants as cannot be accepted are directed by matrons to the appointments offices of the Ministry of Labour and National Service. The co-operation of matrons should be sought in regard to this, in order that they may strongly urge upon girls whom they cannot take into their own schools that they should seriously consider taking up tuberculosis nursing. The responsible officers in the appointments offices should also be instructed to press the claims of tuberculosis nursing upon those who seek their advice. We have received evidence that this is not always being done at the present time.

One of the major deterrents to the entry of young women to nursing in the tuberculosis service has been the objection on the part of their parents, based upon the public's exaggerated fear of the risks of acquiring tuberculous disease. The crusade against tuberculosis ought to contain as an important and integral part a campaign designed to educate the public, first, regarding the size and national importance of the problem, and, secondly, regarding the correct assessment of the risks undertaken by those who take up tuberculosis nursing. Such a campaign should include the dissemination of factual information regarding the degree of protection which can be conferred on tuberculosis workers by B.C.G. vaccination. The public should be informed of the comparative freedom from risk associated with nursing in sanatoria. We suggest that in a thorough and intensive campaign of this sort the co-operation of the B.B.C. should be invoked. We have in mind such a feature as "Focus on Tuberculosis" in which, by using the services of physicians, surgeons, nurses, and patients, emphasis could be laid upon the new and optimistic therapeutic outlook in this disease. The object should be clearly defined as an attempt to raise the campaign against tuberculosis to the level of a nation-wide crusade. It may be that in doing so the services of publicity and advertising experts could also be invoked with advantage.

What has been said in the foregoing paragraphs about the recruitment of trained and student nurses applies equally to that of part-time and part-trained personnel.

Industrial Nurses

The total number of trained nurses at present employed in industry is comparatively small and we do not think that any recruiting campaign should be specifically directed towards nurses so employed. We feel most strongly, however, that the needs of the tuberculosis service are so crucial that in the meantime any further recruitment of trained nurses into the industrial field should be actively discouraged. There is a legitimate demand for the services of nurses in industry, but this can be met, at any rate temporarily, by the greater use of first-aid workers.

Extension of Facilities for Domiciliary Treatment

As an immediate step and pending the successful outcome of an energetic recruiting drive for nurses, a most useful contribution might be made by extending to patients in their homes some of the forms of active treatment normally used only in hospital. It has been within the experience of most practising doctors that patients notified as suffering from pulmonary tuberculosis may wait for months before obtaining hospital beds, and during this time the illness may advance to such an extent as to diminish their chances of recovery or at any rate to ensure that they will occupy the hospital beds which they eventually reach for a longer period of time than would have been the case had they been under active treatment from the start. A proportion of beds should be set aside in sanatoria for short-term cases who could be given, for example, appropriate collapse therapy and then returned to their homes where supervision could be continued. It is possible for such patients to be brought to the dispensary or hospital as often as is necessary for continuation of active treatment.

While the day-to-day supervision of patients undergoing domiciliary treatment should be largely in the hands of their own practitioners, it is desirable that full specialist co-operation should be available, and this may well involve an immediate increase in the specialist staff on present establishments. It is important in this regard that the regional hospital boards should institute some form of direct contact between the specialists in the tuberculosis service and general practitioners. We have in mind not only individual contact in connexion with individual cases but the institution of professional meetings at the hospitals or clinics, at which there could be expounded the modern views of treatment and control of tuberculous disease. We have received so much evidence of the interest which general practitioners are taking in the problem of tuberculosis in their practices that we feel sure that such a procedure would be received with general approval.

Hostels and Night Sanatoria

We have considered the suggestions which have frequently been made that night sanatoria or hostels for tuberculous workers should be provided. There has been little practical experience of these in this country, and it seems to us that grave difficulties would be encountered in obtaining any large measure of consent to their use, both from the sufferers themselves and from their relatives. There persists, unfortunately, a degree of social ostracism of the tuberculous, and this would militate against the wide use of hostels or living quarters for those whose ordinary work and recreation in any case would require to be sought in the general community.

The Ministry of Labour and National Service in their schemes for the tuberculous have up till now been unable to provide for persons with open tuberculosis, because their workshops are manned by persons disabled by various conditions. Difficulty has been experienced in making arrangements for the training even of patients with quiescent as opposed to healed tuberculosis. Consideration might be given to the development in the larger sanatoria of hostel accommodation for ex-patients, both sputum-positive and sputum-negative. The former might be encouraged to stay for relatively long periods if small factories within the sanatoria could offer remunerative work. Under present circumstances any larger attempt at colonization of the tuberculous is not possible, and we doubt whether at any time colonies such as those at Papworth would offer any substantial contribution to the solution of the problem in Scotland.

Preventoria

The institution of preventoria may be expected to play a valuable part in preventing the spread of tuberculous disease. While the policy of instituting preventoria appears to have been accepted by the central authorities, few active steps have yet been taken to implement it. Energetic measures should be taken by central and local authorities to make available suitable buildings for the reception and care of children from homes in which tuberculosis has appeared. In our view such preventoria should be similar in type and organization to the wartime residential nurseries. The recruitment of children's nurses and supervisors for such establishments might not be easy, but we recall that it was found possible to recruit sufficient staff for the wartime nurseries, both day-time and residential.

An appeal for persons to undertake work of this kind, backed as it would be by the general propaganda campaign, is not likely to fail. We would again emphasize that narrow monetary considerations should not be allowed to be a stumbling-block.

B.C.G. vaccination of children involves the segregation of those selected for vaccination for a period of weeks. The preventoria which we envisage would seem to be suitable establishments for this segregation, but we regard it as important that the establishment of preventoria should not await a widespread introduction of B.C.G. vaccination, nor should their use be limited to the segregation of children undergoing this form of immunization.

Housing

The importance of the part played by faulty housing in undermining attempts to eradicate tuberculosis from the community needs no emphasizing by us. Medical officers of health are fully aware of this, and local authorities are doing their best to meet the needs. Improved housing of families affected by tuberculosis attacks the problem in two ways. First, it lessens the danger of spread of the disease by making possible effective room segregation of patients. Secondly, and for the same reason, it makes possible the domiciliary treatment of chronic cases, thus freeing hospital beds for those who can most benefit from hospital treatment. Every encouragement should therefore be given to local authorities to adopt energetic and imaginative measures to provide for affected families. Here again we would stress that the accent should be on "crisis expansion."

Central Responsibility

Because of the national character of the problem the Department of Health for Scotland, as the central authority, would be closely involved in the various projects we have described for tackling the present situation. All these, as we have tried to indicate, are but parts of what is essentially a single operation. For this reason there will clearly be need for effective central co-ordination and direction. It may be that the Department will feel that this need can be met through their present establishment and arrangements, but we suggest that careful consideration should be given to the desirability of appointing an appropriately qualified person to undertake this task. Such an appointment, we suggest, should be of a temporary character, perhaps for a period of three to five years. In our view it should be held by a medical man of proved administrative ability and wide experience in the tuberculosis field. Whether this appointment be made or not, we consider it to be essential, if our proposals are to be successfully adopted, to have in being a consultative committee of experts available to advise on their implementation.

SUMMARY OF PART II

The present situation in the management and control of pulmonary tuberculosis in Scotland is so serious as to be critical, and can be met only by a "crisis expansion" of the tuberculosis service.

1,350 additional beds are urgently required for this expansion.

These can quickly be made available in infectious diseases hospitals by structural improvisation and modification.

The greatest single obstacle is the shortage of nursing staff.

We have made proposals for a recruiting campaign, the principle feature of which is the attraction of trained nurses to the tuberculosis service.

All steps should be taken to make active modern treatment available to the patient in his home.

Much more energetic steps should be taken to provide preventoria.

As part of a "crisis expansion" local authorities should adopt a bold and imaginative policy in the allocation of houses.

Money spent freely but wisely for these purposes will prove to be a sound national investment.

A vigorous, sustained, and well-planned campaign of public education regarding tuberculosis should be undertaken.

We have made recommendations for the central co-ordination and direction of these operations.

A much greater sense of the urgency of the situation is required on the part of all—the general public, the administrators, the nurses, and the doctors. What has hitherto been a desultory and intermittent campaign must be transformed into nothing less than a national crusade.

The subcommittee wish to record their keen appreciation of the tireless work and indispensable assistance given by their secretary, Dr. E. R. C. Walker, and the clerk to the subcommittee, Miss S. V. Williamson, and to express their indebtedness to the British Medical Association for the facilities afforded.

APPENDIX

Beds Required for Optimum Service

TREATMENT OF PAINFUL AMPUTATION STUMPS

BY

W. RITCHIE RUSSELL, M.D., F.R.C.P., F.R.C.P.Ed.

AND

J. M. K. SPALDING, B.M., B.Ch.

(From the Department of Neurology, Radcliffe Infirmary, Oxford)

Last year one of us (Russell, 1949) described a method of treating painful amputation stumps and phantom limbs by repeated percussion to the stump neuromata. This form of treatment was developed on the theory that conduction in a mixed nerve is easily interrupted by repeated pressure without causing pain, and that the regenerating nerve fibres which form neuromata in an amputation stump might well be even more vulnerable to minor trauma than are normal nerves and nerve endings. It was considered likely, therefore, that if painful neuromata are repeatedly hammered their nerve fibres will gradually degenerate and be replaced by fibrous tissue. It was hoped that this process would be followed by relief of spontaneous pain, and in the report mentioned above seven consecutive cases were described, all of which responded remarkably well to this form of treatment. These seven patients have recently been followed up, and the progress report of all of them has been very satisfactory. Most have been able to discontinue treatment to a large extent, but some still give the stump an occasional hammering if the pain shows a tendency to recur. These patients have therefore either lost all tendency for the pain to recur, or, if they have slight twinges, these can be removed by a short period of treatment. This is most encouraging, for the evidence available indicates that with the passage of time there is no tendency for the pains to become resistant to the treatment—rather the reverse.

Further Cases

The purpose of this paper is to give the results achieved in further cases, and to include more details of the methods used.

We have had under consideration 37 further cases, but a number of these had disabilities which rendered them unsuited to percussion treatment. For example, in three cases the amputation followed extensive nerve lesions of the limb concerned; one case had a cold, diffusely tender stump which was relieved by sympathetic nerve block as advised by Leriche (1939); one case had sciatica, one had osteoarthritis of the spine, two had faulty prostheses, one was a major hysteric, and one refused to co-operate.

There were, however, 33 cases, including the seven published in 1949, which seemed to suffer from pain in the stump or phantom limb of such a nature that treatment by percussion was at least worth a trial. The main features of these cases are given in Table I.

Percussion treatment has been adopted elsewhere, and a number of cases which have proved resistant to this and to other forms of treatment have been referred to us. These cases fall into the second half of Table I, and owing to this selection of cases the results shown in that half of the table are not so good as in the earlier cases.

From the table it will be seen that there were 26 cases of lower-limb amputations (22 above the knee) and eight

TABLE I.—*Chief Features of the Main Group of Cases*

Cases 1–7 are those described in a preliminary report (Russell, 1949).
* This man had a double amputation. He complained of pain only in the upper-limb phantom.
† Jactitations occurred at times when these patients were asleep.

Abbreviations:
Amputations: A/K, above knee; B/K, below knee; A/E, above elbow; B/E, below elbow; Disart., disarticulation.
Operations: Amp., amputation; neur., neuromectomy; mes. tract., mesencephalic tractotomy; n.s. (br. pl.), nerve section (brachial plexus); n.s. (sci.), *nerve section (sciatic nerve); sp. an., spinal anaesthetic*; st., other stump operations.
Pain: Ach., aching; burn., burning; comp., complex; lanc., lancinating; rig., rigidity; tend., tender; tick., tickling; ting., tingling; no ph., no phantom limb on first attendance.

Definitions:
Excellent (exc.): Having no pain or able to dispel occasional attacks of pain for certain by percussion.
Good: Much less pain but not completely amenable to percussion.
Improved (imp.): Having less pain.
Unchanged (I.S.Q.): No apparent benefit from percussion treatment.

upper-limb amputations (six above the elbow). One man (Case 8) had had both an arm and a leg amputated, but complained of pain in the phantom arm only. A surprising finding in many cases was the long interval between the original amputation and the onset of pain. This interval was over one year in 16 cases and over five years in nine. Nineteen of the patients were wounded in the first world war, and eight in the second world war. In all cases amputation had been undertaken because of the direct or indirect results of trauma.

The Stump and Phantom Pains

The sensation of a phantom limb appears after nearly all amputations, as has been maintained by Weir Mitchell (1872), Leriche (1939), and Henderson and Smyth (1948). Not only had all our cases experienced phantom-limb sensations, but in all except three (Cases 11, 22, 32) these sensations were still present, generally in association with phantom-limb pains. The persistence of phantom sensations was therefore a marked feature in this group of cases. This contrasts with the experience of Henderson and Smyth (1948), who studied the "normal" phantom sensations in some 300 men with amputations in a prisoner-of-war camp. About 98% of their cases experienced the sensation of a phantom limb after amputation, but after six to twelve months the phantom sensations were only rarely felt, while they had for the most part disappeared after two to three years. Only about 6% of these 300 complained of pain during the period of observation.

The pains of which the patients complained were clearly often of very great severity. They were referred to the phantom limb in 17 cases, to the stump in seven, and to both phantom and stump in nine cases (Table I).

The patients' descriptions of the pain are very varied, but a distinction should be made between the pains which are almost always present in some degree and the pain which occurs in bouts. The latter consists of severe lancinating or stabbing pain recurring several times a minute and lasting for several hours or even days. In severe cases the patient is very miserable during a bout, and the pain is reminiscent of severe trigeminal neuralgia. During an attack the patient is reluctant to allow the stump to be touched, and is careful to prevent even a draught from playing on it, while the stump jumps or jactitates with each jab of pain.

Case 25.—A man aged 64 was wounded in the left leg and thigh in September, 1918, and two days later the limb was amputated just above the upper wound at the level of the mid-thigh. Before amputation he had severe pain in the left hip, upper thigh, and in the foot, but the areas in which he had been wounded felt numb. Since amputation he has been liable to attacks of stabbing pain. It is felt in the phantom limb, mainly in the ankle, especially the lateral side, and each stab is accompanied by a jactitation of the stump. Attacks at first lasted only two hours and recurred every two to three weeks, but in the past two years the pain has grown steadily worse, and attacks last 12 to 24 hours and recur every two to seven days. During an attack he is quite incapacitated. The first follow-up report on this case was not satisfactory, and further observation will be required.

In addition, however, to these "nerve" pains, many patients describe a painful set rigidity of the toes or fingers which can be particularly unpleasant. Other types of pain often accompany this rigidity, as in the following case.

Case 19.—A man aged 58 had a railway goods truck pass over his right leg in July, 1948, and a few hours afterwards the leg was amputated below the knee. Three weeks later he began to feel pain in the phantom limb. It was of four types. The fourth and fifth toes were constantly hyperflexed and painfully rigid; the big toe felt rigid and constricted "as though it were protruding through a hole in his sock but more uncomfortable"; tight cramp-like sensations were felt in the phantom calf muscles; and lastly there were occasional pains shooting into the lateral side and ball of foot, the big toe, and the fourth and fifth toes. This man had an extremely tender stump and gradually improved with percussion treatment.

One may wonder why this feeling of rigidity is so painful. Livingston (1943) describes how he asked a patient "why the sense of tenseness in the [phantom] hand was so frequently emphasized among his complaints. He asked me to clench my fingers over my thumb, flex my wrist, and raise the arm into a hammerlock position and hold it there. At the end of five minutes I was perspiring freely, my hand and arm felt unbearably cramped, and I quit. 'But you can take your hand down,' he said."

Complex sensations may also be described, as in the following case:

Case 7.—A man aged 37 was wounded in the sole of the left foot in October, 1942, and in January, 1943, the leg was amputated below the left knee. Two or three weeks after amputation he began to feel an aching pain in the lateral side of the ankle and to have the sensation both of the presence of the wound in the sole of his foot and of the nail of his big toe being twisted off. When he percussed neuromata in the stump he felt at first a temporary aggravation of the phantom sensations. These included the opening of the wound in the foot and a sensation of blood running between the fourth and fifth toes. He says that he does not remember experiencing this sensation before amputation. Percussion on one spot at first intensified the feeling that the nail of his big toe was being torn off, and then caused the toenail sensation to disappear. The patient responded very quickly to percussion, and nine months later wrote that he was able to play strenuous table tennis. Occasionally when he was taking less exercise he began to get a slight recurrence of pain, but he could at once drive it away with percussion.

Examination of the Stump

The amputation stumps varied greatly, but on the whole the spontaneous pains seemed to depend on factors showing no connexion with the general state of the stump tissues other than nerves.

Most of the cases with frequent or continual pain had tender neuromata or hyperaesthetic scars which on pressure caused pain that was often referred to the phantom and caused jactitation. This tenderness on pressure with pain radiating to the phantom appeared to be due to neuromata of large or small size which were the "touch" spots for the pain. We have come to regard this type of reaction as an indication that treatment by percussion is likely to be successful.

Details of Treatment by Repeated Percussion

Treatment by percussion depends on the view that if the thousands of nerve fibres in a neuroma are repeatedly subjected to trauma they degenerate, cease to be tender, and lose their capacity for causing spontaneous pain.

Every effort is therefore made to find and locate as accurately as possible all tender neuromata. They can generally be felt as nodules a few millimetres to a few centimetres in diameter which on pressure give paraesthesiae referred to the phantom or, less commonly, cause local pain. In some cases the neuromata are so covered by muscle that their presence can be presumed only if a well-localized area can be found where pressure or hammering elicits paraesthesiae in the phantom or marked local pain.

If the neuromata are very tender a sphygmomanometer cuff is applied to the proximal part of the stump and inflated sufficiently to occlude the arterial blood supply

FIG. 1.—Mallet and applicator in use.

After some minutes the anoxaemia makes the neuromata less sensitive* and they can be percussed. This is usually done with a mallet and an applicator consisting of a wooden shaft about 15 cm. long with a metal "dome of silence" on one end to provide a smooth contact that will not damage the skin and a crutch rubber on the other to deaden the sound of tapping (Fig. 1). The applicator is held firmly on the neuroma and hammered with the mallet as hard and as rapidly as is possible without causing the patient undue discomfort. If the patient has sensations referred to the phantom or stump these confirm that the applicator is well placed on the neuroma.

After percussion has been performed for several minutes the cuff is removed and percussion is continued for 20 minutes. After the first treatment the cuff is generally not necessary, and the percussion is repeated three or four times daily.

An electrical vibrator is sometimes preferred to the mallet. It gives percussion over a wider area, but is less powerful and is sometimes more apt to bruise the skin than is the mallet and applicator. Whichever form of treatment is used the patient is taught to apply it himself. Electrical vibrators† are especially useful in upper-limb amputations which the patient cannot himself treat with a mallet and for dealing with lower-limb neuromata which the patient cannot reach. A stand to hold the vibrator firmly in any desired position is an advantage for treatment in hospital (Fig. 2), as prolonged handling of a vibrator causes numbness of the physiotherapist's hands.

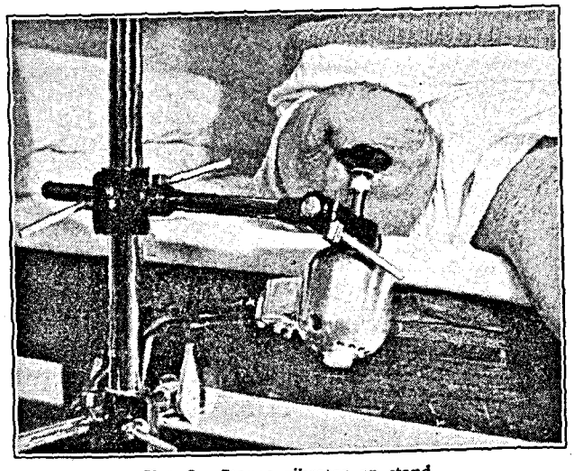

FIG. 2.—Stanco vibrator on stand.

A more powerful percussor‡ (Fig. 3) with a remote drive has been found useful for treating deeply placed neuromata. Only smooth metal or vulcanite applicators should be used with mechanical vibrators: other materials, such as rubber, are apt to damage the skin by friction.

The response of a favourable case is illustrated by the following report:

Case 15.—A man aged 60 was wounded in the thigh in June, 1918. The wound healed quickly, and for six months he walked well, but was then found to have a tuberculous infection of the upper part of the femur. The head and neck were excised, and shortly afterwards, in 1921, the right lower limb was disarticulated at the hip. He had no pain until November, 1948, when he began to feel an intermittent burning sensation in the toes and lateral side of the phantom foot, accompanied by the sensation of jerky and powerful plantar flexion at the ankle.

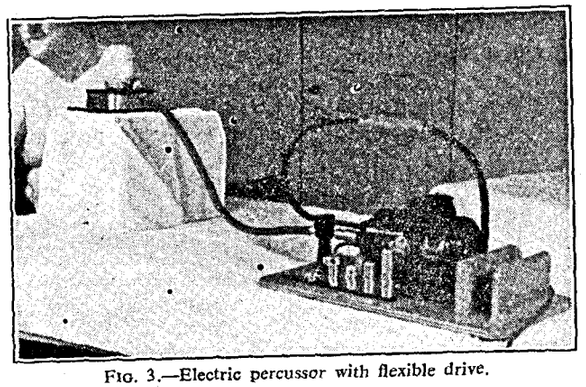

FIG. 3.—Electric percussor with flexible drive.

At other times, especially at night, the phantom limb felt fixed in flexion and he could not get to sleep until he had straightened it.

He had a well-marked sciatic neuroma. When this was percussed he felt a variety of sensations in the phantom leg, mainly a feeling of fixity or tension, but even after a single treatment of 15 minutes he volunteered that his leg was now at rest and within four days he had a longer night's sleep than for four months. Nine months later he was never bothered with pain and he only rarely needed to use the mallet. He was able to withstand the jolts of his local bus and the changes of weather, either of which had formerly brought on pain.

In other instances, however, the benefit of treatment becomes apparent more slowly.

Case 12.—A man aged 53. At the age of 3 years he had an illness which left him with a weak left leg, and in adult life the leg was 2 in. (5 cm.) shorter than the right. In October, 1929, he was involved in a road accident and suffered injuries to his head and left leg. He was unconscious for 13 days, but has had no permanent disability from the head injury. The left leg was amputated at the level of the mid-thigh 14 days after the accident. Eighteen months later he developed a sinus and a sequestrum was removed. After this operation he began for the first time to feel spontaneous pain, which was intermittent with periods of complete freedom. At first he had attacks of pain lasting 18 hours and recurring every month, but in the last six years the attacks had been occurring every 10 days. During an attack he felt in the stump a "drawing" or lancinating pain lasting two to three seconds and recurring three times a minute; and in the phantom a very disagreeable sensation in the toes and sole as though they were being strongly tickled. There was no neuroma palpable in the stump, but he was taught to percuss some tender areas. He obtained no relief for a month, but continued the percussion three times a day, and thereafter the pain became less frequent and could be dispelled by percussion. After six months he was applying percussion for 10 minutes once a day, and wrote: "The

*This method of local anaesthesia was in use in the fourteenth century (de Mondeville, 1320).

†The "Stanco" vibrator is manufactured by Stanley Cox, Ltd., 11, Gerrard Street, London, W.1.

‡The vibrator stand and the percussor were designed by Dr. E. J. Schuster, and manufactured by Mr. H. G. East, instrument maker, Oxford.

phantom makes an attempt to come about once every three weeks now, but it is too feeble to trouble me in any way, and I can usually knock it away in 10 minutes of hammering."

Results of Treatment

The results of treatment carried out as described above are usually highly gratifying. In many cases the first treatment gives relief which is so obvious that the patient quickly becomes an enthusiastic exponent of the method. In others the results are at first less apparent, and, as the patient often at first looks askance at the treatment, considerable time and effort have to be expended in persuading him to continue. Here the advantages of treating the patients in a centre where there is a tradition of cures are obvious.

Though few cases have been under treatment for more than a year the effect of it seems to be better as time passes; in most cases the patient can gradually reduce the number of treatments after some weeks, and in some instances even stop treatment.

For instance, Case 7, nine months after his first attendance, writes: "I do very little hammering these days. Only when it is raining hard or I am very tired or shaky do I need to 'tap,' and then it is to a phantom that seems 'half-hearted' and nothing compared with the feelings of discomfort I had before having treatment."

Case 1 was treated over five years ago in Cairo, and this patient writes from South Africa to say that he has had no further pain in his finger stumps except when on holiday and not using his hands much, when the pain sometimes returns. There is thus no evidence that these pains become resistant to treatment by percussion; indeed, the reverse seems more probable.

In Table II an attempt is made to classify the results of treatment in the 33 cases comprising the main group. Nine of these cases have been entered as deriving no benefit from

TABLE II.—*Results of Treatment in 33 Cases (Definitions as in Table I)*

	Total	Excellent	Good	Improved	Unchanged
No. of cases	33	11	8	5	9
Mean duration of follow-up (months)* ..		6	4	7	—
Range (months) ..		1–11	2–8	4–10	—

* Case 1 (follow-up over 5 years) is excluded.

treatment by percussion. It should, however, be added that there was only one failure among the first 15 cases treated, while in the last 18 there were eight failures. This worsening of recent results is due partly to cases of especial difficulty being referred, and partly to the treatment of some of the later cases being inadequately supervised. One "failure" (Case 26) subsequently obtained complete relief after an operation; this case is described later. It therefore seems that the proportion of failures in this series is higher than it would be in a less selected group. One occasional difficulty in dealing with pensioners depends on their having a vested interest in maintaining a high percentage of disability. There were, however, very few cases in which we felt that this factor seriously interfered with treatment.

Discussion

Although the theoretical prospect of converting a tender neuroma into a painless knot of fibrous tissue by repeated trauma seemed likely enough, the success of our attempts to do this in practice exceeded expectations. It was hard to believe that the well-known effects of pressure or trauma on nerve endings had not previously been fully exploited.

Gordon and Carleton (1923) described a somewhat similar method in a paper entitled "Hysterical Pain," and considered, on the basis of a theory of thalamic function, that the patients must experience pain to improve. Our experience suggests, however, that good results may be obtained whether the treatment is painless or painful, and that the changes observed indicate that the important part of the treatment depends on the physical changes caused at the periphery, in the neuromata and tender scars. Further, it seems clear that, whatever psychological factors there may be, the severe pain usually depends on afferent impulses which originate in the neuromata.

One highly gratifying feature of the treatment is that the patients are often enabled to discontinue drugs they have taken for years, and are again able to sleep without being repeatedly wakened by pain.

The chief complaint of Case 15 was that the pain used to keep him awake at night. There was improvement in this respect within a few days of beginning percussion, and eight months later he wrote: "I have rarely had to use the tapping, and when I have it has only been of very short duration, between three and five minutes. I feel really well and full of energy, and I can safely say when I go to bed that I am going to sleep, and I do sleep well. I really think that nerve is afraid of the mallet."

Dr. John Scarff, of the Neurological Institute, New York, has kindly sent particulars of a patient, a professional man, who after a mid-thigh amputation for embolism 10 years ago had suffered continuous pain. He became dependent on codeine in increasing amounts to enable him to work, until he was taking 20 gr. (1.3 g.) hypodermically each 24 hours. Finally he became exhausted and was obliged to enter hospital. After being treated with prolonged thiopentone he began to hammer the stump neuromata. This brought relief, and two months later he was not only free of pain but had taken no narcotic of any kind since starting the treatment.

The possibility of treating other painful conditions by similar methods has been little explored, except in the case of tender scars, in which excellent results may be expected. Fibrositic nodules are also sometimes quickly rendered painless by a mechanical vibrator.

One point with regard to amputation operations should be mentioned—namely, that our experience suggests that at operation the nerves should not be cut short but left long in an exposed situation. It is often the well-hidden and protected nerves which cause most pain.

In Case 26 we felt obliged to advise disarticulation of a short stump at the shoulder to make it possible to crush the neuromata, which were very high in the axilla, and to leave the nerves as long as possible so they could be easily percussed. He was a man of 65 when he first attended. He had had a minor injury to the middle finger of his left hand in 1915, but the wound did not heal, and a year later the finger was amputated. The hand and forearm were swollen and remained so, and the other fingers became flexed into the palm. The fourth and fifth fingers were amputated in 1925, he had a cervical sympathectomy in 1926, and in 1930 the arm was amputated above the elbow. He had the sensation of a phantom limb after amputation, but it was not painful, and in the last two years he has rarely felt it at all. In 1936 he began to feel a constant burning pain in the whole stump and an aching pain in the left shoulder radiating down the left side of the chest into the left flank. The pain had been relieved for six months in 1942 by excision of neuromata, but the pain had recurred. It was unfortunately impossible adequately to percuss the neuromata, many of which were at or above the apex of the axilla.

At operation the neuromata were not excised but crushed with clamps and left in an easily accessible position over the chest wall. His pain was relieved immediately by this operation, and, should it recur, treatment by percussion is now much more likely to be successful, as the neuromata are easily reached.

In conclusion it should be emphasized that treatment by percussion has not on any occasion in our experience done harm. In some cases benefit has been apparent almost from the first treatment, but in others considerable perseverance has been required to get the desired relief.

Summary

The treatment of painful amputation stumps by repeated percussion to the neuromata has proved successful in most cases.

Of 33 cases considered suitable for percussion treatment, 19 reported good or excellent results and 5 were improved. There was only one failure in the first 15 cases treated, but in the last 18 cases, some of which were especially difficult, there have been eight apparent failures.

Methods of applying the treatment are described. The neuromata are located as accurately as possible. If they are very tender the arterial supply to the stump is occluded by a sphygmomanometer cuff, as anoxaemia renders them less sensitive. Percussion is done with a mallet and an applicator about 15 cm. long. After several minutes the cuff is removed and percussion continued for 20 minutes. An electrical vibrator may be used in place of the mallet, and is of particular value in treating areas beyond the patient's reach. Cases with cold and diffusely tender stumps should be treated by sympathetic block or section rather than percussion.

Illustrative case histories are given.

We are specially indebted to Dr. E. J. H. Schuster for designing and constructing apparatus, also to several members of the Ministry of Pensions staff for their encouragement with this study, and to *Miss Ruth Hurst for her assistance with the treatment of many of* these cases at Headington Hill Hall Rehabilitation Centre, Oxford.

Another highly successful year's working was announced at the annual general meeting on June 6 of the Medical Sickness, Annuity, and Life Assurance Society, Ltd. The chairman, Mr. R. J. McNeill Love, said that when he last addressed the members he had reported on improvements in the policies and policy conditions, and he was now pleased to say that these had produced most satisfactory results. It had been hoped that the new life assurance business might pass the £1,000,000 mark for the first time, and it was gratifying to find that the amount actually achieved was £1,420,734. The figures for the current year indicated that this progress had been fully maintained. A subsidiary company, Medical Sickness Finance Corporation, Ltd., appeared for the first time in the accounts. By the end of last year it had assisted members of the medical and dental professions in the purchase of cars and equipment to the extent of about £100,000. The directors were convinced that this would be a satisfactory investment, especially when there was an increase in the number of cars for the home market. The increase in life assurances effected during the year amounted to £649,614. Claims had increased by £14,646, but were well within the amount expected. The amount paid in sickness benefit was £77,448. The funds of the Society stood at £4,371,026, an increase of practically £330,000.

P.T.A.P.

DETERMINATION OF THE ESSENTIAL Lf DOSAGE

BY

GUY BOUSFIELD, M.D.

Camberwell Laboratory, Public Health Laboratory Service

AND

LEWIS B. HOLT, M.Sc.

Wright–Fleming Institute of Microbiology, St. Mary's Hospital Medical School, London, W.2

P.T.A.P. is an integrated diphtheria prophylactic prepared by the adsorption of highly purified toxoid on to pure aluminium phosphate—each prepared separately. Because of this it is possible not only to duplicate accurately any given composition but also to alter, at will, the amounts of both, as well as their ratios. In this we have a means of answering a number of important questions in diphtheria prophylaxis which previously could not be reliably investigated at all.

Of the several questions that required an accurate answer three have now received attention: (*a*) How much mineral carrier is required to produce the maximal antitoxin response? (*b*) What is the route of choice for inoculation? (*c*) What is the essential or optimum quantity of toxoid necessary?

An account of work done to determine the correct dosage of aluminium phosphate carrier for young children has already been described (Bousfield, 1947a, 1947b; Holt and Bousfield, 1949). This amount was found to be not less than 5 mg. of $AlPO_4$, determined by observing the Schick conversion rate following a single injection. The conversion rate obtained, using 5 or 7.5 mg. of $AlPO_4$, was of the order of 97%; and this was found to persist for at least 15 months in 95% of the children examined. These figures bear interesting comparison with those of Faragó (1935), who, by using a 1-ml. dose of large-precipitate A.P.T., obtained an overall S.C.R. of 93.5% (4,297 cases) following one inoculation, and furthermore reported no significant decline in the S.C.R. after one year.

We have found the route of choice to be intramuscular, in that the relative effectiveness of the intramuscular route to the subcutaneous is 2.6—that is, in order to obtain the same results, 2.6 times as much $AlPO_4$ carrier must be used by the subcutaneous route as by the intramuscular.

Included in these same reports were the results of preliminary attempts to determine the essential toxoid dosage. No statistically significant differences were obtained when the $AlPO_4$ carrier was maintained constant at 7.5 mg. injected, and the amount of toxoid varied from 30 to 5 Lf per dose; the S.C.R.s were determined three months after a single intramuscular inoculation (Holt and Bousfield, 1949, Tables III and IV).

As the solution of this question is one of no small importance or interest the experiment has now been extended. For purposes of accurate comparison it is not a reliable procedure to compare uncritically one set of clinical results with another made at a different time or place. Because of this it is a minimum precaution always to arrange that new materials should overlap, in terms of the variable under investigation, with former preparations used in previous experiments.

It is of some importance also to describe the exact procedure used in making the Schick tests. Schick control was invariably used in all work carried out since

midsummer, 1948 (Bousfield, 1948). Burroughs Wellcome Schick toxin and control were used, 0.2 ml. being inoculated intradermally on the flexor surface of either forearm. The tests were read seven days later without any knowledge of the treatment the child had received. The readings are recorded in such a way that negative results are entered only when the reaction, if any, does not exceed approximately 5 mm. in diameter. For the purpose of this work any reaction greater than this is recorded as positive. This routine is exacting, but is fully justified by the quantitative work of Vahlqvist and Högstedt (1949) on the relationship between circulating antitoxin and the Schick-test result.

Investigation of Minimum Amount of Toxoid which will Produce a Reasonable S.C.R.

A series of preparations was made in which the aluminium phosphate content was maintained constant at 10 mg./ml., and the contents of purified toxoid (1,900 Lf/mg. of protein nitrogen) varied from 10 to 1 Lf per ml. These preparations were made from a sample of P.T.A.P. of exactly known titre and one which had matured at room temperature for nine months; this was appropriately diluted with a 10-mg./ml. suspension of $AlPO_4$, to give the desired concentrations of toxoid.

As in previous work, Schick-positive children between their first and second birthdays were employed. A uniform dose of 0.5 ml. was used, the inoculations were made into the deltoid muscle, and two time intervals of observation were adopted. Four weeks after their single inoculation 494 cases were post-Schick tested, and a further 192 two months after injection. The details of the results are shown in Table I.

TABLE I.—*Schick Conversion Rate in Children (aged 1 Year) Using Samples of P.T.A.P. Containing a Constant Amount of $AlPO_4$ Carrier (10 mg./ml.), but Decreasing Amounts of Purified Toxoid (Intramuscular Inoculation, dose 0.5 ml.)*

Time	Dose of Toxoid (Lf) Injected	Post-Schick Test Result +	−	Total	S.C.R. (%)
1 month after injection	5	11	105	116	90·5
	2·5	11	116	127	91·4
	1	37	98	135	72·6
	0·5	45	71	116	61·2
2 months after injection	5	1	50	51	98·0
	2·5	2	49	51	96·1
	1	6	38	44	86·4
	0·5	19	27	46	58·7

The results of work of this kind may be examined in two ways.

First Examination of Results

The easiest and perhaps slightly naïve way is to present them in graphic form, using percentage S.C.R. on one ordinate and dosage of toxoid on the other. This method of presentation is shown in Fig. 1, supplemented by all previous results obtained, working on the same lines. These latter results are given in Table II.

TABLE II

Dose of Toxoid (Lf)	Post-Schick Results +	−	Total	S.C.R. %
5	20	452	472	95·76
10	6	244	250	97·60
15	51	1,677	1,728	97·05
20	5	251	256	98·05
30	9	244	253	96·44
Total ..	91	2,868	2,959	96·92

χ^2, 5 Lf/the rest = 3·33. P = <0·1

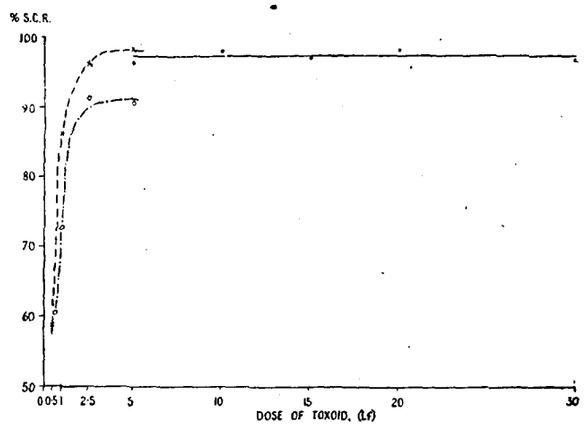

FIG. 1.—Schick-conversion rate in Schick-positive children, aged 1 year, to single inocula of P.T.A.P. containing a constant amount of $AlPO_4$ (5 mg.) and varying amounts of purified toxoid. ——. = previous results Table II. x——x = current results after two months. o——o = current results after one month.

From the graph (Fig. 1) it would appear that the S.C.R. is substantially constant between dosages of about 3 Lf and 30 Lf. If it be conceded that the S.C.R. definitely declines when less than 2.5 Lf of toxoid is used, an approximate evaluation may be made of the critical ratio of toxoid to $AlPO_4$ carrier, which, with those figures, becomes 2.5 Lf/5 mg. of $AlPO_4$, or 0.5 Lf/mg.

These findings—the result of a clinical experiment in immuno-physiology—show an excellent agreement in character with a similar experiment performed in guinea-pigs, in which the critical ratio of toxoid to mineral carrier was found to be approximately 0.2 Lf/mg. of $AlPO_4$ (Holt, 1949). But there seems to be a difference in the amounts of toxoid in the two instances—0.5 Lf/mg. of $AlPO_4$ for children and 0.2 Lf/mg. for guinea-pigs. Although it is difficult to be certain that the difference in these critical ratios is a real one, it would seem that the amount of specific antigen required to convert a normal globulin-producing cell to an antitoxin-producing cell may vary from one animal species to another. Even so, these findings do reveal how very great is the physiological activity of the antigen proper (toxoid protein) when it is administered in this form.

It may be of some interest, at this point, to mention the results obtained in immunizing an exceedingly sensitive adult (combined Schick result) with preparation C (P.T.A.P. Lf 2 and 10 mg. of $AlPO_4$/ml.). This subject tolerated 0.2 ml. of the prophylactic (0.4 Lf). Her antitoxin titre before treatment was <0.005 u./ml. of serum and four weeks after the one inoculation <0.01 u./ml., but four months after a second 0.2 ml. it rose to 0.2 u./ml. This subject, a difficult one, was therefore adequately immunized with a total of 0.8 Lf of purified toxoid, with no more than a transient (48 hours) feeling of slight local discomfort and malaise. The possibility must be admitted, however, that in view of the combined reaction shown there existed the possibility of contact with *Corynebacterium diphtheriae*, although probably not a virulent strain.

These observations do emphasize how appallingly inefficient and inexpertly prepared some samples of A.P.T. obtained from unusual sources must have been in the early days of the war. Even two doses of such material sometimes failed to give a 50% S.C.R. On the other hand, the law governing the amount of toxoid in present-day prophylactics (A.P.T. or P.T.A.P.) demands a minimum

of 50 Lf/ml. From this we see that there is approximately a tenfold margin of safety (against deterioration) in respect of P.T.A.P. as issued for general use.

Second Examination of Results

A more refined analysis is possible by applying statistical methods which permit an examination of the data in several ways and by using devices for checking the accuracy of hypotheses.

For the purpose of a complete-as-possible analysis of the results described above, it was found best to use all the relevant available data; this was done, and the results are given in Table III.

TABLE III.—*Showing all Available S.C.R. Data Following a Single 0.5-ml. Intramuscular Inoculation of Different Samples of P.T.A.P. (All Cases are Children Between Their First and Second Birthdays)*

* χ^2 indicates homogeneity within toxoid doses. All χ^2s with one degree of freedom have been corrected for continuity (Yates's correction).

Although these data are of heterogeneous origin, the materials having been used at different times of the year, and were different, apart from the variable under investigation—namely, a slight variation in the amount of $AlPO_4$ injected, some prepared at *p*H 5, others at *p*H 6.5, and the observations made one, two, three, and six months after inoculation—the results are fairly homogeneous. In fact, all internal analyses show no appreciable differences between these variations. If, therefore, there are differences due to the above-mentioned variations, they must be very small, as the total χ^2 between experiments (within toxoid doses) is 20.151 with 17 degrees of freedom; this indicates a satisfactory homogeneity.

In view of its homogeneity this material seemed to provide a particularly reliable body of data for use (at least in a first-stage analysis) of the Lf-dose-response curve. This curve is plotted as probits of the percentage S.C.R. against log. dose of toxoid (see Carlinfanti, 1948), and is shown in Fig. 2. It will be seen from this curve that there is a tendency towards a maximum response and one that is less than 100%.

An assumption, and one not unreasonable from a biological point of view, is that a small proportion of the child population just does not react demonstrably—

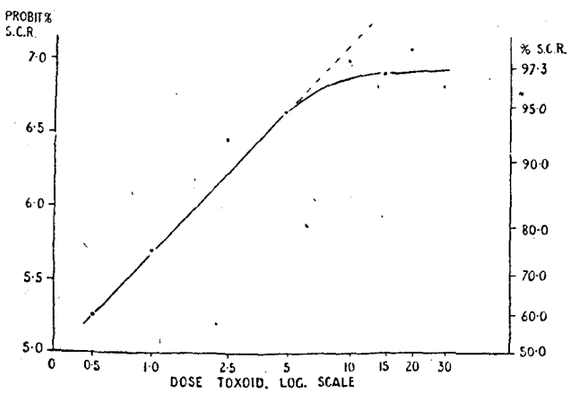

FIG. 2.—Probit % S.C.R./log dose toxoid. C = 0.027. 97.3% convertible, 2.7% non-convertible.

namely, show circulating antitoxin—to any single inoculum, whatever the dose. A similar observation was made by Scheibel (1943) in guinea-pigs, also using diphtheria toxoid. This worker observed that the "non-immunizability" was inherited and in a nearly typical Mendelian manner. It seems, therefore, not unlikely that a similar situation might exist in man, although for the purpose of mass-immunization it does not matter whether the lack of responsiveness in a proportion of the total population is determined genetically or not. It does not follow that the same proportion of refractory subjects will be found following a two-dose system of immunization.

Two well-spaced injections of P.T.A.P. containing 15 or 25 Lf of toxoid with 5 mg. of $AlPO_4$ are now being found to yield virtually 100% S.C.R. two or three months after the *second injection*.

A study of the responses in individual guinea-pigs to one injection and to two spaced injections of toxoid has revealed that most of the poor antitoxin producers—as judged by their responsiveness to a single inoculation—do respond satisfactorily to a second injection (unpublished work). The adult clinical example referred to above may be quoted as a case in point for man.

If we accept the assumption that a proportion of the child population does not respond to a single inoculum, we may try to estimate this proportion, and test whether this hypothesis fits the whole body of data.

From the point of view of statistical analysis this is a problem closely related to one solved by Finney and by

Fisher for the treatment of dose-response curves in the presence of natural mortality. In our present case the situation is reversed in that instead of a lower asymptote we have an upper one. The method of dealing with this problem statistically is by substituting the residual percentage of Schick positives for the natural "mortality," and then working on the decrease of positives with increasing dosage of toxoid—that is, with a negative regression coefficient. The "maximum likelihood" estimate obtained with Finney's (1949) improved method is 2.7 ± 0.5% of "non-convertible" children, and the fit of hypothesis obtained by accepting this figure is very good: χ^2 with five degrees of freedom gives a probability of >50%. The curve corresponding to this hypothesis is shown in Fig. 2. Briefly, this analysis suggests, and supports the suggestion, that when an infinite quantity of toxoid is used with 5 or 7.5 mg. of $AlPO_4$ carrier the maximum S.C.R. obtainable (single dose) is 97.3% (±0.5% standard error), and when 10 Lf are used the expected S.C.R. will be 96.8% and with 5 Lf 95.25%.

This statistical analysis confirms the conclusions drawn from the simple % S.C.R./dose toxoid curve in that there is a maximum (<100%) S.C.R. for P.T.A.P. The maximum is reached asymptotically, and in such a way that the advantage of using more than 10 Lf per dose is negligible.

Summary

Schick-positive children in the London area aged 1 year were given one intramuscular inoculation (0.5 ml.) of samples of P.T.A.P. containing 10 mg. of $AlPO_4$ per ml. and decreasing amounts of purified toxoid.

With an inoculation of only 0.5 Lf a S.C.R. of 60% was obtained, and with 5 Lf one of 93.8%.

By employing all relevant data previously obtained, it appeared that a maximum S.C.R. of about 97% was obtainable using a single 5–10 Lf dose, and that this S.C.R. was not exceeded (on the average) if more toxoid were used.

A special statistical examination of all the results also showed that a maximum S.C.R. of <100% is obtainable with a single inoculation of P.T.A.P. (10 or 15 mg. of $AlPO_4$ per ml.). Using an infinite quantity of toxoid this maximum S.C.R. was calculated to be 97.3% ± 0.5%; using 10 Lf per dose, the expected S.C.R. is 96.8%, and with 5 Lf 95.25%.

These maximum conversion rates for a single inoculation are most probably significantly below those following a two-dose method of immunization.

Our thanks are due to Dr. A. Anderson, M.O. of No. 9, Middlesex area, and to Dr. H. D. Chalke, M.O. of No. 7 Division, L.C.C., for facilities in connexion with the above work. The same thanks would have been expressed in the case of the late Dr. Harry Smith, formerly M.O. of No. 1 Division, L.C.C. Grateful thanks are also due to Dr. L. Cavalli, of the Department of Genetics, Cambridge, for his most valuable assistance in the special statistical analyses demanded by the findings of this investigation.

She is studying gynaecological and obstetrical methods in British hospitals, and is particularly interested in the use of anaesthetics in childbirth.

ILL EFFECTS OF THE RADIUM MENOPAUSE*

BY

HUGH C. McLAREN, M.D., F.R.F.P.S., F.R.C.S.Ed. M.R.C.O.G.

Reader in Obstetrics and Gynaecology, University of Birmingham

Induction of the menopause for non-malignant uterine bleeding is a safe and effective method of treatment, and is much used in the Birmingham School, but the resultant improvement in the patient's health may obscure certain immediate and remote sequelae. In this review attention has been paid to flushing and sweating, loss of libido, and premature senile changes in the genital tract.

In all, 118 cases were examined at an average interval of two years after receiving intrauterine radium (2,400 mg.-hours). The ages of the patients varied from 33 to 58 (average 45). The outstanding symptom after irradiation was flushing, and the cases were grouped according to the following definitions:

(*a*) *Mild Flushing* (commonest).—An occasional sensation of heat and sometimes sweating with an obvious flush of the face and neck. Normal duties are not disturbed and the patient is seldom inconvenienced.

(*b*) *Moderately Severe Flushing.*—From 12 to 20 or more flushes by day severe enough to cause temporarily listlessness and a sense of fatigue. Generalized sweating usually accompanies flushing, and this often causes the patient to waken from sleep with her night attire uncomfortably wet.

(*c*) *Severe Flushing* (rare).—A severe disability causing insomnia, listlessness, and fatigue (20 cases from *b* and *c* were already under stilboestrol therapy in this series).

The results after radium were: severe flushings, 5 (4%); moderately severe flushings, 53 (45%); mild flushings, 51 (44%); and flushings absent, 9 (7%).

The incidence of serious and persistent attacks of flushing after irradiation is three times the normal, or approximately the same as that following surgical castration (Table I).

TABLE I.—*Comparison of Menopausal Flushing**

	Pre-menopausal	Post-menopausal	Radium	*X* rays	Castration	Hyst. Only
No. of cases	74	78	118	17	43	67
Incidence of severe or moderately severe flushing	7 (9%)	13 (17%)	58 (49%)	10 (59%)	20 (46%)	1 (1·5%)

* Comparative figures from previous report (McLaren, 1941).

On the other hand, simple hysterectomy with conservation of ovarian tissue is not followed by the immediate onset of these symptoms. Moreover, the reservation of radium for patients nearer to 50 than 40 years of age does little to alter the incidence of severe flushing (McLaren, 1941).

Spontaneous Cure of Flushing.—It is commonly held that the passing of a few months will cure flushing, and that a little encouragement is all that is required from the doctor. With this in mind we carefully investigated 71 patients who had completed the radium menopause for periods up to four years (average two years), to find that a spontaneous cure had resulted in only 13 cases, while four appeared to be more seriously affected with the passage of time. The remaining 54 cases (76%), however, continued to have flushing of unabated severity, so that "radium" flushes are by no means transient.

*A postgraduate lecture delivered at the Royal College of Obstetricians and Gynaecologists on November 18, 1949.

Sex Function After Radium.—Before any pelvic operation or treatment by radium or *x* rays there arises in the patient's mind the question, "Shall I be able to continue my normal married life?" At the time of writing no adequate controls are available—that is, it is not known how many women become sexually anaesthetic after the normal menopause. It is considered, nevertheless, that the sudden loss of libido and the onset of sexual dysfunction after radium should be recorded.

Method of Study

The difficulties in obtaining accurate information and the degree of selection of cases were as follows: (1) Before radium treatment uterine bleeding had often caused both physical and mental disturbances, so that sometimes sexual activity had been minimal for months. (2) When patients could not be questioned about sex function—for example, embarrassed patients, unmarried women, widows, or women with unfit husbands. (3) When the patient was obviously telling us what she thought might be expected of her—for example, when a woman, alleging normal sex life, was found to have a painful lesion of the vulva or vagina. (4) Lastly, in all cases the sexual performance of the male partner could only be guessed at from questioning the patient.

I interviewed all the patients in privacy, and after a general talk about weight, flushings, amenorrhoea, etc., the subject of sexual function was tactfully opened. After ascertaining that the husband was healthy, I explained that we were anxious to know if their married life had been improved or in any way altered since the cure of menorrhagia. In various forms the following questions were put:

1. "Before treatment, how frequently did intercourse take place—twice weekly or oftener?" Very often the question "after radium" was answered by a shrug, "Oh, I quite lost interest," or, "It became quite hopeless."

2. The orgasm was also discussed in the simplest terms. "Do you get complete satisfaction, just like your husband?" "Do you get satisfaction always, or once every two or three attempts?"

Very occasionally the male partner was accused of being precipitate or ineffective, but more often the patient herself admitted the sudden onset of sexual anaesthesia, sometimes aggravated by loss of secretion at the vulva.

Material

Half the patients were from Aberdeen and district and half from Birmingham and the Midlands. Information was available from a total of 236 cases. The variable ages of the patients were:

Group A: Aberdeen (116 Cases)

Age	No.	Age	No.	Age	No.	Age	No.	Age	No.
27	1	40	3	45	8	50	4	55	3
34	1	41	4	46	10	51	12	56	1
36	1	42	9	47	12	52	3	57	1
37	2	43	7	48	4	53	6	58	2
38	4	44	6	49	9	54	2	61	1

Group B: Birmingham (120 Cases)

Age	No.	Age	No.	Age	No.	Age	No.	Age	No.
33	1	38	1	43	9	48	12	53	9
34	1	39	4	44	5	49	6	54	5
35	1	40	3	45	5	50	4	55	2
36	2	41	9	46	9	51	5	56	2
37	2	42	7	47	10	52	5	58	1

The following is an outline of the degree of selection. *Sex Urge:*—Computed from desire for intercourse or libido plus frequency of intercourse; 76 patients could provide no information (unmarried, widows, those with unfit husbands). The evidence was discarded as unreliable in 17 and accepted in 143. *Orgasm:*—No information, 79; evidence discarded, 31; reliable information available, 126.

Effect of Radium on Sex Urge

Before Radium.—Good, 11 (7%); moderate, 66 (46%); slight, 43 (30%); absent, 23 (16%)—a total of 143 cases. In other words, 66 (46%) of our cases either lacked or had only slight libido before treatment with radium. The remaining 77 cases (54%), however, had normal sexual desire and would therefore have reason to complain if they found themselves anaesthetic or completely disinterested as a result of radium treatment.

After Radium.—(1) *11 patients with "good" sex urge:*—Unchanged, 7 (64%); depressed to "slight," 1 (9%); complete loss of libido, 3 (27%). (2) *66 patients with moderate sex urge:*—Maintained, 15 (23%); depressed to "slight," 9 (13.5%); complete loss of sex urge, 42 (63.5%). (3) *43 patients with "slight" sex urge:*—Improved to "moderate," 2 (4.5%); unchanged, 14 (32.5%); complete loss of sex urge, 27 (63%). (4) *23 patients without sex urge:*—Unchanged, 23.

To summarize: sex urge already depressed or lost in about 50% of cases suffered further as a result of radium castration; for of 77 patients estimated to have normal sex urge 55 (71%) suffered a marked diminution or found themselves entirely without libido.

Effect of Radium on the Orgasm

Before Radium.—Orgasm usually or almost always, 65 (51.6%); orgasm occasionally, 30 (23.8%); orgasm never achieved, 31 (24.6%)—a total of 126 cases. In other words, 61 (48.4%) were unable to achieve the orgasm or did so only occasionally, while 65 (51.6%) normally achieved the orgasm, and would therefore have reason to complain if this faculty were lost as a result of radium castration.

After Radium.—(1) *65 patients who normally achieved the orgasm:*—No effect (orgasm maintained), 28 (43%); depressed (occasional orgasm), 14 (21.5%); absent, 20 (30.7%); doubtful, 3 (4.6%). (2) *30 patients who occasionally achieved the orgasm:*—No effect, 11 (36.7%); complete loss of orgasm, 19 (63.3%). (3) No orgasm before or after radium, 31 (24.6%).

As will be seen, the orgasm, already infrequent or absent in 61 cases (48.4%), was further affected by radium, so that 34 patients (52%) who normally achieved the orgasm found this no longer possible.

Dyspareunia after Radium.—Although the commonest symptoms after the use of radium were sudden loss of libido and a loss of normal genital sensation, dyspareunia was also present in at least 10% of cases. Occasionally patients noticed that lack of normal vulvar secretion at coitus aggravated the condition.

Premature Ageing of the Genital Tract after Radium

The Vulva and Introitus.—Vulvitis secondary to vaginitis was observed in 2 out of 82 cases, but the introitus appeared abnormal in 7 out of 72 cases—in fact, in 5 patients pain prevented the passage of a small speculum.

Atrophic Vaginal Changes.—Total number of Cusco examinations, 68; bleeding mucosal spots, 11 (16%). Clinically, we labelled these spots "senile vaginitis,"

TABLE II.—*Abnormal Introitus*

Case No.	Age	Condition of the Introitus
53	48	Red and inflamed but not painful
184	36	Painless telangiectasis
185	48	Involved in senile vaginitis
188	52	Perineo-vaginal junction split and bled easily
187	39	Tender inflamed introitus
263	58	Tender; periurethral oedema present
103	53	Tender inflamed introitus

although "pre-vaginitis" would perhaps be a more accurate term; for in our experience it requires the irritation of, say, a pessary before purulent vaginitis develops. In Table III

TABLE III.—*Vaginal Spotting*

comparative figures from a previous report (McLaren, 1941) show clearly that surgical castration, like radium, may produce senile mucosal spotting, whereas functional ovarian tissue prevents it.

The Cervix.—The following is a summary of the effect of radium on the cervix: (*a*) atrophy down to the merest rudiment, 27 of 100 cases (27%); (*b*) red spotting on the portio, 9 of 75 cases (12%); (*c*) flat erosions without mucopus, 10 of 131 cases (13%); (*d*) cervical mucus, 56 cases: absent or traces of mucus, 33 (59%); small amount of mucus, 23 (41%). A great variety of bizarre-shaped cells appear in the endocervical canal after irradiation, while radium-vacuolation was occasionally observed in the cytoplasm even six months after treatment. The commonest cells were the polymorph and the endocervical cell, 7 to 10 μ in diameter and possessing a relatively large nucleus. Large "fibre" cells 120 to 180 μ in length with rod-shaped nuclei and small squamae were also seen. Mucus in crenated or web-like form replaced the clear mucus of the sex-mature cervix. On one occasion, however, a small clear piece of mucus was found to contain abundant spermatozoa.

The Urethra.—In a previous report on patients over 60 we noted that in the normal menopausal urethra the external urethral orifice might occasionally show a tongue-like projection of mucosa. These protuberant areas were painless and did not bleed; they were considered to be physiological and not true caruncles. No such appearances were seen in this series. The recent work of H. G. Hanley (1944-5) on menopausal trigonitis and urethritis led us to search for this condition, but only two cases with frequency, sterile urine, and typical trigonal lesions have so far been discovered. (Mr. Guy Baines undertook the cystoscopic examinations.) Urethral smears were taken from 47 smears and compared with the normal. Only three smears could be labelled senile or immature with deep or undifferentiated small cells. The remainder were within normal limits—namely, clumps of intermediate cells (40 μ in diameter), small squamae, globular cells with long nuclei, leucocytes, free nuclei, and so on. Evidence of urethral irradiation was occasionally seen in cytoplasmic and nuclear vacuolation up to six months after treatment.

Vaginal Smears Reflecting Ovarian Activity

Vaginal smears can forecast the actual mucosal histology (1) with adult or mature cells (= adult differentiated epithelium), and (2) with very small or immature cells (= senile undifferentiated epithelium). Most menopausal smears were neither adult nor completely senile. Many smears had a large number of intermediate cells, and though they cannot always be correlated with the histology of the mucosa they do portray a degree of senility or lack of maturity. With these limitations of the vaginal smear in mind, 67 were classified as follows: grossly senile (grade I), 2; moderately senile (mixed or grade II), 44; menopausal clumping (grade III M), 19; and adult, as in sex-mature women (grade III), 2.

Seventy per cent. of the smears therefore had varying numbers of intermediate or senile cells. The 19 smears showing menopausal clumping resembled mid-pregnancy smears, and, indeed, in one case (after 17.5 g. of vitamin E, however) the pregnancy-like or "luteal" smear was found at laparotomy to correspond to the presence of a post-menopausal luteal cyst of the ovary (McLaren, 1949). These menopausal "pregnancy-like" smears appeared to have smaller flat cells lying superficial to deeper and larger cells. It is not suggested, however, that the hormone levels of pregnancy and the menopause are similar, although the resulting vaginal smears may be alike.

The presence of deeper mucosal cells in 70% of the smears probably results from a deficiency of ovarian hormones, and this is supported by the fact that flat squamae replace less mature cells after small doses of stilboestrol. The other possibility is that senile (menopausal) cells result from an excessive level of androgens or a new and increased response to a hormone of this type which is capable of depressing the maturation of the vaginal mucosa. Whatever the exact hormone pattern which produces senility or maturity in cell smears, there is no relation between the cytology and the severity of symptoms; so that patients with no flushings, for instance, produce senile smears and, vice versa, patients suffering intensely from flushing may have a relatively adult cell smear.

Miscellaneous Findings

Ignorance of the diagnosis and the aim of treatment was striking both in this series and in the Aberdeen group—for example, eight patients still practised contraception, while several admitted that they thought they had had cancer. One patient had amenorrhoea and a large abdomen, and was lactating freely. She was busily occupied in knitting baby-clothes for her pseudopregnancy.

Discussion

From the foregoing, the radium menopause is apparently free from any severe delayed effects, but flushings, sexual anaesthesia, and mild involutional changes in the genital tract may be important if not severe disabilities. Most of these ill effects can be improved by the use of stilboestrol. Indeed, 19 of our patients were already under stilboestrol treatment for flushings by their own doctors. However, 40 patients were suffering the discomfort of flushings with loss of sleep, etc., apparently content with the assurance that the effects of the "change" are inevitable and would soon cease.

Flushing and Sweating

Fifty per cent. of normal women approaching the menopause experience occasional flushes or sensations of heat, but in only one case in ten are they of serious type. The figure rises to 17% after the menopause and to 50% after radium or castration (McLaren, 1941). This figure is in agreement with that of Schmitz and Towne (1947), who recorded 48% with "serious menopausal manifestations" in 412 cases treated by *x* rays or radium.

To the severity of "induced" flushes must be added their suddenness of onset. In contrast to this, the normal woman is usually given time to become used to flushes, which may or may not slowly increase in frequency and intensity.

The similarity of the incidence of flushing after radium and castration raises the question—so far unanswered—

of the aetiology of flushing. Does radium destroy the ovary, or is its chief effect on the endometrium, finally preventing it from reacting to hormone stimulation? There seems as yet no clear answer, though probably both endometrial and ovarian irradiation are important in producing amenorrhoea. Ovarian damage and reduced secretion of follicular and luteal hormones (as reflected, for example, in the vaginal smears) may permit overaction of the anterior pituitary, but why this leads to uncontrolled flushing and sweating is not clear.

Loss of Libido

Do women normally become disinterested in sex matters at the menopause? I was somewhat discouraged in several attempts to find a suitable group of (gynaecologically) normal patients—for example, in the surgical wards. So far no controls are available to compare with patients who have been irradiated. Nevertheless, it seems an important finding that libido practically disappeared in well over half the patients under review. The cause of sexual anaesthesia would appear to be more than a temporary effect of irradiation on the sensory-nerve endings in the genital tract, for that might be expected to resolve in time. Ovarian sclerosis with loss of ovarian hormone is another possibility, but it is well known that some castrated women may continue to have a normal and satisfactory married life. The mere fact that the patient has amenorrhoea and knows that she can no longer bear children may, however, be the main factor in disturbing normal sex function.

There seems little doubt, therefore, that radium treatment quickly leads to sexual anaesthesia in 50% of women with normal sexual feelings. It may be that a similar group of patients passing through the normal menopause would likewise find themselves without interest in sex matters, but that does not detract from the fact that radium has caused this *prematurely*.

If, when adequate controls are available, it is found that the normal menopause also leads to sexual anaesthesia in a high proportion of cases, that will provide no support for the induction of the menopause except when it is obvious that no other method of therapy is effective. The development of sexual anaesthesia is a serious matter whether inevitable in the normal menopause or not, and to avoid it our future efforts must obviously aim at a method of controlling haemorrhage short of induction of the menopause.

Premature Involution of the Genital Tract

The occurrence of two cases of vulvitis, five with painful lesions of the introitus, and 11 with red "blood spots" on the vagina perhaps does not portray a picture of serious clinical lesions. But add the fact that dyspareunia was present in at least 10%, and that many of the patients suffering from newly developed sexual dysfunction no longer had Bartholin's secretion at coitus, and it will be obvious that radium does more than simply produce therapeutic amenorrhoea.

Mucosal Spotting.—The passing of a Cusco speculum with distension of the vagina seldom causes punctate areas of bleeding in the vaginal mucosa before the menopause, although in a previous study in normal post-menopausal women in the sixth and seventh decades the condition was found to be quite common—namely, 15 out of 58 (26%) (average age 63). Moreover, in younger women, after surgical castration, similar vaginal spots were found in 11% of cases (McLaren, 1941). It is not possible to say how many years must elapse before these atrophic changes become common in the normal woman, but the appearance of "senile spots" in 16% of cases after radium treatment (aged about 45) is unusual and almost certainly it is a consequence of irradiation. Since small doses of stilboestrol cure the condition it seems likely that lack of ovarian hormones is in fact the cause, and this is borne out in Table III, which clearly shows that conservation of ovarian tissue at hysterectomy prevents, or at least postpones, involutional changes in the vagina. The histological appearance of these "blood spots" is typical, whether on the portio or in the vagina—namely, the superficial epithelium is missing, so that only a few layers of small epithelial cells separate the lumen of the vagina from the submucosa. At the site of the epithelial defect there is a clustering of round cells, but no marked dilatation of blood vessels such as one sees in true senile vaginitis.

The red spotting of the vagina therefore seems to represent a deficiency of ovarian hormones and constitutes a potential rather than an actual disability—that is, it may be only after insertion of a pessary, or after coitus, that a true senile (purulent) vaginitis develops.

The Cervix.—In cases of persistent uterine bleeding in which either radium or surgery would suffice, after curettage has excluded cancer of the uterus, the scales are often tipped in favour of surgery by the presence of a hypertrophic eroded cervix from which excessive amounts of mucopus exude. The choice of surgery implies that the cervical condition will not be cured by radium, but, in fact, in our observations we have never seen a cervix after the radium menopause which produced excessive quantities of mucopurulent discharge. On the contrary, after radium treatment the cervix secretes little or no mucus and becomes less bulky, even atrophic. It is important, therefore, in assessing a clinical case to recognize that the radium menopause will cure what seems to be an unhealthy cervix and relieve symptoms arising from mucopurulent cervical discharge.

Comment

Apart from emphasizing the effects of castration by radium or any other method, our investigations do not answer the difficult clinical problem of selecting the safest and best method of treating a specific case of simple menorrhagia at or near the climacteric. After diagnostic curettage it is often good practice to delay a decision on final treatment, sending the patient to a convalescent home, where rest, fresh air, iron therapy, and so on may continue to improve her general condition.

Especially in metropathia, it is not uncommon for temporary, or even permanent, recovery to follow these simple measures. Very often, however, even after attempts at control with hormone therapy, a decision has to be given on treatment aimed at producing amenorrhoea. The definite morbidity and mortality of hysterectomy *versus* the safety and simplicity of *x* rays or radium is a lengthy subject which will not be discussed here. If, however, irradiation is chosen (and it rightly finds favour in the Birmingham school for certain cases), it is clear that several years of follow-up should be planned. The need for this is exemplified by the fact that, although 19 patients had reported menopausal flushings and were under hormone treatment by their own practitioners, 40 were not being treated, to say nothing of those who obviously required help in restoring their normal married life.

It seems logical and practical that follow-up examinations should fall to the gynaecologist who induced the menopause rather than to the patient's private doctor, who may or may not have retained the report on the pelvic pathology. If patients are seen at three-monthly or four-monthly

intervals for three years, or at least given the opportunity of visiting the clinic if they have any symptoms, severe flushing and minor genital lesions would be diagnosed and a correct dosage of stilboestrol established. By these simple measures most of the criticism levelled at radium could be met and further support given to it as a safe and effective agent in dealing with intractable bleeding at the menopause.

Summary

Severe or moderately severe flushing may persist for months or years in 50% of cases after the radium menopause (three times the normal incidence).

Only 50% of patients had interest in sex matters before treatment. Of the remainder every other case quickly became sexually anaesthetic after radium treatment. (No "controls" are available.)

Premature senility of the lower genital tract may follow soon after radium—for example, 5 out of 72 had a tender inflamed introitus, and 11 out of 68 had "pre-vaginitis" (red spots).

Responsibility for detection and treatment of the effects of radium rests with the gynaecologist rather than with the practitioner.

This report has been read and criticized by Professor H. N. Lloyd, Mrs. B. M. Willmott-Dobbie, Professor Dugald Baird, Dr. John Hewitt, and Dr. A. C. Crooke. Although unable to answer all the points they raised, it is a pleasure to acknowledge their help and useful suggestions. My thanks are also due to Sister M. Scotwell and to our technician, Miss M. E. Attwood, for their assistance in preparing this report.

OBSERVATIONS ON THE TREATMENT OF THYROTOXICOSIS

BY

IAN MURRAY, M.D., F.R.C.P.Ed., F.R.F.P.S.

Physician in Charge, Department of Metabolic Diseases, Victoria Infirmary, Glasgow

There is much diversity of opinion regarding the treatment of thyrotoxicosis. Discussion still centres mainly on the relative merits of thyroidectomy and thiouracil treatment. Neither of these methods can, however, be regarded as wholly satisfactory, and no one would claim invariable success with either. An appreciable proportion of patients are found to relapse after either form of treatment; neither is completely devoid of risk, and there is the possibility, particularly after surgical treatment, of such sequelae as malignant exophthalmos or myxoedema. It is of course recognized that complete remission of thyrotoxic symptoms is obtained in a large number of cases treated either surgically or medically.

Astwood (1948), reviewing 400 cases treated with thiouracil, found that 85% of cases obtained satisfactory remission. Carrick Robertson (1948) noted improvement with the use of this drug in 62% of patients under the age of 21, but only in 43% of a series of 116 cases of all ages, while he claimed almost universally successful results with thyroidectomy. On the other hand, Goldman, cited by Astwood, obtained lasting relief in only 41.8% of cases treated surgically, and Vander-Laan and Swenson (1947) considered the results of thyroidectomy wholly satisfactory in only two-thirds of their cases.

Despite the satisfactory results not infrequently obtained in the treatment of thyrotoxicosis, it is apparent that the current methods are not always successful and that relapses are not uncommon. The purpose of this paper is to inquire into the circumstances which might determine this variability in response to therapy. The investigation is based on the examination of 265 patients referred to me on account of suspected thyrotoxicosis.

Diagnosis of Thyrotoxicosis

While the frank thyrotoxicosis of typical Graves's disease is easy to detect, many cases present difficulty in diagnosis. The recent method of studying excretion of radioactive iodine in the urine has emphasized rather than eliminated this difficulty, as it has shown that there are many "borderline" or doubtful cases. In any case of suspected thyrotoxicosis, nervousness is a feature. The combination of nervousness and thyroid enlargement may be wrongly taken to indicate thyrotoxicosis, as the thyroid may not be overactive although large, while, particularly in men, marked hyperthyroidism or thyrotoxicosis may exist with but slight increase in the size of the gland. Exophthalmos may occur without thyrotoxicosis and may be aggravated by thyroidectomy. Tachycardia is commonly found in nervous patients, whether thyrotoxic or not. Auricular fibrillation in a heart otherwise apparently normal is probably most commonly the result of thyrotoxicosis, but the latter condition may be quiescent although the cardiac irregularity persists. The B.M.R. is certainly raised in thyrotoxicosis, but it may be extremely difficult to obtain a truly basal estimation in a tense, nervous patient, and, in such, high figures may be recorded even in the absence of hyperthyroidism. While the blood cholesterol is commonly below normal its value is too variable to be of much diagnostic help.

Recognizing these difficulties, it is not surprising that in by no means all the cases in the present series could the diagnosis of thyrotoxicosis be accepted. Of the 265 cases as shown in Table I, only 144 were considered toxic, and 93, although having some degree of thyroid enlargement, non-toxic. The remaining 28 cases had no goitre and no symptom other than nervousness; these have been classified as "neurosis." The number of patients in the "non-toxic" group is so high relative to those in the toxic group that it might be considered that too rigid criteria were demanded for a diagnosis of toxicity. Circumstantial evidence in favour of the correctness of the classification is found in the incidence of cardiac arrhythmia among the toxic cases. As shown below, the incidence of this complication in the present series was found to be somewhat lower than that noted by other observers, which is contrary to what might be expected had the grouping been too highly selective. It may, however, be significant, as is considered later, that the average age of patients in the non-toxic group was less than in the toxic patients (Fig. 1).

TABLE I.—*Analysis of 265 Cases Referred to Clinic Suspected to be Suffering from Thyrotoxicosis*

Group	Female	Male	Total
A. Thyrotoxic	116	28	144
B. Goitrous but not thyrotoxic	91	2	93
C. Neurosis—no goitre or evidence of thyrotoxicosis	22	6	28
	229	36	265

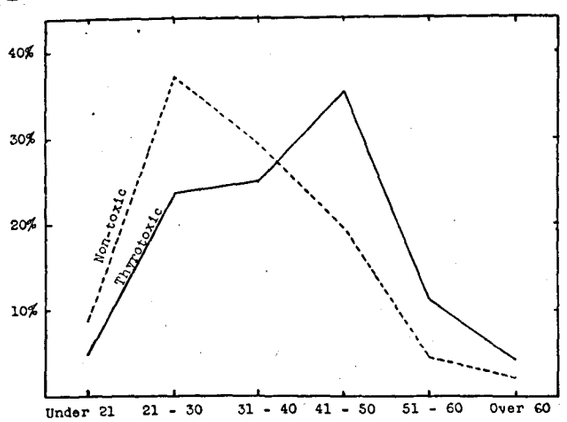

FIG. 1.—Percentage of patients in each age group.

Results of Treatment

Of the 144 thyrotoxic patients 116 were women. The age of the patients is shown in Fig. 2. It is seen that among women the largest age group (comprising 33.5%) was at the time of the menopause, while in men the peak (42%) is reached a decade later.

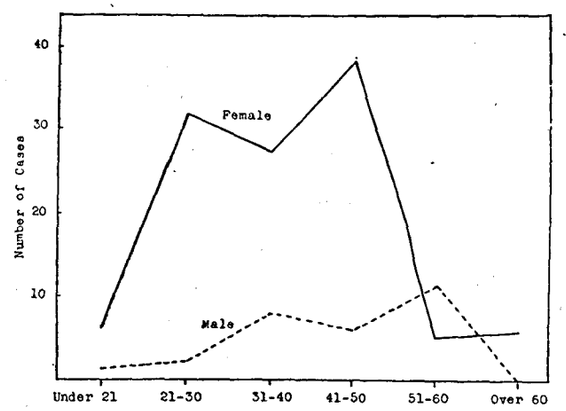

FIG. 2.—Sex distribution of thyrotoxic patients in each age group.

All these patients were treated with methyl-thiouracil, with two exceptions—one who was found to have a persistently low white cell count and for whom it was considered thiouracil might therefore be contraindicated, and another who for social reasons could not attend for the supervision necessary with medicinal treatment. The patients treated with thiouracil have all been observed for at least 18 months. The results of treatment are summarized in Table II. A satisfactory remission of symptoms has been obtained in 85 cases, of which 76 have ceased treatment for more than 12 months. There are 50 patients still receiving the drug, but it is anticipated that a considerable number of them will be able eventually to discontinue it. Thyroidectomy was performed on seven cases following a period of thiouracil treatment. In five of these complete remission of symptoms had been obtained and operation was carried out, for cosmetic reasons, at the patient's request. One patient elected thyroidectomy before satisfactory control had been obtained; while another, who had already undergone thyroidectomy on two occasions, so readily developed marked leucopenia each time thiouracil therapy was attempted that she had to be referred once more for surgical treatment.

TABLE II.—*Analysis of Cases Treated with Thiouracil*

Age Group	Total Treated	Off Treatment		Still on Treatment		Subsequent Thyroidectomy
		More than 12 Months	Less than 12 Months	More than 12 Months	Less than 12 Months	
Under 21	7	4 (1)	—	1 (1)	1 (1)	1
21–30 ..	34	19 (2)	4	9	1 (1)	1
31–40 ..	36	20	2 (1)	14 (3)	—	—
41–50 ..	43	23 (5)	2 (1)	14 (2)	—	4
51–60 ..	16	8	—	8 (2)	—	—
Over 60	6	2	1 (1)	2	—	1
	142	76 (8)	9 (3)	48 (8)	2 (2)	7

The figures in parentheses indicate the number of patients who had relapsed after a previous course of thiouracil.

Relapses

It will be seen from Table II that 21 cases relapsed after treatment with thiouracil. These had received a course of treatment averaging 13 months, and this had been followed by a period of remission, the average duration of which was eight months; thereafter thiouracil was resumed. Eleven patients have again had satisfactory remission of symptoms and have been able to abandon the drug, eight for more than 12 months; the remainder are still receiving thiouracil.

Experience showed that patients who had previously undergone thyroidectomy were more difficult to control and that they tended more readily to relapse if thiouracil therapy was stopped after control had been effected. This is in accord with the findings of Cookson and Staines (1947), who, after treating seven similar cases for 18 months, obtained remission in only two. In the present series there were 14 such cases, the effect of treatment on which with thiouracil is summarized in Table III. It is seen that 10 of these are still receiving the drug (in four cases it has been administered continuously for four years). The case submitted to repeat thyroidectomy is that referred to above in which there was marked sensitivity to thiouracil as indicated by severe leucopenia.

TABLE III.—*Thiouracil Treatment of Thyrotoxic Patients Who Had Previously Undergone Thyroidectomy*

Age Group	No. Treated	Off Treatment	Still on Treatment	Thyroidectomy Repeated
21–30 ..	2	—	2 (1)	—
31–40 ..	2	—	2	—
41–50 ..	9	2 (1)	6 (3)	1
51–60 ..	1	1	—	—
	14	3 (1)	10 (4)	1

The figures in parentheses indicate the number of patients who had relapsed after a previous course of thiouracil.

Comparison is made in Table IV between the results on patients treated initially with thiouracil and on those to whom the drug was administered after previous thyroidectomy. In the former group the relapse rate was 12.5%, while in the latter it was 36%. Of those treated only with thiouracil 64% are in a state of remission after abandonment of the drug. A considerable number of those still under treatment will, it is anticipated, come into this category later, and, even allowing for the possibility of some relapses, it would seem a fair estimate that at least 75% of the cases treated will have satisfactory remission of symptoms after stopping thiouracil. On the other hand,

TABLE IV.—*Effect of Methyl-thiouracil Treatment on Patients (A) Without, and (B) After Previous Thyroidectomy*

	No. Treated	Off Treatment	Still on Treatment	No. of Relapses	Subsequent Thyroidectomy
A	128	82 (64%)	40 (31%)	16 (12·5%)	6 (5%)
B	14	3 (21%)	10 (71%)	5 (36%)	1 (7%)

certain cases seem to require treatment for an indefinite period. This applies particularly to the post-thyroidectomy patient; of such cases in the present series 71% appear to be of this type.

Cardiac Arrhythmia

Brief reference may be made to this complication of thyrotoxicosis. As shown in Table V, auricular fibrillation was noted in 16 cases (11.1%). One patient was treated

TABLE V.—*Incidence of Auricular Fibrillation and its Control with Medical Treatment*

	No. of Cases	Cardiac Arrhythmia	Rhythm Restored
Various authors, 1944–6* ..	268	40 (15%)	27 (67·5%)
Cookson and Staines (1947) ..	95	16 (17%)	8 (50%)
Clarke (1948)	6	3 (50%)	
Goodwin (1949)	144	28 (19%)	13 (46·4%)†
Vérel (1949)	62	10 (16%)	9 (90%)
Present series	144	16 (11·1%)	11 (73%)

* Nussey (1944), Grainger *et al.* (1945), McGavack *et al.* (1945), Cookson (1945), Wilson (1946). † During this investigation into the effects of thiouracil, quinidine was not used.

surgically; of the remainder treated with thiouracil 11 (73%) regained normal rhythm, three requiring quinidine in addition. These results are comparable with those of other observers, which are summarized in the table. As might be expected, the higher the age group the greater was the proportion of patients found to suffer from auricular fibrillation (Table VI).

TABLE VI.—*Age Incidence of Auricular Fibrillation in Thyrotoxic Patients*

Age Group	No. Showing Arrhythmia	Percentage in Each Age Group	Sinus Rhythm Regained	Arrhythmia Persists
Under 21	0	0	—	—
21–30	0	0	—	—
31–40	1	3	1	—
41–50	6	14	4	2
51–60	5	31	4	1
Over 60	3	50	2	1

Complications of Treatment

Some degree of leucopenia was commonly encountered, but was rarely sufficient to call for discontinuance of thiouracil. There were, however, two fatalities—one patient, a young girl who had been treated with thiouracil and had remained well thereafter for several months, relapsed. It was suggested to her doctor that she should again be given methyl-thiouracil as an out-patient. She did not return to the clinic, and it was later discovered that she had developed severe sore throat, and, suspected to be suffering from diphtheria, had been removed to an isolation hospital, where she died soon after admission, throat swabs proving negative for that infection. It seems certain that her death was attributable to acute agranulocytosis.

The other patient, a middle-aged woman, developed marked leucopenia, and thiouracil treatment was stopped. She was kept under observation; folic acid and other therapeutic agents were tried, but the white cell count remained persistently low. More than a year later, although no further thiouracil had been administered, she suddenly developed severe epistaxis and died; necropsy revealed very marked hyperplasia of the bone marrow and splenomegaly, compatible with hypersplenism. Other toxic manifestations of this form of therapy were encountered in mild degrees, but did not interfere with treatment. One strange sequel, which does not seem to have been reported previously, was noted in two male patients who, after thyrotoxicosis was controlled, grew hair on areas of scalp which had been bald for years.

Psychiatric Aspects of Thyrotoxicosis

While it is true that a large proportion of thyrotoxic patients obtain satisfactory remission of symptoms, whether treated surgically or with thiouracil, it is apparent that they vary greatly in the manner in which they respond to treatment and in their liability to relapse. Some factor must exist to explain these differences.

A hereditary tendency is found in many patients. In the present series of 144 thyrotoxic patients a familial history was obtained in 22 (15.3%). In the non-toxic group of 93 patients a familial history was given by 11 (11.8%), while no patient in the third "neurosis" group gave such history. It has been suggested by Bartels (1941) that a defect, probably of the thyroid, is inherited. While this possibility cannot be denied, it is conceivable that a thyrotoxic mother may so affect the environment of the child that the latter may develop emotional disorder which may prove to be the background for the development of thyrotoxicosis.

Although for many years considered as a possible precipitating factor of thyrotoxicosis, emotional disturbance as the essential cause of the disorder has not gained universal acceptance. Langdon Brown (1932) wrote: "I am more and more impressed with the influence of emotion in the causation of Graves's disease." On the other hand, it has been postulated by Linnell and Greene (1947) that the essential lesion is in the hypothalamus, which, it is suggested, becomes hypersensitive and reacts to even a normal blood thyroxine. Dealing with the latter hypothesis, Means (1949) asks why this change in sensitivity should occur. It seems possible that if altered function of the hypothalamus is established the cause may be attributable to emotional influences on it.

Less attention appears to have been given to psychological disturbances in the treatment of thyrotoxicosis. Kiene and Dixon (1931) examined 15 patients who had previously undergone thyroidectomy and, concluding that recurrence of symptoms would not occur if nervous tension could be relieved, recommended complete psychiatric study of all cases of hyperthyroidism. Such a study was made on 200 thyrotoxic patients by Conrad (1934), from which she formed the opinion that therapy should include both means, such as partial thyroidectomy and also psychiatric guidance. The value of the latter form of treatment in restoring these patients to useful satisfactory life has recently been advocated by Lidz and Whitehorn (1949).

In the treatment of the patients in the series under review it soon became apparent that continuing emotional disturbance was always to be found in those who proved difficult to control. At this time the services of a psychiatrist, Dr. Adam Milne, became available, and he co-operated in the work of the thyroid clinic. His assistance in elucidating the emotional difficulties and in advising about their solution was invaluable.

While the association of physician and psychiatrist in the treatment of thyrotoxicosis may be regarded as ideal, one must agree with Lidz and Whitehorn that the brunt of helping the patient to regain emotional equilibrium must in general fall on the internist. Apart from the fact that the services of an expert psychiatrist are not always available, there is usually little difficulty in obtaining information from the patient about the disturbing factors in the life situation, for, as these writers point out, the thyrotoxic subject is generally an "outgoing" person who relates to others easily. Moreover, they consider there may be danger in energetic psychiatric approach, and recommend

an active "superficial" psychotherapy, amounting essentially to prompt decision and advice on practical details.

It is not possible here to give details of all cases in this series, but below are a few typical histories.

Illustrative Cases

Case 1: Rapid Response to Treatment.—A man aged 27, when first seen, was a classical example of thyrotoxicosis, with a large vascular goitre, exophthalmos, and all the typical symptoms. A remarkable psychiatric history was obtained from him. He had been an unstable child, timid and afraid of the dark, because of association with an apprehensive nervous mother and quarrels and drunkenness in his home. At 16 he had a "nervous breakdown" associated with worry and feelings of guilt over masturbation. He was an unsteady worker because, as he thought, conditions always affected his health. Just before joining the Army he had a "nervous breakdown," on account of which he left work. During this time he was "accidentally" called up for the Army. He was sent overseas and seems to have been intensely phobic about his health from the beginning. In India he developed nervous diarrhoea. He became panic-stricken when he got malaria, believing that because of his masturbation he would not be able to withstand it, and from then onwards his diarrhoea continued. He was invalided home with a diagnosis of sprue, although it seems probable that the disorder was of nervous origin. On returning to the United Kingdom he had an acute psychotic breakdown and was admitted to a military mental hospital, being eventually discharged from the Service. Owing to gross instability he lost one job after another. Then he developed syphilis—quite credibly, as he claimed, at the first possible exposure to infection. Although he sought immediate treatment this infection appears to have caused intense nervous upset and phobias of ill-health. Soon afterwards he developed the thyrotoxic symptoms. Although it was thought at the onset that the emotional disturbance was the essential disorder, his thyrotoxic state was so pronounced that it was considered necessary to bring this under control with thiouracil before any psychiatric approach was made. He responded remarkably rapidly to this treatment and soon began to receive simple psychiatric guidance. In a short time he declared he felt better than he ever had, and ascribed this to the reassurance he had got regarding masturbation. Thiouracil was stopped after 10 weeks and he has been under observation now for 16 months. During this time there has been no evidence of recurrence of thyrotoxicosis.

Case 2: Rapid Response to Treatment.—A fireman in the River Fire Service, aged 36, had been at work on a fire aboard ship and was trapped in the burning hold. He thought at the time that there was no way of escape, but eventually got out safely. When first seen nine months later he had lost 22 lb. (10 kg.) in weight and showed all the signs of thyrotoxicosis. He made a dramatically rapid recovery after only eight weeks' treatment with thiouracil. He has been kept under observation for three years and has remained perfectly well. This man, who made an unusually rapid response, seemed, unlike the usual thyrotoxic patient, not to have been nervous previously. Moreover, this form of psychological trauma as a precipitating factor is unusual.

Case 3: Requiring Maintenance Dose.—A woman aged 30, when first seen, showed all the classical features of thyrotoxicosis with considerable goitre which had developed within the previous 18 months. Nervousness had been her complaint for 2½ years, but she denied knowledge of any precipitating cause. She was the daughter of a West Highland crofter and admitted to excessive shyness in childhood. She has always been a nail-biter. At 19 she became a mental nurse and subsequently married an attendant in a mental hospital. She came to Glasgow, where she encountered serious housing difficulties. Shortly before the onset of symptoms her father, to whom she appears to have been over-attached, died. She had one child, and was always apprehensive about her health. Soon after her father's death she gave birth to her second child. At the time of onset of thyrotoxic symptoms, therefore, she had anxiety regarding housing and additional family responsibility, and great emotional disturbance from bereavement. This case illustrates the rather frequent association of bereavement with the onset of symptoms. Moreover, while the history of emotional upset before the onset of symptoms is highly suggestive, it is to be noted that the patient herself was unaware of a precipitating cause of nervousness.

Case 4: Requiring Maintenance Dose.—A man aged 58 presented marked symptoms of thyrotoxicosis with considerable exophthalmos. He appeared to have had a lifelong mild chronic anxiety state, dating from childhood, with fear in the dark, and a psychiatric illness of some severity during the first world war. Ever since that time his consumption of alcohol can only be described as profound, the anxiety state possibly being to some extent causative. In recent years he has worked during the night as a baker, and by day occupied himself as a police-watcher for a street bookmaker. This caused such nervous tension that he found himself incapable of carrying on if he was not "properly drunk." Latterly he became obsessed by the thought of police, seeing them in his sleep and panicking at the least sound. Mere mention of the word "police" caused noticeable increase of upper-lid retraction. He responded satisfactorily to thiouracil, and fibrillation settled eventually after quinidine. He has been under observation now for four years, during which time it has been found impossible to discontinue the thiouracil.

Case 5: Requiring Maintenance Dose, then suddenly able to abandon it.—A woman aged 25 gave a history that she had always been nervous. About two years before the date on which she was first seen she was working as a typist with an employer who was very exacting and sarcastic, and she attributed her greatly increased nervousness to this. At about the same time she got engaged to be married to a man who lived in London. She was markedly thyrotoxic, but made a very satisfactory response to thiouracil treatment. However, she remained nervous. She was obviously of a type that was easily upset, and described how she got very readily "into a flat spin" at her work. It transpired that she could not get a house in London, and under no circumstances would she go and live with her prospective mother-in-law. It was impossible for her to see her fiancé, because of distance and their different times of holiday. She continued in this state, although reasonably controlled with thiouracil, but there seemed no prospect of being able to abandon the drug until some eight months later when she broke the "engagement." Her condition improved immediately, and she was able to give up thiouracil. She has remained well without it for the past twelve months.

Case 6: Relapse.—A woman aged 25 with pronounced thyrotoxicosis gave a history of having been nervous all her life. She lived under poor social conditions in her parents' home, together with her husband and her five children. She was obviously terrified of another pregnancy. Later it transpired that at the age of 18 she had been raped one day returning from work. When she eventually told of this she said that she had forgotten about it, though she was then able to give the most detailed description of the incident. It is possible that she did in fact have amnesia of the event until it was brought to light in the course of psychiatric interview. She made a satisfactory response to thiouracil treatment and appeared to be very well until about six months later, when she again became pregnant. Although she was still on a maintenance dose of 50 mg. of methyl-thiouracil daily, her condition relapsed seriously. The pregnancy was terminated and sterilization performed. From that time onwards she has been well without thiouracil, maintaining her weight and a normal pulse rate. The goitre, however, was still considerable, and as she was worried about the appearance of this she eventually underwent thyroidectomy.

Case 7: Post-thyroidectomy Relapse.—A woman aged 53 underwent thyroidectomy first in 1941 and again 18 months later. Evidence of thyrotoxicosis soon became manifest again. Thiouracil was started in December, 1944. She has never been able to do without it since. On two occasions it was abandoned for periods of two months but had to be started again.

She has always been an emotional, insecure woman. For years she had anxiety about the health of her husband, who suffered from chronic heart disease and mental disorder until his death in August, 1947. She continues to be over-anxious and is easily upset emotionally. She suffers from paroxysmal auricular fibrillation and often complains of varying symptoms of a functional character.

Discussion

The above case histories are typical of the whole series and illustrate the important psychological features present in every patient. It would appear that emotional difficulties not only play an all-important part in precipitating a thyrotoxic state but also account for the differences in response to treatment and the tendency to relapse in certain cases. Accordingly it seems essential that in the treatment of thyrotoxicosis attention must be focused on the psychiatric aspects. In most cases the acute symptoms have to be controlled with thiouracil before the patient becomes responsive to simple psychotherapy, but the latter may, as in Case 1, prove the most important part of treatment. Admittedly the emotional problem may be difficult to solve and the thyrotoxic symptoms be kept in control only by continued therapy. Nevertheless, the discovery of the psychological disturbance may explain why a patient is unable to abandon thiouracil without relapsing and make it possible to give at least some advice and guidance, which often proves beneficial. It seems particularly desirable that examination of the psychological aspects should be attempted before any decision is made on thyroidectomy, as it might be possible in some cases to improve the patient without operation, while it might cause rejection as unsuitable of those cases which subsequently relapse and which then prove so difficult to control with thiouracil.

In conclusion, reference must be made to the second group in this series. These patients were nervous and had thyroid enlargement, but they were not thyrotoxic, at any rate at the time when examined. Yet four of the 93 patients had had thyroidectomy and a considerable number had in the past been treated with thiouracil without benefit. It is to be noted that, as shown in Fig. 1, these patients belonged to the younger age groups and that they gave a family history of thyrotoxicosis almost as high as that of the thyrotoxic group—11.8% compared with 15.3%. It seems an irresistible conclusion that these nervous goitrous patients are potential sufferers from thyrotoxicosis within the next 10 to 20 years. In view of what has been said above, it would appear desirable that such patients should have early psychiatric treatment in the hope that thereby this serious complication may be averted.

Summary

Examination was made of 265 patients suspected to be suffering from thyrotoxicosis. In only 144 cases was this diagnosis accepted.

Over 60% of thyrotoxic patients gained, and possibly at least 75% will ultimately gain, remission of symptoms after treatment with methyl-thiouracil. Patients who had previously undergone thyroidectomy often required a maintenance dose for an indefinite period and proved particularly liable to relapse if the drug was discontinued.

Inquiry into the psychiatric history revealed in every case disturbances which seemed of great importance in precipitating thyrotoxicosis, in accounting for relapse after either thiouracil therapy or thyroidectomy, and in explaining the necessity for continuing a maintenance dose. An attempt to deal with the emotional factor is regarded as an essential part of the treatment of thyrotoxicosis.

Attention is drawn to a group of patients complaining of nervousness and showing some thyroid enlargement but who were not regarded as thyrotoxic. It is suggested that such patients may be prone to develop toxic goitre in the future and that psychiatric treatment might be of prophylactic value.

Grateful acknowledgment is made to Dr. Adam Milne, now physician-superintendent, King's Seat Mental Hospital, Aberdeen, for his assistance in this investigation.

BODY WEIGHT IN GRAVES'S DISEASE

BY

HUGH CONWAY, M.B., B.Sc., M.R.C.P.

(From the Gardiner Institute of Medicine, University of Glasgow, and the Western Infirmary, Glasgow)

Loss of weight is one of the classical features of Graves's disease. It is recognized, however, that sometimes the loss may be insignificant, and occasionally weight may even rise while the disease is still active. Thus Joll (1939) said that "rarely the patient for a time actually gains weight, even very considerably." Linnell, Keynes, and Piercy (1946) pointed out the error of regarding loss of weight as a constant feature of thyrotoxicosis and observed that "maintenance, or even an increase, of weight is not very uncommon even in patients with primary toxic goitre."

Means (1948) noted that the nutritional state in Graves's disease varies greatly but in the average case weight loss is not evident. He added that occasionally a patient actually gains weight while thyrotoxic. A "plump" type of the disease was described by Trotter and Eden (1941). They studied eight patients who were plump in appearance and had gained weight before or after admission to hospital. Apart from the increase in weight these cases had several other features in common, and it was considered that they constituted a special type of Graves's disease. Moreover, differentiation of this type was found to be of practical importance because operative treatment gave unsatisfactory results.

The object of the present investigation was to study the nutritional state in Graves's disease, and the findings are based on 50 cases observed and treated during the past three years. Patients with hyperfunctioning adenoma of the thyroid (Plummer's disease) are not included.

Material and Methods

The series consisted of 47 women and 3 men; their ages varied from 22 to 54 years. Patients were accepted for the investigation only if the diagnosis was undoubted and complications, such as diabetes, were absent; otherwise they were unselected. The following information was obtained about each case.

Basal Metabolic Rate (*B.M.R.*).—A considerable number of estimations were made at short intervals until a constant result was obtained. This "level" was usually reached in 10–14 days.

Initial Weight.—This was expressed as a percentage of the expected weight, obtained from age, height, and sex tables, and compared with the patient's own estimate of weight alteration since the onset of symptoms.

Calorie Value of the Diet.—A full dietary history was taken and the daily calorie intake calculated for the period immediately before admission to hospital.

Energy Requirement.—The method described by Wright (1945) was used, allowance being made for the increased B.M.R. A typical day's activity was analysed, with emphasis on the nature of the occupation, the amount of exercise, and the use of leisure. The daily calorie requirement was assessed on the basis of three eight-hour periods of sleep, work, and leisure.

The difference between the theoretical energy requirement and the calculated calorie intake was noted.

Results

The incidence and range of the initial weights is shown in Fig. 1. Seven patients were definitely heavier and 33 lighter than their expected weight; 10 approximated very closely to it. There was a fairly close correspondence in individual cases between the subjective estimate of weight alteration and the measured variation from the expected weight. Thus two patients who could be described as "plump" complained of getting too fat, 12 noticed no change, and 30 had experienced loss of weight of varying degree. Despite a few marked discrepancies—for example, one patient who said that her weight had been steady was only 80% of her expected weight—it was considered that, overall, the calculated percentage of expected weight was a good guide to the actual weight changes (Table I).

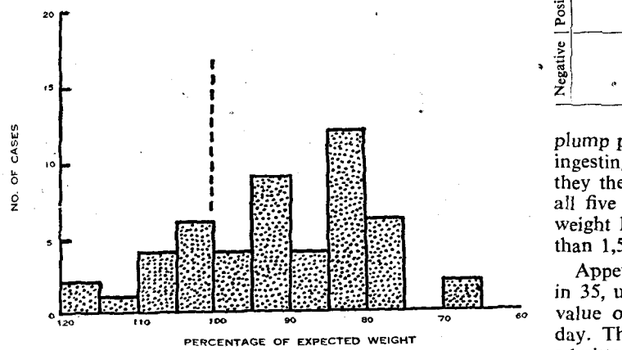

FIG. 1.—Distribution of the initial weights (expressed as a percentage of expected weight) of 50 cases of active Graves's disease.

The level of the B.M.R. bore no relation to the degree of alteration in weight. The B.M.R. was between +25% and +30% in nine patients whose weights varied from 109% to 67% of their expected weight. One patient who was acutely ill with all the classical clinical signs of Graves's disease, including marked loss of weight, had a B.M.R. of only +9%.

TABLE I.—*Comparison of Subjective Weight Change and Percentage of Expected Weight*

Subjective Weight Change	No. of Cases	Average Percentage of Expected Weight
Loss greater than 1 st. (6·3 kg.)	12	83
Loss up to 1 st.	18	88
Nil	12	95
Increase up to 1 st.	6	108
Increase greater than 1 st.	2	118

Age may be of some significance in determining the body's reaction to thyrotoxicosis. With one exception all patients who were heavier than expected were under the age of 30; on the other hand, all over 45 were considerably underweight.

In most cases the balance of daily calorie requirement over intake fell within the range +1,000 to −500 calories. No significance was attached to this degree of difference because of the obvious sources of error in assessing the two figures; when the same methods of calculation were applied to 10 normal adult subjects the range was +700 to −600 calories. The results were striking, however, in the cases at the extremes of the weight range (Table II). The two plump patients (120% and 117% of expected weight) were ingesting 1,850 and 1,600 calories respectively more than they theoretically required. At the other end of the scale all five patients who were 76% or less of their expected weight had a balance of requirement over intake of more than 1,500 calories.

TABLE II.—*The Difference Between the Daily Calorie Requirements and Intakes Compared with the Initial Weights (Expressed as a Percentage of Expected Weight)*

	Balance of Daily Energy Requirements over Dietary Intake (Calories)	No. of Cases	Percentage of Expected Weight	
			Range	Average
Positive	2,500–2,000	2	69–67	68
	2,000–1,500	3	76–75	76
	1,500–1,000	2	102–96	99
	1,000–500	13	107–79	90
	500–0	12	113–81	93
Negative	0–500	14	108–78	92
	500–1,000	1	—	90
	1,000–1,500	1	—	99
	1,500–2,000	2	120–117	118

Appetite was stated to be ravenous in 3 cases, increased in 35, unchanged in 11, and poor in one. The estimated value of the diets varied from 4,250 to 1,600 calories a day. The patient who was only 67% of her expected weight admitted having lost about 3 stone (19 kg.) and was taking the lowest diet of all. The figures for the two plump patients were the highest obtained—4,250 and 4,010 calories.

The Plump Cases

Some clinical details are shown in Table III. In Case 15 the adiposity was most marked on the upper back, anterior abdominal wall, and thighs—there were fresh striae in the latter site. This selective distribution was not obvious in the other patient, who just appeared to be moderately overweight. Biopsy of the abdominal wall showed in both instances normal adipose tissue and there was no clinical evidence of excessive fluid retention. The patients were

TABLE III.—*Clinical Features of the "Plump" Cases*

	Case 15	Case 23
Sex	Female	Female
Age	23	25
Duration of symptoms	4 months	6 months
B.M.R.	+25%	+30%
Percentage of expected weight	120	117
Complaint	Nervousness; goitre; "getting too fat"	Dyspnoea; prominent eyes; goitre; "getting too fat"
Menstrual periods	Regular	Regular
Enlarged tonsils	Absent	Absent
Appetite	Ravenous	Ravenous

considerably incapacitated by symptoms of severe thyrotoxicosis, and emotional instability was very pronounced. There was no menstrual upset.

The family history of Case 15 was of considerable interest. Her elder sister, now aged 36, was treated for Graves's disease by *x* rays in the Western Infirmary, Glasgow, in 1933. When interviewed, the sister said that during her illness she had a voracious appetite and became "puffy all over." The hospital record states that she was slightly obese and her weight was 139 lb. (63 kg.). At present she is very well and weighs 113 lb. (51.3 kg.). Compared with her younger sister she thought that her own obesity developed more slowly and was more generalized. There was nothing of significance in the family history of Case 23.

Methyl thiouracil alone was used in treatment, and satisfactory remissions were obtained. The drug was administered, in gradually decreasing dosage, for 18 months in Case 15 and for 15 months in Case 23; during the period of therapy they lost 16 lb. (7.3 kg.) and 12 lb. (5.4 kg.) respectively. The slow reduction in weight was a very striking feature and compares closely with the post-operative finding of Trotter and Eden (1941). The fall in weight was accompanied by a gradual diminution of appetite, and the calorie values of the diets, originally 4,250 and 4,010 calories a day, were 2,350 and 2,200 calories respectively one year after the beginning of treatment. The classical thyrotoxic symptoms such as nervousness, dyspnoea, and tachycardia subsided within a few months. The follow-up has as yet been short; but neither patient has relapsed, and their weights have remained steady.

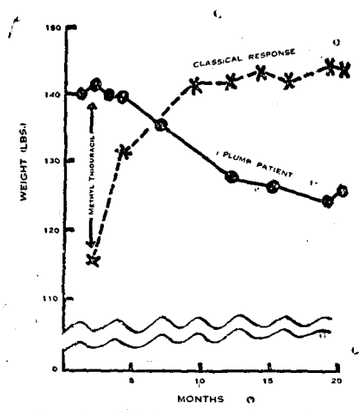

FIG. 2.—Weight curve of a plump patient compared with the classical response to thiouracil therapy.

Fig. 2 shows the striking difference between the weight curves of Case 15 and a patient who was considerably underweight before the start of treatment.

Discussion

Those who are most familiar with toxic goitre in all its manifestations agree that there is no sign of classical Graves's disease which may not be absent. There are many atypical categories, and diagnosis depends on a careful appraisement of the presenting clinical complex. A B.M.R. within the normal range or absence of eye signs does not necessarily exclude active thyrotoxicosis. The same holds for maintenance or even increase of body weight. Provided that natural remission is not taking place, gain of weight reflects an increase in the consumption of food sufficient to counterbalance the raised metabolism.

The plump patients differed from the classical ones in their excessively large appetite. No explanation can be offered for the cause of this bulimia, but its disappearance after treatment probably means that it was specifically due to the hyperthyroidism and not to any chance circumstance. Its occurrence in two sisters suggests the possibility of a familial influence. Whatever its pathogenesis, the large food intake acts in a protective manner and prevents the wasting which may be such a menacing feature of the disease. In the average case more food is eaten, probably in a vain attempt to counteract the nutritional effects of increased metabolism; occasionally the stimulation of appetite is so great that the attempt succeeds. As regards clinical severity, however, the well-nourished state of the plump patients was deceptive and their symptoms belied their appearance. They were no less seriously ill than more typical cases with an equivalent degree of thyrotoxicosis.

Trotter and Eden (1941) postulated that the plump type of Graves's disease was a specific entity; their patients were all young females who had pronounced signs but few symptoms; the incidence of lymphoid tissue overgrowth and amenorrhoea was higher than in ordinary cases and the results of operative treatment were unsatisfactory. The present investigation does not lend support to this theory. Apart from the gain in weight there were no gross differences between the plump patients and the classical ones. At one end of the scale were the fat patients, at the other the thin ones; between there was every nutritional grade. All were suffering from the same disease process—one which affects the balance of calorie intake and output; the latter usually exceeds the former, but the reverse may hold. The conception that weight is gained only in young women with a particular combination of physical signs seems hypothetical. The present study does support the contention that the set of circumstances causing increase in weight occurs exclusively in the young, but the series is small and only 11 patients were over the age of 40. It may be that the older patients have not the necessary resilience to protect themselves from the increased metabolism by excessive stimulation of appetite.

Thyroidectomy was performed on seven of the cases reported by Trotter and Eden (1941). Two died within a few hours and three had a recurrence. The authors considered that the operation was not only unsatisfactory but also dangerous, and suggested that medical treatment be preferred to surgical. This view was challenged by Linnell, Keynes, and Piercy (1946), whose experience of surgery in plump cases was no less satisfactory than in ordinary patients. If there remains any doubt about the wisdom of undertaking thyroidectomy, thiouracil treatment can be recommended.

Summary

The nutritional state has been studied in 50 cases of active Graves's disease. Their initial weights varied from well above to well below the expected weights. Two patients were plump in appearance.

The body weight depends on the balance between calorie intake and requirement. Appetite is specifically influenced by thyrotoxicosis and may overcompensate for the increased metabolic rate.

The fundamental disease process is the same in all patients whether they have lost or gained weight, and varies only in its relative effects on appetite and B.M.R.

The plump patients responded well to thiouracil therapy.

I wish to thank Professor J. W. McNee for criticism and advice in the preparation of this paper and Dr. A. A. Charteris for access to the records of his department.

TREATMENT OF SIMPLE EPITHELIAL CYSTS WITH SECONDARY PHOTO-ELECTRON RADIATION

PRELIMINARY REPORT

BY

LIONEL COHEN, M.B., B.Ch., D.M.R.T.
(From the Radiation Therapy Department, Johannesburg General Hospital)

AND

SAMUEL A. KIMMEL, M.B., B.Ch.
(From the Non-European Hospital, Johannesburg)

This investigation was prompted by the relatively large number of children presenting at the Non-European Hospital, Johannesburg, for treatment of cystic swellings of the neck, generally of the "plunging ranula" type. For the purpose of this report a plunging ranula has been defined as any cystic swelling originating in the floor of the mouth and extending beyond the confines of the mouth.

Surgical removal has in our experience been unsatisfactory on account of technical difficulties encountered in the extensive dissection required and the frequent recurrence of the condition after removal. The injection of sclerosing agents has given uncertain results and produced occasional alarming reactions. Conventional roentgenotherapy with moderate dosage was found to be completely ineffective. For these reasons it was thought that an alternative form of therapy might be worth trying, and the gratifying results obtained with the safe and simple procedure adopted seem to justify publication at this stage.

Although the epithelial lining of these cysts is known to be resistant to ordinary doses of radiation, it was realized that it was possible to produce an intense local ionization in the cavity of the cyst with relatively small doses by exploiting the photo-electric activity of heavy metals exposed to Roentgen rays. It is a common experience in radiological practice that the presence in irradiated skin of heavy elements (ointments or lotions containing zinc, mercury, or iodine) causes a very great increase in the intensity of the skin reaction. It was therefore thought possible to destroy the secreting lining of a ranula by bringing into contact with it an aqueous suspension of a heavy element and exposing it to small doses of Roentgen rays.

The procedure provisionally adopted is to aspirate the contents of the ranula through a wide-bore needle under local analgesia and to introduce into the cavity 2 ml. of a 10% aqueous suspension of bismuth oxychloride ("bisoxyl"). This is followed by exposure to intermediate voltage Roentgen rays (140 to 180 kV) delivering about 300 r to the tissue at a single sitting. This quantity is entirely empirical; responses have been noted with smaller doses.

The photo-electric emission from irradiated matter varies in a complex manner with the atomic number of the elements concerned. It is estimated that, with use of the technique described, the composite value for the photo-electric absorption coefficient of the cyst fluid containing the suspended bismuth (Z = 83) would be not less than 40 times that of soft tissue (equivalent Z = 7); and the ionization in the immediate proximity of a bismuth particle might be many hundred times greater. The range of this secondary radiation, which consists entirely of relatively low-energy electrons, is only a few microns in tissue, so that no more than a single layer of cells could be affected, and no damage could be produced in the tissues underlying this single layer of epithelium.

Reactions to the procedure have been fairly uniform. Initially there is a brisk effusion which persists for the first week after the operation, so that, despite the previous aspiration, the cyst becomes somewhat larger and more tense than it was originally. Thereafter the mass shrinks steadily and within three weeks has become a small fibrous nodule. These reactions produce no discomfort, and treatment in hospital is unnecessary after the first week.

The four cases reported below have been selected from our earliest trials in order to illustrate the effect of the bismuth injection alone and the superiority of the combined injection–irradiation procedure.

Case 1

A coloured girl aged 10 was admitted on January 26, 1949, complaining of a gradually enlarging swelling in the right side of the neck of several years' duration. On examination a soft fluctuant mass was found extending from the floor of the mouth to the clavicle, and from the midline into the right posterior triangle of the neck in front of the sterno-mastoid muscle. It did not move on swallowing and was not attached to the skin.

On February 1, 60 ml. of a watery straw-coloured liquid was aspirated and 2 ml. of bisoxyl introduced. Next day the cyst had become larger and was much tenser; 300 r was administered to the mass laterally, and a further 300 r through the anterior aspect. On February 15 (13 days after irradiation) the lower half of the cyst had become obliterated while the upper half had not changed. A further 2 ml. of bisoxyl was injected into the remaining portion of the cyst, and 300 r delivered through anterior and lateral fields. On March 1 (27 days after the first treatment) a small firmly indurated lump was present in the right submental region.

Case 2

A Bantu boy about 13 years old was admitted on February 16 complaining of a slowly enlarging swelling under the chin of three months' duration. On examination a round fluctuant mass about 8 cm. in diameter was found occupying both digastric triangles of the neck. It was continuous with a small swelling in the floor of the mouth to the left of the fraenulum.

On February 24 the swelling was aspirated and 30 ml. of a yellowish gelatinous fluid was withdrawn. A further 10 ml. was aspirated on March 21 and 2 ml. of bisoxyl was introduced into the cyst. On March 24 the swelling had increased in size and was much tenser. The swelling in the floor of the mouth had also become larger. On April 23 (five weeks after aspiration) the characteristics had remained unchanged except that the cyst was a little firmer in consistency. *X*-ray therapy was administered, 300 r to the left and 300 r to the right side of the swelling. On May 5 (13 days after irradiation) the swelling in the floor of the mouth had disappeared, and that in the neck was hard and measured 3 by 2 cm. On May 17 (25 days after irradiation) the submental swelling was only 1 cm. in diameter, very firm, and loosely attached to the skin.

Case 3

A Bantu girl aged 15 was first seen in 1948, when she had a swelling in the right anterior triangle of the neck and another in the floor of the mouth to the right of the fraenulum continuous with it. She was admitted in March, 1949, complaining of steady enlargement of the lump. On examination there was a soft fluctuant swelling, occupying most of the right anterior triangle, measuring 10 by 7 cm. and extending from the midline to disappear postero-laterally behind the sternomastoid muscle. At this stage there was no swelling in the floor of the mouth.

On March 16, 50 ml. of a thick yellow mucoid fluid was aspirated, and 2 ml. of bisoxyl introduced. Two days later the mass had increased in size and had become firmer. On

April 5 (20 days after aspiration) the characteristics had remained unchanged, and 104 ml. of a pale yellow slightly mucoid fluid was aspirated and another 2 ml. of bisoxyl introduced. Next day a tense swelling larger than the original was again present. On April 27 the characteristics were unchanged, and 300 r was directed to the lesion. On May 10 (13 days after irradiation) a small, firm, indurated right submental nodule was palpable but not visible.

Case 4

A Zulu boy aged 15 first presented in March, 1948, with a swelling of the right side of the neck. Examination revealed two unrelated disorders—an extensive unilateral tuberculous adenitis with suppuration, and a distinct fluctuant swelling in the right submaxillary region communicating with a similar swelling in the floor of the mouth. Deep *x*-ray therapy, generated at 180 kV (cp) with 0.5 mm. Cu and 1 mm. Al

FIG. 1A.—Case 4 before treatment.

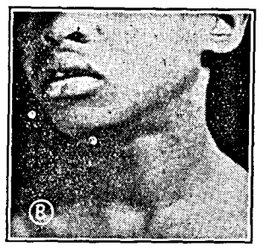

FIG. 1B.—Case 4 six weeks after the injection-irradiation procedure.

filtration, was directed to the cervical lymph nodes, which received 600 r in two weeks. It is estimated that the ranula received a similar dose. The glands responded partially to this treatment; the ranula remained unchanged.

On May 31, 1948, a block dissection of the cervical lymph nodes was performed, and histological examination of the specimen confirmed its tuberculous origin. Post-operative recovery was uncomplicated. On June 19 the adenitis was apparently cured; the ranula, however, persisted, and 10 ml. of glairy fluid was aspirated and 2 ml. of a sclerosing agent ("ethamolin") injected, with little effect.

The patient was readmitted on February 22, 1949, complaining that the swelling had persisted and was again enlarging. From February 23 to March 25 five injections, each consisting of 2 ml. of ethamolin, and three aspirations were done. There followed a pyogenic infection in the cyst, which was then incised and drained.

He was readmitted on October 7 with a complete recurrence (Fig. 1A). Fluid was aspirated on October 20 and 2 ml. of bisoxyl injected and 300 r given. On December 6 (six weeks after irradiation), apart from a hard nodule less than 1 cm. in diameter, there was no perceptible abnormality (Fig. 1B). He was well when seen on January 4, 1950.

Conclusions

It is obvious from a study of these four cases that the bismuth suspension alone did not obliterate the cysts; further, it is our experience that irradiation alone has no perceptible effect; yet the combined action of the two agents is completely curative. It is proposed to excise some of the residual nodules for histological study, though this is cosmetically unnecessary. At the time of writing, one year after starting the procedure, there have been no failures and no recurrences.

We wish to acknowledge the stimulating advice freely offered by Dr. P. Keen, of the Non-European Hospital, Johannesburg, under whose supervision this work was carried out.

Medical Memoranda

Plasmodium Vivax Infection

The following case report is of interest because it draws attention to an unusual symptom-complex of *Plasmodium vivax* infection—namely, severe urticaria, abdominal colic, and fever.

CASE REPORT

A Punjabi Hindu medical student aged 33 was admitted to hospital at 9 a.m. on August 2, 1949, with severe abdominal colicky pain which had started at 7.30 a.m. He developed an itchy rash all over his body within a quarter of an hour of admission, while the distressing colicky pain was continuing.

On examination his temperature was 102° F. (38.9° C.), pulse 100, and respirations 22. His blood pressure was 95/55. His abdomen was uniformly soft and localized tenderness could not be detected. The spleen and liver were not palpable. The rash consisted of weals irregular in shape and size, varying from small papules to moderately large plaques, with a pale centre and slightly reddish margins, and itching intensely.

On further inquiry the following facts came to light. At 9 a.m. on July 27 he first experienced an acute abdominal colic, situated around the umbilicus; the pain persisted for about two hours, with intermittent exacerbations, and then gradually subsided without any treatment. His bowels had been opened by a dose of liver salts. He remained well until July 31, when at about 8.30 a.m. he suddenly developed an itchy urticarial rash all over his body followed immediately by abdominal colic of similar nature. His temperature was 102° F., pulse 104, and respirations 22. Calcium gluconate, adrenaline hydrochloride, and "antistin" were given and the rash and colic disappeared in one hour, while his temperature had gradually subsided by 8 p.m. The defervescence was not associated with sweating. At 9.30 a.m. on August 1 severe and widespread urticaria developed, but there was no colic. He did not feel feverish and the temperature was not recorded. Next morning he was admitted to hospital.

The following therapeutic measures were adopted immediately after admission: absolute rest in bed; 25% glucose, 25 ml., and 10% calcium gluconate, 10 ml., intravenously; adrenaline hydrochloride (1 in 1,000), 0.5 ml. subcutaneously; normal saline enema, 1 pint (570 ml.); and an ice-bag over the abdomen. Colic was not relieved, but further spread of the urticaria was checked. Half an hour later 2 ml. of antistin was given intramuscularly and then continued twice a day. The rash faded completely within the next 20–30 minutes, and the abdominal colic subsided gradually. Antistin, 0.1 g., pulv. calc. lact., 10 gr. (0.65 g.), and mist. alkalin. diaphoret., 1 oz. (28 ml.), were given three times a day, and a sedative mixture with bromides and chloral was taken at bed-time. His diet consisted mainly of fluids—glucose water, barley water, green coconut water, milk, and tea. His temperature fell to normal by 7 p.m.

A blood count showed: Hb, 84% (Hellige); white cells, 7,000 (polymorphs 60%, lymphocytes 36%, monocytes 2%, eosinophils 2%). No malaria parasites were present in thick and thin smears. Examination of the stools (repeated three times) and urine revealed nothing abnormal.

Nothing untoward happened on August 3, but at 8 a.m. on the 4th the patient suddenly felt an attack of abdominal colic, which gradually grew worse and made him restless. His temperature was 103.4° F. (39.7° C.), pulse 102, and respirations 24. No urticarial rash could be detected anywhere on his body. He felt warm, but there was no chill or rigor. An ice-bag was placed over the abdomen and mist. carmin. bellad., 1 oz. (28 ml.), and antistin, 2 ml. intramuscularly, were given. The pain subsided gradually within half an hour. Thick and thin blood smears showed a fair number of B.T. malaria parasites, both ring and amoeboid forms (trophozoites). Proguanil was given immediately, two tablets three times on the first day, followed by one tablet thrice daily for seven days. Urticaria, colic, and fever did not develop during his next three days in hospital or during the subsequent follow-up.

COMMENT

The symptom-complex characterized by fever, abdominal colic, and urticarial rash appeared about the same time of the day.

The absence of chill and rigor, nausea and vomiting, and profuse sweating during defervescence preclude a clinical diagnosis of malaria; but demonstration of malaria parasites in the peripheral blood film during the last attack and the complete disappearance of symptoms after proguanil therapy suggest the unitary nature of the symptom-complex. Further, it was noted that antistin did not prevent the return of abdominal colic and fever.

In the dietetic history nothing was suspected which could be incriminated for urticarial attacks; and examination of the stool revealed no pathological condition which could explain the abdominal colic.

Lastly, the association of malarial attacks with abdominal pain is a common manifestation of malignant tertian infection.

Our thanks are due to the superintendent, Dr. K. L. Sen, for permission to publish this report.

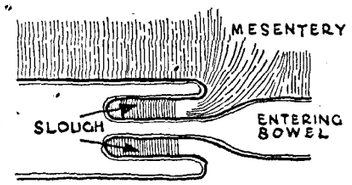
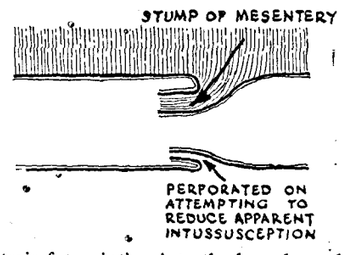
Unusual Case of Subacute Intussusception with Spontaneous Elimination

Cases in which an intussusception has sloughed off and been passed per rectum are rare enough to be placed on record.

CASE REPORT



A child aged 2½ attended the casualty department on July 10, 1949, with vomiting and intermittent abdominal pain. She showed signs of a follicular tonsillitis and a urinary infection, but of no other abnormality. A course of sulphatriad (total 12 g.) cleared these with a temporary decrease of symptoms. However, the vomiting recurred and there was abdominal distension with some apparent constipation; she was therefore admitted for investigation.



On admission on July 20 she seemed to be in good general condition, with no wasting, but was extremely fretful. Her abdomen was grossly distended, tense, and tympanitic; no guarding was elicited and no masses were felt; a few borborygmi were heard. On rectal examination the anus appeared normal, the rectum felt empty, but some soft yellow faeces were seen on the examining finger. Other systems were normal. Her blood count was within normal limits, except for a leucocytosis of 15,000 per c.mm. with 80% polymorphs.

The child ate well and did not vomit. She had from one to four motions a day, which were normal or relaxed, contained no blood, and grew no pathogens. Her temperature was 100° F. (37.8° C.) on admission, and it never really settled till after operation. On the fourth day she passed what appeared to be a necrotic piece of tissue 15 in. (38 cm.) long, followed by a small pale stool. The child appeared relieved and was less miserable; the rectum felt empty and there was no blood on the examining finger. The following day the abdominal distension increased, and there was visible peristalsis, with a step-ladder pattern, an apparent increase in abdominal pain, but no guarding or rigidity and no palpable mass. A radiograph of the abdomen showed several fluid levels in the small intestine. A laparotomy was decided upon, and an intravenous plasma drip was started pre-operatively, as the child had started to vomit.

Operation.—The lower end of the ileum was found to be congested and adherent to other parts of the small intestine; the caecum and appendix were normal, but about 2 ft. (61 cm.) proximal to the ileo-caecal junction a mass resembling an intussusceptum was felt in the lumen of the intestine. On a very gentle attempt to reduce this, the wall of the gut opened and a little faecal matter leaked out; a finger-like projection was then visible inside the intestine. Adhesions were divided and a resection and end-to-end anastomosis were carried out. The wound was closed without drainage, and sulphonamide, penicillin, and streptomycin therapy was instituted; the plasma infusion was continued for 24 hours after operation. Faeces and flatus were passed within 24 hours of operation. Post-operative recovery was uneventful, except for a rectal prolapse on the third day, which was easily replaced.

Specimens.—(1) The slough was found to consist of necrotic tissue containing some moderately large arteries and a band of collagen fibres running longitudinally, suggesting that necrotic whole gut was present, rather than mucosa only. (2) The mass within the resected intestine consisted of fatty tissue containing some rather large blood vessels, and with a covering of mucous membrane.

COMMENT

It seems probable that there was a subacute intussusception in which a portion of the mesentery was drawn into the lumen of the intussuscipiens; that the intussusceptum sloughed off, leaving a projection of mesenteric fat pointing into the bowel; and that the neck of the intussusceptum and the base of the intussuscipiens were joined by adhesions to form a spontaneous anastomosis, which broke down at the lightest touch (see illustration).

Leichtenstern (1877) reported spontaneous elimination in 42% of 593 cases; but since then few cases have been reported. Three cases of gangrenous intussusception have been reported recently (Kerr, 1949; Conway and Dawson, 1949), in one of which end-to-end anastomosis was possible; in none of them did spontaneous elimination occur. The present case resembles these in that diagnosis was made difficult by an unusual clinical picture. Although there was a story of early vomiting, there was no wasting, such as is usually found in subacute intussusception, and no blood was at any time passed per rectum.

We thank Dr. Ursula Shelley and Mr. Harold Dodd for permission to publish this case and for helpful criticism; and Dr. J. G. Bate for the pathological reports and for help and advice in preparing this account.

Reviews

THE SULPHONAMIDES

The Sulphonamides. By F. Hawking, M.D., and J. Stewart Lawrence, M.D., M.R.C.P. (Pp. 390; 46 illustrations, including 12 plates (7 coloured) and 17 tables. £2 2s.) London: H. K. Lewis and Co. 1950.

The authors point out in their preface that it is now 14 years since sulphonamides were introduced into medical practice. During the first 10 our knowledge of their application continually expanded; but this has now had a chance to become crystallized and consolidated, as latterly no outstanding new development of practical importance has occurred. In the last few years only, therefore, has a stage been reached when the subject can be reviewed with that degree of detachment which is essential if the views expressed are to have some permanency. The same is often said about biographies of great men who have played a determining part in world affairs—it is difficult to write with balance and judgment about them till they are very old or dead. The sulphonamides are of course not yet dead, and will still have an important role to play for years to come, but their glory is on the wane as their prerogatives are more and more encroached upon by the new antibiotics.

This book suffers only from the drawback inseparable from all therapeutic works nowadays, in that it has become slightly out of date as it has gone through the press—not in respect of the sulphonamides themselves but in connexion with the long-acting preparations of penicillin, of streptomycin, aureomycin, and chloramphenicol, whose introduction has still further modified the authors' recommendations as regards sulphonamide treatment. The review comprises an interesting, authoritative, and well-expressed account of the chemical nature, pharmacological action, preparations, clinical application, and toxic effects of the sulphonamides. It is written with critical wisdom and is profusely documented (there is a bibliography of 25 pages at the end of the book). The sulphonamides in their splendid old age could hardly have desired a more fitting memorial than this fine book.

D. M. DUNLOP.

A STUDY OF ANTIBIOTICS

Antibiotics. By Robertson Pratt, Ph.D., and Jean Dufrenoy, D.Sci.(Paris). (Pp. 255; 66 illustrations. £2.) Philadelphia and London: J. B. Lippincott Company.

The authors of this book, who are on the staff of the University of California College of Pharmacy, San Francisco, are best known for their studies of the mode of action of penicillin on bacteria. These were largely pursued by an ingenious technique consisting in the treatment of assay plates, after only a few hours' incubation, with solutions of various reagents, which revealed in colour the chemical changes occurring in the zone of inhibition, in that of normal growth, and in the interesting boundary zone between them.

The authors' interest in antibiotics is theoretical rather than clinical, and they bring to it a profound knowledge of chemistry and of plant physiology. They have thus been led to write a book different from any other on its subject, philosophical in outlook, and dealing rather with principles and mechanisms than with the practice of chemotherapy, although much of the information given is of great value in considering treatment. For example, the pharmacological and antibacterial behaviour of penicillin is well described in the usual way, but accounts are also given of the properties of different penicillins, of the influence of unknown enhancement factors and of borrelidin on therapeutic effect, and of the theory of optimum concentration. There is a chapter on industrial production, of which one of the authors has had practical experience, and all the newer clinically valuable antibiotics are well described. One would have liked to see all those derived from bacilli treated together: there is scarcely enough difference between bacitracin and the polymyxins to justify segregating them in separate chapters.

The book is profusely illustrated with charts, graphs, and other figures, many being original. Perhaps the most remarkable is that in which the growth curve of a green alga and the number of synthetic dyes patented yearly between 1850 and 1925 are plotted together to illustrate the argument in a section entitled "Significance of Fields of Diffusion." Altogether it is a most original and refreshing book.

L. P. GARROD.

THE HOUNAMAN MONKEY

The Anatomy of Semnopithecus Entellus. By A. Ananthanarayana Ayer, B.A., M.B., B.S., M.Sc. (Pp. 182; illustrated. 20 rupees.) Madras: The Indian Publishing House. 1949.

Monkeys were known in the days of prehistory and were depicted in early Egyptian times. Hanno, the Phoenician, on his famous journey from Morocco to Upper Guinea in 470 B.C. brought back an account, with three skins, of the greatest of great apes, the gorilla. It is possible that his gorillas were chimpanzees. Pliny records that these three skins still existed in the Temple of Astarte in Rome in the second century A.D. Linnaeus, in his *Systema Naturae* (1735), did not hesitate to place man along with the apes, lemurs, and bats in the order Primates. It is strange that our knowledge of the anatomy, physiology, development, and behaviour of man's immediate congeners has grown so slowly. Knowledge of great value to medicine and surgery might have been gained if more doctors in India and Australasia had devoted themselves to the study of their own local fauna, with the hordes of primates in the one continent and the mysterious medley of marsupials in the other. During the twentieth century there has been a costly and productive study of the anatomy, development, and behaviour of *Macacus rhesus* by Streeter, Hartman, Strauss, and Schultz in Baltimore and of the chimpanzee by Yerkes in Florida. There has been but little study of monkeys and apes in this country of recent years. This is strange, for with the exception of Brazil, the Dutch East Indies, French Equatorial Africa, and the Belgian Congo, most primates occupy the areas on the map of the world which are still coloured red, or a faint pink. F. Wood Jones stated that the dead hand of Charles Darwin and of Henry Huxley inhibited the study of primate anatomy which was so well started by Robert Owen and St. George Mivart.

This monograph on *Semnopithecus entellus*, the Indian langur or hounaman monkey so venerated by the Hindus, is a valuable contribution to primate anatomy. It was completed in 1942, but publication was delayed for six years. The anatomy of this Indian langur is described in detail, system by system, with careful dissections, accurate diagrams, and a wealth of astute observation. The anatomy of the visceral systems—respiratory, alimentary, and urogenital—is very well done. The circulatory system, both arterial and venous, calls for still greater detail, as the pattern differs notably from that seen in man. The vessels of the thorax and abdomen are well worth further study at a time when thoracic and abdominal surgery are becoming more venturesome. In particular, the veins call for close examination, for they are of more significance clinically and a source of greater trouble surgically than the arteries. That despised minusculum, the pisiform bone, is described in detail, and the radiograph shows an epiphysis comparable to the epiphysis on the human os calcis. This proves that the pisiform is not a sesamoid bone. The peripheral nervous system is described in detail, with particular reference to the limb plexuses. The brain is shown to be the most advanced among the Cercopithecidae and has certain features which place it between the brains of *Macacus rhesus* and the gibbon. The fissures of the parietal lobe are certainly an advance on any other monkeys and confirm the early views of Elliot Smith.

It is a credit to the present Professor of Anatomy in Madras that he is following so well the path laid down by his predecessor, Professor U. V. Nayak, who died so young and yet contributed so much to our knowledge of the primates.

H. A. HARRIS.

HANDBOOK OF THERAPEUTICS

The Essentials of Materia Medica, Pharmacology and Therapeutics. By R. H. Micks, M.D., F.R.C.P.I. Fifth edition. (Pp. 438. £1 1s.) London: J. and A. Churchill. 1950.

This handy volume increases in usefulness with each successive edition and achieves this without any noticeable increase in size. It is written from the point of view of a practising physician rather than from that of the laboratory worker, but it is fair to say that the gap between these two has narrowed during the 15 years of the book's existence. The advances in specific, as opposed to symptomatic, treatment are responsible for this very desirable approximation.

The new edition contains an account of all the recently introduced substances, including the antibiotics, and it can claim to be free of any noteworthy omissions in a period when additions to the therapeutic armoury occur almost monthly. Tetraethylthiuramdisulphide is mentioned in the preface, but not in the index.

J. H. BURN.

The pioneers of medical ophthalmology in this country were physicians like Sir Clifford Allbutt and Sir William Gowers. Subsequently, it has been left to ophthalmologists to expound a subject which had become too big for either a physician or an oculist. Mr. Foster Moore's *Medical Ophthalmology* maintained the high tradition of Gowers's work, but like Gowers's book did not attempt to cover the whole field. This ambitious task has been undertaken in recent years by Dr. Tassman, of Philadelphia, and now by Mr. J. H. Doggart. Four introductory chapters in his *Ophthalmic Medicine* (London: J. and A. Churchill; 32s.) describe methods of examination, while the nine succeeding ones are on general concepts like allergy, the different infections, and inflammatory affections. The ocular aspect of the different systemic disorders such as skin diseases, endocrine affections, cardiovascular diseases, head injury, and bone diseases are discussed in other chapters, and there are sections about hereditary diseases, congenital abnormalities, the significance of refractive errors, and other disturbances with widespread manifestations. Though the scope of the book limits discussion in some cases to bare outlines, the text can be recommended as an introduction to a vast subject with a scattered and badly systematized literature. To the physician it should be useful as a guide to the ocular aspects of systemic diseases. The student of ophthalmology will find it a necessary reminder of the fact that the ophthalmologist is a physician as well as a surgeon.

BRITISH MEDICAL JOURNAL
LONDON
SATURDAY JULY 8 1950

CRISIS IN TUBERCULOSIS

With other infectious diseases coming under control, there is no doubt whatever that tuberculosis is now our major public health problem. Yet we all seem supinely to accept a situation in which some 10,000 patients are kept waiting for nine months or longer for hospital or sanatorium beds while some 5,000 beds assigned to tuberculosis are empty for lack of staff. There seems to have been lacking any sense of urgency, and little of the vigour of action that has brought under control the infinitely less tragic infection, diphtheria. Yet in 1948 more than 19,000 patients died of pulmonary tuberculosis in England and Wales and more than 3,400 in Scotland; in the same year close on 44,000 cases of pulmonary tuberculosis were notified in England and Wales, and more than 8,000 in Scotland.

The fact that tuberculosis is a more serious problem in Scotland than elsewhere in Britain lends special weight to the excellent report from Scotland published in the opening pages of the *Journal* this week. Drawn up by a joint subcommittee of specialists and of experts in tuberculosis, it was intended originally to make recommendations for the development of an "optimum service." The recommendations made in the first part of the report provide a basis for discussion of ways and means for attaining this ideal. Much of this part of the report is wise and to the point; its proposals show the way for determining a long-term policy.

But the meat of the report is in the second part, fittingly entitled "Crisis Expansion." It is this which marks it out for distinction and should wake up all those who are responsible for the care of the tuberculous. The committee outlines the present picture boldly, and what it says of Scotland applies with equal force to England and Wales. It records its strong impression "that there is lacking any general appreciation of the urgency of the problem and of the need for a real emergency drive to deal with it. . . . A slow building-up of first-class sanatorium accommodation is not what is called for." The committee urges a crisis expansion on the lines of the Emergency Medical Service. It recognizes that the outstanding problem in the present circumstances is how to provide rapidly more functioning beds for tuberculosis and how to staff them. Two major factors have been responsible for the hold-up of the tuberculous: the first is that more cases are being diagnosed, and the second that advances in medicine have brought an increasing number of cases within the range of effective treatment. In a few areas, it is true, treatment at home is being carried out with relative success, and tribute is due to those who have undertaken the task. But most clinics are not adequately staffed or equipped to conduct domiciliary treatment, and, too, not many homes are suitable for the prolonged treatment of infectious persons. Domiciliary treatment is at best an expedient.

How to provide the beds and how to staff them is the fundamental question in this crisis. Discussion about division of responsibilities under the National Health Service, of divorce of treatment from preventive services, is interesting but irrelevant to the main issue. The shortage of beds has been neither caused nor aggravated by the National Health Service; its origins go much further back. In fact there should be within the framework of the N.H.S. far greater possibility of solving the problem than there was before, because the hospital management committees, and through them the regional hospital boards, have the responsibility for bed allocations throughout large areas. The authors of the Scottish report propose that the beds needed shall be acquired by taking over wards in hospitals for infectious diseases: only about a third of their accommodation is now occupied at any one time. They suggest tentatively that if it were found impracticable to provide in this way all the beds needed wards in general hospitals might be used, though the larger teaching hospitals should be excluded. There is much to be said for their first proposal, but only as a partial solution. The opening of units at present closed down in hospitals for infectious diseases will require much additional staff. Some of these hospitals would be ill equipped for any purpose other than the housing of untreatable tuberculous patients. The main problem is to find beds for patients urgently requiring special observation and subsequent treatment. If the view of the committee is accepted that "not until it [tuberculosis] is tackled in a spirit of crusade will the fight be won," then all the large general hospitals, without exception, should share the task of providing treatment for the tuberculous. It has been demonstrated, for instance, at the Central Middlesex Hospital that tuberculosis can be safely treated in special wards of a general hospital, and Dr. Joules has suggested[1] that general hospitals should help to meet the crisis by allocating to tuberculosis at least 10% of their beds. This would bring many advantages. The staff would be available; and nurses, doctors, and medical students would become acquainted with a disease which, though rife in the community, they have had little opportunity of studying in general hospitals.

[1] *N.A.P.T. Bulletin*, June, 1950.

The report makes many sound proposals for the recruitment of nurses, which is the crux of the matter of caring for the tuberculous. The committee stresses the need for the recruitment of trained nurses. Nursing the tuberculous can, if proper precautions are taken, be as safe as any other nursing. The shortage of tuberculosis nurses is a part of the shortage in all services outside the main teaching hospitals. It is only when nursing conditions are improved, both materially and socially, that recruitment campaigns will have any effect. The tradition of good nursing in this country could be maintained without the outmoded discipline of some of the training schools, and the fully trained nurse must be adequately paid. While there is a shortage nurses should be employed on nursing work and not on tasks well within the competence of untrained domestic staff.

The Tuberculosis Group Committee of the B.M.A. is investigating the tuberculosis services, and a standing advisory committee has reported to the Central Health Services Council. It is hoped that this report will soon be published. But what is needed now—desperately needed—is not reports but action. The well-written, cogent, constructive account of the Scottish Committee's findings and conclusions must be read and digested by those in authority. And if authority does nothing, then those with the welfare of the tuberculous at heart must harry authority ceaselessly until something is done. Here is a chance to test the much-vaunted adequacy of the National Health Service. The coherent Scottish mind has not hesitated to use the word "crisis." Let us as a profession hammer this word home, and insist that something is done as an emergency operation to relieve the burden of sickness which now afflicts the tens of thousands of tuberculous sufferers in Britain.

DEMAND FOR EARLY SETTLEMENT

The Health Service has now been working for two years. That it continues to run fairly smoothly is a tribute to all those who take part in it, and indeed to the general public. But there can now be no doubt that general practitioners are discontented and are labouring under a sense of injustice. And there is good reason for this. Recently the General Medical Services Committee sent to every general practitioner a document[1] setting out the history of its negotiations and discussions with the Ministry of Health. When the general practitioners entered the Service they did so on the understanding that their remuneration, the terms of which were provisional and never agreed, should be reviewed. Their remuneration remains to-day about what it was two years ago, a small exception being the increase in the mileage fund. During this time the Ministry has on one pretext or another postponed making any detailed factual reply to the doctors' claims. Last summer it carried out an inquiry, which took longer than was expected, into the actual earnings of general practitioners. So ineffectual was the method of inquiry that its results were worthless. This summer further inquiries are promised. If general practitioners are becoming impatient the Government has only itself to blame.

When the representatives of local medical committees met on June 29 at B.M.A. House the conference expressed itself as "seriously disturbed at the repeated hold-ups and prolonged delays in the negotiations," but agreed to co-operate in carrying out the new inquiries, emphasizing that these must be made soon and be accurate. Further, the G.M.S. Committee was instructed to make preparations forthwith for the ending of contracts by general practitioners in the Service. Advice will be given to end the contracts if there is no prospect of a satisfactory settlement. Another special conference will be called if that decision has to be made, and in any case one will be held in December if agreement has not been reached. Feeling was evidently running high at the conference and reflected the opinion, ascertained by local inquiries, of many general practitioners not present there.

While the negotiations on pay have been dragging on, the Minister and his officers have taken the opportunity to arouse anxiety on other but related issues. Doubt has been cast on whether the Government intends to implement the Spens recommendations, for the Minister will not state that the present central pool is in accord with them or that it is not. But since the Spens Report was agreed between the Government and the profession doctors have a right to know this, and they would resent any attempt, of which there have been hints, to repudiate the report without their consent and before any other basis for remuneration has been worked out. The conference therefore called on the Minister to state immediately what size the central pool should be to accord with the charter laid down by the Spens Committee.

In emphasizing that changes in remuneration should be made only after proper negotiation and not by the Minister's arbitrary action, the conference expressed the alarm that any doctor, or indeed any employee, must feel when he sees the precipitate speed with which the Minister, without waiting for a full inquiry, has at various times cut the remuneration of other workers in the Health Service, such as the dentists and ophthalmic medical practitioners. To be ever at the mercy of possibly despotic decisions arrived at without taking all the facts into account would cause anxiety intolerable to men who have no alternative way of earning a living but in their profession, and, for most of them, no other

[1] *British Medical Journal Supplement*, 1950, 1, 179.

way of practising their profession but in the Health Service. The great safeguard is the Spens Report. Without this, general practitioners might well fear arbitrary decision. It is now, after two years' working, essential to discover whether the Government considers practitioners are being paid according to the Spens recommendations. It is surely but common sense and common justice that all ambiguity should be removed. Thucydides remarked 2,000 years ago that men resent violence less than injustice, and if the Minister of Health does not deal fairly and squarely with general practitioners, and remove their feelings of injustice, then they may feel compelled to take the very grave step of ending their contracts.

THE ANNUAL MEETING

The 118th Annual Meeting of the B.M.A. begins next week on July 13 and comes to an end on July 21. Liverpool acted as host at the Annual Meeting in 1912 and this is the first time that two neighbouring towns have joined together to offer accommodation and hospitality for such an occasion: the Southport Division is acting as host to the Representative Body and providing facilities for the Annual Representative Meeting; when the debates on medical politics, organization, and administration have come to an end at Southport, Liverpool will take over for the remainder of the Meeting, which will be devoted to the scientific sections. As the published programmes in this *Journal* have shown, those responsible for planning the scientific programme have provided rich and varied fare, and it is good to see in the list of speakers a number of distinguished visitors from overseas. The motions and amendments from Divisions and Branches which will come before the A.R.M., the majority of which have been published in the *Supplement*, well reflect the nature of the problems now worrying the medical profession, especially those engaged in general practice. Hot upon the resolutions recently passed by the conference of Local Medical Committees come another batch couched in similar terms and to be debated by the A.R.M. These motions show that general practitioners are, to say the least of it, dissatisfied with their present terms of service. Their dissatisfaction resides in the fact that they cannot get a plain answer to a plain question, and the elusiveness of the Minister, for example, on the Spens recommendations is something that they find baffling and frustrating. Another matter on which there are many motions is the representation of general practitioners on regional hospital boards and on the medical advisory committees of hospital management committees. This again reflects the uneasiness felt at the tendency to exclude general practitioners from hospital life and experience. Under the heading of consultants and specialists come a number of motions expressing dissatisfaction with the work of grading committees and with the position of senior hospital medical officers. Other motions draw attention to the few specialist appointments awaiting a very large number of trainee specialists and to the fact that so many senior registrars are now unable to find work as consultants. Among many other motions we may note one which asks the Council to investigate the case for and against a whole-time salaried medical service, so that, if in the future such a service be proposed, the medical profession will be in full possession of the arguments for and against.

Those who are aware of the hard work put in during the past year by those responsible for organizing the Annual Meeting at Liverpool and Southport know that the Meeting will be a worthy successor to the other two that have been held since the war. These Annual Meetings do much to encourage and sustain the sense of corporate membership of the B.M.A., and afford a yearly opportunity for those who attend the Meetings to renew old friendships and make new ones and to exchange views on all those things that matter in our professional life, from the effect of the increased cost of petrol on practice expenses to the effect of cortisone on the human constitution.

THE PHYSIOLOGY OF LEARNING

The physiology of learning and retention was discussed by Professor J. Z. Young, of University College, London, in the Ferrier Lecture of the Royal Society, given last week. The problem which he posed was the identification of "the change that happens in the nervous system during learning": for evidently an animal which has learnt something has been changed, and "may remain so for the rest of its life." Professor Young followed a broad review, starting with the admitted inadequacy of Sherrington's classical reflex scheme in relation to higher activities, giving an account of some recent work by his own department on the learning process and associated neurology of the octopus. The learning experiments were carried out by B. B. Boycott and Professor Young at the Zoological Station, Naples. They were illustrated by a film and used the well-known technique of combining a simple food stimulus—in this case the sight of a moving crab—with a further stimulus—in this case the sight of a small white square from which an electric shock could be administered. In the intact octopus it was found that the response to "crab plus square" could be readily reversed as a result of three exposures per day repeated over three days. On the other hand, with either of two higher centres removed, but not with half removed as a control, normal "long-term" learning was prevented, so that interaction between these two centres appeared necessary for the learning process. However, if the interval between exposures was sufficiently reduced, then an octopus which had thus been operated upon could still remember. To be precise, it could remember for five minutes but not for ten; which supported the view that "some stages of learning depend on the maintenance of an activity," and that when this activity has died down the results of "short-term" learning die with it. It would be difficult to imagine that the same process could account for the example of long-term and not consciously refreshed memory which human subjects can provide, or even for the permanent or near-permanent alterations in animal behaviour which can be experimentally effected; and Professor Young's main argument was that "more stable learning depends on the formation of specific pathways by some form of growth process." As a plan of organization common to both cephalopods and mammals he suggested a process of interaction between different higher centres, with the mutual relationships of fibres within their closely woven networks continually influenced by activity, "producing slight changes in form that alter the probable direction of the sequence of excitations." In other words, he considers that learning of the long-term kind is accompanied by morphological changes by which repetition of particular patterns of responses is facilitated so long as the associated changes themselves persist. He showed slides of histological preparations by Armstrong and Tittock, of his department, in support of the neurological plausibility of the suggested mechanism in the case of the octopus, and acknowledged also the assistance of D. Sholl and Dr. J. T. Aitken in regard to other material used in his lecture.

CENTRAL ACTION OF TUBOCURARINE

The property of paralysing the endings of motor nerves in skeletal muscle for which D-tubocurarine is so widely used to-day was demonstrated by Claude Bernard[1] in 1857, and earlier observations that it had a central action as well received less attention. Many workers since Claude Bernard, however, have obtained evidence of this central action, which is excitatory and not paralysing. Recently Euler and Wahlund[2] showed that the intrathecal injection of D-tubocurarine caused generalized convulsions in cats, and Eccles[3] found that it stimulated the frog's spinal cord. He investigated the action on the cord because extracts of curare cause paralysis not only at the neuromuscular junction but in sympathetic ganglia as well. He was therefore surprised to find the reverse effect on the cord. Soaking the cord in a curare solution increased the duration of the discharge of impulses set up by a single dorsal root volley. When the cord was soaked in strong solutions sustained activity was set up without stimulation. Salama and Wright[4] have injected tubocurarine into the ventricles of the cat's brain and have found that both by this route and also by the cisterna the injection causes an increase in the knee jerk and in the flexor reflex, an increase in the rate and depth of respiration, and a rise in blood pressure. General convulsions result. Intrathecal injections differ, however, because the effects are slow to appear, and if the subarachnoid space is blocked above the injection they are very small or absent. Thus in the cat the supraspinal centres are much more sensitive to the stimulant action of tubocurarine than is the spinal cord.

This new information about the central stimulant action of tubocurarine modifies the theory of its peripheral action. It is known that neostigmine augments the muscle strength of patients with myasthenia but weakens that of normal persons when given intra-arterially; thus neostigmine can have both a stimulant action and a paralysing action at the motor end-plate. Tubocurarine causes paralysis only at the motor end-plate but has a stimulant action on the centres of the medulla and above. Some will consider that these two actions of tubocurarine are unrelated. Others will see in them evidence that the process of transmission by acetylcholine at the motor end-plate is closely related to transmission from one neurone to another in the brain. Fortunately the central stimulant action is of no importance in the practical application of tubocurarine.

STILLBIRTHS

The medico-social problem of stillbirths has often been discussed since the publication of the stillbirth rate in 1929 by the Registrar-General. The rate varies consistently in different areas of the country, and the association with economic-environmental indices has led to stress being placed on the importance of social conditions. The results obtained in several investigations suggest that there has been some confusion between correlation and causation, and on the evidence now available the social factor appears to be an inadequate explanation for variations in the rate. In a recent review of this complex subject Sutherland[1] has carefully considered the epidemiology and social significance of stillbirths. There are about 21,000 of these each year in England and Wales, and if the stillbirth rate throughout the country could be reduced to the level of the rate in London there would be nearly 3,000 fewer stillbirths a year.

Medical, social, environmental, and biological factors affect the chance of surviving the process of birth, and it is often impossible to determine the exact cause of a stillbirth. Their classification under various causes has differed greatly in different investigations: the proportion of stillbirths for which no definite cause could be assigned has ranged from 1/5 to 1/3, while complications of labour have been held responsible for between 1/4 to 1/3, and toxaemia for about 1/10, of all stillbirths. A common finding has been that in a large proportion of stillbirths some foetal defect was present or the birth was premature. Much has been written about the effect on the baby of haemolytic disease and of the results of an attack of German measles early in the mother's pregnancy, but these disorders are not necessarily associated with stillbirths and collectively they can have very little influence upon the stillbirth rate. The relation

[3] *Physiol. Rev.*, 1921, **21**, 438.

between social and economic conditions and the chance of a stillbirth has been demonstrated by many workers: for the country as a whole the rate increases from social class I to social class V. In America the rate has been shown to decrease as the father's income rises. Overcrowding increases the risk of infection; this is serious for live infants, but is not likely to affect the stillbirth rate. While the nutrition of the mother is obviously important, malnutrition probably does not have such a great influence on the stillbirth rate as was once believed. The system of rationing and the priorities given to expectant mothers during the war reduced or cancelled altogether the differences between the diets of the various social classes. Despite this levelling of nutrition the stillbirth rate of the higher social classes fell much more than that of the lower social classes. McKinlay[2] found for Scotland that the fall in the stillbirth rate per 1,000 births between 1939 and 1945 was from 33.9 to 20.9 for class I, from 37.8 to 26.0 for class II, from 38.0 to 37.1 for class IV, and from 42.4 to 39.1 for class V. The experience in the occupied countries during the war supported Huggett's contention that the foetus grows at the expense of the mother.[3]

The proportion of first-born among the births affects the stillbirth rate, since these infants are more likely to be born dead than the second or third child, but for fourth and later children the stillbirth rate rises again. It also rises as the intervals between pregnancies shorten and as the mother's age increases. Whether the age of the father has any influence is debatable, but from the results obtained in animal experiments it is unlikely that the age of the father is of any importance. Two causes of stillbirth are often ignored because their influence on the rate is difficult to assess. Attempts by expectant mothers to produce abortion probably have some effect, but more important is the genetic factor. The origin of some congenital malformations, which are a common cause of stillbirths, is undoubtedly genetic, though in many cases both hereditary constitution and maternal environment and other non-genetic factors probably act together. The relationship is, however, a complex one, and its unravelling presents one of the most difficult problems in human genetics. The end-point of many conditions fatal to the foetus is not reached at the same time, and the result may be either abortion, stillbirth, or early neonatal death. The problem of stillbirths is part of a larger one which includes prenatal and early post-natal deaths, and any scheme which aims at lowering the stillbirth rate must, to be successful, be of a comprehensive character.

CHILDREN AND THE CINEMA

One-half of all the children of school age in Great Britain go to the cinema once a week, and nearly a quarter of them go twice a week or more often. Many more children go to the cinema than go to church and Sunday school. It may be said, therefore, that, after home and school, the cinema is the most important influence in the life of the modern child. The report of the Departmental Committee on Children and the Cinema, of which Professor K. C. Wheare was chairman, has recently been published.[1] The committee inquired into the effects of cinema attendance upon children and was asked to make recommendations about the classification of films, the conduct of cinema clubs for children, and other related questions.

Films are classified at present into three categories: "U" for universal exhibition; "A" films, which children may see only if accompanied by an adult; and "H" for horrific films, which children are not permitted to see. The committee presents good reasons for regarding this classification as unsatisfactory. The "A" classification places upon parents or guardians the responsibility for deciding, usually without first-hand knowledge, whether a film is fit for their children to see. It has also had the unforeseen and unfortunate result that children now stand outside cinemas asking adults to take them inside to see "A" films. The following classification is suggested by the committee: "C" films, which are made solely for exhibition to children, and "X" films, which are entirely unsuitable for exhibition to children. It recommends the formation of a Central Committee on Children and the Cinema, and one of its main duties would be the selection and classifying of films for children.

There has been considerable argument about the effect of the cinema on the mind, the behaviour, and the morals of children. There is good evidence that many children are frightened, and that some are terrified, in the cinema, but the Committee does not find any proof that there is a direct relationship between the films and juvenile delinquency. The cinema may sometimes determine the path of the delinquent, but films seldom provide the initial impulses towards delinquency. The threat of the film to the young mind is more subtle. Too many films are stupid, sentimental, crude, or materialistic, and so unlikely to stimulate the quick intelligence, the lively humour, and the idealism of youth.

Children's cinema clubs have been a remarkable development of recent years, and the report gives to them a limited approval. To the disinterested observer they would seem to be an artificial by-product of the industry. The social and recreational activities of children should not have their normal centre in the field of commercial entertainment, and the average manager of a cinema is seldom likely to possess the qualities of an experienced youth leader. The most important problem is the inadequate number of films which are specially produced for exhibition to children. Most of these have been made by the J. Arthur Rank Organization, and it appears probable that financial difficulties may hinder this public-spirited activity in the future. The proposed Central Committee may require therefore the control of some public money, and it must also generate in the film industry something of the enlightened social conscience which animates the B.B.C. The function of the film is admittedly not education but entertainment. Yet a deliberate attempt by the cinema to increase the range of enjoyment and the artistic sensibility of the public at large, and particularly of children, would be a valuable social experiment.

The Gold Medal of the Royal Society of Medicine was awarded on July 4 to Professor E. D. Adrian, O.M., M.D., F.R.S.

REFRESHER COURSE FOR GENERAL PRACTITIONERS

THE MANAGEMENT OF PULMONARY TUBERCULOSIS

BY

F. H. YOUNG, O.B.E., F.R.C.P.

Consulting Physician, Charing Cross Hospital; Physician, Brompton Hospital
Tuberculosis Officer, St. Bartholomew's Hospital

Until recently the part played by the general practitioner in the management of a patient suffering from pulmonary tuberculosis was confined largely to diagnosis at the earliest possible moment, the care of the patient when quiescence had been achieved, and the palliative and symptomatic treatment of patients with advanced disease who were beyond the scope of radical treatment. The radical treatment was carried out institutionally.

The present position, in which patients have to wait for six months and upwards before admission to sanatorium can be obtained, has altered his role completely. He must now be prepared to undertake treatment in the home.

Among the very few facts that have been established beyond question is that, all things being equal, the fate of the patient depends on the stage at which the diagnosis is made. Early diagnosis is arrived at as the result of (1) mass and routine radiographs of symptomless patients, and (2) alertness of the general practitioner to recognize the possibility that certain very mild toxic and lesional symptoms may indicate the presence of pulmonary tuberculosis. Only the second concerns us here. If the practitioner has already in his mind that pulmonary tuberculosis is a likely diagnosis in any patient who complains that he is slightly below par, or has a cough for a month without an obvious cause, the disease will be diagnosed much earlier.

A few fundamental points must be emphasized:

(*a*) That blood in the phlegm comes from the throat so rarely, except in the presence of a definite epistaxis, that this source should never be diagnosed.

(*b*) That it takes a large number of cigarettes smoked over a long period to produce a smoker's cough.

(*c*) Young adults do not get persistently tired without reason; a method of life which has not previously produced tiredness is not likely to be the cause.

(*d*) The patient's explanation of a symptom should not be accepted without investigation if the symptom is sufficient to bring him to the doctor.

(*e*) "Catarrh" is often caused by intrathoracic conditions.

(*f*) Pleurodynia is not a diagnosis. If it is called a pain in the chest no one will be misled.

(*g*) However expert the doctor is in the use of the stethoscope he can never exclude tuberculosis with it.

When tuberculosis is suspected it should not take more than ten minutes to scribble a card to a clinic or a hospital asking for a radiograph, to give the patient a special carton for collection of sputum and instruction what to do with it, and to estimate the erythrocyte sedimentation rate. If these are all normal few cases of pulmonary tuberculosis will be missed. From the point of view of pure economics it is cheaper to take 2,000 negative radiographs than to delay diagnosis of one case of pulmonary tuberculosis for three months. In young adults, by the law of average, five cases with *x*-ray shadows indicating a tuberculous lesion which requires full investigation will be found in every 2,000 cases *x*-rayed at random.

Telling the Patient

The method by which the diagnosis is conveyed to the patient is most important. He must always be told what is the matter as soon as the diagnosis is certain. To many patients the diagnosis will come as a crushing blow; to some it will seem almost a sentence of death; so it is advisable to point out that with adequate treatment and co-operation with the doctor the prognosis is good, but no commitment should be made on time. The patient should be informed that to get well is a full-time job: the important thing is to get him well once and for all and to make a good job of the treatment at whatever expense in time. He should be encouraged to ask questions even if the answers to them cannot be given: it will help the doctor to see his reaction to diagnosis and to understand how to handle him. Fears brought out into the open are less frightening than those which are brooded over.

When pulmonary tuberculosis is diagnosed the patient should be put to bed immediately. Frequently, owing to his commitments, this may be impossible; so if the symptoms of toxaemia are minimal he may be allowed a few days during which he can make some provisional arrangements, provided he rests as much as possible when doing so. The object of insisting on bed rest without delay is to prevent the disease from getting worse while a plan of campaign is being arranged. Few patients who have any real chance of getting well will deteriorate during a month's rest in bed. Even if you could get the patient into a hospital or sanatorium it is unlikely that any specific method of treatment would be embarked upon profitably before he had had a few weeks' rest in bed.

First Measures

Having got the patient in bed the following should be done:

1. The clinical state must be assessed.

2. His temperature should be taken for at least five minutes in the mouth, on waking and at 2 p.m., 6 p.m., and 10 p.m. for a week: after this it need be taken only first thing in the morning and at the other time at which it has been found to be highest.

3. The sedimentation rate should be estimated.

4. If the temperature is 100° F. (37.8° C.) or more the patient should be confined strictly to bed, use a commode, and be blanket-bathed. If it be less, or after it has remained at normal for a week, he may be allowed up once a day for toilet purposes and twice a week for a bath.

The doctor must then go into details about

1. The food—its quality and service.

2. Ventilation and heating of the room.—There is no need to freeze the patient, but the room must be well ventilated and the lighting of his room must be adequate.

3. Visitors.—The daily number and length of stay must be laid down. No more than one, and for half an hour at a time, is the golden rule, unless the patient is atoxic.

4. Rest hours.—The patient should lie flat in solitude without doing anything except listen to the wireless for an hour before and after lunch and before supper.

5. Occupation.—Until the temperature has settled completely for at least 14 days his occupation should be confined to reading, listening to the wireless, and writing occasional letters.

6. Sleep.—A mild hypnotic should be given without hesitation to produce sleep if there is insomnia.

7. Prevention of infection to others.—All handkerchiefs must be put into a bag and soaked in 1/20 lysol before being sent to the laundry; if there is sputum, a proper container must be used with 1/20 lysol at the bottom. When bed-making, the attendants should wear a mask. No children should be allowed in the room, and adolescents should sit near an open window.

8. Small amounts of alcohol may be allowed. Smoking should be cut down without undue delay to about five cigarettes a day.

9. All the instructions must be discussed with the patient and family, and put down in writing. If the doctor does this the patient will realize that they are important.

Main Plan of Treatment

The plan of treatment must then be worked out with the help of an expert—either the tuberculosis physician or a private consultant. Unless the patient is really ill, it will do him little harm to be taken in a car to the consultation, but his doctor should be present to discuss the plan. A place in an appropriate institution must be booked. It can easily be cancelled if not needed. Generally speaking, three months' bed rest will be the start. If cavities are present this will usually be followed by collapse therapy, for which institutional treatment is necessary. Provided that steady improvement in the reduction of toxaemia is taking place as shown by symptoms, fall in temperature, sedimentation rate, and reduction of sputum, rest may be carried on for three months.

At the end of that time the case should be reviewed, with fresh radiographs, sputum tests, etc., in consultation with the expert. There is no need to get the patient up before going to the consultation. There are three possibilities. First, all evidence of toxaemia, occult and manifest, may have disappeared and the radiograph may show much improvement; cavities if present may have closed and the sputum become negative. This indicates a short further period of bed rest to consolidate the improvement and a gradual increase in activity, preferably in an institution or sometimes, if the patient's temperament and home circumstances are satisfactory, at home. The older the patient the less well will he usually settle down in a sanatorium. Secondly, improvement in toxaemia has taken place but improvement radiographically is slow and/or cavities are present. Bed rest must not be relaxed and institutional treatment insisted on, though the latter is not urgent, as further improvement may be looked for. Thirdly, little improvement has taken place. In this event institutional treatment is urgent; for the patient will probably not improve without collapse therapy with or without streptomycin, etc.

Collapse Therapy

The only form of collapse therapy that is normally applicable at home is a pneumoperitoneum with a phrenic nerve interruption. If this is thought to be indicated the patient can be got into a hospital for a week to have the phrenic nerve crushed and the pneumoperitoneum started. A pneumoperitoneum can be kept up by a careful general practitioner who will take the trouble to learn the technique. The complications are very rare, and failure to sustain the optimum rise of the diaphragm is not very serious. Except in early and fortunate cases, this procedure will usually only prepare the patient for more drastic collapse therapy, but often a very marked improvement can be obtained. Artificial pneumothorax should never be handled except by an expert with an *x*-ray plant at his disposal: irreparable harm can be done by an incorrect choice of cases and errors in its conduct. Frequently the actual technique of refills is easy, but it requires long experience to be able to handle cases to the best advantage and to avert and deal with complications.

In recent years apical thoracoplasty has been used more often in cases with small cavitated lesions at the apex, and in skilled hands has a low mortality rate. It is no longer reserved for patients with extensive disease. Resection of part or the whole of a lung is being used on quite a large scale now that the theoretical objections have been found to be unfounded. It is attended, however, by much greater risks than thoracoplasty and should be attempted only by those with very wide experience.

Chemotherapy

Streptomycin is now settling down to its proper place in the treatment of pulmonary tuberculosis. Broadly speaking, its use lies in the treatment of recent infiltrative or pneumonic disease, tuberculous laryngitis, or tuberculous tracheobronchitis, which is a much commoner condition than was previously assumed. In cavitated disease its value lies in getting a patient fit for collapse therapy. A useful simile is that of a boxing match in which you are getting the worst of the contest. If a friend can hold one of your opponent's hands you will be given the opportunity to knock him out. If you fail to do so during the time that the hand is held you will be beaten when your opponent gets the use of his hand again if he is still on his feet. Streptomycin plays the part of the friend, and its favourable action is limited in time. After a varying period the tubercle bacillus becomes resistant to it and your chance has been lost. Accordingly its use should always be part of a well-considered plan of campaign. Complications are by no means negligible, especially in old patients.

P.A.S. (para-aminosalicylic acid) is given in doses of 10–20 g. daily for a month and is used for similar types of case. The effects are less dramatic and certain than with streptomycin, but the development of resistance against it is rare under ordinary circumstances. Unfortunately its use has to be discontinued in a large number of cases because of vomiting and diarrhoea. There are hopes that the use of both of these drugs together may get over many of their disadvantages.

In most cases institutional treatment is necessary sooner or later, but the patient will have to be reassured that in a well-run place superinfection is not a practical risk.

The Convalescent Patient

When the patient becomes convalescent the role of the general practitioner is very important. Even to the specialist it is often difficult to decide when the patient should be allowed to get up; the general practitioner should therefore keep on the safe side: it is much better for the patient to remain at rest for a month too long than to get him up too soon. As a rule at least a normal temperature, a normal sedimentation rate, three negative sputa, and a radiograph showing no cavitation and only retrogressing shadows should be obtained before the patient is allowed up. When the patient is judged fit to get up the time out of bed and the amount of exercise are gradually increased, so that he is up for eight hours and walking a mile at the end of a month, and up all day except for two hours' rest and walking four to six miles a day at the end of three months.

When the patient returns from institutional treatment a full report from the hospital or sanatorium should be obtained and a full assessment of the case made, with the help of a new radiograph. Both for patients who have returned from sanatorium and those who have recovered at home a detailed programme should be drawn up with the assistance of the specialist who is going to help to look after the patient; gradual increase of activities should be permitted if the check-ups show healing of the disease. The temperature chart should be continued and monthly radiographs and sedimentation rate obtained until the patient is judged fit to return to work. Any deterioration of these should lead to careful review of the case and, if necessary, more drastic treatment. Return to work should, if possible, be gradual. Usually the patient should go back to his old job unless the hours are excessive, the work very strenuous, or the conditions unhealthy.

For the first six months a monthly check-up is essential and a comparative radiograph called for at least every two months. Relapse should be spotted as early as possible, but too much attention must not be paid to equivocal radiological changes; small differences in shadows are often due to differences of technique, but the appearance of a new shadow in a reasonably comparable film should be regarded as evidence of relapse. This often appears without any clinical change. Sputum, if present, should be examined regularly.

Any febrile catarrhal attack indicates the necessity for a new radiograph before return to work is allowed. When relapse has been diagnosed prompt treatment is indicated. A second period of bed rest seldom produces as good a result as the first, and collapse therapy is usually indicated. The intervals between the check-ups which have taken place every month for the first six months can be extended to two months, but this should be maintained for two years. After this, every three months will be sufficient for the next two years, but a radiograph should be taken every six months for an indefinite period if the disease has been extensive or slow to respond to treatment. If the patient remains well for two years the chances of healing improve steadily. It must be remembered that worry and strain and excessive activity at home are just as harmful as long hours at work, and are usually much easier to avoid.

Home Contacts

Examination of the home contacts following the diagnosis of pulmonary tuberculosis in a member of the household must not be neglected. All children under 10 should be tested for infection by a jelly test, or by the Mantoux test (up to 1/1,000 dilution) if over 10 years of age. A negative result, provided that six to eight weeks have elapsed since the last contact, indicates freedom from infection, and calls for no further action while contact is not taking place. All positive reactors and older contacts must be *x*-rayed. In contacts over 30 a single negative radiograph is sufficient unless contact is continued with an infectious case. Children who are positive reactors and adolescents should be *x*-rayed again after a further six months and annually for five years.

The use of B.C.G. on negative reactors must be considered if contact with infection is likely to be maintained. B.C.G. is a culture of living avirulent tubercle bacilli. It is used to give an individual who has never been infected with tuberculosis the acquired immunity which he would receive if he had been infected, without the risk of developing the disease. It is obviously not applicable if the Mantoux test is positive. The chances of serious complication are negligible. At present its use should be confined to infants, children, and adolescents who are living in tuberculous households, and medical students, nurses, and the like who are specially exposed to infection.

Arrangements are being made for it to be available at tuberculosis clinics.

Conclusion

The successful treatment of pulmonary tuberculosis depends largely on attention to detail and willingness to assess deviation from normal. Often a doubt will arise: the clue to correct action is the decision whether serious harm will ensue if the solution of the problem is left until the next visit. If the answer is in the negative the patient should not be informed of the doubt, but action should be taken immediately a decision is made. The average tuberculous patient knows a great deal about himself, so the assumption by the doctor of knowledge which he does not possess is fatal, but it is equally bad to give the impression that the lack of knowledge leads to a lack of interest.

THE ITALIAN HOSPITAL

The Italian Hospital in Queen Square, London, which has been closed since 1941 except for some out-patient activity during the last two years, was reopened on June 19. The Earl of Perth, vice-president of the hospital, received the guests, including many representatives of the Italian colony in London. Cardinal Griffin, Archbishop of Westminster, attended to give his blessing, and inaugural speeches were made by the Italian Ambassador, Duke Gallarati-Scotti, and the Consul-General for Italy, Dr. Vita-Finzi, chairman of the committee of management. It was stated that this hospital, the only one of its kind in the United Kingdom, was founded 66 years ago by the generosity of an Italian, Commendatore Giovanni Battista Ortelli.

In accordance with its constitution, the hospital gives preference in its wards (58 beds) and out-patient department to Italians and Italian-speaking people, but actually it has always been open to the sick and injured of all nationalities, and its British patients have almost equalled its Italian patients in number. The hospital was damaged in the war and also suffered much from dilapidation, so that it became a mere shell, but extensive renovations and improvements have been completed throughout the building, which is now furnished and equipped as a modern hospital, although the structure is Victorian.

Cardinal Griffin spoke of the difficulties which had to be overcome in finding money to put the building in order and in enlisting both medical and nursing staff. The nursing is in charge of the Sisters of Verona, assisted by lay nurses.

A vote of thanks to the governors of King Edward's Hospital Fund for London was moved by Mr. H. P. Winsbury-White, chairman of the medical committee, who explained that the hospital had not been taken over by the Ministry of Health under the National Health Service Act and was still dependent on voluntary contributions. The generous help of the King's Fund was gratefully acknowledged.

Commendatore John Sperni moved a further vote of thanks to the Ministry of Health, the London County Council, and the Corporation of Holborn, in which borough the hospital is situated. The Mayor of Holborn spoke of the appropriateness of having such a hospital again functioning in a part of London which has many Italian associations. The proceedings concluded with the singing of the hymn of the Italian Republic, and the company made an inspection of the wards and departments.

The Earl of Bessborough presenting a congratulatory address on behalf of the Royal College of Physicians and Surgeons of Canada to the President, Sir Cecil Wakeley, on the occasion of the 150th anniversary of the foundation of the College.

ROYAL COLLEGE OF SURGEONS

150th ANNIVERSARY DINNER

In the year 1800, by Royal Charter, the Corporation of Surgeons was constituted the Royal College of Surgeons of England. The 150th anniversary of that event was celebrated with fitting state on June 27, when a dinner at the College was attended by H.R.H. the Duke of Gloucester. Before the dinner the President (Sir Cecil Wakeley), assisted by the Vice-presidents (Sir Harry Platt and Professor Ernest Finch), received addresses from each of the other Royal Colleges and Corporations in Great Britain and Ireland, the Royal Society, the Royal Society of Medicine, the Royal College of Physicians and Surgeons of Canada (presented by Lord Bessborough, an Honorary Fellow of the College), the Royal Australasian College of Surgeons, the College of Surgeons of Paris, the Society of Apothecaries of London, the General Medical Council, the American College of Surgeons, the British Postgraduate Federation, the Worshipful Company of Barbers (which is No. 17 in the order of precedence of the City Guilds), and from 13 universities and four London medical schools.

The DUKE OF GLOUCESTER, in responding to the toast of "The Queen, the Princess Elizabeth, the Duke of Edinburgh, and other members of the Royal Family," recalled the associations of the College with the Royal House. The College was incorporated by charter of George III. To mark its centenary in 1900 the institution of the Honorary Fellowship was approved by Queen Victoria, and the first Honorary Fellow elected was the then Prince of Wales, afterwards Edward VII. In its 150th year, as the first event in the celebrations which culminated that evening, the College had elected the Queen to its Honorary Fellowship. His sister, the Princess Royal, and his uncle, the Earl of Athlone, had similar connexions with the College and greatly regretted their inability to attend the dinner.

Mr. S. C. ROBERTS, Vice-Chancellor of the University of Cambridge, in proposing the toast of the College, spoke of the early history of the Guilds of Barbers and of Surgeons and of their combination in the reign of Henry VIII. It was evident, he said, that the present high level of surgical efficiency was not immediately attained, and he gave some quaint accounts of complaints against surgeons in the sixteenth century. The Royal College since its constitution in 1800 had flourished exceedingly, and all the guests would desire to offer their congratulations on this occasion. They honoured surgery, an art rather than a science, demanding the most exquisite skill and the keenest judgment.

At this point the Duke of Gloucester received on behalf of the College a silver tankard presented by the Royal Australasian College of Surgeons and a medal presented by the College of Surgeons of Paris.

Sir CECIL WAKELEY, in responding, said that during its first hundred years of incorporated existence the College progressed steadily as a licensing body. The Fellowship was instituted in 1843 and the licence in dental surgery in 1859, and the Conjoint Board was set up in 1884. The College was twice enlarged, and the museum and library grew apace. During the last fifty years the progress had been remarkable. He referred to the appointment in 1908 of Sir Arthur Keith (an honoured guest that evening) as conservator of the museum; to the institution of primary Fellowship examinations overseas, the first in Canada in 1929 and in Australia in 1931; to the receipt of some great benefactions and the creation of trusts and scholarships. In 1941 came disaster, when three-fifths of the College and museum were destroyed by enemy action. Within two months of that catastrophe Lord Webb-Johnson (as he now was) was elected President, and during his eight years of office the College, maimed and mutilated as it was, developed a vigour greater than at any time in its previous existence. With the help of generous gifts special departments were formed with professors at their head, and the scientific work of the College was systematically organized. The College had played a leading part in organizing postgraduate study and had strengthened imperial ties by the institution of Commonwealth travelling scholarships.

Thanks to the foresight of Lord Webb-Johnson the College had become possessed of nearly the whole of the south side of Lincoln's Inn Fields, which would enable it to benefit from the well-timed generosity of Lord Nuffield, who was giving £250,000 for the erection of the Nuffield College of Surgical Science, where about 100 postgraduate students would be provided with the facilities of collegiate life. With the assistance of the Wellcome trustees, of many kindred institutions, and, above all, of the Fellows of the College who had contributed so loyally to the restoration and development fund, it was planned to build a great hall and enlarge the museum. It was the determination of the College to fulfil with all the energy it could command the duty laid upon it under the charter of George III—the promotion and encouragement of the study and practice of the art and science of surgery.

Lord WEBB-JOHNSON proposed the health of the guests. After a reference to the earlier history of the College he said that the greatest happiness on an occasion like this was to be surrounded by friends, and the College was fortunate in that the friends who surrounded it were so representative and distinguished. The College had passed through a crisis, and in that crisis had sought and found friends in all parts of the world.

Sir JOHN ANDERSON, who responded, referred to the progress of surgery and the new hope it gave to sufferers from abnormalities and diseases formerly regarded as mortal. Thanks to surgery the King had been restored to an active normal life. The achievements of plastic surgery were frequently evident, and by various new procedures lives were saved and suffering diminished. He referred with appreciation to the fact that recently a surgeon had left "his plumber's tools" behind him and stretched with his fingers a valvular orifice of the heart. In congratulating the Royal College on its notable anniversary its guests would desire to acclaim the profession, at the head of which the Royal College with its sister institutions stood.

After the dinner the guests visited the museum and the council room, in which were displayed John Hunter's anatomical specimens illustrating some of his best-known work and specimens which showed the progress towards the rebuilding of the museum series destroyed by enemy action in 1941. It was stated that 158 new specimens had been prepared so far to replace the losses in the anatomical museum, and 215 to replace the losses in the comparative osteology collection. Exhibits were also on view from the odontological series, the unit illustrating ophthalmological research, and a series of colour photographs illustrating the diseases and injuries of modern warfare and their treatment by surgery and antibiotics. The College plate was on view, including the latest acquisition, presented by the Worshipful Company of Barbers, a replica of the cup given to the Barber-surgeons Company by Henry VIII. The records of the College were also shown, including the roll of Honorary Fellows, containing the signatures of all who had received this distinction from Edward VII on July 24, 1900, to the present Queen on March 20, 1950.

HARVEIAN SOCIETY DINNER

LORD LINLITHGOW'S TRIBUTE TO THE G.P.

A large gathering assembled in the Grocers' Hall on June 29 for the Buckston-Browne-Gray-Hill Dinner held by the Harveian Society of London, the president, Dr. R. R. Trail, being in the chair. After the company had toasted in silence the memory of William Harvey and of Sir George Buckston-Browne, the Marquess of Linlithgow proposed the health of the Harveian Society in a thoughtful speech which, despite the heat of the evening, was listened to with deep appreciation.

Lord Linlithgow said that as a layman he had had a long and varied contact with and interest in scientific research. He had seen much money spent on lavishly equipped premises and had been saddened to note that "in some despite the marble and the gilding the sacred fires are untended and the altars cold." The limiting factor was the quality of the research worker. "It is the man that matters." Harvey could have had no research team in the modern sense any more than Pasteur had two hundred years later. "Yet Harvey was very far from being alone. For by great and patient labour he had acquired all the knowledge available in the schools, all such past experience as could be gathered from the written word and amongst contemporaries an unequalled mastery of anatomy founded in the untiring exercise of dissection." There was, Lord Linlithgow believed, nothing to equal Harvey's principal achievement in its significance, its dramatic quality, and its completeness. Though Sir Francis Bacon had employed Harvey he remained without knowledge of his physician's great discovery. It would be of the greatest interest to know whether the Lord Chancellor had called in Harvey as a general practitioner or as a specialist. In his essay "Of Regimen of Health" Bacon wrote this on choosing a doctor: "Forget not to call as well the best acquainted with your Body as the best reputed of for his faculty." Lord Linlithgow hoped that this, which had been so clearly understood 350 years ago, was not now to be forgotten. He went on to say:

The Family Doctor

"For my part, I have a great fear that the position of the family doctor is in serious jeopardy. I doubt very much if the public at large has yet understood how much is at stake in this issue. I would like to say that where medicine in any of its branches is concerned I am without political bias. What concerns me, and most other men of good will, is the health, efficiency, and happiness of the common run of men and women. Nor am I directing my argument this evening to the economic aspect of the National Health Act, though it is true that in my judgment its impact upon our overstrained economy may well—and before many months pass—provide one of the sharpest political issues ever presented to this country. Nor, again, would it be reasonable to expect perfection at the start of so extensive a scheme. Indeed, it must take much experience and some years before the machine can be fully run in.

"What troubles me is that, unless I am mistaken, signs are multiplying to show that the status and usefulness of the general practitioner have already suffered damage, and that unless something is done in good time the public interest is going to be gravely hurt. I admit that my fitness to judge is not strongly founded; for I am no more than a private citizen who reads the newspapers and such literature on these topics as he can make time for. But to-night I am content to present myself to you as a patient, and one insured under the scheme. Not so long ago we patients were encouraged to hope that prevention of disease rather than its cure was to be the target, and I can conceive of none more worthy. But does not prevention depend upon the early recognition of aberrations from the normal? And who in the world is going to do me this service of very early diagnosis if it is not the G.P., who is, or ought to be, my family doctor, the person who as early as 1620 was valued 'as the man best acquainted with my body'? Please, for my sake, cherish him. Please do not leave him and his kind in deepening isolation, cut off from the springs of progressive medicine, deprived of effective contact with the hospital services! Help him to keep abreast of progress and to use effectively the tremendous armoury of therapeutic substances which, almost from day to day, research is providing. Give him a little time in which to think as well as time to work. Make the general branch a worth-while career such as may attract at least its share of the best students.

"I value specialization as much as any man; and if the nature of my case warrants it, I wish my G.P. to send me to a specialist without delay. I must hope that the road to him may not be clogged by large numbers of patients whose state does not, in fact, need his ministration or give warranty to those who have directed them to him. Am I not right in holding that the only way to set right this last matter is to raise the status, capacity, and performance of the G.P.? As a patient, I desire, in fairness both to the medical profession and to myself, that doctors should be adequately remunerated. I am properly anxious that no practitioner should be driven, on grounds of bread and butter, to extend his practice beyond the utmost number of patients to which he can give proper care. I am aware that many issues arise of great moment to the medical profession. Then again, I am left in no doubt about the political significance of the National Health scheme or the cleavage of opinion upon certain of its aspects, although all parties are pledged to support it. For myself and my fellow patients, I will crave but one boon. It is that all concerned should bear constantly in mind that we patients are the most important party in this whole matter, and that it is our welfare that is at stake."

Lord Linlithgow ended by making some remarks about his interest in tuberculosis. With the president of the Society he had taken part in the work done at Papworth and at Enham-Alamein. His father-in-law, the late Sir Frederick Milner, had been one of the earliest and most devoted supporters of Papworth. Lady Linlithgow shared her father's enthusiasm, and when he (Lord Linlithgow) went to India she dedicated herself to the task of founding there an organization for coping with the fearful problem of tuberculosis. In British India and in the Indian States Lady Linlithgow succeeded in raising a fund of about £800,000, which was disbursed upon the establishment of clinics and general anti-tuberculosis measures. When they left India in the autumn of 1943, Lady Linlithgow had succeeded in establishing a tuberculosis association in every Province and in almost every State. These were almost without exception conducted by Indians.

In response to the toast, the president, Dr. R. R. Trail, in a speech of much learning compared the England of Harvey's day with England now. He gave a fascinating account of the manners and customs of those who lived in that turbulent period of British history. Harvey had lived at the time of the Armada and of the Civil War, had been physician to James I and Charles I, had been alive when Shakespeare and Milton were alive, and, when he died at the age of 80, had witnessed revolution and regicide. The toast of the guests was proposed with eloquence and wit by Dr. M. C. W. Long. He reminded those present that the dinner they were enjoying had been endowed by Sir George Buckston-Browne who gave the Harveian lecture in 1901 on urinary [illegible]ay Hill, with whose name the dinner was also associated, in good fellowship and in the ordinary fashion. Among the guests present he welcomed in particular Dr. Arthur Allen, of the U.S.A.

The evening being late, response to the toast of the guests was made with admirable point and brevity by Lieut.-General Sir Frederick Browning and Dr. W. Russell Brain, President

Lm56, M32 N5c2 9887

of the Royal College of Physicians. Dr. Brain, asking what was the state of the circulation of medicine to-day, observed that in consulting medicine they had some large vessels, and in the peripheral circulation, where the most important things took place, there were the general practitioners. Nothing could happen in one part of the circulation without effect on the rest. He, too, stressed the importance of the future of general practice and of general practitioners.

TUBERCULOSIS IN SOUTH KOREA

According to a report issued by the World Health Organization, tuberculosis is the most widespread of all diseases in Korea and the most serious public health problem. The statistics available in the country are unreliable, but in 1947 the death rate was 52 reported deaths per 100,000 population. However, according to local estimates the actual annual death rate is probably more than 300 per 100,000. The disease is present in all forms, but the bovine type is rare, since cow's milk is not commonly drunk in Korea.

Of children entering primary school at the age of 7, about 30% are tuberculin-positive; when they leave at the age of 14 to 16 about 50% to 60% are tuberculin-positive. The percentage seems to be higher in Seoul than in rural areas. Among college students 84% of the males are said to be tuberculin-positive, and 73% of the females.

Some information on the prevalence of pulmonary tuberculosis was obtained by mass-radiography surveys during 1944–9 by Dr. C. S. Cho, formerly professor of radiology at the National Seoul University Medical School. "Active tuberculosis" is defined as "progressive changes in the *x*-ray picture of the lungs, including changes in the apex and elsewhere, pulmonary gland infiltration, and pleurisy signs." In accordance with this definition the incidence of active tuberculosis was found in the surveys to be 3.2% in orphanage children, 1.7% in urban, and 0.9% in rural primary-school children. It was 1.2% in boys at middle schools, and 2.4% in girls. Among college students it was 3.2% in males and 2.7% in females. Among textile workers the incidence was 2.8%, metal industry workers 1.5%, rubber industry workers 2.7%, and clerical workers 3%. Out of 426 children admitted to the paediatric ward of the Seoul Red Cross Hospital in 1949, 134 (31.4%) had tuberculosis; and out of 8,647 children examined at the paediatric out-patient clinic of the Taegu Presbyterian Hospital in 1949, 1,266 (14.7%) had tuberculosis. Mass-radiography surveys showed that about 2% of the total population of twenty million in South Korea had active tuberculosis. The total number of tuberculosis beds was 530, but there were no beds for tuberculous children. The report states that there are about 3,800 doctors, 1,500 nurses, and 1,500 midwives in South Korea, though only half of the nurses and midwives are in practice.

Among measures suggested for controlling tuberculosis are: sending a W.H.O. consultant to advise on training in medical schools and on the development of public health measures; additional laboratory equipment; and—urgently needed—more beds for tuberculous cases.

An account of the Nutrition Research Laboratories at Coonoor, India, is given in a pamphlet written by the director, Dr. V. N. Patwardhan. He outlines the history and development of the laboratories, and the great work done by Sir Robert McCarrison, the founder-director, on research into nutrition in India. Inquiries into the nutritive value of foodstuffs have been carried out at the laboratories, as well as diet surveys and research into the nutritional status of the people and into nutritional deficiencies. Many medical and other workers have been trained there, including social welfare workers, health visitors, and teachers. In an introduction Rajkumari Amrit Kaur, Minister of Health for India and President of the World Health Organization, emphasizes the need for nutritional research in India and of raising the standard of nutrition there.

MEDICAL LIBRARIANSHIP IN GREAT BRITAIN

MEDICAL LIBRARY ASSOCIATION CONVENTION

As principal guest speaker at the annual convention of the Medical Library Association held at Boston, Massachusetts, Mr. W. J. Bishop, librarian of the Wellcome Historical Medical Library and honorary secretary of the Medical Section of the Library Association of Great Britain, opened the proceedings on June 21 with an address on medical libraries and librarianship in Great Britain.

Taking as his theme the part played by medical libraries in the advance of medicine, Mr. Bishop examined the means by which their usefulness has been, and could be yet further, improved. Most important were inter-library and international co-operation; the organization of librarians into professional groups for the mutual exchange of information and ideas; and the recruitment, training, and examination of juniors in order to build up a well-educated and highly trained body of registered medical librarians. The first attempt in Britain along these lines had been the Medical Library Association of Great Britain, which was founded in 1908 and came to an untimely end in 1910. It owed its origin to the fact that Professor Walker Hall in 1906 moved from Manchester, where there was an excellent medical library, to Bristol, where there was a poor one. Mr. C. Clayton, then librarian of the Manchester Medical Society, served him so well with inter-library loans that he suggested that this practice should be extended and organized by an association of medical libraries. Other provincial libraries, in the same stage of development as Bristol, saw great possibilities in the scheme. The big London libraries were not so anxious to see their stock dispersed far and wide.

The outcome was that 32 library representatives attended a preliminary conference held during the annual meeting of the British Medical Association at Sheffield in 1908. In January of the following year, at a meeting in the Leeds School of Medicine, a committee was formed with Osler as its president. The inaugural meeting of the new Medical Library Association was duly held at Queen's University, Belfast, on July 28, 1909, again on the occasion of a B.M.A. annual meeting. Osler gave an address on "The Medical Library and Postgraduate Work," and an exhibition of manuscripts and rare books was arranged in the university.

In July, 1910, once more "by kind permission of the British Medical Association," the second annual meeting was arranged in London at the same time as the B.M.A. meeting, and several papers were read. Thereafter little more was heard of the M.L.A., probably because its energetic secretary, Mr. Clayton, left the Manchester Medical Library and nobody was found to take his place. Within a short time the B.M.A. Library began to fulfil one of the M.L.A.'s objects by improving its facilities and introducing postal loans. Then after the 1914–18 war Professor Leiper and his assistants compiled the "Union Catalogue of Periodicals" (published by the B.M.A. in 1923), which had been another of the chief aims. Short as was the existence of the Medical Library Association, it had achieved something in stimulating these advances. The reasons for its failure, in Mr. Bishop's opinion, were the faulty conception of an association of libraries instead of librarians; the small number of well-trained medical librarians at that time; and the prominence given to the study of medical history, a good aim in itself but not one of the chief functions of such an association.

Medical Section of the Library Association

Sir John MacAlister, secretary and librarian of the Royal Society of Medicine and a former secretary and president of the Library Association, writing in 1910 gave it as his considered opinion that the scheme would have stood a better chance of success if it had been constituted as a branch of the Library Association. Later events showed the wisdom of this opinion. When a group of London medical librarians suggested in 1947 that the time had come to establish a professional body, preliminary discussions resulted in its formation as a subsection of the Library Association. It is significant that on that occasion the initiative was taken by librarians themselves, that the stimulus came from London, which had proved the stumbling-block in the old association, and that it quickly received the warmest support from medical librarians throughout the country, as well as encouragement from the parent association. Prominent among its aims were the establishment of an exchange system, the compilation of union lists and similar co-operative projects, and the encouragement of inter-library loans. At the preliminary meeting held at Chaucer House, the headquarters of the Library Association, on October 4, 1947, there were 33 librarians present; by October 29 the new body already had 60 members. By the end of 1948 membership reached 100, and the group was accorded the status of a full section of the Library Association. Present membership is 180 and is rising steadily.

An exchange scheme was established within the first three months of the existence of the new section, and by now many thousands of periodicals and books have been collected and distributed to libraries at home and abroad. Valuable work has been done by a special committee studying the selection of subject-headings for medical libraries, and another committee has published a select book-list and hints on the organization of medical libraries in hospitals, which last has been asked for by more than 300 hospitals in all parts of the world.

Turning to the future, Mr. Bishop spoke of the "crisis" in medical bibliography: the cessation of the index-catalogue, the myth of "complete coverage of the literature," when the year's output in one specialty might take ten years to read; and the problems of selecting from and organizing the literature, problems which could not be solved by any of the mechanical methods now becoming fashionable. The best solution, said Mr. Bishop, lay in the improved training of the medical librarian so that he could act as an expert guide through the complexities of the overwhelming mass of periodical literature. In this matter the infant Medical Section of the Library Association had gone ahead of the veteran Medical Library Association of America and had already succeeded in introducing into the final examinations for the Fellowship of the Library Association special papers in medical literature and medical librarianship. The syllabus, which is of university standard, is exacting and comprehensive and could be mastered only by assistants who had spent some years of hard work and study in a medical library.

In concluding his address Mr. Bishop made a plea for a movement in medical librarianship back to the study of the reader and the book, urging his audience to remember that the library was one of the greatest factors in medical progress.

At the end of the Boston Convention on June 25 Mr. Bishop began a tour of medical libraries in the eastern States of the U.S.A. and in Canada.

A two-day conference is being arranged jointly between the Institute of Biology and the Atomic Scientists' Association, with the support of the British Association, on the subject of atomic energy and its biological hazards. It will be held at the Royal Institution, Albemarle Street, London, W.1, on October 20 and 21. Other societies interested in the meeting include the British Institute of Radiology. The object of the conference is to consider, on the basis of the available facts from both the biological and physical aspects, the possible biological hazards arising from the development and application of atomic science now and in the future. The meeting will comprise four sessions as follows: (1) Biological and medical effects of nuclear radiations. (2) Tolerance levels and measures of protection. (3) Biological implications. (4) Atomic energy and the future. In each session opening addresses will be given by invited speakers, and they will be followed by discussion. Preliminary arrangements are being made by a joint committee, of which the chairman is Professor Alexander Haddow, of the Chester Beatty Research Institute, Royal Cancer Hospital, London.

ORDER OF ST. JOHN OF JERUSALEM

The *London Gazette* has announced the following promotions in, and appointments to, the Venerable Order of the Hospital of St. John of Jerusalem:

As Knight: Dr. J. H. G. Robertson, C.B.E. *As Commanders (Brothers):* Surgeon Captain T. Madill, O.B.E., M.B., R.N., and Dr. J. C. Ashton. *As Officers (Brothers):* Surgeon Captain A. W. McRorie, M.D., D.P.H., K.H.P., R.N., Colonel F. A. Bearn, C.B.E., D.S.O., *M.C.*, M.D., Brigadier T. W. Davidson, M.B., Lieutenant-Colonels E. H. R. Altounyan, O.B.E., *M.C.*, M.D., F.R.C.S., and E. G. Montgomery, M.B., Messrs. H. S. Taylor-Young, F.R.C.S., and I. Newton, F.R.C.S., Drs. H. Middleton, *M.C.*, D. A. B. Hopkin, D. L. Johnson, N. M. Maclennan, B. O. Bradshaw, P. Pringle, C. W. Isaac, S. H. Ward, R. A. H. Fulton, E. E. Butler, and W. S. Wallis. *As Associate Officers (Brothers):* Squadron Leader F. S. Krusin, M.R.C.S., L.R.C.P., and Dr. T. Seshachalam. *As Serving Brothers:* Surgeon Commander D. F. Walsh, M.B., F.R.C.S., R.N., Squadron Leader L. E. Claremont, M.R.C.S., L.R.C.P., Mr. J. S. Grant, M.D., F.R.C.S., Drs. G. M. Kay, T. W. H. Porter, A. G. N. Weatherhead, L. E. Jones, R. V. C. Richards, J. A. Thompson, W. W. Wilson, R. C. J. Meyer, D. K. Fisher, R. W. S. Ashby, A. Strang, D. R. Edwards, and S. L. Mainland. *As Associate Serving Brothers:* Drs. A. A. Masser and F. Rassim. *As Serving Sister:* Dr. Margaret Melvin.

Nova et Vetera

JOHANN MIKULICZ-RADECKI

Last month Sir Gordon Gordon-Taylor led a delegation from the Royal Society of Medicine to attend the 67th Congress of the Deutsche Gesellschaft für Chirurgie, which was held on May 31 at Frankfurt-am-Main. The occasion coincided almost exactly with the centenary of the birth of the German surgeon Johann Mikulicz-Radecki. In paying tribute to his memory, Sir Gordon Gordon-Taylor said:

"It is a proud privilege that is granted me to pay a tribute to the memory of a great German surgeon, for the centenary of the birth of Johann Mikulicz-Radecki coincides almost exactly with the date of this congress of German surgeons, of which he was so strong and stalwart a pillar during the latter half of the nineteenth century and in the first few years of the present one. I am further honoured in following this morning so famous a surgical figure as Ferdinand Sauerbruch.

"Not only am I here in Frankfurt to pay this tribute to Mikulicz on behalf of the Royal Society of Medicine, of which I am acting president at this juncture, but I am also commissioned by the President of the Royal College of Surgeons of England, the headquarters of British surgery, to associate the name of our surgical college with this eulogy directed to the memory of a master surgeon. Nay, if I might venture for one minute to assume a wider responsibility, I feel sure that to-day I am speaking for all the surgeons of all nations in the world in rendering homage to that great shade, who did so much and achieved so much to promote the science and art of surgery.

"I am by no means assured that the subject on which I myself propose to speak later on—interinnomino-abdominal amputation—is one that would have particularly commended itself to the famous surgeon, for in the well-known textbook of surgery which was my surgical bible in more youthful years and of which he was joint author with Ernst von Bergman and Bruns one senses a tendency to relative conservatism in respect of the treatment of neoplasms in the vicinity of the hip.

"The exteriorization method of ablating cancer of the large intestine, for ever associated with the name of Mikulicz, must always rank as the most monumental milestone in the onward progress of colonic surgery, and the so-called Mikulicz–Paul technique did far more to promote the safety of colonic resection than any single factor, save perhaps the sulphonamide or streptomycin therapy of very recent years. Not only were the lives of countless cancer sufferers all over the world saved by the Mikulicz technique, but during the last world war the application of the principle of exteriorization of the colon was

almost universally applied by British surgeons to the treatment of war injuries of the large bowel and did much to diminish the mortality of this serious lesion.

"As one of the surgical acolytes of the famour Theodor Billroth, of Vienna, he assisted at the actual birth of gastric surgery, and in 1881 at this congress he reported three cases from the Vienna clinic in which Billroth had performed gastrectomy, one of them being the first successful case ever performed. By a curious trick of fate Mikulicz was destined to die at a premature age from malignant disease of an organ the surgery of which he had done so much to promote.

"This is no place nor is there the time to catalogue all his achievements, but in 1885 he was the first to operate for gastric haemorrhage. The pioneer is rarely the one who exploits, and Mikulicz was not spared to see the operative treatment of haematemesis established as the appropriate method of treatment in certain cases; a sweet reasonableness on the part of the internist towards the problem has only been secured after fierce discussion and by hard endeavour, and in this German-speaking surgeons have played no unimportant a part. Nor in Britain has the subject passed unnoticed, and my friend Norman Tanner and even I myself have taken a very active interest in the pioneer work of Mikulicz, Finsterer, and others.

"In every generation there are a chosen few who shed a special lustre on it by reason of their character, their attainments, and their record of service, God's greatest gift to man; and when the riband of surgical history is finally unrolled, in glittering and golden letters will be found inscribed thereon the name of Johann Mikulicz-Radecki. I offer to him, on behalf of surgeons everywhere, my tribute of laurel for honour and of rosemary for remembrance."

Reports of Societies

SOME UNUSUAL CASES

Dr. A. HILLYARD HOLMES delivered his presidential address, on April 5, to the Manchester Medical Society. He referred to the amalgamation of five societies to form the newly constituted Manchester Medical Society, with sections of medicine, pathology, surgery, anaesthetics, and odontology. The oldest of these societies, the Manchester Medical Society, was formed in 1834; the present Pathological Society was formed in 1885 to replace the microscopical section of the Medical Society, which had been in existence since 1875. The other three societies were of much more recent origin.

After references to the early meetings of the Medical Society and to some notable presidential addresses, the speaker detailed a number of interesting clinical cases, illustrating them by lantern slides. Three cases of haemoptysis proved to be due to hydatid cysts, malignant haemangioma of the right auricle, and a congenital pulmonary cyst, respectively. In the last-named condition haemoptysis had recurred for nearly twenty-five years, and *x*-ray films taken in 1928 supported the diagnosis.

There followed descriptions of a case of dissecting aneurysm of the aorta, observed for three and a half years, and of a congenital cerebral aneurysm causing an isolated third nerve palsy, observed over fourteen years and finally treated by ligation of the artery. Brief allusion was made to four diseases which were incurable when the speaker was a student—namely, Addison's disease, pernicious anaemia, tuberculous meningitis, and diabetes mellitus with coma.

Sir HARRY PLATT proposed a vote of thanks to the president.

The paraplegic branch of the British Legion performs a useful service for its members in producing a quarterly magazine called the *Cord*. It gives disabled readers up-to-date information about the various appliances designed to help them, and mingles light comment on the difficulties of the disabled with instruction on how to overcome them. Information may be obtained from the editor at 114, Arran Road, Catford, London, S.E.6.

Correspondence

Stress and the General Adaptation Syndrome

SIR,—In view of the fate which has overtaken all previous attempts to construct a monistic pathology and its corollary, monistic therapeutics, it required no little courage on the part of Professor Selye to make the attempt, especially at a time when the knowledge of disease is a thousandfold greater than it was at the time of the systematists who have preceded him. Moreover, the despair into which we are plunged by the centrifugal force of scientific medicine makes any attempt at integration welcome and compels us to give it our earnest consideration and at the same time to subject it to critical analysis.

Any such system must satisfy two criteria: first, it must be sufficiently catholic to embrace all pathological and clinical evidence whether this is obtained collaterally or directly; secondly, the theory on which it is based must be logically unassailable.

As to the first, Professor Selye (*Journal*, June 17, p. 1383) lists a large number of heterogeneous diseases which are responsive to cortisone. I do not for a moment doubt the validity of his claims. It is, however, worth pointing out that a list equally long and equally heterogeneous can be and has been made of diseases responsive to *x* rays, though some of the claims have not stood the test of time. The remarkable thing is that though the two lists are not identical they have a large number of diseases in common: eczema, dermatitis, rheumatoid arthritis, spondylitis, Hodgkin's disease, the leukaemias, lymphosarcoma, Boeck's sarcoid, hyperthyroidism, psoriasis, keloid, etc. If *x* rays have not the dramatic action of cortisone on rheumatoid arthritis, what could be more dramatic than their action on many forms of cancer, a field in which cortisone is useless? We thus have two large groups of diseases of widely differing pathology whose members are partly identical and partly different, responding to two agencies as far apart in origin and character as they could possibly be. Are we to conclude that *x* rays act not directly but through the intermediation of the hypothalamus–hypophysis system? I find this hard to believe. Moreover there are many diseases which respond up to a point, and usually almost the same point, when treated by the most diverse agencies. Hodgkin's disease, for example, responds to *x* rays, to urethane, to derivatives of mustard gas, and now to cortisone and A.C.T.H. All kinds of things retard malignant growth to some extent. How do these facts square with Professor Selye's theory?

Turning now to the theory itself, I quote extracts verbatim from the opening paragraphs of his address. Each is followed by the deductions which, according to my reasoning, should be drawn from it: the italics are mine.

1. *Living organisms can respond to stress as such. . . .*"
   Stress is something to which organisms can respond.
2. "*We called this response the general adaptation syndrome.*"
   The general adaptation syndrome is the means by which the organism responds to stress.

3*a*. "*Anything that causes stress endangers life, unless it is met by adequate adaptive responses.*"
   Stress is a condition caused by anything which endangers life in the absence of adaptive responses.

3*b*. "*Conversely, anything that endangers life causes stress and adaptive responses.*"
   Stress is a condition caused by anything which endangers life; it is accompanied by adaptive responses. 3*a* and 3*b* are therefore not the converse the one of the other; they are partly identical and partly inconsistent.

4*a*. "*In the general adaptation syndrome the manifestations of passive non-specific damage are intricately intermixed with those of active defence.*"
   The general adaptation syndrome has two components, damage and defence. It is not clear to me how damage can be part of an adaptive process. Note that damage is passive.

4*b*. "*This* [i.e., 4*a*] *is an inherent characteristic of the stress which elicits the general adaptation syndrome.*"
   The dual nature of the general adaptation syndrome (4*a*) is a characteristic of the stress which causes the general adaptation syndrome.

5. "*In addition to damage and defence, every stressor also produces certain specific actions. . . .*"
   In the diagram which accompanies this paragraph stressor is represented as the cause of the whole train of reactions, but stress which forms part of the title of the article and the pivot of the argument is omitted. The word "stressor" is introduced incidentally and without being defined. In common parlance it should of course mean something which causes stress, and this would seem to be its meaning here if we assume with 4*b* that the two things which it produces—namely, damage and defence—are the components of stress. Since, however, damage and stress are also described as the components of the general adaptation syndrome (4*a*) which is caused by stress, stressor seems to be the same as stress.

6. "*In the biological sense stress is the interaction between damage and defence, just as in physics tension or pressure represents the interplay between a force and the resistance offered to it.*"

Damage has been represented as passive (4*a*). But a thing that is passive cannot take part in an interaction. Similarly, in a physical system a resistance which is passive cannot play. Stress must therefore be the unilateral action of defence upon damage, that is, of one of its own components upon the other. To return to the physical analogy, the truth is that tension is not the interplay of force and resistance (when resistance is active) nor the play of force upon resistance (when resistance is passive). It is the *result* of interplay or play as the case may be. Stress therefore becomes the result of the action of one of its components (defence) upon the other (damage). But stress has been described as the action itself. Therefore stress is not only itself but the result of itself. According, however, to 1 and 2 (above) all living organisms can respond to stress by the general adaptation syndrome, which, according to 4*a*, consists of damage and defence. Therefore stress, in addition to being itself and the result of itself, is also the cause of itself.

The above remarks, I assure Professor Selye, are not dialectic fireworks but a sincere expression of my intellectual difficulties and of my desire to comprehend his meaning. As an earnest of my good will may I express my admiration of his humility, especially welcome in these days of scientific arrogance? "The complete comprehension of life," he says, "is beyond the limits of the human mind." He thus echoes Herbert Spencer's belief: "Both science and religion must recognize that the Power which the Universe manifests to us is utterly inscrutable."—I am, etc.,

Cambridge. FF. ROBERTS.

SIR,—The Heberden Oration and your leading article of June 17 provide much material for thought and reflection: thought, to grasp the meaning and implications of the present outlook; reflection, to discern what progress the passage of years has brought, to distinguish revolutionary theories and new ground from ideas which are merely modifications of earlier thought.

Often in the natural course of evolution conceptions can be so developed, expanded, modified, elucidated, or integrated that they finally present as an entirely new creation something whose advent might possibly be expected to herald the opening of a new era in medical progress.

Your leading article implied that the theory of stress diseases and adaptation evoked little enthusiasm until the effect of hormones in the treatment of rheumatoid arthritis was so dramatically demonstrated. This may be so; but it is difficult to believe that practitioners in the past were wholly oblivious to the reactions of the individual or his adjustments to hostile assault, stress, and environment.

A conception so all-embracing as the general adaptation syndrome must inevitably initiate a volume of research work covering a wide field, and it might not be unhelpful to future investigations if a review of earlier ideas were made at this stage.

In September, 1931, I moved to unearth the opinions of the giants of the day about rheumatic disease in general. This is what I read:

Poynton and Schlesinger[1]: "New methods of approach are badly needed, and, above all, fresh conceptions of disease. . . . Real advance will only be made by breaking away from traditional experiments with cultures *in vitro*, and by paying more attention to the reactions of the patient."

Macinder Wetherby[2]: "Clinically I am unable to place a sharp dividing line between cases termed rheumatic fever, and those with an apparently similar onset that progress to chronic articular involvement."

Rolleston[3] noted how the manifestations of rheumatic disease changed with the passage of time.

Swift, Derrick, and Hitchcock[4]: "The state of the tissues of the patient is the most important characteristic factor of the disease, and the specificity of the streptococci recovered may play a relatively unimportant role."

Gross[5] showed that the nature of a reaction was often influenced by the age of the patient, citing cardiac disease in rheumatism, and nephritis.

Pemberton,[6] after the 1914–18 war, was able merely by prescribing rest and a reduced carbohydrate diet to cure many cases of atrophic arthritis, even when focal sepsis was present. He gave a notable contribution to the work when he demonstrated that in arthritis not only was there lowered blood sugar tolerance, which recovered as the patient improved, but that even after this the impaired tolerance could be reproduced in 40% of patients by interference with the peripheral circulation. He also wrote: "Extreme nervousness, apprehension, and irritability are conspicuous features, also depression and melancholia, while many examples of functional insanity originate from the common background productive of arthritis and should be regarded as branches of the same pathological state."

The day of the haemolytic streptococcus and focal sepsis was waning. More and more did workers tend to concentrate upon the reactions of the individual. As Pemberton said: "It is necessary to admit a disturbance of underlying function expressing itself widely throughout the economy and subject to many influences."

In 1932 and 1933 cases of rheumatic disease which occurred in my own limited sphere of general practice were investigated in a somewhat elementary fashion; the findings were submitted in 1934 as a thesis entitled "The Autonomic Nervous System and the Rheumatic Diathesis." The following extracts are taken from it:

(1) "In acute rheumatic fever of children, subacute rheumatism of the adult, and many if not all forms of chronic rheumatism one complete disease, and one only, is confronted."

(2) "Rheumatic disease, with diabetes, exophthalmic goitre, and asthma, should be defined as offshoots of the same pathological root, and that the victims, through weakness in their reaction to physical and mental bombardment, render themselves prone to attack."

(3) "Physiology furnishes proof daily of the influence of psychological stimuli on this mechanism. One sees the palpitation or cold sweat of fear, the blush of embarrassment and anger, or the dilated pupils of the startled, but it may not be so apparent that in the susceptible not only these acute exacerbations, but also prolonged fatigue, worry, overwork, apprehension or gross mental strain, may either immediately, or over the course of time, give rise to definite pathological conditions which involve some portion of the autonomic endocrine scheme."

(4) "Other hostile factors exist, in the form of psychical unrest, emotion, mental conflict, nervous shock, anaemia, chill, barometric variations, susceptibility to which has been found to be a characteristic weakness of the rheumatic subject."

(5) "An unstable autonomic system is a prominent feature of the rheumatic state. It is usually an inherited and familial weakness, which prevents the subject from responding adequately and efficiently to external influences, whether physical or mental."

(6) "It is not possible entirely to resist the suggestion that conditions, whether physiological or pathological, which are associated with high blood sugar are also those which are favourable to the onset of rheumatism, and the autonomic system is the only connecting link whereby these conditions can be co-ordinated in the mind's eye."

(7) "Each ailment invested its victim with a power of antagonism to any other one of the diseases of the group. It was as if the severance of the weakest link had relieved the tension throughout the whole structure of the system."

(8) "The controlling mechanism of the autonomic endocrine apparatus is in the hypothalamus, which is connected with the posterior lobe of the pituitary gland; furthermore, this part of the pituitary may even influence the controlling nuclei of the autonomic system in the hypothalamus through a recently described vascular portal circulation (Cushing and Fulton)."

(9) "Focal sepsis itself, or at any rate its activity, may be a phenomenon induced by the rheumatic state."

(10) "Treatment must be adequate to deal with the effects of emotion, exhaustion, and shock."

Sufficient has been written to show that eighteen years ago we had begun to direct our gaze towards a picture not very dissimilar from that which the brilliant work of Professor Selye has now unveiled before us.

His words describe the background[9]:

"Adaptation to our surroundings is one of the most important physiological reactions in life; one might perhaps even go so far as to say that the capacity of adjustment to external stimuli is the most characteristic feature of living matter. It is not unexpected therefore that some of the most common diseases of man appear to be diseases of the adaptive mechanism."

Previously one could only say:

"Examples show the association between dysfunction of the endocrine organs and rheumatic disease. Naturally the story is incomplete, for insufficient knowledge of body chemistry and endocrine action leads into a veritable maze of complexity. But this halt in progress has its function, for it deflects the mind from the test tube to the simpler conception of man as a part of the universe, endowed with a pedigree, subject to assault, and girt with environment."[9]

When, in 1932–3, focus began to be concentrated on the defensive reaction rather than on the invader, it at once became obvious that a much closer affinity existed between all forms of rheumatic disease than had previously been thought possible; further, that other pathological entities should be added to this group, for the common factor was stress. But one never imagined that the list of diseases could reach its present dimension, for then there was no knowledge of Professor Selye's valuable pathological and experimental work; this reason also accounts for the fact that more emphasis was placed on the autonomic and vascular aspect of the defence than on the endocrine. There were other divergences. Small importance was assigned at that time to the role of the anterior pituitary gland and suprarenal gland. They were merely considered as part of the general endocrine scheme; nor would a postulate which held that attack by one disease of the group rendered the individual relatively immune to assault by another agree with the outlook of to-day. Hypertension may still create difficulties, for a characteristic feature of the rheumatic state is low blood pressure. These, however, are but fragments. The main picture remains. Its title has not changed. "The gods approve the depth but not the tumult of the soul."

Professor Selye's publications form a milestone in medical progress. Not only this, they are of absorbing interest to anyone who, in the past, may have striven, however crudely and however inadequately, to comprehend the nature of the reaction of the host to the assaults of his environment.—I am, etc.,

High Wycombe, Bucks. G. S. W. EVANS.

SIR,—Professor Hans Selye's article on his concept of the adaptation syndrome in the *Journal* of June 17 (p. 1383) was of great interest to me. I noticed that he did not include sprue and allied conditions in the list of diseases which have responded to A.C.T.H. and cortisone.

I have thought for some years that sprue might result from adrenal strain or "stage of exhaustion." Sprue occurred in "epidemic" proportions in the Burma campaign, where stress existed, and the added upset of salt and water metabolism could well have had a "specific action" on the adrenals; also the diarrhoeal diseases which abounded provided the "extraneous conditioning of the target organ." There is much suggestive evidence that the adrenal may play some part in fat absorption and in the aetiology of sprue. Perhaps A.C.T.H. and cortisone have been tried and found wanting? I know that some adrenal cortical hormones have been tried in sprue without success.—I am, etc.,

Delayed Feeding of Premature Infants

SIR,—Employing similar methods to those of Professor W. Gaisford and Dr. S. Schofield (*Journal*, June 17, p. 1404), we have been using delayed initial feeding of premature newborn infants in Cardiff for the last eighteen to twenty-four months. In our experience we confirm most of the points illustrated in their article—namely:

1. Though infants lose more initial weight—and, relatively, the smaller they are the greater the percentage loss of weight—the result seems to be a more virile infant.
2. Oedema (occurring in 12% of our series) disappears much more quickly.
3. Once feeding is commenced, difficulties (e.g., regurgitation or vomiting, cyanotic attacks, etc.) are more rarely encountered.
4. The nursing staff all favour a demand-initial-feed technique and soon become expert in detecting the true "hunger cry" of the newborn infant.

Very rarely have we found a rise of temperature during the initial starvation period. Nothing approximating to the text-book "inanition fever of the newborn" has been seen—not even in the series of mature infants treated by this delayed feeding technique. No infants in our series required parenteral fluid, and we are persuaded that when a raised temperature is present the aetiological factor is probably infection.

Table A is presented for comparison with Tables I and II of Gaisford and Schofield.

Table A

Weight	No.	Hour of First Feeding		Weight Loss		Percentage Weight Loss (of birth weight)
		Range	Average	Range	Average	
lb. (kg.)				oz. (g.)	oz. (g.)	
5 -5½ (2·27–2·5)	102	16 - 80	38	½-14 (14·0–397)	5½ (156)	6%
4½- 5 (2·04–2·27)	78	19 -119	45	1 -12 (28·3–340)	5½ (156)	7%
4 -4½ (1·81–2·04)	55	19 - 123	55	½-12 (7·0–340)	5 (142)	7%
3½-4 (1·59–1·81)	34	17½–104	60	2 - 13 (56·7–368)	6½ (184)	10%
3 -3½ (1·36–1·59)	17	17½–104	64	1 -10½ (28·3–297)	6½ (184)	12%
2½-3 (1·13–1·36)	12	27 124	58	1 -11 (28·3–312)	6 (170)	14%
2 -2½ (0·91–1·13)	8	24 -104	56	2 - 7 (56·7–198)	5½ (156)	14%

The delayed or demand-initial-feeding technique has been similarly adopted for mature as well as for premature infants. It has been found to be especially advantageous in the carrying out of the "non-touch" technique treatment of those mature infants who have undergone a difficult delivery—i.e., breech delivery, difficult forceps, etc. Even the so-called normal baby has less feeding upsets on this technique. Table B shows the findings in 1,218 mature infants.

Table B

Weight	No.	Hour of First Feeding		Weight Loss		Percentage Weight Loss (of birth weight)
		Range	Average	Range	Average	
lb. (kg.)				oz. (g.)	oz. (g.)	
10+ (4·54+)	11	12 - 58	40	5–18 (142–510)	12 (340)	7%
9 -10 (4·08–4·54)	61	3½–66	33	1–16½ (28·3–482)	8 (227)	5½%
8 - 9 (3·63–4·08)	281	7 -88	29	1–17½ (28·3–496)	8 (227)	6%
7 - 8 (3·17–3·63)	467	6 -58	30	0–16 (·0–454)	7 (198)	5½%
6 - 7 (2·72–3·17)	322	5 -92	35	1 13 (28·3–369)	6 (170)	5½%
5½- 6 (2·49–2·72)	76	12 -75	37	2–15½ (56·7–439)	6½ (184)	7%

In using a demand-initial-feeding technique in premature and especially in mature infants great care must be taken of the maternal breasts. Some form of expression of the breast at regular intervals must be employed (we favour three-hourly hand expression) in preparation for later feeding at the breast.

Finally, we would like to support the suggestion of Professor Gaisford and Dr. Schofield that practitioners and midwives should practise this non-feeding technique in the care of premature babies pending their transfer to hospital, so helping to lessen early inhalation asphyxia.—We are, etc.,

Vascular Changes in Diabetes

SIR,—I should like to answer a few questions and probably raise some others in connexion with Dr. C. Shiskin's letter (June 24, p. 1490) on vascular changes in diabetes. In this I do little more than repeat the opinions expressed in the Banting Lecture (*Lancet*, September 3, 1949, p. 401), in which I mentioned the same case as Dr. Shiskin does, in which after thirty-nine years (now forty-one) of diabetes there are no vascular stigmata. His diabetes has been unusually well "controlled." Dolger may find in New York that 100% of diabetics of twenty-five years' duration have retinal haemorrhages, but I have several patients, myself included, who have escaped such initial signs of vascular involvement—and many more who have not.

The most interesting and important suggestion of Dr. Shiskin's last paragraph is that vascular degeneration is independent of diabetic control and depends on a common unknown factor which causes both "diabetes" and vascular degeneration. It is easy in this respect to postulate, as I did some years ago, some pituitary Cushing-like (A.C.T.H.) factor, but against this simple and vague explanation are two facts: (1) Retinal complications have occurred in haemochromatosis and relapsing pancreatitis, in which the disease is a straight attack on the islet of Langerhans without other endocrine involvement. (2) No diabetic, except in the mildest disturbance of carbohydrate metabolism found by some routine chemical test, has ever a normal sugar metabolism. All insulin cases show inevitably phases of hyperglycaemia, and to talk of physiological normality of blood-sugar control only displays ignorance of the real metabolic condition. Different degrees of uncontrol would be a truer description. In view of (1) and (2) we cannot rule out and must still consider years of continued and varying hyperglycaemia as a possible prime factor in these dreadful complications of retinopathy, hypertension, and renal glomerulosclerosis.—I am, etc.,

London, W.1. R. D. LAWRENCE.

Cancer of the Lung and Smoking

SIR,—With reference to your annotation on smoking and cancer of the lung (June 24, p. 1477), may I be permitted, as a non-smoker and therefore presumably uninterested in the defence of tobacco, to indicate other possibly relevant environmental changes between the years 1920 and 1947?

The first of these is, in Great Britain, the systematic surfacing of roads with tarmac and associated tar spraying. When motor-cycling many years ago and when tarred roads were not so universal I was compelled to wear goggles on account of the intense conjunctival irritation caused by tar dust. Prior to the use of goggles, upon squeezing my eyes with my handkerchief I have observed my lacrimal secretion to be deeply stained by tar. If such an amount of tar dust could fall on the surface of the eye a much larger amount must have been respired. Motorists requiring demonstration of the amount of tar dust floating above a road on a dry day are asked to observe the condition of their hands after handling a steering wheel for a short time with even a portion of a window open.

Another environmental change is the increased amount of exhaust fumes, which render walking on our main roads a doubtful pleasure. In this connexion I would mention particularly the fumes of Diesel-engined heavy vehicles, and express surprise that no woman member of the public appears to have commented on these filthy exhausts.

It must be noted that I confine myself to mentioning some possibly relevant environmental changes, and that I leave any question of causal relationship to malignant disease as a matter for investigation.—I am, etc.,

Swansea. H. R. TIGHE.

Smallpox in the Unvaccinated

SIR,—In your issue of June 24 ("Points from Letters," p. 1492), Dr. H. Tudor Edmunds, after referring to the Asian seaman who initiated the recent outbreak of smallpox in Glasgow, makes the assertion, "Had this seaman not been vaccinated previously his attack of smallpox would have been recognized as soon as he was examined. . . ." He therefore opposes vaccination and the ensuing state of possibly incomplete immunity because, should an attack of smallpox supervene, the clinical picture may be so modified and atypical that the disease is not recognized and its spread thereby facilitated. He thus reiterates an argument against vaccination previously expounded many times and notably by Dr. C. Killick Millard. According to this argument it is always the atypical case modified by previous vaccination that is emphasized as a menace.

It is unfortunate for these views that Dr. Edmunds should also mention the doctor who was infected and died. This case was atypical and very difficult to diagnose. It was well that information regarding contact with the primary case soon became available, because the haematemesis at the outset of her illness did not justify a diagnosis of smallpox even to be entertained in the first instance. The exanthem did not at any time show a papular element. She had never been vaccinated.

A better example of the same type is the first case in the Glasgow outbreak of 1942. He was a seaman of pure white stock who sickened on board an inward-bound ship. On May 24 a rash appeared and the illness was diagnosed as measles by the ship surgeon. This diagnosis was confirmed by two more medical officers on board, and again confirmed by another medical officer when the ship reached the Clyde on May 29. Finally, on the patient's arrival at the hospital for admission to a measles ward the correct diagnosis was made by the physician superintendent, a man of great experience. This patient, who later died, initiated the subsequent outbreak of smallpox in Glasgow. He had never been vaccinated.

It would appear that, while smallpox may be unrecognized because it is atypical due to previous vaccination, it may also be unrecognized because it is atypical for precisely the opposite reason—viz., the patient has never been vaccinated at all.

This argument against vaccination is manifestly absurd when related, for example, to the resulting situation among the above ship's complement if all of them had been previously unprotected by vaccination. Those who died of confluent or malignant smallpox would have had the final satisfaction of knowing, although beyond mortal aid, that they had at least done everything to ensure, if one can believe it, their own early and accurate diagnosis.—I am, etc.,

Glasgow. J. S. GEMMILL.

Multiple Primary Carcinoma

SIR,—As there seems to be an interest in multiple primary carcinomata I thought that it might be interesting to report two cases, one a case with simultaneously two primary carcinomata each in an entirely different system of the body to the other, and a case of three primary carcinomata occurring consecutively and in different places.

CASE 1

The first case was a fisherman, aged 76, from Littlehampton, who in January, 1943, came to my out-patient clinic for carcinoma of the left upper eyelid. It was arranged that this growth should be treated by *x* rays. It is an old maxim that a rectal examination should be performed on every surgical patient, but in this case it seemed unnecessary. However, while awaiting *x*-ray treatment the patient was admitted as an emergency for intestinal obstruction, and it was found that he had a carcinoma of the rectum. I carried out an abdomino-perineal resection of the rectum in two stages, and his eyelid was treated by *x* rays.

The pathologist reported on a biopsy of the eyelid that the condition was a squamous epithelioma. The rectal growth was an adenocarcinoma with moderate penetration of muscle coat and a tendency to colloid production. He did very well, and in spite of wartime conditions returned to work as a fisherman and somewhat embarrassed my domestic staff by leaving at the door as a token of his gratitude a live lobster.

CASE 2

The second case is that of a woman, who is now alive and well, aged 75, and who was shown at a B.M.A. meeting recently.

In 1941 she had a panhysterectomy and salpingo-oophorectomy for adenocarcinoma of the uterus. The operation was carried out by Mr. Alan W. Douglas, who was then R.S.O. at the Royal Sussex County Hospital. In 1946 Mr. Leslie Lauste, who was acting for me, saw this patient, who was admitted as an emergency for intestinal obstruction. He found a carcinoma of the ascending colon and carried out a two-stage removal.

In 1948 I carried out a local mastectomy of the right breast for carcinoma and removal of axillary glands by means of diathermy, and she was afterwards treated by Dr. Millington with deep x rays. The glands were invaded by growth histologically.

All three growths were confirmed histologically, and were in entirely different systems of the body—uterus, bowel, and breast. I am indebted to Dr. L. R. Janes in each case for the histological reports.

I have not met with another case of triple primaries.—I am, etc.,

Hove, Sussex. H. J. MCCURRICH.

Popular Health Journal

SIR,—When Sir Robert Hutchison suggests the title "The Hypochondriac" for the B.M.A.'s new popular health journal he exhibits an attitude of mind which is the despair of all public health officers engaged in health education. It would not be so bad if the general public were merely ignorant of health matters, but, unfortunately, they are actively ill-informed by popular journalistic efforts and by advertisements relating to patent medicines, and our task in public health is made unnecessarily difficult because of this. We at least welcome a popular journal which will convey accurate information because it is edited under medical auspices, and, whether it is read by hypochondriacs or not, it can do nothing but good in giving real instruction to the public.

One group of readers of whom Sir Robert Hutchison seems quite unaware is formed by school-teachers and others having to do with education of children; they are avidly searching for accurate information on which to base their lessons in hygiene and applied biology.—I am, etc.,

Cambridge. CYRIL G. EASTWOOD, Medical Officer of Health.

Ogilvie's Syndrome of False Colonic Obstruction

SIR,—In the *Journal* of October 9, 1948 (p. 671), Sir Heneage Ogilvie reported cases in which intestinal upset suggesting obstruction of the bowel followed interference with the splanchnic plexus by new growth. MacFarlane and Kay (*March 12, 1949, p. 1267*) reported three further cases of such pseudo-obstruction but with no pathological findings at operation. I felt that the following case, in which symptoms of interference with the physiological functioning of the alimentary tract followed destruction, partial or completed, of the splanchnic ganglia, would be of interest.

The patient, a man in his sixties, had had Von Recklinghausen's disease since his early twenties. He had multiple subcutaneous nodules and much pigmentation. For three months two nodules on his chest had begun to grow fast. For a month he had been vomiting, and for a few days before admission to hospital this vomiting had been incessant. While being examined in out-patients prior to admission he had a marked Stokes-Adams attack in which his heart block was so complete that death almost supervened. A few weeks' treatment in hospital failed to relieve his almost incessant vomiting but gave time for a biopsy of one of the enlarging lumps on the chest wall. This proved to be a secondary neoplasm of doubtful pathological origin. In view of continued vomiting a laparotomy was performed, but the stomach and colon and upper small intestines were found to be quite normal. At the back of the upper abdomen round the crura of the diaphragm and extending upwards and into the diaphragm on both sides was a large irregular mass, obviously of new growth.

The growths on the chest were of course secondaries from the growth in the abdomen, and in view of the Stokes-Adams attack, suggesting cardiac involvement, Dr. Harold Avery (who had seen the patient) and myself both felt that they may have been due to direct extension of the growth, involving to some degree the heart itself.

The interesting fact is that this patient had such persistent and uncontrollable vomiting without any demonstrable lesion or obstruction either to the oesophagus, stomach, or bowel generally. This was demonstrated not only radiographically but operatively. The vomiting seemed to be due to involvement of the nerve supply of the stomach from the splanchnic plexuses. It is interesting to note that since operation, and without any different treatment, the vomiting has since been much less marked and the patient's life more comfortable and endurable.—I am, etc.,

London, W.1. A. J. HOBSON.

The Medical Bill

SIR,—Mr. P. C. L. Diggory's letter (*Journal*, June 24, p. 1492) is welcome evidence that the British Medical Students Association, over which he presides, is alive to certain defects in the Bill as it stands, among them the one to which my own letter drew your attention—i.e., the injustice of enforcing an onerous new condition, to wit twelve months' compulsory resident medical service *after qualification but before registration*, against medical students who signed on, and have since done years of their training, on the old basis. This injustice, which was not mentioned in the House of Lords debates, Mr. Diggory's association would remedy by deferring the appointed day "until after the expected date of qualification of those who have already commenced their studies." A simpler and at the same time more effective remedy would, I suggest, be by way of a proviso exempting from the new condition those who were bona fide medical students when the Bill was presented to Parliament or passed into law. I don't like the word "expected."

It seems to me important also to stress the fact (mentioned by Lord Llewellin in the debate) that until 1939, 50% of qualified students went into general practice immediately upon registration, including (as the Goodenough report says) "some well-qualified students who on account of their own or their families' financial circumstances felt unable to take advantage of the benefits offered by postgraduate experience in hospitals." This fact is a useful measure of the hardship which the new restriction may inflict upon many students. Unless something is done now the large class of students who hitherto for one reason or another have not been able to manage as free agents and as doctors even six months in a hospital job will in future be forced to do an extra twelve months' (or more) resident service as students or "interns" (another ominous word!). This criterion is in no way weakened by the further fact that during the war 94% of newly qualified doctors took hospital jobs immediately after registration; because, of course, this increase was obviously due to purely wartime measures such as (*a*) compulsory national service, and (*b*) compulsory direction of doctors of military age into civil hospital appointments.

Two other points made in the Lords also need comment. Lord Llewellin, by way of support for the new restriction, "recalled that both in the case of barristers and solicitors part of the preliminary training was spent in practical work under an experienced lawyer." This statement conveys a very wrong impression. A Bar student is entitled (*a*) immediately upon qualification to be called to the Bar, and (*b*) immediately upon call to practise anywhere; and no barrister is required as a condition precedent to qualification or call or practice to undergo any sort of practical training. Many of them do in fact learn some of the ropes, either before or after call, in the chambers of a busy practitioner—I did so myself, after call and concurrently with practice on my own account; but none is obliged to. It is hard indeed to imagine the Inns of Court—those ancient champions of law and justice—trying, as this Bill apparently seeks to do in the case of medicine, to enforce an onerous unilateral change in the conditions upon which they accepted their students. As to the would-be solicitor, he spends the whole period of his training (five years or less, according to circumstances) as an articled clerk in the office of a private practitioner.

Secondly, Lord Horder limited his commendation of the proposed new condition to the ground that a doctor newly registered under the present conditions goes out into practice "ill fitted in respect of responsibility and judgment"—i.e., lacking a sense of responsibility. This may possibly be true of some of the youngest of them, though I should have thought that daily experience, during their long years of clinical training, of disease and death must surely by the end of their course have sobered the least responsible among even them. But how can it be true of the fine ex-Service types, with their war experience and their training in responsibility, of the many men with wives and families, and of the 30+, 40+, 50+, and occasionally even 60 + ancients who together form a considerable proportion of the total number of medical students? Are all these irresponsible too? If not, why should they all be treated as if they were?—I am, etc.,

Guildford. W. B. MANLEY.

Scarlet Fever, Rheumatic Fever, and Acute Nephritis

SIR,—Dr. T. W. Buchan (May 27, p. 1268) asks for information on the average duration of fatal cases of scarlet fever, rheumatic fever, and acute nephritis. From study of a short series of thirty fatal cases of acute nephritis occurring between the years 1939 and 1946 in the R.A.F. and W.A.A.F. it appears that the mean duration was 47 days, the median figure being 36 days. The cases were distributed as follows:

Duration of case in days	1–9	10–19	20–29	30–39	40–49	50–59	60–69	70–79	80–89	90–99	More than 100
Number of cases	2	6	5	5	0	1	3	3	0	3	2

Six deaths occurred in October, five in March, four in January, three in May and August, two in June and July, and one in February, April, September, November, and December. I can give no information about the duration of fatal cases of scarlet fever or acute rheumatism as the numbers of deaths from these causes in the R.A.F. and W.A.A.F. were even fewer than those from acute nephritis.

I am indebted to the Director-General, Medical Services, Royal Air Force, for permission to publish these figures.

—I am, etc.,

Stanmore, Middlesex. C. G. BURGESS, Wing Commander.

Acute Tubular Necrosis

SIR,—In the discussion at a meeting of the Section of Experimental Medicine of the Royal Society of Medicine on acute tubular necrosis Professor J. H. Dible, according to your report (May 27, p. 1262), stated that the lesion affected the whole nephron; that there was cellular necrosis of the tubules; that the cast material in the early stages in the secondary convoluted tubule was hyaline and not pigmented; and that the ascending limb and secondary convoluted tubule were especially affected, although the whole of Henle's loop showed the lesion. Granular material was present in the glomerular space. It is clear from Professor Dible's statements that the mechanical blockage by blood products is not the aetiological factor, as it was absent at the early stages in all cases, and at all stages in a proportion of cases.

Dr. E. M. Darmady went further in stating that, in view of Professor Jean Oliver's experiments, tubular blockage by pigment casts could no longer be regarded as responsible for this type of renal lesion. In certain cases, he said, nervously intermediated renal vasoconstriction remained a possible explanation, but in others it appeared to be excluded, and one had to consider other mechanisms—e.g., Professor Selye's alarm syndrome might be concerned. But he gave no details about the Johns Hopkins experiment on which he based his opposition to a common neurogenic aetiology: for example, he did not state at what level the cord was transected, nor what functional tests were applied to ascertain that all the renal nerves had in fact been divided. So I personally cannot regard this evidence as excluding the possibility suggested by the experiments of Trueta *et al.* in 1947.

With regard to Dr. G. M. Bull's dismissal of the "Oxford shunt" as a possible factor, I should in the first place like to know what he implies by the term in question, for it was invented abroad and is as yet very variously interpreted. Secondly, though acute nervous diversion of the renal cortical blood flow may be associated with low degrees of desaturation of the reduced total renal blood flow, I am unaware of any experimental evidence of the degree of desaturation associated with a diversion lasting long enough to produce inactivity of the tubular cells such as was found by Dr. Bull in his patients.

Dr. Hingson, by his method of continuous caudal analgesia, which appears to abolish afferent glomerular arteriolar spasm, has dealt successfully with the clinical state of anuria in various fields, and his results are dramatic. Professor Oliver, from the evidence provided by his dissection of nephrons, has attempted to show a distinction between damage caused by primary ischaemia and by toxin producing a renal shut-down. Dr. Hingson's therapeusis logically covers the former group in its entirety. It should encroach on the latter at the stage when the ischaemic protective mechanism is no longer serving a purpose and is in fact inimical to recovery.—I am, etc.,

London, W.1. JOHN SOPHIAN.

Intestinal Obstruction Due to Food

SIR,—The article by Mr. Neil Ward-McQuaid (May 13, p. 1106) and the letters which have followed show that many cases of this condition have been recorded and that future interest may well settle upon the foods which form rare causes. I therefore think that one of my two cases at least is worth mentioning. So far it seems to be the only case resulting from the "pickled onion."

Case 1.—A lady aged 52 was admitted to hospital on November 16, 1949. She had had abdominal colic for several days which had been severe for twenty-four hours. She had been vomiting since November 11. On November 15 she had passed a watery stool but there had been no flatus since then. On examination she was dehydrated and distended. She was tender to the left of a subumbilical scar of an incision for a hysterectomy in 1946. There was vigorous audible peristalsis. Laparotomy through a right paramedian incision showed a firm lump in the lumen of the ileum about 6 in. (15.24 cm.) above the ileocæcal valve. There was gross distension of the gut above the obstructing mass, which on removal was found to be a large pickled onion. Her convalescence was uneventful. Inquiry showed that she had eaten this onion about ten days previously at a party.

Case 2.—A lady aged 59 was admitted to hospital on January 8, 1946, with pain which had commenced on January 6. She had been vomiting since her last bowel action on January 6. She had a distended resistant abdomen and acute bronchitis. Exploration showed that her acute intestinal obstruction was due to orange pith. The only special interest in this case lies in the fact that she had hurriedly eaten an orange which was part of her grandchild's ration.

I am forced to wonder to what extent these cases are caused by hurried eating and failure to masticate food adequately.—I am, etc.,

Northampton. A. R. BANHAM.

SIR,—The article on "Intestinal Obstruction due to Food" by Mr. Neil Ward-McQuaid (May 13, p. 1106) recalled my meeting with a case in 1947. The obstructing material, grapefruit, was finally vomited.

The patient was a woman of about 50 and of moderate physique who had been seized with spasms of violent, diffuse abdominal pain of colicky type some three-quarters of an hour before, followed by vomiting. When I saw her she was pale and shaken; a spasm of abdominal pain came on within a few minutes. She went pale, sweated, and her pulse slowed. She drew her knees up and was tense, and any physical movements made were an attempt to curl herself up in a ball. About five minutes later the pains eased and she vomited some bile-stained fluid. In the interval before the next bout of pain the temperature and pulse were normal; there was no abdominal rigidity; something appeared to be palpable in the anatomical location of the pylorus, and it seemed to harden and soften; tenderness was present to the left of the mid-line slightly below this level.

She was advised that she should be removed to hospital or a surgeon should see her. She refused these suggestions but agreed to going into hospital next morning if no better. Obstruction due to some food eaten and lodged at the duodeno-jejunal flexure was considered at this stage.

Since the lady remained obdurate about seeing a surgeon, it was decided to see if the effect of posture and gravity would achieve anything; two to three bouts of pain had occurred in the meantime. Accordingly her head was lowered and pelvis elevated by manipulating pillows, and she was turned on her right side inclined towards the bed. The next access of pain, her last, was followed by the vomiting up of nearly a half of a grapefruit "eaten" the same day. It had been incompletely divided with a knife into four or five pieces, as is usual before serving it at a meal.

It was as surprising that she had managed to bolt such a large piece of food as it was gratifying that the simple manœuvre had been successful. She was up and about as usual next day.

—I am, etc.,

Reading, Berks. GEORGE A. JACKSON.

Morphine in Status Asthmaticus

SIR,—I was particularly glad to read Dr. Clement Francis's letter of June 17 (p. 1429) because I deplore the attempt to completely ban the use of morphine or its derivatives in this condition. This is a time-honoured remedy, and it would appear to me that deaths from asthma and bronchial asthma have become more frequent since the introduction of modern adrenaline therapy with the exclusion of morphine and atropine.

I entirely agree with Dr. Francis that other therapy should be given at first, and whenever possible I give an expectorant mixture, with ephedrine or "neo-epinine," get the patient well propped up in bed, warm, and with plenty of fresh air, and obtain oxygen if possible.

If I am called at night to a patient in a bad attack, I endeavour to assess the condition of the heart and lungs and inquire what drugs have already been taken, and I usually start by giving an injection of one of the pituitary-and-adrenaline preparations or adrenaline alone, and nikethamide sometimes seems helpful. After watching the patient I then decide the dose of morphine or "omnopon" that is safe to inject, and this varies from ⅛ gr. to ¼ gr. (8 to 16 mg.), always with atropine 1/100 gr. (0.65 mg.).

I am convinced that I have saved lives by this method, and shall be sorry if young doctors become afraid of its judicious use, and doubt if there is any new treatment at present that will adequately replace it.—I am, etc.,

London, W.14. C. WATNEY ROE.

Mission to Lepers

SIR,—The Mission to Lepers was founded in 1874 as an international and interdenominational society in order to enable Protestant missions to undertake work for those suffering from leprosy—and from its social consequences—by giving financial support and general guidance. Since then it has grown into a great society with extensive work in many lands. In the past it has not been the policy of the Mission to send out its own doctors and nurses. This was not necessary so long as the co-operating societies were able to provide the personnel. But to-day they are unable to do so in sufficient numbers. And this is just at a time when the prospects of curing leprosy have been brought nearer by the introduction of sulphone treatment. This has led the council of the Mission to decide that the time has come to send out itself a certain number of doctors, nurses, and other medical workers.

There are vacancies at present in India and China for a few men doctors and women nurses. Those who may consider offering themselves should be young, and wholly sympathetic to Christian missions. They should be prepared themselves to serve as medical missionaries and to co-operate wholeheartedly with missions and churches in the countries to which they go. The field of work offers no financial prizes; ordinary medical missionary allowances will be given; but the work does afford a fine field for Christian doctors eager to give themselves to a difficult task at a time of great opportunity. Those who wish to apply should be under 30 years of age and should send, along with details of qualifications and experience, references from those who know their character and capabilities.—I am, etc.,

7, Bloomsbury Square, London, W.C.1. A. DONALD MILLER, General Secretary.

Obituary

S. ERNEST DORE, M.D., F.R.C.P.

Dr. S. E. Dore, who died on June 27 at the age of 77, was until his retirement a few years ago one of the most prominent dermatologists in London.

Samuel Ernest Dore was educated at Mill Hill School and St. John's College, Cambridge. He studied medicine at St. Mary's Hospital, and there he came under the influence of Sir Malcolm Morris, whom he assisted in the skin department until Morris's retirement, afterwards continuing to help him in private practice. After leaving St. Mary's Dore became assistant to Dr. Pringle at the Middlesex Hospital, and on the retirement of Dr. Colcott Fox he was appointed physician to the skin department at the Westminster Hospital. Later he was also physician to the skin department at St. Thomas's Hospital, holding the two posts together until he reached the age for retirement. He also held similar appointments at the Hampstead General and the Evelina Hospitals, and in 1924 accepted an invitation to join the reconstituted staff of St. John's Hospital for Skin Diseases.

Dore proceeded M.D. in 1906 and took the M.R.C.P. a year later, being elected F.R.C.P. in 1920. He was a corresponding member of the French Dermatological Society, and assistant editor of the *British Journal of Dermatology and Syphilis* from 1916 to 1918. During the greater part of that period he was in charge of the journal because of the editor's absence on war service. He was a very active member of the dermatological section of the Royal Society of Medicine, exhibiting many cases and taking a very active part in the discussions. He was honorary secretary of the section in 1914–15 and president in 1930–1. He also attended regularly meetings of the British Association of Dermatology and Syphilology, and was honorary secretary from 1930 to 1932 and president in 1933. He was president of the St. John's Hospital Dermatological Society from 1928 to 1930. Apart from all these activities Dr. Dore was a vice-president of the Section of Dermatology at the Annual Meetings of the B.M.A. in 1921 and 1932, and president of the section at the 1936 Meeting.

While working with Morris, Dore's interests were particularly directed to the uses of radiotherapy in the treatment of skin diseases. With Morris he wrote a book entitled *Light and X-ray Treatment of Skin Diseases,* and he also translated Wickham and Degrais's work on radium therapy. He was undoubtedly one of the pioneers of the use of radium in the treatment of rodent ulcer in this country. He contributed many papers on dermatological subjects to different journals, the most notable being one on the contractibility and nervous supply of the capillaries and one on a chronic mild localized type of acrodermatitis perstans, which is by some associated with his name. In 1941 he delivered the Malcolm Morris Memorial Lecture on advances in dermatology during the past forty years.

Dore was a man of retiring disposition, with an immense knowledge of his subject. He was always accessible to his colleagues, who made full use of his wisdom and mature judgment. His extremely equable temperament made him beloved by his colleagues and pupils. He married late in life, and leaves a widow to whom the sympathy of everyone who knew him will be extended.—A. G.

R. M. B. MacK. writes: While others who have more knowledge of the details of his life must write their appreciation of his career, it is perhaps fitting that one of his pupils should attempt to pay tribute to the memory of Dr. S. E. Dore. If one was asked to name the characteristics for which he was most beloved one would say for his equanimity and kindliness; if asked to answer a question concerning his ability one would say that it was in diagnosis and in knowledge of the writings of the French school that he excelled. Many in our profession seem always to be pursued by time, but Dore, although he accomplished as much work as most of his contemporaries, seemed always to be unhurried. His work was characterized by accuracy, urbanity, and friendliness; often the monotony of routine was relieved by a flicker of humour. His ability was often underestimated because he made no effort to impress his students; it followed that his work was appreciated more by postgraduate students than by undergraduates. It was characteristic that during the nineteen-twenties one of his colleagues should have remarked, "I have often been surprised to find that if there is anything new that is remotely connected with dermatology it is usually being tried out in Dore's department quite a while before the rest of us have even heard of it." In recent years it has been pleasant occasionally to see one's old master, apparently but little aged by the passing of the years; but as in his active days time had never succeeded in fretting him, it was natural that as he grew older he should have been but little changed. One had hoped, until recently, that he would continue to enjoy the tranquillity of his later years. That hope has been broken, but those of his pupils who continue in the practice of his specialty can but be grateful for the benisons of friendship, tutelage, and encouragement which for many years they received from him.

"R. O." writes: Dr. Dore's out-patient department at St. Thomas's had an atmosphere of its own, stamped with the characteristics of the man himself. It was kindly, genial, and unhurried. There was a guarded optimism and friendliness affecting patients, nurses, students, and staff—and without this one gets nowhere in medicine. The dermatological mysteries were expounded with skill, but with a diffident charm; and such searching questions as the one about the difference between eczema and dermatitis were dealt with to enduring satisfaction. The lurking acarus curled infallibly round the point of the pin, and the microscope—rather an ancient one—showed up the secrets of the fungus scraping. No session went by without some humorous touch, for this was in Dore's make-up, and he drew on a long experience.

Dr. Thompson Barron writes: After an association with Dr. Dore extending over 25 years it is difficult to do justice to his memory. We became close and intimate friends, having much in common apart from professional affairs. His was a charming personality, but he was of such a retiring nature that comparatively few got to know him intimately. He was always ready to do a good turn and to assist others in any way in his power. I mourn him with feelings of great personal loss. He was one of my dearest friends.

J. F. WARD, M.D., F.R.C.P.

Dr. John Forbes Ward, who died on June 29 after a short illness, was educated at the Stockport Grammar School and Manchester University, graduating M.B., Ch.B. in 1909. He then held a number of house appointments, including that of resident medical officer at the Manchester Royal Infirmary. At this time, too, he travelled in the United States and Europe. During the 1914–18 war he served with the R.A.M.C. in Gallipoli, Egypt, Sinai, France, and Belgium. Returning to this country he took the M.R.C.P. in 1919; and in 1920, when he proceeded M.D., he became visiting physician to the Royal Manchester Children's Hospital at Pendlebury and to St. Mary's Hospital for Women and Children. From then on Ward devoted all his time and energy to the care of children, becoming well known as a paediatrician in Manchester and in Lancashire generally. He had a wide medical knowledge, and a degree of understanding and kindness which impressed not only his young patients but also their parents. He was appointed University lecturer in the diseases of children at St. Mary's Hospital, and both here, at Pendlebury, and on the many committees on which he served his opinions, always honest, were often sought by his colleagues. He was elected F.R.C.P. in 1938.

An original member of the British Paediatric Association, Dr. Ward always looked forward to the annual meetings, especially those held at Windermere, as he knew and loved the Lake District and especially its bird-life and flora. Modest and retiring by nature, his friendship, once won, was enduring and firm, and he was a splendid companion at meetings such as these. Among other appointments Ward held was that of visiting physician to the Ethel Hedley Hospital for Crippled Children at Windermere, and in spite of the distance from his home he was a regular visitor there. At the outbreak of the 1939–45 war he rejoined the Forces. He served as lieutenant-colonel both at home and abroad, and he was not demobilized until 1945.

Ward was an expert numismatist and had a valuable and interesting collection of coins, but his chief delight was his beautiful garden, where he and his wife worked in their spare time. Never a "clubman," Ward spent a lot of his time during off-duty hours browsing in old bookshops in search of volumes to add to his large library. He was much loved and will be much missed, but he will always be remembered for his great qualities of high principle and integrity. He is survived by his widow and two daughters, to whom the deepest sympathy of his friends and colleagues will be extended.—H. T. A.

Dr. JAMES LYONS died suddenly on June 1 at his home in Lincoln at the age of 61. Born in Omagh, County Tyrone, he received his medical training at Queen's University, Belfast, and graduated M.B., B.Ch., B.A.O. in 1912. After holding resident appointments in Belfast, he was later house-surgeon at the Rotherham Hospital and senior house-surgeon at the Lincoln County Hospital. During the 1914–18 war he served in France as a captain in the R.A.M.C. and was medical officer to a cavalry regiment. Soon after demobilization James Lyons proceeded M.D. He went on to take the Dublin D.P.H. and the F.R.C.S.Ed. in 1920 and the M.Ch. of Belfast a year later. After a time spent as medical superintendent of the Bucknall Hospital, Stoke-on-Trent, he settled in Lincoln in 1923. Combining surgery with general practice, he was appointed surgeon to the Burton Road Hospital and subsequently consultant to Lincoln Corporation, Lincoln City Maternity Home, and Bracebridge Heath Hospital. In 1934 Dr. Lyons became police surgeon for Lincoln, and in 1947 he retired from general practice and thereafter specialized in obstetrics and gynaecology. A keen member of the B.M.A., he rarely missed attending a meeting, and he was chairman of the Lincoln Division in 1934–5 and president of the Lincolnshire Branch in 1938–9. During the 1939–45 war he undertook the onerous duties of honorary secretary to the local medical war committee and earned the gratitude of all his colleagues. James Lyons was one of the kindest of men and never spared himself in his patients' interests. In addition he had a most generous nature, and this, combined with marked professional ability, made him popular alike with patients and with his colleagues.

He leaves a widow and two daughters, to whom the sympathy of many friends will be extended in their sudden bereavement. —G. A. B. W.

Dr. BETHIA MUIR NEWLANDS, a senior assistant medical officer in Middlesbrough, died in Aberdeen on June 2. She received her medical education at the University of Aberdeen, where she graduated M.B., Ch.B. in 1919, going on to take the D.P.H. in 1925. Dr. Newlands held resident appointments at the Royal Victoria Infirmary, Newcastle-upon-Tyne, and in the children's hospitals of Nottingham and Bradford. After working in the Aberdeen public health department, she was appointed a school medical inspector, in 1928, by the West Riding County Council, where she remained for 14 years. In the last two years of her service there she was senior administrative medical officer. During the 1939–45 war she held the post of acting medical officer of health for Brighouse, and in 1946 she became senior assistant medical officer for Middlesbrough County Borough.

J. C. writes: Although Dr. Newlands was of a retiring disposition, her breadth of vision and eye for detail made her an excellent organizer. Right to the end of her working life, despite the handicap of mortal illness, she showed untiring zeal and was endlessly painstaking in the performance of her duties —to an extent that compelled the admiration even of those who are tempted, in moments of weakness, to act on Talleyrand's cynical admonition in the matter. Her monument is the vastly expanded maternity and child-welfare section of the health service in Middlesbrough.

Dr. KENNETH MCALPINE died on June 11 after a brief illness. A student of Glasgow University, he graduated M.B., Ch.B. in 1917. He had a brief period of service in the R.A.M.C. before starting on his career in the school medical service at Birmingham and at Stoke-on-Trent. He went to Leicester in 1924 as assistant school medical officer, and since then as an officer of the education authority he had given loyal and devoted service until his final illness just over a month ago. He became senior school medical officer in 1946, when he had to handle the many difficult problems of the immediate post-war years.

A. J. S. writes: Dr. McAlpine was an able and efficient administrator in a highly important public capacity, dealing with the health and well-being of the child population of Leicester. To many thousands of people in the city as well as to his intimate friends he was much more than that. His nice sense of punctilio in administrative affairs could never mask the kindly, generous nature of the man himself. His professional experience among children must have been unique; his personal dealings with each one of them, young and old, was of a texture not found in books, but stemmed from his deep love of children and his own innate charm. To those of us who worked with him and under his supervision, clerical staffs, nurses, professional colleagues, Dr. McAlpine will be remembered with sincere and lasting affection. To all who sought his advice at any time, he was an immediate guide, counsellor, and friend. But beyond those there must be thousands in Leicester who, meeting him as children and now grown up, would wish to pay generous tribute to a fine doctor and a most lovable personality.

The Hungarian Government has recently decreed the terms of service of Civil Servants and doctors and others working in the health services. According to the Hungarian News and Information Service the decree lays down a working week of 48 hours—8¼ hours a day for five days, and at least four hours on Saturday. Except on Saturdays employees are entitled to a 30-minute break a day for meals, which is counted and paid for as part of the working hours. After six months' service employees are allowed six working days' holiday with pay a year. This is increased by one day's holiday for each month's work up to one year. For each succeeding year of employment the annual holiday is increased by one day to 25 working days.

Medical Notes in Parliament

MEDICAL BILL

Second Reading

The Minister of Health, Mr. ANEURIN BEVAN, moved the second reading of the Medical Bill in the House of Commons on June 27. In the House of Lords the Bill was given a second reading on April 18 (*Journal*, April 29, p. 1011), and had been subsequently amended in committee (May 13, p. 1146) and on the report stage (May 27, p. 1275).

Mr. Bevan said the Bill did not undertake a complete revision of the medical Acts—which would be a major task, involving prolonged study and possibly evoking a great deal of controversy—but only set out to provide for a number of matters of urgent public importance, and for a few less important matters in which some early change in existing arrangements was obviously desirable. From discussion with representatives of the medical profession, and from the welcome given to the Bill in the House of Lords, the Government believed it would command general support.

Of the four main purposes of the Bill, the first was to improve the standard of medical education. In this the Bill gave effect to the main recommendations requiring legislation contained in the report of the Goodenough Committee issued in 1944. It provided in Clauses 1 to 6 that from a day to be appointed every medical student after passing his final examination, but before admission to the *Medical Register*, was to be required to serve satisfactorily for a prescribed period in one or more approved hospitals and institutions. An amendment in the House of Lords made it clear that the institutions should include, subject to certain safeguards, approved health centres. The intention was that this period of "intern" service should normally be one year, but by an amendment made in the House of Lords the period was left to be fixed by the General Medical Council, subject to the approval of the Privy Council, without any specified minimum. This would facilitate any modifications which might be necessary in the event of an emergency, and there was also just the possibility that at the outset there might be difficulty in enforcing a full year's service.

It would obviously be some time before a day could be appointed for giving effect to the requirement of intern service. It was necessary, for example, to ensure that there were sufficient house appointments or other suitable posts before the requirement could be imposed, and there were also accommodation problems. Further, some period of notice would have to be given to existing students. It was possible that some parts of the British Isles might be ready for the introduction of the compulsory intern service before others, and the Bill made it possible for it to be introduced piecemeal in different parts of the country if that should ultimately be considered desirable. He mentioned that the G.M.C. still exercised some jurisdiction in relation to the Republic of Ireland, and said that complete agreement had been reached between the two countries on the arrangements outlined in the Bill.

The G.M.C. had reciprocal arrangements with other countries, and provision was made that newly qualified doctors from these countries who applied here for registration should show that they had served an intern period or otherwise acquired equally extensive experience. This provision, too, it might be necessary to apply at different times to different countries; New South Wales and the Union of South Africa were already prepared for its introduction, but other countries were not, and time for consultation and adjustment would have to be given.

There was a further provision for the visitation of medical schools. The Bill empowered the G.M.C. to appoint visitors to places where medical students were taught. This again was in accordance with the views of the Goodenough Committee. Hitherto the Council had only been able to appoint visitors and inspectors of examinations, to report on the sufficiency or otherwise of examinations, but the standard of professional practice obviously depended more on the teaching given in the medical schools than on any control that could be exercised by visiting and inspecting the examinations. The general standard in the schools would have a profound effect or whether or not the intern period would be advantageous. Accordingly, the powers of the G.M.C. were being widened to enable them to visit the actual places where the medical students were taught, and to report on the training actually given.

There was power to give directions to the G.M.C. in connexion with the arrangements for visitation, and this was to be exercised by the Privy Council. He emphasized that the Government had been careful at all times to ensure that any influence over the academic side of medicine should be exercised by authorities like the Privy Council and the General Medical Council, and not directly by the Government. Here, as in the National Health Service Act, he had been particularly scrupulous to see that there was no governmental interference with academic medicine. The G.M.C. and the university authorities should have no difficulty in making arrangements so that there should be some agreement about these inspections. This particular provision required no long advance administrative arrangements, and should come into operation almost immediately.

The second purpose of the Bill was to alter the constitution of the General Medical Council. Its numbers were to be increased from 39 to 47; the number of Crown members was to be increased from five to eight, the number elected by the medical profession from seven to eleven, and the number appointed by the universities, medical corporations, and royal colleges (27) would be increased by the addition of a representative of the Royal College of Gynaecologists and Obstetricians.

The third part of the Bill was the improvement in the disciplinary machinery and procedure of the G.M.C. It was proposed by Clause 14 to entrust decisions on professional discipline to a new medical disciplinary committee of the Council which would have 19 members, including the President of the Council, at least six elected members, and at least two laymen. It was now provided, as a result of an amendment in the House of Lords, that cases should normally be dealt with not by the full committee of 19, which was rather large, but by between five and nine of the members, including at least one layman. The President would, however, be entitled to arrange for the full committee to deal with a particular case if he thought the circumstances warranted it.

Provision was made for evidence to be taken on oath and for witnesses to be subpoenaed. There was no similar power at present, and as a result it had often been impossible to secure the attendance of necessary witnesses. This change in law was exceedingly important from the point of view of the doctors. A doctor whose name was erased from the *Register* was given a right of appeal to the Judicial Committee of the Privy Council either on law or on fact, or against sentence. These were exceedingly important improvements on the existing situation. There was also provision for rules to be made both for the procedure of the disciplinary committee—rules made by the committee and subject to the Privy Council's approval—and about the functions which the legal assessors to the Council would exercise. All these changes would come into operation on a day to be appointed; this was necessary because the rules to be made would require careful consideration and discussion with the interests involved.

The fourth provision of the Bill was to increase the fees payable for registration. The present maximum which the G.M.C. could charge was £5, originally fixed in 1858. The functions of the G.M.C., carried on without imposing any charge on public funds, had obviously much increased, and the income from registration—the main source—and other sources had become quite insufficient to enable the Council to pay its way. The Bill provided for a maximum fee of 11 guineas for full registration, including five guineas for provisional registration when that was operative. There was power from the Privy Council to vary the maxima by order. The provision for increased fees would take effect on the passing of the Act.

G.M.C. and B.M.A.

Mr. WALTER ELLIOT said the proposed alterations in medical education were more important than all the other purposes of the Bill, because they would affect every graduate. The second, third, and fourth purposes—the machinery purposes—were unexceptionable. He hoped that consideration of the Bill would help to dispel the popular superstition that the General Medical Council was in some way or other the same thing as the British Medical Association, and that tremendous disciplinary powers were given to what was after all a trade union. The G.M.C. was in no way a trade union, as could be seen from the large number of persons appointed to it from outside.

They would all welcome the increase in the disciplinary powers of the G.M.C., because miscarriages of justice had taken place in the past owing to the lack of those powers. They were all glad, too, that a right of appeal had been given, although he thought the question would have to be examined further in committee whether the appeal direct to the Judicial Committee of the Privy Council in preference to the High Court was the right solution. He did not think that the danger which the Minister had mentioned, of different standards arising if appeals were made to the separate High Courts in the United Kingdom, was very great.

In the improvement of medical education the important step had been taken of recommending that an additional year should take its place in the medical curriculum. The danger was that the curriculum might be unduly prolonged, that the final period might be projected further and further away until it came to a time in a man's life when he could no longer take full advantage of it. The curriculum was already overloaded. The masses of information which the medical student had to acquire, and which were appropriate in other days, were not appropriate to-day. Medical education should constantly be remodelled to suit the necessities of the time, to avoid subjects piling up on each other instead of substitutions taking place.

He yielded to no one in his admiration of the training which the great hospitals gave to the young graduates, but responsibility was never felt when all the resources of a great hospital were around one as it was when starting to grapple with the multifarious emergencies of private practice with one's own hands and knowledge. It was said that a new set of posts would have to be created to give greater responsibility to the housemen. These posts would be difficult to get, and appropriate responsibility would be difficult to devolve upon them. This extra year would need to be looked at with very great care, to make sure that a sense of responsibility was really developed and that it was not merely used as a further occasion for learning. The Opposition welcomed the Bill and would do their best to give it an easy passage.

L.S.A. and T.U.C.

Dr. H. B. MORGAN strongly opposed the Bill. The first of the three chief functions of the G.M.C., he said, was the supervision of the *British Pharmacopoeia*. That was the one function which had been done very well. The second function was medical education—and that was very bad. There should be a one-portal system of entering the profession, on one fixed standard, so that everybody who came into the profession should pass a qualifying examination and be recognized throughout the world as being of a certain standard. Instead of that there were different standards. Too high a tribute could not be paid to the great university schools, but there were also undemocratic bodies of no great concern to the public but only to themselves. He mentioned the London Society of Apothecaries, and in reply to a question by Surgeon Lieutenant Commander R. F. B. BENNETT said that the standard of medical education and of the knowledge asked for was too low for qualification. There should be one governing professional qualifying examination, with an examiner—not examiners from the schools—to see that every man had a fair deal. Many organizations like the Colleges took no responsibility for training but were purely examining bodies, sometimes claiming revenue from those they deliberately flouted.

The Trades Union Congress wanted the subject of industrial diseases taught in the medical schools. It had asked the G.M.C. to include this subject of the relationship between occupation and health in the ordinary curriculum. The medical schools had done nothing. Only in Glasgow, Manchester, Durham, and Newcastle-upon-Tyne was there an organized course of lectures. One specialist in London, Dr. Donald Hunter, was doing

excellent work in the London Hospital, but the other schools did not bother about it at all.

Working-class parents had to make a great sacrifice for six years to get their son through the medical school. Now it was proposed to add another year. There were not sufficient institutions to keep all the doctors that would come out. Suppose a man did not want to go into general or even consulting practice but wanted to be a specialist or to go in for medical literature, to become, perhaps, Editor of the *British Medical Journal*. Suppose he wanted to go into medical research, or tropical medicine. Must he waste another year on a subject in which he was not interested?

This Bill was a rotten Bill. It was a Conservative Bill. Extended registration would hurt the working-boy. The composition of the G.M.C. should be such that it should include no nominee, or very few in comparison with the elected members. It should be a purely professional body. He was ashamed to say that the Government had not yet approached the T.U.C. for its views on a matter of such importance to industrial workers—medical education and conditions. The Bill should be taken back and reconsidered.

A Minimum Standard

Dr. CHARLES HILL said that in his argument for the common portal of entry Dr. Morgan had ignored the fact that the role of the G.M.C. was to secure a minimum standard and leave the licensing bodies to apply a standard in excess of that if they chose. On the question of industrial medicine in the curriculum, Dr. Morgan should apply himself to that part of the Bill which strengthened the power of the General Medical Council in visiting medical schools, and so enabling the G.M.C. to exercise a stronger influence over those schools. On the third point, he hoped it was not right to assume that, as a result of this new and important arrangement under which there was first qualification and then registration, this was merely a year added to the curriculum. If that assumption was right the full purpose of this Bill in relation to medical education would not be served. He welcomed as a most important change this arrangement under which, towards the end of a student's career, when examinations were out of the way, a man or woman was enabled to assume a post of some responsibility under supervision.

He hoped the Bill would lead to a re-examination of medical education, and to the elimination of some unnecessary parts. He hoped too that the new posts to be created for internship would be designed for the purpose, and in relation to the function they had to fulfil in medical education, and not be house appointments as they now knew them multiplied for the purposes of the additional year. They would get the full fruits of this important new development only if that year was related to a revised medical curriculum, and if special posts with the right kind of responsibility were created for the purpose.

In regard to the disciplinary provisions of the Bill, he was glad that discipline was going to be a matter not for the Council as a whole but for a committee specially established for the purpose; that would lead the Council to think more and more about medical education, and save them having so much of their time taken up with disciplinary work. He did not like the arrangement whereby any person involved in the original sorting out and assessment of cases might also be a member of the disciplinary committee.

The answer to Dr. Morgan's point about the use of the extra year to a man who was going to be a medical journalist, or an expert on tropical diseases, was that the man might subsequently decide to enter practice, and if he had not done this extra year, which was a part of the curriculum, not something grafted on to it, there would be two standards in operation. He welcomed the Bill as making a substantial qualitative contribution to medical education.

Mrs. JEAN MANN suggested that the Bill should be amended to let the year of provisional registration be served not only in hospital but under an experienced general practitioner. Otherwise the extra period as a houseman in her view would be just a waste of time and of no help to the general practitioners who were now overworked.

Mr. RICHARD FORT asked what were the chances of there being room in the hospitals for all the house appointments envisaged first by the Goodenough Report and now by the Bill. Would it be possible to administer the extra year's planning so that the interns would be able to have the 20 or 30 beds in conformity with the Goodenough recommendations? There was also the question of free board and lodging for the interns. Would provision be made for that, and if so what sums of money were likely to be involved? Could anything be said now about the rates of remuneration? They should know whether they were talking about an improvement in medical education which would take place within the next two years or so, or whether they were looking forward to something which would only take place within the next decade.

Revision of the Curriculum

Dr. A. D. D. BROUGHTON welcomed the Bill as seeking to raise the standards of medical efficiency and conduct. That part of it which related to the G.M.C. and its disciplinary committee he saw as designed to maintain a high standard of ethics. On that part which affected medical education, he pointed out that now that all intern postgraduate appointments carried remuneration the financial obstacle had been removed from the path leading to greater proficiency, and a period of service for every doctor would raise the standard of subsequent professional work. The argument that it was sought to add another year to the course of medical training was only correct in so far as it affected a minority of students. The majority of newly qualified men and women, in their desire to gain useful experience, already undertook postgraduate duties in hospitals.

Supporting the contention that there was a need for close examination of the medical curriculum, he said he wished that the Government had gone further in the Bill, because the system of medical education required review, revision, and reform. In this connexion he hoped that it could be revised soon in such a manner as to allow the schoolboy to learn more about the arts, and possibly the classics, before going to a university to embark on years of intensive scientific study. That would provide the doctor with wider knowledge, and make him still more capable of carrying the heavy burden of responsibility when he entered practice.

Surgeon Lieutenant-Commander R. F. B. BENNETT agreed that a good deal of lopping in the curriculum was possible, and mentioned in particular the extremely minute knowledge of anatomy and his studies of botany and zoology. He asked if the inspection of medical schools by the G.M.C. would mean that those schools within a university which could already be inspected by their own university and the University Grants Committee were to be liable to three forms of inspection.

He referred, on the proposed disciplinary provisions, to the selection of the crime of adultery as the one type of civil case in which the G.M.C. disciplinary committee should not have the power to call further evidence before pronouncing judgment on an erring doctor. He understood that criminal charges could be regarded as proved on conviction, and action taken accordingly by the disciplinary committee. But adultery was a civil offence. Why, when that was found proved, should that alone be selected as the one civil offence on which no further evidence could be offered to the G.M.C. before a decision was reached? Finally he referred to the increased registration fee, remarking that it was a little hard on the student of all people to have to pay more, and asking if the fee could not be eased.

Practical Training

Mr. SOMERVILLE HASTINGS said that although the Bill did not go as far as he would have liked, he welcomed it because it made the education of British doctors, already the most practical in the world, even more practical. The trouble to-day was that there was too sharp a division between the time when as a medical student the young doctor had few responsibilities and never had to make decisions, and the time when he suddenly became qualified and found that the life or death of his patients depended on his diagnosis and treatment. The Bill was good in that its proposals would make this transition more gradual, but careful thought would be needed on how the principles of the Bill were to be carried out. He could not see that there were enough suitable appointments for interns to go round. There would be difficulties in deciding whether a young doctor's work was "satisfactory," and there was also the case of the physically handicapped person. A man who had lost all or part of his hand could not be an efficient house-surgeon, or take an appointment as an obstetrician, yet the Bill said that he had to serve part of his time in one of these capacities.

They were told that service in a health centre would do as well as service in a hospital, and he was glad of it, but at present the health centres did not exist. Moreover, while he agreed that to help an efficient doctor in a health centre would be most valuable training for a general practitioner, he thought that service in a special department in a health centre should only count as training for a specialist.

He was disappointed about the constitution of the G.M.C., in that only 11 of its 47 members were to be elected by the profession. The General Nursing Council had 34 members, of whom 17 were elected by the profession. On disciplinary procedure, he would like to see some less penalty than that of being struck off the *Register*. According to the Bill a doctor struck off could not apply for replacement for eleven months, and in that time any doctor's practice would have gone to pieces.

Dr. BARNET STROSS, questioning the denigration of the Bill by Dr. Morgan because it did not contain power to compel every medical school to set up a chair in industrial medicine, said every school would readily and gladly do so—and set up a chair in social medicine too—if they had the money available.

There were some questions to be answered when the Bill was in committee. For example, what was meant by the word "satisfactory" as used in connexion with the year's extra work? Further, if a person was crippled during training, or fell ill—possibly with infantile paralysis—was he to be denied the opportunity of further work or of service with approved institutions? How long would they have to wait, and if there were no immediate opportunities for entry, how long would it be before they could register?

On the penal side there were also certain changes which it was hoped to bring about in committee. They must separate the judicial from the executive functions of the Council, and be certain that no one who had been concerned with a preliminary investigation should sit later on the disciplinary committee itself. He hoped to see also that no action in future was taken against a medical man unless a formal and written complaint was sent in and could be supported by whoever had made it.

Undue Specialization

Mr. H. H. LINSTEAD said he thought someone might have seized the opportunity to pay a tribute to the G.M.C. for the work they had done in the educational and disciplinary fields over a long period of years, and in conditions of some difficulty. He had attended sessions of the G.M.C., sitting in its disciplinary capacity, and he had been amazed at the way in which an extremely clumsy machine managed to function with what certainly appeared to an onlooker to be efficiency and justice. It was not the quality of the Council which was at fault, but the difficulty of appeal which tended perhaps to give it a bad name.

Overloading and undue specialization was something from which every profession suffered. There was no simple answer. They could not cut out of the curriculum of a scientific profession any substantial amount of its basic science. As science advanced the medical practitioner must keep pace with it. If there was to be found any answer it must be partly, he thought, in the direction of the qualified practitioner relying upon specialists in other branches in professions allied to medicine for a great deal of the technical work which at present he did himself. The radiographer and the physiotherapist, for example, must have responsibility on their shoulders. Moreover, in the teaching of sciences more attention must be paid to making them part of a liberal education.

Some consideration would have to be given to the conditions in which health centres were to be approved for the year's training. Only one of the dozen centres in existence was fit for the training of general practitioners. The disciplinary machine must be examined more closely. No member of the G.M.C. should at the same time be a member of the penal cases and disciplinary committees. The penal cases committee must not assume to itself part of the function of the disciplinary committee. If the finding of the High Court in the one case involving adultery in a matrimonial cause was to be accepted as binding on the Council, they must examine carefully why a similar state of affairs was not to apply to other cases.

He welcomed the introduction for the first time in this type of legislation of the Judicial Committee of the Privy Council. Most professions valued their association with the Privy Council, and if they could gradually substitute the Judicial Committee for the High Court as the court of appeal for professional tribunals they might find that they had introduced a useful innovation in the legal system. Finally he pointed out supervision of the *British Pharmacopoeia* was one of its functions which the G.M.C. did not carry out. With the passage of years they had ceased to be the appropriate body for this work, and had handed the duty over to the Pharmacopoeia Commission, composed of one or two doctors but mainly of chemists and pharmacists.

Government Reply

Miss MARGARET HERBISON, Joint Under-Secretary of State for Scotland, replying to the debate, said there had been much criticism of the overloading of the curriculum in the medical schools and she felt that the debate, in which so many had spoken from full knowledge of the subject, might bear some fruit. She hoped there would be an examination of the curriculum.

She agreed that the teaching of industrial medicine was of the greatest importance. The Trades Union Congress considered that insufficient time was given to it, but Dr. Morgan was less than fair when he suggested that in our medical schools and universities almost nothing was being done in that field of medicine. In the Glasgow, Manchester, and Newcastle universities the courses in industrial medicine had been financed by the Nuffield Foundation. There were one or more lecturers in the subject in Birmingham, Bristol, Edinburgh, London, and Sheffield. The Government was satisfied that the correct way of getting this or any other subject into the curriculum was not by vesting power of direction in the General Medical Council. That would be found objectionable not only by the medical profession but also by the public.

To deal with the duplication of examinations the Government hoped to arrange that there would, in effect, be only one set of examiners. One great improvement in the Bill lay in providing that visitors not merely examined an examination but really examined what was being taught in the medical schools. In that way they hoped that the General Medical Council would be able by persuasion, not by force, to make those changes in the curriculum which public opinion seemed to think necessary.

When a doctor was provisionally on the *Register* he would be able to sign a death certificate. It had been asked why there had been selected in the Bill one case where the disciplinary committee could not re-examine evidence. It would create great difficulties if this were not so. On the other hand, it might be that after examination the Government might decide that other cases ought to be put in the same category. This one was chosen because it was the one that in the past had often come before the General Medical Council.

The suggestion that this intern period might be spent in general practice as a trainee assistant was completely contrary to the findings of the Goodenough Report. It would be contrary also to the views expressed by the General Medical Council. The Government felt that the best experience could be got in hospitals and similar institutions, and if they were to yield to this new suggestion there would be great difficulty in supervising the course properly. It would be better to wait, and find out how the provisions of the Bill worked before making any extension for experience in general practice.

Some fear had been expressed that those who served on the penal services committee would be serving also on the disciplinary committee. What had been found out in other fields did not bear out the contention that this would be wrong. There was nothing in other fields to justify the contention that a man's judgment would be prejudiced if he tried in the first instance

to find whether there was a prima facie case for inquiry. This was the procedure in the case of solicitors, and there was another instance among the justices of the peace in England, who, after they had committed a man for trial at quarter sessions, could, and often did, sit at the quarter sessions. It could not be contended that they had been prejudiced, but it was a point worth discussion in committee.

Although there had been questions about the supply of posts for intern training, the Government intended to leave the period of twelve months in the Bill, but they could not say at this stage how soon they could make it work. In Scotland there might be more difficulty than in England and Wales, for one-third of the doctors produced in the whole of Britain were trained there. They had come to the conclusion that it would not be possible to provide a great number of places in Scotland, and that perhaps England would provide the beds for these other doctors who were trained in Scotland. A doctor qualifying in Ireland who wanted to get on to the *Register* must from the appointed day do intern service there in the same way as doctors qualifying here.

The motion for the second reading was agreed to.

Cost of Drugs in N.H.S.

Colonel ROPNER asked the Minister of Health on June 29 why, without effective consultation with their Central Committee or awaiting the findings of the Whitley Committee which was inquiring into the matter, he had imposed on chemist contractors under the National Health Scheme a cut from 33% to 16% in the on-cost allowance on drugs supplied by them on prescription.

Mr. BEVAN in reply said that he was determined that all unnecessary expenditure on the National Health Service should be eliminated, and after consultation with the chemists' representatives in accordance with the regulations he was satisfied that there were grounds for an immediate provisional reduction in this allowance. Negotiations were proceeding, however, and he had undertaken to accept whatever final percentage might be agreed by the Whitley Council or awarded by an arbitrator.

Mr. E. L. MALLALIEU asked the Minister of Health whether, having regard to the fact that many doctors prescribed expensive proprietary preparations for which cheaper non-proprietary preparations of equal therapeutic value might be substituted, he would consult the British Medical Association as to the best way of bringing the matter to the notice of both doctors and chemists, with a view to saving expenditure without in any way impairing the service to the patient.

Mr. BEVAN said he had been in consultation with the British Medical Association about the action to be taken on the Report of the Joint Committee of the Central and Scottish Health Services Councils, which had been considering prescribing under the National Health Service. The report was to be published, and would be available on July 1. Copies were being sent to all doctors, both general practitioners and hospital medical staffs, taking part in the National Health Service, with a covering letter asking for their help in avoiding unnecessarily expensive prescribing. The question of other action on the report was under consideration.

The report to which Mr. Bevan referred is summarized at page 24 of this week's *Supplement*.

Midwives' Uniform

The terms of the Midwives (Amendment) Bill in relation to the wearing of the proposed national uniform for midwives were finally determined when the Bill was considered on Report in the House of Commons on June 28.

Clause 6, which authorizes the rules to be made on this matter, was amended in the following terms:

"(3) Any agreement made (whether before or after the passing of this Act) between a local health authority or other body or association and a midwife employed by them for the purpose of attending on women in their homes as a midwife or maternity nurse shall be void in so far as it precludes the midwife from wearing a uniform prescribed by virtue of subsection (1) of this section."

Mr. A. BLENKINSOP, Parliamentary Secretary to the Ministry of Health, moving this amendment, recalled that in the earlier debates, although the Government felt that the balance of advantage might be in allowing the local authority to decide the matter for themselves, in view of the strong feelings fairly generally expressed that there should clearly be full opportunity for the midwives to wear the new national uniform that was being approved, he promised to put down an amendment to clarify the intention of that made in the House of Lords. The amendment he now moved made it clear that the midwife would have the full right to wear the new national uniform if she so desired, even though there might be an agreement with the local authority about some locally designed uniform. This arrangement was limited to domiciliary midwives. There had been some criticism of this amendment from the local authorities. If in some localities there was in use a local distinctive uniform, he was sure that the midwives in the area would be content and happy to continue to wear it, but should a midwife desire to wear the new nationally designed uniform she would now have full power to do so.

Dr. A. D. D. BROUGHTON supported the amendment on the ground that there should be a national uniform for midwives, and that they should have the right to wear it if they so desired. Dr. BARNET STROSS put some questions at the request of his local authority. Would the amendment confer on midwives the right to wear the prescribed uniform irrespective of the wishes of the local authority; would it mean that this was a departure from the principle that all matters concerning conditions of service should pass through the appropriate Whitley Council, as in the past; and would not a new anomaly be created with respect to other members of local authority staffs, such as the domiciliary nursing service, which would be wearing a uniform prescribed by the local health authority whereas there would be a uniform for midwives prescribed by the national authority?

Miss HORSBRUGH said the choice was now left to the midwife as to the uniform she would wear, and she welcomed the amendment. Mr. W. Ross suggested that they were falling into error through this modern curse of uniformity in pressing for a national uniform instead of taking into account regional considerations.

Mr. BLENKINSOP said they were allowing a wide freedom, and in a case like that of Glasgow, where a uniform was universally respected and was specifically worn, midwives would naturally desire to continue to wear it. He was sure that local authorities on consideration would be able to secure a satisfactory working of this arrangement, and that where there was a satisfactory local uniform in use already the midwife would desire to continue to wear it.

The amendment was agreed to, and the Bill was afterwards read a third time.

Medico-Legal

CLAIM AGAINST DOCTORS FAILS

[FROM OUR MEDICO-LEGAL CORRESPONDENT]

A man of 59 with a long history of mental ill-health sustained a fracture of the neck of the left femur while undergoing electric convulsion therapy at Barnsley Hall Mental Hospital, Gloucester, on May 20, 1947. He made no complaint at the time. Next day his wife telephoned to the hospital, and the resident surgeon advised her to call in the family doctor. She accordingly sent for Dr. George F. Henderson, of Headless Cross, near Redditch, who did not find the fracture. On June 10 the patient, William Dawe, returned to the hospital, and Dr. Andrew Shepherd, the medical superintendent, and Dr. John P. McGuinness, the resident surgeon, pressed him to become an in-patient and have a full examination, but he refused. He was then limping and using a stick, but was not assisted. On June 19 he became an in-patient, and on examination the fracture was discovered. He subsequently sued the three doctors, and Dr. Elizabeth Eleanor Henderson, the wife of Dr. George Henderson, for damages for alleged negligence, stating that as a result of the failure of the mental hospital doctors to diagnose the fracture until June 19, and

of the two Drs. Henderson to diagnose it at all, his left leg had been shortened by 1½ inches (3.75 cm.) and had suffered limitation of movement.

At the trial before Mr. Justice Hallett at Worcestershire Assizes at the end of January,[1] the patient's wife gave evidence that she was now living apart from him and that for many years before 1947 he had been full of complaints and had made many absolutely unfounded accusations against her. When Dr. George Henderson had seen him on May 21 the doctor had said that the matter would be better in the hands of the people at Barnsley Hall, but the patient had flatly refused to go there. Dr. George Henderson said in evidence that when he saw the patient on May 21 he was walking in a downstairs room but complained of pain in his left leg. The doctor had regarded his complaints as unreliable: he had been complaining for seven years and in addition was in a confused and hysterical condition. He had examined him honestly and carefully and had noticed that there was a limitation of movement of the leg, but no obvious shortening or abnormal position. Dr. Shepherd testified that an impacted fracture might be missed by a general practitioner after such a treatment. Dr. McGuinness did not agree that he could have discovered the fracture on June 10. An examination had not been possible then because Dawe had refused to become an in-patient.

Judgment

The learned judge stressed that the evidence of the patient was quite unreliable. Electric convulsion therapy was beneficial in certain mental disorders, but involved a degree of risk. The patient had been free to refuse to re-enter hospital, and after this advice of the doctors had been refused it seemed a very strong proposition to suggest that they were guilty of negligence because they did not then suggest a second, third, and fourth best course in the hope that the patient would accept one of them. He gave judgment for the doctors with costs.

[1] *Birmingham Post*. January 27 and 28, 1950.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

The following candidates have been approved at the examination indicated:

FINAL M.B.—*Part I (Surgery, Midwifery, and Gynaecology)*: T. D. Anderson, W. D. Anderson, V. Armett, A. M. Baker, J. A. C. Bamford, A. P. Barclay, J. H. F. Batstone, J. F. Bennett, J. W. Bradbeer, E. J. F. Brewer, G. S. Brindley, J. M. Brown, P. B. Brown, M. J. Clarke-Williams, R. A. Cooper, J. C. M. Currie, N. L. Dallas, J. M. H. Dickson, J. W. Draper, H. B. Eckstein, M. L. E. Espir, R. M. F. Fox, M. Gibbs, J. N. Gibson, P. H. Gorodi, I. M. Guiver, A. T. G. Gunn, U. M. P. Hill, R. P. Holmes, M. L. House, P. E. Huddy, H. F. Juckes, Mrs. M. E. Kendrew, C. D. Lacey, K. UNIVERSITY OF ST. ANDREWS

The following degrees have been conferred:

M.D.—C. R. Baxter, J. M. Gilmpre, K. G. Lowe (with honours and a Rutherford gold medal), E. J. Michie, Marjorie S. Milln, D. S. Macphail, J. H. Prain (with commendation and a Rutherford silver medal), *D. H. Smith.

CH.M.—A. A. Douglas (with honours).

The following candidates have been approved at the examination indicated:

FINAL M.B., CH.B.—Mary R. Kerr (with distinction), *J. N. Gale, *Ruth Y. Golder, *Marjorie M. Kinnear, *Marion C. Miller, D. Allan, G. C. Azie, J. Bartholomew, F. Bell, Veronica M. Bowman, Edith M. B. Bryant, Marjorie F. Carnan, J. D. Carr, Helen M. Crockatt, A. A. Duncan, E. E. Ecoma, Antonia Firnberg, H. Fyfe, Jean O. Gerrard, D. B. Gibb, Anne L. M. Graham, A. B. Grant, P. H. Harley, R. G. Hendry, B. O. Igwebe, Elinor K. Johnston, M. Kirstein, Elizabeth F. Laird, A. J. Lawson, Irene Leeser, R. L. MacDonald, J. D. Macgregor, A. R. Mackenzie, J. M. McKenzie, Muriel J. Martin, I. M. Mennie, Margaret G. Millar, H. R. Milne, I. G. Murray, P. W. O'Brien, W. L. Ogilvy, D. B. L. Rankine, H. C. Renney, Marie Renwick, Madeline M. Russell, J. H. F. Silver, T. Sonnenschein, D. C. C. Stark, J. K. Steel, S. A. Stephen, B. R. D. Suttie, Pauline F. Taylor, M. G. Wagg, Jane M. Wallace.

*With commendation.

UNIVERSITY OF EDINBURGH

The following Macarthur Postgraduate Lectures will be given at the Anatomy Lecture Theatre, University New Buildings, Edinburgh: Thursday, July 13, 5 p.m., "Experimental Studies on the Eye Based upon the Regeneration of the Neural Retina and the Lens" (to be illustrated by coloured films), by Professor L. S. Stone, M.D., Bronson Professor of Comparative Anatomy, Yale University School of Medicine; Tuesday, July 18, 5 p.m., "Benjamin Rush, M.D.: His Edinburgh Student Days and What Came of Them," by Dr. George W. Corner, Director of the Department of Embryology, Carnegie Institution of Washington, Baltimore, U.S.A. Senior students and graduates in medicine are invited to attend the lectures.

UNIVERSITY OF WALES

The Council of the Welsh National School of Medicine has appointed Harold Scarborough, Ph.D., M.B., Ch.B., F.R.C.P.Ed., Professor of Medicine and Director of the Medical Unit at the School. Dr. Scarborough is at present Reader in Medicine in the University of Birmingham.

The following candidates for the degrees of M.B., B.Ch. at the Welsh National School of Medicine have satisfied the examiners at the examination indicated:

PATHOLOGY AND BACTERIOLOGY.—A. S. Baier, Joyce M. Bennett, Vyvien J. Bennett, J. W. Bough, D. R. Boyns, P. Callaghan, J. S. Campbell, G. W. Clark, R. L. Corpock, Bronwen N. Davies, D. B. S. Davies, Barbara C. Edwards, J. C. Evans, Marjorie J. S. Evans, J. N. Glanville, A. M. S. Hansrod, P. I. Harry, W. E. J. Horton, A. P. Jones, D. J. Jones, Nesta Lewis, Rachel B. J. Lewis, Mary I. Lloyd, J. E. Merrell, Janet M. Moffat, I. B. Morgan, J. H. Naysmith, E. J. Phillips (with distinction), R. P. Phillips, D. H. Richards, Joyce M. Smith, Glenna Thomas, G. Williams, W. Williams.

OBSTETRICS AND GYNAECOLOGY.—Ilid M. L. Davies, Dilwyn T. Jones, T. M. Morgan, S. J. S. Polwin, J. W. Rees, Esther H. Thomas.

UNIVERSITY OF BIRMINGHAM

On July 1 the honorary degree of D.Sc. was conferred on Dr. Herbert M. Evans, director of the Institute of Experimental Biology, University of California, and on Dr. Leonard Colebrook, F.R.S., director of the Burns Unit at the Birmingham Accident Hospital from 1944 to 1948. The honorary degree of D.Litt. was conferred on Mr. Stanley Morison, typographical adviser to the Cambridge University Press.

UNIVERSITY OF LEEDS

W. J. O'Connor, M.D., has been appointed Senior Lecturer in Physiology, and T. K. Marshall, M.B., Ch.B., Lecturer in Forensic Medicine.

No. 24

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended June 17.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1950 (a)	(b)	(c)	(d)	(e)	1949 (Corresponding Week) (a)	(b)	(c)	(d)	(e)

Stillbirths	187	22	28			192	36	26		
Rate per 1,000 total births (including stillborn)			28					26		

* Measles is not notifiable in Scotland, and the returns are therefore an approximation only.

† Deaths from measles and scarlet fever for England and Wales, London (administrative county), will no longer be published.

‡ Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales, London (administrative county), are combined.

‖ Includes puerperal fever for England and Wales and Eire.

¶ Primary pneumonia no longer notifiable in Eire.

EPIDEMIOLOGICAL NOTES

Smallpox on s.s. Strathnaver

A Goanese seaman was landed from s.s. *Strathnaver* at Aden on June 19 believed to be suffering from chicken-pox. The diagnosis was later confirmed as modified smallpox. Passengers and crew were vaccinated during the voyage. The vessel arrived in the port of London on the morning of July 2. There was no case of sickness on board on arrival. Some 1,200 passengers and crew disembarked and were placed under surveillance until July 5 in the areas to which they travelled.

Practitioners are advised by the Ministry of Health to consider a diagnosis of smallpox if a person who travelled on this vessel falls sick. Revaccination may cause extreme modification of the clinical illness and of the exanthem.

Poliomyelitis

Notifications during the week ended June 24 were: paralytic cases 104 (77), non-paralytic cases 38 (16). Figures for the previous week are shown in parentheses. Although this is a substantial increase, the high prevalence still seems to be chiefly confined to a relatively limited area of the Midlands. There were 45 notifications in Warwickshire (41 in Birmingham C.B.), 9 in Staffordshire, and 14 in Worcestershire. Thus the epidemiological picture differs from that in the corresponding weeks of 1947 and 1949.

Discussion of Table

In *England and Wales* there were decreases in the notifications of measles 1,855, acute pneumonia 49, and diphtheria 22. There were rises in the incidence of whooping-cough 212 and poliomyelitis 14.

The largest falls in the incidence of measles were Warwickshire 214, Durham 147, Middlesex 147, Kent 145, Cheshire 138, Lincolnshire 113, Northumberland 104, and Shropshire 95. The largest exceptions to the general decline were rises in Gloucestershire 69 and Hertfordshire 62.

The local trends of scarlet fever remained almost unaltered. The largest rises in the notifications of whooping-cough were Gloucestershire 57, Lancashire 41, and Essex 39; the largest falls were Yorkshire West Riding 44 and Durham 30. The fall in the incidence of diphtheria was mainly due to two counties, Durham and Kent, with 10 and 8 fewer cases, respectively, than in the preceding week.

The incidence of dysentery was maintained at a high level. The chief centres of infection were: Lancashire 119 (Oldham C.B. 33, Chadderton U.D. 17, Preston C.B. 16, Crompton U.D. 14, Manchester C.B. 8, Burnley C.B. 8, Liverpool C.B. 7, Lees U.D. 7); Yorkshire West Riding 81 (Sheffield C.B. 24, Spenborough U.D. 21, Leeds C.B. 8, Bradford C.B. 8); Durham 43 (Stanley U.D. 19, South Shields C.B. 8, Gateshead C.B. 6); London 17 (Southwark 6); Staffordshire 15 (Walsall C.B. 12); Northumberland 15 (Newcastle-upon-Tyne C.B. 14); and Yorkshire East Riding 14 (Kingston-upon-Hull C.B. 14).

Notifications of acute poliomyelitis in Birmingham C.B. rose from 20 to 28; the other large centres of infection were Lancashire, Liverpool C.B. 4; Staffordshire, Rugely U.D. 4; and London, Stepney 3, Woolwich 3.

In *Scotland* there were decreases in the notifications of measles 125, acute primary pneumonia 32, and scarlet fever 20. There were rises in the incidence of whooping-cough 22, acute poliomyelitis 9, and dysentery 9. The largest returns for dysentery were Glasgow 78, Midlothian county 23, and Edinburgh 13. Areas with more than one notification of acute poliomyelitis were Glasgow 8, Renfrew county 3, and Fife county 2. All the cases of diphtheria were notified in the western area.

In *Eire* decreases were recorded in the notifications of whooping-cough 62 and measles 25. The decline in the incidence of whooping-cough was general throughout the country. In Dublin C.B. notifications of measles increased by 22 in contrast to the general fall.

In *Northern Ireland* the trends of infectious diseases showed only slight variations from those of the preceding week.

Week Ending June 24

Notifications of infectious diseases in England and Wales during the week included: scarlet fever 973, whooping-cough 3,746, diphtheria 39, acute pneumonia 344, measles 9,086, acute poliomyelitis 142, dysentery 213, paratyphoid fever 9, typhoid fever 13.

Quarterly Returns for Northern Ireland

The quarterly report for the third quarter of 1949 shows that the birth rate was 21.2 per 1,000. The infant mortality was 43 per 1,000 registered births, and was 2 more than in the preceding third quarter. The general death rate was 9.5 per 1,000 and was 0.5 below the average of the five preceding third quarters. Of the 84 deaths from the principal epidemic diseases, 58 were attributed to diarrhoea and enteritis and 14 to whooping-cough.

Medical News

Honorary Physicians to the King

The following have been appointed Honorary Physicians to the King for a period of three years as from July 1: Dr. Samuel Barron, M.R.C.P.I., Medical Officer of Health, City of Belfast; Dr. Walter Eric Chiesman, F.R.C.P., Medical Adviser to H.M. Treasury; Dr. Sydney Walter Fisher, Principal Medical Inspector, Mines Department, Ministry of Fuel and Power; Dr. Arthur Massey, C.B.E., Chief Medical Officer, Ministry of National Insurance; Dr. Robert Hughes Parry, F.R.C.P., Medical Officer of Health, City of Bristol, and Professor of Preventive Medicine, University of Bristol; and Dr. Harry James Rae, *M.C.*, Medical Officer of Health, City of Aberdeen and Counties of Aberdeen and Kincardine. The following have now completed their term of office as Honorary Physicians to the King: Dr. James Boyd, F.R.C.P.I., Sir William Allen Daley, M.D., F.R.C.P., Dr. A. M. Fraser, Sir Walter Haward, O.B.E., M.B., B.S., Sir William Wilson Jameson, G.B.E., K.C.B., M.D., F.R.C.P., F.R.C.O.G., and Dr. Norman Tattersall.

Relief of Widows and Orphans

The annual general meeting of the Society for Relief of Widows and Orphans of Medical Men was held on June 7, with Mr. Hope-Gunning, vice-president, in the chair. Seven members were elected to the court of directors, and Mr. G. T. Mullally was elected a vice-president. The report and financial statement for 1949 were adopted. At the end of the year the membership of the society was 244. During the year 43 widows were in receipt of grants, and the total sum distributed was £4,311 10s. The by-law relating to the income limit of widows enabling them to receive grants has been raised from £125 to £150 per annum. The meeting concluded with votes of thanks to the chairman and to the president of the society, Sir Robert Young, for his services during the past year. Further details about membership of the society may be obtained on application to the Secretary, 11, Chandos Street, London, W.1.

Immunization Stopped in Birmingham

Owing to the rising incidence of poliomyelitis in Birmingham, schemes for immunization against diphtheria have been temporarily stopped there on the advice of the Ministry of Health. The relation between recent inoculation and paralytic poliomyelitis was discussed in a leading article in this *Journal* on July 1 (p. 28).

The Royal Society of Medicine

At the annual meeting of Fellows of the Royal Society of Medicine on Tuesday, the gold medal of the society was presented to Professor E. D. Adrian, O.M., M.D., F.R.S. Sir Henry Dale, in making the presentation, said the medal was awarded triennially, and this was the eleventh occasion on which it had been presented. He spoke of the outstanding contribution which Professor Adrian's researches had made to medicine. The diploma of Honorary Fellowship was presented to Professor Alfred Gigon, M.D. (Basle). There were four other recipients of the diploma who were prevented for various reasons from attending. These were Professor Gosta Forssell, M.D. (Stockholm), Professor Alberto Houssay, M.D. (Buenos Aires), Professor Abdul Mooro Pasha (Cairo), and Professor Wilder Penfield, C.M.G., M.D., F.R.S. (McGill University, Montreal). The scrolls, said Sir Henry Dale, would be transmitted to them, except in the case of Professor Mooro, who was expected to be in England shortly, when an occasion would be taken to present it to him in person. The report of the council of the society, which was presented at the meeting, stated that there were now on the roll of membership 9,714 names (9,203 of them being Fellows), an increase of 325 on the year. Lord Webb-Johnson was unanimously elected to the presidency of the society.

Medical Insurance Agency

The annual meeting of the Medical Insurance Agency was held on June 23 at B.M.A. House. The report of the committee of management for 1949 disclosed a record amount of service to the profession, a record total of rebates of premium granted to clients, and a record profit available for medical charities. New covenants were entered upon with the Royal Medical Benevolent Fund, the Royal Medical Foundation of Epsom College, and the Benevolent Fund of the British Dental Association. Re-elected to the committee were Dr. Charles Hill, Dame Barrie Lambert, Professor J. W. McNee, Dr. Henry Robinson, Sir Arnold Stott, and Dr. E. R. C. Walker; Mr. R. L. Newell was also elected. Dr. James Fenton was re-elected chairman and Dr. Henry Robinson honorary secretary. The total of life insurance negotiated by the agency and completed with various companies was about £2,976,000; it was reported that in 1950 this figure might be exceeded. The chairman paid tribute to the work of the general manager, Mr. A. N. Dixon, and his staff, and to the honorary secretary. The establishment of branches at Cardiff and Birmingham is being considered, in addition to those already existing at Edinburgh, Leeds, Manchester, and Dublin.

Wills

Professor Thomas Porter McMurray, C.B.E., Emeritus Professor of Orthopaedic Surgery, Liverpool University, President-elect of the B.M.A. for 1950–1, left £92,215. Dr. Henry Walker, of Louth, Lincs, left £11,047; Dr. Thomas Mulvany, of Muswell Hill, £7,801; Dr. William Edmond, formerly of Shrewsbury, £17,275; Dr. Walter Lazarus-Barlow, formerly of Smithy Hall, West Mersea, late Professor of Experimental Pathology at London University and Director of the Cancer Research Laboratories, Middlesex Hospital, £5,782; Major-General Andrew Gibbs, formerly honorary physician to King George V, £12,668; Dr. John Gordon-Munn, formerly of Heigham Hall, Norwich, who had been Lord Mayor of Norwich, £64,970; Dr. Gordon Lane, O.B.E., of Eastbourne, £15,447; Dr. Lilias Emily Frazer-Nash, of Kingston Hill, Surrey, one of the first women doctors to qualify in medicine in this country, £15,254; Mr. Norman Patterson, of Ashridge Park, Berkhamsted, late surgeon, Throat Hospital, Golden Square, W., £17,856; Lieutenant-Colonel Charles Deyns, J.P., of Bletchley, £50,176; Dr. Thomas McKiernan, of Falmouth, £22,792; and Dr. William Branson, C.B.E., of Bury St. Edmunds, for some years on the consulting staff of the Royal Free Hospital, £38,419. Dr. Thomas Glynn-Morris, of Liverpool, left £22,703; Dr. Charles Evans Jenkins, of Sale, Cheshire, £10,218; Dr. William Caldwell Steele, late of Walthamstow, £17,494; and Dr. James Arthur Unitt, of Quorn, £50,020.

COMING EVENTS

The Osler Club

The annual dinner of the Osler Club will be held at the South Kensington Hotel, Queen's Gate Terrace, London, S.W.7, on July 12, at 7.45 p.m. The guest of honour will be Sir Henry Souttar, who will deliver the Oslerian Oration. The charge is 15s., and members are invited to bring other members of the medical profession interested in the club and its work. Dress: lounge suits. Those wishing to attend should write to the secretary, Dr. M. J. Linnett, 70, Shooters Hill Road, Blackheath, London, S.E.3.

Industrial Radiology

The summer meeting of the Industrial Radiology Group of the Institute of Physics will be held at the New Horticultural Hall, Victoria, London, S.W.1, from Tuesday, July 25, to Friday, July 28. Admission to the lectures and Group summer exhibition (and to the technical exhibition of the International Congress of Radiology) will be by ticket only, obtainable free from the Institute of Physics, 47, Belgrave Square, London, S.W.1, from which details of the lectures are also obtainable. Early application is advised.

Salford Mental Health Services

An informal conference to discuss better co-ordination locally of home and hospital services for mental health will be held at the Town Hall, Salford, on July 14 at 2.30 p.m. Dr. Joshua Bierer, of the Institute of Social Psychiatry, London, will speak on individual and social psychiatry, and Dr. J. W. Affleck, of the Leeds Mental Healtn Services, will also speak.

Speech Therapy

The Eighth International Conference on Speech Therapy will be held in Amsterdam on August 21–26. Particulars may be obtained from the secretary, Dr. Hanny Veldkamp, 27, P.C. Hooftstraat, Amsterdam-Z.

Health Education

The Central Council for Health Education will hold a Summer School at St. Hugh's College, Oxford, on August 14–27. The fee will be 17 guineas. Under the direction of Dr. Robert Sutherland there will be tutorial discussions on health-education principles and methods and the theory of group discussion. Experts will give five lectures, and students will form small groups to exchange experiences from their jobs in youth clubs, schools, clinics, and the home. The school is intended to appeal to educational and medical administrators, doctors, teachers, youth leaders, public health nurses, industrial nurses, welfare workers, training organizers, and students. Further information may be obtained from the medical adviser and secretary, Central Council for Health Education, Tavistock House, Tavistock Square, London, W.C.1.

Entomology

The Ninth International Congress of Entomology will be held on August 17–24 at Amsterdam. Entomologists wishing to receive in due course the programme and application forms are asked to communicate with the Secretariate, Physiologisch Laboratorium, 136, Rapenburgerstraat, Amsterdam.

SOCIETIES AND LECTURES

A fee is charged or a ticket is required for attending lectures marked ●. Application should be made first to the institution concerned.

Tuesday

EDINBURGH POSTGRADUATE BOARD FOR MEDICINE.—At University New Buildings (Anatomy Lecture Theatre), Edinburgh, July 11, 4.30 p.m., "*Some Principles of Antenatal Pathology*," by Professor R. A. Willis.

Wednesday

CAMBRIDGE UNIVERSITY.—At Addenbrooke's Hospital, Cambridge, July 12, 2.30 p.m., "*The Social Background of Tuberculosis*," by Dr. W. Paton Philip.

LONDON COUNTY MEDICAL SOCIETY.—At Queen Mary's Hospital, Carshalton, Surrey, July 12, 2.30 p.m., clinical meeting.

ROYAL SANITARY INSTITUTE, 90, Buckingham Palace Road, London, S.W.—July 12, 2.30 p.m., paper: "*The Prevention and Control of the Rheumatic Diseases*," by Dr. Oswald Savage.

Thursday

EDINBURGH UNIVERSITY.—At Anatomy Lecture Theatre, University New Buildings, July 13, 5 p.m., "*Experimental Studies on the Eye Based upon the Regeneration of the Neural Retina and the Lens*," Macarthur Postgraduate Lecture by Professor L. S. Stone (Yale University). To be illustrated by coloured films.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, London, S.W.—July 13, 5 p.m., "*The Bearing of Protein Structure on Clinical Problems*," Bertram Louis Abrahams Lecture by Professor E. C. Dodds, F.R.S.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, London, W.C.—July 13, 5 p.m., "*The Diagnosis and Treatment of Acute Deep Venous Thrombosis*," Surgery Lecture by Dr. Gunnar Bauer (Mariestad Hospital, Sweden).

Friday

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, London, W.C.—July 14, 3.45 p.m., "*The Jaws in Generalized Skeletal Disease*," Charles Tomes Lecture by Professor Lester Cahn (Columbia University); 5 p.m., "*Epulides*," Charles Tomes Lecture by Professor A. B. P. Amies (University of Melbourne).

ROYAL SANITARY INSTITUTE.—At Great Yarmouth, Norfolk, July 14, 10 a.m., papers: "*The Work of the Public Analyst*," by Dr. Eric C. Wood, A.R.C.S., F.R.I.C.; "*The Fishing Industry of Great Yarmouth*," by Mr. G. H. Spinks. Afternoon: visits will be made.

Saturday

●RENAL ASSOCIATION.—At Ciba Foundation, 41, Portland Place, London, W., July 15, 11.30 a.m., "*Development of Modern Renal Physiology*," by Dr. Homer Smith.

APPOINTMENTS

BAIN, J. W. L., T.D., M.B., Ch.B., D.A., Anaesthetist, Aberdeen General Hospitals and Special Hospitals Groups (Consultant Status).

CRUICKSHANK, ERIC KENNEDY, M.D., M.R.C.P., Professor of Medicine, University College of the West Indies.

DAWSON, MARJORY A., M.B., Ch.B., D.P.H., Assistant County Medical Officer, Assistant School Medical Officer, Medical Officer of Health for Samford and Gipping Rural District Councils and Stowmarket Urban District Council.

EAST ANGLIAN REGIONAL HOSPITAL BOARD.—*Consultant Psychiatrist at St. Audry's Mental Hospital, I. K. Marshall, M.R.C.S., L.R.C.P., D.P.M. Consultant Anaesthetist (part-time) at County Hospital, Huntingdon, G. H. W. Keates, M.B., B.S., D.A. Senior Registrar in Anaesthetics at Norfolk and Norwich Hospital, A. L. Reynard, M.R.C.S., L.R.C.P., D.A.*

SHELLEY, WILLIAM HADFIELD, M.D., D.P.M., Consultant Psychiatrist, Warlingham Park Hospital, Warlingham, Surrey.

SLEIGH, JOHN, M.B., Ch.B., D.P.H., Medical Officer of Health, Andover Municipal Borough and Andover and Kingsclere and Whitchurch Rural Districts, Hampshire.

WIGLEY, GUY SIMPSON, M.R.C.S., L.R.C.P., D.P.H., Deputy County Medical Officer of Health, Middlesex County Council.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Cleobury.—On June 23, 1950, at Bromley, Kent, to Brenda Julie, wife of John Cleobury, M.B., B.S., a son—Nicholas Randall.

Jefferiss.—On June 30, 1950, at Poltimore House Nursing Home, Exeter, to Vivien, wife of Derek Jefferiss, B.M., M.R.C.O.G., a daughter.

DEATHS

Dore.—On June 27, 1950, Samuel Ernest Dore, M.D., F.R.C.P., of London, W.1, and N.W.11.

Gleed.—On June 28, 1950, at 38, Ballard's Lane, Finchley, London, N., Seymour Richard Gleed, M.R.C.S., L.R.C.P., aged 68.

Johnstone.—On June 24, 1950, at Torbeckhill, Lockerbie, Dumfriesshire, George Johnstone, M.B., C.M., late of Middleton, Lancs.

Knapton.—On June 28, 1950, at Oaklands, Lynton, N. Devon, Henry Alfred Forbes Knapton, M.R.C.S., L.R.C.P., Lieutenant-Colonel, I.M.S., retired, aged 80.

Lang.—On June 25, 1950, at Drumassie, Crossford, Lanarks, *John McCallum* Lang, M.D., D.P.H., aged 60.

Lewers.—On June 26, 1950, at his home, Corinella, Ilfracombe, Hugh Bunnett Lewers, D.S.O., O.B.E., M.B., B.S.

Mann.—On June 29, 1950, at 4, Wellington Circus, Nottingham, Dorothea Jane Mann, M.D.

Mell.—On June 9, 1950, at Broad Green Hospital, Liverpool, Felix Oswald Newton Mell, C.I.E., M.B., C.M., Lieutenant-Colonel, I.M.S., retired, of Mona House, Castletown, Isle of Man, aged 80.

Milne.—On June 24, 1950, at St. Ives, Dorridge, Warwicks, Colin Milne, M.B., Ch.B., D.P.H., aged 57.

Poison.—On June 27, 1950, at Miramar, Milford-on-Sea, Hants, James Ronald Poison, M.D., late of Worcester, aged 91.

Shortall.—On June 15, 1950, at Newry, Co. Down, N. Ireland, Christopher Joseph Shortall, M.D., M.Ch., F.R.C.S.I., aged 45.

Thomson.—On June 27, 1950, at 10, Ripon Road, Harrogate, Yorks, Joseph Alexander Thomson, M.B., Ch.B., D.M.R.E.

Ward.—On June 29, 1950, John Forbes Ward, M.D., F.R.C.P., of Deepdene, Manor Road, Cheadle Hulme, Cheshire.

Young.—On June 28, 1950, at Chichester, John Charles Young, M.R.C.S., L.R.C.P., of 43, West Drive, Aldwick, Sussex, aged 78.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Adenoidectomy

Q.—*What are the indications for, and the advantages of, adenoidectomy without tonsillectomy? In a child of 6, with apparently healthy tonsils, would adenoidectomy alone be of any value in preventing recurrent attacks of otitis media, or should it be combined with tonsillectomy? To what other conditions should attention be directed in cases of recurrent otitis media in young children?*

A.—The indications are all troubles caused by enlarged adenoids, such as post-nasal obstruction, with consequent nasal catarrh and often sinusitis; mouth breathing with maldevelopment of the hard palate; and obstruction of the Eustachian tube openings leading to intermittent or chronic infection or catarrh of the middle ear. Sometimes enlarged adenoids interfere with sleep, causing nightmares possibly, and perhaps being related in some cases to nocturnal enuresis. The advantages are that it is such a minor procedure compared with tonsillectomy, and it can, if indicated, be performed on young infants. Tonsils should never be removed unless they are causing trouble, certainly not in the case cited. Other conditions which should be considered in any child with recurrent otitis media are infections of the nasal sinuses, which are shown on *x*-ray examination, and the general lack of resistance caused by bad food and bad housing. Occasionally after adenoidectomy small collections may persist behind the tubal openings, and these may have to be destroyed by radium or *x* rays.

Parkinsonian Rigidity

Q.—*Can you tell me if "myanesin" has been extensively used in the treatment of Parkinson's disease of the predominantly rigid type? What is the usual dosage? Are there any harmful effects resulting from daily administration? What are the advantages, if any, over radiant heat or other palliatives in a fairly advanced case?*

A.—"Myanesin" is an α-substituted glycerol ether and its action is different from that of curare. Curare exerts its effect at the neuromuscular junction, while there is evidence that myanesin acts centrally on the synapses of the spinal cord. Myanesin has been used in an attempt to reduce the rigidity of Parkinson's disease, but no account of a carefully studied series of cases appears to have been published. In the writer's experience with a few cases myanesin by mouth may reduce rigidity, but there tends to be increased muscle weakness and the tremor may become more marked. No harmful effects were caused unless a large dose was given, when the patients complained of double vision and dizziness. The dose of the elixir advised by the makers (B.D.H.) is ½ to 1 drachm (1.8 to 3.5 ml.) from one to six times a day. There is more likely to be a reduction of the Parkinsonian rigidity with a full dosage of one of the solanaceous alkaloids, such as hyoscine or stramonium, or with one of the recently introduced antispasmodics, of which "artane" is often the most efficacious.

Kraurosis Vulvae

Q.—*Have there been any recent advances in the treatment of kraurosis vulvae?*

A.—It depends upon what is meant by kraurosis vulvae. The term should be restricted to a condition of extreme atrophy, with secondary infection, fibrosis, and contracture, occurring after the menopause and related to the cessation of ovarian function. There are no new forms of treatment, but there is an increasing awareness that it is important to be cautious about the diagnosis. In this respect it should be noted that kraurosis is a comparatively rare disease causing pain and dyspareunia. If the symptom is pruritus another cause should be looked for. The disease as it occurs in post-menopausal women responds well to oestrogen therapy, at least temporarily. The difficulty is to discontinue treatment without the condition relapsing. When the skin has become healthy the dose should be gradually reduced, but in some cases intermittent treatment over a prolonged period seems necessary. Local applications of emollient preparations are also helpful.

Anti-gas-gangrene Serum

Q.—*What is the value of anti-gas-gangrene serum?*

A.—Anti-gas-gangrene serum has been employed in both prophylaxis and treatment of this grave infection. The general practice is to use a polyvalent antitoxin against the toxins of *Clostridium welchii, septicum*, and *oedematiens*, the anaerobes most commonly associated with gas gangrene. Opportunities to assess the value of these antitoxins are limited to times of war, since gas gangrene is a rare infection in civilian practice. Towards the end of the 1914–18 war a controlled trial in the prophylaxis of gas gangrene with *Cl. welchii* antitoxin was carried out and gave results which showed that the serum reduced both the incidence and case mortality of the infection. In the 1939–45 war, assessment of the value of gas-gangrene antitoxin, either in the prophylaxis or in the treatment of war wounds, was made difficult by the simultaneous use of chemotherapeutic substances, such as the sulphonamides and, later, penicillin. The available evidence, however, indicated that the case mortality in established gas gangrene was lowered by large doses (50,000 units or more) of polyvalent antitoxin, although the antitoxin was effective only in patients receiving adequate surgical treatment. *Cl. welchii* antitoxin has also been used in the treatment of gangrenous appendicitis, peritonitis, and puerperal infections. It seems likely that penicillin or some other antibiotic will largely replace gas-gangrene antitoxin in the prophylaxis and treatment of infections associated with this group of anaerobes.

Dangerous Drugs Issued to Nurses

Q.—*An instance has occurred where a district nurse has been given a supply of a scheduled drug for administration to a number of patients in accordance with the doctor's instructions, and, owing to the cessation of the treatment for one cause or another, the nurse has been left with a residual supply. By holding a supply the nurse is technically infringing the regulations. Is there any provision in the regulations for the disposal of such excess supplies of dangerous drugs?*

A.—A registered medical practitioner can provide a patient with a supply of a scheduled drug for administration in accordance with his directions either by issuing a prescription to that effect or by handing to the patient, or a competent relative, or a nurse in charge of the patient the scheduled drug he considers appropriate for the treatment of that patient. It is not necessary to enter in the register of supplies particulars of drugs administered to a patient by the doctor personally or by someone acting under the direct personal supervision of the doctor and in his presence. On the other hand, drugs handed to the patient or to the nurse in attendance on the patient for subsequent administration must be recorded in the doctor's register of supplies. An entry must be made on the day on which the drug is supplied or on the following day. Each patient must be considered and recorded separately.

There is no provision in the Dangerous Drugs Regulations for dealing with excess supplies of scheduled drugs that are left over unused after the recovery, removal, or death of the patient. These excess supplies are the property of the patient when they have been provided through the medium of the issue of a prescription; they may be the property of the practitioner when they have been handed over by him out of his personal store of scheduled drugs. In any event, if the practitioner is of opinion, or has reason to believe, that there will be a surplus unused after certain events have occurred, it is only common sense to take suitable steps to recover that surplus from the patient's relatives or the nurse concerned. The regulations are

silent on this point, but clearly the practitioner should take some steps to ensure that the surplus is destroyed or, where desirable, recovered by him and placed in his locked cupboard.

Treatment of Naevus

Q.—*A baby girl, aged about 4 weeks, has a naevus which covers the nose, with small flecks on both upper and lower eyelids on each side. What is the best time to start treatment, and what type of treatment is recommended?*

A.—It is presumed that this is a naevus of the port-wine stain type. Painting with an alcoholic solution of thorium X, 1,500 e.s.u. per ml., once every month or six weeks for, in the first instance, twelve paintings may effect considerable paling of the lesions. The part should be cleaned gently with spirit before painting, and treatment may be started immediately.

Inheritance of Spina Bifida

Q.—*A patient aged 45 has a spina bifida occulta which has never given any trouble, and which was only discovered accidentally in the course of an x-ray examination. The brother of the patient has an only child, aged 7, who has recently undergone an operation for a cerebellar tumour. A first cousin (daughter of the patient's father's sister) has had two children, of whom the first died at the age of 3 months from spina bifida; the second child has survived to the age of 6 with a spina bifida, but cannot walk. The cousin's siblings have produced nine normal children, but the patient's siblings (apart from the brother) have produced none. The patient contemplates matrimony, and wants to know what are the chances of his producing healthy children. Nothing is known of the heredity of the proposed spouse.*

A.—This is rather a difficult question, because the chances for relatives other than brothers and sisters of affected persons are hardly known. Nor is the genetic relation of spina bifida occulta to the manifest condition understood as yet. Nevertheless, on the facts given, the increased risk for any children of this patient is probably very small. It is probably not larger than the *one-in-forty chance that any random pregnancy will* end in a serious malformation of one kind or another. Hence it seems safe to advise that the patient should ignore the slight added risk implied by a family history of this type.

Prognosis of Primary Syphilis

Q.—*What is the prognosis of primary syphilis with modern treatment? What are the chances (a) of a complete cure, and (b) of being able to produce non-syphilitic children?*

A.—The prognosis of primary syphilis treated by modern methods is extremely favourable, particularly if treatment is started in the sero-negative stage. (*a*) No method of proving biological cure has yet been devised, but presumptive cure, as evaluated by absence of clinical signs and persistently negative serum reactions (including tests of the cerebrospinal fluid) over a period of at least two years after treatment, may be expected in nearly 100% of adequately treated sero-negative primary cases and in 90% or more of sero-positive primary cases. (*b*) Adequate treatment of both males and females should ensure their children being non-syphilitic. Penicillin, which is the treatment of choice for syphilis, has been employed only since 1943, so that some years must elapse before we can be sure that late manifestations such as cardiovascular syphilis and neurosyphilis will not appear; however, provided it is used in optimum dosage, preferably combined with bismuth and perhaps an arsenical, there is every reason to suppose that cure will be obtained in the vast majority of cases.

Treatrent of Iritis

Q.—*What mydriatic should be used in the treatment of iritis in a patient of 65 to 70? The tension of the eye is normal.*

A.—In most cases it would be safe to start treatment with ½% atropine twice daily, increasing the strength up to 1% three times a day. If, however, there is some question whether the tension of the eye is raised—and this rise may be due to the iritis—it is better to start with ½% homatropine twice daily. If after twelve hours there is some relief of symptoms, go on to 1% homatropine three times a day. With continued improvement proceed to 1% atropine twice daily, and later three times a day if necessary. The point about using homatropine is that its effect can be overcome fairly quickly by eserine.

Thymus and Growth

Q.—*Can you please tell me of any substances—for example, thymus gland—which may be used to increase growth? I want to try out their effects with exotic fish, which I breed as a hobby.*

A.—Some years ago Rowntree in America reported experiments with extracts of thymus gland which appeared to indicate that growth and development were accelerated through several generations. The effect reported was really an increase in the rate of development, rather than any absolute increase in growth. These experiments have never been repeated with similar results, and it is generally held that they can no longer be sustained as indicating such an action of the thymus gland. The growth hormone of the pituitary gland was originally used with salamanders, a point which might be of interest in connexion with experiments on tropical fish.

NOTES AND COMMENTS

What is a Chill?—Dr. A. V. ADAMS (Heathfield, Sussex) writes: May I request enlightenment about the disturbance of normal physiology underlying the clinical condition—so conspicuously unmentioned in medical literature—known as "a chill"? At sea I have found that a sudden fall in relative atmospheric humidity is followed almost invariably by a high incidence of chills. There may well have been no corresponding fall in atmospheric temperature, and the victim may well have not been exposed to draughts. An especially bad zone for chills is the Gulf of Suez when travelling north from the Red Sea, and I have become a victim myself on all too many occasions, despite the most careful precautions in the direction of avoiding draughts and putting on extra clothing. These chills may take many forms. . . . The diagnostic importance of this syndrome is clearly considerable. If the chill is sudden and severe in onset, as is frequently the case, and if the ship has come from India, both smallpox and the typhoid group immediately call for exclusion. But the problem of differential diagnosis is of obvious enough importance. The problem on which I seek enlightenment is what disturbance of physiology is going on, and what organ or organs are the seat of the disturbance. Can one incriminate a sudden alteration in ionic balance and water metabolism due to environmental changes of similar suddenness and violence, which renal function cannot deal with fast enough? . . . My own view, and I have no evidence to prove it, is that a violent change in *milieu extérieur* produces a concomitant change in *milieu intérieur*, and that it takes a while for the *status quo ante* of the *milieu intérieur* to be restored.

Management of Diverticulosis.—Dr. C. EDWARDS (Bournemouth) writes: I would suggest that one answer to this question is this. Since the removal of roughage from the food affects the quantity to be evacuated, the addition of one of the gel-forming preparations would increase the bulk in the rectum. Instead of the dried scybala (in spite of liquid paraffin) a bulky soft stool is formed, and the paraffin may be reduced and perhaps abandoned.

The "Medical Directory."—The Editor of the *Medical Directory* (104, Gloucester Place, London, W.1) writes: To maintain the accuracy of our annual volume we rely upon the return of our schedule, which has been posted to each member of the medical profession. Should the schedule have been lost or mislaid, we will gladly forward a duplicate upon request. The full name of the doctor should be sent for identification.

Correction.—In the later issues of the *Journal* of June 10 (p. 1351) it was incorrectly stated that Barrowmore Hospital was previously known as "Borrowdale Sanatorium." This should have been "Barrowmore Sanatorium."

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: *Aitiology, Westcent, London.* ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone. 2,665 CASES OF ABORTION

A CLINICAL SURVEY

BY

ALBERT DAVIS, M.D., Ch.M., F.R.C.S., M.R.C.O.G.

Gynaecological Surgeon, Prince of Wales's, St. Giles', and Dulwich Hospitals

This review is based on a series of consecutive cases of abortion under my care at St. Giles' and Dulwich Hospitals, London. The two hospitals are relatively closely situated in a working-class suburb, with approximately the same number of gynaecological beds, under the same consultative direction. They therefore offer excellent opportunity for comparison of different methods of treatment, for these can be carried out under fairly comparable conditions. During the past 15 years (with the exception of a wartime interval) advantage has been taken of this opportunity to assess the value of varying treatments, and it was the primary object of the present investigation to determine the relative merits of active and passive treatment in cases of incomplete abortion, and to settle, if possible, some of the issues of this perennial source of argument. A second object was to compare the potency (if any) of different chemotherapeutic agents in infected cases. For these purposes a detailed analysis was made of enough cases to reduce percentage error to a reasonable minimum—the actual number recommended by our statistical adviser was 2,500, and this has been only slightly exceeded, the cases being almost evenly divided between the two hospitals concerned. The results of this analysis are given below, and it is suggested that they are definite enough to be of therapeutic significance.

During the course of this investigation various secondary factors—age, parity, morbidity, etc.—had necessarily to be considered. These proved of sufficient interest to merit analysis, and they are classified below under the appropriate headings.

Age

The average age of the patients was 29 years, the youngest being 17 and the oldest 49. This corresponds with the figures given by Gellert (1926), who found the average age between 20 and 30 years; only 3% of his cases were younger than 20 years. Similarly, the report of the Children's Bureau of New York (1934) gives an average of 25 to 29 years.

The age incidence seems at first sight surprisingly high, but this is explained by the fact that abortion is much commoner among married women, and that the average age of marriage is fairly high—the Registrar-General's report for 1945 gives it as 24 years. Again, however, the type of patient is important. At St. Mary Abbots Hospital, which admits a large number of "luxury trade" women—manicurists, hairdressers, West End shop assistants, dancers, etc.—the average age of 100 consecutive abortion patients was 23 years, 14 being below 19 years. This type of girl, attractive, away from home, and fascinated by "glamour," is much more liable to abortion than the more respectable working-class girl. She is also, *pari passu*, much more subject to dangerous complications (see below).

Civil State

Of the 2,665 woman 2,350 were married, 303 were single, and 12 widows. This is in accord with McIlroy's (1929) report, that abortion is most frequent amongst the married, and with the statistics of Roesle (1929), who states that one-sixth of all his cases were unmarried. Richelt, on the other hand, found that 65% of his large series were unmarried.

These figures seem to vary considerably, not only in different countries but in different parts of the same country or even town. In rural communities, and in the purlieus of wealthy districts, the proportion of single girls is higher. At Paddington Hospital nearly 50% of all full-term deliveries in the large maternity unit are in single women, and a similar proportion exists amongst the abortion cases. In the two hospitals under consideration, however, convention again shows its influence, the great majority of the patients being "respectable" married women.

Analysis of the cases on this basis shows that the question of wedlock is an important one from the clinical aspect, for the complication rate is much higher in illegitimate abortions. In the present series of 315 unmarried women severe complications—gross haemorrhage, virulent infection, pelvic abscess, etc.—were present in 43 (14%) of the cases, while the corresponding figure for the 2,350 married patients was only 6%. This difference is *not* due, as is generally supposed, to later abortion, with its increased risk, in the single women, for the average duration of the pregnancy in these patients was 12.4 weeks, as against 12 weeks for all the cases. The most likely explanation lies in a combination of several factors—the inexperience of these girls, their isolation, and the desperate nature of their predicament.

Period of Gestation

The average period of gestation was 12 weeks. This corresponds roughly with the figures given by Roesle (1929) and Kopp (1936). The former found 60% of abortions occurring at the third and fourth months, the latter 58% between the second and third months. The main reason is that the average woman waits for two missed periods before being quite certain of her pregnancy. It then takes

another two or three weeks for her to make the necessary "contacts" to terminate the pregnancy.

The great majority (87%) were between ten and fourteen weeks pregnant, and there was wide variation in the remainder, from the earliest at five to the latest at 26 weeks. In two cases the patient was not pregnant at all, but had attempted criminal abortion in the belief that she was.

Period in Hospital

The average stay in hospital was thirteen days, the longest being fourteen weeks, and the shortest one day. These figures are somewhat deceptive, for 86% of the women went home eight or nine days after admission. The high average is provided by the very long periods of hospital treatment in infected and other complicated cases.

Previous Abortions

In 253 (9.5%) of the cases there was a history of one or more abortions, details of which are given in Table I.

TABLE I.—*Previous Abortions (253 Cases)*

No. of Abortions	No. of Cases	No. of Abortions	No. of Cases
1	189 (74%)	5	3 (1·2%)
2	38 (15%)	6	1 (0·5%)
3	15 (6%)	7	1 (0·5%)
4	5 (2%)	8	1 (0·5%)

These figures do not correspond with those given by Kopp (1936), who found that 25% of cases had had one previous abortion, 30% two, and 34% three; but her patients belonged mainly to the more prolific section of the population of New York, and are hardly comparable with our own.

Previous Full-term Pregnancies

Of the patients 669 (39%) had one or more children; this series is further analysed in Table II.

TABLE II.—*Previous Full-term Pregnancies (669 Cases)*

No. of Children	No. of Cases	No. of Children	No. of Cases
1	209 (31%)	7	3 (0·5%)
2	202 (30%)	8	7 (1%)
3	90 (14%)	9	3 (0·5%)
4	86 (13%)	10	6 (1%)
5	49 (7%)	11	3 (0·5%)
6	13 (2%)	12	2 (0·3%)

Roesle (1929) found that 10% of all his cases had one child, 7% two, 7% three, and 10% four or more. Kopp's analysis similarly gives a less steeply descending scale than my own, the ratio being 9:1, 8:2, 6:3, 4:4, 3:5, 2:6, the first figures applying to cases and the second to children.

It will be observed that roughly one-third of all the women had one or more children, and that two-thirds of these had either one or two, with a rapidly descending scale for the rest. The explanation of this is somewhat obscure. It might lie in the fact that sterility is a common post-abortal complication, or in the similar decrease in fertility following the second or third child. Another explanation may be that the somewhat crude circumstances attendant on criminal abortion might make many women prefer to go through with the subsequent pregnancy.

Spontaneous or Induced Abortion

The figures given by different authorities on this subject are variable. In their large individual series the indicated percentages of spontaneous abortion are given by du Puy (1932) as 58, Plass (1936) as 34, Kopp (1936) as 28, Sangmeister (1943) as 25, and Berle (1942) as 18. Parish (1939) found that 25% of 1,000 cases were spontaneous, 48% admitted illegal interference, the causation in the remaining 27% being unknown. The Derby City Hospital (1939) statistics give about 40% as due to criminal interference, while the corresponding figure given by the Society for the Provision of Birth Control Clinics (1939) is 27%. Of 3,000 cases investigated by the Joint Council of Midwifery (1939) 23% admitted to induced abortions, and the Interdepartmental Committee on Abortion (1939) came to the conclusion that 40% of the abortions in this country may be due to illegal interference.

My own view is that all these figures are vitiated by the fact that they depend on two fallacies: one, the very doubtful veracity of such patients, and, two, the individual opinion of medical officers. Most of the latter are psychologically inexperienced, and do not realize that a direct inquiry is practically useless. It is remarkable how often a patient who has denied interference will react affirmatively to a sudden accusation, and my own impression is that the great majority—perhaps 90%—of all abortions are induced in one way or another. The testimony of ward sisters, who are in the closest personal contact with the patients, bears this out; for most of them, when asked for their opinion, will corroborate this impression.

Methods of Procuring Abortion

The methods employed to procure abortion vary widely. The great majority were self-induced, either medicinally or by douching. Purgatives, "female pills," quinine, and herbal preparations comprised most of the former, but a curious specialty of the district was a tablespoonful of powdered ergot taken in a wineglassful of hot port.

The douche apparatus was usually a simple enema syringe, but, as it was found too difficult to insert the nozzle into the cervix, most patients preferred to use a "whirling spray" the top of which had been unscrewed. In both cases the injected solution was usually hot soapy water, with varying added quantities of lysol or other antiseptic. Sticks of slippery-elm bark were not very popular, being regarded as ineffective—due, probably, to the difficulty of inserting them into the cervix. They were indeed usually recovered from the vagina, and occasionally from the urethra or bladder. Knitting-needles, crochet hooks, and similar instruments were used only by a very few desperate patients.

Midwives and others acting as professional abortionists usually preferred a vaginal or uterine douche to more active measures, but some "stirred up" the uterine contents with a long sound. Curettage—usually without anaesthesia—was occasionally resorted to by some medical practitioners, but these generally preferred intrauterine paste injection.

Paradoxically, all but one of the deaths and the most severe complications in this series followed douching and not the theoretically more dangerous intrauterine manipulations. This corresponds with the figures cited in the Memorandum presented by the London County Council to the Interdepartmental Committee on Abortion (1939), which show that in nearly half of the 55 fatal cases in which there was known interference some kind of douching or uterine injection had been employed, while instruments were responsible for only 12. The explanation no doubt lies in the comparative infrequency of instrumental abortion, the dangers of which must be disproportionately high compared with those of douching. In the latter the degree of pressure employed is probably the important factor.

Injection introduced gently can be rapidly isolated by local uterine reaction, but fluid injected under the considerable tension of a vigorously squeezed enema syringe easily strips up the decidua and penetrates the sinuses, or passes directly through the tubes to the peritoneal cavity.

Types of Abortion

These are classified in Table III. Of the 95 cases of threatened abortion 61 continued with the pregnancy, 9 aborted completely, and 25 incompletely, the last all necessitating curettage. Of the 62 cases of inevitable abortion

TABLE III.—*Types of Abortion*

Type	No. of Cases
Threatened	95 (3·6%)
Inevitable	62 (2·3%)
Complete	192 (7·2%)
Incomplete	2,250 (84·4%)
Therapeutic	28 (1·0%)
Ectopic	32 (1·2%)
Molar	6 (0·2%)

44 aborted completely and 18 were surgically evacuated. The incomplete abortions were completed spontaneously in 771 cases (34.3%) and by operation in the remaining 1,479 cases.

Morbidity

The great majority of the cases showed some rise of temperature (Table IV). This was practically always initial, and usually subsided after evacuation—spontaneous or operative—of the retained products.

TABLE IV.—*Highest Recorded Temperature*

Temperature	No. of Cases
Normal	431
99° F. (37·2° C.)	913
100° F. (37·8° C.)	794
101° F. (38·3° C.)	341
102° F. (38·9° C.)	87
103° F. (39·4° C.)	77
104° F. (40° C.)	16
105° F. (40·6° C.)	6

In 431 of the patients the temperature was normal throughout. Included in this number were all the spontaneous, most of the therapeutic, and many of the threatened abortions. This high figure does not contradict the suggestion of the high incidence of criminal interference, for, though Taussig's dictum that practically every case of induced abortion shows some rise of temperature is undoubtedly true, there remain many afebrile cases in which such interference is undoubted and even admitted. A temperature of 101° F. or over is, however, diagnostic of an attempt to procure abortion, and it is noteworthy that such a rise can occur from abortion following the simple self-administration of abortifacient drugs or from local manipulations which leave the pregnancy undisturbed.

The cause of the fever in the great majority of cases is local in the uterus, as shown by the immediate fall after spontaneous or operative completion of the abortion. The pathology is an acute endometritis, secondary either to the introduction of an external infecting agent or to the presence of necrotic retained products. In the more heavily infected cases the pyrexia varies with the degree and rapidity of septic extension, from the prolonged remittence of pelvic abscess to the fulminating rigors of septicaemia; all types were present in this series. The temperature chart is, in fact, one of the most valuable adjuncts in the diagnosis of the infective complications of abortion, for most varieties give a characteristic record, from the low remittence of uterine sepsis and the higher remittence of pelvic abscess to the "Matterhorn" record of general infection.

Bacteriology

Swabs were taken from the vagina, cervix, and uterus in 50 consecutive cases. (It was impossible at first to avoid contamination of the uterine swab, but later this difficulty was mainly overcome by protecting it with a surrounding glass cannula. The results, however, were so similar in both series of cases that it was found unnecessary to separate them.)

In only two cases were the swabs sterile on culture. In all the rest a copious growth was obtained, the predominant organisms being *Staphylococcus albus* and *Bact. coli*, with smaller numbers of several of the commoner bacteria in many cases (Tables V and VI).

TABLE V.—*Cultures from the Genital Tract (50 Cases)*

This high incidence is significant of active infection, for, though the vagina is more heavily contaminated in the later weeks of pregnancy, it is relatively "clean" during the first three months, when the bacteriology corresponds roughly with that of the non-pregnant organ (Miller, 1933). In the latter Eeles (1925) found non-haemolytic streptococci in only 20% of nulliparae and 25% of multiparae, with a correspondingly low percentage of staphylococci, *Bact. coli*, *B. proteus*, diphtheroids, and Gram-positive bacilli. No *Cl. welchii* or haemolytic streptococci were present in any of his 50 cases. The figures given by Duncan (1947) in 133 consecutive patients admitted for hysterectomy are as follows: 90 smears were negative and 44 positive, the latter showing Gram-negative cocci and bacilli and Gram-positive cocci; only 46 of the group had positive cultures, the majority of which were *Bact. coli*. Even immediately before delivery the vaginal contamination is considerably less than during abortion, as shown conclusively by Taylor and Wright (1930), who in 1,123 cases found *Staph. albus* in 58%, *Staph. aureus* in 1%, Doederlein's bacillus in 35%, diphtheroids in 25%, coliforms in 31%, and various types of streptococci in 5%. The difference in the bacteriology of the uterus is greater, for, though all uterine swabs in the abortion series gave a heavy mixed growth on culture, it has been shown by several workers that the puerperal cavity investigated at caesarean section is sterile in 50% of cases (Harris and Brown, 1928; Armstrong and Burt-White, 1929; Gundel and von Oettingen, 1930).

The cervix showed the greatest difference. In almost all the abortion cases it was heavily infected, while in the course of another investigation I found the cervix sterile in 50% of third-day puerperas, with relatively poor growth in the remainder; in only 25% were rich cultures obtained. (There was no difference in the incidence of virus infection, for inclusion bodies were universally absent.)

Complications

The complications and related conditions encountered in this series are shown in Tables VII, VIII, IX, and X.

Retroversion

There were 13 cases (0.5%) in which the abortion was associated with retroversion. The period of gestation varied from eight to twelve weeks, with an average of ten weeks. Three of the patients gave a history of one previous abortion and one of two, while nine had at least one living child. In nine cases the patient had aborted incompletely before admission. The uterus was replaced in the remainder, but in only one case was this successful in producing continuation of the pregnancy. Acute retention of urine occurred in two patients, both of whom subsequently miscarried. It is difficult to be certain, particularly when abortion is already in progress, how far it has been caused by incarceration, and in only four of these cases was actual impaction definitely present. But even if all the abortions were due to this factor, the frequency of retroversion as a general cause remains almost negligible. The difficulty of conserving such pregnancies once bleeding has begun is also well demonstrated in these figures.

Injuries

Rupture of the uterus occurred in four cases. In one, an inexperienced surgeon extracted a piece of what he thought was omentum during the course of a therapeutic abortion. This proved to be a very fatty appendix epiploica, and at laparotomy (A. D.) the corresponding hiatus was found at the border of the pelvic colon. The intestinal mucosa itself was intact, but there was a perforation at the lowest part of the body of the uterus on the right side of the cul-de-sac. The tear had incidentally produced a complete rupture of the uterine artery (a rare accident), with profuse parametric haemorrhage. This was fairly easily controlled by suture, and the patient made a rapid and uninterrupted recovery. In two other cases the perforation had been followed by traction on the small intestine, a loop of which presented at the vulva. In the first the bowel was almost undamaged, and was returned through the uterine tear into the abdomen. In the second there was extensive damage with strangulation, necessitating resection and anastomosis. This was carried out *in situ*, and the repaired gut replaced in the same way. Both patients were too shocked to withstand laparotomy, but both made a complete recovery. In a further case the rupture was self-produced.

Mrs. A, aged 38, a 4-para, was admitted as an emergency case with the history that during an attempt to induce abortion by means of a syringe she had felt a pain of extreme intensity in the abdomen at the moment she was injecting the contents of the syringe. She was nearly three months pregnant, and had had some haemorrhage that morning. Seen four hours after the injection, she was collapsed and in great pain. Temperature was 97° F. (36.1° C.), the pulse 110 and thready, and the colour good. There was some loss per vaginam, the abdomen was tense, very tender all over, but not rigid. The signs of initial shock soon disappeared, but were rapidly replaced by those of internal haemorrhage, and operation six hours later revealed an abdomen full of blood. This was scooped out and was found to contain the foetus in its sac with the placenta, both lying quite free. The uterus was raised, to expose a perforation on the anterior wall high up, 2 cm. long, and bleeding freely. A rapid supravaginal hysterectomy was carried out with continuous blood transfusion, and the abdomen closed with interrupted silkworm-gut sutures taking in all layers. (This rapid method of abdominal closure is ideal in these cases; the scar seems to hold at least as well as the more orthodox layered one, and acute herniation is not more common.) The patient made a good recovery, except for an intra-abdominal abscess which had subsequently to be drained.

Careful subsequent questioning of this very frank patient led to the conviction that this was not a case of perforation by direct trauma, but of explosive rupture due to a forcible injection. There was a long clean hole too extensive and clear-cut for a perforation, and absence of the mucosal protrusion which seems characteristic of the former. The foetus and placenta seem rather to have been literally blown out of the uterus than squeezed through the narrow rent by muscular contraction.

Ectopic Abortion

There were 32 cases of extrauterine gestation in the series—an incidence of 1.2%. Of these, 28 were married and 4 single. The average age was 33 years, the youngest being 18 and the oldest 44.

Two patients had one child, three had 2 children, three had 3, two 4, one 6, and one 12. Only two of the patients had previously aborted, each of them twice. The period of gestation varied from 5 to 18 weeks, with an average of 7 weeks for all cases. The gestation was in the right Fallopian tube 15 times and in the left 17, and there was a coincident intrauterine pregnancy in two cases. The mortality rate was 0.3%, only one patient dying at operation.

Mortality

There were six deaths in the series—a mortality rate of 0.26%. This figure is considerably less than that given in most foreign statistics. Freudenberg (1932), for example, gives a figure of 1.2% for Germany, and Taussig (1936), collecting statistics from a variety of countries, obtained an average of 2.1%, and assumes a mortality of somewhat less than 2% for the United States.

The discrepancy is a considerable one, but is probably explained by the exclusion from our own figures of patients dying at home under local medical care, and of the not inconsiderable number of cases of sudden death. Two of the latter were seen at necropsy, but as they were not admitted they are not included in this hospital series.

The cause of death was *Cl. welchii* septicaemia (2 cases), traumatic vaginal and uterine necrosis with pelvic abscess (2 cases), traumatic perforation of the uterus with secondary peritonitis (1 case), and staphylococcal septicaemia (1 case).

The physical signs and post-mortem changes found in these cases are characteristic, and are almost exactly paralleled in the large series described by Hill (1936) and by Dawbarn and Williams (1938). A point of interest is the high average length of gestation, which was 15 weeks, compared with the average of 12 weeks for the whole series. This corroborates the well-known fact that the dangers of abortion rise proportionately with the period of gestation, with considerably added risk after the third month.

Of great interest is the actual cause of death in those patients dying suddenly during an attempt to procure abortion. One such patient, found dead in a bathroom with an enema syringe by her side, showed no fatal post-mortem pathology, the only positive finding being some soap solution in the uterus, which also contained an undisturbed foetus of about 14 weeks.

The actual injection of fluid is apparently unnecessary for a fatal issue, for cervical stimulation alone can cause sudden death. Michel and Morin (1922) have reported the case of a woman who, under the mistaken impression that she was pregnant, attempted abortion with an enema syringe, but died before any fluid had been injected; and cases have been recorded of women dying during the course of an ordinary vaginal examination (Mondor, 1936).

It is possible that reflex sympathetic shock may be the fatal factor in some of these cases, and the recent discovery of a rich submucous nerve plexus surrounding the external cervical os (Davis, 1938) provides considerable support for this theory. It is probable, however, that death in the majority of cases is due to cerebral embolism of injected fluid, for there are several reports of such patients dying in convulsions. These are usually epileptiform (Möller, 1922), but they are commonly followed, if death is not immediate, by signs of gross cerebral damage. Thus one of Neidhardt's (1915) cases showed hemiplegia, facial palsy, and unequal pupils; and similar signs were present in cases reported by Walcher (1926) and others. Cerebral symptoms are also seen in some of the cases which recover (Burgerhout, 1926), and I recently saw a woman in whom epileptiform convulsions were followed by transitory hemiplegia shortly after a paste injection.

The pathology in these cases is that of air embolism, and confirms the clinical view that the symptoms are due to multiple capillary gas embolism in the lungs or brain. It is true that the normal post-mortem intravenous formation of gas may sometimes be extremely rapid, but in two cases seen by me there had certainly been no time for this process, and it may be accepted that the air found in these and other cases was introduced, and not the natural gas of putrefaction. Confirmatory evidence is provided by the histological appearance of the affected organs, which show small multiple perivascular necroses.

In spite of these findings, however, it appears that air alone is not responsible for the changes described, but that it must be injected in soap-bubble form to cause embolism. Parade (1929) has shown experimentally that intravenous injection of a moderate amount of air is relatively safe, but that in combination with soap it is fatal; and a patient in the present series injected enough air (under considerable pressure) into her uterus to produce abortion, but without any apparent metastatic effect. It is true that soap and extraneous fat have rarely been chemically identified in the affected organs, but the amount necessary to provide bubble covering is so minute that it might easily escape ordinary analysis. On the other hand, Müller-Hess and Hallermann (1932) believe that the solid constituent of the injected material is the sole embolic factor, and Brack (1932) found paste emboli in the lungs in two cases.

Lipiodol, which is not easily miscible with air, may similarly be embolic to the lungs (where it can occasionally be demonstrated radiologically), but never, apparently, with fatal result. The accidental intravasation of this material is a fairly common phenomenon, and as its employment is frequent and universal the absence of distant complications indicates that it is relatively safe in intravenous injection. Other theories have been advanced to explain the peculiar changes of injected soap solutions. Balthazard (1920) suggests that strong emulsions change the haemoglobin into alkaline haematin, causing death by asphyxia, but I was unable to effect this change *in vitro*. Környey (1934) states that the soap may cause haemolysis and also destroy the capillary walls, allowing of extravascular permeation and direct damage to the surrounding tissues, which are also rendered ischaemic by the same process. There is, however, no histological proof of this theory, and the same applies to the suggestion made by Haselhorst and Schaltenbrand (1933) that the basic process is a rapid and universal clot formation.

On the whole, therefore, the most reasonable theory of the cause of death in these cases is that of a multiple minute air-bubble embolism. This explains the infrequency of pure air or pure fat embolism, and the danger of their combination. That this danger is a considerable one has repeatedly been stressed by a variety of authors, and the reported deaths from embolism following abortion are almost universally due to the intrauterine injection of some sort of soap solution. (The uterine paste employed by many abortionists is composed of olive oil, cocoa butter, caustic soda, and potassium iodide, and so is essentially a soap. Otherwise a simple household soap emulsion is used, some tincture of iodine being added as an antiseptic.) Englemann (1932) reports 17 deaths from this cause, and the literature abounds with records of similar fatalities, the result of either therapeutic or illegal abortion.

It may be assumed, therefore, that, though a few of these patients die suddenly from reflex sympathetic inhibition of the cardiac or respiratory centres, the result of cervical plexus stimulation, the cause of death in the majority is some form of soap-bubble embolism—cerebral, pulmonary, or coronary.

The presence of a direct venous pathway to the brain has been demonstrated by Batson (1940), who found a free anastomosis between the pelvic and perivertebral veins, material injected into the former being easily conveyed via the latter to the dural sinuses. This by-pass from the caval

pathway is facilitated by a rise in intravenous tension, and it is easy to understand how it may equally be opened under the pressure—often 100 mm. Hg—exerted by the Higginson syringe. It is unnecessary, therefore, to postulate patency of the foramen ovale to explain the mechanism of pelvic-cerebral embolism.

Treatment

The uterus was evacuated immediately in all cases of gross haemorrhage, except for the necessary interval for resuscitation and blood transfusion where required. Other incomplete abortions were treated with hot enemata and oxytocics, with operative evacuation within a few hours if these failed or were incompletely successful. An exception was made in those cases with high temperature, general peritonitis, or other signs of gross sepsis, when operation was delayed until improvement in the patient's general condition allowed of safe intervention.

The argument of active versus passive treatment of infected incomplete abortion has provided endless but inconclusive controversy. The statistics collected by Taussig from several clinics in many countries endorse the view of most teachers that expectant treatment is the safer, but the more recent figures given by Corston and Stallworthy (1947) and by Purdie (1947) indicate that immediate evacuation is apparently as safe. Our own experience confirms the latter finding. The duration in hospital of 251 consecutive cases treated by immediate operation was 9.5 days, while that of a control series of 338 cases treated expectantly was 13 days. This discrepancy may be explained partly by the varying degrees of experience of the operators concerned. Operative evacuation of an infected uterus is a delicate, highly dangerous procedure, and when performed by junior house-officers, who are so often delegated to this inconvenient task, the results are inevitably bad. In the hands of the skilled obstetrician, however, accidents are rare and the advantages considerable. The infecting agent is removed, the abortion is properly completed, and the period of convalescence is materially shortened.

The employment of an injection of oxytocin direct into the uterus is another factor which has materially modified the older view of the greater safety of conservative treatment. The contraction so produced materially reduces the risks of infective embolism, of perforation, and of gross haemorrhage, and makes evacuation so much the safer. The disadvantages of the method are the possibility of shock and the reactionary atony which occasionally follows the contractions. The former is rare and usually slight, and the latter is easily controlled by bimanual compression and the intravenous injection of ergometrine. Packing the uterus is unnecessary.

Chemotherapy

Various types of sulphonamide were given to 373 patients. The average stay in hospital of these cases was 13 days, while that of a control group of 200 untreated cases was 12 days—a difference of no statistical significance. These figures correspond with those of Studdiford (1939) and confirm the impression that chemotherapy here is largely useless, except in a few cases of specific susceptible infection. This is hardly surprising, in view of the mixed and very varied bacteriology generally present (Studdiford, 1939), and it is probable that the indiscriminate routine administration of sulphonamides to all cases of abortion is at least misdirected.

Peritonitis

There were four cases of true general peritonitis, as distinct from the common local pelvic peritonitis with associated "peritonism." Two were treated conservatively and both recovered, while a third died following laparotomy and drainage. This confirms the general experience that opening the abdomen in these cases serves mainly to introduce fresh organisms into an already virulently infected cavity, and that drainage of the meagre quantity of semi-purulent exudate usually present is both harmful and unnecessary. On the other hand, Falk and Blinick (1947) found that medical treatment, including sulphonamides and penicillin in varying dosages and routes of administration, fluid balance, and the use of small and large repeated blood transfusions, serums, vaccines, various non-specific therapies, oxytocics, Wangensteen drainage, etc., were equally of no avail in their relatively large series of cases.

There would thus appear to be little choice between simple drainage and conservative treatment, so that the bias must necessarily be in favour of the latter. There remains, however, the more radical treatment of hysterectomy. This once popular method has recently been revived, with good results, by Falk and Blinick, but it is at best a desperate measure, and the radical removal of uterus, tubes, and ovaries which it involves would make most surgeons hesitate before embarking on so formidable a procedure in a desperately ill and generally young patient. However, in one of our cases, that of a 4-gravida in fair condition, in whom perforation was certain, the operation was completely successful, and one must conclude that there is a definite though necessarily limited indication for its use in post-abortal peritonitis.

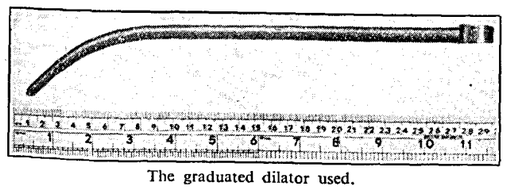
Pelvic Abscess

There were 13 cases of pelvic abscess. Three resolved under medical treatment, two ruptured spontaneously (one per rectum, the other per vaginam), and eight were drained by operation. This was invariably colpotomy, even when the abdomen had been opened for other complications, as occurred in two of the cases, and it is undoubtedly the ideal method of drainage. It is easy, moderately safe, and provides excellent gravity drainage, and it should more often replace the relatively inefficient abdominal methods commonly adopted, all of which necessarily involve intraperitoneal spread of the pus, apart from the added risk and discomfort of a major operation.

Therapeutic Abortion

There were 28 cases in the series, an incidence of 1% (Table XI). The indications were cardiac disease (6), chronic nephritis (5), molar pregnancy (5), pulmonary tuberculosis (3), epilepsy (2), disseminated sclerosis (2), pernicious vomiting (2), hydronephrosis (1), malignant hypertension (1), and carcinoma of cervix (1).

The indications were those usually accepted as necessary for therapeutic induction, with the possible exception of pulmonary tuberculosis, but the difficulty of obtaining suitable sanatorium accommodation for these patients is usually an overriding factor. Two further conditions—rubella in early pregnancy and high multiparity—have recently been added to our list of indications, but there are none in the present series. Several patients with temporary mental instability were referred by psychiatrists, but this was invariably transient, the result of unwanted pregnancy, and interruption was refused.



Methods of Therapeutic Abortion

The uterus was evacuated vaginally in 18 cases and abdominally in ten. Intrauterine paste injection was used in two cases, both patients being too ill for more direct

procedures. General anaesthesia with thiopentone–cyclopropane was usually employed, except in patients with cardiac failure or extensive pulmonary tuberculosis, when heavy premedication and local procaine injection was the method of choice. In vaginal evacuation oxytocin is withheld until adequate dilatation of the cervix, which it renders spastic. The special dilator used (see Fig.) is

The graduated dilator used.

tapered to the end, and has the advantage over the non-graduated Hegar type in minimizing cervical laceration. With the largest necessary dilator remaining in place, 10 units of oxytocin are injected direct into the uterine body, and firm retraction awaited. This usually takes place within three minutes, the amniotic sac being extruded intact and with very little haemorrhage. The sequence is by no means invariable, but it approximates most nearly to the mechanism of spontaneous abortion, and even when broken allows of considerable reduction of the profuse haemorrhage which is the invariable accompaniment of non-medical evacuation.

Oxytocin contraction also reduces the risk of instrumental perforation, and allows of curettage when the uterine contents have been fragmented. Extrusion may be similarly aided during abdominal hysterotomy: the contraction produced minimizes the blood loss of the incision and expresses the gestation sac intact after some minutes.

Sterilization was carried out in five cases at the time of the abortion, in two by the vaginal route. This method is comparatively easy, and is eminently suitable for cardiac cases, but haemorrhage from "catspaw" laceration in the soft uterus may be troublesome, and the operation is best performed after an interval of some weeks.

Summary

The average age of 2,665 abortion patients was 29 years, the youngest being 17 and the oldest 49; 2,350 of the women were married, 303 were single, and 12 were widows.

The average period of gestation was 12 weeks, 87% of the cases being between 10 and 14 weeks pregnant.

The average stay in hospital was 13 days, but 86% of the patients went home eight or nine days after admission, the high average being due to the relatively few complicated cases.

A history of previous abortion was obtained from 9.5% of the patients: 74% of these had had one, 15% two, 6% three, 2% four, 1.2% five, and 0.5% six, seven, and eight respectively.

Of the patients 29% had one or more children: 31% of these had one, 30% two, 14% three, 13% four, 7% five, 2% six, 0.5% seven, 1% eight, 0.5% nine, 1% ten, 0.5% eleven, and 0.3% twelve.

The incidence of spontaneous abortion is low. Probably 90% of the cases were induced, in the majority by the patient herself.

The method of choice for procuring abortion was vaginal douching under pressure. Professional abortionists employed intrauterine douching or catheterization. A small minority used slippery elm and similar foreign bodies.

Of the clinical types of abortion 3.6% were threatened, 2.3% inevitable, 7.2% complete, 84.4% incomplete, 1% therapeutic, 1.2% ectopic, and 0.2% molar.

There was a rise of temperature in 84% of all cases. This was usually moderate and initial, subsiding rapidly after completion of the abortion.

Genital infection was present in all but two of 50 consecutive cases examined bacteriologically. Cultures yielded a copious growth, the predominant organisms being *Staph. albus* and *Bact. coli*. Inclusion bodies were not identified in any case.

Gross infection was the commonest complication. There were five cases of septicaemia, one of pyaemia, and 118 with severe local septic involvement. Of these 41 had severe metritis, 25 parametritis, 19 salpingitis, 16 pelvic abscess. Gross haemorrhage, necessitating blood transfusion, occurred in 68 cases. Retroversion was present in 13 cases, showing the comparative rarity of the association. There were four cases of traumatic rupture of the uterus.

Of the abortions 32 were ectopic, an incidence of 1.2%. In two a coincident intrauterine gestation was present.

There were six deaths, a mortality of 0.26%. Three patients died from *Cl. welchii* septicaemia, two from burns (the result of local corrosive injection), and one from *Staph. aureus* septicaemia. A further patient (not included in the series) died from soap-bubble cerebral embolism. It is suggested that this last is the mechanism in most sudden fatalities.

Treatment was mainly directed, when the abortion was irritable or incomplete, to evacuation of the uterus, either medically or surgically. Active treatment was apparently superior to conservative, as shown by the lessened period in hospital and incidence of complications. Chemotherapy was largely useless in the presence of infected retained products, except in a few cases of specific susceptible infection. (Penicillin was not available for this series, but survey of a more recent group in which it was administered as routine shows it to be similarly ineffective.) Peritonitis remains the most fatal complication, and it is probable that radical operation is the treatment of choice. For pelvic abscess colpotomy provides the most direct route for drainage and the shortest convalescence.

Therapeutic abortion was performed 28 times, combined with sterilization in five cases. The indications were invariably gross

physical disease: in no case referred for psychological reasons was the mental factor regarded as strong enough for interruption of the pregnancy.

Before the war the Department of Scientific and Industrial Research produced a series of twelve leaflets, "Methods for the Detection of Toxic Gases in Industry." Leaflet No. 7, "Carbon Monoxide," has just been completely revised and now describes a new, simpler, and more accurate method of detection developed during the war at the Royal Aircraft Establishment. Dangerous concentration of carbon monoxide may occur in many industries, particularly steelworks, foundries, gas works, coke oven plants, and wherever gas producers and water gas plant are used. It is most dangerous when formed unknowingly, as by the improper use of geysers, boilers, braziers; in mine explosions ("after-damp"), in the smoke from fires; and in the exhaust gases from internal combustion engines. In the new test a sample of air is drawn through an indicator tube which is stained by the carbon monoxide. The length of the stain gives the concentration present in the air. Complete instructions for carrying out the test are given in the leaflet (H.M.S.O. Price 6d., 15 cents U.S.A., by post 7d.)

HABITUAL ABORTION

PROPHYLACTIC VALUE OF PROGESTERONE PELLET IMPLANTATION

BY

P. M. F. BISHOP, D.M.

Endocrinologist to Guy's Hospital and Chelsea Hospital for Women, and to the Department of Obstetrics and Gynaecology, Postgraduate Medical School of London

AND

N. A. RICHARDS, M.B., M.R.C.O.G.

Chief Assistant, Chelsea Hospital for Women

With Statistical Assistance from

RICHARD DOLL, M.D., M.R.C.P.

Statistical Research Unit, Medical Research Council

For the purpose of this study "habitual abortion" is defined as "idiopathic" abortion before the end of the fifth month of pregnancy, occurring on two or more consecutive occasions immediately preceding the pregnancy, in which pellet implantation has been used. Abortion is regarded as "idiopathic" if no recognized organic cause has been found. "Primary" habitual abortion refers to the condition in which all previous pregnancies have resulted in abortion. "Secondary" habitual abortion indicates that one or more previous pregnancies have proceeded beyond the 28th week.

Material

The present series consists of 45 patients who have received an implant of six 25-mg. pellets of progesterone during the pregnancy under consideration. The implantation was carried out according to the technique described elsewhere (Bishop, 1949).* No other treatment or precautionary regime was prescribed. These 45 cases represent all the patients with a history of habitual abortion treated by this method at the Chelsea Hospital for Women since 1947. It has been possible to obtain direct information concerning the outcome of the treated pregnancy in each of these cases.

Of these patients, 33 fall into the group of "primary" habitual abortion and 12 into the group of "secondary" habitual abortion.

Implantation was performed as early as possible—that is, as soon as the patient was referred to us for treatment. In most cases this was before the tenth week of pregnancy.

Results

TABLE I.—*Results*

No. of Successive Abortions Immediately Preceding the Treated Pregnancy	No. of Patients	Outcome of Treated Pregnancy		Percentage Successful Results
		Success	Failure	
A. Primary Habitual Abortion				
2	20	18	2	90
3	8	7	1	88
4 or more	5	3	2	60
B. Secondary Habitual Abortion				
2	8	6	2	75
3	1	1	0	100
4 or more	3	3	0	
C. Primary and Secondary Habitual Abortion Combined				
2	28	24	4	86
3	9	8	1	89
4 or more	8	6	2	75

*It should be emphasized that progesterone pellets, unlike other compounds suitable for implantation, tend to extrude unless implanted deeply: in this series the pellets were implanted beneath the deep fascia of the thigh.

The case recorded as a failure in the primary habitual abortion group, in which there had been three previous abortions, was that of a patient who started to bleed on her way home from hospital after the implantation, and the abortion was completed the following day (Table I). There would therefore have been no time for the progesterone to have any effect in this case. Of the two failures in the group having had four or more abortions one had had five previous abortions and the other seven.

A successful result was defined as one in which the pregnancy proceeded to 28 weeks. In fact, 26 of the 28 patients who were "successfully" treated for primary habitual abortion had live babies. In one of the two cases in which the baby died caesarean section was performed for fulminating toxaemia at the 28th week of pregnancy and the baby lived only 30 minutes: in the other case there was a stillborn breech delivery at the 36th week.

One case recorded as a success in the secondary habitual abortion group (Table I, B) in which there had been more than four abortions had miscarried nine times before the implantation.

All 10 successfully treated patients in this group had live babies. One of these was born with osteogenesis imperfecta, but the mother had previously had one child suffering from the same condition. This was the only case in the whole series in which there was any foetal abnormality.

Four other cases of repeated abortion treated by pellet implantation were not included in this series of 45 cases, because they did not conform strictly to our definitions of primary and secondary habitual abortion. A summary of these four cases is given.

Cases Not Included in the Series

Case 1.—Primary habitual abortion: three abortions at six weeks, then one abortion at 22 weeks. The next pregnancy carried to 33 weeks with an implant, and the baby lived. This case (a success) was excluded from the series because one pregnancy before the treated pregnancy had carried to more than five months.

Case 2.—Primary habitual abortion: two abortions at four and a half months and one abortion at three months, followed by another abortion at five and a half months. The next pregnancy carried to 30 weeks with an implant, but the baby lived only a few hours. This case (strictly a success according to our definition) was discarded for the same reason as Case 1.

Case 3.—Primary habitual abortion: one abortion at two months followed by two abortions at five months. Another abortion at five and a half months preceded the treated pregnancy, which carried only to 22 weeks after an implant. This case (a failure) was discarded for the same reason as Cases 1 and 2.

Case 4.—Primary habitual abortion: two abortions at five months followed by an abortion with twins at 28 weeks after an implant. One twin was born macerated and the other lived 32 hours. This case (strictly a success) was not included in the series, because it so barely conformed with our requirements.

Had these cases been included in the series there would have been no alteration in the success rate of 90% in the primary habitual abortion cases (group A) with two successive abortions, nor in the success rate of 86% in the same group under C. The success rate in A with four or more successive abortions would have risen to 62% and fallen in the same group in C to 72%.

Incidence of Habitual Abortion

In studying reports of many thousands of pregnancies in women attending antenatal clinics and birth-control centres it was concluded by the Biological and Medical Committee of the Royal Commission on Population (1949) that "the proportion of all pregnancies ending in spontaneous abortion may be placed between the relatively narrow limits of 7 and 11%."

Complete information regarding the incidence of habitual abortion is not yet available. In order to obtain a true random sample it would be necessary to have details of all the pregnancies of the total population of a certain area, such as a borough or an urban or rural district.

Most of the figures at present available are derived from studies of patients attending antenatal clinics or obstetric departments. For instance, Javert (1948) analysed 56,803 pregnancies cared for at the Woman's Clinic of the New York Hospital during the 15-year period 1933–47, and classified 189 as cases of "primary habitual abortion (i.e., having had three or more consecutive spontaneous abortions beginning with the first pregnancy) and 115 as cases of secondary habitual abortion." He concluded that this corresponded to an incidence of 1 in 300 (0.3%) for primary and 1 in 493 (0.2%) for secondary habitual abortion.

Malpas (1938), studying about 6,000 pregnancies, found that 84 women had three or more consecutive abortions or stillbirths, an incidence of 1.4%.

These incidences have been calculated by relating the number of cases of habitual abortion to the number of pregnancies seen, whereas they might more usefully be related to the number of women.

Bishop (1937) analysed 2,687 case histories from Guy's Hospital Maternity Service and found that 0.4% of women had more than one initial idiopathic abortion at less than five months, and 0.1% (i.e., three cases) had three initial idiopathic abortions.

The "Spontaneous Cure Rate"

Various attempts have been made to calculate the likelihood of a pregnancy proceeding spontaneously beyond the 28th week, or to term, when preceding pregnancies have terminated in abortion. Though some believe that any series of consecutive abortions may be due to coincidence, it is generally thought that there is a recurrent factor in abortion sequences. The figures most commonly quoted are those of Malpas (1938) and Eastman (1947). The "spontaneous cure rate," according to the calculations of Malpas, is as shown in Table II.

TABLE II.—*Malpas's Figures*

No. of Previous Abortions	Spontaneous Cure Rate of a Subsequent Pregnancy
1	50 to 78%
2	9 „ 62%
3	7 „ 27%
4	0·3 „ 6%

Eastman's calculations are based on the assumption that 10% of pregnancies terminate in spontaneous abortion and that a recurrent factor causes 0.4% to abort repeatedly. (This is the 0.4% in Bishop's series of 2,687 cases, mentioned above.) With these figures in mind he follows 100,000 hypothetical women through successive pregnancies (Table III).

Assuming the validity of these two sets of calculations, it is clear that the chances of a fourth pregnancy going to term are considerably less than those of a third pregnancy. This assumption is the basis of the definition of "habitual abortion" as representing three, rather than two, preceding abortions. It will, however, be obvious that a

TABLE III.—*Eastman's Figures*

Previous Abortion	Will Abort from Accidental Causes	Will Abort from Recurrent Causes	Total Abortions	Per cent. will Abort	Spontaneous Cure Rate
0	9,600	400	10,000	10·0	—
1	922 (9·6% of above figure)	400 (Same 400)	1,322	13·2	86·8
2	88 (9·6% of above figure)	400 (Same 400)	488	36·9	63·1
3	8 (9·6% of above figure)	400 (Same 400)	408	83·6	16·4

ence of three or more consecutive abortions represents e occurrence, and it is therefore unlikely that any idual set of observers will be able to present an essive series of three or more consecutive abortions. e present series there were only 17 such cases. We therefore included details of 28 cases with two ous abortions.

gnificance of Results Obtained in the Present Series

cepting Eastman's figures and projecting them further clude the spontaneous cure rate of four (or more) ious abortions as 2%, the probabilities of obtaining by ce the results obtained in the present series of primary tual abortions (see Table I) are:

With 2 previous initial abortions	0.007594
„ 3 „ „ „	0.000018
„ 4 „ „ „	0.000078

ombining the probabilities together, the overall probity is much less than 0.001 ($P = 0.001$ for $\chi^2 = 22.5$ $n = 6$; in this instance $\chi^2 = 50.5$).

, however, recurrent factors operate less often, say 0.1% of women, the expected success rates increase to , 44%, and 8%, and the probabilities of obtaining the ent figures are:

With 2 previous initial abortions	0.2758
„ 3 „ „ „	0.0157
„ 4 „ „ „	0.0045

the combined probability lies between 0.01 and 0.001. the true incidence of abortion due to recurrent factors till less, say 0.01%, the expected success rates increase 89%, 82%, and 45% (i.e., reasonably close to the erved figures) and the probabilities of obtaining the sent results are:

With 2 previous initial abortions	0.62
„ 3 „ „ „	0.56
„ 4 „ „ „	0.41

l the combined probability lies between 0.50 and 0.70. Thus, provided the "normal" incidence of spontaneous rtion is of the order of 10% and the incidence of ction due to recurrent factors is not much less than 1%, it is reasonable to conclude that the present figures dicate an effect of treatment. Should, however, the true cidence of "recurring" abortion be of the order of 01%, the present results could easily be attributed to ance. If the secondary habitual abortions are included e results are not materially affected.

*In calculating these probabilities we have assumed that all the tients referred to in Table I as having had four or more successive ortions had had four abortions. In fact, several had had five or ore, but there were not enough of these for separate consideration. his approximation results in the calculated probability being slightly gher than the real one, so that the test errs on the strict side.

Discussion

If there is a recurrent factor in habitual abortion it is obviously not easy to identify, and prophylactic treatment is therefore difficult to assess. Rest in bed, sedatives, correction of vitamin, nutritional, and thyroid deficiencies, and even psychotherapy, have been cited as useful prophylactic measures, apart from the administration of sex hormones. Smith (1948) has propounded the theory that many of the disorders of pregnancy, including habitual and threatened abortions, toxaemia, pre-eclampsia, and eclampsia, are due to an imbalance of placental hormones (excessive chorionic gonadotrophin and deficiency of oestrogen and progesterone), and that they can be counteracted by administration of oestrogens, and especially stilboestrol, in doses increasing from 5 mg. daily at the sixth week to 115 mg. daily at the 35th week, when treatment is discontinued. In a series of 127 patients with a history of habitual abortion (some of whom had previously had live births, and some of whom were treated for threatened abortion), she obtained the results shown in Table IV.

TABLE IV.—*Smith's Series*

Previous Abortions	No. of Cases	Carried to 28 Weeks	Live Babies
2	67	84%	81%
3	38	87%	87%
4	17	65 } 59%	59 } 50%
5	5	40 }	20 }
Total ..	127	80%	77%

It will be noted that this series (which is much larger than ours) has yielded substantially similar results. It was possible to obtain such a large number of cases by enlisting 117 obstetricians to co-operate in the study and to conform to certain standards in recording the results. Some doubt has been expressed, however, with regard to Smith's contention that stilboestrol stimulates the placenta to produce adequate quantities of oestrogen and progesterone (Davies and Fugo, 1947; Sommerville *et al.*, 1949), and it should be noted that this series of cases included both primary and secondary habitual abortions as well as cases of threatened abortion.

It has always seemed to us that the most important hormone for the maintenance of pregnancy is progesterone and that habitual abortion in many cases may be directly due to lack of this hormone. Attempts have been made in the past to counteract this deficiency by means of injections of progesterone given at intervals up to a week; indeed, some of the patients in the present series had been unsuccessfully treated in previous pregnancies with progesterone injections or ethisterone by mouth. We have been impressed, however, with the necessity for maintaining a constant level of exogenous administration. This can be achieved adequately only by means of pellet implantation, and it is for this reason that we have used this mode of administration. The choice of dosage has been arbitrary and may well seem to be low. It should, however, be pointed out that pellet implantation provides the most effective means of complete as well as constant absorption, and we feel that this route of administration may be more efficient than other methods of progesterone therapy.

The substantially similar results obtained by Smith (1948) and ourselves suggest the following possibilities: (1) That administration of oestrogen leads to adequate endogenous secretion of progesterone, and that a constant exogenous supply of progesterone is equally effective in preventing abortion due to recurrent factors. (2) That any therapeutic discipline will induce the patient to take the necessary precautions to prevent another abortion from occurring. (3) That each of the "successfully" treated pregnancies proceeded beyond the 28th week by chance.

The second possibility seems to us unlikely. The last suggestion has been fully considered above. As to the first possibility, our results would indicate that progesterone is the essential hormonal factor for maintaining pregnancy, and that adequate progesterone therapy should not be discounted as a method of preventing the recurrent factor in abortion sequences. The results certainly do not conform with Hamblen's (1939) warning that exogenous progesterone may hinder the intrinsic metabolism of progesterone, nor do they support the contention (Hoffman, 1944) that progesterone therapy should be employed only in cases in which the pregnanediol level has been shown to be subnormal.

Summary

A series of 45 cases of habitual abortion treated prophylactically with progesterone pellet implantation (six 25-mg. pellets) yielded successful results in 86% of the patients with a history of two previous abortions, 89% with three previous abortions, and 75% with four or more previous abortions.

The series was subdivided into "primary" habitual abortion (in which all previous pregnancies had resulted in abortion) and "secondary" habitual abortion (in which one or more previous pregnancies, but not those immediately preceding the treated pregnancy, had proceeded beyond the 28th week). In these groups the results for primary habitual abortion were: 90% success with two previous abortions, 88% success with three previous abortions, and 60% success with four or more previous abortions; and for secondary habitual abortion, 75% success for two consecutive abortions immediately preceding the treated pregnancy and uniform success for the four cases of three or more abortions.

If the true incidence of "recurring" abortion is not much less than 0.1% these results indicate that the treatment was of value.

Statistical Methods Used.—The probabilities of obtaining the observed number of successes and failures in each group have been calculated direct from the binomial theorem, using the three different sets of estimates of the expected success rates. The combined probabilities for each set of three groups have been calculated from the formula: $\chi^2 = -2\Sigma \log_e p$.

Our thanks are due to Professor A. Bradford Hill and Mr. P. Armitage for their interest and advice concerning the statistical methods used, and to members of the staff of the Chelsea Hospital for Women, who have referred many of the cases in this series to us for implantation.

The British Standards Institution has published a British Standard on "Industrial Safety-Gloves." The material, size, and dimensions of many types of safety-gloves are specified, and appendices list the information to be given when ordering the gloves. The specification is obtainable from the institution at 24–28, Victoria Street, London, S.W.1 (4s., post free).

HAEMATEMESIS AND MELAENA

BY

C. D. NEEDHAM, M.D., M.R.C.P.
Assistant Physician, Aberdeen Royal Infirmary

AND

J. A. McCONACHIE, M.B., Ch.B.
Registrar, Aberdeen Royal Infirmary

Widely differing opinions have been expressed concerning the risk to life which accompanies bleeding from non-malignant ulceration of the stomach or duodenum (Chiesman, 1932; Cullinan and Price, 1932; Burger and Hartfall, 1934; G. Gordon-Taylor, 1937; Hurst and Ryle, 1937; Andresen, 1939; Meulengracht, 1939).

Some of the fallacies which abound in the published statistics relating to this condition have been critically discussed by Smith (1945) and also by Avery Jones (1947), who treated a large series of cases in a special gastro-enterological unit, with a mortality of 7.8%. He considered that the mortality has declined to between 5 and 10% during the past decade, but Baker (1947), reporting a series of 576 cases treated in a general hospital, found a mortality of 13.4%, and a recently published series by Lewin and Truelove (1949) showed a mortality of 19.5%. These figures are more likely to be representative of the results obtained in most hospitals, and they show that the management of gastro-duodenal haemorrhage is still far from satisfactory, many patients dying and many more causing grave anxiety and uncertainty regarding the best course to be adopted in their treatment.

More precise knowledge of the features which are of value in assessing the prognosis of the individual patient under the usual routine treatment would be very useful in distinguishing at an early stage which patients are in grave danger of dying from the haemorrhage. Until this particularly serious group of patients can be distinguished it will often be difficult to know whether one can reasonably persist with the routine conservative regime, or whether some other form of treatment should be considered. Much useful information regarding prognostic indications may be obtained from a study of the many papers published on the subject, in particular, Cullinan and Price (1932), Rafsky and Weingarten (1942), Heuer (1946), Baker (1947), Avery Jones (1947), and Lewin and Truelove (1949). But we believe it to be useful to see what further information may be obtained from an analysis of a large series of patients treated recently in the North-east of Scotland, more especially since some characteristics of peptic ulceration—for example, G.U./D.U. ratio—vary with the geographical area (Jamieson, Smith, and Scott, 1949), and it is possible that some features of gastro-duodenal bleeding might vary in the same way.

Present Series

This is a consecutive series of 476 cases of haematemesis and/or melaena admitted as emergencies because of bleeding to the three general medical units of the Aberdeen Royal Infirmary from January, 1941, to December, 1948, inclusive. The series is presumed to include only patients bleeding from peptic ulcers or erosions, because the notes of all cases of haematemesis and melaena from all causes were reviewed, but all those where some other cause was found—for example, gastric carcinoma, portal hypertension with oesophageal varices, blood dyscrasia—

were excluded. Cases in which the notes gave no good evidence of recent appreciable blood loss were also excluded. The patients came from the city and surrounding country, none being refused on account of age or complications.

The mortality rates did not differ significantly in the three medical units despite some differences in the details of the conservative treatment employed.

Occupation.—The patients were drawn from the middle and lower classes. A study of the list of occupations of the patients failed to reveal any sort of predominance of class level or type of occupation within the series. Schanke (1946), in Northern Norway, found a high proportion of gastric ulcers among fishermen; in our series there were only seven fishermen, although there is a large fishing population in the region, and in only one of these was a gastric ulcer demonstrated, though another died and the site of the ulcer is unknown.

Case Records.—Detailed information about each case was obtained from a combination of the medical notes and the nursing charts, both being very full. The case notes of each of these patients have been extracted by one or other of us personally; as observed by Baker (1947) this personal scrutiny is absolutely necessary if the information obtained is to be reliable.

Diagnosis

A history of an ulcer shown by a previous barium meal examination or of an operation for perforation, stenosis, or ulcer pain was obtained in 127 patients (105 men, 22 women), and 157 had suffered a previous haematemesis or melaena. In 384 of the 410 surviving cases barium meal examination was carried out very soon after the test for occult blood in the stool became negative, but in the other 26 survivors it was omitted for various reasons. The results are shown in Table I.

TABLE I.—*Results of Barium Meal Examination*

Gastric ulcer	33
Duodenal ulcer	209
Gastric and duodenal ulcer	4
Jejunal or stomal ulcer	5
No ulcer seen	133
Total barium meals	384

Gastroscopy was never carried out during the bleeding, and in very few cases was it done at a later date. An ulcer was found at operation in 15 cases, and in every one of the 32 that came to necropsy. The situation of the bleeding-point is shown in Table II. Duodenal ulcer

TABLE II.—*Situation of Bleeding-point*

Site of Ulcer	Cases	Deaths
Gastric ulcer	46	11
Duodenal ulcer	240	30
Gastric and duodenal ulcer	5	1
Jejunal or stomal ulcer	7	2
Unknown site	178	22
All cases	476	66

was much commoner than gastric ulcer, which contrasts with the findings in series reported from London (Hurst and Ryle, 1937; Avery Jones, 1947; Tanner, 1949b), but agrees with the increased proportion of duodenal ulcers in Scotland found by Jamieson, Smith, and Scott (1949).

Mortality

Of the 476 patients 66 died (13.9%). This figure includes not only deaths due solely to exsanguination but also: (1) Those in which associated grave complications played a major part, since these complications would probably either not have occurred or else would not have proved fatal in the absence of bleeding (Table III). (2) Those due

TABLE III.—*Deaths Due to Bleeding Associated with Complications (16 Cases)*

Perforated duodenal ulcer following soon after the haemorrhage	4
Pulmonary embolism	3
Severe pyloric stenosis necessitating emergency operation	2
Cerebral thrombosis	2
Pneumonia	2
Congestive heart failure	2
Coronary thrombosis	1

to a haemorrhage in patients enfeebled by pre-existing disease (Table IV). We consider it unrealistic to exclude any of these deaths.

TABLE IV.—*Deaths from Bleeding Associated with Pre-existing Disease (5 Cases)*

Tuberculous right kidney and nephrotic left kidney	1
Coronary thrombosis	1
Paraplegia and general debility	1
Severe mental depression	1
Idiopathic steatorrhoea	1

For reasons to be considered later the series is divided into two groups—those in whom the bleeding recurred after medical treatment had been started following admission to hospital (recurrent), and those who did not suffer such a recurrence (non-recurrent). In only 11 of the 51 fatal cases of the smaller (124) recurrent group was there a major complication in addition to the bleeding to account for death, but in the larger (352) non-recurrent group no fewer than 10 out of the 15 deaths were due to or hastened by major complications.

Acute and Chronic Ulcers

It was not easy to decide which patients were bleeding from a chronic and which from an acute ulcer, but a rough estimate of the number suffering from chronic ulcer may be arrived at by adding together the following groups.

Barium meal showed ulcer crater present after bleeding had ceased	251
Chronic ulcer found at operation	13
Chronic ulcer found at necropsy	29
Some of the 44 patients in whom no direct evidence of the type of ulcer present was obtained—that is, 22 survivors who escaped having barium meal and 22 fatal cases subjected to neither operation nor necropsy. If we take note of the findings in groups 1 and 3 above we can estimate, by simple proportion, that 15 of the 22 survivors and 20 of the 22 fatal cases were suffering from chronic ulcer	35
Total chronic ulcers	328
Total acute ulcers (total cases minus chronic ulcers)	148

On the basis of this calculation 61 (18.5%) of the 328 patients suffering from chronic ulcer died, as opposed to 5 (3.4%) of the remaining 148 patients assumed to be suffering from acute ulcer. These figures are only estimates, but they agree with the findings of other observers (Avery Jones, 1947; Baker, 1947).

Length of Previous History

A previous history of indigestion, epigastric pain, melaena, and other symptoms suggestive of peptic ulcer of more than one year's duration was obtained in 379 cases (79.6%). In the other 97 cases (20.4%) such previous history was either absent or of less than one year's duration.

It is of interest to determine whether the length of history bears any significant relation to the mortality rate or to the type of ulcer present. Table V shows that there was no significant difference between the mortality rates for the two groups.

TABLE V.—*Effect of Length of Previous History*

	Cases	Died
History less than one year	97	11 (11·3%)
History more than one year	379	55 (14·5%)
Total	476	66 (13·9%)

The type of ulcer present is to some extent related to the length of history. Only 11.7% of patients with proved ulcers gave a history of less than one year, but this was obtained in 34.6% of those in whom barium meal failed to show an ulcer.

A dyspeptic history of one year's duration rather than a longer time—for example, five years—was taken as the best dividing-line for distinguishing between the "proved ulcer" and "unproved ulcer" groups at the onset of the bleeding, because it was found that although the number of negative barium meal cases having a history of less than one year—namely, 46 (34.6%)—increased to 66 (49.5%) with a history less than five years, yet the number of "proved ulcer" cases rose proportionately more—from 35 (11.7%) to 91 (30%)—so that the longer history was even less useful in deciding which patients would have a demonstrable ulcer. But the length of history gave little help in the individual case.

Age and Sex Incidence

A considerable proportion (53%) of the patients were aged 50 years or over, and it was in this age group that most of the deaths occurred (Table VI). Many authors take

TABLE VI.—*Age and Sex Incidence*

Age Group	Male		Female		Both Sexes	
	Cases	Died	Cases	Died	Cases	Died
<30	32	1	6	0	38	1
30–39	48	1	13	1	61	2
40–44	43	4	15	1	58	5
45–49	48	2	18	2	66	4
50–59	78	17	36	5	114	22
60–69	43	8	40	7	83	15
70–79	33	10	16	4	49	14
80+	3	2	4	1	7	3
All ages	328	45 (13·8%)	148	21 (14·2%)	476	66 (13·9%)
<50	171	8 (4·6%)	52	4 (7·7%)	223	12 (5·4%)
50+	157	37 (23·5%)	96	17 (17·7%)	253	54 (21·3%)

50 years as the point where the mortality rate rises rapidly, though Thorstad (1942) suggested 45 years, and Avery Jones (1947) found that 60 was a more critical age. The fifth decade of the present series was divided into ages 40–44 and 45–49 to see if any sharp rise of mortality occurred before 50, but this again shows 50 to be the critical point; furthermore, the mortality for the 60–69 age group is no worse than for the 50–59 group, but the figure rises sharply after that. The sex incidence of 69% male and 31% female is in agreement with most reported series; the mortality was roughly equal in the two sexes, and this was true through all the age groups.

Effects of Previous Haemorrhage

There is a difference of opinion whether the prognosis is worse if the patient has suffered one or more previous haemorrhages. This was not so in the present series (Table VII)—a finding in agreement with that of Lewin and Truelove (1949). Of the 26 patients who had had a gastro-enterostomy performed at some earlier date, no fewer than 20 had had at least one haemorrhage subsequent to the operation and previous to the haemorrhage necessitating the present admission—a much higher proportion than in any other group. In seven of these a stomal or jejunal ulcer was later demonstrated, and all of these patients had bled previously.

TABLE VII.—*Effects of Previous Haemorrhage*

	D.U.	G.U.	D.U. and G.U.	Jejunal or Stomal	No Ulcer Demonstrated	Total	Deaths
Had bled previously	92	12	1	7	45	157	21 (13·4%)
Had not bled previously	148	34	4	0	133	319	45 (14·1%)
Total	240	46	5	7	178	476	66 (13·9%)

Severity of the Haemorrhage

The amount of bleeding seen by the patient or attendants gave little help in assessing the actual blood loss. The pulse rate, the haemoglobin level, and the blood pressure have generally been used in attempts to express the patient's condition and progress in an objective manner, and a study of the hourly and half-hourly pulse charts confirmed the general view that a rising or maintained fast pulse rate usually indicated further bleeding, but it showed equally clearly that to wait till the pulse reaches 120 a minute (Baker, 1947; Cecil, 1947), or even 140 a minute (Dunlop, Davidson, and McNee, 1949) before deciding that the patient is ill enough to need transfusion is to wait too long in many cases (Table VIII).

TABLE VIII.—*Maximum Pulse Rate Attained in 66 Fatal Cases*

2 (3%)	failed to reach 100 beats a minute at any time before death
30 (45%)	" " 120 " " " " " "
53 (79%)	" " 140 " " " " " "
13 (21%)	reached 140 beats a minute before death

The well-recognized fall in blood pressure occurred in many cases, but the blood pressure was often well maintained even in the presence of serious haemorrhage, and in a few cases there was a deceptive temporary rise. As observed by Avery Jones (1939), blood transfusion raised lowered blood pressures (as was intended), but not to above normal levels.

It seems that delay in haemodilution following haemorrhage detracts greatly from the value of simple haemoglobin estimation, since in the two days after admission a further fall of 10–20% often occurred unaccompanied by other evidence of bleeding. The lowest haemoglobin level reached perhaps provides some measure of the severity of the bleeding in the group as a whole: in 243 (51%) of the patients it fell to 50% (Haldane) or lower; in 87 (18.3%) it fell to 30% or lower.

Recurrent Bleeding

If the age factor was excluded little guidance regarding the ultimate outcome could be obtained at the time of admission, however carefully the patient's history and condition were assessed. But the next few days after admission supplied a more definite guide. Brisk recurrent haemorrhage after admission to hospital has been generally recognized as being of serious prognostic significance. Of the 476 patients, 124 (26%) suffered a recurrence and 51 (41%) of these died; 352 (74%) did not bleed again, and only 15 (4.25%) of this group died. Table IX gives details of the combined effects of age and recurrence of bleeding, and Table X shows that sex had little influence on the mortality in either group.

The difference between mortality in the male and that in the female recurrent group is not statistically significant.

TABLE IX.—*Effect of Age and Recurrence of Bleeding*

Age Group	Non-recurrent		Recurrent	
	No. of Cases	Died	No. of Cases	Died
<30	29	0	9	1
30–39	47	0	14	2
40–44	45	1	13	4
45–49	50	1	16	3
50–59	77	3	37	19
60–69	61	3	22	12
70–79	37	5	12	9
80+	6	2	1	1
All ages ..	352	15 (4·25%)	124	51 (41·1%)
<50	171	2 (1·2%)	52	10 (19·2%)
50+	181	13 (7·1%)	72	41 (57%)
50–69	138	6 (4·5%)	59	31 (51·5%)

Table IX shows that it is the sudden worsening in the prognosis at the age of 50 years in the recurrent group which influences the mortality figures for the whole series, because the non-recurrent group does not experience a sharp rise in mortality until 20 years later. It seems to us that the high mortality in these two decades—which

TABLE X.—*Effect of Sex and Recurrence*

Sex	Non-recurrent		Recurrent	
	No. of Cases	Died	No. of Cases	Died
Male	237	10 (4·2%)	95	35 (38·5%)
Female	115	5 (4·3%)	33	16 (48·5%)
Both sexes ..	352	15 (4·25%)	124	51 (41·1%)

are of great domestic and economic importance—shows that a critical review of the usual methods of treatment is necessary, for this age group at least. Patients over 70 showed a still higher mortality, but this is not so disquieting as in younger age groups. The mortality under the age of 50 has sometimes been considered to be negligible, but this was certainly not true here if bleeding recurred; the youngest death was in a man aged 22 who died after many recurrences.

The mortality at all ages rises abruptly as soon as there is a recurrence of the bleeding (Table IX). Other authors have considered that the risk of dying is greater if there is more than one recurrence of bleeding (Cullinan and Price, 1932; Baker, 1947; Avery Jones, 1947); our figures show the same trend, but the number of such cases in any one series is small.

The risk is not to be estimated by a comparison of the mortality rates in the "single recurrence" and the "multiple recurrence" groups, because it is not known at the time of the first recurrence whether any given patient is going to suffer a further recurrence; what is known is that he now belongs to the "total recurrent" group, and so it is by a comparison of the mortality in this group with the mortality in the "multiple recurrence" group that the physician can decide whether he will obtain a more definite indication of the danger to his patient's life if there is a further recurrence. Table XI shows that the furtner rise in mortality in the "multiple recurrence" group is relatively small (it is not statistically "significant" even in the collected total of cases) compared with the very large increase in risk which the first recurrence indicated.

Although it has long been recognized that recurrent bleeding is of grave prognostic significance, it is probably not generally realized how little is to be gained by waiting to see if there is going to be a further recurrence before considering the question of surgical intervention. The importance of recurrent bleeding is more apparent when one recalls that grave complications were present in only 11 of the 51 patients dying from recurrent bleeding as opposed to 10 of the 15 dying from a first haemorrhage; thus if we deduct these cases from each of the two groups

TABLE XI.—*Effect of Recurrence (Various Authors)*

	Single Recurrence		Multiple Recurrence		Total	
	No.	Died	No.	Died	No.	Died
Cullinan and Price (1932) ..	18	4 (22%)	21	12 (60%)	39	16 (40%)
Baker (1947) ..	151	44 (29%)	34	14 (40%)	185	58 (31·4%)
Avery Jones (1947)	46	9 (20%)	57	17 (30%)	103	26 (25·3%)
Present series ..	83	32 (38·5%)	41	19 (46%)	124	51 (41%)
Total ..	298	89 (30%)	153	62 (40%)	451	151 (33·4%)

we obtain: 5 deaths (1.45%) in 342 patients without recurrent bleeding, and 40 deaths (35.4%) in 113 patients with recurrent bleeding.

This shows that, whereas recurrent bleeding by itself often causes death, a first haemorrhage is rarely fatal in the absence of complications.

Throughout all these years blood was readily available from the blood bank and was freely used. Not all fatal cases were transfused, because, as shown earlier, some were suffering from complications which would have made transfusion merely one further hazard. But, however much blood was used, there were some patients who bled so rapidly or so persistently that it was impossible to maintain an adequate circulation.

The reason for this was obvious at necropsy, which was performed in 32 of the 66 fatal cases. In every case an ulcer was found; two had perforated and so caused death, and in 24 of the remaining 30 an eroded artery was present in the ulcer base. In addition, spurting arteries in the ulcer base were seen at operation in two patients who recovered and in one who died but did not come to necropsy.

Surgical Treatment

There is general agreement that an eroded artery of some size is commonly found in the base of the ulcer in fatal cases (Heuer, 1946; Avery Jones, 1947). Conservative treatment of bleeding from a vessel in an ulcer probably immobile through adherence to other structures seems to us to be a hazardous procedure, depending for success as it does upon the formation of enough firm adherent clot at the bleeding-point. Not infrequently arrest of the haemorrhage does occur in this fortunate manner, and the patient recovers (if he does not bleed again); but often the bleeding does not cease. Therefore the question of direct operative attack on the bleeding-point must at least be considered when it is felt that the haemorrhage may be coming from an eroded artery.

In this hospital, as in most clinics, operative treatment for bleeding peptic ulcer was undertaken only after severe long-continued bleeding (11 cases with 7 deaths), or when some complication forced the issue (4 times for severe pyloric stenosis, once for perforated duodenal ulcer—all fatal).

Obviously these results in no way reflect the surgical risk involved in operating on patients who are not in such desperate straits. The mortality rate and necropsy findings in this and other reported series show that some cases at least must be treated surgically. The most pressing problem must be the group showing the highest mortality under the present methods of treatment—namely, those

who suffer a recurrence of bleeding, especially those aged over 50 (Table IX). Other reported series agree in showing an alarmingly high mortality in the "recurrent" group (Chiesman, 1932; Cullinan and Price, 1942; Avery Jones, 1947).

For several years Finsterer (1947) has strongly advocated early operation—immediate if the patient's history makes it probable that he is suffering from a chronic peptic ulcer, but after the first recurrence if there is no such history. More recently, Tanner (1949a, 1949b) has adopted this routine. Despite the good results obtained in their hands this seems inadvisable as a general policy, because most patients who are bleeding even from a known peptic ulcer are not in danger under conservative treatment. Even in the "recurrent" bleeding group those patients already known to be suffering from a peptic ulcer fared no worse than those with no definite history: among 39 patients known to be suffering from peptic ulcer there were 15 deaths, and among 85 not known to be suffering from peptic ulcer there were 36 deaths.

Sometimes the patient is bleeding from an acute ulcer, as indeed was the case in two of the men who were treated surgically; both survived, but both had bled very alarmingly for several days before operation was decided upon; Ives (1949) quotes two similar cases. In our series death was due to recurrent haemorrhage from acute D.U. in one man and acute G.U. in two women: eroded arteries were found in the base of two of these ulcers—a finding in agreement with Heuer (1946). Therefore, although it is true that haemorrhage from an acute ulcer is less likely to prove fatal than that from a chronic ulcer, it seems that this may be only because acute ulcers are less apt to cause severe recurrent haemorrhage; but when they do so they may cause death.

Analysis of the results in the present series shows that the first recurrence of bleeding was the real warning of the grave danger which threatened these patients (Table XI). Little further information could be obtained by waiting, or at least not until an almost terminal stage, which was too late to be useful. If operation is to be done it should be carried out as soon as the patient can be resuscitated from the shock of this first recurrence. The problem arises whether the risk of operating at the time of the first recurrence on all such patients, including those who would survive if treated medically, is outweighed by the gain in operating on all those who would die without surgical intervention.

We weighed up all the available information obtained from a careful study of the case notes of the 124 "recurrent" cases and found it possible to classify the patients into three groups as regards operability at the time of the first recurrence (Table XII).

In the group with the worst prognosis—namely, the 72 "recurrent" cases aged over 50, of whom 41 (57%) died—we find that 47 were certainly operable, and 24 of these died (but in 5 of these 24 fatal cases the bleeding was so rapid that only a speedy decision to operate could have prevented death). Operation at the time of the first recurrence should improve the results in this type of case. The indications in those aged under 50 are less definite.

TABLE XII.—*Operability at First Recurrence*

Age		Group 1: Operable	Group 2: Probably Operable	Group 3: Not Operable	Total
50 plus ..	Survived	23	6	2	31
	Died	24	7	10	41
Less than 50	Survived	42	0	0	42
	Died	9	1	0	10
Total ..		98	14	12	124

The question of what operation should be done depends to a great extent on the individual case, and must be left to the discretion of the surgeon at the time of operation, but it seems that the actual bleeding-point should be removed if at all possible, and partial gastrectomy, including removal of a duodenal ulcer, seems to be the operation of choice (Ives, 1949; Tanner, 1949b). Lesser measures, such as simple oversewing of the ulcer, cannot always be relied on to stop the bleeding (Heuer, 1946; Baker, 1947; Ives, 1949). If gastrectomy with removal of the part of the duodenum containing the ulcer is done and the patient survives, his future prospects of freedom from ulcer pains, haemorrhage, or perforation should be better than if the ulcer were still present. This would apply especially to the patient with a long-standing history of persistent pain, for whom partial gastrectomy is often done even apart from any question of haemorrhage. However, these are difficult cases requiring much experience in gastric surgery, and in the weaker patients Tanner (1949a, 1949b) advises that a modified procedure be used.

When a chronic ulcer is not found it would probably be wiser to do a partial gastrectomy (Ives, 1949), at least in patients over 50, and especially if there is a long history of dyspepsia. Operation will be done only in patients who have suffered recurrent haemorrhage, and, as we have seen, eroded arteries of some size may be found in small acute ulcers.

Associated Pyloric Stenosis.—Pyloric stenosis, by which we mean not merely transient pylorospasm, was present in 25 cases (5%), and proved to be a dangerous complication, as 12 of those 25 patients died. It occurred more commonly in the higher age group (age less than 50 years—4 cases, 1 death; age over 50—21 cases, 11 deaths). Operation was carried out in nine cases because of the combination of bleeding and stenosis, and six of these patients died. Of the 16 treated without operation six died. It seems unlikely that any of the nine patients operated upon would have survived without surgical intervention. The operative mortality was high, but since operation was done on the worst cases, excluding those actually moribund, the conservative and operative treatment cannot be compared.

Baker (1947) pointed out the poor prognosis which attends a combination of pyloric stenosis and recurrent haemorrhage; the present series bears this out (see above), and it seems that this is an added indication for operation at the time of the first recurrence.

Surgical Consultation

It has been suggested that cases of gastro-duodenal haemorrhage should be admitted direct to a surgical ward, but this view is not likely to gain general support, because in the majority of cases there is never any question of necessity for surgical treatment; moreover, medical wards are usually quieter and more restful than surgical wards, and quiet surroundings are important in the treatment of bleeding from peptic ulcer. But it is necessary to avoid delaying consultation with the surgeon until the patient is in a very weak state and appears about to die fairly soon under continued medical treatment. Surgical consultation should not automatically mean that an operation will be done. A reasonable arrangement, which would ensure that the surgeon's time is not wasted in seeing many patients unnecessarily, but which would enable him to see at an early stage those in whom operation must be

considered, would be to regard the first recurrence of bleeding in all cases, below 50 years of age as well as above, as an indication for joint medical and surgical consultation on immediate treatment. Furthermore, such a definite plan would make it possible to deal promptly with those patients who bleed rapidly at the time of the first recurrence.

Summary and Conclusions

An analysis of the case notes of the 476 patients admitted to the medical wards of the Aberdeen Royal Infirmary on account of haematemesis and/or melaena from peptic ulcer during the years 1941–8 inclusive is presented. Reference is made to some of the publications on this subject.

Sixty-six patients died: this mortality of 13.9% probably represents that obtained in most general hospitals; therefore many patients still die from this complication of peptic ulcer.

In the 298 cases in which the ulcer site was known, duodenal ulcer was found to be five times more common than gastric ulcer.

The difficulties in deciding whether the bleeding is coming from an acute or from a chronic ulcer are discussed. The risk of death from bleeding from an acute ulcer is less than when the bleeding is coming from a chronic ulcer, but is by no means negligible.

There was a sudden marked increase in the mortality at the age of 50; the next sharp rise did not occur until 70; 53% of the patients were over 50.

The mortality rate was not higher in the group of patients who gave a history of one or more previous haemorrhages.

It was difficult to judge the degree of the severity of the bleeding. The hourly pulse chart was a useful guide, but in many patients who died the pulse rate never reached even 120, much less the 140 beats a minute often considered to be an indication for starting blood transfusion.

Recurrent haemorrhage after admission to hospital was the most reliable warning of the serious nature of the bleeding in all age groups, the risk of dying being eight to ten times greater in the recurrent group. An eroded artery in the base of an ulcer is usually the source of this type of haemorrhage.

The limitations of medical treatment and the possibility of employing surgical measures for recurrent bleeding are considered, and it is concluded that surgical treatment is indicated in the majority of patients aged over 50 who suffer a further haemorrhage after admission to hospital.

A scheme for close co-operation between physician and surgeon over these cases is suggested.

We are indebted to Dr. R. J. Duthie, Dr. Ian Gordon, and Professor H. W. Fullerton for permission to make use of the case records from the medical wards.

HAEMORRHAGE FROM PEPTIC ULCER

A REPORT ON 170 CASES

BY

A. G. OGILVIE, M.D., F.R.C.P.

AND

I. O. B. SPENCER, M.B., M.R.C.P.

(From the Royal Victoria Infirmary, Newcastle-upon-Tyne)

The general trend of mortality from gastro-duodenal haemorrhage has fluctuated considerably since the beginning of the century. Mortality was relatively low at 4% to 7% during the first 20 years, but from 1920 to 1935 the reported figures showed a rise to 25%. More recently there has been a general fall to a level of 8% or below. The explanation of these variations has been considered in detail by Avery Jones (1947), to whose writings reference is advised.

The recent decline in mortality is generally attributed to the introduction of drip-transfusion by Marriott and Kekwick (1935), to the wider recognition of the need of these patients for an adequate fluid intake, and to the abandonment of complete starvation as a routine treatment. Lewin and Truelove (1949), however, seemed to sound a note of alarm. They reported a mortality of 16.6% in a series of 252 cases of haemorrhage from peptic ulcer admitted to the Radcliffe Infirmary over a period of 10 years (1938–47), and speculated on the advisability of gastrectomy as a prophylactic measure in patients of middle age with a known peptic ulcer.

The cases which we wish to record include all patients with gastro-duodenal haemorrhage encountered over a period of seven years (1941–8). This period is not a selected one; it is simply the time during which the wards concerned have been under the charge of one of us (A. G. O.).

The clinic serving these wards is a general medical clinic in a teaching hospital, and if it has a bias this is not in favour of gastro-enterology. Gastric cases receive ordinary and careful treatment (we believe), but no claim to any special interest or experience in this type of case is made. To our treatment of peptic haemorrhage the same remarks apply, and yet we have not found that this complication holds any remarkable terrors.

The general line of treatment may be briefly summarized. Morphine is administered on admission as a general rule and 6-oz. (170-ml.) milk feeds are given every two hours. Fluid by mouth is encouraged in addition to this, and little difficulty has been experienced in maintaining an adequate intake by this route. Magnesium trisilicate is given only if the patient complains of pain. A routine daily dose of 150 mg. of ascorbic acid was given (this was later increased to 500 mg). Iron is administered at a later stage if required for anaemia.

The criteria of the need for blood transfusion have been two in number—the hourly pulse rate and our personal assessment of the patient's condition and progress. The blood pressure and the haemoglobin level have been taken into account, but have not been allowed to deflect our judgment. The necessity for maintaining an adequate haemoglobin level as a condition of general recovery and local healing, as emphasized by Avery Jones, has been recognized. A study of the cases in retrospect has shown a tendency for transfusion to be employed more often in the treatment of those patients with low haemoglobin levels and low blood pressure, but patients with normal or slightly subnormal readings were among those in whom transfusion was regarded as necessary. Out of 170 cases 42 were treated by transfusion, or roughly one in every four.

Surgery was only occasionally employed. Only two patients were treated surgically on account of bleeding, though after recovery seven were operated on because of pyloric stenosis or large chronic ulcer. Surgical treatment on an extensive scale has recently been advocated (Tanner, 1949), but we feel that the mortality figures given do not compare favourably with our own or with other reported series treated mainly by medical means.

Diagnostic Criteria (Table I)

Every patient gave a clear history of the vomiting of bright or altered blood and/or the passage of definitely melaenatous stools. Cases in which the amount of blood lost was evidently small have been omitted. The diagnosis of peptic ulcer was based on a careful consideration of the history and on the general examination. Radiological examination was carried out in only 71 cases out of the 170, owing to the limitations imposed by wartime conditions. The results in these 71 cases are given in Table II.

TABLE I.—*Diagnostic Criteria in 170 Cases of Haemorrhage from Peptic Ulcer*

Criterion	Gastric Ulcer	Duodenal Ulcer	Site Uncertain	Total
Radiology ..	8	16	0	24
Operation ..	3	8	0	11
Necropsy ..	2	0	0	2
Clinical ..	0	0	133	133
Total ..	13	24	133	170

Note.—All the ulcers diagnosed radiologically or by other means were chronic ulcers, with one exception. Certain cases diagnosed radiologically were later operated on, the diagnosis being confirmed. These have been included under the head of "operation."

TABLE II.—*Radiological Diagnosis in 71 Cases of Haemorrhage from Peptic Ulcer*

Duodenal ulcer	16
Gastric ulcer	11
No abnormality	44

The length of the digestive history is shown in Table III. It will be observed that patients with a long history of indigestion predominated (more than five years in over half of the cases). It would not be right to assume, however, that this implies an equivalent preponderance of chronic ulceration. The age and sex distribution of our cases is shown in Table IV; and in Table V a comparison is made with the series of Avery Jones and of Lewin and Truelove.

TABLE III.—*Length of Digestive History*

Duration	No. of Cases
Less than 3 months	41 (20·6%)
3 months to 5 years	34 (23·5%)
Over 5 years (average 17·1 years)	95 (55·9%)

TABLE IV.—*Age and Sex Distribution in Present Series*

Age in Years	Males	Females	Deaths
Under 30	14 (8·2%)	6 (3·5%)	0
30–39	21 (12·4%)	7 (4·1%)	0
40–49	34 (20·0%)	17 (10·0%)	1
50–59	28 (16·5%)	16 (9·4%)	1
60–69	11 (6·5%)	13 (7·6%)	0
70 and over	2 (1·2%)	1 (0·6%)	2
Total ..	110 (64·8%)	60 (35·2%)	4

Note.—It is clear that the sex ratio is much the same as in other reported series.

TABLE V.—*Comparison with Other Series*

Age in Years	Present Series		Avery Jones		Lewin and Truelove	
	No. of Cases	Percentage of Deaths	No. of Cases	Percentage of Deaths	No. of Cases	Percentage of Deaths
Under 30 ..	20	0	40	2·5	20	0
30–39 ..	28	0	81	1·2	37	5·4
40–49 ..	51	2·0	146	4·1	58	6·9
50–59 ..	44	2·3	145	5·5	69	21·7
60–69 ..	24	0	108	12·5	46	30·8
70 and over ..	3	66·7*	75	21·3	22	31·8
All ages ..	170	2·4	615	7·8	252	16·6
Under 60 ..	143	1·4	412	3·9	184	11·4
Over 60 ..	27	7·4	203	15·6	68	30·9

* This value is not significantly different from the percentages of the other two series—that is, 2 deaths from 3 cases could occur by chance when the percentage fatality was either 21·3 or 31·8.

The Four Fatal Cases

Case 1.—A man aged 72 gave a 14-years history of intermittent epigastric pain, occurring three-quarters of an hour after meals and during the night. He had had an occasional vomit, but this had always been small in amount. He had lost 2 st. (12.7 kg.) in weight gradually over the two years prior to admission. Ten days before admission he vomited about a pint (570 ml.) of black fluid during a bout of severe pain. On the day of admission he vomited fresh blood. On examination his general condition was quite good. His pulse was 96 and his blood pressure 110/80; he was not obviously dehydrated, and no abnormality could be made out on cautious examination of the abdomen. He was treated on the general lines already mentioned, and his condition remained satisfactory, except for a single vomit of bile-stained fluid, until the fourth day after admission, when he died suddenly. Unfortunately permission for necropsy could not be obtained. Death was thought to have been caused by a coronary thrombosis.

Comment.—Coronary thrombosis is a recognized complication of haematemesis, but it is difficult to see how it could have been prevented in this case.

Case 2.—A man aged 77 had suffered perforation of a duodenal ulcer 30 years previously, and gastro-enterostomy had been performed. There was no history of any indigestion since that time, and in August, 1948, he was apparently in good health. He then vomited a "large" amount of blood, and was at once admitted to hospital. He was found to be wasted (weight 8 st. 9 lb. = 55 kg.) and dehydrated, but apart from this was in fairly good general condition (pulse 90, blood pressure 110/80, haemoglobin 109%). On the day after admission he vomited several times, but the vomitus contained no blood. One pint of saline and 2 pints (1.14 litres) of plasma were infused, but his condition deteriorated, and he died on the third day after admission. At necropsy an acute gastric erosion, pulmonary atheroma and anthracosis, and dilatation of the right ventricle were the only abnormal findings. Death was thought to have been caused by myocardial insufficiency and peripheral circulatory failure. There was no indication that the infusion had played any significant part in the fatal issue.

Comment.—This man was old and debilitated, and we think that these were the main factors preventing recovery from a haemorrhage which in itself was not particularly severe. Death was regarded as inevitable.

Case 3.—A woman aged 49 gave an eight-months history of abdominal pain, radiating to the left shoulder, occurring after meals and during the night. On March 4, 1946, while shopping, she vomited bright red blood, and a further haematemesis occurred after she reached home. On admission to hospital her general condition was found to be good. Transfusion did not seem to be required. She progressed satisfactorily on dietetic treatment until March 17, when a third haemorrhage took place necessitating a transfusion of 2 pints of blood. Three days later her haemoglobin level was 68%, and she seemed to be fit for operation. Surgical advice was sought on account of the repeated haematemesis, and laparotomy was performed on March 22, but no abnormality was discovered. Three days after operation a further bleeding occurred, and in spite of blood transfusion she died following a sudden collapse two days later. Necropsy showed a chronic gastric ulcer adherent to the pancreas, with an eroded artery in its base. A large amount of blood was present in the intestinal tract.

Comment.—This woman died of haemorrhage. The decision to operate was justified by the findings at necropsy and by the eventual fatal outcome. The patient was in good condition at the time of the operation, and had the ulcer been found she might well have been alive to-day.

Case 4.—A man aged 57 was admitted to a surgical ward on account of indigestion. A blood examination showed a red cell count of 5,000,000 per c.mm. and a haemoglobin percentage of 95. Next day he vomited bright red blood, and was transferred to the medical side. Further haematemesis occurred during the succeeding 48 hours, and he died on the fifth day after admission. Transfusion was carried out on the day of death, but without effect. Permission for necropsy was not obtained.

Comment.—The treatment in this case is open to criticism. Transfusion was too long delayed and no surgical opinion was sought. When the case is surveyed in retrospect it seems clear that prompt and adequate transfusion followed by operation would probably have saved the patient's life.

Discussion

The series is not a very large one, but it must be remembered that the cases were spread over seven years. The mortality has been very low over this period, and might have been even lower, as a study of our four fatal cases shows that in two of them errors of judgment were made.

The comparison of one series of haemorrhages from peptic ulcer with another is difficult and full of pitfalls, and it is perhaps tempting to avoid it by simply stating the results and leaving the conclusions to the reader. As, however, our object in reporting these cases has been to advance the conclusion to which our experience has led us—namely, that these patients can be successfully treated in an ordinary medical ward—we feel that such a comparison must be attempted.

Any series with a low mortality, such as ours, is open to four main suggestions or criticisms. First, that there may be an excess of females, with their lower mortality. This is disproved by the figures in Table IV, which show that our sex ratio is almost exactly that of Avery Jones, with his 615 cases. Secondly, it may be suggested that our low death rate may be due to the fact that we have met with a somewhat younger age group than either Avery Jones or Lewin and Truelove. We have, however, analysed our cases in age groups, and the mortality is seen to be lower in each age group than in either of the two quoted series, with the exception of the "over 70" group. The numbers here are, however, too small for conclusions to be drawn.

Thirdly, a much more serious criticism may be advanced. Avery Jones's figures show that the mortality of haemorrhage from chronic peptic ulcer is seven times that of the bleeding acute ulcer (12.3% as against 1.8%). Here our relative lack of radiological and complete lack of gastroscopic evidence may seem to be a grave defect. It has, for instance, prevented a reliable classification of our cases into acute and chronic ulceration. We regard the criterion of mere duration and periodicity, used by Lewin and Truelove, as insufficiently reliable. The only way in which accurate classification can be made is by the full investigation of each case as carried out by Avery Jones.

We see no reason why the incidence of acute ulcers in our series should differ widely from that of Avery Jones, but we cannot deny the possibility that we encountered a high proportion. This, however, does not in our view affect our main thesis as stated above. We have, after all, proved 36 chronic ulcers, in one way or another, as shown in Table I. (At necropsy one of our fatal cases showed an acute ulcer.) These 36 cases included one fatal case, and we are left with one known fatal acute ulcer and two fatal cases with no necropsy out of the remaining 134 cases. Even were we to suppose that all our unproved cases had bled from an acute ulcer, a hitherto unparalleled incidence, the mortality remains satisfactory (3% for chronic ulcers and 2.3% for acute ulcers).

The fourth and final criticism which we have to anticipate is that our series included an unduly large number of duodenal ulcers. Avery Jones has shown that the mortality of bleeding duodenal ulcers is only half that of the chronic gastric ulcers which bleed. It is indeed likely that this is so. The incidence of duodenal ulcer is much higher in the North of England than it is in London and the South. Strang and Spencer (1950), in a study of perforated ulcers admitted in one year to the Royal Victoria Infirmary, Newcastle-upon-Tyne, noted 145 duodenal ulcers and 43 gastric ulcers in 189 cases, a ratio of 3.4:1. A study of reported figures for London and the South shows that the incidence there is roughly equal, approaching 1:1.

Here again, however, the main argument regarding the mortality achieved in a general medical ward remains unaffected. We proved, in one way or another, as shown in Table I, 13 gastric and 24 duodenal ulcers, and we know that two of our fatal cases bled from gastric ulcers. Again making the most unlikely supposition that all our "unproved" cases bled from duodenal ulcers, we obtain a mortality of 15.4% for gastric ulcers and a mortality of 1.3% for duodenal ulcers, to set against the figures of 20% for chronic gastric ulcers and 9% for duodenal ulcers given by Avery Jones.

The *reductio ad absurdum* method of argument can of course be criticized. But, given our regrettable and unavoidable lack of radiological and gastroscopic evidence, we feel that no other method was open to us.

The series suggests that surgery has a small though important part to play in treatment. It is, however, essential that when necessary it must be utilized in good time. When it is clear that haemorrhage is continuing, or is recurrent, the surgeon must at once be called. He must of course be presented with a patient in reasonably good condition and with a haemoglobin of over 70%, or as near 70% as possible. It is unfair to ask a surgeon to operate on an anaemic wreck, thus forcing him to a hurried survey of the abdomen and a hasty operation.

We can see little indication that prophylactic gastrectomy is likely to reduce the mortality of a possible complication which in itself has a mortality as low as, if not lower than, that of the operation designed to prevent it.

The essentials of medical treatment seem to be replacement of fluid loss by mouth, regular fluid and thickened feeds at frequent intervals, and prompt, adequate, and accurately timed transfusion. This entails active observation and careful supervision of all cases; but it does not seem to call for very unusual skill or facilities. We have been impressed by the value of the hourly pulse chart, maintained for at least a week after cessation of bleeding, and by the need for frequent and regular consideration of the patient's general condition, if transfusions are to be timed and controlled properly.

We have admitted one medical failure, but submit that one failure in 170 cases in a period of seven years does not invalidate our claim that the ordinary medical ward is a suitable place for the treatment of haemorrhage from peptic ulcer. The other failure was surgical in the sense that the ulcer was not found at operation. We cannot judge of the advisability of gastrotomy in such a case, but to us the argument in favour of partial gastrectomy, even in the absence of a palpable ulcer, is supported by this example.

The opportunities which these cases provide for the teaching of students and the training of house-physicians seem to be an additional argument in favour of continuing the present practice of admitting the cases to general medical wards.

Avery Jones has emphasized the advantages of the concentration of all gastro-enterological emergencies into special wards as a means of reducing mortality. We are here concerned only with haemorrhage from peptic ulcer, but as our experience has not lent support to a widespread adoption of such a system we have felt obliged to report it.

The value of special gastro-enterological clinics is not in dispute. The work of Avery Jones and others is in itself a demonstration of it. We feel, however, that such clinics should be centres of research over the whole field of gastro-enterology and of the treatment of cases requiring special skill and facilities, and that the concentration of all gastro-enterological emergencies into special wards would be a mistake.

Finally, we believe that the figures presented show that haemorrhage from peptic ulcer is not the highly dangerous condition it is sometimes thought to be. In fact, we would contend that, with a few exceptions, patients under the age of 70 who bleed from a peptic ulcer should recover. Whenever a death occurs in a patient under this age it should stimulate a critical inquiry. If this were done, we think it would be found that the treatment was faulty in one or more respects, as we ourselves have discovered in two out of our four fatalities.

Summary and Conclusions

A series of 170 cases of haemorrhage from peptic ulcer with an overall mortality of 2.4% is reported. Although in the majority radiological evidence of the site and chronicity of the ulcers was lacking, the mortality was found to be low enough to compare favourably with other reported series, even if all our "unproved" cases are assumed to have been acute or duodenal ulcers with their generally accepted high recovery rate.

The patients were treated in a general medical clinic where the bias of interest was not in favour of gastro-enterology.

The treatment given was replacement of fluid loss by mouth (except in the occasional case in which special circumstances compelled the use of the intravenous route), regular fluid or semi-solid feeds at frequent intervals, and blood transfusions as and when required. Ascorbic acid was given as a routine, but magnesium trisilicate powder was given only to relieve pain, which it usually did.

There were only four deaths in the series, and of these two might possibly have been prevented. One was a medical failure, the other a surgical failure. Nevertheless, these results are regarded as a vindication of the general medical ward as a suitable place for the treatment of gastro-duodenal haemorrhage.

There were only two inevitable deaths in 170 cases: it is considered that this fact constitutes an argument against prophylactic operations.

It is suggested that whenever a patient under the age of 70 dies from peptic haemorrhage a critical review of the treatment is indicated.

The treatment demands strict attention to detail and close and continuous observation of the individual patient, but special experience and facilities are not essential.

The indications for blood transfusion used were the hourly pulse rate and a personal assessment of the patient's condition and progress.

Surgical aid was invoked on only two occasions, though it is now realized that in a third case an operation was indicated and might well have saved the patient's life. Of the two patients treated by operation, one recovered and one died.

We gratefully acknowledge the invaluable assistance given by Dr. C. Strang and by a succession of energetic and competent house-physicians in the medical treatment of the patients, and also the work of the late Sister M. Andrews, who was responsible for the nursing throughout the relevant period. We are also indebted to Dr. C. Strang and Dr. D. Maclean for their help in the not inconsiderable labour entailed in the analysis of the case records, and to Dr. W. J. Martin for statistical assistance.

VALUE OF TUBERCULIN-JELLY TEST

BY

W. POINTON DICK,* M.R.C.S., L.R.C.P.

(From the Tuberculosis Research Unit, Medical Research Council)

The tuberculin-jelly test to determine tuberculin sensitivity has gained considerable support in this country and abroad. It has been used in mass immunization campaigns to select persons suitable for vaccination with B.C.G. Its great advantage over the Mantoux test is that no injection is involved. In addition, its application is so simple that this can be entrusted to a wide range of personnel.

In the past, estimates of the equivalent of the jelly test in terms of old tuberculin injected intradermally have varied from concentrations of 1 in 50,000 to 1 in 100 (Wolff, 1934; Kereszturi, 1941; Holm and Holm, 1943; Grozin, 1943; Paterson, 1944; Climie, 1945). Doubts of the reliability of the test having been expressed, the following investigations were undertaken in order to find a type of jelly and a technique which would give a sufficiently high degree of accuracy and sensitivity in terms of the established Mantoux test. Part of this work was done prior to the Medical Research Council's Tuberculin Survey (now being completed). The technique subsequently used throughout the Survey was based on the findings reported here.

Three tuberculin jellies were compared. Each was made up with a tragacanth base and enough glycerin to bring the total concentration of the latter in the jelly to 40–50%. The first jelly contained 0.2% of purified protein derivative (P.P.D.)†; this concentration was chosen so that the jelly should be approximately equal in tuberculo-protein content to undiluted old tuberculin. The second jelly contained 60% of old tuberculin (O.T.) v/w, and the third 85% of O.T. v/w.

Techniques

Original Technique.—The skin over the interscapular region was cleansed by vigorous rubbing with acetone on cotton-wool and allowed to dry. Tuberculin jelly was then applied from a collapsible tube to the prepared area of skin to form a V with arms about 2 cm. in length and 2–3 mm. in width. This was covered with a strip of adhesive plaster measuring about 2 by 1 in. (5 by 2.5 cm.), and with its long axis parallel to the spine. The examinee

*Seconded from the service of the North-west Metropolitan Regional Hospital Board.

†I am indebted for the supply of this tuberculin to the Veterinary Laboratory, Ministry of Agriculture and Fisheries, Weybridge, Surrey.

was instructed to remove the plaster after 48 hours and the test was read on the following day. This method will be referred to as the original technique.

Modified or Flourpaper Technique.—Deane (1946) modified the original technique by rubbing the skin with sandpaper after the cleansing with acetone and before application of the jelly. It has been found, however, that the grade of sandpaper, "O," recommended is too abrasive and can cause very severe reactions in persons with a high degree of sensitivity to tuberculin and with delicate skins. A type of fine abrasive paper, termed "flourpaper" in the trade, has therefore been substituted in the present work. This was used in 1-in.-wide strips, six *gentle* strokes being given. A new piece of flourpaper was used for each test.

Comparisons were made between the original and the flourpaper techniques and between the three types of jelly, the more promising being measured against intradermal O.T. Where two jelly tests were compared they were applied one on each side of the spine of each person examined. At the time of the reading of the tests one side would remain covered while the other was read. The tests were read 24 to 48 hours after the removal of the plaster—that is, 72 to 96 hours after the application of the jelly. Erythema was ignored. Four or more vesicles at the site of application of the jelly were read as a positive reaction. Less vesiculation was read as a doubtful reaction and classified as negative.

Evaluation of Flourpaper Technique

Comparisons of Jelly Tests With and Without Flourpaper

A total of 350 school-children aged 11 to 15 and 524 aged 14 to 19 received two tests, using the P.P.D. jelly. In one test the original technique was used, in the other flourpaper was applied as described above. On a further 339 children aged 11 to 15 and 338 aged 13 to 18 similar tests were performed, but using 60% O.T. jelly. The results of these tests are given in Table I. They show the marked increase in the number of positive reactions that were obtained following the use of flourpaper. With the P.P.D. jelly the number of positive reactions after the test with the original technique was in one group only 21% and in another group only 9% of the number obtained with the flourpaper technique. With the O.T. jelly the corresponding figures were 38% and 42%. All four differences were statistically highly significant.

From these results it was evident that preparation of the skin with flourpaper greatly increased the number of positive reactions obtained. It was essential to determine if these were true tuberculin reactions or false positives attributable solely to the abrasion.

TABLE I.—*P.P.D. and O.T. Jelly, With and Without Flourpaper*

Age in Years	No. Examined	Test A, with Flourpaper		Test B, without Flourpaper		Positives to B as Proportion of Positives to A
		Jelly Used	No. Pos.	Jelly Used	No. Pos.	
11–15	350	P.P.D. 2 mg./g.	62 (18%)	P.P.D. 2 mg./g.	13 (4%)	21%
14–19	524	,,	139 (27%)	,,	13 (2·5%)	9%
11–15	339	O.T. 60%	71 (21%)	O.T. 60%	27 (8%)	38%
13–18	338	O.T. 85%	197 (58%)	O.T. 85%	82 (24%)	42%

Note.—There were no cases giving a positive reaction to Test B but a negative reaction to Test A.

Comparison of Modified Jelly Test With Intradermal Test

Comparisons were now made between the modified jelly test, using flourpaper, and the Mantoux test, to check for the presence of false positive reactions and to assess the value of the flourpaper test in terms of the intradermal. The jelly test and the intradermal test were read by separate observers who had no knowledge of the result of the test they were not recording. The standard for a positive intradermal test was taken as 5 mm. or more of oedema after 72 hours. These results are shown in Tables II and III.

From Table II it would seem that, using flourpaper, the P.P.D. jelly is approximately equivalent, between the ages of 5 and 20, to an intradermal injection of 0.1 ml. of O.T. of strength 1 in 10,000, while the 60% O.T. jelly, using flourpaper, is equivalent to intradermal O.T. of strength 1 in 1,000.

TABLE II.—*Comparison Between Flourpaper Technique and Intradermal O.T.*

Age in Years	No. Examined	Test A, Mantoux		Test B, Jelly with Flourpaper		Positives to B as Proportion of Positives to A
		Strength of O.T.	No. Pos.	Jelly Used	No. Pos.	
5–7	219	1/1,000	10 (4·5%)	P.P.D. 2 mg./g.	8 (3·5%)	80%
8–10	279	1/1,000	39 (14%)	,, ,,	28 (10%)	72%
11–15	630	1/1,000	96 (15%)	,, ,,	79 (13%)	82%
15–20	143	1/10,000	44 (31%)	,, ,,	43 (30%)	98%
11–15	223	1/1,000	69 (31%)	O.T. 60%	66 (30%)	96%
15–20	124	1/1,000	46 (37%)	O.T. 60%	44 (35%)	96%

The 11 persons (Table III) who gave a positive reaction to the jelly test and a negative reaction to the intradermal test were retested with intradermal O.T. of strength 1 in 100. Nine were positive and two were negative. There were thus two apparently false positives by intradermal standards among a total of 224 positive to the modified jelly test—that is, rather less than 0.9%. It is fair to conclude that the great increase in positive reactions with the flourpaper technique as compared with the original jelly technique was a true increase of specific tuberculin reactions. This increase greatly enhances the value of

TABLE III.—*Detailed Results*

the jelly test as a sieve to be used before proceeding to an intradermal test with O.T. of strength 1 in 100. If the original technique were used then a number of persons who would be positive to the flourpaper technique and yet have a relatively high sensitivity would give a negative reaction. On retesting these persons with O.T. 1 in 100 some extremely severe reactions might result.

The next step was to determine whether overuse of the flourpaper would produce any false positive reactions. With this in view, 327 children, aged 11–15, had two tests using flourpaper. In the second test the flourpaper was grossly overused. The results (Table IV) show that there was 99% agreement between the tests. Two persons who gave a negative reaction with the normal technique had a positive reaction to the overuse of the flourpaper. These were retested with intradermal O.T. strength 1 in 1,000. One was positive to this test and one was negative.

TABLE IV.—*Overuse of Flourpaper*

Age in Years	No. Examined	Negative Both Tests	Positive Both Tests	Pos. Normal Flourpaper; Neg. Overuse Flourpaper	Neg. Normal Flourpaper; Pos. Overuse Flourpaper
11–15	327	264 (81%)	59 (18%)	2 (0·5%)	2 (0·5%)

It should be noted that these tests were carried out by an experienced observer. In the hands of one less experienced there is a definite risk of false positive readings if the flourpaper be overused. For this reason it is essential to apply a control jelly, also using flourpaper, until reactions—e.g., scoring or abrasion, due to over-rubbing—are readily recognized.

Comparison of the Three Jellies Used

Two final comparisons, flourpaper being used, were now made. The P.P.D. jelly was compared with the 60% O.T. jelly, and the 60% O.T. jelly was compared with the 85% O.T. jelly. The results are given in Tables V and VI, and show (1) the marked superiority of the O.T. jelly over the P.P.D. jelly, and (2) that no advantage was gained by increasing the strength of the O.T. jelly from 60% to 85%.

TABLE V.—*Comparison Between P.P.D. Jelly and 60% O.T. Jelly*

Age in Years	No. Examined	Test A, with Flourpaper		Test B, with Flourpaper		Positives to B as Proportion of Positives to A
		Jelly Used	No. Pos.	Jelly Used	No. Pos.	
11–15	348	O.T. 60%	122 (35%)	P.P.D. 2 mg./g.	76 (22%)	62%

Note.—There were no cases giving a positive reaction to Test B but a negative reaction to Test A.

TABLE VI.—*Comparison Between 60% O.T. Jelly and 85% O.T. Jelly*

Age in Years	No. Examined	Negative Both Tests	Positive Both Tests	Positive O.T. 60%; Negative O.T. 85%	Negative O.T. 60%; Positive O.T. 85%
11–15	233	191	42	0	0

In the comparative tests between 60% O.T. jelly and 85% O.T. jelly agreement was complete; this also applied to the type and extent of the reactions from the two jellies in each individual tested. It is difficult to account for the superiority of the 60% jelly over the P.P.D. jelly, which was approximately equal in tuberculo-protein content to undiluted O.T. Differences in the physical characteristics of the two tuberculins may be responsible, P.P.D. being less easily absorbed through the skin, particularly when this is intact. Various substances, including lipoids, which are retained during the preparation of O.T. but excluded from P.P.D., could be expected to assist absorption. It is of interest that confirmation of this difference between the two jellies has been obtained at the Veterinary Laboratory, Ministry of Agriculture and Fisheries, Weybridge, by Paterson (1950—personal communication) working with guinea-pigs. It must be stressed, however, that, when presented intradermally, P.P.D. gives similar results to O.T. of similar tuberculo-protein content.

Conclusions

The flourpaper technique described greatly increases the sensitivity of the tuberculin jelly test and extends its usefulness to include persons up to the age of 20 years. With an experienced observer there is little or no risk of false positive readings with the overuse of the flourpaper, but, until experience has been gained, a control flourpaper–jelly application is essential.

Where it is proposed to use the jelly test as a sieve before proceeding to an intradermal test with O.T. of strength 1 in 100 it is advisable to employ the flourpaper technique. Otherwise some extremely severe reactions to the intradermal test may result.

Using the flourpaper technique and a jelly containing 60% O.T., the proportion of positive reactions obtained will closely approximate, in the age group 5–20, to those obtained using intradermal international standard strength O.T. of dilution 1 in 1,000.

Using the methods and formulae described, O.T. is to be preferred to P.P.D. as the active component of the jelly.

The present method offers an alternative to the Mantoux test when this is contraindicated.

I wish to thank Dr. H. H. Green, of the Veterinary Laboratory, Weybridge, for his technical advice, particularly in regard to the tuberculo-proteins, and Professor A. Bradford Hill for his advice on the statistical aspects of this paper. Messrs. Allen and Hanburys very kindly prepared and supplied the tuberculin jellies used in the investigation.

Addendum

Notes on the Reading of the Test.—This should be done 24 to 48 hours after the removal of the plaster—that is, 72 to 96 hours after application. The longer period will give any pseudo-positive reactions time to fade and any delayed positives time to appear. In reading the test erythema should be ignored. A positive reaction will show vesiculation at the site of application of the jelly. There may be coalescence of the vesicles to form a V-shaped or heart-shaped area of induration. Fewer than four vesicles should be considered to indicate a doubtful positive, and either the test should be repeated or an intradermal test with O.T. 1 in 1,000 performed. Scoring of the skin is an indication of overuse of the flourpaper and can cause confusion in the reading of the test. For this reason it is essential, until the observer has become familiar with these reactions, that a control jelly, with flourpaper, should be applied to the opposite side of the spine.

DIETARY TREATMENT OF HYPERTENSION

BY

H. UCKO, M.D.

Until recently there was a general consensus that hypertension was not benefited by diet unless it was due to or accompanied by renal disease or obesity. Kempner (1944a, 1944b, 1945, 1946, 1948) produced evidence that a diet consisting of rice, fruit, and sugar without the addition of other foodstuffs led to a reduction of the mean blood pressure by more than 20 mm. in 62% of cases of hypertension and caused marked improvement of the symptoms and signs of hypertensive disease. In some patients small amounts of non-leguminous vegetables, potatoes, lean meat, and fish can be added later, but this is often followed by a rise in blood pressure, which always occurs on return to normal food. Yet prolonged adherence to the strict diet may lead to a negative nitrogen balance (Schwartz and Merlis, 1948).

These results have in part been confirmed (Flipse and Flipse, 1947; Canter, 1948; Contratto and Rogers, 1948). In Page, Corcoran, and Taylor's (1949) series less than 20% of cases improved. The diet has also been found effective in dogs with experimental hypertension (Dick and Schwartz, 1947).

Some authors have attributed the results of the rice diet to starvation. If 10 oz. (280 g.) of rice and 5-6 oz. (140–170 g.) of sugar are eaten daily the caloric intake can be kept up to 2,000. Yet many patients prefer insufficient calories to the full ration. Starvation can reduce normal and high blood pressure (Lups and Francke, 1947; Brozek, Chapman, and Keys, 1948); this effect has been attributed to the deficient protein intake.

Kempner's rice diet contains as little as 150 mg. of sodium a day. It has experimentally been found that sodium chloride administration potentiates the hypertensive effect of deoxycortone (D.C.A.), while animals on a salt-free diet show no or a greatly reduced response (Knowlton, Loeb, Stoerk, and Seegal, 1947). On the other hand, sodium restriction is capable of reducing the blood pressure of hypertensive rats, and such animals choose a diet with a low sodium content (*Yearbook of Endocrinology, Metabolism, and Nutrition*, 1948). In the chicken, hypertension and reversible renal changes have been produced by the mere addition of salt to the drinking-water (Lenel, Katz, and Rodbard; 1948). It has been shown that the action of salt is due to its sodium ion (Friedman, Friedman, and Polley, 1948).

In human beings the pressor effect of D.C.A. on hypertensives (Perera, 1945; Goldman and Schroeder, 1948) can similarly be prevented by rigid salt restriction (Perera, 1945). While the addition of salt does not affect the blood pressure of normal people (Grant and Reischman, 1946), Goldzieher and Salmovitz (1943) observed salt retention in hypertensives and decrease in blood pressure after salt restriction and ammonium chloride medication. The latter is capable of preventing the effects of D.C.A.-overdosage in animals (H. Selye, 1946) and returns to normal the increased Na/Cl ratio in the serum of D.C.A.-treated animals (F. L. Selye, 1947). An increased Na/Cl ratio was found by the last-named author also in the blood of some hypertensive patients with high diastolic pressures, and Goldzieher and Stone (1949) have shown that sodium and chloride can be retained independently of each other. There is no other reliable evidence for the existence of sodium retention in essential hypertension, but Perera (1947) observed that the reaction of hypertensives to salt restriction differs from that of normal subjects.

The value of sodium restriction in the treatment of congestive heart failure and oedema has been established (Bridges, Wheeler, and White, 1946); Wheeler, Bridges, and White, 1947; Peters, 1948). Grollman (1946) reported good results in hypertensive disease from a diet with less than 500 mg. of sodium a day but not from moderate sodium restriction. Perera (1947) observed a decrease of the "resting" blood pressure by a diet containing 280–320 mg. of sodium. Bryant and Blecha (1947) found the disappearance of symptoms and a fall in pressure to or below 155/95 in 20% of cases on a diet containing 200 mg. of sodium. Successes were also reported by Rosenberg, Rosenthal, and Rosenbluth (1948) and by Schroeder (1948). Bang, Bechgaard, and Nielsen (1949) observed a decrease of blood pressure in 16 out of 26 patients with hypertension on a diet with less than 400 mg. of sodium. The addition of salt caused renewed rise of the pressure. In one case of chronic nephritis salt deprivation led to uraemia.

Present Investigation

Kempner's rice diet, a barley diet, and a low-sodium diet were tested on 14 unselected cases of hypertension—3 men and 11 women. The ages ranged from 35 to 72 years, the mean age being 54.5. Two patients, a man and a woman (Cases 6 and 9), suffered from chronic renal disease with albuminuria, cylindruria; and azotaemia; the male patient was also a moderate diabetic and had a trophic ulcer of the toe. The youngest female patient was a typical case of Cushing's syndrome. All other patients suffered from essential hypertension. In all cases hypertension had been present for many years.

The observation periods varied from one to eleven months. Only the "casual" blood pressures were recorded, as all patients were ambulatory and continued with their normal activities. No rest or change of life was enforced. Blood-pressure readings were taken on the same arm with the patient in the same position, and the mean value of four readings was recorded. When the blood pressure had not been observed for a long time before treatment, preliminary blood-pressure estimations were made on at least three different occasions. As an index of the sodium chloride intake the urinary chloride excretion was determined once a week. In cases with renal disturbances the blood urea was estimated before and during treatment. All patients were clinically examined and records of their heart silhouettes were taken at intervals.

Six patients were put on the rice diet; five of them continued on the low-sodium diet, one after an interval of several months. Four of the five patients on the barley diet continued with the low-sodium diet. Four patients were put on the low-sodium diet from the beginning.

Diets

1. Kempner's rice diet was used in its original form.

2. A barley diet was given which was identical with the rice diet, except that rice was replaced by pearl barley. According to McCance and Widdowson (1946), from whose publication the figures in this paper have been taken, pearl barley contains 2.6 mg. of sodium per 100 g., while rice contains 6.3 mg. per 100 g.

3. The following low-sodium diet was used. All food must be prepared without salt, and no self-raising flour, baking powder, or sodium-containing medicine must be taken.

Results

me fall in blood pressure occurred in all patients, but xtent varied. Tables II and III illustrate the findings. patients were on the rice diet for three to six weeks, for almost three months. Cases 1–4 had essential rtension, Case 5 suffered from Cushing's syndrome, Case 6 had chronic renal disease with azotaemia d urea, 90 mg. in 100 ml.). In only two patients s 4 and 6) did the blood pressure reach approximately al levels, though the diastolic pressure remained ly above normal. One was the patient with chronic nephritis and diabetes mellitus; his preliminary fasting blood sugar was 375 mg. in 100 ml., and the carbohydrates of the diet were covered by 32 units of globin insulin. The other patient had essential hypertension, no cardiac dilatation or ocular changes, but minimal albuminuria and slight oedema of the ankles. The variable loss of weight which occurred in the patients of this group bore no relation to the extent of the fall in blood pressure, but seemed to be greater in over-weight patients.

Comparable results were obtained in patients on the barley and low-sodium diets, except that the loss of weight was less marked in the latter group. Case 3 had normal food for five months after the rice diet. The blood pressure had risen to an average of 200/113 when the patient started the low-sodium diet. The average fall in blood pressure of the patients on the barley diet was higher than it was on the low-sodium diet and lower than on the rice diet, but the number of patients in each group is far too small for general conclusions to be drawn from these figures.

Table III shows the results obtained by the low-sodium diet in patients who started on the rice or barley diet and continued on the low-sodium diet. It is evident that the blood pressures of all the eight patients in this group were maintained satisfactorily; in most of them the pressure decreased even further. Case 11, the only one showing a rise in blood pressure, did not adhere strictly to the diet. She was the second case of chronic nephritis and showed marked improvement in general health; urinary protein and cylindruria decreased considerably, the blood urea fell from 150 to 50 mg. in 100 ml., and retinopathic changes of the ocular fundus regressed. All patients, except Case 7, felt better, oedema and slight albuminuria disappeared if present, and the heart size decreased slightly in patients with cardiac dilatation. The blood urea in Case 6 remained unchanged; his albuminuria diminished considerably, his fasting blood sugar dropped to 165 mg. in 100 ml., and the

ulcer of the toe healed. No signs of salt deprivation were observed, but some patients felt slightly weak at times; extreme coldness and blanching of fingers and toes occurred in two patients, and one patient (Case 4) had two attacks of faintness when the blood pressure was very low and the pulse pressure dropped to 25 mm. Gastric upsets occurred in several patients on the rice diet.

Two major incidents occurred which may not be related to the treatment. Patient 9 developed melaena after she had been on the barley diet for four weeks and on the low-sodium diet for three weeks. A cause for the bleeding was not found, but the diet was discontinued. Patient 2, who never kept rigidly to his diet and whose urinary chloride excretion ranged between 120 and 170 mg. per 100 ml., as compared with 20–60 mg. per 100 ml. in people who adhered strictly to the diet, had a coronary thrombosis 40 days after his return to normal food and died as the result of the thrombosis seven weeks later.

The results obtained from the low-sodium diet are of special interest, as it supplies an adequate amount of protein and includes leguminous vegetables and fat, which, according to Kempner, upset the effect of his diet.

A close scrutiny of the menus and the chloride excretion of the patients showed that the lowest observed blood-pressure levels were maintained only with a daily intake of under 250 mg. of sodium. It is also important to realize that the tendency of the hypertensive blood pressure to vary unduly during the day remains unchanged and that morning and evening pressures may therefore diverge considerably. The Chart illustrates these points. It is a typical example

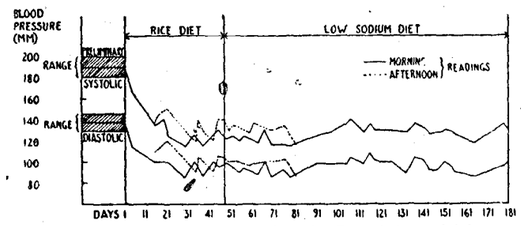

Chart showing blood-pressure readings in Case 4 (essential hypertension of many years' standing).

of the influence of dietary treatment, and shows the morning (not the resting) pressures of the best- and longest-observed patient (Case 4), and some of his afternoon pressures in comparison.

Discussion

The results indicate that the described diets are effective in reducing the blood pressure in hypertensive disease and in chronic renal disease, and they suggest that it is chiefly the low sodium content which is responsible for this effect. The fall in blood pressure is usually accompanied by improvement or disappearance of the hypertensive symptoms and signs and by improvement in general health. Though only a small number of patients seem to respond with normalization of the pressure, it appears that improvement of the hypertension is beneficial to the patient's health.

The figures in Tables II and III show that the systolic pressure after treatment was still well over 200 mm. in two patients and the diastolic pressure over 110 in two others. If one considers the wide daily variations and the effects of small deviations from the strict diet, it appears that only a certain number of patients will benefit enough from sodium restriction to warrant the institution of a regimen that can be upheld only with great personal and social inconvenience. In patients who respond well, however, sodium restriction may have important therapeutic consequences. It has benefited patients after unsuccessful sympathectomy (Bryant and Blecha, 1947) and may well be tried in selected cases before operation is considered. Decisive successes cannot usually be expected from mere salt restriction: the daily intake of sodium must not exceed 200 to 250 mg. The low-sodium diet is the diet of choice, as it provides the full supply of essential foodstuffs and so can be maintained for a long time; rice or barley days can be included.

The effect of sodium restriction on hypertension may have great theoretical significance. It appears that the body needs sodium for the production of hypertension and that its withdrawal may create a metabolic situation in which high blood pressure cannot be properly maintained. Sodium drainage may be the cause of the hypotension in Addison's disease. Black (1946) found hypotension, low serum sodium values, and an undue loss of sodium in the faeces in some cases of tropical and non-tropical sprue. Conversely, there is a tendency towards sodium retention in pregnancy toxaemia, in not too advanced chronic nephritis, and also in some cases of Cushing's syndrome; and drastic sodium restriction benefits the hypertension of all these conditions.

There is a striking similarity between D.C.A. intoxication and such diseases as essential hypertension, pregnancy toxaemia, and Cushing's syndrome. The part played by the sodium metabolism in these conditions favours the hypothesis that overproduction of adrenal mineralocorticosteroids may be one of their essential features. H. Selye (1946) has shown that "diseases of adaptation" may originate from a faulty mechanism of adaptation to unspecific damaging stimuli, and that overproduction of adrenal corticosteroids under pituitary stimulation constitutes one of the most important physiological events in the defence mechanism of the body. It is therefore conceivable that intoxication of the body with adrenal mineralocorticoids may occur as a result of maladaptation and that deficiency or loss of sodium may prevent or mitigate such an intoxication in the same way as it lessens the effect of D.C.A. intoxication. That sodium restriction does not affect the neurogenic component of hypertension is borne out by the observation that external and emotional stimuli influence the blood pressure of a patient who has responded to diet in the same way as that of an untreated hypertensive.

Summary

The results of Kempner's rice–fruit–sugar diet, of a barley diet, and of a low-sodium diet on 14 unselected cases of hypertension are described.

It is suggested that the effect of Kempner's rice diet is mainly due to its low sodium content.

The clinical effect of sodium restriction on hypertension and its theoretical consequences are discussed.

EFFECT OF VITAMIN B_{12} ON NEUROPATHY IN PERNICIOUS ANAEMIA TREATED WITH FOLIC ACID

BY

H. FULD, M.D., M.R.C.P.
Physician, Newsham General Hospital, Liverpool

The remarkable effectiveness of vitamin B_{12} in severe lesions of the central nervous system caused by folic-acid treatment of pernicious anaemia is well illustrated by the record of a patient who came recently under observation.

Case Report

A woman aged 74, whose previous history was one of good health, developed lassitude and dyspnoea on exertion about three years ago, when pernicious anaemia was diagnosed and confirmed by blood examination. Concentrated liver injections were given. After the third injection she developed a sensitization dermatitis, for which she was admitted to the skin department of a hospital on February 15, 1948—that is, four months after the onset of the skin disease. Apart from the dermatitis she appeared to be in good health and the case report did not record any neurological disorder. Her blood count on February 18 was: red cells, 3,690,000; white cells, 8,650; haemoglobin, 80%; colour index, 1.1. Her skin condition cleared up with local application and *x*-ray therapy, and she left hospital on February 25 with a haemoglobin level of 99%. Whilst in hospital, liver injections were stopped and she was put on 15 mg. of folic acid daily, which she had taken until her admission to this hospital.

In May, 1949 (after 15 months' folic-acid treatment), she complained of weakness and unsteadiness of her legs and loss of appetite. From August her diet consisted of bread, margarine, butter, and tea. She had an egg on rare occasions, but took practically no vegetables, meat, or fish. Towards the middle of October she became mentally deranged, bed-ridden, and incontinent.

On admission to the medical division of Newsham Hospital on November 8 her condition was as follows. She lay in a curled-up position, unable to give any history. She was disorientated about place and time, extremely restless, incontinent, delusional, and very dirty in her habits. There was no gross wasting. The skin was dry, with a scaly papular dermatitis of the lower third of both legs. There was angular stomatitis, and the tongue was glazed and beefy. The lymph nodes were not enlarged. Fibrillation was present. B.P. 90/60; chest clear. There was no enlargement of liver or spleen and no tenderness or any mass in the abdomen. The urine was normal. A blood count showed: red cells, 3,500,000; haemoglobin, 78%; colour index, 1.1; M.C.D., 7.8 μ (Eve). White cells, 4,000: lymphocytes 2,150 (54%), monocytes 50 (1%), polymorphonuclears 1,700 (42%), eosinophils 100 (3%). The blood film was consistent with treated pernicious anaemia.

Examination of the nervous system revealed no disorder of the cranial nerves, and the fundi were normal. Investigation of the upper limbs showed gross ataxia, brisk tendon reflexes, Hoffmann's sign present on left side, impaired superficial sensation, joint and vibration sense lost, and muscular power not grossly impaired; the abdominal reflexes were absent. The lower limbs showed gross ataxia, brisk tendon reflexes, bilateral extensor response, impaired muscular power, loss of vibration sense and joint sense, impaired sensation for touch and pain.

A diagnosis was made of neuropathy following folic-acid treatment of pernicious anaemia in a woman who also suffered from nutritional (vitamin B) deficiency.

On November 15, 2 ml. of "cytamen," containing an equivalent of 40 μg. of vitamin B_{12}, was injected. Subsequently 1 ml. was injected every third day until December 1, every fifth day until December 13, and every seventh day afterwards until February 28, 1950, when she was put on fortnightly injections of 2 ml. The total dose of vitamin B_{12} given was 0.5 mg.

Progress.—For five days she had to be fed on fluids only. Her appetite returned after the second injection. She remained incontinent until December 12, by which time she could sit on a chair. Towards the end of December walking exercises were started. On January 5 the ataxia of her upper limbs had disappeared. The reflexes of her lower limbs were still brisk and there was an extensor response on the left side. Superficial and deep sensation were both impaired in her legs. Her mental condition had greatly improved, and she was able for the first time to give a clear history of herself except for the period after August, 1949.

On January 21 the case record states: "Mentally alert and rational; lively sense of humour. Upper limbs—no weakness of either hand. Reflexes brisk; no impairment of superficial or deep sensations; vibration sense normal. Finger-nose test normal. Lower limbs—brisk tendon reflexes. Bilateral flexor response—some impairment of sensation to cotton-wool and pin-prick. No loss of muscular or joint sense. Vibration sense absent. Heel-knee attempt still poor. Gait unsteady but not spastic."

On February 7 she walked without help and was quite steady. There was still some impairment of deep sensation. On February 14 she walked quite normally and climbed two flights of stairs unaided. Her physical and mental condition was good. Blood examination showed normal values from December 13 onwards. The patient left hospital in March with a recommendation to her doctor for maintenance doses of 40 μg. vitamin B_{12} every fortnight.

Discussion

The above case record confirms the dangers of folic-acid treatment of pernicious anaemia pointed out by Israëls and Wilkinson (1949). The patient, who had had no previous neurological lesion, developed a severe neuropathy involving the brain, spinal cord, and peripheral nerves, in the fifteenth month of folic-acid treatment, during which period her blood remained at a fair level. The resulting psychosis and the neurological lesions were promptly arrested by

vitamin B_{12} and fully restored within three months, a period which, in an aged patient, seemed to be extraordinarily short.

Our observations confirmed the experiences of Berk *et al.* (1948), Hall and Campbell (1948), Hall *et al.* (1949), Mollin (1949), and Ungley (1949), who found vitamin B_{12} effective in the treatment of neurological complications of pernicious anaemia.

Summary

A case of severe psychoneuropathy in the course of folic-acid treatment of pernicious anaemia is reported.

Its complete and rapid restitution with injections of vitamin B_{12} is described.

My thanks are due to Glaxo Laboratories Ltd. for the generous supplies of cytamen.

Medical Memoranda

Prolonged Retention of Dead Foetus in Utero

A report of the following most unusual case is worth recording.

CASE REPORT

A Chinese 3-para, aged 47, was admitted to hospital on January 4, 1950, complaining of an abdominal lump which had been present for over two years and weakness and inability to leave her bed for two months. She had been pale for five months. Her youngest child was aged 20. In August, 1946, she became pregnant and, apart from the fact that the size of the abdomen led to a suspicion of multiple pregnancy, the antenatal period was uneventful. At term, in May, 1947, there was a little vaginal bleeding and she had pains resembling those of labour. Foetal movement ceased, the membranes did not rupture, and nothing was expelled. Menstruation returned and was normal and regular until four months before her admission to hospital. The abdomen varied in size, being smaller when the periods were regular and increasing when they ceased. There was some upper abdominal pain.

The patient was thin and pale, and looked ill. Her temperature was 97° F. (36.1° C.), pulse 78, and respirations 20. Her blood pressure was 82/58. The heart and lungs were normal. An abdominal tumour the size and shape of a 28-weeks pregnant uterus was found. It was much firmer than an ordinary pregnant uterus, but neither hard nor fluctuant. It was tender, fairly fixed, and resonant to percussion. There was shifting dullness in the right flank, but resonance in the left, even when the patient was lying on her left side. Vaginal examination revealed a firm effaced cervix with a closed external os and a hard mass like a small foetal head above it. The abdominal mass seemed continuous with the uterus. At a later examination it was thought that foetal parts could be palpated.

The urine was acid and contained albumin, a few pus cells, and red blood cells. A blood count showed: white cells, 15,850 (neutrophils 81%, lymphocytes 17%, monocytes 3%); red cells, 2,710,000; haemoglobin 52%. The Kahn reaction was +.

The patient was kept under observation for nine days, during which efforts were made to secure donors for blood transfusion. These were not forthcoming. Many of the Chinese peasants look upon their blood as their life, and do not feel called upon to give it even for a relative. In this case, however, the husband and daughter were willing, but were unsuitable. Eventually a lady missionary with poor and much-covered veins, but compatible blood, volunteered. Only a small volume was obtained, and this was given to the patient, whose condition was deteriorating. Her red count had fallen to 1,670,000 and her haemoglobin to 28%. She had spells of vomiting and was irrational in the evening. In spite of a warning that a fatal issue was likely, the relatives desired operation.

On January 13, using a rectus sheath field block and a small amount of intravenous thiopentone, a lower midline abdominal incision was made. Adhesions were so dense and extensive over the tumour that it was difficult to tell when the peritoneal layer had been penetrated. The incision was extended beyond the umbilicus in an unsuccessful endeavour to get above the adhesions. Palpation of the mass at this stage revealed unmistakable foetal parts, so the uterus was opened vertically. It contained a putrid mass comprising an apparently full-term foetus considerably decomposed. This was removed almost intact. There was some slight retraction of the uterus in the upper part only. On the lower posterior wall, and apparently covering the internal os, was a leathery mass which was taken to be the placenta, but as the patient was unable to stand further blood loss no attempt was made to disturb it. The uterus was irrigated with saline, a drainage tube was inserted, and the uterus and the abdominal wall were closed. Intravenous saline was administered throughout the operation and the patient was returned to bed in fair condition.

Next morning her condition was still fair, and there was a copious foul seropurulent discharge from the drainage tube. Through this, using a two-way metal catheter, a continuous drip lavage was instituted, but the patient gradually lapsed into coma and she died 40 hours later.

COMMENT

The special interest in this case centres round the length of time the dead foetus remained in the uterus. The dates given were according to the Chinese calendar, but there is no reason to doubt their accuracy. The positive Kahn test could account for the death of the foetus, but it is difficult to know why labour did not continue, and why there was not more distress at the time.

Many points made diagnosis difficult. The age of the patient, the fact that she had not been pregnant for 20 years, the length of time since the alleged pregnancy, and the history of subsequent normal periods made it hard to believe that she had been pregnant in 1946. The resonant percussion note with absence of bowel sounds over the tumour was puzzling. It was no doubt due to putrefactive gases in the uterus, though there was no special rush of these when the organ was incised. At the time of operation the provisional diagnosis was infected uterine fibroids.

The cause of death was not quite clear. It was to be expected that the patient would succumb during or soon after the operation, but her condition next morning was quite satisfactory. No facilities were available for blood chemistry tests, but the absence of any other obvious cause of coma suggested uraemia. This could have resulted from amyloid changes in the kidney after the long period of septic absorption. The vomiting and mental confusion prior to operation would support this diagnosis. No post-mortem examination was possible, as this procedure is unknown in rural China.

Mention might be made of the use of the rectus sheath field block anaesthesia according to the technique advocated by Minnitt and Gillies (1948). Owing to its easy administration and its complete lack of after-effects this has been found most satisfactory when patients are apparently *in extremis*. The relaxation it provides is fully adequate.

A. HALLAM HOWIE, M.B., Ch.B.,
China Inland Mission Hospital, Langchung, China.

Post-operative Paralysis of the Brachial Plexus

Several instances of post-operative injury to the brachial plexus have been reported recently by Ewing (1950) and by Kiloh (1950), and it seems reasonable that more publicity should be given to such an avoidable complication of surgical operation. The following two patients received a muscular relaxant, but it is considered a fallacy to associate the rising incidence of this complication entirely with the introduction of these drugs.

CASE REPORTS

Case 1.—A married woman aged 44 had a total hysterectomy performed on March 24, 1949. Anaesthesia was obtained by sodium thiopentone, nitrous oxide, and ether, and relaxation by "flaxedil" given into a right forearm vein, with the arm abducted to 90 degrees. The patient was tilted into a fairly steep Trendelenburg position, with padded shoulder-rests in support. The right arm was abducted for 100 minutes and the Trendelenburg position maintained for 50 minutes. On regaining consciousness the patient complained of generalized weakness of the right arm, with numbness of the right thumb and forefinger. There was a complete paralysis of the right deltoid, biceps brachii, and brachialis. In one month the arm had improved but elbow flexion and forearm supination were still weak, and the patient complained of some dull pain on the outer aspect of the shoulder and arm. She was discharged from hospital on April 28, and at the follow-up on July 26 the arm was quite normal.

Case 2.—A spinster aged 43 had a subtotal hysterectomy performed on July 29, 1949. Anaesthesia was obtained by sodium thiopentone and nitrous oxide, and relaxation by flaxedil given into a right forearm vein. The arm was abducted to 60 degrees, with slight external rotation and slight forearm supination. A fairly steep Trendelenburg position was maintained with padded shoulder-rests in support for some 65 minutes, and the arm was abducted in all for 104 minutes. On recovery from the anaesthetic the patient complained of generalized weakness of the right arm. There was complete paralysis of the right deltoid, biceps brachii, and brachialis, though the spinati were normal and enabled the patient to abduct her arm fully. There was also paresis of the radial nerve. Full normal against resistance being 5, thumb extensors were 4, finger extensors 2, and wrist extensors 2. Median and ulnar nerve supplies were normal, and there was no sensory loss. She was discharged home on August 18, the arm greatly improved with treatment, which she continued as an out-patient, and by mid-September the arm was practically normal.

MECHANISM OF INJURY

The first references to brachial plexus injury occurring at operation suggested a pressure injury when the plexus was nipped between the clavicle and the first rib (Büdinger, 1894), or between the clavicle and transverse processes of the fifth and sixth cervical vertebrae (Krumm, 1895), or by pressure of the plexus on the head of the humerus when the arm was in external rotation and extension (E. Braun, cited by Garrigues, 1897). Later, the theory that the plexus was injured under anaesthesia by traction of the nerves rather than by compression was suggested by Horsley (1899) and Stevens (1934). Clausen (1942) considered that the injury was essentially one of stretch.

Anatomically the nerves are fixed at the transverse processes by invaginations of the prevertebral fascia, and in the arm by the axillary fascia, and any structure tending to increase beyond normal limits the distance between the points of fixation of the nerves will cause injury. An example is the head of the humerus, which becomes more prominent in the axilla when the arm is in external rotation, abduction, and extension. Normally the head of the humerus is maintained in a neutral position on abduction of the arm by rotation of the scapula and an upward movement of the shoulder girdle. If a shoulder-rest prevents this upward movement of the shoulder, the humeral head is kept low and the neurovascular bundle, passing round this structure, is apt to be stretched. If now a Trendelenburg position is adopted the weight of the patient tends to slide down between the shoulder rests, which in turn push the shoulders towards the feet, and with the arm in abduction the head of the humerus becomes increasingly prominent in the axilla. It seems that abduction of only 60 degrees is enough to cause tension on the nerves in these circumstances (see above).

A conscious patient in this position will probably not suffer injury, provided that the protecting muscles do not tire. Under anaesthesia, however, the musculo-tendinous protection of nerves is partially or entirely absent, and the incidence and degree of injury will depend on the relaxation of the muscles, the steepness and duration of the Trendelenburg position, and to some extent on the weight of the patient. No doubt the relaxant drugs produce great flaccidity in these protecting muscles, but a similar relaxation is produced in deep general anaesthesia by ether (Clausen, 1942).

If the incidence of this unfortunate complication is on the increase it may be due to the more frequent use of this position of abduction of the arm, whether for intravenous anaesthesia or therapy. In particular, this vulnerable position of abduction of the arm should be avoided in the Trendelenburg position.

The injuries described are considered to be due to stretching of the nerves, and Denny-Brown and Doherty (1945) have said that in milder degrees of stretch there occurs damage to the epineurial vessels, with resultant patches of ischaemic changes in nerve fibres. After these ischaemic lesions one can expect efficient regeneration. Although the injuries discussed here are relatively mild, in that complete recovery is the rule, nevertheless they are avoidable and do cause unnecessary prolongation of convalescence.

My thanks are due to Dr. J. F. B. Wyper for his permission to publish these cases, and to Mr. A. M. Rennie for his clinical reports.

The Minister of National Insurance, Dr. Edith Summerskill, has completed the setting up of local advisory committees to advise her on questions relating to the local administration of the National Insurance Act. In all, 230 committees have been set up—186 in England, 26 in Scotland, and 18 in Wales. The committees consist of representatives of employers, employed persons, local authorities, and friendly societies. In addition, persons with special local knowledge likely to be of value to the committees have been appointed as members.

Reviews

PSYCHOLOGY AND DUODENAL ULCER

Duodenal Ulcer. A Sociopsychological Study of Naval Enlisted Personnel and Civilians. By Jurgen Ruesch, M.D., C. Christiansen, M.A., R. E. Harris, Ph.D., S. Dewees, M.A., A. Jacobson, M.D., and M. B. Loeb, M.A., in co-operation with the medical staff of the San Leandro Naval Hospital. (Pp. 118. £1 2s. 6d.) London: Cambridge University Press.

This study is one which others interested in psychosomatic medicine would do well to emulate. Two groups of patients with clinical and radiological evidence of duodenal ulceration were investigated; one consisted of forty naval ratings, and the other of twenty civilians. The problems studied were the particular social and psychological aspects of the patient with duodenal ulcer. It was hoped that the simplified environment of the Navy with its more or less known stresses would, by contrast with the more complex circumstances of civilian life, throw light on the situations which precede the appearance of symptoms.

The patients had an average age of about 30 years; their interests, hobbies, and intelligence were somewhat above normal level, and an unstable married life with a high rate of divorce was common. In the naval patients acute ulcers were more common than chronic; in civilians the reverse was true. Anxiety symptoms preceded those of ulcer in 69% of the first group and in 85% of the second. In many naval patients a situation of clear-cut psychological significance seemed to precipitate the breakdown; in 70% of civilians there had been a change in social or home environment.

The patient with duodenal ulcer was found to have a personality different from that of the general population; there were points of similarity to the hysteric, but the variations were more complex in the civilians than in the ratings. The patients were often younger or youngest children; they were dependent, conforming, overtly combative but covertly passive, and hungry for affection. Relations with parents differed in the two groups: the common pattern in the ratings was a dominant mother with an uninfluential father, and in the civilians an idealized mother with a punitive father.

Dr. Ruesch has made an interesting contribution to our knowledge of one of the commonest and most important latter-day diseases. He makes no claim that peptic ulcer is psychogenic; indeed, he is at pains to point out that the aetiology of ulcer must ultimately be explained in terms of tissue erosion and vascular changes. This careful and methodical study proves once again that in the treatment of the patient sick of a duodenal ulcer the physician must concern himself as much with social and psychological rehabilitation as with the control of gastric acidity.

R. BODLEY SCOTT.

THROMBOSIS IN THE LEG

Thrombosis in Arteriosclerosis of the Lower Extremities. By Edward A. Edwards, M.D., F.A.C.S. (Pp. 74; illustrated. 15s.) Oxford: Blackwell Scientific Publications.

This monograph is an addition to those on the circulation already published in the popular "American Lecture Series." In common with its predecessors it is beautifully printed and illustrated.

The author treats the subject from the clinical viewpoint, and illustrates the pathology with a number of excellent low-power photomicrographs. He points out that thrombosis is the most important accident that can befall the arteriosclerotic vessel and hopes that a greater awareness of its frequency will minimize its harmful effects.

The first three chapters cover aetiology and pathology, the clinical picture, and treatment. The author insists on the adequacy of clinical methods of diagnosis and is a firm believer in the value of immediate sympathectomy for the relief of ischaemia. In the last two chapters he presents a series of informative case reports illustrated by diagrams of the lesions concerned.

Most of the information about the state of the vessels has been obtained by examination of amputated limbs, and arteriography and other special investigations are not mentioned. This omission exemplifies the author's premise that clinical signs alone are quite sufficient to determine the probable progress of events in the severer forms of ischaemia, whatever the more precise interpretations of special methods may reveal.

The book is easy to read and is based on accurate clinical observation and sound judgment; it is stimulating and the material is concisely expressed. It will be valuable to all who are interested in the subject.

C. J. LONGLAND.

OBSTETRICS AND GYNAECOLOGY

Handbook of Obstetrics and Diagnostic Gynecology. By L. Doyle, M.S., M.D. Illustrated by Ralph Sweet. (Pp. 240. $2.) California: University Medical Publishers, Palo Alto.

This is a pocket-sized paper-backed synopsis, with the subject-matter presented in some detail but in note form. It will therefore appeal only to those who find such a style palatable for revision purposes. The obstetric section, well illustrated with line drawings, has much to commend it. Indeed, the chapters on the emotional aspects of pregnancy, the minor discomforts of pregnancy, analgesia in labour, and the care of the patient in the puerperium contain more useful information than do many of the larger textbooks.

Fewer than 40 pages are devoted to gynaecology—surely an exaggeration of the relative unimportance of this subject for the student and the practitioner. The adjective "diagnostic" does not mean that the author discusses only clinical methods, but that the chapters are classified according to symptoms rather than pathology. The most serious omission is a proper emphasis of the importance of genital carcinoma—the types, diagnosis, and treatment of growths at all sites being covered by one simple table.

T. N. A. JEFFCOATE.

COMPARATIVE ANATOMY

The Vertebrate Body. By Alfred Sherwood Romer. (Pp. 643; illustrated. £1 7s. 6d.) Philadelphia and London: W. B. Saunders Company. 1949.

The teacher who thinks of the broad education of his students is at a loss when asked to recommend a textbook of comparative anatomy. It is strange that no substitute has been found for the three German classics. Jeffrey Bell translated and Ray Lankester edited Gegenbaur's *Elements of Comparative Anatomy* in 1878, and W. N. Parker translated Wiedersheim's *Elements of Comparative Anatomy of Vertebrates* in 1886. G. B. Howes edited and annotated

the translation of Wiedersheim's *The Structure of Man* in 1895. These three books have dominated the teaching from 1880 to the present day. The two earlier compendia of English origin were too bulky and too encyclopaedic to influence teaching to the extent they deserved. Todd and Bowman's *Cyclopaedia of Anatomy and Physiology* (1835–59) in five volumes and Richard Owen's *The Anatomy of Vertebrates* (1866–8) in three volumes did not have the wide distribution and popularity of the later German texts. In a sense they were before their time.

The frank anatomical dissection of living forms was greatly influenced and modified by two antipodal factors. On the one hand the science of palaeontology founded by Baron Cuvier focused the mind of man on the anatomy of the forms of the past which had persisted as fossils. On the other hand the rapid strides in the study of embryology by Pander, von Baer, F. M. Balfour, and many others attracted students away from formal comparative anatomy. Human anatomy became the handmaiden of surgery and comparative anatomy became a hobby for museum minders.

This new book by the distinguished director of the Museum of Comparative Anatomy at Harvard is the work of a master of the subject who is deeply sensitive to the progress made in physiology, experimental embryology, and genetics. In the preface, which he calls his apologia, he gives six essentials for an adequate treatment of the subject. They are adequate illustration, truly comparative treatment, proper palaeontological background, a developmental viewpoint, inclusion of histological data, and consideration of function. This is a whole-hearted statement in the good Hunterian tradition.

Little time is wasted on conflicting theories, and so the ground is covered by unusually direct methods. He rids the student of the bugbear of nomenclature in a few lines and castigates the absurdities of the B.N.A. terminology.

The chapters on the skeleton and the muscles are refreshing, and his great palaeontological experience makes for a succinct presentation. It is a pity that the author has not the space to discuss some minutiae such as the epiphysis on the pisiform bone or to present the story of the development of the chondrocranium. Yet it is remarkable to see how closely he sticks to his six desiderata.

There is but little on the subject of man, the primates, and the endocrine glands, for, as he emphasizes, the knowledge of the endocrines is based almost entirely on man and a few laboratory animals. He prophesies that the lower forms will have their endocrine days later, and already the various attempts to control insect pests have directed attention to the internal secretions of these invertebrate forms.

The text and illustrations are excellent. There are three appendices of great value, particularly to the English-speaking student unversed in the classical tongues. The first gives a synoptic classification of vertebrates; the second is a working glossary designed to avoid mental indigestion, and gives the simpler Latin noun and adjective in declension form so that gender, number, and case can be free from hurtful errors. The third gives a select list of references in which the author has dared to sift the dross from the gold.

No teacher of zoology or anatomy can do without this sorely needed book. No medical student should fail to possess it in common with Dorland's *American Illustrated Medical Dictionary*. They will last a lifetime and continue to give pleasures untold.

ABORTION

In a recent lecture[1] to the Royal College of Obstetricians and Gynaecologists Mr. Linton Snaith expressed the view that the problem of abortion had received inadequate attention, cases of abortion being almost excluded from the wards of the teaching hospitals. This may not be true of all teaching hospitals, but it is the fact that entirely different facets of the problem are presented by those cases admitted to teaching hospitals and the more numerous cases admitted to other hospitals. In the opening pages of this issue, in a survey of 2,665 cases falling into this second category, Mr. Albert Davis reaches the startling conclusion that probably 90% of these abortions were criminally induced, mostly by the patient herself. The woman admitted to the teaching hospital is much more likely to have been referred from the antenatal or the fertility clinic. The problems here, in teaching hospitals and from the point of view of Mr. Snaith, are concerned with the aetiology, prevention, and treatment of spontaneous, threatened, and so-called habitual abortion. The problem presented to the gynaecologist working in a non-teaching hospital is usually that of treating the complications of criminally induced abortion.

Mr. Davis has compiled statistics, dealing with many aspects of this problem, which are fascinating from the sociological as well as from the purely medical angle. Thus, his hospitals being situated in "respectable" neighbourhoods, no fewer than 2,350 of his patients were married; in other neighbourhoods of less "respectability" the proportion of unmarried patients might be as high as 50 to 65%. This factor is important because of the much higher incidence of complications in the unmarried: 14% as compared with 6% for married women. The commonest complication found by Mr. Davis was gross infection; there were five cases of septicaemia, one of pyaemia, and 118 with severe local sepsis. Haemorrhage requiring blood transfusion occurred in 68 cases, and there were four cases of traumatic rupture of the uterus. Six of his patients died, a mortality of 0.26%; two from *Cl. welchii* septicaemia, two from burns following local corrosive injections, and one from *Staph. aureus* septicaemia. A further patient, not included in the series, died from soap-bubble cerebral embolism, and this, Mr. Davis suggests, is the mechanism in most sudden fatalities, douching with soap solution being the commonest method of inducing abortion. Treatment, when the abortion was incomplete (84% of cases) or inevitable, was mainly directed to evacuation of the uterus, either medically or surgically, the superiority of active to conservative measures being shown by a lessened stay in hospital and by a lower incidence of complications. Chemotherapy was unavailing in the presence of retained infected products, except in a few rare instances, and peritonitis remained the most fatal complication.

If criminal abortion is largely a sociological problem, spontaneous abortion, and particularly recurrent spontaneous abortion, is essentially a problem of reproductive physiology. It is generally agreed that spontaneous abortion occurs in approximately 10% of patients who are clinically pregnant and is present, but unrecognized, in some patients complaining of sterility. Two explanations of this ovular wastage have often been put forward. Mall and Meyer[2] believed that an abnormal uterine environment was mainly responsible. Streeter,[3] on the other hand, considered that defects of the germ plasm were more important. Snaith discussed these two points of view, and found little reason to believe that Rh incompatibility or obvious seminal defects played any significant part aetiologically. He went on to say that though vitamin E and progesterone appeared to have little real value in the prevention or treatment of abortion, oestrogens, in the form of oral stilboestrol, seemed to be promising when treatment was started sufficiently early in the pregnancy. He admitted that one could do no more than speculate on the mechanism whereby this apparently beneficial result was achieved.

Cogent evidence for the "germ plasm defect" theory has recently been provided by the outstanding studies of Hertig and Rock.[4] Among 136 fertile patients, who had each had, on the average, nearly five pregnancies before being subjected to hysterectomy for some therapeutic reason, a search for conceptuses resulted in the discovery of 28, none older than 16 days. Twelve of these ova were abnormal and, of these, seven were certainly destined to abort; of the latter, four were so markedly abnormal that it is probable that no clinical evidence of pregnancy would have been observed. Thus, of these 28 potential pregnancies three would almost certainly have ended as spontaneous abortions—the same 10% as was mentioned before. The ova destined to abort, either with or without evidence of their ability to produce clinical pregnancy, showed fundamental defects such as multinucleated blastomeres, absence of embryonic disk, chorionic cavity, or of both, or there was profound hypoplasia of the future placental tissue. In all of the cases described the endometrium appeared to be entirely normal and the authors concluded that ". . . the evidence, such as it is, indicates that the defective fertilized ovum is due to intrinsic germ plasm quality rather than to its environment and is the main factor in the production of spontaneous abortion." If this view is indeed correct, then it follows that attempts to treat spontaneous abortion are not only largely doomed to failure but are an attempt to obstruct nature's own method of disposing of mistakes in the most satisfactory fashion. It is doubtful, however, whether most clinicians faced with patients complaining of threatened or habitual abortion would easily be persuaded of the rightness of this conclusion.

HAEMORRHAGE FROM PEPTIC ULCER

Two papers published in this issue are on the subject of haemorrhage from peptic ulcer. From Newcastle-upon-Tyne Drs. A. G. Ogilvie and I. O. B. Spencer report a mortality of only 2.4% in a series of 170 in-patients between 1941–8, whereas Drs. C. D. Needham and J. A. McConachie, from Aberdeen, report a mortality of 13.9% in 476 patients admitted to hospital during the same period for haematemesis and/or melaena from peptic ulcer. A number of papers already published provide information about the mortality of bleeding peptic ulcer in the past decade. In 1945 Smith[1] reported a mortality of 6% among 180 cases treated in Glasgow, and Avery Jones[2] in London found that 8% of 615 in-patients died. It seemed that liberal transfusions and adequate fluids and nourishment by mouth had brought down the mortality from the much higher rates recorded in the nineteen-thirties. Unfortunately further series in the past few years have disclosed higher figures. From Birmingham Baker[3] reported 576 cases with 77 deaths (13.4%) over a six-year period from 1940–5. Tanner[4] found there had been 62 deaths (10.5%) among 586 patients admitted to a south London hospital between 1941 and 1948. Lewin and Truelove[5] recorded a mortality of no less than 19% among 305 patients admitted to the Radcliffe Infirmary, Oxford, between 1938–47. These higher figures are confirmed in this issue by the Aberdeen authors but refuted by the experience at Newcastle.

How can such differences arise between hospitals to-day? Both the composition of the various series and the place of surgery in treatment must be considered when trying to find an answer to this question. Both Avery Jones and Tanner claim help from surgery in lowering mortality; without this help their series might have been on equal terms with those of Oxford, Birmingham, and Aberdeen, where comparatively little assistance was requested from the surgical units. There is also the question whether, apart from the frequency of surgical intervention, the quality of medical care can vary sufficiently to account for the large differences. The essentials of adequate medical care are a good blood bank, a registrar to back up the house-physician, a readily available consultant, satisfactory dietetic facilities, and good nursing care. But these are common to all these series. It would be convenient to attribute the low Newcastle figures to better-than-average medical care, but this cannot be the explanation, though it is certain that the patients were closely supervised and great attention was paid to detail. The alternative possibility is that the composition of the series is significantly different from others. Ogilvie and Spencer point out that they have been favoured by a low proportion of patients over 70 years of age and probably by a higher proportion of duodenal ulcers, which have a lower mortality than chronic gastric ulcers. Without doubt one of the most important variables is the age distribution. In patients over 50 the mortality rises appreciably, and it increases greatly in those over 70. In Ogilvie and Spencer's series there were three patients over 70 (1.8%), and two died. Smith was equally fortunate with only 1.5% of his patients over 70. On the other hand, in the series of Baker, Truelove, and Avery Jones the percentages of patients over 70 were 7, 8.5, and 12.2 respectively. It appears that the age of patients with bleeding peptic ulcer is rising, and Avery Jones[6] has reported a steady increase in his patients over 70—from 6.5% in 1940–1 to no less than 19% in 1947–8. It is also probable that Ogilvie and Spencer had a lucky sequence in the age group 60–69: no deaths among 24 in-patients cannot be equalled in any other series, and it can hardly be expected that their future experience in this age group will be quite so fortunate. The proportion of patients with chronic gastric ulcers cannot be compared in these series, but it seems probable that there may have been fewer of these cases in the Newcastle series, and this again would contribute to the excellent figures.

The authors of both papers in this issue stress the need for surgery in selected cases, and most clinicians will agree with Needham and McConachie's plea for closer co-operation between surgeons and physicians in order that operation may be considered especially in the patient with recurrent bleeding who is past middle age. They again demonstrate very clearly the risk of recurrent

bleeding after admission to hospital, and a mortality of 50% in patients over 50 years of age considered, in retrospect, to be operable clearly provides ample scope for the surgeon. It is impracticable for the busy surgeon to see all patients admitted for haemorrhage, but he can be informed about every case which may need surgery if bleeding recurs, particularly when the patient is over middle age, probably has chronic ulcers, and is free from gross medical complications. Bleeding often recurs at a particularly awkward time: if the senior surgeon on call is aware of the possibility he can if necessary rearrange his work, and the danger of delay is thus reduced. If possible a partial gastrectomy undoubtedly provides the best protection for the patient against further complications, though difficulty often arises, as in the third case described by Ogilvie and Spencer, when an ulcer could not be found by the surgeon, yet at necropsy a chronic ulcer was demonstrated with penetration into the pancreas. The location of an ulcer at operation is not dependent on surgical skill and is at times impossible. In these circumstances, when the history points to a peptic ulcer, it is undoubtedly advisable to proceed to a partial gastrectomy. Whether this is necessary in the case of patients with no history of dyspepsia is still debatable.

In spite of the number of papers on gastro-duodenal haemorrhage in recent years there is still room for good clinical studies on the lines of the two papers published this week. The results of emergency surgery and the demonstration of geographical differences are particularly wanted: the figures quoted by Tanner[4] and by Bohn[7] were encouraging. Other subjects for study are the diagnosis on admission, prognosis, and indications for surgery. The initial diagnostic difficulties tend to get lost in tables of final diagnoses. In England and Wales there are probably between 20–30,000 patients admitted to hospital annually for gastro-duodenal bleeding, and nearly half the 5,000 deaths each year from peptic ulcer may be the result of this complication. Some reduction in this annual toll is practicable, but the closest liaison between physicians and surgeons is needed, and a definite policy has to be accepted. This is more important than the segregation of patients into one unit, though this automatically ensures a standard policy. Staff co-operation is aided by analysis and discussion of the local figures. It is not always appreciated how time-consuming these analyses can be and how greatly the work can be expedited by the skilled assistance of statisticians and clerical workers. Simple clinical research of this nature, even if not prepared for publication, pays handsome dividends in clarifying difficult therapeutic problems and thereby in assisting to reduce mortality. Such schemes deserve financial assistance from hospital management committees.

REHABILITATION OF THE TUBERCULOUS

The London County Council is considering what it can do towards providing better accommodation for tuberculous patients who, while well enough to be discharged from hospital and to work during the day, need lodging and facilities for rest under medical supervision. There are also other patients who can do little or no work, have infectious sputum, and live in overcrowded homes. It is estimated that 160 such persons are living in common lodging-houses in London. Before the National Health Service was introduced the council under its tuberculosis scheme arranged to accommodate such persons in small voluntary sanatoria, but it is now difficult to find room for them owing to the pressure on hospital beds for acute cases. The health committee of the council considers that the responsibility for providing such accommodation belongs to the regional hospital boards rather than to the local health authorities. The matter has been discussed with the four Metropolitan regional hospital boards, and it is proposed to ask the Minister of Health to receive a deputation to discuss the question.

One project of the council has been the erection of a night sanatorium and industrial workshops on the site of St. Peter's Hospital, Stepney, which was not transferred for hospital purposes and remains the council's property. It would be cheaper to demolish the existing building and rebuild for this purpose, instead of making adaptations, but the Minister will not pass the project. In his reply he says that, while he fully approves the provision of night sanatoria for the tuberculous and regards this as among the necessary developments of the tuberculosis services, he cannot allow additional expenditure in present circumstances. But the health committee of the council is going to press the Minister on this matter. Meanwhile the Minister has issued a memorandum (see page 162) to regional hospital boards and local health authorities suggesting ways in which more hospital beds may be used for the treatment of the tuberculous and drawing attention to a scheme now operated by the Central Middlesex Hospital and a neighbouring chest clinic whereby home treatment is supplemented by short periods in hospital. The resettlement of the tuberculous patient no less than his treatment is the concern of the chest physician. Local health authorities, chest physicians, and officers of the Ministry of Labour are urged to work closely together in order to find a satisfactory occupation for the patient who cannot enter, or is not suitable for, a village settlement.

THE TUBERCULIN-JELLY TEST

After half a century of tuberculin testing no satisfactory simple technique has yet been evolved. The Pirquet test, the intradermal Mantoux test, and the percutaneous tests have been used with many variations, but the intradermal test remains the most satisfactory, being the most exact because controllable. The percutaneous tests have the advantage of being easily applied and of not requiring injections, but there have been growing doubts whether a percutaneous test can reveal most positive reactors.

Dr. W. Pointon Dick reports in this issue an investigation of the tuberculin-jelly test. He has demonstrated that this test as generally applied detects only a small proportion of tuberculin-positive individuals, and he recommends a technique of skin preparation which makes the test approximately equivalent to the intradermal injection of old tuberculin in a 1/1,000 dilution. The reading of the test requires some experience if false positive readings are to be avoided, but it is certainly an advance in the use of the jelly test. Without the recommended skin preparation the jelly test, if used alone, is quite inadequate, and a severe reaction may occur if an intradermal test with a 1/100 dilution of old tuberculin is given afterwards. The technique of tuberculin testing has become a more important matter now that B.C.G. is being used in this country, and the question remains whether the intradermal test with a 1/1,000 dilution of old tuberculin or an equivalent percutaneous test as recommended by Pointon Dick is adequate to separate positive from negative reactors for the purposes of vaccination. In the past only those negative to 1/100 dilutions of O.T. have been considered definitely tuberculin negative. Unless there is proof that this dose causes non-specific reactions in many cases (as Scandinavian workers have suggested), that standard should probably be maintained in preference to running the risk of inoculating with B.C.G. children who may be tuberculin-positive.

PHYSIQUE OF LONDON'S CHILDREN

One of the duties of medical officers of health is to supervise the health of school-children and to study the way in which their physique may have reacted over the years to changes in the conditions of life, particularly the changes caused by war. In such supervision statistical methods can be invaluable, and the recent report[1] on the height and weight of London school-children by Sir Allen Daley is an excellent example of their use. For many years records have been kept of the height and weight at different ages of children in the L.C.C. area. In the interpretation of the results of current surveys it is essential to take into account long-term changes which have taken place, and comparisons between pre-war and post-war years can be made with confidence only when the results are truly representative of all children in the London area at the appropriate point in time. By the procedure described in Sir Allen Daley's report it was possible to obtain both speedily and economically representative samples of the school population in 1949. The results show that the improvement in physique—measured in terms either of average height or average weight at each age—which took place between 1905 and 1938 was maintained in 1949. Between 1938 and 1949 the average height for London school-children between 5 and 15 years of age increased by about three-quarters of an inch (1.8 cm.), and the average weight by about one and three-quarter pounds (800 g.). This increase has been consistent for both boys and girls and within each age group in each sex. There is indeed a remarkable stability in the results which is typical of the statistical description of all natural phenomena. As in 1938, boys are heavier and taller than girls up to the age of 11 years, but the position is reversed from 11 to 14; after 14 years of age the boys resume their lead. Again, although the average height and weight have both increased they have done so in step, and the height–weight ratio was the same in 1949 as it was 10 years before. In short, the London school-child of to-day has an overall physique equal to that found in children three months his senior in 1938.

The disparity of physique between children attending school in different parts of London which was noted before the war still persists. Broadly speaking, the advantage lies with those who live south of the Thames. Fortunately surveys of children's physique were continued on a restricted scale throughout the war in typical south-western and north-eastern London areas. By 1943 there was an all-round increase in height and weight in the south-west, but in the north-east the 1938 standards in height were barely maintained and there was a slight loss in weight. By 1946 the progress in the south-west slowed down, while in the north-east there were, in many age groups, further reductions in weight. These north-eastern areas were, of course, the areas of London most severely affected by the war, and it is perhaps significant that although there has been in the past two years a definite improvement in these areas the greatest improvement in physique has been observed in the south-western parts of the county. Precise knowledge about these trends among children in the different social classes is lacking. The continued superiority in physique of the children in the south-western areas, even with rationing and school meals, shows that this is a subject worth studying.

SYPHILIS IN GREENLAND

To judge by a recent report,[1] the history of syphilis in Greenland and the sex habits of the Greenlanders are both remarkable. To all intents and purposes syphilis does not exist in Greenland, though gonorrhoea was first noted in 1864 and occurred epidemically after 1913. The country escaped the European syphilis pandemic which followed the return of Columbus, and only sporadic cases introduced by seamen were seen till 1872, when the local population was infected by workers in a cryolite mine near by. Half the population of about 100 contracted syphilis between 1872 and 1890, but the disease gradually died out. It was not seen again until 1947, when a man with secondary syphilis from a near-by meteorological station infected four of seven women with whom he had had sexual intercourse. Energetic contact tracing and the imposition of quarantine limited the epidemic to five cases of the acquired disease and one case of congenital syphilis. No doubt poor communications and the relative immobility of the population contributed to this result, since there were no fewer than 52 "contacts." The authors of the report state that the explanation lies in "chance biologic factors" rather than immunity, for which no evidence was discovered. This investigation revealed the fact that, though promiscuity and

[1] Marcussen, P. V., and Rendal, J., *Amer. J. Syph.*, 1950, **34**, 144.

extramarital intercourse are not common, premarital sexual intercourse is the rule. This may be explained by the relatively late age of marriage, poor housing, lack of amenities, and limited communications, and is in keeping with the marked frankness in sexual matters which was noted. It seems all the more surprising that Greenland is the only country in the world where syphilis has not gained a footing.

ANTIHORMONES AND A.C.T.H.

The development of "antihormones" in response to the prolonged injection of certain hormones has been a subject of interest and controversy since the phenomenon was first reported from Collip's laboratory in 1934.[1-3] It is now well known that the repeated injection of thyrotrophic or pituitary or chorionic gonadotrophic hormone into animals of different species induces a refractory state in which the animal becomes resistant to further injections of the hormone.[4] Antihormones can be demonstrated in the serum after the development of this refractory state, which may be passively transmitted to a test animal by injecting it with serum from the resistant animal. Experimental evidence suggests that the hormone behaves as an antigen and that its antihormone has many of the properties of an antibody. The injection of homologous trophic hormones does not ordinarily give rise to antihormone formation, and when this does occur the resistance is much less marked. It has been difficult to draw conclusions from these observations because the trophic hormones used have been crude and the antihormones observed in other species have been attributed by some to the presence of impurities in the hormone preparation.

In 1934 Thompson and Cushing[5] tried to produce Cushing's syndrome in a puppy by injecting large doses of crude sheep's pituitary extract. The failure of this attempt was attributed to the formation of an anti-adrenocorticotrophic hormone. Recently the preparation of "purified" hog adrenocorticotrophic hormone (A.C.T.H.)[6] and its extensive use in clinical research has renewed interest in the subject of antihormones. Chase[7] injected mice with 50 mg. of A.C.T.H. over a period of 25 days. When the serum from these animals was injected into rats it prevented the increase in weight of the rats' adrenals normally caused by injections of A.C.T.H. Chase was able to demonstrate *in vitro* a precipitin reaction between the specific mouse antiserum and the A.C.T.H., and also an agglutination reaction if the A.C.T.H. was first absorbed on to collodion particles, so that the antigen (A.C.T.H.) was made macroscopically visible when agglutinated. Working independently, Gordon[8] has obtained similar results. He injected rats for seven weeks with an amount of A.C.T.H. proportionately similar to that used by Hench[9] for the treatment of rheumatoid arthritis in man. These rats became resistant to a test dose of the hormone which consistently depleted the ascorbic-acid content of the adrenals of control rats. The serum from the resistant animals contained a substance which when injected into hypophysectomized rats reduced the fall in adrenal ascorbic-acid concentration which normally occurs after administration of A.C.T.H. Although the number of animals used by both workers was small, adequate control experiments were carried out, and it seems probable that after prolonged injection purified hog A.C.T.H. induces an antihormone in rats and in mice.

The significance of these findings in relation to the administration of A.C.T.H. to man is not clear. So far no observations appear to have been made to discover whether or not an antihormone develops in the serum of patients given prolonged A.C.T.H. treatment, nor has any refractory state been ascribed to this cause. Perhaps the duration of treatment has been too short. In a recent report from the Mayo Clinic[10] the average duration of treatment with A.C.T.H. lasted four weeks (range 12–87 days). Nevertheless resistance to treatment or decreased responsiveness to A.C.T.H. may prove to be due to the development of a refractory state, and further evidence on this point must be awaited.

THE B.M.A. WAR MEMORIAL

An appeal has now been sent to members of the B.M.A. asking for contributions to the fund being raised to honour the memory of the medical men and women who fell in the second world war. Though the memorial will be dedicated to the 493 members of the Association who died, it will stand also as a tribute to all those of our profession in the British Commonwealth and Empire who lost their lives. A fountain with symbolic figures, designed by Mr. James Woodford, R.A., will be erected in the Court of Honour at B.M.A. House, and the surplus funds will be used to assist in the education of sons and daughters of members of the profession. An illuminated roll of honour like that for the first world war will also be displayed at the Association's house, a page being turned daily in perpetuity. The cost of the fountain will be about £10,000, but it is hoped that a much greater amount will be subscribed, so that there may be both an enduring witness to the sacrifice of those who died and substantial help available for their children. Contributions to the fund should be sent to the Chairman of Council, Dr. E. A. Gregg, B.M.A. House, Tavistock Square, London, W.C.1.

On July 8 the honorary degree of LL.D. of the University of Liverpool was conferred on Sir Henry Cohen, Professor of Medicine in the University and President-Elect of the B.M.A.; on Dr. E. A. Gregg, Chairman of Council of the B.M.A.; and on Dr. C. O. Stallybrass, former Deputy Medical Officer of Health for the City and Port of Liverpool.

REFRESHER COURSE FOR GENERAL PRACTITIONERS

DIAGNOSIS AND TREATMENT OF PERNICIOUS ANAEMIA

BY

RONALD BODLEY SCOTT, M.A., D.M., F.R.C.P.

Physician to H.M. Household; Assistant Physician, St. Bartholomew's Hospital

Addisonian pernicious anaemia is the commonest and most important member of a group of diseases known as the megaloblastic anaemias. In pernicious anaemia the primary fault lies in a failure of gastric function. The mucosa of the stomach normally contributes a secretion (the intrinsic factor) which modifies, or combines with, a dietary factor to produce the anti-anaemic principle which is absorbed from the alimentary tract and stored in the liver. Pernicious anaemia arises when the glands of the gastric mucosa fail to secrete the intrinsic factor: its anatomical basis is an atrophy of the mucosal lining of the stomach.

Diagnosis

The importance of precise diagnosis before treatment is carried out cannot be overemphasized, for it may be impossible later. An incorrect diagnosis may mean that some other condition is overlooked until it has progressed beyond the possibility of cure; or, at best, that the patient is sentenced unnecessarily to regular injections for the rest of his life.

The logical steps in establishing a diagnosis of pernicious anaemia are to prove, first, that the anaemia in question is of the megaloblastic variety, and, secondly, that it has originated from failure of gastric function. Megaloblastic anaemias are characterized by a reduction of the red blood cell count proportionately greater than the fall in the haemoglobin level, and thus by a colour index greater than 1. Inspection of stained films of the blood will reveal variation in the size of the red blood cells, many of which will be abnormally large (megalocytes). This megalocytosis is shown by an increase in the mean corpuscular volume, an easily estimated index, of which the normal value lies between 75 and 95 μ^3.

In pernicious anaemia the figure is almost always above 100 μ^3 and usually in the range 110–140 μ^3. The leucocyte count is usually reduced, figures of 3,000 per c.mm. being common; the differential count shows no characteristic changes, but it is the rule to find some neutrophils whose nuclei have undergone abnormal segmentation to give rise to five or even six lobes. Complete proof that the anaemia is megaloblastic is given by examination of the bone marrow by puncture biopsy. Films of the aspirated material will show an increased cellularity with a predominance of megaloblasts. Although this investigation is always desirable, because its results are conclusive, it is not essential unless the diagnosis is in serious doubt.

Addisonian pernicious anaemia accounts for more than 90% of megaloblastic anaemias met with in this country, and is thus by far the most probable cause of any instance seen in practice. Probability is made virtual certainty by establishing the absence of other possible causes; by demonstrating gastric achlorhydria; and by the presence of signs indicating subacute combined degeneration of the spinal cord.

Megaloblastic anaemia occurs also as a result of tropical sprue, idiopathic steatorrhoea, and other variants of the sprue syndrome; it may be due to dietary deficiency (nutritional megaloblastic anaemia), or to various disorders of the alimentary tract, such as intestinal stricture and regional ileitis. It may occur in pregnancy or the puerperium; it may follow operations on the stomach and particularly total gastrectomy; it has been reported in infants, probably due to nutritional causes. A few questions put when taking the history will help to exclude these uncommon conditions. Collateral evidence of impaired gastric function will be provided by the fractional test meal: the diagnosis of pernicious anaemia should never be entertained unless achlorhydria after injection of histamine is established. Finally, subacute combined degeneration of the spinal cord accompanies pernicious anaemia in 40–50% of cases, but it is very rarely associated with other megaloblastic anaemias; thus evidence of this disease provides strong support for the diagnosis.

In brief, it may be said that a megalocytic anaemia with achlorhydria is probably pernicious anaemia. The diagnosis is made more probable by the presence of signs indicating subacute combined degeneration of the spinal cord. It is established beyond doubt by the demonstration of a megaloblastic bone marrow or by the presence of megaloblasts in the circulating blood, and by the exclusion of other causes of anaemia of this type.

Initial Treatment

The patient with severe anaemia should be at rest in bed, and it is wise to insist that he should remain there until the haemoglobin level has risen above 65% (Haldane). An exception must be made of those patients in whom there is evidence of disease of the spinal cord, for their disability is increased by prolonged immobilization.

It has long been known that certain foods are particularly favourable to blood regeneration: highest in the list are liver and kidney; apricots, peaches, grapes, and apples have considerable potency; while in this respect green vegetables, dairy products, and the farinaceous foods rank low. The immediate importance of these foods in pernicious anaemia, for which a specific therapeutic agent exists, is not great; nevertheless, a well-balanced diet, containing a liberal supplement of vitamins and a representative selection of the articles mentioned, should be prescribed. Bread, cakes, pastry, potatoes, and fats should be taken only in moderation and to ensure an adequate calorie value, for in excess they diminish the appetite for more valuable foods.

Blood transfusion is now seldom required in the patient with pernicious anaemia. The indications are anaemia severe enough to constitute an immediate danger to life; the presence of an infection or other process likely to interfere with the adequate response to specific treatment; and the urgent necessity for raising the haemoglobin level rapidly when, for example, immediate surgical operation is necessary. It is not easy to give a precise figure for the haemoglobin level below which transfusion is essential. Some patients with a reading as low as 20% (Haldane) are obviously not in immediate danger, while others with a level of 30% (Haldane) as clearly require transfusion.

Mental disturbance due to cerebral anoxia, extreme venous congestion, and generalized puffy oedema afford the clearest indications for transfusion of blood. This must be undertaken with extreme caution, for circulatory overloading is particularly prone to occur in the gravely anaemic patient : not more than 1,200–1,500 ml. should be given at a time, and the rate of administration should not exceed 1 ml. per kg. body weight an hour.

Specific Treatment

The specific treatment of pernicious anaemia consists of the administration of the anti-anaemic principle. Many effective preparations are available. Of these, raw liver and the liquid extract of liver for oral administration have little more than historical interest.

Proteolysed Liver for Oral Administration.—This is a powder obtained after papain digestion of liver : 1 g. contains the product of about 5 g. of the original liver. It is believed to contain substances which are needed for the repair of some of the less common megaloblastic anaemias but are removed in the preparation of refined extracts. It is an active and satisfactory preparation, and the first choice in the treatment of pernicious anaemia when parenteral injection is refused or contraindicated. A dose of one teaspoonful two or three times daily is usually adequate.

Liver Extracts for Parenteral Injection.—In general, two varieties are available,—crude and refined. Crude extracts have undergone the minimum of processing necessary to make them safe for injection, and contain a large amount of material other than the active principles. Each millilitre is derived from 2.5 to 10 g. of original liver. Refined extracts are derived from crude extracts by further purification, and the quantity of inert material they contain is less. Each millilitre is derived from 50 to 200 g. of liver. These definitions do not mean that the crude or refined extracts of different manufacturers are strictly comparable. It was long believed that crude extracts contained substances, removed during further purification, which made them more effective in some megaloblastic anaemias. It has often been stated that they should be employed when subacute combined degeneration is evident, but there is no foundation for this belief. Intramuscular injection of a refined liver extract of known potency is a completely effective method of treating pernicious anaemia, whether neural degeneration is present or not. Dosage varies with the product used. There is no indication for the use of crude extracts in treating pernicious anaemia.

Vitamin B_{12}.—Vitamin B_{12} appears to be the anti-anaemic principle of liver; it has proved as effective in the treatment of pernicious anaemia and subacute combined degeneration of the spinal cord as liver extract. When *Streptomyces griseus* is grown in fluid media it elaborates a substance as active therapeutically as the vitamin B_{12} obtained from liver and probably identical with it. This product of the *Streptomyces'* metabolism is marketed as vitamin B_{12}.

It is probable that vitamin B_{12} will replace liver extracts in the treatment of pernicious anaemia; it is cheaper, apparently as effective therapeutically, and never gives rise to the allergic complications which may follow prolonged use of liver extract.

The vitamin is given by parenteral injection: 20 μg. weekly is sufficient for the initial treatment of an average case; if signs of neural degeneration are present the dose should be raised to 40 μg. weekly.

Desiccated Hog's Stomach for Oral Administration.—This is, in a sense, the most logical remedy for pernicious anaemia, because it contains the intrinsic factor which the patient lacks. It is prescribed as a dry powder with an unpalatable taste, and the dose required is one to two tablespoonfuls daily. Some authorities believe it to be particularly indicated in the presence of subacute combined degeneration of the cord, although this view has not gained general acceptance. It is fully effective in the treatment of pernicious anaemia, but it is not to be recommended as a routine method. It is useful, as an alternative to proteolysed liver, when parenteral injection is impossible.

Folic Acid.—Pteroylglutamic acid, or folic acid, is effective in raising the blood levels in pernicious anaemia, but it has been found to exert no control on the nervous degeneration. In fact, its administration is often followed by the explosive onset of nervous symptoms which progress rapidly even while the anaemia is improving. Further, it has been shown that folic acid is not always able to maintain the haemoglobin reading and red blood cell count at normal levels. For these reasons folic acid must in this respect be regarded as a dangerous drug which has no place in the treatment of pernicious anaemia.

Dosage

The problem of dosage in using liver extracts and related preparations has always been difficult. There is no officially recognized "unit" of activity in this country, although the *United States Pharmacopoeia* has attempted to define one. The practitioner is forced to take the recommendations of the manufacturer until he has used one preparation long enough to be familiar with its potency. Recently it has become the practice for preparations to bear a statement of the number of microgrammes of vitamin B_{12} contained in a millilitre. This figure may well be fallacious because of technical difficulties in estimating the vitamin B_{12} content of liver extracts. For these reasons it is unwise to accept such figures as indicating with any precision the potency of a liver extract.

At present the method to be recommended is the intramuscular injection of a refined liver extract of proved potency or of vitamin B_{12}. In the first case dosage varies with the product, but, on an average, 1–2 ml. at intervals of 7–14 days will procure a maximal effect. If vitamin B_{12} is used, 20 μg. at intervals of 7–14 days is adequate. The response is easier to follow if daily reticulocyte counts can be made; a peak, the height of which is inversely proportional to the original red blood cell count, is reached between the fourth and ninth days after the initial injection. Thus a satisfactory response is indicated by a reticulocyte peak of about 40%, with an initial red blood cell count of 1,000,000 per c.mm.: with counts of 2,000,000 and 3,000,000 per c.mm. figures of 19% and 6.5% respectively would be anticipated. The increase in red blood cells follows hard on the reticulocytosis, and, whatever the initial count, a level of about 5,000,000 per c.mm. should be reached by the eighth week of treatment.

It is generally thought to be advisable to increase the dose of liver extract or vitamin B_{12} if subacute combined degeneration of the spinal cord is present. It is reasonable to give twice the quantity which would otherwise have been prescribed.

Inadequate response raises three possibilities. First, the preparation may be inactive: this should not arise if a reputable product with which the practitioner is familiar is employed, for most manufacturers subject each batch to clinical trial before it is marketed. Secondly, the diagnosis may be incorrect: this will require careful revision, and further investigation may be necessary. Thirdly, some condition known to impair the effect of the liver principle may be present. Infective processes are of particular importance in this respect. The most frequent is chronic infection of the urinary tract, which should always be excluded. Myxoedema and advanced arteriosclerosis are additional causes of an unsatisfactory response to liver.

Maintenance Treatment

When a normal blood picture has been restored the task of maintenance treatment is to preserve it. It is important to have exact criteria by which to judge normality, and the aim should be to keep the red blood cell count above 4,500,000 c.mm., the haemoglobin level above 90% (Haldane), and the mean corpuscular volume below 100 μ^3. Adequate control is possible only by means of regular examinations of the blood, and these should be made at least once in three months. At most clinics undertaking the treatment of pernicious anaemia a count once a month is the routine. The dosage required and the interval between injections vary with the patient; in the great majority 3–4 ml. of a refined extract or 40 μg. of vitamin B_{12} once a month will maintain a normal blood picture. If nervous symptoms are present it is advisable to give this quantity once a week for six months to a year. In any patient the dose should be increased if there is complaint of paraesthesia or sore tongue.

At the onset it is advisable to warn patients that they will require injections at regular intervals of a month for the rest of their days.

Complications of Liver Treatment

The only complication of parenteral injection of liver extracts is the occasional development of hypersensitivity. A small proportion of patients will complain, after a period, of collapse, sweating, vomiting, palpitation, skin rashes, or asthma immediately following an injection. When such symptoms appear parenteral injections of all liver extracts must be stopped, because hypersensitivity is seldom limited to one proprietary brand. Oral treatment with proteolysed liver or desiccated hog's stomach may be substituted. In some cases desensitization to liver extract is worth consideration; but the alternative, which will probably prove most satisfactory, is to continue with parenteral injections of vitamin B_{12}, to which no such reactions occur.

Adjuvant Treatment

It is rare to encounter patients in whom any symptoms, other than nervous, remain after effective liver treatment. The exceptions are those in whom some dyspepsia persists : in these, dilute hydrochloric acid (*B.P.*) in doses of 15–30 min. (0.9–1.8 ml.) three times a day in water or fruit juice is usually successful in relieving symptoms. Medication with iron is quite unnecessary unless a complicating iron-deficiency exists.

It should be noted that carcinoma of the stomach is at least three times as common in patients with pernicious anaemia as in the general population. The appearance of dyspeptic symptoms, loss of weight, or hypochromic anaemia should always arouse this suspicion. A radiological examination of the stomach once a year is a wise precaution.

Physiotherapy, and sometimes the assistance of the orthopaedic surgeon, will be needed in the treatment of patients with subacute combined degeneration of the spinal cord. It is usually found that symptoms and signs referable to peripheral neuritis improve rapidly, and usually vanish within two years of starting liver treatment. Damage to the cord becomes arrested, but little improvement is to be anticipated.

INCIDENCE AND TREATMENT OF NEUROSIS IN INDUSTRY

BY

T. M. LING, D.M., M.R.C.P.
Medical Director

J. A. PURSER, M.B., B.S., M.R.C.P.
Boots Lecturer in Occupational Health

AND

E. W. REES, M.R.C.S., L.R.C.P., D.P.M.
Senior Physician

Roffey Park Rehabilitation Centre, Horsham, Sussex

It is becoming increasingly recognized that psychiatric and psychosomatic conditions comprise many of the recurring and chronic forms of illness, but their occupational aspects are still insufficiently appreciated. Characteristically, these disorders incapacitate rather than kill, so that morbidity statistics should provide the basic source of information. Unfortunately, emphasis in the past has been placed on mortality rather than morbidity as a criterion of national health, so that relevant figures are lacking. This paper is designed to bring some aspects of industrial neurosis to the general notice and to suggest measures for dealing with the problem.

The incidence of neurosis among working groups of the population has been investigated from time to time by different workers. Culpin and Smith (1930) examined 1,000 people, including factory, clerical, technical, and administrative workers, by means of a planned interview and specific psychological tests. They found the incidence of nervous symptoms or emotional maladjustment was not confined to any one group, sex, or age. Approximately 16% had serious emotional difficulties and a further 20% had minor difficulties. Comparable figures were found by Halliday (1935), Bashford (1940), Collier (1943), Stocks (1945), and Wyatt (1945). Figures of the incidence of neurosis in the Services are in general conformity with these findings. More recently, Russell Fraser *et al.* (1947) carried out a survey on a sample of 3,000 male and female workers employed in 13 light and medium engineering factories situated mainly in the Birmingham region. They showed that 9.1% of the men and 13% of the women had suffered from definite and disabling neurotic illness, and a further 19% of the men and 23% of the women from minor forms of neurosis during the course of six months. Neurotic illness caused between one-quarter and one-third of all absence from work due to ill-health.

Prevention of Neurosis in Industry

Clearly the incidence of neurosis in industry is influenced by working environment, both physical and psychological, so it is essential that both doctors and industrial management should have a satisfactory understanding of these problems. Evidence of the need for training at this level is shown in a recent report of a committee set up by the Minister of Education. The suggested syllabus of training includes such subjects as personnel selection, placement, health, welfare, and safety; general psychology and psychiatry; the measurement of intelligence, attainments, and special aptitudes; social psychology, including the human factor in industrial relations, rehabilitation, individual and group morale, and the psychological basis of morale.

Stewart (1948) points out that it is not clear who is to provide teaching of this type, which is preventive work in the sphere of mental health. A beginning has been made in the resident training department at Roffey Park, where already 540 works managers and supervisors and 122 doctors have received teaching in human relations in industry in the past two years. It is to be hoped that, in the future, postgraduate departments of occupational health and social medicine will interest themselves in this important field. Psychiatry should give a lead and not leave these biological problems to be elucidated by laymen. An important field of prevention obviously lies in the factory, and this is largely a matter of the health of groups of people. In effect, the problem is not dissimilar to the situation found in the war, where, as J. R. Rees pointed out, happy ships and good regiments had a low incidence of neurosis, while unhappy ships and poor regiments engendered a sense of insecurity that led to neurotic breakdown or various forms of antisocial behaviour.

A hundred years ago this country was faced with serious epidemics of disease, a high infant mortality rate, and a high death rate among low-income groups—interrelated problems produced by rapid urbanization and industrialization. To-day the country is faced with a similar challenge in the field of mental health, and once again emphasis must be placed on prevention and public education rather than *ad hoc* treatment of the casualties.

Out-patient Departments

Since the publication of the Blacker Report in 1946 there has been a substantial increase in psychiatric clinics, an increase greatly accelerated since July, 1948. Thus in the four Metropolitan regions there are now 137 out-patient clinics, which are doing much to decrease neurotic illness. Nevertheless, in an industrialized society, whose prospects of survival as an independent power depend on national productivity, it is surprising that so few systematic attempts are made by medical schools to provide an understanding of industrial conditions for those who will be doing out-patient work. Here again Service example, with its introductory courses for all doctors, seems far ahead of civilian practice.

In-patient Treatment

As in other branches of medicine, in-patient facilities are necessary for cases needing intensive treatment, especially if this involves rehabilitation after a spell of sickness absence. A number of neurosis centres were established by the Services during the war, with the emphasis on early return to duty where possible and making full use of various social techniques in addition to individual treatment. Comparable facilities for industrial neurosis cases were non-existent before the war and are still much below current needs.

For the long-standing unemployed case, a 100-bed in-patient unit was established at Sutton Neurosis Centre in 1947, and is dealing with a difficult problem with vision and courage. Selected patients go out to part-time work in neighbouring factories and shops, thus helping to bridge the gap between hospital and work. Roffey Park at Horsham, with accommodation for 120 patients of either sex, provides treatment and resettlement facilities for early cases of neurosis in which employment seems a relevant factor. Special emphasis is placed on the morale-structure of the whole centre in the belief that this is an important therapeutic weapon, perhaps the best form of treatment for many psychosomatic conditions when the individuals have become "desocialized." Neurosis is characterized by a *failure to adjust to the environment*, and the restoration of this adjustment is essential for recovery. This morale-structure can be built up, given time and considerable thought, and it involves active participation by those involved. This is helped by the layout of the centre, and more particularly by the joint participation encouraged in all activities. The patients have their own elected *committee and meet weekly to offer* suggestions, elect representatives, and plan leisure-time activities. The daily routine includes practical occupational therapy in workshops or gardens, *directed towards the welfare* of the group, together with graded physical training. The whole emphasis is towards return to work, and the staff's regular contacts with industrial medical officers and personnel *managers attending refresher* courses give practical help in this connexion. The D.R.O. spends one day a week in the centre in co-operation with the medical staff and the industrial *psychologist to secure suitable placement.*

Not least of the centre's functions is the assessment of those cases unlikely to benefit from short-term treatment and advising upon their appropriate disposal. Psychotherapy *is directed along eclectic lines* and purposely kept at a fairly superficial level. Emphasis is placed upon the elucidation of relatively recent factors which have prevented the patient's successful adaptation to life and thus brought him under medical care. "Talking out" of problems, "counselling" techniques, and narco-analysis are extensively employed. Electric convulsion therapy, modified *insulin therapy, and other physical methods* of treatment are utilized where necessary. The average duration of treatment is from six to eight weeks, and this period is rarely exceeded, thereby minimizing the loss of confidence which prolonged stay in hospital may engender. On the patient's discharge the doctor referring the case receives a report in which detailed recommendations upon placement and *future handling form an essential feature.*

Treatment of the individual without appropriate modification of his environment is often only of transitory value, and this modification can be carried out only when *there is mutual understanding* between the industry and the hospital. A happy relationship has been built up over the last five years between Roffey Park and over 150 industrial *organizations, and this is augmented* by the fact that many of these companies send members of their staff on training courses in human relations to Roffey, where the preventive aspect of these problems is stressed.

Selection of Cases

Cases are referred by full-time industrial medical officers and by out-patient psychiatrists, and the majority of patients live in the Metropolitan hospital regions. Selection of suitable material for such *treatment is highly important*, but—it is necessary to be clear—selection for what? Should preference be given to the mild case that may well recover spontaneously or to the really difficult case that is a *major problem to the community* and that may well prove intractable? Should the skilled man with a good work record have priority over the unskilled man with a poor work record? *Should apparently unemployable cases* be admitted at all?

These are highly relevant problems that are shared with sanatoria and other special hospitals, and the answer involves *various ethical and economic questions.* It is pertinent, in these days of shortages of skilled man-power and of money, to inquire whether the individual is more important than the community. Clearly, during the war the individual was subordinated to the community, and in the Services emphasis was placed on employability. Again, priorities change. To-day industrial medical officers state that much time is lost and man-power wasted through *patients* having to wait many months for admission for hernia operations which will restore the man to full working capacity, probably for life. In the hospital world hernias have a low priority, as they are non-fatal and uninteresting, which is one of the reasons for the long waiting period.

Again, should hospital doctors and social workers devote considerable time to rehabilitation and resettlement, or should they leave these biological subjects to be undertaken by the Ministry of Labour, whose staff, of necessity, lack the clinical experience for work of this type? It would appear that these medico-social problems will become of increasing importance as the Health Service settles down and economists start asking what the community is receiving in exchange for the very substantial outlay.

At Roffey Park the admission rate is approximately 900 cases a year, those being selected who present serious occupational problems in the form of obvious maladjustment or long absence from work but who appear to have fundamentally good personalities. In general, the cases referred by industrial medical officers have better basic personalities than those referred by hospital psychiatrists. This is probably because the former are more concerned about those who have a good work record. It may be of interest to compare the work record, as judged by the medical staff, of those patients coming direct from industrial medical officers with that of those from other sources.

	Industrial M.O.	Other Sources
Good work record	64% (54 cases)	26% (111 cases)
Average work record	28% (24 ,,)	46% (195 ,,)
Poor work record	8% (7 ,,)	28% (116 ,,)

These differences would appear to be significant. Curran and Guttmann (1943) have also emphasized the importance of a good work record as evidence of temperamental stability.

Results of Treatment

To determine accurately the end-results of treatment in medicine is never easy, and it is especially difficult in morbid disorders where the alternatives of life or death are not relevant. Ross (1936), in a series of 1,186 patients, found 45% recoveries and 25% much improved when followed up one year after discharge. Knight (1941), combining experience at the Menninger Clinic with the results of various analytic institutions, analysed a composite series of almost 1,000 cases and found that 63% of the psychoneurotics had apparently recovered or had very much improved. Slater (1943) reported an improvement rate of 60 to 70% in his cases of war neurosis. Lewis (1943) reviewed the social and economic effects of neurosis in a series of 120 soldiers discharged from the Army on account of neurotic illness and subsequently treated in a neurosis centre. He found that 15 were unemployed and that 39 were socially unsatisfactory otherwise than in their occupations.

The after-effects of treatment of cases at Roffey Park seems to be of interest and has been analysed for 1948, the postal follow-up system being used. Individual follow-up by a social worker is impracticable owing to lack of staff and to high cost. All patients who leave hospital are followed up by letter at six-monthly, yearly, and two-yearly intervals, in which they are asked to comment on their state of health and working capacity. Adequate information was obtained regarding 512 patients, all of whom had been discharged between six and twelve months. The results were: much improved, 33.8% (173 cases); improved, 44.7% (229 cases); unimproved, 21.5% (110 cases).

It is difficult to determine occupational capacity from written replies from individual patients, therefore the follow-up reports of 85 cases which were obtained direct from full-time industrial medical officers of certain firms are of particular value. Clinically, these cases were recorded by the industrial medical officers as follows: Much improved and working full time, 54.1% (46 cases); improved and working full time, 37.7% (32 cases); unimproved or had left the company, 8.2% (7 cases).

In 28% of the cases in which follow-up inquiries were made we received no reply. Obviously some of these ex-patients are unlikely to be well, but some who are now well wish to forget their nervous illnesses and will not answer, as they desire to sever contact with the hospital. The same situation arises in connexion with the follow-up of ex-sanatoria patients. It is to be hoped that, in the future, social workers will be available to carry out personal follow-ups on random samples of all hospital populations and also survey their adjustment to work.

One of the important lessons learnt at Roffey Park is the necessity that hospital out-patient staffs, both general and psychiatric, should have a better understanding of the occupational problems of their neighbouring industries. If this understanding existed—and there is reason to believe that there is a closer link in provincial centres than in London—there would be fewer instances of requests for "light work" and other indeterminate recommendations, and there would be a better appreciation of the social responsibilities of contemporary medicine.

Summary

A review of recent trends in morbidity is given and reference is made to the interrelationships of psychosomatic conditions and the working environment.

A description of treatment and some follow-up results of 512 cases at Roffey Park are reported.

The necessity for a comprehensive preventive programme is reviewed, and it is emphasized that all doctors should have an understanding of the occupational background of their patients.

This paper would not have been possible without the co-operation of a considerable number of full-time industrial medical officers, to whom our thanks are due.

TREATMENT OF TUBERCULOSIS

MORE BEDS TO BE PROVIDED

The following memorandum has been sent by the Minister of Health to regional hospital boards and local health authorities.

The Minister has sought the views of his Tuberculosis Standing Advisory Committee on the operation of the National Health Service in connexion with tuberculosis. They have made certain recommendations which he feels it would be possible to act upon forthwith, as matters of organization, without going beyond the limitations which the present need for economy imposes. These are dealt with in the following memorandum, which the Minister is sending also to local health authorities, having regard to the responsibilities of both in different aspects of the tuberculosis services and to the necessity for the closest co-operation between them if these are to work efficiently as an essential entity. The importance of the part to be played by general practitioners in the campaign against tuberculosis also needs to be borne in mind.

In-patient Beds

The most pressing problem is the long waiting-list for institutional treatment and the consequent lapse of time between diagnosis and admission to such treatment. Many more beds must be made available quickly, without waiting on progress in making good the lack of staff which is a major cause of the present shortage of accommodation. The Minister, with the agreement of his advisory bodies, deems it necessary to augment the insufficient resources of sanatoria and tuberculosis hospitals by using a proportion of beds in general hospitals for tuberculosis cases. He therefore asks regional hospital boards and boards of governors to apportion for the admission of respiratory tuberculosis patients as many beds as reasonably possible in suitable general hospitals. It is desirable that they should be in a separate section or block, and in any event in separate wards. Boards are also asked to consider to what extent they can arrange to use beds in isolation hospitals not required as essential epidemic reserves. The Minister would propose to invite reports from boards in due course about the arrangements they have been able to make in these matters.

With the present shortage of beds the available accommodation must clearly be used as advantageously and economically as possible. The use of beds should be limited as far as practicable to recoverable cases. Patients for whom further active treatment is unlikely to be of avail, but whose condition or circumstances do not permit of discharging them, should if possible be provided for in accommodation distinct from that for cases under active treatment; but this should be only an administrative distinction, with discretion in giving effect to it so that difficulties do not arise from overt classification of certain cases as beyond remedy.

It will assist in making the full and best use of institution beds if there is central oversight of admissions and discharges by headquarters medical staff of the regional board through a bed-bureau system. In some parts of the country (notably the London area) inter-regional organization will doubtless need to be considered.

There should be a check on any tendency to retain patients in institutions longer than is justifiable. Regional boards should consider whether they have adequate arrangements for keeping under expert medical review the length of stay in their several sanatoria or tuberculosis hospitals.

Boards should make themselves familiar with a scheme at present operating in connexion with the Central Middlesex Hospital and a neighbouring chest clinic which combines rest and collapse therapy in the home with short periods of in-patient treatment. A system of this kind depends on local conditions and resources, but it is clearly one which may prove suitable in some areas as an expedient for alleviating a local insufficiency of institutional beds.

The Minister has sought the views of the appropriate standing advisory committees on the arrangements which might be made to second student nurses to sanatoria and any further advice which can be given to safeguard the health of nurses engaged in the nursing of tuberculosis, and hopes that he may be able shortly to issue further guidance to hospital authorities based on their advice.

Chest Clinics

Attention should be given to ways in which the work of chest clinics can help to relieve the pressure on institutional beds. A high standard of clinical judgment is necessary to avoid recommendation of institutional treatment for cases in which it is not essential and for which domiciliary care would suffice. Selection at this stage should be aimed at using the special treatment available in institutions only for those cases best able to benefit from it and so avoiding the use of such treatment when consequential complications may only protract the stay in the institution.

Every effort should be made to discover active tuberculosis at the earliest stage and to give the closest attention to contacts and the ascertainment among them of non-reactors to tuberculin with a view to raising their immunity by B.C.G. vaccination. Chest physicians will recognize that it is important to concern themselves no less with prevention and aftercare than with their clinical work; and that it is necessary to give sedulous attention to case-finding and the supervision of the tuberculous family, including visitation in the home.

Mass Radiography

Mass radiography is of first importance in case-finding and in discovering latent infective cases among groups of the population so as to check the spread of infection. There should be the closest co-operation between regional boards and local health authorities in applying mass radiography to groups in which significant tuberculosis is most likely to be found. A local health authority should be informed by the board of all surveys arranged in the authority's area and also of the general results of the surveys. There should also be co-operation with regard to propaganda regarding mass radiography.

The system should not be regarded as a diagnostic service independent of the chest clinic service, and the medical officer in charge of a mass radiography unit should be on the staff of a chest clinic with responsibility for clinical sessions there. It is desirable that a period of duty with a unit should form part of the training of a chest physician.

So far as resources permit the work of a mass radiography unit should include periodical repeat examinations of selected groups.

Resettlement of the Tuberculous

The occupational resettlement of the tuberculous is part of their aftercare. It needs to be closely co-ordinated with the treatment of the individual case and, therefore, to be no less the concern of the chest physician than the clinical management of the case. The value of village settlements in this field has long been recognized; but the extent to which the need can be met in this way is limited, and other methods also need to be followed. Local health authorities, with the participation of chest physicians in their preventive and aftercare functions, can do much by closely associating themselves with the work of Ministry of Labour and National Service officers in connexion with the Disabled Persons (Employment) Act.

There is no better way of consolidating the good effects of sanatorium treatment than for the patient to undertake work under sanatorium conditions. Tuberculous persons should therefore be considered wherever possible in staffing tuberculosis institutions. The Minister hopes that he may shortly be able to issue further guidance as to the terms on which ex-patients not yet capable of full-time work may be engaged.

Open-air Schools

The scope of prevention and rehabilitation extends to children who are, or are at risk of being, tuberculously affected. In this field a particularly important part can be played by open-air schools whether residential or for day scholars, provided that the right type of case is admitted to them, which depends on skilled diagnosis and accurate assessment of the clinical needs of the individual child coming to the notice of the chest clinic. Co-operation between the hospital paediatric service, the general-practitioner service, child-welfare authorities, and education authorities is essential.

Nova et Vetera

EARLY DAYS OF GYNAECOLOGICAL SURGERY

The Development of Gynaecological Surgery and Instruments. By James V. Ricci, M.D. (Pp. 594; illustrated. $12.) Philadelphia and Toronto: The Blakiston Company. 1949.

This book purports to give an account of gynaecological procedures and instruments "from the Hippocratic dawn to the antiseptic age." Not unnaturally a full half of the volume is devoted to the pre-Listerian nineteenth century, for gynaecology as we now know it is almost entirely the product of the last hundred and fifty years, and the growth of the knowledge and the art of treating "the diseases of women" was meagre in all the previous centuries. Nevertheless there is a great deal of picturesque, interesting, and occasionally valuable information to be extracted from the earlier literature about what would be called gynaecological treatment, the instruments and appliances used, and the men who used them. In this province Professor Ricci is obviously quite at home. His sixteen hundred references are remarkable, many of them containing long verbatim extracts from the original sources. For checking these the author gives credit to Dr. Curt Proskauer, who deserves this tribute for the fine accomplishment of a Herculean labour. There are numerous but unnumbered reproductions of old illustrations; their usefulness would be greatly increased by being numbered and more specifically related to the text.

Unquestionably America made a great—perhaps a disproportionately great—contribution to the early development of gynaecology, but, while this work rightly receives full consideration, the author has by no means neglected the contemporary work that was done on this side of the Atlantic. Professor Ricci disclaims any attempt "to explain why or how gynaecology originated," or any intention "to dwell upon what has been designated the 'philosophy' of medical history." Although, as a matter of fact, he does not keep within his self-appointed limits, there is no reason to complain. He has made his work primarily and predominantly factual, and as such it is a volume to be consulted rather than read. It may well be called a mine of information, fully documented; and it will be a most helpful guide to all who have either the desire or the occasion to delve into the early history of the subject. The book will prove a useful addition to all medical libraries.

R. W. JOHNSTONE.

A circular from the Ministry of Health to hospital boards and committees discusses the use of duty-free spirits in hospitals and hospital stills. Full duty is payable on potable spirits. Rebate of duty may be obtained on spirits used in the manufacture of certain medical and surgical preparations. Applications for rebate should normally be made once a quarter to the local officer of Customs and Excise, who can supply full details about the scheme. The arrangements for supplying duty-free spirits have been revised. The Commissioners of Customs and Excise have in certain cases required the enactment of a bond before authorizing the receipt of duty-free spirit by a hospital. This requirement can now be dispensed with, and the Ministry advises hospitals to end any existing arrangements with sureties. This concession obtained by the Minister is made in the form of an individual authority granted to the management committee or board of governors concerned. To obtain the authority the secretary or a responsible member of a committee or board should send Customs and Excise Form Ex.240 to the local officer of Customs and Excise.

Correspondence

Auto-antibody Formation and Disease

SIR,—This letter is stimulated by the very interesting report by Keith Ball on "Abacterial Form of Endocarditis with Necrosis of the Ears" which appeared in the *British Medical Journal* of May 27, 1950 (p. 1236).

In the absence of knowledge concerning aetiology and pathogenesis there is a tendency to lump together different diseases on the basis of similar clinical manifestations or post-mortem findings. Contrariwise, a disease with manifold clinical and pathological manifestations may be divided into several categories until the common aetiological agent is discovered. Thus it was not until isosensitization to the Rh factor was demonstrated that it was possible to connect with certainty the diverse manifestations of erythroblastosis foetalis.

According to the principle of "horror autotoxicus" enunciated by Ehrlich it was believed that antibodies are never produced which are directed against substances which are normal constituents of the body. It has been found, however, that certain individuals exist who have a remarkable propensity to form antibodies and can even form auto-antibodies. When the newer sensitive techniques for demonstrating univalent Rh antibodies, such as the conglutination and anti-globulin tests, or tests with enzyme-treated red cells, are applied in such cases, the presence of auto-antibodies against the erythrocytes can readily be demonstrated in the serum of such individuals. In this way it has been possible to explain certain cases of acquired haemolytic anaemia.

It seems that there are a number of other clinical syndromes which were formerly considered to be unrelated which can be explained by the same mechanism. This explanation would apply, for example, to the syndrome designated as thrombotic thrombocytopenic purpura. This almost uniformly fatal condition shows at post-mortem examination multiple thrombi which have been interpreted on the basis of their staining reactions to be platelet thrombi.[1] A more reasonable interpretation[2] of these lesions is that the thrombi consist of lysed and autoconglutinated red cells. The theory that these lesions are due to autosensitization seems plausible, and this would also account for the frequently associated haemolytic anaemia.

Autosensitization appears to play a part also in the ill-defined syndrome designated as disseminated lupus erythematosus. In a case recently seen by the writer, by using trypsinated test cells, there was no difficulty in demonstrating auto-antibodies in the serum of the patient, who also exhibited purpura and haemolytic anaemia. The so-called L.E. inclusion phenomenon of Hargraves *et al.*[3,4] can probably be explained as due to coating of the patient's red cells by auto-antibodies followed by phagocytosis of the sensitized cells by leucocytes. Thus in the writer's opinion the inclusion bodies probably do not consist of nuclear material, but of damaged red cells. The remarkable propensity of patients with lupus erythematosus to form antibodies in general is illustrated by the interesting case report of Callender and Race.[5]

It is tempting to apply the same explanation to explain the case of Keith Ball. Autosensitization could account for the rapidly developing anaemia which the patient exhibited. The necrotic lesions in the ear could be explained by the blockage of the circulation by autoconglutinated cells. The disseminated nature of the condition was demonstrated by the presence of similar infarcts in the heart, kidneys, and brain. The fact that no bacterium could be isolated seems to refute the diagnosis of endocarditis. It is unfortunate that no tests were made for auto-antibodies, and it would be interesting to determine the results of such tests in future cases of so-called abacterial endocarditis.

Sensitization of type Rh$_1$ individuals by type Rh$_2$ or type Rh$_1$Rh$_2$ blood either by pregnancy or by transfusion is rare. We have encountered six anti-rh″ sera from such individuals, and in every case tested we were able to demonstrate the presence of auto-antibodies with the aid of trypsinated red cells, while two of the patients were also sensitized to the hr′ factor.[6,7,8] Moreover, in three cases of haemolytic anaemia with serological evidence of autosensitization, sensitization to the hr′ factor occurred following blood transfusion. Yet hr′ is a poor antigen, as shown by our experience with normal male volunteers.[9] In such individuals sensitization to the Rh$_0$ factor is readily induced by two or more injections of small amounts

of blood, but attempts to induce hr' sensitization have so far been unsuccessful. Our observations therefore tend to support the concept of the existence of rare individuals with a striking constitutional ability to form antibodies.[10] Further evidence is provided by the remarkable case reports of Collins *et al.* and Malone and Cowen in the *British Medical Journal* of June 3, 1950.[11] One can predict that in these cases, also, suitable tests would demonstrate the presence of autosensitization. In the cases of rh" sensitization mentioned above the auto-antibodies present in the patients' sera were apparently doing no harm. It remains to be seen whether or not the presence of auto-antibodies demonstrated with the aid of enzyme-treated red cells is a warning that some time in the future the patients may develop haemolytic anaemia, lupus erythematosus, or some other clinical sequel of autosensitization.—I am, etc.,

General Adaptation Syndrome

SIR,—In your leading article of June 17 (p. 1410) you eulogize the work of Dr. Hans Selye in terms that cannot fail to have their influence on future textbooks. You say that his work was neglected until "in 1949 the application of his work to the treatment of rheumatoid arthritis suddenly changed neglect into enthusiasm." May I ask you, Sir, in all humility just how the work of Selye applies to the effects produced by A.C.T.H. and cortisone in rheumatoid arthritis? Is it his experimental or theoretical contribution that most impresses you? Among much published experimental work, possibly his most striking report was that rats deprived of one kidney, fed salt, and injected with 11-desoxycorticosterone, developed an arthritis. There was little in this to suggest, at the time, that a suprarenal corticoid might relieve rheumatoid arthritis. Is it not, therefore, a little fanciful to describe, as you do, the distinguished chemist and physician at the Mayo Clinic who made this great discovery as "decorators" of Selye's building—the General Adaptation Syndrome which he invented? It is presumably this theoretical contribution that you think most significant, since you say, "No theory in living memory has possessed these virtues . . . etc." Of what does this theory consist?

The general idea, as I understand it, is that the body reacts to all forms of stress in a general non-specific way; but unfortunately no one can define precisely what that way is, because the response is always complicated by "conditioning" factors, including the local effects of the particular "stressor." We get few clues about the precise nature of this general response from the published account of Selye's Heberden Oration (p. 1383) except that "the systemic defence measures . . . are co-ordinated through the hypothalamic vegetative centres and the hypophysis" and "all stressors cause an A.C.T.H. discharge." This naturally makes it plain that whenever A.C.T.H. is discharged or, by implication, in any disease that responds to A.C.T.H., the general adaptation syndrome is at work and that stress has set the process in motion. It does not seem to matter that some of these "defence measures" are positively harmful, such as impairment of wound healing and the diminished resistance to infections induced by A.C.T.H. These, you say, are "because the derailment of the defence mechanism is on the other side of the track." Personally I don't know what this means, but I am sure that you do.

Obviously this is a comfortable new theory that helps us to think that we understand what we are doing in the practice of medicine, and allays some of our uncertainties and unquiet thoughts. My chief complaint against it is that it overlooks one of the basic rules of science. Admittedly, there have been rare occasions when science has been helped forward by brilliant deductive intuition, but its solid splendour has been founded on the less spectacular process of induction: observing the particular phenomenon, "asking Nature simple questions one at a time," and finally arriving at a tentative hypothesis that provisionally explains the observed facts. In my view, the theory of the general adaptation syndrome has not been subject to this discipline; it has been arrived at by the opposite intellectual process—that of deduction, from the general to the particular. A simple diagram may make my meaning clear:

General Over-all Direction
↓
Hypophyseal Stimulation
↓
General Adaptation Syndrome
↓
Several Possible Unborn Deductive Speculations

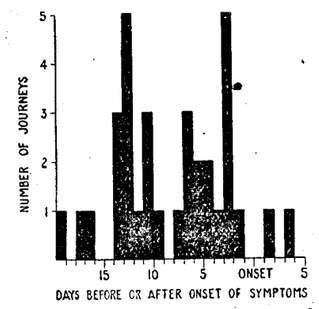
The theory of the general adaptation syndrome having been postulated, it was, in Selye's words, "tempting to survey all diseases of unknown aetiology from this new point of view and to determine whether those among them which apparently can be caused by a variety of agents belong to the category of diseases of adaptation." He adds: "This has been accomplished." Thus, we are confronted on p. 1389 with what you yourself call an "astonishing list" of diseases, including agranulocytosis, blepharitis, and nasal polyps in which A.C.T.H. is said to do good, and adding acne and others in which it is said to be harmful; is it implied that these are all "diseases of adaptation"? If so, where is the evidence that they have been initiated by stress?

I think, Sir, that we would do well to remember that, through deductive speculation, civilized society was once plunged into the Dark Ages, from which it was rescued only by the inductive reasoning of Harvey, Descartes, and their contemporaries. We are now constantly threatened by the possibility of a new Dark Age; this time dressed up in all the outward trappings of science rather than of religion. Some signs of this have already come from elsewhere—in the field of genetics. A book that would give us a comforting and apparently satisfactory explanation of a host of obscure diseases, under a "general" all-embracing theory, might serve very well the same purpose that Galen's book did in the former Middle Ages. As Selye himself says, "It will take many years, indeed many generations, before the details of the general adaptation syndrome are satisfactorily elucidated." Finally, imagination boggles at his implication that the health services of the future should include "the specialist in stress and adaptation."—I am, etc.,

Edinburgh. A. P. MEIKLEJOHN.

Poliomyelitis and Fatigue of Travel

SIR,—In the poliomyelitis outbreak of 1947 one feature was the apparently capricious selection of victims. A common occurrence was the simultaneous appearance of cases in a locality in such a way as to suggest widespread infection which was intense enough only to cause a few cases. Why were the victims chosen and others—many in the same households—left unharmed?



Russell (1947 and 1949) demonstrated in a number of cases a causal relationship between muscular effort and intramuscular injection on the one hand and the onset and severity of paralysis in cases of poliomyelitis. Hargreaves's (1948) results bear out this observation. Nisbet (1949) in a small series of cases found no correlation between muscular effort and the onset of paralysis.

In a series of 84 confirmed cases occurring in Moray and Nairn over the three years starting in 1947, confirmatory evidence of the findings of Russell and Hargreaves has largely been lacking. In no instance was the onset of paralysis specially linked with muscular effort. In one instance, a journey made on the second day after the onset of symptoms was associated with fatal bulbar paralysis. In the other case where the patient

indulged in travel after the onset no paralysis ensued. Many of the cases received intramuscular penicillin into the gluteal region. Equally, many of the cases so treated developed no paralysis, and in no case could it be determined that paralysis of the gluteal musculature was associated with injection.

The foregoing is not to be taken as a statement of disbelief in the findings of these two observers, but merely that their good fortune in securing evidence on the point has not been shared. This is made particularly clear, because evidence which suggests that fatigue may favour the onset of poliomyelitis, paralytic and otherwise, and that in particular the fatigue of travelling may do so, has been secured and is now set out.

In correlating the evidence concerning the movements of patients and their contacts it was noted at an early date that in quite a number of instances the patient had travelled during the two or three weeks immediately before the date of onset. This led to further inquiry into the incidence of travel, and the results are here expressed graphically, 33 journeys made by 21 patients being recorded. The term "journey" is perforce an elastic one, varying as it does from a day of travel from Surrey to Elgin to relatively short bus journeys within the area of the county. None of the journeys were features of the daily lives of the persons who made them; similarly, 63 other patients in the series were not regular travellers.

Travelling in relation to the onset of poliomyelitis.

One-quarter of all cases in the series made journeys. I cannot but treat this as a fact of significance. Further, a substantial preponderance of these journeys was made between the thirteenth and tenth days prior to onset, both days included, and similarly between the sixth and second days prior to onset.

There appears to be an association between the journeys made longer before onset and the date of infection. This supposition tallies fairly well with the theory of Casey (1942) concerning the length of the incubation period, particularly with the formula 12.2 ± 1.1 days.

If the supposition that travel coinciding with exposure to infection predisposes to infection is accepted as a hypothetical *terminus ad quem*, it then follows that the vehicle employed for travel is a place particularly favourable to the passage of infection, or that by travel the bodily threshold of resistance is lowered, so that an otherwise unrecognizable infection becomes clinically recognized. The latter supposition is the more likely. The most likely effects of travel appear to be excitement and fatigue, both of which are phenomena pertaining to the nervous system. It seems therefore not too far-fetched a theory to propound that the excitement or fatigue of travel, coinciding with infection, predisposes towards an attack of poliomyelitis.

Journeys made in the period immediately before the onset are less likely to be associated with the date of infection. Study of the diagram will show that a peak is reached two days before the onset. The shortest period of incubation for which authority has been found is three days. Hypothetical explanations for this phenomenon are put forward as follows. In the case of journeys made four or more days prior to onset, the arguments already advanced hold good, and the occurrence could be due to infection and predisposition at that date. Alternatively, the effect of travel, fatigue, and excitement is so to alter the physiological reactions of the nervous system that the incubation period is shortened. Thirdly, the effect of travel with its attendant fatigue is to bring to clinical levels a pre-existing infection; the condition may be aggravated but not caused by the travel. This last supposition appears to be the most likely, though a naturally short incubation period is a possibility which cannot be entirely ruled out.

To summarize, therefore, evidence has been set out to show an association between the date of onset and the patient's travelling. The most probable explanations for the occurrence appear to be conditioning the body to the reception of infection, and, nearer the moment of onset, to aggravate the virus potency for harm in its victim. This conditioning or aggravation is most probably due to the lowering of the resistance of the nervous system to the virus through the agency of fatigue.

I desire to express my indebtedness to the Senatus Academicus of the University of Edinburgh for permission to use the subject matter of this letter for publication.—I am, etc.,

Elgin, Morayshire. I. C. MONRO.

Crisis in Tuberculosis

SIR,—In your important leading article under this heading (July 8, p. 92) you suggest that the Scottish proposal to bring unused beds in infectious diseases hospitals into the tuberculosis scheme is only a partial solution, as many of these beds could only be used for "untreatable tuberculous patients." This is probably true if bed rest with care and attention no longer ranks as treatment. It seems to me, however, that with the greatly increased possibilities of active treatment there is a tendency to shelve the untreatable case who needs admission so badly, not only on humanitarian grounds but even more because of his potential danger to others. Surely he is the greatest spreader of tuberculosis except the chronic ambulant sputum-positive case, known or unknown. The problem of the latter is a difficult one, but must be tackled more conclusively in any really effective attack on this disease. No scheme, however, can be called effective which does not provide almost immediate admission for the open case desiring and requiring hospitalization, and the isolation hospital seems particularly appropriate for this purpose.

Surely the first plank in any campaign to deal with tuberculosis should be the creation of a large pool of beds which are frankly only suitable for routine treatment. These are more easily provided, need a smaller proportion of trained staff, and are not necessarily permanently dedicated to tuberculosis. They might be graded for advanced, intermediate, and convalescent cases. Only in this way can we make full use of the available treatment beds. The teaching hospitals can hardly be expected to take their proper share in the treatment of emergency tuberculous patients and cases for assessment or special treatment without a guarantee that they will be promptly relieved of cases which reach the routine bed-rest level. The higher grade sanatorium could save innumerable bed-weeks if the system was sufficiently fluid to allow easy transfer of treatable patients during the considerable periods when their treatment may be said to descend to the routine, with, of course, arrangements for taking them back when required.

Lastly, one might suggest that those institutions which remain on a somewhat lower level of medical and nursing provision might well be compensated by special efforts to secure a high level of comfort, catering, occupation, and interest. While this entails expenditure, it need not make demands on trained nursing staff, and it is good treatment.—I am, etc.,

London, S.W.1. IAN S. THOMSON.

SIR,—As your leading article (July 8, p. 92) so rightly says, there is a crisis in tuberculosis; how to provide beds and how to staff them is the fundamental question. There is in Montana, Switzerland, a British sanatorium, fully equipped for treatment of every type of tuberculosis, which is at the moment only occupied by twenty patients instead of the hundred which it is capable of taking. The reason for this is partly that most patients cannot afford the fees which now have to be charged, since the sanatorium is only quarter full. Before 1948 the majority of patients were subsidized by their local health authorities, which in most cases were only too glad to pay a proportion of the fees when they saw the opportunity of getting

these cases into a sanatorium within reasonable time. There seems now little opportunity of getting patients into sanatoria within reasonable time unless such a place as Montana Hall is utilized.

Eighty beds may be only a drop in the ocean of beds required, but at least it is a drop.—I am, etc.,

Sidmouth, Devon. A. H. DUNKERLEY.

Inoculation and Poliomyelitis

SIR,—The recent indication of association between inoculation and poliomyelitis (July 1, p. 1) raises the question whether this is yet another manifestation of the stress and general adaptation syndrome (Selye, June 17, p. 1383).

It seems possible that, during the incubation phase of an infection with the poliomyelitis virus, the body is in a state of stress comparable with that called by Selye the "alarm reaction." During this phase the individual is more sensitive to conditioning factors, such as an inoculation. This may explain why many cases of poliomyelitis do not reach the stage of paralysis, as in them there has not been any antecedent selective conditioning factor. Theoretically, conditioning factors of many types such as inoculation, tonsillectomy, exercise (Ritchie Russell), or even severe mental strain may play a part in the aetiology of each case of poliomyelitis showing paralysis.

If this hypothesis is correct, it should eventually be possible to treat, by the injection of adrenal hormones (corticoids), cases of poliomyelitis in the early stages, either to prevent the onset of paresis or to halt its course. It is believed that A.C.T.H. has no helpful effect on poliomyelitis, but other corticoids with theoretically a similar action on the general adaptation syndrome may be synthesized in the near future. It would seem well worth while to subject them to prolonged clinical trial on a disease which so far has no specific therapy.—I am, etc.,

London, S.W.7. JOAN LLEWELYN.

Chloromycetin and Typhoid Haemorrhage

SIR,—This report of the timely arrival of "chloromycetin" in saving the life of a moribund patient with daily typhoid haemorrhages is considered worthy of record.

On December 7, 1949, a young Arab of Bahrain aged 20 was admitted to the Bahrain Government Hospital with a 3-day pyrexia of acute onset. On admission he had a temperature of 103° F. (39.4° C.) and pulse of 108. Patient was quiet. The abdomen showed no definite signs other than an enlarged spleen. The chest was normal. There was a leucopenia of 3,200. The urine was normal.

During the first week the pyrexia ran the usual high intermittent course of 103°–104° F. (39.4°–40° C.), and the pulse was 108–118. On the tenth day of the disease the Widal reaction showed a high positive for *S. typhi* of 1/250. By then the abdomen was distending with right-iliac-fossa tenderness and tympanites. The general condition was that of a restless early delirium. After reaching a peak temperature of 104.6° F. (40.3° C.) on the tenth day a slow lysis took place during the second week, where it settled at 102° F. (38.9° C.) well into the third week. The general condition was now deteriorating. His bowels, loose at the onset, then confined, became again active.

On the twenty-first day four roundworms were passed. Early the next morning 2–3 oz. (55–85 ml.) of dark red blood was passed. Morphine was given, ice bags were applied to the abdomen, and intravenous saline therapy was at once adopted. After a pause of one day a specimen stool showed a large quantity of blood, about 10 oz. (280 ml.), and two roundworms. More rigorous saline treatment was given, and also nikethamide. The pulse rate did not rise above 120, and the temperature remained at 102°–103° F. He was weakening fast, with high delirium. He was not expected to live more than another two days, and with tense anxiety we were awaiting the arrival of chloromycetin.

The following morning the drug arrived on the twenty-fourth day of the disease. A course was planned as follows: first day, 4 g.; second day, 4.5 g.; third day, 4 g.; fourth day, 3.5 g.; fifth and half the sixth day, 5 g. A total of 21 g. was therefore given over five and a half days. Dosage was 0.5 g. and 0.25 g. alternately every two hours the first two days; 0.5 g. two-hourly the third day, and 0.5 three-hourly and then four-hourly for the remaining time.

Intravenous saline therapy, ice to abdomen, and nikethamide were also kept on for four days of the chloromycetin treatment, because two subsequent small haemorrhages, each of 2 oz., occurred during the next two days. Three more roundworms were also passed.

Results of Treatment.—First day: temperature dropped to 101° F. (38.3° C.); haemorrhage. Second day: temperature 101° F.; pulse 118 all day; delirium improving; haemorrhage. Third day: temperature 101° F.; pulse 118; speech rational, and patient aware of his surroundings; bowels not open. Fourth day: the same. Fifth day: temperature 100° F. (37.8° C.); pulse 112; abdominal distension greatly diminished; mental condition normal; sleeping all day. Sixth day: temperature lysing; bowels still confined.

Two days after cessation of the chloromycetin treatment the temperature was normal and the pulse was 100. After four days of constipation from the last haemorrhage, enemas were given every second day. Twelve days from the last haemorrhage solid diet was begun, and progress thereafter has been excellent and uneventful, without relapse.

There was no dramatic fall of temperature till the sixth day of chloromycetin treatment, presumably because of the widespread involvement of the lower small intestine. The subacute abdominal signs improved progressively daily despite the two haemorrhages after the start of treatment. The most dramatic effect was the mental change from high delirium and restlessness to quiet awareness in three days.—I am, etc.,

Bahrain, Persian Gulf. R. H. B. SNOW, State Medical Officer, Government of Bahrain.

Treatment of Reiter's Syndrome

SIR,—Dr. O. B. Appleyard's report of a case of Reiter's syndrome (June 17, p. 1435) clearly demonstrates all the yet unsolved riddles, clinical, aetiological, and therapeutic, connected with this fascinating problem. I have read his notes with great interest, but I would like to correct his statement that the case reported is the first one to be treated with streptomycin and "sulphamezathine." Soon after Powell and his co-workers (1946) and Bushby (1947) had made known their results on the action of streptomycin on "L" organisms, which are believed to play an important part in the causation of Reiter's syndrome (Harkness and Henderson-Begg, 1948), clinical trials with the antibiotic were undertaken. Warthin (1948) reported four cases and Dienes *et al.* (1948) published the results obtained in six cases.

My earliest personal experience with the antibiotic in Reiter's disease goes back to 1948, when the first two patients were treated at St. Charles's Hospital; both received 10 g. of streptomycin (0.25 g. six-hourly for ten days). The results have been reported and commented on elsewhere by Harkness (1950), who also mentions a third case treated with 20 g. of streptomycin (0.5 g. six-hourly), which is of special interest because the patient developed typical lesions of keratodermia blennorrhagica during treatment, thus demonstrating the inability of the drug to overcome the disease. On the other hand, another patient, aged 35, in a severe relapse of Reiter's disease was treated in July, 1949, with 18 g. of streptomycin (0.5 g. four-hourly for six days) and completely recovered. Although he developed a toxic skin eruption after the last dose, this cleared with antihistamine drugs in thirty-six hours and the patient was discharged home a week after completion of treatment.

However efficacious such treatment may be, such large doses of streptomycin, even for a short period of time, are obviously dangerous. An interesting point mentioned by Dr. Appleyard is the rise in the erythrocyte sedimentation rate during streptomycin therapy, when a fall would be expected. I can confirm this paradoxical finding in four streptomycin-treated cases of Reiter's syndrome, and Dienes has made the same observation. Moreover, the temperature may behave in a similar fashion and not return to normal till some time after the injections have been discontinued.

The most urgent problem in connexion with Reiter's syndrome is, to my mind, the elucidation of its aetiology. The first step in this direction must be the co-operation of clinicians and bacteriologists in the investigation of all cases of Reiter's syndrome and, furthermore, the realization that nearly all cases of so-called gonococcal rheumatism or gonococcal polyarthritis are really cases of the incomplete form of Reiter's syndrome. It is also important to recognize that the syndrome is either of the dysenteric or venereal type and that the latter is a true venereal disease with all its epidemiological implications. Harkness (1949) suggested the name "venereal syndrome" for the condition following sexual intercourse, and "dysenteric syndrome" for the disease described originally in 1916 by Reiter, and he holds the view that the infective agent in both conditions is probably the same, the portal of entry in the first condition being the urethra and in the second the bowel (Harkness, 1949 and 1950).

Recent advances in the study of the venereal syndrome as described by Harkness include the microscopical demonstration of a virus in the scrapings from the urethra, conjunctivae, and skin lesions. Attempts to infect suitable laboratory animals and isolate the virus are proceeding, and from the therapeutic point of view preliminary results with aureomycin are so far very encouraging. Recently two patients admitted to St. Charles's Hospital in the acute stage of Reiter's disease (venereal syndrome) were treated with 23 g. of aureomycin (0.5 g. six-hourly) and improved in an almost spectacular way. It is hoped that a detailed report will be published later.—I am, etc.,

St. Charles's Hospital, W.10. A. I. SUCHETT-KAYE.

Morphine and Histamine in Bronchial Asthma

SIR,—In their letter (May 20, p. 1199) Drs. Feldberg, Paton, Nasmyth, and Stewart say that histamine is released by morphine in isolated perfused mammalian tissue. They suggest that the strong reaction of patients with chest trouble to morphine may be due either to the fact that they release more histamine after morphine has been given or to their increased sensitivity to histamine. I have not much doubt that the second suggestion is the correct answer. Recently I have compared the response of asthmatic subjects and normals to histamine aerosol and found, as others have done before, that very small doses produce a violent bronchial obstruction in asthmatics, whereas in normal subjects much larger amounts caused only mild responses. Moreover, in normal subjects systemic effects of histamine appeared before or together with a bronchial response, while in most asthmatics no systemic effects were observed: the small amount given was sufficient to cause a strong local bronchial effect but not large enough to produce a systemic one.

Most of your correspondents have come to the conclusion that in the circumstances the use of morphine in asthma should be abolished. I am not sure that this rigid attitude is justified. There are some cases of asthmatic state in which sedation is urgent but barbiturates have not the desired effect. In such cases I have given morphine together with adrenaline or isoprenaline, often with success, but I have never seen ill effects from it. This absence of ill effects is easily understandable, as adrenaline and its relatives have a strong antihistaminic action and can neutralize any histamine released by the morphine. I think morphine should be given only in those cases in which it is really necessary, and never without adequate cover by adrenaline.—I am, etc.,

London, W.C.1. H. HERXHEIMER.

Case-finding in Pulmonary Tuberculosis

SIR,—The importance of case-finding in the control of pulmonary tuberculosis is well recognized, and mass radiography has been used on a wide scale for this purpose. However, mass radiography is not easily available to all sections of the community and other methods of case-finding must be employed.

It is now realized that pulmonary tuberculosis is more common among the middle-aged and elderly, especially males, than was formerly believed. The predominant symptoms of cough, sputum, and shortness of breath suggest a diagnosis of chronic bronchitis and emphysema, and often no investigations are made to exclude more serious disease. It is quite possible that some of these patients may, in fact, be suffering from pulmonary tuberculosis and be a potent source of infection to the general community. Most of these patients will escape a mass-radiography survey as many will be retired or unfit for serious employment, but many of them have sputum for testing, and if this were done on a wide scale a surprising number might be found to be positive for tubercle bacilli. In view of the cheapness and ease with which it can be done it would seem to be the first examination that should be made in cases of this type in order to arrive at a correct diagnosis.

While the disposal and treatment of such cases as are found to be positive constitute an enormous problem, yet identification of the disease is an essential preliminary to eradication, and sputum-testing is the cheapest and easiest method of doing this and is particularly applicable to the older patient.—I am, etc.,

Frodsham. M. B. PAUL.

Spontaneous Dehiscence of Coverings of Incisional Hernia

SIR,—From time to time cases are encountered of ulceration of the skin over the fundus of a large hernial sac, and occasionally spontaneous faecal fistulae may occur from the contained intestine. Unheralded and spontaneous external rupture of an incisional hernia would appear to be a very rare complication, and the whole chain of events in the following case is unusual enough to be worthy of record.

A woman aged 74 was first admitted to Tindal General Hospital, Aylesbury, in November, 1942, under the care of Mr. G. C. Laurie Pile. Three weeks before admission she had complained of repeated bouts of abdominal pain and vomiting, and had noticed the appearance of a lump in her left groin. The lump had increased in size, and throughout the following period she had had intermittent attacks of abdominal pain, vomiting, and a tendency to constipation. Finally, she had gone to her doctor and drawn his attention to this swelling. On admission she had had no bowel action for three days. She was a frail, thin old lady, moderately dehydrated and in a good deal of pain. Her abdomen was distended and tympanitic, with increased peristaltic sounds. In her left groin was a large, tense, inflamed, and irreducible swelling. It was considered that she was suffering from a strangulated femoral hernia, probably of the Richter category, with abscess formation over the femoral canal.

Operation was undertaken on November 24, 1942, by Mr. Pile under gas, oxygen, and ether anaesthesia. The mass in the groin was incised, several pints of faecal pus were drained, and a good deal of necrotic omentum was removed. The problem at the time was whether (1) to risk retraction of the strangulated loop into the abdomen, and hope that a faecal fistula would form; or (2) to proceed to immediate laparotomy and resection. The former course was considered the wiser and appears to have been correct in the light of subsequent events.

After the operation a faecal fistula developed at the site of incision, and continued to discharge for the following six weeks, in which time, under treatment, the patient's condition improved greatly.

After this period laparotomy was performed through a left paramedian incision. The affected portion of small intestine was freed from the femoral canal, resected, and side-to-side anastomosis carried out to establish continuity. Apart from some superficial wound sepsis recovery was uneventful, and the patient was discharged from hospital four weeks later.

After this remarkable episode she was lost sight of until July, 1949, when, at the age of 81, she returned to the out-patient department. She had a large incisional hernia through her paramedian wound with a neck to the sac of some 2½ in. (6 cm.) in diameter, situated just below the level of the umbilicus.

The skin over the fundus of the sac was parchment-like, and visible peristalsis was obvious within the hernia. The skin itself showed a little superficial reddening, suggestive of external abrasion from her clothes. A surgical corset was immediately ordered, and she was advised to rest as much as possible at home until this was available. However, two months later, she was seated on the lavatory one morning, and, while straining, the fundus of the sac gave way. According to her statement she precipitated several coils of small intestine into the lavatory—but possibly she exaggerated. There had been no premonitory symptom to herald this event, and there was no suggestion that the hernia had strangulated or that any gross skin sepsis had occurred before the incident.

She was admitted to hospital two hours later, and, in spite of her age and the nature of her complaint, was in a reasonably good condition. Through a small defect over the fundus about four feet of small intestine had extruded themselves on to the abdominal wall.

Operation was undertaken within an hour of admission (heavy nupercaine spinal analgesia, by Dr. R. B. Clayton). The extruded bowel was returned to the abdomen, and through a transverse

incision the hernial sac and redundant skin were excised. A formal repair of the hernia was carried out. All the abdominal parietes were thin and papery, and a stainless steel wire darn was incorporated in the anterior rectus sheath as reinforcement.

Recovery from this operation was uninterrupted, and the patient was discharged home on the twelfth post-operative day.

I am indebted to Mr. G C. Laurie Pile for permission to quote from his old notes on the case, to Mr. R. H. Gardiner, under whose care the case was admitted, and to the medical superintendent, Dr. R. H. M. Stewart, for permission to publish the case record. —I am, etc.,

Aylesbury, Bucks. RICHARD R. L. PRYER.

Treatment of Arterial Thrombosis

SIR,—Professor A. M. Boyd and Mr. R. P. Jepson in their article describing two cases of external iliac artery thrombosis in the *Journal* of June 24 (p. 1457) rightly stress arterial block rather than angiospasm as the cause of claudication. While the arteriectomy and sympathectomy done on each of their patients produced improvement, yet by doing both procedures together they missed the opportunity of testing the theory of reflex vasospasm initiated by an artery locally blocked, and this theory still requires proof before it is tenable.

The increase in peripheral pulsation produced in both patients is small, and, as the authors state, the ultimate prognosis may not be good. Endarteriectomy rather than arteriectomy with or without sympathectomy might have given better results. The lesions were small in extent and the patients young, and the photogravures show a thrombus almost asking to be shelled out of an artery which has a good wall. Dr. Henri Reboul, of Paris, has recently shown me some of his work on endarteriectomy, and the main purpose of this letter is to draw attention to important publications on this subject.[1 2]

The didactic quality of the statement by Boyd and Jepson, quoting Ratcliffe and Jepson that only by removal of the first lumbar ganglion can a high thigh denervation be obtained, is not sustained by the preceding sentence, where it is stated that "the diaphragmatic crus is split to ensure section of the highest lumbar ganglion": this description might be interpreted to mean that the chain runs through the crus (which it does not) rather than underneath the internal arcuate ligament (which it does in very nearly all cases, though sometimes in the substance of psoas[3]).

Assuming that the word "acral" used in discussing the onset of thrombo-angiitis obliterans is not a misprint, I think I have gathered the meaning after considering possible derivations of the word: a common word or phrase instead of acral would be better.—I am, etc.,

Ankle Amputation

SIR,—In view of the renewed interest in Syme's amputation of the ankle, I thought it worth while to send you a summary of the operation described in J. M'Lachlan and A. A. Scot Skirving's *Applied Anatomy*, fourth edition, 1908. The book was published by Messrs. E. and S. Livingstone, Edinburgh. It is now out of print, but they have kindly lent me a copy from their library of old publications.

A special knife is used—"Syme's knife"—with a stout blade some four inches long, with a still stouter handle. Foot is held at right angles, and sole cut made down to the bone. Careful reflection of the heel flap till the prominence of the os calcis is turned and the tendo achillis visible. Keep close to the bone. Foot extended, and cut in front of ankle made down to the bone, and probably opening the ankle joint. Disarticulation, dividing the lateral ligaments from within. Removal of foot by section of the tendo achillis. Clearance of the ends of the tibia and fibula; removal of the malleoli and articular surfaces.

The sole incision starts at tip of external malleolus and ends at a point exactly opposite it on inner side.

In making the second incision across the ankle joint, the operator unites the two ends of the first incision, forming an angle of 45° to the sole of the foot and long axis of the leg. In other words, he cuts straight across the front of the ankle down to bone, dividing all the tendons, nerves, and vessels.

—I am, etc.,

Newton Abbot, Devon. W. H. STEELE.

Time and the Doctor

SIR,—I was extremely interested in Dr. Joan Malleson's able letter (June 24, p. 1487), but I think she is mistaken in the cause of what she writes about. *Surely it is not because the* symptoms are not serious enough that doctors will not trouble to treat menopausal disorders, but because in most cases they have not got the time to spend in thorough investigation of cases of this sort. Here is the real bed-rock of the trouble—most men would like to be good clinicians if they could afford it, but at the present rate of remuneration of general practitioners it is the time factor that counts. Might I be allowed to quote from my letter in the *Lancet* of May 6, 1950, p. 883?

"Unless the doctor is the fortunate possessor of private means, he is nowadays forced to be a head-hunter in order to live, pay his way, and maintain his wife and family. . . . *To meet his commitments* the practitioner needs a minimum of 2,250 on his list at the present rate of remuneration; and any doctor who has that number is likely to be required to supply, on average, 45 items of service per day—slightly less in the summer, and slightly more in the winter. If he has children to bring up he will require more money and must therefore collect more heads and get through more work."

There is the *real* answer to Dr. Malleson's complaint: relieve the doctor of financial anxiety; *give him the time to regain his* lost status, the time to become a clinician instead of a head-hunter for a living; and a new dawn of hope instead of despair will spread like a prairie fire throughout the profession.—I am, etc.,

Worthing, Sussex. HAROLD LEESON.

Revaluing the Levators in Colporrhaphy

SIR,—It is usual in prolapse cases to have an abnormal gaping between the levatores ani muscles, which form the greater part of the pelvic diaphragm. This may be due to low function in these muscles, or to their lateral anchoring by fibrotic tissue following parturient injury, or to development of a hypertrophic bulge in the walls of the enclosed viscera. Reasonably, therefore, gynaecologists have for half a century included mid-line suturing of the levators, *between the rectum and vagina*, as an essential feature in the operation of colpoperineorrhaphy. At its termination the reconstituted perineum can be felt as an impressive wedge, a large portion of this mass consisting of the surgically opposed levatores ani.

During the years when I followed the orthodox technique I noticed that the perineal wedge *diminished in size during convalescence*, but felt fairly confident that this was not due to faulty technique or to mild sepsis, and, as the final result appeared to be quite satisfactory, I ceased to worry about this phenomenon, though I kept it in mind. I could find no reference to it, or explanation, in gynaecological literature. In later years, when I had appreciably altered my operative procedure, the same feature persisted.

By bi-digital examination of the recto-vaginal septum in normal nulliparae while the levators were being contracted I had already noted the apparent absence of any levator muscle in the septum above the level of the sphincter ani externus; careful dissection at operations also confirmed the absence of any macroscopic muscle fibres in the septum. The occasionally described pubovaginalis ends by being inserted into the fascia on the lateral wall of the vagina. An examination of the septum, comparable to the above, after the formation of a new well-formed perineum, can best be performed by "opposable" palpation, using thumb and index finger, and this method eventually supplied me with the explanation of the perineal shrinkage phenomenon. Contrary to expectation, the levators, in the majority of cases, retract to a lateral position soon after the chromic catgut sutures dissolve. In the meantime they have served the useful purpose of acting as a splint while the reconstituted posterior vaginal wall and adjacent fascia have been healing and consolidating. The degree of retraction is limited by the soundness of the excision of the visceral bulge.

On several occasions I have had the opportunity of confirming that the same levator divagation had occurred in quite successful

colporrhaphies performed by other gynaecologists, and this will continue to occur unless unabsorbable suture material, such as nylon, is substituted for chromic catgut. The operative results are, however, so good that nylon might be necessary only for operations involving the rectum, and could be avoided when pregnancy and delivery by the natural passages is anticipated. Comparable observations by proctologists and urologists should be interesting.

The levator retraction stimulated my views about the importance of fascial conservation in colporrhaphy, especially in regard to the lateral recto-vaginal fascial bands (see my letter in the *Journal* of May 13, p. 1142). These bands can more easily be brought into perspective and their outer borders defined if gentle forward tension is applied intermittently at their insertions into the posterior vaginal wall; but during this process of dissection it is necessary to keep a protective coating of perineal tissue in position around their friable inferior fringes. Unlike striped muscle in other parts, the substance of the levators presents normally the same dull-grey look as the adjacent fascia.

Digging into their substance during orthodox colpoperineorrhaphy prevents the demonstration of these bands, by shredding them to bits, and is comparable to a similar process in the base of the broad ligaments[1-3] which prevented the identification of its sustentacular (Bonney, 1914)[4] ligaments for about three decades.

I have had opportunity, at secondary operations, to observe the substantial fibrosis that can occur in the extrapelvic perineal extension of the endopelvic fascia—an effective support that will, however, soften temporarily in response to the normal hormones of pregnancy, making caesarean section unnecessary, with certain exceptions.—I am, etc.,

British Spas and Health Resorts

SIR,—A few meetings have been called at 11, Chandos Street for the revival of the pre-war British Health Resorts Association. The physicians who took part in these meetings, although rendering homage to the efforts of the late Dr. Fortescue Fox and of Dr. Alfred Cox, considered that the revival of that association was not indicated, but that a new association for the scientific study and development of the British spas and climatic health resorts was necessary. I was entrusted with the task of ascertaining the views of the medical profession on this subject, and the following is the result of this small referendum.

The association to be created should be on strict scientific lines and centred on the physicians of the health resorts. It should encourage these physicians to study their particular hydromineral or climatic therapeutical agent. It should organize lectures by these physicians to various schools and societies on their particular spa or climatic health resort. It should collaborate with the civic authorities so as to develop the therapeutical installations, and to afford facilities to the physicians for their hydrological or climatological studies. It should encourage visits to these health resorts by students and physicians so that they may obtain direct information about the special balneological and climatological methods, and, last but not least, it should endeavour through various publications to bring these methods and their results to the notice of medical men in this country and abroad. This association should include all those interested in British spas and health resorts, and thus non-medical as well as medical men and women. Medical work is not the exclusive privilege of those possessing a medical diploma, because medicine is not only a natural science but also a social science.

The policy delineated above is followed with success by the British Spas Federation, but unfortunately only for eight spas, whereas other spas and the numerous and important climatic health resorts are not included. A more complete organization is indicated and can be in fact obtained by enlarging the scope of the British Spas Federation. Such a comprehensive organization would be not only more effective but also more powerful scientifically and politically.

Notwithstanding the great discoveries of specific remedies the constitutional methods of treatment remain the most important for the majority of diseases, particularly for the chronic and degenerative diseases which dominate our contemporary pathology. Spa and climatic treatments represent probably the most powerful constitutional therapeutical procedures, and those who, like myself, have studied health resorts on the Continent as well as in England realize that this country is second to none in wealth of such centres of physical medicine, centres of which many possess remarkable installations. It is time to set aside all ideas of local interest so as to place the British spas and health resorts on a comprehensive scientific basis for the benefit of our patients.

Who is going to take the lead in this movement, so important from a national as well as from a medical point of view?—I am, etc.,

London, W.1. A. P. CAWADIAS.

Tuberculosis Service in Scotland

SIR,—In a footnote to the Report on Tuberculosis Service in Scotland published in the *Journal* of July 8 (p. 61) my name is given among the members of the Subcommittee nominated by the Tuberculosis Society of Scotland. The word "resigned" appears in parentheses after my name. May I state that my resignation took place in the very early days of the subcommittee's deliberations and that I had no part in the preparation of the report?—I am, etc.,

Edinburgh, 9. CHARLES CAMERON.

The G.P. at the Crossroads

SIR,—Has nobody a good word for general practice? I deny none of the recent complaints—in fact, can contribute my own. I find the excessive number of "services" for trivial departures from health the most trying single new factor. This is a matter that could be controlled not by charging for prescriptions—a most difficult plan to implement—but by charging a given total sum for the first so many services rendered to an individual in any financial year. Details and exceptions could be worked out. Incidentally, this sum could be used to implement the Spens Report without further cost to the Treasury, and there is not the slightest doubt that general practitioners are inadequately paid for the amount of work they are doing.

However, my present purpose is to put in a word for general practice. Most G.P.s did not choose this province of medicine with the intention of making a lot of money. It was to them, in a greater or less degree, a vocation. If not, then they were not likely to be happy anyway.

The varieties of general practice are many; for myself I would not exchange the life of a country-town and country doctor for that of a specialist. Country practice is a way of life, and it still has its compensations even in the midst of present-day uncertainties. Remember that many of the trials and frustrations of which we complain are not peculiar to the medical profession but in some comparable guise are common to other walks of life and are due to the times.

In a practice of this nature, if one were adequately paid, then 2,500 persons per doctor is the ideal maximum if one wishes really to know one's patients, continue to look after them well, and be a "family doctor." Life is more pleasant with a compatible partner or partners. My partners and I are still regarded as "family doctors" by the majority of our patients. Many still honour us by coming for advice other than strictly medical. One is not too old to be flattered by the child who calls out as one passes, "Hello, Doctor!" and announces to his companions, "That's my doctor." There at least is one who will not be frightened if by chance he has to be examined in acute illness. In fact to us these are people, not mere cases.

It is a delight to motor round the countryside on a spring morning (I know all about the other sort of day, but just now I wish to show some random good things). There are many other attractions of a similar nature in the country. In the summer in a well-arranged partnership there is off-time for

sport and country pleasures. In fact, in spite of the increased tempo and other adverse conditions, I believe I can get away from work more easily than my grandfather did. I do not see that he *ever* got away except when he was ill—though the spending value of his financial reward was very much greater. For those who are not attracted to the country, cannot some town G.P. name a few amenities to show that his life is not all purgatory?

As for this grouse that a general practitioner has become a mere forwarding agent—that depends on the individual. If he has, it is unnecessary, his own fault, and he ought to be ashamed of himself. Admittedly there are many things at one time done by the G.P. and now done better or more conveniently by the hospital and laboratory. After the first war there was a crop of ex-wartime surgeons who went into general practice inadequately experienced for the operations they assayed. Is it a loss to general practice that such a type is unlikely now? What is it the G.P. feels he is deprived of? Does he want to do his own blood examinations? Is it not satisfying to find one's clinical suspicions confirmed and to take charge of the treatment? Is it not satisfying to collaborate with one's colleagues on the staff of the local or other hospital? I expect the consultant to know far more than I do about his subject, but possibly there is much on other aspects of disease where I know more than he, and especially about the personality and background of the patient. The infinite variety of general practice remains a constant interest and challenge throughout one's practising life.

If there is loss of prestige, then either a majority of G.P.s are not giving of their best or an inferiority complex is at work somewhere. I have never felt any sense of humiliation in my contacts with specialists (I *have* felt ashamed of failures in diagnosis or treatment where they were my fault), nor have I noticed that reputable consultants treat one as an inferior being. On the contrary, it is most rare to receive other than consideration and courtesy. There is still dignity in general practice, and if pomposity has gone out of it that is all to the good. Let us hope it has been replaced by a sense of humour.

Do not mistake me. I am not saying that general practice is Utopia—far from it. What I wish to say to the young graduate is that general practice is not as black as many people are painting it. It is a way of life, hard, not yet adequately paid, not without its constant trials, but teeming with its own peculiar interests. It is going through a crisis which I believe will be successfully negotiated. Do not enter it unless you are prepared to bring something to it in the way of service; then its rewards can be most satisfying.—I am, etc.,

Maldon, Essex. IVAN PIRRIE.

SIR,—It would appear from the correspondence following Dr. E. Anthony's letter (May 6, p. 1077) that it is realized that the lowered status of the average G.P. since the inception of the N.H.S. is due to the fact that he must pander to a blackmailing public in order to maintain an adequate panel list and ensure a reasonable income—a system endured in industrial areas from N.H.I. days. One way to break this stranglehold would be by the much-maligned State-salaried service, which was rejected on the grounds that it would lead to control of the profession by Government Departments, but in the light of present events it would seem that our position could not be much worse.

Freed from the domination of the public, we could give patients the treatment, medicines, etc., they require, not what they think they require, without fear of loss of patients and income. Authoritative direction and control of patients in medical matters would be re-established—essential in my view—for on such matters they are extremely ignorant, though they do not believe this, and treatment is unduly prolonged in some cases through unwillingness to follow instructions. Dispensing costs would be cut, as trivial prescriptions could be refused; the strain on hospital out-patient departments would be reduced, as only those requiring investigation would be sent, and not the demanding neurotics; and a general tightening up of the efficiency of the N.H.S. in general would result.—I am, etc.,

Kelty, Fife. A. SANJANA.

Obituary

G. R. B. PURCE, *M.C.*, M.Ch., F.R.C.S.Ed.

Mr. G. R. B. Purce, of Belfast, who in 1948 was elected president of the Association of Thoracic Surgeons of Great Britain and Ireland, died on June 29 at the age of 59. George Raphael Buick Purce, the eldest son of the late Mr. James Purce, was born in Ballyclare, Co. Antrim, and educated at Coleraine Academical Institution and the Queen's University of Belfast. There he gained a number of scholarships and prizes, and was soon marked out as a man of exceptional promise. After graduating M.B., B.Ch., B.A.O. with honours in 1914 he was for some months house-surgeon in the Royal Victoria Hospital before joining the R.A.M.C. As regimental medical officer to the 8th Bn., Royal Ulster Rifles in some of the worst fighting on the Western Front his personal gallantry and resourceful skill won for him a Military Cross and a name which is still gratefully remembered by many veterans. In the 110th Field Ambulance and the 48th C.C.S. he rapidly gained a wide experience of surgery. On his return to civil life he took the M.Ch. of Queen's University in 1920 and the F.R.C.S.Ed. a year later.

One hospital after another soon availed itself of his services. The Ulster Volunteer Force Hospital, the Ulster Hospital for Children and Women, and the Royal Victoria Hospital demanded much of his time, and he was also consulting surgeon to the County Antrim Infirmary, the Down County Infirmary, the Massereene Hospital, Antrim, the Benn Ophthalmic Hospital, and the Samaritan Hospital, Belfast. For many years Purce was interested in thoracic surgery, of which he was the pioneer in Northern Ireland, and he became increasingly preoccupied with this specialty in the Forster Green Hospital and in the Municipal Sanatorium, Whiteabbey, as well as in his own unit at the Royal Victoria Hospital. This valuable work was recognized by his election in 1948 to the office of president of the Association of Thoracic Surgeons of Great Britain and Ireland. He was also president of the Ulster Medical Society, and gave the Robert Campbell Oration in 1944. He was a past-president of the Ulster Tuberculosis Association and a member of the British Medical Association.

R. M. writes: Purce was a surgeon of amazing versatility. Like his famous predecessors, MacCormac and Fullerton, his experience in war served him well in peace. At the Ulster Hospital he had a long apprenticeship in paediatric and orthopaedic surgery, and for many years was responsible for almost all the neurological surgery in the province. Younger surgeons found him a mine of information, and he knew who was responsible for the origin and subsequent modification of every surgical instrument in ordinary use. Then if need arose he would improvise his own instruments in his own workshop. During his last illness he wrote in the *British Medical Journal* of his friend and teacher, the late Mr. Howard Stevenson (April 29, p. 1010), that "he had the gift of making a difficult procedure appear simple," and that "he was incapable of intrigue." These words were as true of the pupil as of the teacher. It was not only to the observer that difficult things became easy, for patients found that confidence and gentleness robbed bronchoscopy and even thoracoplasty or pneumonectomy of their terrors.

Of his personal qualities it is difficult to write without emotion. His search for perfection revealed itself even in his recreations. In his early days he played hockey for Ireland. Each hobby that absorbed him filled his shelves with expert literature embracing in turn golf, badminton, fly-fishing, shooting, the navigation of small craft, and, more recently, reflecting a remarkable proficiency in rifle-shooting and the study of ballistics. It is not surprising that his distaste for the careless and inaccurate use of words almost equalled his dislike of lightning diagnosis and slovenly surgery.

"Barney" Purce had the qualities of greatness. His judgment was not confined to surgical problems nor was it uttered without consideration of the issues at stake or the feelings of others: it was therefore the more highly valued. He never sought applause, for the sound of it seemed to embarrass his ears. He never knew the place he had won in the life of our community and in the hearts of his friends. We shall not look upon his like again. Many of us felt that he never recovered from the bereavements he sustained in the death of his elder son, who was killed when serving in the R.A.F. in 1944, and that of his wife, who died in 1946. He is survived by his daughter, Mrs. William Wagener, and by his son George, a student of medicine.

G. W. writes: Much will be written by others of the academic attainments and long, useful service to medicine of John Forbes Ward. I write of him purely as a friend—and was he not a friend to everybody young and old alike, and of whatever station? It was one of the greatest privileges of my life to have known John Ward so intimately for 46 years and to have profited so much personally from his guiding philosophies. In my long knowledge of him I have never heard one wrong or hurting word said of him. He was a faithful, honest soul without an enemy, and he was a man with many friends who will always think of him in their hearts with the deepest affection and regard.

Dr. RODERICK MACLEOD died at Hetton-le-Hole, Co. Durham, on May 13 at the age of 73 years. Born at Gairloch, Rossshire, he was a Gaelic speaker, and first learned English at school. He won his way to Glasgow University, where he had a distinguished career, obtaining the class medal in medical jurisprudence and public health. He graduated M.B., Ch.B. in 1904, and eventually settled in Hetton-le-Hole, where for 38 years he gave unstinted service to his patients. He was one of those rarities, a man completely happy in his lot. His sole aim and ambition was the well-being of his patients and the happiness of his home. He held that good housing was one of the corner-stones of good health, and he was a pioneer in slum clearance and an untiring advocate for higher standards in council housing. He took his D.P.H. in 1921, and for over 25 years was medical officer of health for Hetton Urban District Council. In 1941 the council made him a presentation to mark their appreciation of his services. Part of his duty was to act as medical superintendent of the Rainton Bridge Isolation Hospital and the conjoint Hetton and Houghton-le-Spring Smallpox Hospital. At this latter hospital he looked after more than 1,300 cases of smallpox during the years 1925 to 1928. Dr. MacLeod was also the local police surgeon and colliery doctor. A keen St. John's man, he lectured the ambulance class at Elemore Colliery for over 30 years. He was made first an Officer and then a Serving Brother of the Venerable Order of St. John. In his early days he had been a ship surgeon, and never failed to attend the functions of the Blue Funnel Club at Newcastle-upon-Tyne, of which club he was a past chairman. After the 1914–18 war he was made an honorary captain in the 8th Battalion (Volunteer) Durham Light Infantry. During the 1939–45 war he was responsible for organizing the A.R.P. casualty services in the area, and was a member of the local medical war committee. He was chairman of the Sunderland Division of the B.M.A. in 1928–9, and assistant secretary in 1933–4. He was a member of the Association's Committee on Anaesthetics in Midwifery, 1929–30. A fellow and past-president of the Society of Medical Officers of Health (Northern Branch), he had written several papers on housing problems. He never forgot his Northern origin and was an annual visitor to Glasgow Highland gatherings and a keen supporter of the Northumberland and Durham Caledonian Society. He was never happier than when he was at home, and the sympathy of all his colleagues will be extended to his widow and daughter.—J. M. H. R.

Mr. CHRISTOPHER JOSEPH SHORTALL died at Newry on June 15. Born in 1905, he graduated with first-class honours at the National University of Ireland in 1928. He was at once appointed to the extern department of St. Vincent's Hospital, Dublin. He took the F.R.C.S.I. in 1931, the M.Ch. a year later, and he proceeded M.D. in 1933. He was appointed surgeon to the Daisy Hill Hospital in Newry, County Down, in 1935. Here he covered a vast district, and by his own ability, his endless energy, his personal charm, and his honesty of purpose he readily built up a large surgical practice. Fifteen months before the war he joined the R.A.F.V.R., and so he was called up at the outset of hostilities, being finally demobilized with the rank of wing-commander, after serving in Egypt, Aden, Palestine, and Cyprus. Shortall rarely spoke about his war experiences, and few people ever knew that he had been shot down off Portugal and with difficulty escaped with his life. Despite his extensive surgical commitments he was a regular attender at all meetings of the B.M.A. His opinion was often sought by the committee of the Northern Ireland Branch. On this and other committees there was no one more admired by his colleagues. He was a man of his word, without bias, and all that mattered to him was to do the right thing. Many people in Ulster will mourn his death from leukaemia, and to his widow and their four boys the deepest sympathy of his colleagues and friends will be extended.—I. F.

Medico-Legal

TRESPASS BY A HOUSE-SURGEON

[FROM OUR MEDICO-LEGAL CORRESPONDENT]

A Folkestone antique dealer suffered from hernia, and at the end of 1947 his general practitioner advised him to consult Mr. Hickman W. L. Molesworth, senior surgeon at the Royal Victoria Hospital, Folkestone. He did this and was admitted to the hospital and operated upon on March 23, 1948, with complete success, but by the house-surgeon, Mr. L. P. Ribet, not by Mr. Molesworth. When he discovered this fact he took the view that he had been wrongfully treated, and brought an action[1] against Mr. Molesworth for breach of an alleged oral agreement to operate, and for procuring a trespass upon him by the house-surgeon. He did not sue Mr. Ribet.

In evidence before Lord Justice Singleton in the King's Bench Division on June 7 the plaintiff said that he had told Mr. Molesworth that he would prefer the operation to be performed near home, and the surgeon had said that he could arrange for him to go into the local hospital and could "do the job" there for him. The patient said he had agreed to the fee of 25 guineas. He had entered the public ward, and after the operation he had begun to suspect that Mr. Molesworth had not operated. When the surgeon had spoken to him some days after the operation he had not answered, and from that time they had ignored each other. He said he had been shocked that an apprentice had practised his skill on him without his consent when he had engaged a craftsman. He had been worried and anxious for a considerable time.

Mr. Molesworth, also giving evidence, said that Mr. Ribet had been trained at Guy's and was a very able young man. He himself had never charged a fee to a patient in a public ward. At the consultation he had said that his minimum fee in a private ward would be 25 guineas, but there were no private wards in Folkestone, the nearest being in Canterbury

[1] *Folkestone Herald*, June 9, 1950.

or Ashford. He thought he had made it quite clear to the patient that he would be in a public ward in the Folkestone hospital. He had undertaken no personal obligation in the case. On the day before the operation, and near the patient's bed, he had told the house-surgeon in an ordinary tone: "You will do this one."

Judgment

The Lord Justice, in giving judgment, remarked that the patient had had the benefit of an entirely successful operation by a competent surgeon for no charge, so that he was £26 5s. better off than he might have been. Accepting the evidence of the surgeon against that of the patient, he found that there had been no breach of contract by the surgeon to perform the operation. Mr. Molesworth was a man of honour and a witness of truth, and probably had not realized on the day before the operation that the patient expected him to perform it. He had not led the patient to think he would operate. When stating his fee he had been considering an operation in a private ward of another hospital, and that fee had had no reference to an operation in the public ward at Folkestone. The patient's right to choose his own surgeon had not been challenged.

On the other hand, Mr. Ribet had operated without the patient's consent or "leave or licence," and the form of consent to the operation which the patient had signed did not bar his right to bring an action of trespass. For an unauthorized person to do, in a highly competent manner, an act that another was authorized to do was a highly technical form of trespass. The patient had been treated everywhere with consideration, and the surgeon had behaved properly in accordance with his duties and his high professional standing. Nevertheless there had been a technical trespass, for which the patient would be awarded the nominal damages of 20s. The surgeon won his counterclaim for three guineas, the fee for the consultation, which was not contested.

His lordship added that the action ought not to have been brought. The patient had received excellent treatment at the hospital, and might well have remembered that he had received it for nothing and that the medical and surgical profession were working for the good of the people generally. He might have recognized that their time could be better spent than in resisting claims of this nature. He did not allow the patient costs on his claim, but did not think it would be right to order him to pay any part of the surgeon's costs, except appropriate costs of the counterclaim.

Medical Notes in Parliament

Silicosis in Cornwall

Mr. HAYMAN asked the Minister of Fuel and Power on June 26 how many fresh cases of silicosis were reported among miners employed in Cornish tin mines during each of the last five years.

Mr. PHILIP NOEL-BAKER stated that the figures were as follows: 1945, 12; 1946, 23; 1947, 13; 1948 and 1949, taken together, 22.

Specialists in Ministry of Pensions Hospitals

Sir IAN FRASER asked the Minister of Pensions on June 27 when it was proposed to apply the scales of remuneration authorized by the Minister of Health to specialists employed in Ministry of Pensions hospitals.

Mr. MARQUAND said that the question of the remuneration of specialists in the Ministry of Pensions Hospitals was being remitted to an independent committee set up in accordance with the recommendations of the Chorley Report, which would review the pay and grading of all medical officers in the Civil Service.

Sir IAN FRASER said that many of these specialists, who were doing comparable work, were being paid less than half what was paid to similar grades in the National Health Service, and the position was so bad that the *British Medical Journal* refused to advertise for these grades.

Mr. WALTER ELLIOT asked when the Minister expected the committee to report. There was a serious drain on the Service owing to the difference in the conditions between the two Ministries.

Mr. MARQUAND said that he was not aware of any serious drain. The committee was just beginning its deliberations, and it would really be for the Financial Secretary to the Treasury to answer questions about the date of the report.

Fainting as a Military Crime

Major H. JOHNSON asked the Secretary of State for War on June 27 if he was aware that a guardsman was put on a charge for fainting during the Trooping the Colour rehearsal on May 29, and received punishment of five days' extra drill; and what action he proposed to ensure that fainting on parade ceased to be treated as a punishable offence.

Mr. STRACHEY said that while each case of fainting was investigated, no charge was preferred unless the man had fainted as a result of some action or negligence on his part which had rendered him unfit for parade. This guardsman was not guilty of such an act, and was not put on a charge. King's Regulations provide that if in the opinion of the authorities the fainting has been due to some negligence on the part of the man or officer then a crime might be committed, but this did not arise in this case.

Mr. SOMERVILLE HASTINGS asked what were the conditions which could be prevented by the individual and which might give rise to fainting?

Mr. STRACHEY said three conditions had been given to him, one of which was being out late at night on the eve of the parade.

Merit Awards

Mr. MARLOWE asked the Minister of Health on June 29 upon what considerations the medical committee of a hospital was expected to make recommendations to the Distinction Awards Committee; what qualities in a doctor were to be regarded as justifying a recommendation for merit money; upon what grounds the medical committee was to grade those recommended for the highest, the second, and the lowest rate of merit money; and whether the decisions of the Awards Committee would be published.

Mr. BEVAN said that a medical committee, like any other body wishing to make a recommendation, would no doubt form its own judgment on these matters, and he did not intervene. He had not yet received any recommendations of the Awards Committee, and it was too early to decide about the desirability of publication.

Mr. MARLOWE: Does the Minister realize that he is asking medical committees to express an opinion on matters about which they knew practically nothing, a course which they found very difficult?

Mr. BEVAN: There is not the slightest need for that supplementary question. This is a very competent medical body, which is deciding upon the merits of members of its own profession, and I do not propose to intervene. I will pronounce no judgment whatever on the awards that it makes.

Mileage Allowances for Country Doctors

Dr. A. D. D. BROUGHTON on June 29 asked the Minister of Health whether he would increase the mileage allowance for general medical practitioners in rural areas to compensate for the rise in the cost of petrol. Brigadier MEDLICOTT asked if the Minister was aware that the rise in the cost of petrol had added appreciably to the expenses of general medical practitioners in country districts; and if he would arrange for an appropriate increase in their mileage allowance.

Mr. ANEURIN BEVAN replied that he is always ready to discuss with the profession any ideas for the better distribution of the total moneys available for general practitioners. But he could not regard the imposition of a new tax as justifying any addition to the total amount.

Dr. BROUGHTON said that much of the help the Minister gave to rural practitioners by increasing the mileage allowance a short time ago had been counteracted by the rise in the cost of petrol.

Mr. BEVAN said that if every time a new tax was imposed reliefs were given to meet it there would be no revenue from new taxation.

Mr. A. E. BALDWIN said that there might be greater difficulty in getting doctors for scattered areas as a result.

Hospital Beds for Tuberculosis

Brigadier MEDLICOTT asked the Minister on June 29 whether, in view of the fact that 11,000 people suffering from tuberculosis were awaiting hospital beds, he would give favourable consideration to the suggestion that a minimum of 10% of the beds in general hospitals should be set aside for tuberculosis cases.

Mr. BEVAN said that he was doing so, but that there could clearly be no set rule about it.

Urine-testing Sets for Diabetics

Mr. W. TEELING asked the Minister of Health on June 29 what steps he had taken to implement his promise to make "clinitest" sets and tablets for diabetics available under the National Health Scheme; and whether he was aware that it was over two months since he had answered a question on this subject by saying something would be done immediately.

Mr. BEVAN said that he was anxious not to make a series of regulations. If a regulation were made about this it would stand by itself, and he wanted to accumulate a number of regulations in one Order. That situation had now been reached, and he was doing it shortly.

Difficulties of Entry into Practice

On July 7, Dr. A. D. D. BROUGHTON drew attention to the difficulties being experienced by young doctors wishing to enter general practice. He said there was comparatively little difficulty in obtaining openings as assistants, but after a period the majority wanted greater security. The attempt to enter by means of a partnership presented many difficulties. Vacancies were advertised by executive councils, but there were surprisingly few. In the current issue of the *British Medical Journal* there were three. A practice with a list of reasonable size could attract more than 50 applicants; only one could be successful. After a number of failures some young men felt a sense of inferiority; the majority blamed the executive councils, and claimed that 90% of the openings were "fixed." He did not share that view, but he could readily understand men being driven to believe it.

The difficulties of entering general practice by means of executive council appointments were so great that most people tried to enter as partners with established practitioners. This method had now become far from easy. All too often it was found by applicants that they were up against what could only be called a racket. The principal could not sell his practice, but there was nothing to prevent a principal insisting that the partner should occupy a certain house, and no limit was fixed on the price that could be charged for it. A medical man of his acquaintance answered an advertisement for a partnership. He received no reply from the doctor, but received a communication from a house agent in which it was stated that the partnership was conditional on the purchase as a place of residence of a small bungalow at the price of £6,500; further, during the first three months of the partnership additional expenses would have to be incurred to the amount of £2,500, making a total of £9,000. Certainly, said Dr. Broughton, not all doctors were trying to rob new entrants into general practice in that manner, but he believed that far too many of them were doing this. It was still far more difficult than it should be for young men and women to gain a foothold in general medical practice.

Dr. BARNET STROSS said the problem was not less disturbing because evidence of it might be confined to a few examples. Anything the Minister of Health could do to ensure that there was not this back-door way of making men pay twice for a medical practice would be welcomed.

Mr. BLENKINSOP said that, although there might be only few cases, the matter was a serious one. Opportunities for young men to enter medical practice should be made more available, and not less. There had been many changes to the benefit of the intending practitioner. For example, the valuable effect of reducing the maximum number of patients on a doctor's list; and the defining by the executive councils of different parts of the country as "under-doctored" or "over-doctored" areas, which had encouraged intending doctors to concentrate attention on those areas where medical attention was needed. There was no doubt that this had been an encouragement in easing the entry of doctors into practice.

There was no special problem about assistantships. The Ministry shared the view put forward in the first report of the Medical Practices Committee that preliminary apprenticeship as an assistant was still the best method of entry, and had done everything they could to encourage that. There was much greater opportunity for entry by merit to-day as a partner or as a sole practitioner than by the chance contact and succeeding to a practice as in the past. There had been criticisms of particular appointments, but on the whole the procedure adopted by the executive councils had brought comparatively little complaint, and was widely regarded as a desirable method of appointing new practitioners. There had been the encouragement of the building up of new practices by payment of a basic salary, and there was the further consideration that claims could be made on the special inducement fund by doctors in particularly difficult areas.

Even so there were still very real difficulties. The problem of accommodation was very difficult for the young doctor. If the house included the surgery accommodation, clearly it should come within section 35 (3) of the Act, and if an excessive price was being charged it was an attempt to evade the Act and should be reported to the Medical Practices Committee. Where the house was separate from the surgery, the position was more difficult to define. It was a matter which was largely one of professional conduct, where they would hope to get the co-operation of the medical profession in insisting that this was a type of conduct that should be condemned. They would like to secure the co-operation of the B.M.A. in trying to secure the ending of this practice by voluntary action. It might be rather difficult to interpret the Act in such a way as to bring the ordinary living accommodation of a doctor within its confines if the accommodation was distinct and separate from the surgery, but he was prepared to examine the matter further.

The difficulty of doctors being appointed to a practice and not being able to take it up because of the lack of accommodation was already being discussed with the B.M.A., and he hoped they might be able to find some way round it. They were most anxious to try to help in every way possible, and to encourage in every way they could the setting up of additional practices, either by means of partnerships or sole principals, in the many areas which had been judged open areas where extra medical help was badly needed and existing lists were far too high.

Universities and Colleges

NATIONAL UNIVERSITY OF IRELAND

On July 3 the honorary degree of D.Sc. was conferred on Sir Alexander Fleming, F.R.C.P., F.R.C.S., F.R.S., Professor of Bacteriology in the University of London and Principal of the Wright-Fleming Institute of Microbiology, St. Mary's Hospital Medical School, London.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

On July 6 Mr. A. Hedley Whyte, Mr. E. W. Riches, and Sir Arthur Porritt were elected members of the Council of the College. The result of the poll was as follows:

	Votes
Elected	
Angus Hedley Whyte (Royal Victoria Infirmary, Newcastle-upon-Tyne)	904
Eric William Riches (Middlesex Hospital)	831
Sir Arthur Porritt (St. Mary's Hospital)	691
Not Elected	
Ian Aird (Postgraduate Medical School of London)	679
Robert Leech Newell (Royal Infirmary, Manchester)	661
Victor Wilkinson Dix (London Hospital)	398
Nils Lovold Bjarne Victor Eckhoff (Guy's Hospital)	296

In all 1,709 Fellows voted; in addition 25 votes were found to be invalid.

No. 25

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended June 24.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1950 (a)	(b)	(c)	(d)	(e)	1949 (Corresponding Week) (a)	(b)	(c)	(d)	(e)

* Measles is not notifiable in Scotland, and the returns are therefore an approximation only.

† Deaths from measles and scarlet fever for England and Wales, London (administrative county), will no longer be published.

‡ Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales, London (administrative county), are combined.

‖ Includes puerperal fever for England and Wales and Eire.

¶ Primary pneumonia no longer notifiable in Eire.

EPIDEMIOLOGICAL NOTES

Food-poisoning at Horden

Horden is a Durham mining town with a population of about 13,000. A firm of three doctors there was at work almost continuously from late on Saturday, July 8, attending patients complaining of diarrhoea and vomiting of varying severity. Food-poisoning was early suspected, and it seems likely that the vehicle of infection was pork sandwiches.

More than 300 people have been affected in this outbreak, but at the time of going to press, though some of them were regarded as very ill, none had been admitted to hospital and there had been no fatalities. By the time an investigation was initiated on the Sunday all the suspected pork sandwiches had been sold, but it was possible to obtain for investigation the remainder of the carcass from which they had been prepared. The usual bacteriological investigations are under way but are not yet completed.

Poliomyelitis

The incidence of poliomyelitis is still highest in the three adjacent counties of Staffordshire, Worcestershire, and Warwickshire. Notifications in this area were 30 more than in the preceding week: Warwickshire 45 (Birmingham C.B. 41); Worcestershire 14 (Dudley C.B. 2, Halesowen M.B. 8, Oldbury M.B. 2); and Staffordshire 9 (Smethwick C.B. 4, Rowley Regis M.B. 2).

London with 13 notifications (Woolwich 5, Deptford 2, Greenwich 2) became an important centre of infection during the week. Three cases were notified in Yorkshire West Riding. Baildon U.D., Middlesex, Uxbridge U.D., and Essex, Thurrock U.D. There are indications, too, that a rise has begun in other areas. A comparison of the trends of the notifications during the first twenty-five weeks of the year for the past four years may be of interest.

Notifications of poliomyelitis in the week ended July 1 were: paralytic cases 124 (104), non-paralytic cases 36 (38). Figures for the previous week are shown in parentheses.

Discussion of Table

In *England and Wales* increases were recorded in the notifications of measles 229, scarlet fever 123, and whooping-cough 97. There were decreases in the incidence of dysentery 138, acute pneumonia 87, and diphtheria 12.

The largest fluctuations in the local incidence of measles were increases in Kent 117, London 116, Cheshire 89, Gloucestershire 87, and Lincolnshire 83; with decreases in Lancashire 177, Sussex 90, Warwickshire 74, and Northumberland 62.

A small rise in the incidence of scarlet fever was general except in London and the south-east and south-west counties, where there was a decrease of 31. Notifications of diphtheria were the lowest ever recorded. The chief features of the returns for the week were a rise of 5 in Durham and a fall of 8 in Warwickshire. Only small variations were noted in the local incidence of whooping-cough.

Notifications of dysentery were the lowest for 21 weeks, but the incidence continues at a high level. The chief centres of infection were Yorkshire West Riding 75 (Sheffield C.B. 23, Leeds C.B. 11, Batley M.B. 9, Bradford C.B. 7); Lancashire 42 (Oldham C.B. 11, Preston C.B. 10); Durham 26 (South Shields C.B. 12, Stanley U.D. 11); Essex 15 (Wanstead and Woodford M.B. 8); and London 13.

A large outbreak of food-poisoning, with 309 cases, was reported from Surrey (Guildford R.D. 154, Hambledon R.D. 142).

In *Scotland* there were decreases in the notifications of measles 279, whooping-cough 60, and dysentery 15. There was a rise in the incidence of acute poliomyelitis 20. Only 8 cases of diphtheria were notified. The fall in the incidence of measles was mainly due to the experience of Glasgow.

The incidence of dysentery is still at a high level. During the week falls in the number of notifications were reported from the south-eastern area 23 and the western area 13, but there was a rise of 21 in the combined north-east and eastern area; the largest returns were Glasgow 57 and Paisley 12. The areas where more than one case of poliomyelitis was notified were the cities of Glasgow 15, Aberdeen 6, and Edinburgh 4: two cases were notified from Paisley, from Airdrie, and from Aberdeen county.

In *Eire* there were increases in the notifications of measles 20 and diarrhoea and enteritis 15, the latter rise being contributed by Dublin C.B., where the notifications rose from 10 to 24. The increased incidence of measles was due to an outbreak of 30 cases in Dublin, Dun Laoghaire U.D.

In *Northern Ireland* the notifications of measles decreased by 20 in Belfast C.B. but rose by 22 in County Antrim. An increase in the notifications of scarlet fever was reported from Belfast C.B. 12 and County Tyrone 9.

Week Ending July 1

Notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,085, whooping-cough 3,920, diphtheria 46, measles 8,918, acute pneumonia 335, acute poliomyelitis 160, dysentery 262, paratyphoid 17, typhoid fever 7.

Medical News

Protection of Children from Tuberculosis

The Minister of Health has agreed to certain recommendations made by the Joint Tuberculosis Council on the protection of organized groups of children against risk of infection from tuberculous adults, and he has notified local health authorities of them. They are as follows:

(1) No person with respiratory tuberculosis should be engaged for employment which involves close contact with groups of children unless and until the disease is certified as arrested. A candidate for such employment should therefore not be engaged without a medical examination, including an *x*-ray examination of the chest.

(2) Persons whose employment brings them into close contact with groups of children should have an *x*-ray examination of the chest annually.

(3) If a person while thus employed is found to be suffering from respiratory tuberculosis, such employment should at once cease, and not be resumed until two consecutive medical certificates are given, the first stating that the disease is no longer active, and the second (after a further interval of six months) stating that the improvement in the general and local condition has been maintained—both certificates being based on *x*-ray and bacteriological, as well as clinical, investigation. After resumption of employment similar investigations should be carried out at three-monthly intervals for the first year and at six-monthly intervals for the next two years.

(4) If any unusually high incidence of respiratory or non-respiratory tuberculosis occurs in an organized group of children, a full investigation of the staff employed should at once be undertaken.

Medical Research in Scotland

The Secretary of State for Scotland has appointed an Advisory Committee on Medical Research in Scotland. Its purpose will be to see that, with the close co-operation of the Medical Research Council, suitable facilities and opportunities are available to make the Scottish contribution to the advancement of medical science as full as possible. It will advise the Secretary of State on the "initiation, direction, co-ordination, and conduct of medical research." The committee's appointment follows discussions with the principals of the universities, the deans of faculties of medicine, and the presidents of the Royal Scottish Medical Corporations. Besides advising the Secretary of State on research projects and recommending financial aid, the committee will be available to give advice to regional hospital boards, local health authorities, and any other organization which feels it could benefit by it. Close contact will at all times be maintained between the committee and the Medical Research Council, representatives of which are included in the committee's membership. The new committee will concern itself mainly with investigations that can best be done within the framework of the health services in Scotland.

Membership of the new committee is as follows:

Sir Edward V. Appleton, F.R.S. (chairman); Professor T. Ferguson, Professor of Public Health, Glasgow University (vice-chairman); Professor D. Baird, Professor of Midwifery, Aberdeen University; C. A. Bignold, Medical Officer of Health, Ayr County; Professor N. Feather, F.R.S., Professor of Natural Philosophy, Edinburgh University; Professor T. Ferguson Rodger, Professor of Psychological Medicine, Glasgow University; Professor J. H. Gaddum, F.R.S., Professor of Materia Medica, Edinburgh University; Professor R. C. Garry, Regius Professor of Physiology, Glasgow University; Professor S. Graham, Professor of Child Health, Glasgow University; H. P. Himsworth, Secretary of the Medical Research Council; Professor Sir James R. Learmonth, Professor of Surgery and Regius Professor of Clinical Surgery, Edinburgh University; Professor J. W. McNee, Regius Professor of Practice of Medicine, Glasgow University; Professor W. J. Tulloch, Professor of Bacteriology, St. Andrews University; Professor C. H. Waddington, F.R.S., Professor of Animal Genetics, Edinburgh University.

F. J. C. Herrald, of the Medical Research Council, and J. M. Johnston, of the Department of Health for Scotland, will be joint secretaries of the committee. Communications should be sent to Dr. Johnston.

At the first meeting in St. Andrew's House on July 4 the committee considered the uncompleted work of various subcommittees of the Scottish Scientific Advisory Committee whose functions are included in the wider remit of the new body. The committee also agreed on procedure and discussed methods of handling new projects.

Child Welfare

The International Union for Child Welfare—the body which unites the "Save the Children" movements in various countries—held its Grand Council in London from July 6 to 12. The Union, whose headquarters are in Geneva, was formed in 1946 by the merging of the Save the Children International Union, founded in Geneva in 1920, and the International Association for Child Welfare, founded in Brussels in the following year. This is the first occasion on which it has met outside continental Europe. The present number of member organizations is 53, representing 36 different countries in Europe, Asia, Africa, and North and South America. The conference was opened in St. Pancras town hall by H.R.H. the Duchess of Kent, with the Countess Mountbatten of Burma in the chair, and short

addresses of welcome were given by Mme. Gordon Morier, of Geneva (president of the International Union), the Lord Mayor of London, and the mayor of St. Pancras.

Honorary Fellowship

The Honorary Fellowship of the Royal College of Surgeons of Edinburgh was conferred by the President, Mr. W. Quarry Wood, on Dr. Donald Church Balfour, director of the Mayo Foundation and past president of the American College of Surgeons, and on Dr. Arthur Wilburn Allan, a former president and now chairman of the Board of Regents of the American College of Surgeons, during their recent visits to Edinburgh.

Bagdad Appointment

Dr. A. Michael Critchley, a Principal Medical Officer at the Ministry of Supply, is being seconded to the Iraqi Government to take up the post of professor of public health at the Royal University of Bagdad and adviser in public health to the Ministry of Social Affairs.

Pharmaceutical Society

Mr. Adam Meldrum, of Aberdeen, has been elected president of the Pharmaceutical Society and Mr. Frank Wilson vice-president.

National Institute for the Deaf

At the annual general meeting of the National Institute for the Deaf on July 5, when Lord St. Audries, vice-president of the institute, presided, Dr. Charles Hill said that the problem of deafness had never been sufficiently recognized. It was not to the public mind as dramatically moving as some other disablements. Most of the registered blind were regarded as unemployable; even those totally without hearing would regard themselves fit for work if they had learned to speak. Greater understanding of the problem was needed from the Government, the public, and every agency in this field. The institute had the job of co-ordinating the work of many separate bodies, of giving advice to Governments, local authorities, welfare societies, and special schools. It could look back on a history of achievement since it was founded in 1911 and of a promise of further achievement. A particularly difficult field was deafness in children. The institute was doing much work here; so also was the Deaf Children's Society. Education of the deaf should begin very early in life, but it had been stated recently in the House of Commons that there was still a waiting-list of 450 to get into deaf schools. The Minister of Education had promised that everything possible was being done to increase accommodation in the next year or two. This should be pressed on with.

Register of Chiropodists

The 1950 edition of the *Register of Chiropodists* has now been published by the Board of Registration of Medical Auxiliaries, and medical practitioners may obtain copies free of charge on application to the registrar of the board, Tavistock House North, Tavistock Square, London, W.C.1.

COMING EVENTS

Princess Tsahai Memorial Hospital

It is hoped that the Princess Tsahai Memorial Hospital will begin work this year, but some of the equipment has still to be paid for. A garden party will therefore be held on behalf of the hospital fund on July 26 at 3.30 p.m.–9.30 p.m. at "The Holme," York Gate, Regent's Park, London. The speakers include Brigadier G. S. Parkinson, formerly of the London School of Hygiene and Tropical Medicine. The cost is 2s. 6d. Donations to the fund will be gratefully acknowledged by the honorary treasurers, Lord Horder and Lord Amulree, c/o Messrs. Gould and Prideaux, 88, Bishopsgate, London, E.C.2.

Homoeopathic Congress

A Joint Congress of the Council of the International Homoeopathic League, the Faculty of Homoeopathy, and the British Homoeopathic Congress will be held on July 26–28 at the Royal London Homoeopathic Hospital, Great Ormond Street, London, W.C.1. The congress fee is four guineas. Particulars may be obtained from the Medical Secretary, Dr. W. Lees Templeton, 146, Harley Street, London, W.1.

The British Association

The annual meeting of the British Association for the Advancement of Science will be held at Birmingham on August 30–September 6. The preliminary programme may be obtained from the secretary, the British Association, Burlington House, Piccadilly, London, W.1.

Congress of Pathology

The First Argentine Congress of Pathology will be held in La Plata, Buenos Aires, on August 24–27 under the auspices of the Argentine Ministry of Public Health and Social Welfare. Particulars may be obtained from the secretary of the Centro Medico Argentino-Britanico, Buenos Aires, Argentina, South America.

SOCIETIES AND LECTURES

A fee is charged or a ticket is required for attending lectures marked ●. Application should be made first to the institution concerned.

Tuesday

EDINBURGH UNIVERSITY.—At Anatomy Lecture Theatre, University New Buildings, July 18, 5 p.m., "*Benjamin Rush, M.D.: His Edinburgh Student Days and What Came of Them*." Macarthur Postgraduate Lecture by Dr. G. W. Corner (Baltimore, U.S.A.).

MIDDLESEX COUNTY MEDICAL SOCIETY.—At Edgware General Hospital, July 18, 5 p.m., "*Success*," John Tate Lecture by Sir Alexander Fleming, F.R.S.

SOCIETY FOR THE STUDY OF ADDICTION.—At 11, Chandos Street, Cavendish Square, London, W., July 18, 4 p.m., "*Biochemistry and Alcoholism*," by Mr. Leslie D. Macleod, B.Sc. A discussion will follow.

Friday

BIOCHEMICAL SOCIETY.—At Department of Biochemistry, University New Buildings, Teviot Place, Edinburgh, July 21, 11 a.m., 288th meeting.

Saturday

KENT PAEDIATRIC SOCIETY.—At Star Hotel, Maidstone, Kent, July 22, 2.30 p.m., "*Mental Deficiency as a Social Problem*," by Dr. L. T. Hilliard.

APPOINTMENTS

Dr. H. T. P. Young, O.B.E., has been appointed Inspector of Retreats, under the Inebriates Acts, 1879 to 1898.

BRAMWELL, J. B., M.B., B.Chir., D.P.H., Medical Officer of Health and Area Medical Officer, Southern Area, Warwickshire.

HAMILTON, JOSEPH STEWART, M.B., Ch.B., D.P.H., Deputy Medical Officer of Health, City of Stoke-on-Trent.

HOWAT, D. D. C., M.B., D.A., Consultant Anaesthetist, Thoracic Surgery Unit Nottingham Group.

SHEPLEY, WILLIAM HADFIELD, M.D., D.P.M., Consultant Psychiatrist, Warlingham Park Hospital, Warlingham, Surrey. (*Corrected announcement.*)

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Bartlett.—On June 9, 1950, at Bristol, to Anne (formerly Cousins), M.B., wife of Charles Bartlett, F.R.C.S., a daughter—Alice.

Burfield.—On July 3, 1950, at Shifnal Cottage Hospital, to Phemie, wife of Dr. George Burfield, a daughter.

Charlton.—On July 2, 1950, to Dr. Phoebe Charlton, wife of E. F. Bradford, Esq., Orchard House, Castleton, North Yorkshire, a daughter.

Evans.—On July 3, 1950, at 387, Queen's Road, New Cross, London, S.E., to Alexa (formerly Mitchell), wife of Dr. Carlton John Evans, a daughter—Alexa.

Porritt.—On July 6, 1950, at the Lindo Wing, St. Mary's Hospital, London, W., to Kay, wife of Sir Arthur Porritt, K.C.M.G., a son—Jonathon.

Saunsbury.—On July 7, 1950, to Lorna, wife of Edward Saunsbury, M.B., Ch.B., 57, Walsall Road, Lichfield, Staffs, a daughter.

Thomas.—On June 20, 1950, at Nuffield House, Guy's Hospital, London, S.E., to Jane McQueen, wife of Richard Sevmour Thomas, M.R.C.S., L.R.C.P., of 207, Hither Green Lane, London, S.E.13, a son—David Richard Moore.

Tighe.—On June 23, 1950, at 101, Ashted Row, Birmingham, to Nora (formerly Cregan), S.R.N., S.C.M., wife of John Robert Tighe, M.R.C.S., L.R.C.P., a son—John Kevin.

DEATHS

Cameron.—On July 2, 1950, at Exeter, Colin John Norman Cameron, M.R.C.S., L.R.C.P., of Moyvanine, Raddenstile Lane, Exmouth, Devon.

Cooper.—On July 4, 1950, at The Royal Portsmouth Hospital, Duncan Gordon Cooper, M.D., Major, I.M.S., retired, of Ravelston, 125, London Road, Waterlooville, Portsmouth, Hants.

Dutton.—On July 5, 1950, at Taplow, Bucks, Hugh Reginald Dutton, C.I.E., F.R.C.P., D.T.M.&H., Lieutenant-Colonel, I.M.S., retired.

Flintoff.—Suddenly, at The Mill House, Pateley Bridge, Yorks., Charles Ashley Flintoff, M.R.C.S., L.R.C.P., aged 71.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Reducing Infant Mortality

Q.—*A recent article ended with the following: "... The vital role of a highly organized and efficient health service in reducing infant mortality has been amply demonstrated in Chicago." Is it possible to give a summary of this work, with references?*

A.—The most common causes of death during the first year of life are infective conditions, prematurity, birth injury, and congenital malformations; a marked reduction of the infantile mortality rate would result from the prevention or satisfactory treatment of the first two of these conditions. In 1922 a premature-baby unit was established in Chicago, and in 1932, owing to the demand, a further unit was opened. As a result of the reduction of the mortality rate in these two units the board of health in Chicago in 1935 inaugurated a scheme to cover the whole city. A regulation was passed requiring a report of premature births within one hour by telephone and within 24 hours in writing. The plan also provided for a specially equipped ambulance service available at all hours, adequate hospital accommodation (6% of all newborn infants are premature), a field nursing service for instruction of the mothers, a supply of heated cots for home nursing of premature babies, breast milk supplied free of charge, and adequate follow-up arrangements. In 1935 standard regulations for all nurseries for all newly born babies (mature and premature) in Chicago were drawn up by the Joint Maternal Welfare Committee; they were put into operation in 1937.

The infantile mortality rate in Chicago in 1934 was 47.7 per 1,000 live births and in 1945 it had fallen to 29.6 per 1,000. In 1935 the mortality rate among 1,862 premature infants was 42.6% and in 1945 the rate among 3,716 premature infants was 30.7%. There was also a striking reduction in morbidity among premature infants, particularly with regard to infections of the eyes, skin, respiratory system, and gastro-intestinal tract. Further studies of the causes of infantile deaths have been undertaken during the past three years, and Fitzgerald and Sanford consider that the situation with regard to premature infants in Chicago is "being handled as well as possible and needs no study," so that the efforts of the paediatricians are now being directed towards the prevention and treatment of congenital defects and other conditions. Programmes with similar objectives have been introduced elsewhere, notably in this country in Birmingham, where in 1931 a unit for the care of premature babies was established. The results of a planned programme, so far as the mortality rate is concerned, have been similar to those obtained in Chicago.

"Golf Elbow"

Q.—*Is there such a thing as "golf elbow"? The pain in the cases I have seen seems to be localized to the epitrochlear region. What is the cause, what is the precise lesion, and what is the treatment?*

A.—Pain at the outer aspect of the elbow may follow a variety of activities, including golf. The symptoms and physical signs are identical with those of "tennis elbow." The point of greatest tenderness is over the anterior aspect of the lateral epicondyle. Diffuse radiation of the pain towards the back of the forearm is often complained of by the patient. The cause and the exact pathology of the condition are not known with certainty. It is believed that the lesion is an incomplete rupture of some of the fibres of origin of the extensor muscles of the forearm. Usually no pathological lesion can be demonstrated macroscopically when the site of pain is exposed at operation. In the treatment of this type of painful elbow many different measures have been advocated, but none, with the possible exception of operation, can be relied upon to afford relief in every case. It is usual to start with the simplest measures, such as short-wave diathermy, deep massage, and faradism to the extensor muscles of the forearm. If these are unsuccessful the injection of a solution of local analgesic into the exact site of tenderness may occasionally give dramatic results. It is worth while repeating the injection if the first is incompletely successful. If this also fails the effect of immobilization in plaster should be tried. The plaster should extend from the upper arm to the metacarpal heads and should hold the elbow at an angle of 90 degrees. Immobilization should be maintained for six to eight weeks, and is successful in a fair proportion of cases. Manipulation under anaesthesia (local or general) is also worth a trial in obstinate cases.

As a last resort operative treatment may have to be considered, but as tennis elbow, or "golf elbow," will almost invariably resolve spontaneously if given sufficient time (often 12 months or more), operation should not be advised unless the condition is so severe as to be the cause of significant incapacity. The operation consists in raising the humeral origin of the forearm extensor muscles from the bone. This is the most certain way of relieving the symptoms within a reasonable time, and in some cases it should perhaps be advised in preference to the more time-consuming conservative methods, simply on economic grounds.

Vomiting and Menstruation

Q.—*Is vomiting at each menstrual period common? What is the treatment in an Indian girl, aged 14, suffering from severe vomiting at each period, particularly at the beginning, but continuing through the time menstruation lasts? She is otherwise quite normal for her age.*

A.—Vomiting in varying degrees and circumstances is by no means an uncommon association of menstruation in young girls. Most often it is seen with spasmodic dysmenorrhoea, when it is probably the result of the intense colicky pain; it disappears once the dysmenorrhoea is cured, by pregnancy or dilatation of the cervix, for example. Vomiting may also occur without dysmenorrhoea and is then the result of some as yet undefined disturbance in the autonomic nervous system, other manifestations of this being colonic spasm, a change in bowel habit (constipation or diarrhoea) and flatulence. Such upsets are sometimes described as part of the menstrual tension state, and nearly always there is an important underlying psychological factor. The case in question calls for a careful inquiry into the background and a sympathetic explanation of the significance of the menstrual function. Apart from that, treatment may be as for the menstrual tension state with a restricted intake of fluid and sodium for 10 days premenstrually. Alternatively the case may be treated as for spastic colon with a low residue diet and tinct. hyoscyamus or one of the proprietary antispasmodic preparations.

Tuberculin Testing

Q.—*Is there any place in a country practice for a skin test for tubercle applicable by the general practitioner? If so, could details be given?*

A.—There is no reason why any general practitioner should not carry out tuberculin tests provided he has received instruction in the technique and, most important of all, in the reading of the result. There are three methods of tuberculin-testing that can be used in a country practice: the adrenaline Pirquet test, the jelly patch test, and the intradermal Mantoux test. All of these are simple procedures, but reading the result and determining whether a person is tuberculin-positive or negative requires a certain amount of experience. It is probable that this experience in reading the result can be obtained at the local chest clinic. Details of the technique of the tests are

given in most textbooks on pulmonary tuberculosis and in a Ministry of Health memorandum (322/B.C.G. 1949). The materials for carrying out the test can be obtained from most reputable pharmaceutical chemists. (The tuberculin-jelly test is discussed on pp. 141 and 154 in this issue.)

Normal Variations in Blood Pressure

Q.—*Is it possible to explain the wide variations in diastolic readings in the same individual on different occasions? Would you suspect an error by the observer if I found, say, 165/98 mm. Hg, and later my partner recorded the blood pressure in the same patient as 135/85 mm. Hg?*

A.—A variation of blood pressure from 165/98 to 135/85 mm. Hg is perfectly normal, although it suggests that the patient is a hyper-reactor and is therefore more likely to develop permanent essential hypertension than a hypo-reactor. The nature of the stimulus matters very little, but in day-to-day life it is of course emotional. It is hard to define arbitrarily the limit of such variation, but in nervous subjects with a normal basal pressure of 120/75 casual readings of 160/90 are extremely common, and the upper range may certainly reach 170/100.

Prolapse of an Ileostomy

Q.—*What are the methods available for the treatment of persistent prolapse of an ileostomy performed for ulcerative colitis? The use of special belts has so far been unsuccessful. Are there any special techniques in the performance of the original ileostomy to prevent prolapse occurring?*

A.—Prolapse of an ileostomy is a troublesome and difficult condition to deal with. Usually the best treatment is to control the projection by means of an anti-prolapse disk, such as that devised by Donald Rose for use in conjunction with his pattern of ileostomy bag or box. This might be tried in the first instance. Operative treatment is generally unsatisfactory. Simple amputation of the prolapse, as in rectosigmoidectomy for rectal prolapse, is soon followed by recurrence. Probably the most effective measure is to fix the ileum just proximal to the ileostomy securely to the anterior parietal peritoneum by multiple sutures, closing the opening in the abdominal wall round the bowel as tightly as possible compatible with its viability. It would be wise to follow this with the regular wearing of an anti-prolapse disk. As for prevention, no operative technique that has yet been devised for the performance of ileostomy can guarantee freedom from prolapse. Fixation of the ileum to the abdominal wall by sutures is generally avoided at the original operation because of the very real risk in these debilitated patients of the stitches cutting out and causing tiresome and dangerous subcutaneous fistulae. Suture of the ileal mesentery alone to the peritoneum is powerless to prevent the development of a subsequent prolapse.

Cracked and Painful Fingertips

Q.—*What is the treatment for painful splits of the tips of the fingers or thumbs in a man of 57? These used to occur only at long intervals and in cold winters, but are now becoming commoner and persist into the summer.*

A.—In the absence of any circulatory, metabolic, or hormonal dysfunction and of any general skin disease such as xerodermia, psoriasis, or eczema, it may be assumed that the cracks result from increased susceptibility to the effects of exposure and external irritants. Prophylaxis should include the appropriate use of gloves, emollients, barrier creams when gardening or undertaking dirty work, and the avoidance of unnecessary washing. It is helpful sometimes to fill cracks with "durofix" or some similar fixative. It is probable that circulatory tone plays a part, and small doses of thyroid or of thyroid and phenobarbitone with local treatment by *x* rays, light, heat, or wax baths may be of value temporarily. An affection of this kind is sometimes a local expression of chronic eczema, lichen simplex, or psoriasis, and there may be some constitutional background factors which should receive attention.

Tuberculous Prostatitis and Vesiculitis

Q.—*What are the symptoms of tuberculosis of the prostate and seminal vesicles? How is the diagnosis made and what is the treatment?*

A.—Tuberculous prostatitis and vesiculitis are rarely primary; they are almost always associated with a tuberculous epididymitis. It is the swollen epididymis, therefore, which calls attention to the fact that something is wrong. The central lesions in the prostate and vesicles give rise to few symptoms beyond a little frequency sometimes and perhaps pain on micturition. In advanced cases the disease may spread to the bladder, and these symptoms are then much increased. The urinary tract must be investigated fully and acid-fast bacilli sought for in the urine. Treatment is directed primarily to the lesions associated with the prostatitis and the vesiculitis. If these are satisfactorily dealt with, by, say, an epididymectomy, followed by measures to improve the general health, the disease in the prostate and vesicles is arrested An operation has been evolved for the complete removal of the genital tract, but it is seldom carried out at the present time. Streptomycin may also be helpful, but it should be borne in mind that an ordinary pyogenic vesiculitis or prostatitis is often diagnosed as tuberculous.

Guanidine in Myasthenia Gravis

Q.—*Is guanidine, in conjunction with prostigmin, of any value in the treatment of myasthenia gravis? What are its toxic effects and where can it be obtained?*

A.—Guanidine hydrochloride has been used in the treatment of myasthenia gravis with some success. It is more effective when given in conjunction with prostigmin, although it has been found effective alone in some cases. It is prescribed in the form of 125-mg. tablets by mouth. The dose has to be regulated by the therapeutic effect and by the disagreeable symptoms which it may cause. The latter are similar to those which occur with prostigmin but are often more troublesome. Guanidine also tends to cause paraesthesiae around the mouth and in the fingertips. Guanidine hydrochloride is obtainable from most of the larger drug houses.

Tuberculosis and Occupation

Q.—*Are there any figures for the mortality rates of pulmonary tuberculosis in relation to occupation?*

A.—Yes. Almost all the standard textbooks on tuberculosis publish tables showing the mortality rates in relation to occupation. The figures are what one would expect from the nature of the disease. Apart from special hazards, such as dust inhalation, the dangerous occupations are those which involve conditions liable to lower the resistance—long hours, mental strain, poor working conditions, heavy physical work, and low economic standards. The most favourable jobs are those which are sedentary and well paid.

NOTES AND COMMENTS

Mosquito Bites.—Dr. MARY VOIGT (Gibraltar) writes: I see the local treatment suggested to prevent irritation by bites ("Any Questions?" June 17, p. 1445) places reliance on sodium bicarbonate solution or calamine lotion. Eucalyptus oil is an effective remedy in preventing or relieving local irritation from mosquito or other insect bites, both in children and adults.

LONDON SATURDAY JULY 22 1950

British Medical Association

ONE HUNDRED AND EIGHTEENTH ANNUAL MEETING, LIVERPOOL AND SOUTHPORT, 1950

President's Address

MEDICINE, SCIENCE, AND HUMANISM

REFLECTIONS ON THE FIRST HALF OF THE TWENTIETH CENTURY

BY

Sir HENRY COHEN, M.D., LL.D., F.R.C.P.

Professor of Medicine, University of Liverpool; Senior Physician, Royal Infirmary, Liverpool

My first duty, and it is most agreeable, is to express my heartfelt gratitude to the Association, and especially to my colleagues in Liverpool and Southport, for the honour they have done me in choosing me as their President. Can any man's ambition desire more than the affirmation by his professional colleagues of his title to fill an office which in the past has been held by such giants as Stokes and Acland, Ferguson and Russell Reynolds, Clifford Allbutt, Macewen, and Dawson of Penn? It is heartening to be assured that, despite the conflicts which are the inevitable accompaniments of our professional life in these days of change and confusion, there exists a bond of fellowship and community of spirit and understanding which softens the asperities and survives the dissonances.

My second duty is to welcome you all on behalf of my local colleagues to Liverpool and to express to them my thanks and yours for having provided for this meeting a fare, both social and intellectual, which is so rich in variety and, even at this early stage, so warmly acceptable.

My third duty is that, prescribed by custom, of delivering a Presidential Address. There is a danger, of which history gives ample warning, that at so early a stage in office a President may by high promise encourage hopes which will too often dwarf the performance. Indeed, the longer I reflect the deeper is my conviction that the appropriate time for this address is at the end of the President's year of office, when he might reasonably be called upon to give an account of his stewardship. I propose, therefore, to emulate Sir Charles Hastings in his inaugural address to this Association and to eschew current medico-political controversies. The closing year of the first half of a century is a fitting time in which to take stock. I have therefore chosen in this address to reflect on the changing order in the first half of the twentieth century and to note its influence on medical practice, training, and research. For a profession contemptuous of its own history runs grave dangers.

Changes have occurred in the pattern of disease in the past fifty years which appear to have been beyond our control. For example, chlorosis has virtually disappeared; scarlet fever has changed both in character and in severity; epidemics of encephalitis lethargica have appeared and recrudesced; and there has been an increased incidence of cancer of the bronchi and lungs which yet may prove to be a by-product of the manners and customs of our age—for cigarette-smoking, the fumes of motor exhaust pipes, and the surface tarring of roads have all been arraigned. But in their ultimate analysis the changes in medicine which have occurred in the first half of the century will be found to result from two major influences; first, from the rapid and vast expansion of knowledge and technical skills in the cognate sciences; and, secondly, from the evolution of our ideas of social responsibility.

A Change in Outlook

At the beginning of the century medicine was still essentially the art of healing (*ars medendi*), and empiricism played the major part both in diagnosis and in treatment. It is true that in the last decade of the nineteenth century important advances in bacteriology and biochemistry had been made and *x* rays had been discovered, but these had not yet significantly influenced the practice of medicine. The practitioner still wore his frockcoat and silk hat, too often symbols of his dogmatic pretensions. But there was then a much more intimate relationship between doctor and patient: the doctor was in truth a guide, philosopher, and friend, and he held a unique position of leadership, especially in the smaller communities. The era of specialization was still remote.

Man continued to be regarded as greater than the sum of his parts and as a member of a family and of society. The doctor entered his patients' homes and there saw the effects of overcrowding and ill-ventilation, the undernutrition occasioned by poverty, the effects on family life of chronic illness in the wage-earner and the moral cankers of unemployment, and he realized from daily example the part which these play not only in causing disease but in preventing better standards of health. Moreover, even when he developed an interest in, and practised, a special branch of medicine he continued in general practice. At the beginning of this century there were in Liverpool no doctors, not even surgeons, who confined themselves solely to their specialty. In brief, the doctor's outlook at the birth of this century was, to

use Smuts's phrase, "holistic." Man was regarded by his doctor as a whole human being, in health and disease, and his reactions to and on his environment were not overlooked.

The March of Scientific Medicine

Then came the scientific age. Not that medicine had neglected science and the scientific method in earlier centuries. There can be few, if any, more striking examples of the application of scientific method than Harvey's demonstration of the circulation of the blood over three centuries ago. But as the twentieth century advanced, the torrent of scientific discovery rushed on so impetuously that it all but engulfed the humanism of medicine. In the pursuit of knowledge man was fragmented and his organs, tissues, cells, and secretions were subjected to intensive study. For science concerns itself with isolates and ponderables. It detaches from the tangled skein of nature a thread which it can examine and measure untrammelled. And its prophets have declared that "only when natural phenomena can be measured are they to be clearly apprehended."

If achievement be the measure of their contribution it is difficult to resist the claim of the basic sciences to the leading position in the vanguard of medical discovery. Almost before they have cooled, the newly forged weapons of science have been applied to the mysteries of medicine with almost unqualified success. The secrets of nutrition and of metabolic processes, and the agents which govern them, have been in large part revealed, so that there are now no medical obstacles to the proper feeding of the people. Hormones and vitamins have been isolated and synthesized; indeed, chemists have improved on Nature and given us agents which perform her work more simply and satisfactorily. Drugs have been produced in the laboratory which have all but replaced the old galenicals. The sciences of bacteriology and protozoology have concerned themselves not only with discovering the organismal causes of disease but with devising measures for increasing individual immunity to infectious diseases and of preventing their spread; and astounding success has attended their efforts both in temperate and in tropical climes. Bacteriologists have combined forces with the chemists and chemical manufacturers in producing remedies such as the newer antimalarials, sulphonamide drugs, and antibiotics which have revolutionized our treatment of established disease and altered its clinical pattern; they have been associated with engineers in improving methods of sanitation, ventilation, and food preservation.

Improvement in the techniques of radiology, especially the use of contrast media, has enabled us to visualize indirectly practically every crevice and cavity of the body and has advanced accuracy in diagnosis to an almost incredible degree. But it has in consequence whetted the appetites of those with the "penny-in-the-slot" type of mind who seek short cuts to diagnosis, and who have forgotten, if they ever appreciated, that "it takes a man and not simply a machine to understand a man." Radioactive isotopes promise to solve many fundamental problems in physiology, biochemistry, and pathology and to add to our diagnostic and therapeutic implements. Physics, by devising electrical instruments of such precision that infinitely small variations of voltage can be measured and recorded, has led to an extended knowledge of the mechanisms of the heart, of muscle, and of brain and nerve, and of disease of these organs which results in disturbances of normal function. At the beginning of the century the simple ophthalmoscope and laryngoscope, illuminated indirectly, represented the sole members of their class. Ingenious arrangements of mirrors and lenses, and electrical illumination, have in the past few decades given us direct visual access to the bronchi, oesophagus, stomach, peritoneum, rectum, and bladder, and even to the spinal theca and ventricles of the brain, and have led to the construction of cameras which will make permanent records of our findings.

Indeed, practically no advance in the fundamental sciences is without its influence on medical research and practice. Surgery has not modified its aims. It still seeks to repair the injured, to reconstruct the deformed, and to ablate diseased structures, but its operations can with safety be bolder and more daring through advances in diagnostic accuracy, in the design of instruments, in anaesthesia, and in measures for combating infection, shock, and haemorrhage. The successful extension of surgery to the brain, the lungs, and the heart in the last forty years bears irrefutable testimony to the shortsightedness and ineptitude of some of the great surgeons of the past in their assertions that the craft of surgery had reached its zenith in their day.

The nineteenth century had been dominated by the morbid anatomists: the structure of the diseased body was the focal point of pathological research. Improvements in microscopy, in microtomes, and in the methods of staining tissues had led to valuable additions to our knowledge both of morbid histology and haematology. But this century, which has seen the mass invasion of medicine by physics, chemistry, biology, and even mathematics (for, despite its more than a century-old history, medical statistics has come into its own only in the past fifty years), has reorientated its lines of advance. Functional conceptions of disease have gradually replaced the structural. Tests have been devised which will assess the functional efficiency of practically all the organs and tissues of the body. Moreover, this emphasis on function has led to a wider appreciation of the influence of psychological factors in the genesis of somatic disease and has added strong support to the view that, whatever its philosophical status, dichotomy of body and mind in medicine is untenable.

Some Examples of Progress

It may be of interest to illustrate by detailed examples what half a century of scientific endeavour has contributed to human welfare. Since the beginning of the century the expectation of life at work has increased for the male by 18½ years and for the female by over 20 years; the man of 40 to-day can expect to live another 31 years and the woman 35 years, as compared with 25½ and 27¾ years a half-century ago. In 1901 in each thousand of the population there were only 47 persons over the age of 65; in 1947 there were 105. In the first five years of the century out of every thousand live births 138 infants died before reaching one year of age; in 1948 only 34 succumbed. The death rates per million of the population were reduced between 1898 and 1948 for typhoid fever from 182 to 1, for scarlet fever from 113 to 1, for whooping-cough from 124 to 17, and for diphtheria from 244 to 4. Indeed, the total deaths from zymotic disease in 1898 amongst the 31½ million inhabitants of England and Wales were 86,755; in 1948, when the population had increased to 43½ millions, the total deaths were 7,490 from the same causes. In the South African War the annual incidence of typhoid fever per thousand troops was 105, with a death rate of 40.6; in the first world war vaccine prophylaxis had reduced the incidence to 2.35 and the death rate to 0.139. The antibiotic chloramphenicol now gives promise of cure in the typhoid infections. In the early part of the 1914–18 war passive immunization by antitetanic serum diminished the incidence of tetanus, but in the early stages it was still 15 to 30 per thousand wounded; this dropped to less than 1 per thousand when the serum was generally used. In the second world war, however, with active immunization against tetanus the incidence dropped to about 1 in twenty thousand wounded. A striking example of profitable co-operation between the general practitioner and the preventive-medicine service is seen in Detroit, where in 1927, before immunization against diphtheria was introduced, 270 deaths occurred from the disease; in 1947, after immunization was general, there were but three deaths from diphtheria, and in the first six months of 1948 none. This is no isolated instance; analogous figures may be quoted for other localities.

Sulphonamides; Antibiotics; Insulin

As an example of the benefits which recent therapeutic advances bring to the individual patient rather than the community, let me quote first the effects of sulphonamides in pneumonia. Flippin *et al.* reported in 1943 that of 1,906 cases of pneumonia treated before sulphonamides were introduced the mortality was 40.1%; of 1,635 cases treated after the introduction of sulphonamides only 10.6% died. In another series recorded by Ungeleider and his colleagues in the same year the pneumonia mortality-rate for 1935 to 1937 before sulphonamides were used in treatment was 20.8%. In 1938 the case mortality was 79 per 100,000. In the period 1938 to 1942 the case mortality had been reduced by the use of sulphonamides to 3.9%, which represented for 1942 a death rate of 32 per 100,000. Thus in the United States alone 25,000 lives had been saved yearly by the sulphonamide drugs, and the reduction in the length of illness resulting from treatment had added at least a million days to the working capacity of the nation. In the American Civil War the death rate from meningococcal meningitis was estimated at about 90%; towards the latter part of the first world war, when antimeningococcal serum became generally available, the mortality was reduced to about 30%; in the second world war treatment with sulphonamides reduced the mortality to under 3%, and in many epidemics where efficient treatment was instituted early no life was lost. The importance of early diagnosis, which depends more on human skill and judgment than on laboratory tests, is strikingly demonstrated by the fact that in the first month of one outbreak 12.8% of the victims died, in the second month 7.3%, and in the later four months only 2.25%. Familiarity with the clinical manifestations of the disease had in the later period led to much earlier diagnosis.

The triumphs of penicillin and other antibiotics have been too recent in the memory to justify repetition, and as yet only the fringe of their potential usefulness appears to have been reached. If an example need be chosen to illustrate the benefits of chemotherapy few would be more informative than that of puerperal sepsis. Before the sulphonamide era the puerperal sepsis crude death rate was 154 per million; in 1939, when sulphonamides were in general use, this rate dropped to 63; in 1947, when penicillin was readily available, the rate had fallen to 16—a decrease of nearly 90% in less than fifteen years.

It is not only in the field of infectious disease that such victories have been gained. Before the days of liver therapy over 80% of the victims of pernicious anaemia died within twelve months of the recognition of their disease, and only occasionally did the patient live for more than three years. Yet in 1949 Wilkinson was able to record that, of 1,480 patients treated with liver since 1929, 1,179 were still alive; of the 301 who died, 149 had lived more than five years, 51 more than 10 years, and 12 from 16 to 20 years. How often do we mark the *total* effect of the discovery of insulin on the welfare of the diabetic patient? Before 1922 the expectation of life of a diabetic child of 10 was about fifteen months; to-day it is over 45 years. Even at the age of 30 the diabetic before insulin could expect to live only about four to six years, and this with the strictest dietetic control; now his expectation of life is over 30 years, only a little short of the normal average. Translate these facts in the light of the known incidence of diabetes mellitus—in the United States alone over 700,000—and you will have some measure in terms of the saving of life brought about by one therapeutic agent.

These examples—and hundreds of others could be quoted—reveal how great are the reductions in the incidence, morbidity, and mortality from disease brought about in the past fifty years by measures directed towards the community as a whole, such as improvements in housing, ventilation, sanitation, or the supplies of pure water and uncontaminated food; by preventive measures applied to the individual, for example, immunization against diphtheria, smallpox, typhoid, and tetanus; by recent therapeutic agents and by improvements in personal hygiene. The cure of disease has always been more spectacular than its prevention, and public imagination has been fired by the triumphs of chemotherapy and modern surgery. The greater victories of preventive medicine have too often passed unheeded and unsung.

That Essential Humanity

What has been the effect of this almost whirlwind advance in our scientific knowledge of disease, its prevention and control? It has tended to change the orientation and ambit of medical research; it has modified the structure of medical practice and changed the face of disease; and it has provided many lessons for those entrusted with the training of the doctor. But before discussing these in their wider aspects let me reiterate, since it must pervade and transcend other considerations, that the achievements of science have too often led us to forget that essential humanity which is indispensable to the best practice of medicine. For medicine is not all science. There are indeed many medical problems which defy measurement. Human life is full of imponderables, for man is not a physical being only. He has emotions and appetites which cannot be measured though they profoundly influence his physical welfare. Bodily disturbances may be, and commonly are, the expression of his loves and hates, his passions and fears, his worries and anxieties: the thumping heart, the cold sweat, the weak and tremulous knees of fright are but simple examples of this unity of body and mind.

The greatest danger to which medicine in the scientific era has been exposed is that of overlooking that men, both patient and doctor, are sentient social beings, and of forgetting that, however sensitive and specific our laboratory tests and however elaborate and complicated our instrumental methods of investigation may be, they are not ends in themselves. When Moynihan declared that "we have made surgery safe for the patient; we must make the patient safe for the surgery," he little thought that the ensuing few years would bring the achievement so close to his goal. Yet I venture to suggest that these great advances in surgical craftsmanship and technical skills, and of measures to control infection, shock, and haemorrhage, will avail but little if they obscure the need to foster sympathy and kindness, without which no surgeon is safe for

the patient. Recent years have given the doctor increasingly more potent weapons of diagnosis and treatment; but it is by the understanding and wisdom with which he uses them that he will be judged.

The poet has written:

> "True it is Nature hides,
> Her treasures less and less; Man now presides,
> In power, where once he trembled in his weakness;
> Science advances with gigantic strides."

Yet we must not neglect Wordsworth's added caveat:

> "But are we aught enriched in love and meekness?"

Medical Education

Medical research, practice, and education are closely interrelated. Indeed, over a wide territory they overlap, but I propose to discuss medical education first because I believe that in the long run it is standards of medical education which determine standards of practice. Buildings and instruments are indispensable, but they do not create a health service. In the practice of medicine men count more than materials. The Association has devoted both time and energy to the problem of medical education. As chairman of both the committees charged with the tasks of reviewing medical education in the light of modern requirements, and in particular of the needs of the general practitioner, you will, I trust, forgive me if I devote a little time to these topics. It is not always appreciated that the statutory aim of undergraduate medical education remains that of 1886, when the Medical Act provided that, for registration as a legally qualified practitioner, candidates shall show a standard of efficiency at their final examination which shall "be such as sufficiently to guarantee the possession of the knowledge and skill requisite for the efficient practice of medicine, surgery; and midwifery." This year may well see an additional requirement—a period of residence in hospital in a responsible appointment before registration is granted.

A careful study of the detailed curricula of our medical schools shows that, despite the vast corpus of knowledge and the consequent changes in the scope and emphasis of medical practice, the goal at which their undergraduate course aims is that on its completion the student shall be fitted to begin independent general practice. The B.M.A. Committee on the Training of a Doctor took a different view, which they asserted was dictated by the inexorable circumstance of the rate and extent of advancing medical knowledge. The undergraduate curriculum, they held, cannot now embrace even a tithe of the theory and practice of medicine. Its aim should be limited to laying foundations; it should be concerned, not with presenting masses of facts, but with indicating the scope, potentialities, duties, and responsibilities of medicine, both curative and preventive. It should illustrate those basic principles which are indispensable to all forms of medical practice by apt and sapient examples which will implant an appreciation of the methods of medical practice and research. It is not concerned with minutiae. The student is to be trained in reading the map of medicine, but the scale should be three miles and not three yards to the inch. The details must be left to special postgraduate study, and in this category, as our later report emphasized, general practice takes its place among the other specialties.

Basic Principles

It may well appear paradoxical that expanding knowledge should have affected medical education adversely. The explanation is to be found in the inevitable specialization which followed. The various subjects of the curriculum have developed as autonomous independent compartments of knowledge; yet for medical education they must be viewed primarily as different facets of the same subject. We have failed to secure coherence, continuity, and interdependence in our teaching. New developments and techniques in radiology, psychiatry, orthopaedic surgery, and social medicine, for example, have been forcibly fitted into, rather than integrated with, the existing curriculum. Snippets of allegedly necessary information have been added to an already congested syllabus, so that too often it justifies the taunt with which Cromwell castigated the laws of England: "A tortuous and ungodly jumble." And, perhaps most serious of all, narrower and more rigid specialization in practice has led to the evils which cannot be dissociated from increasing compartmentalism in teaching. Textbooks are rarely imbued with a general philosophy of medicine; they have become accretions of monographs by different authors into which only a stern and exacting editor can instil some semblance of unity of purpose. Too often books and courses of study are things of "shreds and patches" instead of being tapestries of clearly evident and purposive design.

Again, the population of our teaching hospitals reflects in increasing degree the rarer maladies. The interests of our consultants are becoming more and more confined, so that in many teaching hospitals whole wards are occupied by patients all of whom are suffering from the same type of disease. We may well have to ask ourselves in the near future if the narrow specialization in our teaching hospitals which results in this segregation of groups of disease is in the best interests of basic medical education, whatever other advantages it may carry. Some have urged that the student will gain most by pursuing intensively one special branch. This view is wholly indefensible. Its dangers for all learning have been denuded by many scholars. Asquith, in his Rectorial Address delivered before the University of Glasgow in 1907, referring to the study of history, speaks of both teacher and student as being "peculiarly exposed to the risks of specialism, and of the morbid excesses to which specialism leads—pedantry, want of perspective, over-emphasis of the unimportant, the passionate pursuit of small game which is not worth the efforts of the chase." And with peculiar appropriateness to medicine he said, "The mind of the . . . student is indeed in danger . . . of becoming a kind of pantechnicon, in which every sort of furniture is heaped and packed together, instead of being a habitable home where things useful and beautiful are arranged in their proper places, and in due relation to their special purposes."

Man is neither a pantechnicon nor a robot. His various organs and tissues, and his body and mind, are so closely knit in maintaining or restoring health that our medical teaching must be pervaded by a "synoptic" view. Unless basic medical training be directed to the study of the *whole* man, in relation to his external and internal environments, it will be misconceived in aim, in structure, and in balance. Theory and practice must be closely integrated; for without theory practice lacks a guiding hand, and without practice theory wilts. Nor must we forget, as Sir Richard Livingstone wrote, that "the prior task of education is to inspire and to give a sense of values and the power of distinguishing in life, as in lesser things, what is first-rate from what is not"; and, "the test of a successful education is not the amount of knowledge that a pupil takes away from school, but his appetite to know and his capacity to learn."

These were the liberal principles which my committee believed should guide the basic vocational training in medicine, and by detailed example ways were suggested by which they might be translated into practice. These were not intended to be rigid syllabuses, for we were by long experience alive to the dangers of attempting to stereotype methods of teaching or the content of the curriculum, of reducing medical education to a formula. Students vary in their capacity to learn and to be taught; they are as little suited to a uniform regimen of study as to uniformity of diet, exercise, or hobbies. Hence the need for individual tuition. No one should pretend that they can all be treated by the same method, unless he be a quack, or possessed of that demon of planning and uniformity which used to make the Minister of Education across the Channel reflect with complacent satisfaction that, at a particular minute of a particular hour of a particular day in the year, every schoolboy in every school of France was being informed of the same fact in Roman history.

Training after Graduation

The report on "General Practice and the Training of the General Practitioner" carried to its logical conclusion the recommendation of the earlier committee and emphasized the need for special training after graduation if the general practitioner was to fulfil his purpose and achieve his proper status in the field of medical practice. The general practitioner has with good reason long become increasingly suspicious and indeed resentful of the lip-service paid to him in such phrases as the "backbone of the profession," the "front line of defence," and the "flower of our profession." He must have been heartened at the reception which this report had from the national press, which appreciated, in the words of *The Times* leader, that the proposals it put forward would not only go far to bring about the betterment of the practitioner but would also make for economy, since an "efficient front-line service would relieve the more expensive services in the rear." The committee was "not unaware of the idealistic trends of its recommendations and of the criticisms to which it may in consequence be exposed." But ideals often create machinery, and machinery without ideals rusts into decay. Until we have so reformed the conditions of general practice that students of merit will wish to enter it we shall not have achieved our objective.

I need say but little of medical research. I have already pointed to its major achievements, but on the human side I welcome most cordially the signs which indicate a bridging of that breach between laboratory and clinical research which developed in the earlier part of our century and gradually widened. It stemmed from the differing public prestige and the lower material rewards of the laboratory worker. In the past few years the economic injustices have been partly redressed and there has been a wider realization of the lesson of history, that practically all research fruitful for medicine has begun by clinical observation and has achieved its ultimate successes by the combined efforts of laboratory worker and clinician. The whole story of the hormones, from the description of Addison's disease to the discovery of cortisone, is an arresting illustration of their fertile partnership.

Social Responsibilities

The second of the two influences which have fashioned the medicine of the last half-century is the evolution of our attitude as physicians to our social responsibilities. There has been increasing recognition that the perceptions and tasks of the physician of the twentieth century must be shaped by his function as a citizen, and that we must look upon the society in which we live, and our responsibilities to it, as parallel to our responsibilities to our individual patients. This is no new doctrine. It was towards the latter part of the eighteenth and the early part of the nineteenth century that humanitarian trends in their wider social implications began to influence the practice of medicine. Doctors and clergy in their everyday work were brought face to face with the sufferings of the poor, and it was natural that they should take a leading part in ameliorative movements. But, whilst the parson was more concerned with spiritual and moral welfare, the doctor sought to improve the physical amenities of the people, for he clearly apprehended the relationship between poverty and health and disease. Hence it was that in the forefront of social reform in the nineteenth century which led to the social security of the twentieth were two distinguished medical men.

One of these, Sir John Simon, wrote in his *English Sanitary Institutions*, "If given wages will not purchase such food and lodgement as were necessary for health, the ratepayers, who sooner or later have to doctor or perhaps bury the dead labourer when starvation or filth have laid him low, are in effect paying the too late arrears of wages which must have hindered the suffering and sorrows." The other, Dr. Southwood Smith, indignant at the continued indifference of Parliament to the conditions of the working classes, wrote over a century ago: "For every one of the lives of these 15,000 persons who have thus perished during the last quarter, and who might have been saved . . . those are responsible whose proper office it is to interfere and endeavour to stay the calamity—who have the power to save, but who will not use it. But their apathy is an additional reason why you should rouse yourselves. Let a voice come from your streets, lanes, alleys, that shall startle the ear of the public and command the attention of the legislature."

Is it then surprising that, since the practice of medicine reflects the social philosophy of its time, there should have grown with the years an increasing demand for social security which culminated in that National Health Service Act which will influence, for good or evil, all our lives, be we doctors or patients? I have already promised to refrain from provocative reference, but I would venture to make one or two comments outside politics. A national health service must take due cognizance of the nation's resources both in skilled workers and in materials; it therefore behoves not only the doctors to play their part but also the public, who must be educated either by persuasion or by retribution not to make unnecessary demands on doctors or on hospital services. In such education, however, we must avoid producing a nation of hypochondriacs, for that will aggravate the situation rather than remedy it. I would plead also that there should be within the service the opportunity for experiment. There is a real, and I believe increasing, danger of rigidity and inflexibility; indeed, we run the risk, despite varying needs and widening horizons in medicine, that our hospital system will fail to reflect the changes. And I need hardly re-emphasize that prevention is better than cure, and that a service which maintains health is to be preferred to a service which promotes doctoring.

I am not one who subscribes to the view that in the changing conditions of medical practice doctors will lose pride in their vocation and faith in their future. Whatever career in medicine we are destined to follow, as practitioners, teachers, or research workers, the same motives

which guided our predecessors will yet guide us, for our purpose is to help our fellow man, and the fulfilment of that purpose should be our most satisfying reward. Research workers will still find intellectual relish in gratifying their innate and compelling curiosity, and not a few will advance the frontiers of medicine. Many will leave behind something of permanent value for suffering mankind.

"Here on the level sand,
Between the sea and land,
What shall I build or write
Against the fall of night?
Tell us of runes to grave
That hold the bursting wave,
Or bastions to design
For longer date than mine."

The teacher of medicine may be fortunate enough to see the fruits of his labours, but the most precious are those which he may never see, for they are hidden in time and in the remoter corners of the earth. The practitioner, despite the overwhelming burden which is imposed by conditions which leave him so often frustrated, can still be the leader and the friend of his fellow citizens. Changing conditions provide not only a challenge but also an opportunity. Let us grasp it firmly, for through it we may more richly and abundantly keep faith with our ideals.

The Association's Work

In all the work which I have touched upon the B.M.A. has played a noble part. It has necessarily been concerned with medical politics, but, since the events of recent years have unduly illuminated in the public mind this aspect of its tasks, let me adjust the balance. That it has satisfied the needs of its members in bulk, if not always individually, is shown by the fact that in 1900 its membership was 18,500 at one guinea subscription, whilst in 1950 it has 60,000 members at four guineas subscription. During the half-century it has co-operated with practically every Government department, giving advice when sought and occasionally offering unsolicited advice which has not always proved welcome. It has had fruitful and friendly associations with the Trades Union Congress, with local authorities, and with its sister professions of law, nursing, veterinary science, and pharmacy. It has created a library of 50,000 volumes which, in co-operation with the Royal Society of Medicine, has provided all the needs of the inquiring practitioner. It publishes a weekly medical journal which has deservedly a world-wide circulation, and in recent years it has been responsible for the production of special journals which are the envy of other countries. Moreover, no other medical association or society in this country has combined with its annual meetings four days of concentrated scientific work covering all branches of medicine, where a galaxy of our brightest medical stars strive with current medical problems.

The Association has issued reports on medical topics which have profoundly affected medical practice. Among them may be mentioned those on ophthalmia neonatorum, and the early recognition of uterine cancer; on puerperal morbidity and mortality, and on the medical aspects of abortion; on the treatment of fractures and rehabilitation. It early influenced, in the light of modern developments, hospital policy and the problem of the out-patient, and long before there was wide recognition of the need it had proposed a general medical service for the nation and a national maternity service. The many victories over disease, and the preventive measures which have led to the rapid increase of the aged in our population, led to a report on the Care of the Elderly and Infirm which has formed the basis of all subsequent recommendations. Its reports on psychiatry and the law, on nutrition, and on medical ethics deserve approbation, and its exposures of "secret remedies" and the unfounded claims of the unqualified practitioner have had beneficent national repercussions. The Association, too, has by its scholarships and prizes encouraged the early work of those who have later carved a permanent niche in the medical Hall of Fame. Among these (and it would be invidious to mention the more recent) are to be found the names of Watson Cheyne, Priestley, Waller, Starling, Leathes, Elliot Smith, Major Greenwood, Charles Bolton, and A. J. Clark.

There is one other characteristic of the Association which has impressed me deeply in the years that have just passed, years fraught with difficulties. For, when decisions of great moment have to be taken, differences of viewpoint and conflicting policies must inevitably emerge, and rightly so; for history reveals that unanimity of opinion in an assembly is the forerunner of its decline. But in the B.M.A. these differences can be expressed without the fear that they will be translated in terms of personal malice and venom; and so we remain staunch and sincere friends throughout the vicissitudes of our differing medico-political outlooks.

"Combined Operations"

And so it should be. Our design is not victory in the debating chamber, but the conquest of disease. If we aim at lessening physical distress in others we should refrain from inflicting mental distress by the harsh and unguarded word or, worse, by intrigue and malice. For we are still far from many of our goals. We have not yet conquered some of our most prevalent ills, such as influenza and the common cold; and our ageing population has thrown into relief many of our failures, for the operative secrets of cancer and arteriosclerosis—now the captains of the men of death—still elude us. Many of the disabling diseases, too, such as peptic ulcer, rheumatism, and the visceral neuroses, await a satisfactory therapy. But advances will and must continue. No one can predict, with confidence, the limits of future achievement in curative, preventive, and social medicine and social welfare if all branches of medicine work in harmony among themselves and collaborate with colleagues in other scientific fields; for "combined operations" may well provide the answer to many of our problems—scientific, social, and humanitarian. The record of medicine in the first half of the twentieth century has been fortunate beyond belief; a greater duty remains, and it is shared by every doctor—to see that the future is not unworthy of the past. For, as Walt Whitman wrote in the copy of *Leaves of Grass* which he sent to Emerson, "We have not come through centuries, to halt in this land of ours."

Conclusion

May I in concluding this address express again my warm appreciation of the honour you have done me in inviting me as President to address you. I would remind you of the words used to describe his audience on the occasion of the inaugural lecture some sixteen years ago, by the then Professor of Poetry in the University of Oxford. He described that audience as "the most accomplished and exacting in the world, which no excellence can surprise, for which nothing is too good or possibly good enough." I am convinced that my audience does not fall short of that standard. I have therefore prayed that your tolerance might equal your accomplishments.

A POSSIBLE MODE OF TRANSFER OF INFECTION BY SYRINGES USED FOR MASS INOCULATION

BY

R. J. EVANS, M.B., B.S.

AND

E. T. C. SPOONER, M.A., M.D.

(From the London School of Hygiene and Tropical Medicine)

A common mass-inoculation technique (M.R.C., 1945) employs a separate sterile needle for each injection, but does not sterilize the syringe, which contains several doses of inoculum, between injections.

Accidental infections attributable to this practice do not seem to have been described, and experience generally suggests that the technique is, so far as any injection technique can be, a safe one. We do not wish to suggest that the experiments to be described mean that this "separate needle, common syringe" procedure carries a high risk; if a fresh sterile syringe cannot be used for each subject, we think it is the best technique at present available for mass-inoculation purposes.

It seemed, however, worth while to investigate the advantages of using a fresh needle for each injection, partly because of the observations of Hughes (1946), discussed below, and partly because of the association of poliomyelitis with prophylactic inoculation (McCloskey, 1950; Bradford Hill and Knowelden, 1950). It seems unlikely that the transmission of poliomyelitis virus by syringe can account for this association; other hypotheses are more probable in the light of our present knowledge. But, clearly, if there is any risk at all of syringe transmission, the possibility, however remote, should be evaluated as accurately as circumstances permit.

Experiment 1

This first experiment was therefore made with mice and virulent pneumococci. The virulence of a smooth strain of *Streptococcus pneumoniae* Type I was assured by three mouse-to-mouse passages. Twenty-four mice were then inoculated intraperitoneally with diluted peritoneal washings from a dead animal. Next day nine were dead and the remainder were sick. Thirteen which appeared moribund were killed and used immediately in the experiment.

The plan was to fill a sterile syringe with 1 ml. of sterile broth, to inject 0.1 ml. intraperitoneally into one of the recently killed pneumococcal mice, to change the needle and to inject 0.2 ml. of broth into a normal mouse, and then, the needle having been changed again, to inject 0.5 ml. into the same infected mouse's peritoneal cavity; finally, after a third needle change, to inject the remaining 0.2 ml. into a second normal mouse. One normal mouse was therefore injected from a syringe which had delivered 0.1 ml. into an infected animal, and a second normal mouse from the same syringe after delivery of 0.1 and 0.5 ml. into the infected mouse. Two normal mice and one infected mouse were thus injected from one syringe, the needle being changed after each injection.

This procedure was adopted because it was thought that the second injection of 0.5 ml. into the infected mouse might produce a higher intraperitoneal pressure and so a bigger change of reflux of infected fluid into the syringe.

Nine 1-ml. syringes of various makes were used, and 40 needles, sizes 15 and 17. All were oven-sterilized initially; resterilization during the experiment was achieved by boiling. In order to minimize as far as possible the risk of cross-infection occurring between the infected and the normal mice, the conduct of the experiment was divided into three tasks, each of which was performed by one operator alone.

The first operator killed the infected mouse by breaking its neck, and pinned it out belly upwards on a cork mat ready for the second operator.

The second operator handled the syringes and made all the injections. He performed the following operations in strict sequence: (1) filled a sterile syringe to the 1-ml. mark with sterile broth; (2) injected 0.1 ml. of broth intraperitoneally into an infected mouse; (3) disconnected the needle from the syringe and placed it in the sterilizer; (4) fitted a sterile needle to the same syringe and then injected 0.2 ml. of broth intraperitoneally into a normal mouse; (5) discarded the second needle into the sterilizer, fitted a fresh sterile needle to the syringe, and injected 0.5 ml. of broth intraperitoneally into the same infected mouse as at stage 2; (6) discarded the third needle to the sterilizer, and, after fitting a fresh sterile needle to the syringe, injected the final 0.2 ml. of broth intraperitoneally into a second normal mouse; and (7) discarded the syringe and needle to the sterilizer.

The sequence of operations was repeated for each of the 13 infected mice, and, in all, 26 normal mice were inoculated in this way. No attempt was made to clean or sterilize the belly walls of the mice. Injections were made in the usual manner. Care was taken not to withdraw the plunger of the syringe after giving the injection. No reflux into the syringes was observed.

The third operator handled the normal mice, holding them for injection, and placing them after injection into cages so that mice inoculated at stage 4 were caged together, labelled "0.1 ml.," and those inoculated at stage 6 were caged together, labelled "0.5 ml."

By the morning after injection, five of the 26 "normal" mice were dead. Fourteen more died in the course of the next 48 hours. The distribution of dead mice between batches is shown in Table I. Blood-agar cultures and stained films prepared from the heart blood of each dead mouse showed abundant pneumococci. The seven surviving experimental mice were alive and in apparently good health three days after injection.

TABLE I.—*Experiments with Pneumococcal Mice*

Experiment	Batch	No. of Mice Injected	No. of Mice Developing Pneumococcal Septicaemia
1 ..	"0·1 ml."	13	8
	"0·5 ml."	13	11
	"Record" control	5	0
2 ..	"Record" test	10	8
	"Tuberculin" control	5	0
	"Tuberculin" test	10	8

It appeared from this experiment that a change of needle gave very little protection against the carry-over of infection from infected to normal mice.

Experiment 2

Later, the experiment was repeated, using mice of a different strain and four 1-ml. glass-metal Record syringes together with five 1-ml. all-glass tuberculin syringes. One of the Record syringes was re-boiled during the experiment and used a second time. In this second experiment procedure was simplified, the steps of the operation being

as follows: (1) Record syringes were sterilized by boiling, all-glass syringes by hot-air sterilization; (2) the syringe was filled with 1 ml. of sterile broth; (3) 0.1 ml. of broth was injected intraperitoneally into a normal control mouse; (4) 0.1 ml. of broth was then injected intraperitoneally into a "pneumococcal" mouse killed immediately beforehand by neck-breaking; (5) the used needle was removed and discarded and a fresh sterile needle fitted to the syringe; and (6) 0.1 ml. of broth was then injected intraperitoneally into each of two normal mice.

As they were injected the mice were caged in six separate groups of five mice—"Record" and "tuberculin" controls, "Record" and "tuberculin" first and second test mice.

During the next 48 hours all control mice remained in good health, but 16 of the 20 test animals developed a fatal pneumococcal peritonitis and septicaemia, which was confirmed by culture and smear. The result is shown in Table I.

These mouse experiments were intended to simulate the ordinary technique of mass inoculation carefully performed. As a test of transfer of infection they were, however, very sensitive, because the number of virulent organisms needed to produce pneumococcal septicaemia in the mouse is very small, and the peritoneal cavities of the pneumococcal mice used contained very large numbers of pneumococci.

An attempt has therefore been made to assess the risk of carry-over of micro-organisms in the "separate needle, common syringe" technique of inoculation by means of quantitative experiments using bacterial cultures instead of pneumococcal mice.

Experiments 3 to 5

These were performed with an "artificial mouse" consisting of a length of glass tubing bent at a right-angle, the shorter arm being fitted with a 2-in. (5-cm.) length of rubber tubing, plugged at the far end with a glass rod (Fig. 1). Overnight broth cultures of *Shigella flexneri* (Y6R or NCTC 4832) were pipetted into the tube, filling the rubber and the horizontal glass limb, and rising in the vertical limb to a height which determined the hydrostatic pressure inside the rubber tube. Six syringes were employed in each of these experiments—1-ml. all-glass "tuberculin" syringes in experiments 3 and 4, and, in experiment 5, four 1-ml. "Record" syringes and two all-glass "tuberculin" syringes.

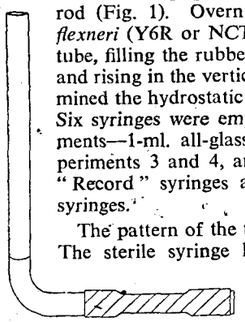

FIG. 1.—"Artificial mouse." A length of glass tubing bent at right angles: the shorter arm is fitted with a 2-in. length of rubber tubing, plugged at the far end with a glass rod.

The pattern of the three experiments was the same. The sterile syringe having been filled with sterile broth, 0.1 ml. was injected through the rubber tube into the "artificial mouse." The needle was then withdrawn. It was changed and not changed on alternate syringes, even-number syringes not having their needles changed, odd-number syringes receiving a fresh sterile needle before the next step in the experiment, which was to discharge 0.2 ml. of broth from the syringe into each of three tubes containing 0.8 ml. of sterile broth. From these tubes suitable dilutions were prepared, and six-plate surface counts (Miles and Misra, 1938) of their contained bacteria were made.

Table II shows the result of these experiments in terms of the number of colony-producing bacilli contained in each of the successive 0.2 ml. volumes of broth discharged from the syringe after injection of 0.1 ml. into the "artificial mouse," with and without intervening changes of needle.

R = Record glass–metal 1-ml. syringe.

Two of the nine tests in which the needle was changed showed no carry-over of infection, but in the remaining seven change of needle showed very little advantage over the nine tests in which the needle was not changed.

The height of the fluid column in the vertical limb of the "artificial mouse" in these experiments varied between 2 and 6 cm. There was no apparent correlation between height of fluid column and result. However, it seemed possible that the positive pressure against which the first injection was made might be forcing culture along the needle, although no plunger movement was evident. To test this, another experiment was performed.

Experiment 6

In this experiment the procedure was similar except that, instead of injecting through rubber into culture under a few centimetres head of pressure, the first injection was made into a small volume of culture held in a small bottle, the point of the injecting needle being held one or two millimetres below the surface, and the syringe necessarily at an angle with the horizontal, such that the pressure on the broth in the syringe must throughout have been greater than the pressure in the culture around the needle point. The result of this experiment is shown in Table III. One

TABLE III.—*Result of Experiment 6*

Needle Change	Syringe No.	Bacterial Counts per 0·2 ml. Volume		
		Vol. 1	Vol. 2	Vol. 3
Not changed	1	83,333	1,083	4,083
,, ,, ...	3	45,000	1,250	300
,, ,, ...	5	31,666	1,916	216

,, ...	4	25,000	2,146	893
,, ...	6	0	0	0

out of three syringes in which the needles were changed still showed a considerable carry-over of bacteria. In this experiment, as in all the preceding ones, the injection into the infected mouse or culture had been made without emptying the syringe. It seemed possible that, unless the plunger were pushed home against the bottom of the syringe, small plunger movements might cause a reflux into the needle.

Experiment 7

In this experiment injection was not made into the infected material. Instead, each sterile syringe was first washed out with a small volume of sterile broth and

emptied. The point of the needle was then dipped into a culture of *Sh. flexneri* to a depth of one or two millimetres, after which it was withdrawn and the needle was changed. A small volume, up to 1 or 2 ml., of sterile broth was drawn into the syringe through the new needle. Three drops were then expelled on to an agar plate and spread with a sterile spreader.

Sixteen syringes were used, ranging from 1 ml. to 10 ml. in capacity, and of various makes. They were fitted with needles of differing lengths and bore. Next day two of the 16 plates showed numerous colonies of *Sh. flexneri*, the remaining 14 showing none.

This experiment shows that if the needle point is contaminated, even when the syringe is empty and with the plunger pushed home and not moved, and even when there is no appreciable pressure forcing infected fluid back into the needle, it is still possible for the syringe to become contaminated when the needle is changed. It is clear, however, that the frequency of such contamination was less than in those experiments in which the plunger was moved, or in which injections were made into infected fluid under a small head of pressure.

Experiment 8

A final experiment was performed to help separate these two factors of plunger movement and pressure of infected fluid. The "artificial mouse" used in experiments 3 to 5 was employed again, but this time the injecting syringe contained only about 0.1 ml. of fluid, the whole of which

TABLE IV.—*Experiment 8*

++, +++ = Large numbers of colonies, not counted.

was injected through the rubber, so that at the end of the injection the plunger was "home" against the bottom of the syringe.

One "artificial mouse" was used to test four syringes. Sixteen syringes in all, of various sizes and patterns, from 1 ml. to 10 ml. in capacity and fitted with various needles, were tested, using four "artificial mice." The order of procedure was: (1) Sterile broth was drawn into the syringe and discharged until about 0.1 ml. remained in the syringe. (In 1-ml. and 2-ml. syringes this volume could be measured easily. In 5-ml. and 10-ml. syringes it was judged by eye, and checked by the change in height of fluid column noted after its injection into the "artificial mouse.") (2) This terminal volume of broth was then injected through the rubber into the culture of *Sh. flexneri* and the rise in height of fluid column noted. (3) The needle was then discarded, being replaced by a fresh sterile needle. (4) About 0.5 ml. of broth, sterilized in a small individual tube, was then sucked into the syringe through the new needle. (5) Three drops were then discharged on to the surface of an agar plate and spread with a sterile glass spreader.

Next morning, after overnight incubation at 37° C., three of the 16 plates showed no growth, but the remaining plates showed colonies of *Sh. flexneri*, checked by slide agglutination, varying in numbers from six to several hundreds, as is shown in Table IV.

Discussion

Syringes used for intravenous injections often become contaminated with blood (Salaman *et al.*, 1944; Droller, 1945; Mendelssohn and Witts, 1945; Darmady and Hardwick, 1945; Morton, 1948) and may, therefore, transfer infection if used on more than one subject without intervening sterilization. Hughes (1946) demonstrated that the nozzles of syringes used to administer intramuscular injections to human subjects often become contaminated with red corpuscles. He found that the drop of fluid on the end of the syringe nozzle after removal of the needle contained red corpuscles after 15 out of a total of 27 injections made into contracted muscles, and after two out of a total of 12 injections into relaxed muscles.

The experiments here reported show that contaminants on the needle point, even when no injection is made and when the contamination is derived from fluid under negligible hydrostatic pressure, may travel back along the needle and contaminate the syringe when the needle is removed from it. Without further extensive quantitative experiments, it would not be possible to assess the frequency with which this happens; probably the pattern of syringe and of needle would affect the degree of risk.

It is likely, from the experiments reported, that small movements of the plunger and the hydrostatic pressure around the needle tip are factors which increase the risk of syringe contamination, and, of course, both of these factors are involved whenever any injection is given.

If, as appears from experiments 6 and 7, contamination of the needle tip can lead to contamination of the syringe, though the pressure around the needle tip is not significantly raised, then some explanation of the passage of the contaminant back from the needle tip to the syringe nozzle must be sought. The most probable explanation seems to be that offered by Hughes: that withdrawal of the nozzle of the syringe from the socket of the needle may suck fluid back from the lumen and point of the needle to contaminate the point of the syringe nozzle. Measurement of the length and internal diameter of some of the needles used in these experiments indicated that the lumen volume varied between 2.5 and 5.8 c.mm. for small needles of the kind usually employed for subcutaneous and intramuscular injection. These

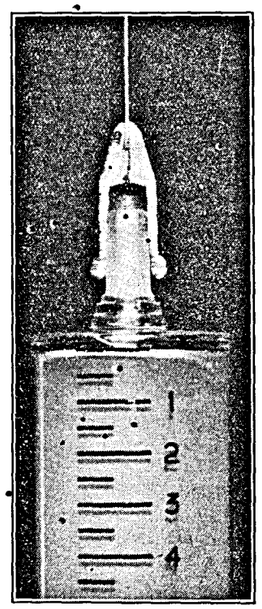

FIG. 2.—Needle cut in half longitudinally and fitted to syringe.

volumes are probably smaller than the displacement volume of the syringe nozzle in the needle socket. Fig. 2 shows a needle which has been cut in half longitudinally and then fitted to a syringe. The displacement volume of the nozzle in the socket is of the order of 100 c.mm.

It seems clear, then, that the "separate needle, common syringe" technique might transfer infection from one subject to the next if the tissue into which the first injection was made were itself infected. Our experiments indicate, however, that syringe contamination does not always follow removal of a contaminated needle, and therefore the "separate needle, common syringe" technique is safer than the use of one needle and syringe for inoculation of several subjects.

The actual risk of syringe transmission of infection during mass immunization is evidently a very small one, because it depends not only on the imperfection of the syringe technique but also on the probability that muscle, skin, or subcutaneous tissue may harbour an infective agent capable of being transmitted.

Where bacterial infections are concerned the risk is probably very small. An injection made into a subject with an undetected incipient septic lesion might cause, by syringe contamination, lesions in several subjects subsequently inoculated, and all the lesions, including that which in fact caused the infections, might be wrongly attributed to prior contamination of the injection material. Several mass-inoculation accidents, such as the Ring disaster of 1939 (Report, 1939) in which multiple tuberculous abscesses followed inoculations with T.A.F., remain unexplained. Bigger, Blacklock, and Parish (1940) draw attention to the risk of transferring infection from a subject who already has some small infective lesion in his muscle or fascial planes.

Virus infections are more difficult to discuss, for knowledge about the distribution of viruses in tissues is very inadequate. Serum hepatitis is clearly apt to be passed by a faulty injection technique (Hughes, 1946), or even by imperfect sterilization of blood guns used for collection of blood samples in diabetic clinics (Malmros, Wilander, and Herner, 1948). Among neurotropic viruses, the group of encephalitides transmitted by insect bite and due to viruses recoverable from the blood may be important in some parts of the world. Hughes (1944) has drawn attention to various neurological complications which may follow inoculations and which might conceivably be syringe-transmitted. The possibility that poliomyelitis or other neurotropic viruses may exist in relatively high local concentrations in the nerves lying in muscles or in skin or subcutaneous tissues cannot, in our view, be entirely excluded, although on the evidence available this seems an unlikely explanation of the association between poliomyelitis and inoculations.

The hazards of the "separate needle, common syringe" technique may well be greater in countries where malaria and blood-borne viruses are more frequent.

Conclusion

The common practice of giving multiple injections from one syringe is not made entirely safe by using a separate needle for each injection, even when the injection is given into a tissue other than a vein; but this technique is safer than is the use of a single needle for injection of several subjects. The risk probably lies in aspiration of fluid along the needle by suction created when the nozzle of the syringe is withdrawn from the socket of the needle.

DIPHYLLOBOTHRIUM INFESTATION AND ANAEMIA IN GREAT BRITAIN

BY

J. C. HARLAND, M.D., M.R.C.P.
Senior Medical Registrar, Westminster Hospital

J. G. HUMBLE, M.R.C.S., L.R.C.P.
Haematologist, Westminster Hospital

AND

P. G. MANN, M.B., B.Ch.
Assistant Pathologist, Westminster Hospital

Diphyllobothrium latum, the fish tapeworm, is uncommon in the British Isles, although cases occur from time to time among the inhabitants of the lake districts of western Ireland. In 1944 Duguid and Sheppard found the trout and sticklebacks of a reservoir in South Wales heavily infested with the plerocercoids of *Diphyllobothrium dendriticum*, and Hickey and Harris (1944) found the adult worm in seagulls in Ireland. Human infestation is virtually unknown in Great Britain, though it is prevalent in other parts of the world, including the United States of America, where it has been introduced by immigrants. In 1924 Passay and Braine referred to an Estonian seaman who expelled a worm in hospital in Aberdeen, and Duguid and Sheppard mention a Belgian soldier who was found to be a carrier. Otherwise no case has been published in this country.

The associated megaloblastic anaemia is remarkable in that it is almost entirely confined to the Finnish race, although there are many other nationalities equally heavily infested with the worm. Even in Finland it is uncommon. Ehrström (1926) stated that it occurred in only one of every 5,000–10,000 carriers, but later workers have found it more frequently. The case recorded below is notable not only on this account but because of its haematological interest and because it raises an important public health problem.

Case Report

A Finnish domestic servant aged 22 had lived in England for two years. Her health had always been good until six to seven months before admission to hospital on July 7, 1949, when she began to notice increasing tiredness, followed later by breathlessness and occasional morning vomiting. She had attended another hospital in May, 1949, where a tentative diagnosis of pernicious anaemia was made and an injection

of liver was given. It was stated that a reticulocytosis occurred five days later. She received no more liver injections, as she then left that neighbourhood.

Apart from obvious pallor there were no abnormal physical signs. Her nutritional state was good. Haematological examination showed the following: haemoglobin, 60% (8.2 g.%); red cells, 2,500,000; colour index, 1.2; packed cell volume, 30 ml.%. The Price-Jones curve (Humble and Belyavin, 1948) showed (Fig. 1, Curve II): mean corpuscular diameter, 8.34 μ; standard deviation 0.9 μ; megalocytosis, 36%. The mean corpuscular volume was 120 μ^3; mean corpuscular haemoglobin, 32.8 $\mu\mu$g.; mean corpuscular haemoglobin concentration, 27.3%; white blood cells, 5,600 (normal differential count). The sternal marrow showed an excess of nucleated red blood

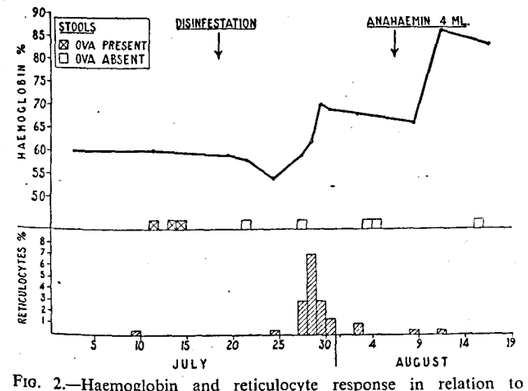

FIG. 2.—Haemoglobin and reticulocyte response in relation to treatment.

cells, most of which could be classified as macronormoblasts. A feature of the films was a large number of fully mature (orthochromic) late normoblasts. Many definite megaloblasts were seen in various stages of development. The appearances were not those of classical Addisonian anaemia.

A histamine-fast achlorhydria was present. The faecal fats were within normal limits, and occult blood was not found in the stools. There was no radiological evidence of pulmonary disease.

When considering the differential diagnosis steatorrhoea was excluded, and it was felt that pernicious anaemia was unlikely on account of the patient's youth. Because of her nationality, diphyllobothrium anaemia was suggested, and three successive stool examinations revealed diphyllobothrium ova.

On July 18 she was given 90 min. (5.4 ml.) of extract of male fern in divided doses of 30 min. (1.8 ml.), having previously been starved for two days. After a dose of magnesium sulphate two hours later, two adult worms were expelled, one with the head intact, which were identified as a species of diphyllobothrium. No further treatment was given, and on July 27 a reticulocytosis began; this continued for the next four days, reaching a maximum of 7% on July 28 (Fig. 2). An injection of 4 ml. of "anahaemin" on August 6 produced no more reticulocytes, but the anaemia was improving rapidly, and on August 11 the haemoglobin amounted to 86%. Ova were not found in the stools examined between disinfestation, and the patient was discharged from hospital on August 19. In November, 1949, she was well and her stools were free from ova. The histamine-fast achlorhydria was still present. Her haemoglobin was 105% and the Price-Jones curve showed: M.C.D., 7.71 μ; standard deviation, 0.59 μ. Megalocytosis was 4.4% (Fig. 1, Curve II).

The atypical bone-marrow appearance can probably be attributed to the liver injection given two months earlier. Also, this case emphasizes the inadvisability of diagnosing true pernicious anaemia in a young person without considering all the possible aetiological factors.

Helminthology

The identity of the tapeworm in this case was determined from specimens of ova and an adult worm. The ova were ellipsoids, measuring about 68 by 48 μ and having

FIG. 3.—*Diphyllobothrium latum*. Two ova, one ruptured to show operculum. (× 150.)

an operculum which was readily opened by applying gentle pressure to a coverslip over a wet film. The embryo appeared as a cluster of granular cells occupying most of the egg. Some specimens showed a small nodular thickening opposite the operculum (Figs. 3 and 4). The adult worm was six metres long (Fig. 5) and was composed of typical proglottides having a central rosette-shaped uterus with genital and uterine pores on the ventral surface (Fig. 6). The testes were not continuous across the mid-line. The scolex was smooth and elongated, was marked

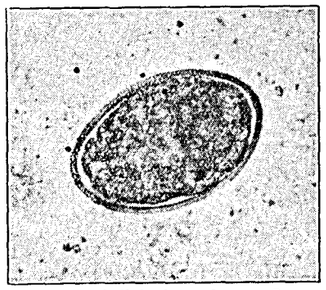

FIG. 4.—*Diphyllobothrium latum*. Ovum. (× 450.)

by two grooves (bothria), but had no hooklets or suckers.

Members of the Diphyllobothriidae have a complex life-cycle, requiring two intermediate hosts as well as the definitive host. On hatching, the eggs liberate a small ciliated spherical larva or coracidium. This develops in

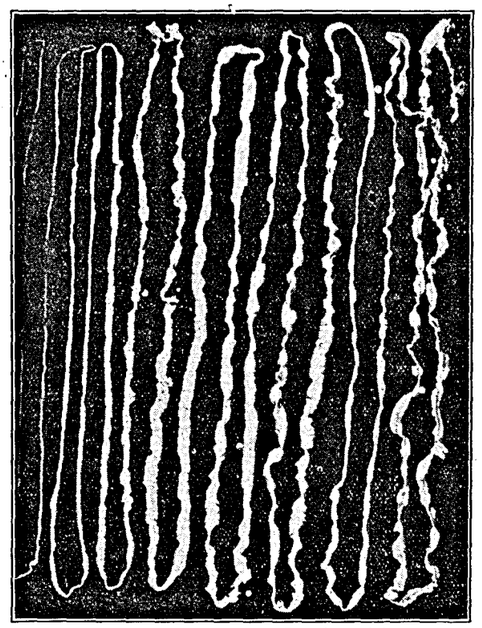

FIG. 5.—*Diphyllobothrium latum*. Complete adult tapeworm. ¼ natural size.

the body cavity of a water-flea, usually *Cyclops* or *Diaptomus*, into a hexacanth form known as a procercoid. When infected water-fleas are swallowed by fish the procercoids pass through the wall of the alimentary canal into the body cavity of the fish, where they develop into plerocercoids, which are small unsegmented worms, some 1–10 cm. long, possessing a deeply grooved scolex. The fish most commonly infested include the stickleback and those species that prey upon it, such as perch, pike, and trout. Fish such as the grayling, which are only spasmodically carnivorous, are much less commonly infested (Unsworth, 1944).

FIG. 6. — *Diphyllobothrium latum*. Unstained segments to show general outline and central uterus. (× 1½.)

If the infested fish is eaten raw or partially cooked by a suitable host the adult worm will develop. The definitive host for *Diphyllobothrium latum* may be the cat, dog, bear, or man. There are also a number of species of diphyllobothrium which infest sea-birds, such as the cormorant and gull, as reported by Hickey and Harris (1944). The outbreak among fish in a reservoir in South Wales described by Duguid and Sheppard (1944) was probably due to this group (Baylis, 1945). It is noteworthy that the avian parasites require the same intermediate hosts as *Diphyllobothrium latum*, and that one species, *Diphyllobothrium dendriticum*, has been reported to have produced human infestation (Talysin, 1932; Markowski, 1950).

Symptoms

The diphyllobothrium tapeworm can be found in man at all ages, but is less common in children than in adults. The worm is acquired by eating raw or partially cooked or cured fish infested with the plerocercoids. The roe as well as the flesh may be affected, and many cases have occurred from eating caviar. Properly cooked or cured fish is harmless. Most carriers have good health, but bowel irritation may cause such symptoms as nausea, vomiting, colicky abdominal pain, and diarrhoea. There is no foundation for the majority of abdominal and nervous symptoms ascribed to the worm. Stomatitis and glossitis occasionally occur, and are certainly common in anaemic cases. Achlorhydria is no more common in the non-anaemic carriers than in the general population (Grönburg, 1912, cited by Birkeland, 1932). Eosinophilia is occasionally found, but is inconstant. When anaemia occurs the symptoms do not differ from those of other anaemic states.

The terminal proglottides are not shed as in taeniasis, and the host may notice nothing unusual in his stools although more than a million ova a day are being discharged. It is common, however, for varying lengths of the worm to be passed from time to time. The life span is not easy to determine, as the worms are often multiple and reinfestation may be continuous, but Leiper (1936) has shown that the worm can live many years. It can be removed by anthelmintic treatment in the usual manner.

The Anaemia

Until recently the characteristic anaemia had been considered a rare manifestation. Birkeland (1932) could find only 544 recorded cases. Of these, no fewer than 391 were of Finnish stock, and the relative tendency of Finns to develop the anaemia compared with other races is very striking. Tötterman (1939) and von Bonsdorff (1948) have indicated that when systematic blood counts are performed the frequency of the anaemia is much greater than Ehrström's (1926) estimation.

The anaemia is commonest in the third and fourth decades—a younger age-group than in Addisonian anaemia (Lindström, 1930)—but is very uncommon in childhood. The blood and bone-marrow appearances are identical with those of the other megaloblastic anaemias. The anaemia is fatal unless treated, but responds well to either liver therapy or disinfestation. No satisfactory evidence has ever been produced that spinal cord degeneration occurs.

Achlorhydria occurs in about 80% of cases, but hydrochloric acid may return to the gastric juice when the worm is expelled. This has not so far happened in our patient. Hernberg (1947) has found that even when hydrochloric acid returns the acidity is diminished, and there is a reduced secretion of gastric juice in response to histamine. From this he infers that tapeworm anaemia occurs in those with a constitutionally defective gastric secretion.

Recent work on the pathogenesis of this anaemia has shown that the intrinsic factor is present. Hernberg (1941) found that an incubated mixture of meat and gastric juice from a patient with diphyllobothrium anaemia will produce a reticulocyte response in patients with true pernicious

anaemia in relapse. Deficiency of the extrinsic factor is not usually present, but the incidence of anaemia seems to have been particularly notable in Finland in 1942, a year when the food situation, especially protein deficiency, was very serious. The anaemia will not clear up after the worm is expelled if the extrinsic factor is deliberately withheld from the diet, indicating that the liver stores of haemopoietic principle are depleted.

In tapeworm anaemia the administration of meat and healthy gastric juice mixtures, whether fresh or incubated, will not produce a remission until the worm is expelled. There is no impairment of absorption in such cases, for folic acid and liver given by mouth are as effective as liver injections. It therefore seems that the worm in some way interferes with the interaction between the extrinsic and intrinsic factors.

Incubating dried or emulsified worm with liver extracts will not reduce their anti-anaemic effect. Nor does the mixture of meat and gastric juice from worm-anaemia patients have any lessened effect in pernicious anaemia if fresh or dried worm extracts are added. Neither does the worm extract, fed to an anaemia patient after the worm is expelled, in any way prevent recovery from occurring.

The available evidence indicates quite clearly that it is the live worm in the intestine which causes anaemia by inhibiting the formation of haemopoietin. How this happens is not yet clear, but von Bonsdorff (1948), in an admirable review of this subject, has suggested that the position of the worm in the ileum may determine the onset of anaemia. By passing a tube into the small intestine he has found that diphyllobothrium ova can usually be withdrawn at a distance of 100–150 cm. from the mouth in anaemic patients. In non-anaemic patients the distance is usually more than 150 cm. The more proximally the worm lies in the ileum the more likely is anaemia to occur. Moreover, by administering a partial vermifuge von Bonsdorff has been able to produce a remission in an anaemic carrier without killing the worm—presumably by causing the worm to retreat once more to the distal part of the small intestine.

If von Bonsdorff's work is confirmed it will explain the following facts: (*a*) A person can be a worm carrier for many years before becoming anaemic—presumably because his worm inhabits the distal rather than the proximal ileum. (*b*) Persons with tapeworm anaemia who recover after expulsion of the worm do not necessarily become anaemic when they are reinfested. (*c*) The presence of anaemia is not related to the intensity of infestation. (*d*) Worms removed from anaemic patients are often discoloured and decomposed, owing to the powerful digestive action of enzymes in the upper ileum. (*e*) Spontaneous remissions occasionally occur without the worm being expelled.

Geographical Distribution

Diphyllobothrium latum is widely distributed throughout the temperate regions of the world wherever there are rivers and lakes well stocked with fish. It is uncommon in the Tropics, where the anaemia is unknown (Manson-Bahr, 1940). Of the three main endemic areas, one is in the Far East, with its centre in Japan. The second area comprises eastern Scandinavia and the Baltic States. The rate of infestation here is high. Birkeland (1932) states that in Finland it is probable that 25% of the population (some 500,000–750,000 people) are carriers of the worm. Figures are not available for the other Baltic countries, but the carrier rate may well be of the same order. From this region the worm has spread to other countries in central and eastern Europe, where the disturbance of the late war has no doubt increased its prevalence.

The third area where the parasite is often found is in North America—in Minnesota and adjoining States in the U.S.A. and Canada. The geographical conditions here are suitable for the propagation of the worm, and, in addition, many of the inhabitants are of Scandinavian descent. Magath (1933) states that there is no evidence that the worm has been indigenous to this area for more than a short time, and there seems little doubt that it was brought there by immigrants from the Baltic States, and now appears to be ineradicable. Essex (1938) found that the proportion of infested fish in Long Lake, Minnesota, was the same in 1937 as in 1929.

Diphyllobothrium in Great Britain

This American experience is worth noting. Duguid and Sheppard (1944) and Hickey and Harris (1944) have shown that fish tapeworms related to *Diphyllobothrium latum* and affecting the same intermediate hosts have already appeared in this country. Although fresh-water fish is not a common article of diet, it has recently been estimated (*The Observer*, December 11, 1949) that there are about two million amateur fresh-water fishermen in Great Britain, who presumably handle and consume what they catch. No doubt human infestation has not previously occurred in this country, as visitors from affected areas have not been numerous in the past. Since the end of the war, however, the position has altered. On April 1, 1942, the number of Estonian, Latvian, and Lithuanian nationals living in this country was 3,212. By the end of October, 1949, this number had increased to 26,745. Similarly the number of Finns living here has increased from 447 in 1939 to 1,208 on July 31, 1949 (figures kindly supplied by the Aliens Department, the Home Office).

These immigrants have come from areas heavily infested with *Diphyllobothrium latum*, and there are probably many carriers among them. If such persons should live in rural areas where sanitation is often primitive there would be a grave risk of sewage containing diphyllobothrium ova being discharged into a fish-bearing river or lake and ultimately causing human infestation. Further investigation of this problem by the public health authorities would appear to be desirable.

Summary

A case of megaloblastic anaemia caused by diphyllobothrium infestation, the first to be recorded in this country, is presented. It is emphasized that a diagnosis of idiopathic pernicious anaemia should not be made under the age of 30 years without considering all the possible aetiological factors.

The appearance and life history of the parasite and symptoms caused by human infestation are discussed. Diphyllobothrium anaemia is also described, and its predilection for the Finnish race is pointed out. The anaemia seems to be caused by the live worm inhabiting the proximal part of the ileum and thus interfering, in some way as yet unknown, with the interaction of the intrinsic and extrinsic factors.

An account is given of the geographical distribution of the worm, and it is pointed out that, as in America, there seems to be a risk of the worm becoming indigenous to Great Britain owing to large-scale immigration from the heavily infested Baltic States since the end of the war.

ADDENDUM

Since the preparation of this paper a further case of diphyllobothrium infestation has been observed.

A married Finnish lady aged 34, who had lived in England for three and a half years, attended the out-patient department

on January 16, 1950. She stated that since the age of 10 she had often been infested with tapeworms. She had noticed worm segments in her stools on one occasion a year previously, and again in September, 1949. For a fortnight before coming to hospital she had suffered from postural dizziness, a symptom she associated with the presence of worms. Apart from slight abdominal discomfort, she had no other symptoms of note. On examination there were no abnormal physical signs. Her blood count was normal. Diphyllobothrium ova were present in the stools. Disinfestation has not yet been carried out.

We are grateful to Sir Arnold Stott for permission to publish this case. We are also indebted to Dr. A. J. Shinnie, medical officer of health for the City of Westminster, and Professor J. J. C. Buckley, of the London School of Tropical Medicine and Hygiene, for help and advice. We wish to thank Professor N. F. Maclagan and the staff of the Biochemical Department, Westminster Hospital, for performing the fractional test meals.

A SPECIFIC SEROLOGICAL TYPE OF BACT. COLI FOUND IN INFANTS' HOME IN ABSENCE OF EPIDEMIC DIARRHOEA

BY

A. M. M. PAYNE, M.D., M.R.C.P.

AND

G. T. COOK, M.D.

(From the Public Health Laboratory, Oxford)

During the past few years attention has been drawn to the association of a particular serological type of *Bact. coli* with outbreaks of infantile diarrhoea and vomiting and with intercurrent attacks in hospital wards (Bray, 1945; Bray and Beavan, 1948; Giles and Sangster, 1948; Giles *et al.*, 1949; Holzel *et al.*, 1949; Taylor *et al.*, 1949). The symptoms of cases excreting this organism have often been severe, and a number of outbreaks have shown a high mortality rate.

In contrast to the frequency with which these observers isolated the organism from infants with symptoms of gastro-enteritis, a very low incidence has been reported among control groups of symptomless children. These control observations to determine the incidence of the organism among healthy children have been carried out on single samples from hospital patients suffering from other conditions and from babies attending welfare clinics and in residential homes.

The present investigation developed from the isolation in a residential babies' home of a strain of *Bact. coli* reported by Dr. Joan Taylor as serologically identical with *Bact. coli* D 433 (Taylor *et. al.*, 1949), and the organism will be described as such in this paper. In view of the control observations made by previous workers on a single sample, it was decided to examine rectal swabs for *Bact. coli* D 433 from all babies in the home at frequent intervals for an extended period. Throughout this time, a period of one year, the clinical condition of the babies was kept under constant observation by one of us (A. M. M. P.).

The purpose of this paper is to give an account of the incidence of *Bact. coli* D 433 during this survey, and to relate its occurrence in babies to the presence of gastro-intestinal symptoms.

Previous Infection in the Home

The home is a private residential one with a training school for nursery nurses. It takes up to 18 infants at a time, the ages ranging from a week or two to 2 years. Most children are from a few weeks to a year old. They are usually admitted singly at an average rate of about one a week. The majority are admitted from the London boroughs, having been abandoned, for adoption, or because of the illness of the parents. Some are "private" residents admitted during the illness or absence of the parents. There is no distinction between the two groups in the home. The home is well run and the children are happy and well cared for. Almost all infants are bottle-fed.

In the winter of 1943–4 there was a sporadic outbreak of infantile diarrhoea and vomiting with five deaths spread over a period of four months. Ever since then there have been frequent attacks of diarrhoea with offensive motions, sore buttocks, vomiting, and loss of weight lasting about a week. Almost every child has been affected more or less, usually soon after admission and sometimes more than once. In June, 1948, two children (twins) were seriously ill, and this was the immediate cause of a request to this laboratory for assistance.

Present Investigation

The home was first visited on June 23, 1948. It was found that one infant (T. H.) was ill with diarrhoea and vomiting of moderate severity, and, since it appeared likely that she might need intravenous therapy, her admission was arranged to the Hospital for Sick Children, Great Ormond Street. Her twin sister (M. H.) was convalescent from a moderate attack of diarrhoea and vomiting. No other children had had significant symptoms during the previous month. Rectal swabs were taken on June 23 from all infants and from the three permanent staff. Including both T. H. and M. H., five out of sixteen infants were found to be excreting *Bact. coli* D 433. The organism was also isolated from T. H.'s vomit. None of the other three children had suggestive symptoms, but one of them (L. M.) developed symptoms on June 24 compatible with a mild attack of infantile diarrhoea and vomiting. The other two had no previous history suggestive of infantile diarrhoea and vomiting, and remained well. These four children were isolated, with separate staff and equipment. No further children were found to be excreting *Bact. coli* D 433 or had developed symptoms. Rectal swabs taken on July 5 showed that one of the two symptomless infants and M. H. were then free from the organism, and on July 15 all swabs were negative. On her return from hospital on July 24 a swab from T. H. was also negative.

Since then all infants have had rectal swabs examined for the presence of *Bact. coli* D 433 on admission and at intervals of two to four weeks up to the end of December, 1948. During January, 1949, few swabs were taken owing to shortage of agglutinating serum, but from February to June, 1949, swabs were taken from all children at intervals of one to two weeks. Records were kept of all gastro-intestinal symptoms. These varied from mild feeding difficulties to attacks of infantile diarrhoea and vomiting. The symptoms have been divided into two groups: (1) intestinal symptoms associated with feeding difficulties, and (2) infantile diarrhoea and vomiting. In some cases it was difficult to decide into which category the symptoms should be placed. The criteria adopted were as follows:

Feeding Difficulties.—A mild disturbance associated with fretfulness; colicky pains; slight looseness of the motions, not more than three or four daily, which might be tinged with green and contain curds or undigested fat with traces of slime; failure to gain weight, or the loss of up to about 4 oz. (113 g.); no temperature; excoriation of buttocks not prominent; no dehydration; responding in a few days to reduction in strength of feeds.

Infantile Diarrhoea and Vomiting.—A definite illness, usually of sudden onset, with frequent loose motions with or without slime, frequently green and offensive, and often associated with vomiting; loss of weight, usually more than 4 oz., with or without obvious dehydration; excoriation of the buttocks; reluctance to feed; some fretfulness when disturbed, but as a rule lethargy; temperature sometimes raised, especially at the onset; colicky pain not marked.

Diarrhoea associated with parenteral infection is excluded, but this did not occur in the presence of *Bact. coli* D 433.

Bacteriological Investigation

Since Bray (1945) first reported the occurrence of serologically homogeneous strains of *Bact. coli* var. *neapolitanum* among infants suffering from "summer diarrhoea" a varying nomenclature has been adopted by subsequent workers for the same serological strain of *Bact. coli*. The position has recently become more confused by the isolation of a new type of *Bact. coli*, also frequently associated with infants suffering from gastro-enteritis and called the β-type (Giles *et al.*, 1949; Smith, 1949). This type differs from the original or α-type antigenically and in certain of its cultural characteristics. Both types were also recognized among the cases studied by Holzel *et al.* (1949).

A summary of the names by which the α-type of *Bact. coli* has been previously described is given in Table I. A study of the literature reveals that all these strains are, in fact, antigenically identical (though different from the β-type), and they are the same as that described in this paper. It must be emphasized that the identity and similarity of the strains depend primarily on serological behaviour, though they can be regarded as a serologically homogeneous group of coliform organisms usually having the biochemical reactions ascribed to *Bact. coli* var. *neapolitanum*.

TABLE I.—*Nomenclature Used by Previous Authors for Strains of Bact. coli Serologically Identical*

Author	Nomenclature
Bray (1945)	*Bact. coli* var. *neapolitanum*
Bray and Beavan (1948)	
Giles and Sangster (1948)	*Bact. coli* (later referred to as α-type)
Giles *et al.* (1949)	
Holzel *et al.* (1949	*Bact. coli* var. *neapolitanum*
Rogers *et al.* (1949)	*Bact. coli* B.G.T. (Bray–Giles–Taylor)
Smith (1949)	*Bact. coli* α-type
Taylor *et al.* (1949)	*Bact. coli* D 433

Methods

During the period of 12 months that this investigation was being undertaken 337 rectal swabs from babies were examined. In the absence of symptoms, each swab was inoculated on to a layered horse-blood/digest-agar plate and a MacConkey plate, both of which were incubated aerobically at 37° C. Swabs from babies with symptoms of gastro-enteritis were also inoculated on to desoxycholate citrate agar and on to Wilson and Blair's medium, both directly and after enrichment in Kauffmann's tetrathionate broth and in selenite F. Non-lactose fermenters and suspicious colonies on Wilson and Blair's medium were further investigated.

The first five strains of *Bact. coli* D 433 isolated were identified from blood-agar plates sent to Dr. Taylor for investigation. The remaining strains were recognized in this laboratory as a result of slide agglutination of at least four colonies from the primary blood-agar or MacConkey plate. Except in two instances, when first isolated from a baby each positive strain was inoculated into a set of "sugars" and also sent to Dr. Taylor for serological confirmation. In subsequent isolations the identification of *Bact. coli* D 433 was made by slide agglutination only.

Results

Bact. coli D 433 was isolated from 40 of the 337 rectal swabs examined. It was often present on the primary blood plate as a practically pure growth, and in 24 of the 40 cases 75% or more of the colonies tested gave a positive agglutination result. The 40 positive swabs were obtained from 17 of the 60 babies investigated. Strains from 15 of these 17 babies were examined biochemically and showed similar reactions.

All these strains were non-motile when grown in broth at 37° C., were indole-positive, and failed to produce H_2S. All fermented lactose, glucose, mannitol, and maltose with acid and gas production after overnight incubation at 37° C. except one strain which did not ferment maltose till the third day. Fermentation of sucrose and salicin was usually delayed for 48 hours and fermentation of dulcitol for four days. Rarely sucrose, salicin, or dulcitol was not fermented. The strains were M.R.-positive, V.P.- and citrate-negative, and gave acid and gas in MacConkey broth at 44° C. All strains were agglutinated to titre by *Bact. coli* D 433 K and O sera. No member of the *Shigella* or *Salmonella* group was isolated from any of the babies with symptoms of gastro-enteritis.

Use of MacConkey Agar

During most of the course of this investigation MacConkey agar was used in parallel with blood agar. It was hoped that on those plates where *Bact. coli* D 433 formed only a small proportion of the total growth the colonies might be more readily recognized on MacConkey agar than on blood agar. It was found, however, that the relatively small colonies of *Bact. coli* D 433 were usually overgrown or suppressed by the heavier growth of other intestinal organisms.

There was reasonably good correlation between the results on blood agar and on MacConkey agar. Of 28 instances in which a positive result was obtained, both media were positive in 24, blood agar only in three, and MacConkey agar only in one. The blood-agar plate on this occasion was overgrown by a spreading *Proteus*. When a *Proteus* strain rendered the blood-agar plate unsuitable for examination, slide agglutination was done on colonies from the MacConkey plate.

In view of the occasional failure to isolate the organism from MacConkey agar when the blood agar was positive, it is possible that slightly better results might have been obtained by using chloral hydrate blood agar as an alternative medium. The proportion of blood-agar plates

contaminated by spreading *Proteus* strains was not large—24 out of 337. A few babies consistently produced *Proteus* organisms, and the 24 strains isolated were, in fact, all obtained from 12 of the 60 babies examined.

Epidemiological Findings

The epidemiological results are summarized in Tables II, III, IV, and V.

TABLE II.—*Incidence of Bact. coli D 433 Related to the Number of Examinations Made*

* Three of these had been positive in February–March.

During the course of the investigation rectal swabs were examined from 60 infants, and it was found that 17 of these excreted *Bact. coli* D 433 on one or more occasions. The number of examinations made on each infant varied considerably, and Table II shows the association between this and the incidence of *Bact. coli* D 433. The organism was isolated from as many as 11 of the 12 infants examined on twelve or more occasions, but from none of the 23 infants examined once or twice only.

Symptoms of infantile diarrhoea and vomiting were observed among only 5 of the 17 infants with positive swabs and 11 infants had no symptoms at all while excreting *Bact. coli* D 433. Four of these 11 infants were under 3 months old (Table III) and five infants continued to excrete the organism for at least three weeks (Table IV). The frequency of symptoms among those infants who were not excreting *Bact. coli* D 433 at the time is not shown in the tables. In the course of the year six of these developed infantile diarrhoea and vomiting, and symptoms associated with feeding difficulties occurred on 13 occasions.

When *Bact. coli* D 433 was first recognized in the home in June, 1948, it was isolated from five babies. The organism was not detected in any of these babies after the beginning of July and, in fact, was not again isolated in the home until the third week of February, 1949. It then spread rapidly through the home, and during the next four weeks was isolated from 10 of the 15 infants at risk, though only two of these developed symptoms of infantile diarrhoea and vomiting (Table V).

Weight charts were kept for all infants throughout the year, and it was thought that irregularity of the charts might provide a more sensitive indication of the effect of carriage of *Bact. coli* D 433 than the presence of intestinal symptoms. It was found, however, that all 11 infants who did not develop symptoms while excreting *Bact. coli* D 433 continued to gain weight steadily.

Discussion

It can be seen from the findings of some previous observers (Table VI) that the incidence of this serological type of *Bact. coli* among the healthy infants forming the control groups is low. These control infants were taken from a number of different environments, and the results are based on single examinations of different infants.

* Mainly hospital patients, including "healthy" contacts. † Includes groups A to E (*loc. cit.*). ‡ Includes groups F, G, and H (*loc. cit.*). § Infants in residential and day nurseries.

Recent findings by Smith (1949) and Rogers *et al.* (1949) cannot be tabulated in the same way, but both confirm the frequent association between a specific serological type of *Bact. coli* and infantile diarrhoea and vomiting. Smith also describes the occurrence of a different serological type of *Bact. coli*, known as type β, in cases of diarrhoea and vomiting. This type was not looked for in the present investigation. Rogers *et al.* (1949) found that 25 out of 86 infants excreting *Bact. coli* B.G.T. (see Table I) did not develop symptoms. The remaining 61 developed gastro-intestinal disturbances which varied from severe gastro-enteritis to a mild diarrhoea with or without vomiting. It is worthy of note that 82 of these infants acquired the organism after admission to hospital.

In the present investigation the infants were selected by the fact that they were in the home, and not because of any symptoms. Therefore the best estimate of the general incidence of *Bact. coli* D 433 must include all positive results irrespective of the presence of symptoms. Sixty babies were examined and 17 of them were found to be excreting *Bact. coli* D 433 on one or more occasions in the course of a year. It appears that the frequency of isolation of *Bact. coli* D 433 is related to the number of times the infants were examined (Table II). However, the relatively high incidence among babies examined on twelve or more occasions may equally well be due to the length of their stay in the same semi-closed community resulting in an increased risk of exposure.

In many intestinal infections some susceptible children may excrete the causative organism for a short period without developing symptoms. Prolonged excretion without symptoms is, however, unusual. In the course of this investigation five infants were found to be excreting *Bact. coli* D 433 in large numbers for three weeks or more and yet did not develop symptoms. One further infant had very mild symptoms due to feeding difficulties during a long period of excretion. The ages of these six infants at the time were 4, 8, 8, 12, 16, and 20 weeks. Adequate past histories were obtained for all these children and only one had had infantile diarrhoea and vomiting. She was under observation in the home at the time and was not excreting *Bact. coli* D. 433. Breast-feeding is widely accepted as affording a degree of protection from infantile diarrhoea and vomiting, but none of these six infants was breast-fed at the time of excreting the organism and four of them had never been breast-fed. Eleven infants developed infantile diarrhoea and vomiting during the year, but only five of them were excreting *Bact. coli* D 433.

These findings, and the fact that 11 of the 17 children excreting the organism did not develop symptoms at the time, do not support the hypothesis that there is an aetiological connexion between *Bact. coli* D 433 and infantile diarrhoea and vomiting, though they are compatible with such a theory. However, the figures of previous workers summarized in Table VI strongly suggest some such connexion unless an alternative explanation of the very high incidence among ill children is found. It has already been suggested that the incidence among healthy babies may be higher than earlier results have shown. The present methods of isolating the organism cannot be considered satisfactory, and in the absence of selective media it is probable that scanty infections might be missed.

In this survey the organism was not isolated from any infant for more than four weeks at a time. The strain then died out or was present in the faeces in insufficient numbers to be detected. In the latter case it is possible that the appearance of the organism in the home in May was not due to a fresh introduction from outside, but to its persistence in small numbers in the stools of one or two children. In this event some unknown factor may have caused rapid proliferation of the organism. The fact that three of the four babies excreting the organism in May are known to have previously excreted it in February and March might be regarded as supporting this suggestion. No evidence of the possible nature of this factor was found. It is not necessary for the stools to be loose for the organism to flourish. Further work is necessary to determine whether such a factor exists.

The part played by *Bact. coli* D 433 in the aetiology of infantile diarrhoea and vomiting remains uncertain, but it has been shown that an outbreak of infantile diarrhoea and vomiting did not follow the spread of the organism among a group of infants, the majority of whom were presumed to have been susceptible to the disease.

Summary

A clinical and bacteriological investigation of infants in a residential home was carried out for a period of one year. Sixty infants came under observation.

A specific serological type of *Bact. coli* identified as D 433 (Taylor *et al.*) was isolated from 17 infants on one or more occasions. Eleven of these infants had no symptoms, one had slight symptoms associated with feeding difficulties, and five had infantile diarrhoea and vomiting. Six infants developed infantile diarrhoea and vomiting in the absence of *Bact. coli* D 433.

At one time as many as 10 out of the 15 infants in the home were excreting *Bact. coli* D 433, but no outbreak of infantile diarrhoea and vomiting occurred.

The aetiological relationship between *Bact. coli* D 433 and infantile diarrhoea and vomiting is discussed.

We are indebted to Dr. Joan Taylor for identifying the first five strains of *Bact. coli* D 433 reported in this paper, for confirming the identity of strains isolated subsequently, and for the supply of agglutinating serum. Our thanks are due to the matron and staff of the home for their whole-hearted co-operation.

BACT. COLI D 433 IN CASES OF DIARRHOEA IN ADULTS

BY

JOHN S. STEVENSON, M.D.

Department of Bacteriology, Stobhill Hospital, Glasgow

Recent investigations concerning the causal factors of diarrhoea and vomiting in infants have indicated that the disease is very often associated with the presence in the intestine of a particular variety of *Bact. coli*. An organism of this nature (*Bact. coli* var. *neapolitanum*) was isolated by Bray (1945) from over 90% of cases of summer diarrhoea; Giles and Sangster (1948) isolated a similar organism from over 90% of cases occurring in an outbreak in 1947. Taylor *et al.* (1949) described the isolation of a non-motile variant of *Bact. coli*. (D 433) from a large number of cases occurring in eight outbreaks of infantile diarrhoea and vomiting, and identified this organism with that previously isolated by Giles and Sangster.

In order to investigate strains of *Bact. coli* encountered in this laboratory from cases of infantile diarrhoea and vomiting, D 433 antiserum was kindly supplied by Dr. Joan Taylor. At the time the investigation was begun, however (April, 1949), there were few cases of infantile gastro-enteritis, and it was decided in the first place to confine attention to adults and establish a routine method of procedure which could be used in the summer months if and when outbreaks developed.

Procedure

Specimens of faeces arriving at the laboratory for routine investigation were inoculated on to blood agar, MacConkey, and Difco "bacto S.S." agar. The plates were inoculated

by the usual stroke method and incubated overnight. The following morning two colonies of coliform organisms from each plate were picked off into peptone water and incubated at 37° C. for six hours—that is, six colonies from each specimen of faeces were isolated. From the peptone waters the routine sugar media and an agar slope were inoculated and incubated for 18 hours; the agar slope growths were then tested by slide-agglutination against D 433 antiserum.

In this way coliform organisms from the faeces of 72 adults were examined over a period of several weeks, and it was with some surprise that positive slide-agglutination reactions were obtained with two cases on the first day of the investigation. Further positives were encountered within a few days, and over a period of three weeks a total of 14 was reached. Brief details of these cases are set out in the Table. The 14 strains isolated were sent to Dr. Taylor for confirmation; all 14 were identified as *Bact. coli* D 433. No members of the *Salmonella* or *Shigella* groups were isolated from any of these patients.

Details of Cases

Case No.	Sex	Age	Clinical Notes	Diagnosis	D 433 Isolated	Contact with Children
1	F	25	Admitted 12/3/49. Diarrhoea 7 weeks' duration. Jaundice developed 6/4/49. Died 26/5/49	P.M. "Intestinal polyposis. Carcinoma of duodenum with secondary spread"	2/4/49	Not known
2	M	69	Admitted 15/3/49. Cough, haemoptysis, diarrhoea 3 weeks. X-ray showed gastric ulcer. Partial gastrectomy. Discharged 19/8/49	Gastric ulcer	2/4/49	None
3	F	72	Admitted 21/2/49. Jaundice. Diarrhoea developed in hospital. Discharged 1/6/49	Infective hepatitis	4/4/49	None (nor with other cases of this series)
4	F	53	Admitted 11/2/49. Diabetes and diarrhoea. Discharged 30/4/49. Readmitted 16/6/49. No diarrhoea. Discharged 12/7/49	Diabetes mellitus	4/4/49	Not known
5	F	30	Admitted 3/4/49. Pregnant. Diarrhoea. Slight bronchitis. Discharged at own request 9/4/49	Bronchitis	5/4/49	One child aged 4 years. Well
6	M	50	Indian seaman. Admitted 29/3/49. Pneumonia; jaundiced; slight diarrhoea. Discharged 11/5/49	Lobar pneumonia	5/4/49	None
7	F	12	Vomiting and diarrhoea for 24 hours. Temperature 104° F. (40° C.). Speedy recovery	Enteritis. ? food-poisoning	12/4/49	Not known
8	F	72	Admitted 23/3/49. Diabetes and diarrhoea, with severe colic. Discharged 1/7/49	Diabetes mellitus	13/4/49	None
9	M	42	Admitted 24/3/49. Diarrhoea for several weeks; blood and mucus for 6 days. Died 17/4/49	Ulcerative colitis (no necropsy)	13/4/49	2 children—6 and 8 years. Well
10	F	5	Admitted 10/4/49. Abdominal pain, diarrhoea, and vomitting. Discharged 7/5/49	Mild appendicitis	14/4/49	Not known
11	F	12	Admitted 4/4/49. Acute rheumatism with diarrhoea	Acute rheumatism	14/4/49	" "
12	F	59	Admitted 5/1/49. Diarrhoea with blood and mucus; rheumatoid arthritis. Discharged 7/6/49	Non-specific "dysentery"	18/4/49	None
13	F	43	Admitted 11/3/49. Asthma and severe diarrhoea for several days. Discharged 22/6/49	Asthma; colitis	18/4/49	Not known
14	F	23	Admitted 20/4/49. 28 weeks pregnant—vaginal bleeding. Diarrhoea 2 days. Slough of bowel passed 25/4/49	Pregnancy; colitis	21/4/49	2 children—3 and 2 years. Well

In this way coliform organisms from the faeces of 72 adults were examined over a period of several weeks, and it was with some surprise that positive slide-agglutination reactions were obtained with two cases on the first day of the investigation. Further positives were encountered within a few days, and over a period of three weeks a total of 14 was reached. Brief details of these cases are set out in the Table. The 14 strains isolated were sent to Dr. Taylor for confirmation; all 14 were identified as *Bact. coli* D 433. No members of the *Salmonella* or *Shigella* groups were isolated from any of these patients.

Further investigations were carried out during May, 1949, but no more instances of D 433 in adults were encountered. Pressure of work unfortunately made it impossible to continue the work during the summer months. During September and October over 60 more cases of adult diarrhoea were investigated, with negative results so far as the isolation of D 433 was concerned.

Discussion

These brief notes are not intended to be in any way the results of exhaustive research, but are presented merely to draw attention to a possible reservoir of *Bact. coli* D 433. It is difficult to assess the importance, if any, of the present findings, but it is thought that the following points may be of interest.

1. All the patients had diarrhoea. In some it was of trifling severity, but was marked in others. Several of the latter, notably Cases 1 and 9, were the seat of pathological processes which could explain the diarrhoea without the intervention of an infective agent.

2. Eleven of the patients were females. In such a small series it is to be doubted if much significance can be placed on this finding, but there remains the fact that women are in contact with young infants to a greater extent than men, and thus are more prone to infection from, or to infect, babies than are males.

3. Of three patients with jaundice, two had definite liver damage.

4. So far as could be ascertained, none of the patients had direct contact with young infants, and no cases of "gastro-enteritis" could be traced to their homes. In the series described by Taylor *et al.* (1949), D 433 was recovered from the faeces of 4 out of 84 adult contacts of infantile diarrhoea and vomiting. None of these four cases had suffered any intestinal upset.

While it cannot be stated that D 433 is a likely cause of the diarrhoea in even some of these 14 cases, it may be that the reverse is true—that is, that the washing-down effect of the diarrhoea caused the organism to be present in the faeces. This suggests the possibility that D 433 is a normal inhabitant of the adult duodenum or jejunum, and would to some extent explain the presence of the organism in cases of such diverse diagnoses.

I wish to thank Dr. Joan Taylor for her interest and help during this investigation; my thanks are also due to the medical superintendents of Stobhill and Southern General Hospitals, Glasgow, for permission to make use of the clinical details of the patients concerned.

In recent years evidence has accumulated of the rapid external corrosion of cast-iron and spun-iron pipes used for water supply, especially those laid in clay subsoils containing sulphates. In view of the large number of bursts and premature replacement of mains which had resulted, the Minister of Health set up a Departmental Committee in December, 1948, to investigate the matter. This committee has now issued its *Interim Report of the Departmental Committee on the Deterioration of Cast Iron and Spun Iron Pipes* (H.M.S.O., 3s. 6d.). It covers the scientific and technical aspects of corrosion, deals with the extent of the problem and its implications, and suggests measures for protecting pipes in areas where the soil formation is known to be corrosive.

BONE-MARROW INFUSIONS: INTRATIBIAL AND INTRAVENOUS ROUTES COMPARED

BY

L. W. C. MASSEY, M.B., B.S.

From the Gastro-enteritis Unit, South-western Hospital

The bone marrow as an alternative to the venous route for injections and infusions in man was described by Henning (1940) in Germany and by Tocantins (1940) in the U.S.A. In this country the method was recommended by Barford (1943) and by Bailey (1944), and a suitable needle was devised for use in infants by Gimson (1944). Since then a large number of workers have used the method, and it was found that the intrasternal route was suitable for adults, though there was some danger of perforating the sternum, and the intratibial route for infants. Many cases of osteomyelitis were described as following bone-marrow infusions, and in a review of the literature up to 1945 Quilligan and Turkel (1946) concluded that the bone marrow should be used only as an "emergency" route for parenteral fluids.

In this country, however, Ellison (1944) and Gunz and Dean (1945) regarded the method as a satisfactory alternative to the intravenous route, while in the U.S.A. Elston *et al.* (1947) came to the same conclusion, stating that the incidence of complications is "very low."

Further favourable reports have come from Higgins *et al.* (1947), Sutton and Kelley (1947), Williams and Lockhart (1948), and Texter and Kaump (1948) in the U.S.A., Couder (1948) in France, and from Heinild *et al.* (1947) in Denmark after experience with nearly 1,000 infusions.

The reported series of bone-marrow infusions in the literature together with the incidence of osteomyelitis have been compiled in Table I.

TABLE I.—*Incidence of Osteomyelitis after Bone-marrow Infusions*

Author	Total in Series	No. of Cases of Osteomyelitis

	3,214	21

* Gunz and Dean refer to two further cases of osteomyelitis which they do not include in their series.

† Texter and Kaump gave more than one infusion through the same needle (325 punctures were made).

The small series have not been included—for example, 20 intrasternal blood transfusions without osteomyelitis reported by Giraud *et al.* (1945). A series of over 400 reported by Tocantins and O'Neill (1945), in which it is not made clear how many, if any, cases of osteomyelitis resulted, is also omitted.

Comparison of the Two Methods

Both intratibial and intravenous infusions have been used at this hospital for some years. In January, 1948, a ward for gastro-enteritis in infants was opened and both methods were used in the treatment of cases with clinical signs of dehydration. By June, 1948, 72 infusions of each kind had been successfully performed. The two series of infusions were comparable in that they were carried out by the same staff and on similar patients. Often the same patient would be treated by both methods.

The fluids used were Hartmann's solution, glucose-saline, "casydrol," diluted plasma, and blood. Our previous experience had shown that the latter two were not very satisfactory for intramedullary use, so that blood was always, and plasma usually, given intravenously. The fluids were delivered by the standard "drip" method, and in most cases the infusion was allowed to run for as long as possible.

Intratibial Series

Method.—Gimson's (1944) method was used: a local analgesic was infiltrated down to the periosteum at a point medial and below the tibial tubercle, a Gimson needle was pushed in through the cortex of the bone, a little marrow aspirated, and the needle attached to a continuous-drip apparatus. One infusion was omitted from the series because of insufficient data and 12 because there was failure to perform the bone puncture or the "drip" failed to run. These failures were in some instances due to the use of too short a needle and were unusual in the case of the more experienced operator.

Complications (Table II).—A mild periostitis was seen in all cases examined radiologically but caused no trouble. On three occasions some necrosis of the bone was seen on the film, described by Tocantins as "pressure necrosis," but this also required no treatment. One case of osteomyelitis occurred and was transferred to surgical care. The child was not operated on, and is reported to have been discharged cured. In another case regarded as a failure the shaft of the needle broke off while being inserted and was left embedded in the bone for five months with no ill effect. For some months after the infusion most cases were left with a little nodule in the skin adherent to the bone at the site of the puncture, as noted by Elston *et al.* (1947). A small slough at the site of the puncture was seen four times; this was due to pressure on the skin by the needle guard where too short a needle was used. Seven other cases showed a mild infection of the puncture wound.

TABLE II.—*Complications*

	Intratibial	Intravenous
Leaking connexions of the apparatus	3	4
Needle loose or dislodged	5	11
Local oedema	12	28
General oedema	4	8
Inflammation of wound or puncture	7	7
Endocarditis	0	1
Small slough at puncture site	4	Nil
Periostitis	1	"
Necrosis of bone and periostitis	3	"
Osteomyelitis	1	"
Thrombophlebitis	Nil	6
Abscess in track of vein	"	3

Intravenous Series

Method.—The saphenous vein at the ankle was usually employed; it was exposed by a small incision under local analgesia and a double needle of the Bateman type tied in. The lumen of the vein was frequently so small that only the fine inner needle could be used.

Omitted from the series were 17 instances in which there was failure to perform the attempted infusion or in which the "drip" failed to run.

Complications (Table II).—In most of the cases some degree of phlebitis could be detected clinically in that the vein was thickened and tender on palpation. This was thought to be a physiological response. Thrombophlebitis was manifested by signs of phlebitis extending along the

course of the vein accompanied by red, swollen, and tender areas of overlying skin. It occurred in six instances and subsided rapidly. A mild infection of the incision was found seven times.

Discussion

An examination of the records of the infusions showed that by the intratibial route an average of 40 oz. (1.14 litres) of fluid was given (Table III). The duration of the infusion

TABLE III

	Intratibial	Intravenous
Total fluid given in series	2,873 oz. (81·6 l.)	3,046 oz. (86·5 l.)
Average amount given	40 ,, (1·14 l.)	42 ,, (1·2 l.)
Average time	34 hours	42 hours

was anything from 12 hours to four or five days (average 34 hours). By the intravenous route an average of 42 oz. (1.2 litres) was given, and the duration of the infusion ranged from 12 hours to three or four days (average 42 hours). It also appeared that the maximal rate of flow of the intratibial "drip" was almost as good as that of the intravenous and quite adequate for infusions at the rate we required.

In none of the cases of intratibial or intravenous infusions were embolic or septicaemic complications noted, with the exception of one case in which the patient died after an intravenous infusion and in which "agonal endocarditis" was found at necropsy.

Local oedema occurred round the site of the intratibial needle in 12 cases and round the intravenous needle in 29 cases towards the end of the infusion. In the former the cause is probably due to fluid leaking back along the needle when it has been in the bone for some time and becomes loose, while in the latter it is probable that the needle is pushed through the vein while adjustments are being made to it or the baby is being moved for nursing purposes.

The intratibial needle is more firmly held in place than the intravenous needle and became loose in only five instances, while the latter was dislodged 11 times.

It would seem that the advantages of the intratibial method are "ease and speed in introducing the needle and its firm fixation" (Behr, 1944), while, on the other hand, the intravenous method is better for blood or plasma. It was also often found to be possible to deliver fluid at a faster rate by the intravenous route, though this was seldom required.

The disadvantage of the intratibial method is the occasional osteomyelitis, as compared with the complication of thrombophlebitis or abscesses in the track of the needle in the case of the intravenous method.

By improvements in technique and by removing the needle earlier it may be possible to reduce all these complications, and it should be noted that the reports in the literature indicate that the osteomyelitis is usually amenable to treatment, since it is provided with an artificial sinus by the needle puncture (Ellison, 1944).

However, it would be best to reserve the intramedullary infusion for those occasions when, for various reasons, the technical difficulties of the intravenous method are too great for the operator.

Summary

The literature on bone-marrow infusions is briefly mentioned and the incidence of the complication of osteomyelitis is assessed (approximately 1 in 150 cases).

Seventy-two intratibial infusions are compared with the same number of intravenous infusions.

One case of osteomyelitis is reported in the intratibial series, and the intratibial method is recommended as very satisfactory for the administration of the parenteral fluid in infants when difficulty is found with the intravenous method.

My thanks are due to Dr. J. C. Blake, physician-superintendent, for his advice and permission to use the hospital records, and to my colleagues for permitting me to include their cases in the infusion series. I wish also to thank the librarian of the Royal Society of Medicine, and Miss Helen Bayne, of the Library of the New York University, Bellevue Medical Centre, for assistance with the list of references.

Medical Memoranda

Transfixion by a Muck Fork

Accidental transfixion by a muck fork or similar tined implement is not uncommon in country districts. The following case is reported in order to stress the importance of leaving the implement *in situ* until the patient reaches hospital.

CASE REPORT

The patient, a lad of 16, was admitted to the County Infirmary, Louth, at 6 p.m. on September 19, 1949. At 5 p.m. he had fallen off a lorry load of straw on to the

points of a muck fork. When seen just after admission he was lying on his right side with the business end of the fork transfixing him from behind forwards as in the accompanying drawing. The fork was thickly coated with manure. At the

suggestion of the doctor who was called to the accident, the wooden shaft had been sawn through just above the metal, for ease of transportation.

The upper tine had missed him but the three others had passed right across the buttocks and groins. The second in series entered the left buttock as shown, passed lateral to the femur, and lay with the point just under the skin of the front of the thigh. The third in series entered the posterior surface of the left buttock, passing medial to the femur, and emerged between femoral artery and vein, with the point pushing forward the overlying skin about 2 in. (5 cm.) without piercing it. The lowest tine passed deeply across the right thigh, medial to the femur, emerged momentarily in the right groin, entered the scrotum after ¼ in. (0.6 cm.), and appeared just below the pubic ramus, protruding through the skin at the base of the penis and apparently transfixing the urethra. There was no clinical evidence of sciatic-nerve involvement and the patient's general condition was good.

The four entry holes and the two exit holes were "ringed" with gentian violet for ease of identification. Catheterization revealed no blood and the urethra was assumed to be undamaged. Under general anaesthesia (Dr. Swallow) at 7 p.m. (that is, two hours after the accident) the fork was extracted—a strong pull being required. All the puncture wounds were excised within ellipses of skin as far as the deep fascia, and the tracks were enlarged slightly and generously powdered with sulphathiazole and penicillin powder; ¼-in. diameter drainage tubes with holes cut at ¼-in. (1.25-cm.) intervals all along were then put into most of the length of each track. The patient received 6,000 I.U. of tetanus antitoxin and 2 ml. of polyvalent gas-gangrene antitoxin pre-operatively. The tetanus antitoxin was repeated on the third day and the A.G.G.S. on the third and sixth days. He received 1 ml. of tetanus toxoid on the seventh day. Procaine penicillin, 600,000 I.U., was administered twice daily for seven days. The bacteriological report on the manure removed from the implement was as follows: "Culture—a proteolytic anaerobe morphologically typical of *Clostridium tetani* was cultured."

Convalescence was uninterrupted. The tubes were removed on the fourth post-operative day, and secondary closure of the wounds was made on the 15th day. The patient was discharged from hospital with all wounds healed on the 36th day.

Not a single drop of blood escaped until the fork was withdrawn, when the entry holes bled briskly. If a tine had entered the femoral artery or other large vessel, premature withdrawal would have complicated the issue by probably producing internal haemorrhage. Had some well-intentioned person removed the fork before admission to hospital the difficulties of visualizing each track and its relation to important structures would have been greatly increased.

My thanks are due to Mr. N. J. Nicholson, consulting surgeon to this hospital, for permission to publish this case and for advice; to Dr. W. J. Mozdzierz for his assistance; and to Nurse Pope for the drawing.

CHRISTOPHER CUMMINS, F.R.C.S.Ed.,
Surgical Registrar, County Infirmary, Louth, Lincs.

Chronic Myeloid Leukaemia and Pregnancy

The association between chronic myeloid leukaemia and pregnancy is rare. McGoldrick and Lapp (1943), in an exhaustive review of world literature (94 references), could find only 41 substantiated cases for statistical use. They quote a maternal mortality of 36.5% and a foetal mortality of 16.4%. Li, McBride, and Mettier (1947) recorded four cases and Williams (1948) a further seven cases, with a maternal mortality of *nil*, bringing the total up to date, of this variety of leukaemia, to 52.

CASE REPORT

A woman aged 25 was first seen at hospital on June 23, 1947, complaining of swellings of the legs. On examination these swellings were seen to be subcutaneous haemorrhages and the spleen was found to be enlarged, extending for 10 in. (25 cm.) below the xiphisternum. The blood count was: haemoglobin, 67%; red cells, 3,200,000; colour index, 1.04; platelets, 84,000; white cells, 188,800. The diagnosis of chronic myeloid leukaemia was established. She was admitted to hospital and treatment with urethane was begun. During the remainder of 1947 and 1948 she continued to work, and the white cell count was kept under control with urethane.

On November 9, 1948, her blood count showed the haemoglobin to be 72% and the red cells 2,950,000, but the white cells had risen to 202,000. She was referred to the radiotherapy department for *x*-ray treatment of the spleen, which reached to the iliac crest and almost to the midline. From December 15 to January 19, 1949, a total of 900 r to the skin over the spleen was given, reducing the white count to 6,800. The blood count on April 25, 1949, was: haemoglobin, 62%; white cells, 8,200.

On July 8 she was referred for a gynaecological opinion as she had noticed a swelling of the lower abdomen; she was otherwise symptom-free and was at work in a factory. On examination the uterus was found to be the size of a 28-weeks pregnancy and the foetal heart could be heard; the spleen was palpable, extending for 4 in. (10 cm.) below the costal margin. The patient, still unmarried, did not know she was pregnant and could only give the date of her last menstrual period as some time in January. The blood count on July 11 was: haemoglobin, 60%; red cells, 3,620,000; white cells, 33,200. No myeloblasts were seen.

On September 19, with a normal delivery, she gave birth to a living female infant weighing 6 lb. 12 oz. (3.1 kg.). The placenta was expelled with a total blood loss of only 8 oz. (230 ml.). The placenta contained numerous infarcts. The infant, which appeared to be a full-term child, had a spina bifida and myelocele extending for 3 in. (7.5 cm.) over the lumbar region associated with a spastic paraplegia. The infant's blood count was: haemoglobin, 128%; red cells, 6,350,000; white cells, 10,400 (polymorphs 60%, lymphocytes 30%, monocytes 10%). The baby died on September 26.

Post-mortem Report (Dr. A. J. McCall).—The body was that of a female infant apparently full-term with a swelling over the sacrum about 2 by 3 in. (5 by 7.5 cm.) in diameter. The skull was normal except for an unusually large gap between the two frontal bones. There was intense engorgement of the leptomeninges, and the cerebrospinal fluid in the ventricles was obviously purulent. Examination of the pus revealed numerous *Bacterium coli*. The lungs were congested and oedematous. There was a defect in the lower lumbar and sacral vertebrae due to spina bifida. The skin over the swelling had not ulcerated but the cavity contained pus. Histological sections from the lung, kidney, suprarenals, liver, spleen, and one rib showed no evidence of leukaemia. Death was due to *Bact. coli* meningitis from infection of a spina bifida.

The puerperium was uneventful and involution satisfactory. The mother's blood count on September 21 was: haemoglobin, 54%; red cells, 3,840,000; white cells, 74,000. On September 27 it was: haemoglobin, 62%; red cells, 3,410,000; white cells, 110,000. Moderate hypochromasia, anocytosis, and poikilocytosis were present. There were over 600 normoblasts for every million red cells, and rare myelobasts were found. She remained symptom-free and returned to work.

Reviews

MODERN DERMATOLOGY

Modern Practice in Dermatology, 1950. Edited by G. B. Mitchell-Heggs, O.B.E., M.D., F.R.C.P. (Pp. 836, with 319 figures and 7 colour plates. £3 3s.) London: Butterworth and Co. (Publishers), Ltd.

This imposing volume has been planned to meet the needs of general practitioners, medical officers in the Services, and medical advisers to commercial organizations. Not only does it fulfil satisfactorily the purpose for which it was designed, but it can be recommended to senior students who want to possess a conspectus of dermatology. There are fifty chapters, most of them written by different authors. Three are on maladies which are of paramount importance in tropical countries, so the work will have a wider appeal than most books which emanate from the temperate zone. The editor has introduced certain innovations which are likely to influence the planning of other textbooks, for he has included chapters on disorders of the skin with ocular involvement, cutaneous manifestations of general diseases, pharmacy, social aspects of dermatology, and psychosomatic disorders—matters which hitherto have not been given much space in the average standard work on skin diseases.

In reviewing a book to which so many have contributed it would be invidious to select certain chapters for commendation and others for dispraise, but—as is inevitable—some are considerably better than others; nevertheless, only a few fall below a high level of merit. Most of the distinguished contributors have loyally obeyed the editor's injunction to keep "small-print information" to a minimum, and most have succeeded in the difficult task of keeping their contributions at the correct standard for most of their readers.

The publishers are to be congratulated on the lay-out, the generous use of expensive paper, and on the excellence of reproduction of the many illustrations. This is a notable contribution to British dermatological literature

R. M. B. MACKENNA.

CROHN'S DISEASE

Regional Ileitis. By Burrill B. Crohn, M.D. (Pp. 229; illustrated. £1 10s.) London: Staples Press. 1949.

A few months ago a reviewer in these columns admitted a penchant for monographs. He can be recommended to include this book in his collection. It is seldom that such an authoritative work appears, and rarer still for an author to display the modesty which prevents Dr. Crohn from mentioning that the complaint in question is universally known as Crohn's disease.

The author reports an analysis of 298 private cases which he had treated himself and whose course he has followed during the past 18 years. Of these, 222 were examples of chronic regional ileitis, 16 of acute ileitis, 38 of ileojejunitis, and 22 of ileitis combined with disease of some part of the large bowel. Because it is more common, the first group has the greatest interest. The aetiology, pathology, and clinical picture are considered in great detail and reviewed in the light of the many relevant publications. He insists on the necessity for surgical treatment, strongly favouring ileo-colostomy with exclusion. In the hands of his colleagues at the Mount Sinai Hospital, New York, this procedure has carried no operative mortality, and has had a lower rate of recurrence than any other operation.

Acute regional ileitis, he believes, is related to the chronic form, but as there is a strong tendency to spontaneous resolution he regards operation as inadvisable. The book ends with chapters on ileo-jejunitis and ileo-colitis in which the difficulties of treatment are fully discussed.

The volume is patently the fruit of many years' patient and careful study of this group of diseases; it is balanced and exhaustive, as well as authoritative; and it will be an essential addition to the library of the physician interested in gastro-enterology.

R. BODLEY SCOTT.

RADIOGRAPHIC TECHNIQUE

Atlas of Roentgenographic Positions. By V. Merrill. Volumes 1 and 2. (Pp. 664; fully illustrated. £7 10s.) London: Henry Kimpton.

Miss Vinita Merrill has written an elaborate work—in two large volumes—on radiographic technique, designed as a practical reference book for radiographers. It will be found of great value in the *x*-ray room, since the technique of *x*-raying patients is described in minute detail. Indeed, the main criticism in this respect is that too many methods for each examination are given—an *embarras de richesses* that may confuse the less-experienced radiographer. In a future edition—and one will surely be called for—a division of these methods into two classes, standard and special, would increase the value of the work.

The price will probably place this publication beyond the reach of most radiographers, but it is to be commended to hospitals for use in their *x*-ray departments.

S. COCHRANE SHANKS.

SCHISTOSOMIASIS

Schistosomiasis in South Central Africa. A Clinico-Pathological Study. By Michael Gelfand, M.D., M.R.C.P. (Pp. 240; illustrated. £1 5s.) Capetown and Johannesburg: Juta and Co. London: H. K. Lewis and Co. 1950.

This book is a thesis which has justly been accepted for a higher medical degree. Careful editing before publication would have reduced its length and might have increased its value. It is based on an extensive pathological and clinical experience in Salisbury, Southern Rhodesia. After an introductory chapter, which includes brief historical and biological summaries, the author considers the incidence of schistosomiasis and calls attention to the much more frequent finding of ova after the digestion of organs obtained at necropsy than from examination of excreta during life.

He then discusses urinary schistosomiasis and finds that in Africans urinary symptoms are often absent. Sandy patches were the most frequent lesion. He emphasizes the value in diagnosis of small fragments of mucosa snipped from the bladder or rectum when other examinations are negative. Unless albumin and red cells are present in the urine, it is unlikely that ova will be found in that specimen. Vesical calculus was rare. Calcification of the bladder was found in 17% of adult Africans with *S. haematobium* in the urine. Lesions of the ureters were present in about a third of the cases with bladder lesions. From a general consideration of the incidence of bladder cancer in Europeans and in Africans in areas infected with and free from schistosomiasis he suggests that there is need for further evidence on the causal relationship of the infestation to the malignancy.

Intestinal schistosomiasis is next considered. In many cases no lesions are visible through the sigmoidoscope. The examination of rectal snips for ova is of value in diagnosis. From his findings schistosomiasis of rectum or colon does not appear to predispose to malignant disease, appendicitis, portal cirrhosis, or primary cancer of the liver. Chapters, each a short article in itself, are devoted to schistosomiasis of lungs, liver, pancreas, gall-bladder, brain, spinal cord, and female genitalia, and also to diagnostic aids. He regards the cercarial antigen skin test as a diagnostic aid which cannot replace the finding of ova. In well-developed infections the eosinophils in the blood were less than 4% in over half the cases.

This book will be of value for the clinical and pathological material to all interested in schistosomiasis and to all medical practitioners over a wide area of Africa.

C. J. HACKETT.

STRUCTURE OF BACTERIA

The Cytology and Life-History of Bacteria. By K. A. Bisset, Ph.D. (Pp. 136; illustrated. 18s. 6d.) Edinburgh: E. and S. Livingstone. 1950.

The average medical bacteriologist knows little about the minute structure of bacteria beyond the fact that some possess capsules, spores, or flagella. The granules in diphtheria bacilli are of interest to him only as an aid to identification. It is to this end only that his staining methods are adapted, but other methods have now been introduced by bacterial cytologists which reveal the existence of a cell wall, cell membrane, division into septa, and nuclei. It has been shown that reproduction may be sexual, at least in the sense that cells within a rod-shaped organism undergo fusion in the course of it. The appearances of colonies can be explained in terms of the structure of the cells composing them. Of these and other related matters this book is a simple, straightforward, and authoritative account, well illustrated by line drawings and photographs. The author suggests that on a morphological basis the classification of bacteria requires radical alteration and simplification.

L. P. GARROD.

A PAEDIATRIC SYNOPSIS

The Compleat Pediatrician. Practical, Diagnostic, Therapeutic, and Preventive Pediatrics. By Wilburt C. Davison, M.A., D.Sc., LL.D., M.D. Sixth edition. (Pp. 256. £1 18s.) Durham, N.C.: Duke University Press. London: Cambridge University Press. 1949.

For those who do not know *The Compleat Pediatrician* by Professor W. C. Davison, now appearing in a sixth edition, it is necessary to explain that this is a remarkable reference book resembling, as the author remarks, a telephone book or a mail-order catalogue. It began as a notebook of easily forgotten facts and methods during a vintage period at the Johns Hopkins Hospital and it now is based upon nearly 20,000 authoritative articles. Essentially this is a skilfully cross-referenced synopsis. A typical entry describes the disease, lists the causes, and then summarizes laboratory investigations, treatment, prognosis, and prevention. It is necessarily dogmatic, although its very completeness tends to eliminate any personal prejudices. Many who have at first recoiled from such a volume have come to use it frequently. Casting for a fish is always rewarded (provided the index and the other devices are intelligently used), but any resemblance to Izaak Walton's classic is limited to one-third of the title.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY JULY 22 1950

THE PRESIDENTIAL ADDRESS

The local habitation of the British Medical Association is London, but the meeting of its general assembly, the Representative Meeting, is held each year not in London but in different places in Britain. This is a constant reminder of the fact that it was in the provinces that the B.M.A. had its birth. There is virtue in this, and still more in the custom that the place of the meeting should, out of its medical population, provide a President for the coming year. Last year the Liverpool Division put forward the name of Professor T. P. McMurray as President-Elect—a fitting choice because of the great contributions of the Liverpool School of Medicine to orthopaedic surgery. After the widely regretted death of Professor McMurray, the Liverpool Division was happily able to call upon one of our most distinguished physicians to fill the gap thus unhappily made. Accepting this new obligation towards an Association for which he has already done so much, Sir Henry Cohen has quickly shown himself to be a worthy successor to many notable forerunners, and not least in the admirably phrased and thoughtful address which he delivered at the Adjourned Annual General Meeting on Tuesday of this week. It is printed in the opening pages of this issue.

Sir Henry Cohen, in taking stock of the first 50 years of this century, sees Medicine subjected to two major influences: first, the expansion of knowledge and technical skills in the basic sciences; secondly, the evolution of ideas of social responsibility. There is a certain paradox in Sir Henry's view that the latter was coincident with the "all-but" engulfing of the humanism of medicine by discoveries in science. The increasing application of techniques in Medicine accelerated the growth of specialism, with its appeal to those unfortunate enough to possess what Sir Henry calls the "penny-in-the-slot type of mind." This has to some extent led to a neglect by doctors of the patient as a whole person. Too often the patient has been looked upon as a parcel of the results of special investigation, and in this strange and unnatural metamorphosis has been so presented to the student. But for the doctor as for the poet the proper study of mankind is man, and the medical mind, distracted from its holistic approach to the individual, has, by way of compensation, sought a wider synthesis in a study of the impact of the environment on the individual and of the effect of individuals upon each other. This has found its expression in the somewhat ill-defined concept of "social medicine," more succinctly described by Cambridge as human oecology. It is possible to see in Sir Henry's approach to his theme a protest against the replacement of the consultant by the specialist. The posterior triangle of the neck and the mediastinum seem, indeed, to be the only parts of the body which have not as yet a corps of specialists devoted to them. But just as the hand lens has had to make way for the electron microscope, so too has the general physician to yield in part to the specialist. It would be foolish to ignore the benefits and discoveries of specialism. The danger lies in the slavish use of the instrument and the neglect of method. The more the doctor allows "special investigations" to come between him and the clinical examination of the patient the more will he cease to be a practical exponent of his craft. What is needed in Medicine to-day is a return of the general consultant, to adjust the balance against the atomization of medical practice into an ever-increasing series of small specialties.

One effect of specialization is that it has become difficult for anyone to be appointed to the staff of a teaching hospital unless he has devoted himself to the study of one of the "-ologies." It is not surprising, therefore, to hear the complaint of examiners that students at their final examination will display the latest knowledge of electrocardiography but be unable to make a clinical diagnosis of mitral stenosis. It is in the teaching hospitals that the influence of the general consultant is most needed and now least manifest. Sir Henry Cohen has been chairman of two B.M.A. committees whose published reports on medical education have come as an inspiration to those who have read them. As he says in his presidential address: "Medical research, practice, and education are closely interrelated." And he summarizes the aims of student education in this memorable sentence: "The student is to be trained in reading the map of medicine, but the scale should be three miles and not three yards to the inch." It is significant that after surveying some of the outstanding results of 50 eventful years of medical progress Sir Henry should concentrate his attention on medical education. It has not kept pace with medical research and practice. Medical research has caused a revolution in medical practice, but there has been no corresponding revolution in medical education. Here, if anywhere, is the need for experiment, for innovation—and for the teacher who can inspire his students with something other than the mere aim of passing the next examination. Sir Henry applies to the teaching of medicine the observations made in 1907 by Asquith on the teaching of history: "The mind of the student . . . is indeed in danger . . . of becoming a kind of pantechnicon, in which every sort of furniture is heaped and packed together, instead of being a habitable home where things useful and beautiful are arranged in their proper places, and in due relation to their special purposes." Medical students should be taught to observe and to think; too often they are encouraged to do neither.

Sir Henry Cohen has avowedly eschewed medical politics in his presidential address. But in referring to the influence on Medicine of the growing awareness of social responsibility he puts this question: "Is it then surprising that, since the practice of medicine reflects the social philosophy of its time, there should have grown with the years an increasing demand for social security which culminated in that National Health Service Act which will influence, for good or evil, all our lives, be we doctors or patients?" It is indeed necessary to see the National Health Service in the perspective of the social evolution of the past hundred and more years. Sir Henry sounds the one warning note that is needed when he says that in the Service "there is a real, and . . . increasing, danger of rigidity and inflexibility. . . ." But, as his presidential address shows, we have men in our profession whose power of intellect and force of character are the safeguards against this. Under his presidency the B.M.A. may, during the coming year, face the problems it has to tackle with confidence that it will be helped by someone who will bring to bear on them a mind that is constructive and fully possessed of the highest ideals of an ancient profession.

STUDIES ON STREPTOMYCIN THERAPY

The body is not a test-tube, and, though the laboratory's aid is essential in assessing the action of antibiotics, the results of laboratory tests in relatively simplified conditions should not be applied too rigidly to disease. Jensen,[1] for instance, has pointed out how the tissues may influence the action of streptomycin in tuberculosis. For some years he and his colleagues have been studying tuberculosis in guinea-pigs infected by inhalation of bacilli, and they have now applied this technique to the study of the action of streptomycin. A number of guinea-pigs were infected in this way and a group of them was treated with streptomycin. Two treated and two control animals were killed at intervals and counts were made of the numbers of tubercle bacilli in the tissues (such quantitative studies have proved difficult in the past,[2] and it is unfortunate that no details of technique are given in this paper). It was found that up to the thirteenth day after infection the bacilli seemed to be multiplying at the same rate in the treated and in the control groups. This corresponded to the pre-allergic phase. After the thirteenth day, when the animals had become allergic, the counts continued to rise in the control group, but in the treated group the number remained steady for a few days and then fell. In some animals treatment was stopped after six weeks. For 28–38 days after this there was little change in the counts; then the bacilli began to multiply rapidly.

In the pre-allergic phase mononuclear cells crowded with tubercle bacilli were found on histological examination in both treated and control groups. At the beginning of the allergic phase nodules appeared in the lungs of the control animals, with extensive inflammatory changes around numerous tubercle bacilli scattered throughout the nodules. Similar changes were noted in the treated animals, except that the tubercle bacilli were confined to a few large mononuclear cells in the centre of the nodules. A little later abscesses appeared in the centre of the nodules in the controls, and innumerable tubercle bacilli were seen. In the treated animals a few leucocytes were seen but no abscess formation, and there was great destruction of tubercle bacilli. Jensen points out that at the time when the animals became allergic there were as many tubercle bacilli in the treated as in the control animals, but that the histological changes differed: those in the treated guinea-pigs resembled the reactions to infection of animals previously immunized with B.C.G. With continued treatment the tendency was at first towards productive lesions and later towards regression, though even after 180 days occasional tubercle bacilli could still be detected. If treatment was stopped after six weeks little change was noted at first, but after three weeks or so there was a slight increase in the numbers of tubercle bacilli and a tendency to abscess formation. After this the pathological changes progressed more rapidly than the bacilli increased. Jensen emphasizes the divergence between the numbers of bacilli and the histological appearances, and he suggests that streptomycin may specifically inhibit the formation by tubercle bacilli of a toxin which causes necrosis. Alternatively, streptomycin may have a specific anti-allergic effect: guinea-pigs under treatment became less sensitive to tuberculin, although a significant number of bacilli were still demonstrable.

A third possibility might be suggested. Eagle[3] has shown that bacteria exposed to penicillin lose their virulence temporarily and become more susceptible to the defences of the host. It is reasonable to suppose that these temporarily attenuated organisms may act as powerful immunizing agents. Such an immunizing effect is suggested by some of the experiments of Schmidt and

his colleagues[4] with differing penicillin dosage schemes. Other observations of Jensen support this view. He found that, after allergy had developed, the histological appearances in the treated animals resembled those in animals immunized with B.C.G. and later infected with virulent tubercle bacilli. When immunized guinea-pigs so infected were treated with streptomycin there was much less initial multiplication of the bacilli than in unimmunized animals. But it may be that in unimmunized animals in the pre-allergic phase streptomycin fails to prevent the multiplication of tubercle bacilli not because the drug requires the supporting action of immune processes but because it does not reach the bacilli. Bacillary multiplication in this phase is intracellular, and there is some evidence from studies in tissue culture that streptomycin does not penetrate the cells, or at any rate does not affect tubercle bacilli within them.[5] Thus in the earlier stages of streptomycin treatment the differences between the bacillary counts in the animals immunized with B.C.G. and in those unimmunized would be due solely to the immune processes in the former; the inhibitory action of streptomycin would become apparent only when the bacilli had burst out of the cells. These experiments are an indication of the complexity of chemotherapy in tuberculosis.

SYRINGE STERILITY

During the past 20 years there has been an enormous increase in the number of doses of drugs and other materials given by injection. From time to time what should be an aseptic injection conveys infection, which is usually pyogenic, but others so conveyed have been gas gangrene, epidemic hepatitis, and even tuberculosis. Most of the graver accidents on record have been due to gross failures in technique, but others have been attributable to methods of sterilization in common use; inherent in these there is a slight risk, of which such accidents are examples. Such a method is the use of spirit, which will not in fact sterilize a contaminated syringe and may indeed itself contain living sporogenous bacteria. These facts led the Medical Research Council during the war to appoint a committee to consider methods of syringe sterilization, and their report[1] is now recognized as the authoritative guide in this matter, though it has not been accepted altogether without criticism. This has been of two kinds: most critics complain that the methods advocated, although ideal, are impracticable in some circumstances, but a commission of the Swiss Society of Surgery, whose conclusions were reported by Baumann,[2] regard the precautions suggested as not stringent enough. These two opposite views may not perhaps cancel each other, but they suggest that the report is at least a reasonable compromise.

Several pages of the M.R.C. report deal with mass inoculation technique—i.e., the procedure to be followed when large numbers of persons are given injections of the same material, such as a toxoid or vaccine. There is clearly some risk in using the same needle and syringe for a series of injections, but it has usually been considered perfectly safe to use the same syringe if a fresh needle is fitted to it for each injection, and this is the method described in the report. Some doubt was first cast on the safety of this method by the observations of Hughes[3] in this *Journal*, who found red blood cells in the fluid in the nozzles of syringes when the needle was removed after an intramuscular injection. By counting these cells after injections made in different conditions, Hughes concluded that the pressure produced, especially by a rapid injection into contracted muscle, may force a little fluid back into the nozzle of the syringe. No suggestion is offered in his paper that any other mechanism may be concerned. That a syringe may be so contaminated is confirmed by the observations, published in this issue, of Dr. R. J. Evans and Professor E. T. C. Spooner; in an ingenious series of experiments they have proved that the reflux of fluid has another, perhaps more obvious, and certainly more inevitable, cause. Having first imitated the conditions of Hughes's experiments by injecting against pressure, they eliminated this factor and the possible one of plunger movement and found that bacteria in the tip of the needle were still made to enter the syringe nozzle by the mere act of removing the needle. It is thus fairly evident that the negative pressure induced as the needle is detached causes fluid to traverse the entire length of the lumen, which has a very small cubic capacity relative to the space behind it. There seems to be no way of avoiding this if the usual practice is followed, and therefore there is a risk of conveying micro-organisms in small numbers from the tissues of one person to those of another.

It must be very uncommon for an immunizing injection to be made into an area of cellulitis, although this is a possibility. It is also exceedingly unlikely that transmission of this kind has anything to do with post-injection poliomyelitis, since this virus is not found in the blood and tissues generally, but confined to the nervous system. On the other hand, the virus of infective hepatitis could well be so transmitted, and there are other possible risks which are discussed in Evans and Spooner's paper. It is no easy matter to decide whether mass injection methods ought to be changed in view of these findings. The dangers are in ordinary circumstances remote, and it is tempting to take the view that there must be lengths beyond which doctors cannot be expected to go in safeguards of this kind because the expense and trouble are out of all proportion to the results achieved. This is perhaps a dangerous doctrine, but if the existing rigid safeguards in all kinds of clinical proceedings are contrasted with the far greater and ever-present dangers from infection in everyday life, of which the average person is oblivious, it does seem that caution can be carried to almost fantastic lengths. If the lesson of these experiments is to be applied in inoculation clinics two methods can be considered: one is the use of platinum needles, which can be flamed between one injection and the next; the only other is the use of a separate syringe and needle for every injection made.

BACT. COLI AND DIARRHOEA

There have been many reports, both in this country and abroad, of the isolation of certain serological types of *Bact. coli* from babies suffering from infantile and neonatal diarrhoea. As Drs. A. M. M. Payne and G. T. Cook mention in their paper published elsewhere in this issue, there is some confusion in the nomenclature of these types; the serological type *Bact. coli* D 433 has been called *Bact. coli neapolitanum*,[1,2] *Bact. coli* var. *neapolitanum*,[3,4] *Bact. coli* serological type,[5] *Bact. coli* α-type,[6,7] *Bact. coli* B.G.T.,[8] *Bact. coli* D 433,[9,10] *Bact. coli* Bray,[11] and *Esch. coli* O group 111 (one hundred and eleven).[12] In addition a different serological type of *Bact. coli*, also associated with infantile diarrhoea, has been described by Giles and his colleagues,[6] Smith,[7] and Holzel, Martyn, and Apter[4] and referred to as *Bact. coli* β or *Bact. coli* beta, and also by Kauffmann and his colleagues[12] as *Esch. coli* O group 55. None of the names is entirely satisfactory. *Bact. neapolitanum* was used by Winslow and his co-workers[13] as the name for a variety of *Bact. coli* identifiable by biochemical tests; this is composed of many different serological types and should not therefore be limited to one serological type. The term α was used by Stamp and Stone[14] as a name for a labile antigen sometimes present in certain strains of *Bact. coli* as well as in other enterobacteria. This antigen has no relationship to the *Bact. coli* α of Giles. The term β has been used by Mushin[15] to indicate a labile antigen found in some strains of *Bact. coli* and other enterobacteria: this is serologically distinct from *Bact. coli* β of Giles. Thus the symbols α and β have each been used for two unrelated antigens in *Bact. coli*. In the classification of the *Bact. coli* group by Kauffmann,[16] based on the identification of the somatic (O), the surface (K), and the flagellar (H) antigens, *Bact. coli* D 433 has the O symbol 111 and *Bact. coli* β the O symbol 55. Even though Kauffmann's method of classification may be modified in the light of increased knowledge, his notation could be adopted with advantage for the sake of international understanding and clarity.

The papers referred to emphasize the close association, which is statistically significant, between infantile diarrhoea and *Bact. coli* O groups 111 and 55. This association, first recognized in this country, has now been noted in Sweden, Denmark, Holland, and the U.S.A., but the exact role which these types play in the causation of the disease is not clear. Payne reports the isolation of *Bact. coli* O group 111 on many occasions from healthy babies of a susceptible age; possibly a precipitating factor, or some property of *Bact. coli* that has not yet been determined, may be responsible for the onset of clinical disease. In another paper appearing in this issue Dr. J. S. Stevenson reports the isolation of *Bact. coli* O group 111 from adults suffering from diarrhoea in the course of other debilitating diseases; only one had no known contact with other patients. Most outbreaks of infantile diarrhoea affect only babies, but it may be that *Bact. coli* O group 111 is able to cause diarrhoea in the debilitated adult, or, as Stevenson suggests, diarrhoea of unknown origin may cause an organism normally present in the small bowel to be detected in the faeces. The belief that *Bact. coli* O group 111 and O group 55 cause infantile diarrhoea at present rests only on epidemiological evidence; there is little support for the theory from other methods. Some investigators are not convinced that antibodies, as shown by the agglutination reaction, are present in the serum of recovered cases, and the technique used for the isolation of these organisms may not be sensitive enough to show them in small numbers. Several authors in the U.S.A. have referred to a possible virus cause of this disease,[17-20] but it is well to remember that it may be caused by more than one agent and that these may differ in this country and in the U.S.A. The work that has been done on infantile and neonatal gastro-enteritis is most valuable, but there is no real proof that the cause has been found.

HORMONAL TREATMENT OF PEPTIC ULCER

Both gastric and duodenal ulcer are now commoner in males of all ages than in females. Peptic ulcer as a complication of pregnancy is very rare, and even when a woman with an established ulcer becomes pregnant spontaneous regression generally occurs.[1] The presence of fat in the upper intestinal tract leads to liberation of a chalone, enterogastrone, which inhibits gastric secretion and motility. Enterogastrone can be extracted from intestinal mucosa, while urogastrone, which has a similar action, can be obtained from normal human urine.[2] These observations have led to suggestions that gastroduodenal ulceration might be treated successfully with hormones. Salzstein and his colleagues[3] recently reported the results of an investigation in which 374 dogs were subjected to the Mann–Williamson operation, in which the duodenum is isolated and anastomosed to the ileum and the pylorus anastomosed to the jejunum, which is thus exposed to acid secretion.[4] After this operation ulcers almost invariably form just beyond the pylorus, and in fact all untreated control animals in this series died of ulcer within 135 days of operation, few of these ulcers showing any microscopic evidence of healing. Of the preparations used in the treatment of the dogs with ulcers so induced commercial extract of human pregnancy urine gave the most benefit. Significant increase in survival time, in the proportion of dogs dying without ulcer, and in the incidence of ulcers

with microscopic evidence of healing were observed after its administration. Less marked benefit was obtained from extracts of normal male and female urine given parenterally, while extracts from the urine of patients with peptic ulcers had little, if any, effect. Some improvement was obtained with the follicle-stimulating hormone, but none with posterior pituitary extract, oestrone, or progesterone. No improvement was observed after vagotomy, and enterogastrone was also without effect. It is worth noting that Bernstein and Friedman,[5] who emphasize the rarity of ulcers during pregnancy, have observed the complication of bleeding peptic ulcer during pregnancy in four patients. All four had been treated with progesterone to combat threatened abortion, and they therefore suggest caution in the use of this hormone in women with suspected peptic ulceration.

Pollard and his colleagues[6] gave enterogastrone to 17 patients with peptic ulcers, but were unable to demonstrate clinical improvement or alteration in fasting secretion, volume of HCl, pepsin concentration, or response to the caffeine test meal. Using an extract of pregnant mare's urine Page and Heffner[7] treated, over a period of 20 months, 26 patients with chronic duodenal or jejunal ulcer who had previously failed to respond to a prolonged period of "conventional ulcer therapy" or Sippy regime. All other treatment was discontinued and a normal schedule of meals established, though intermediate feeds were still permitted. These authors claim that all except three patients improved considerably, but their period of observation was too short to permit of definite conclusions, and the absence of control cases further reduces the value of the experiment. Some of these observations throw light on the physiology of the alimentary tract and its disorders, but as yet there is little prospect of their leading to new and generally applicable methods of treating peptic ulcer. The results obtained in experiments on dogs submitted to the Mann–Williamson operation are perhaps significant, though the lesion so caused differs from spontaneous human peptic ulcer in its fatality rate, in the absence of healing and remission, in the accompanying great nutritional disturbance, and, presumably, in its freedom from psychogenic aggravation. The psychosomatic changes of pregnancy are not confined to the endocrine system, and it may be too much to hope that hormone therapy can give the male duodenum that immunity from ulcer apparently developed in the female during normal pregnancy.

IMPORTED HELMINTHIC INFECTIONS

About 90% of the known species of human helminths are excluded from Britain by such factors as climate, hygiene, and sanitation, and by the absence of the appropriate intermediate hosts which are essential for the life cycle and transmission of many of these parasites. These factors do not of course exclude the importation of adult parasites into Britain by persons who have acquired them in foreign countries (these may be retained by their hosts for many years); rather they act as a check on the survival of the parasites' offspring, which, on departing from the parental host, find themselves in an unfriendly environment, lacking either an intermediate host to nurse them through their early growth or a benign climate to permit their development to an infectious stage in the soil. Thus during and after the war many exotic helminths, such as bilharzia, hookworm, and filarial worms, were unwittingly smuggled into Britain by returning troops, displaced persons, or prisoners-of-war. The carriers of such foreign parasites are fortunately a menace only to themselves, not to the local community, for the eggs or larvae they disseminate are not immediately infective to man and are doomed to perish before they can attain infectivity and another human host. An interesting exception was formerly provided by the hookworm, which succeeded in overcoming Britain's climatic barrier and established itself in Cornwall—but only by going underground in the tin mines, where the conditions of temperature and moisture proved admirably suited for development and transmission of larvae.

It is questionable whether the normal incidence of human infestation in Britain by such well-known species as *Ascaris lumbricoides, Trichuris trichiura, Enterobius vermicularis,* and *Taenia saginata* would be affected by an influx of infected persons from abroad. Factual evidence about the first three species is not easily obtainable, but the possibility of increased transmission must at least be admitted. Many believe, however, that in post-war years infestation of beef with the larval stages, *Cysticercus bovis,* of the beef tapeworm (*T. saginata*) has been increasing in many parts of Britain and that this could be accounted for by an increase in the number of tapeworms imported from abroad by prisoners-of-war and others, who have contaminated pasture land and infected the cattle. There is little evidence of increase in the cattle-to-man part of the life cycle of this tapeworm. The inquiries of Seiler and Norval[1] in Edinburgh, where an upward trend in the incidence of *Cysticercus bovis* was observed in the abattoir during the period 1948 to 1949, suggest that there was no corresponding increase in tapeworm infection in the human population. On the other hand, Jepsen and Roth[2] record that in Denmark during the period 1941 to 1947 there was a rapid rise in the number of patients admitted to hospital with *T. saginata* infestation together with a rising incidence of *C. bovis* in the slaughterhouses. A similar survey carried out in British hospitals might prove equally informative.

In a third category of imported helminthic infections are those which are potentially indigenous in Britain but are apparently non-indigenous at the present time. These are few in number, and the outstanding representative is the fish tapeworm, *Diphyllobothrium latum,* which is a parasite of temperate regions and is indigenous in parts of Ireland, where it was first recorded over 100 years ago. Besides being widely distributed elsewhere in Europe it is now firmly established in parts of the northern United States and Canada. The possibility of its establishment in this island is by no means remote, because of the large numbers of displaced persons and foreign workers who have arrived in recent years; some of these have undoubtedly brought with them this unwelcome "fellow traveller." Elsewhere in this issue Drs. J. C. Harland, J. G. Humble, and P. G. Mann describe the clinical and epidemiological aspects of this infection, and they rightly emphasize the need for further investigation by the public health authorities.

REFRESHER COURSE FOR GENERAL PRACTITIONERS

THE PROBLEM OF PSORIASIS

BY

R. M. B. MacKENNA, M.A., M.D., F.R.C.P.

Physician (in charge), Dermatological Department, St. Bartholomew's Hospital

The principal difficulty in regard to psoriasis is that we still do not know the cause of the malady; therefore theories concerning the aetiology abound and become more numerous and more complex as the years pass, while treatment remains empirical. Nevertheless, despite this empiricism, treatment is not so hopeless a proposition as *some would have us believe,* although we still have to tell our patients that no one can guarantee that they will not suffer from future attacks of the eruption.

Aetiological Factors

The incidence is said to be higher in cold than in warm climates, but psoriasis has been noted in almost all races; it is rare, however, in pure negroes. It is suggested that the reason for this geographical selectiveness is that a psoriatic skin requires a certain amount of exposure to sunlight for its full health, and that in countries where the inhabitants have to keep themselves muffled up for many months of the year the apparent incidence of the malady is higher than elsewhere. This, however, is not the whole story: during the recent war we learned that in some cases the climatic benefits might be nullified by environmental factors, and that heavy physical work in conditions of dry heat and much dust, with often little opportunity for ablutions, could provoke severe exacerbations. The lesson to be drawn from this appears to be that if a patient asks, "Would I be less troubled with psoriasis in a warmer country?" the answer should be, "Probably, provided you abstain from hard physical work." It may be noted here that when psoriasis relapses severely in hot countries the lesions tend to be very troublesome in the flexures and thus lead to incapacity for work.

It is usually agreed that psoriasis is slightly more common in men than in women, the ratio in Europe being 3:2. The malady tends to occur in certain families, but the genetic factors are little understood; for practical purposes, when asked about the matter of inheritance, Jonathan Hutchinson's dictum is worth quotation: "Psoriasis does not very often affect several brothers and sisters, but it frequently seems to be transmitted from parent or grandparent. Thus it may persist through many generations, but still affect very few individuals." There is considerable variation between the figures given by leading authorities concerning the familial incidence of psoriasis in those who demand treatment, but probably less than 50% can state that the malady has occurred in other members of their family.

The age of onset varies considerably. Psoriasis begins most often at puberty or in adolescence, but has been noted in infants and is not uncommon in children. It is unusual for a first attack to develop after the patient has reached the age of 45.

Whilst the patient with psoriasis is usually robust and often heavy-set, in some cases the malady is associated with progressive arthritis deformans of the rheumatoid arthritis type. This arthritis may be very severe. For this reason dermatologists are at the moment alert concerning "compound E," for they feel that there may well be some factor of adrenal metabolism that is associated with the disease.

There is some dispute concerning the factors which, in susceptible persons, precipitate the attacks of psoriasis. Many regard the malady as a "type reaction" which occurs in certain predisposed skins. They consider that the reaction may be provoked by certain stimuli, of which two have received some attention—namely, absorption of toxins, particularly from streptococcal foci of infection, and mental worry and overstrain. It is worth noting here that psoriasis may be persistent in neurotic persons.

Köbner's phenomenon has attracted some attention in recent years, although the matter was first discussed in 1878. Köbner was apparently the first to note that, during the active phase, minor types of physical injury sustained by unaffected skin are followed by the appearance of the eruption on the injured part. It is now known that the provoking agent can be mechanical, physical, or chemical, that the injury must involve the papillary layer of the skin, and that the phenomenon cannot be produced in the cleared centre of a patch of psoriasis. This matter is of practical importance, for, in the active phase, pressure of clothing or the injudicious use of a bath-brush may cause an efflorescence of the lesions. Patients should be warned of this matter, and women should be told of the advisability of discarding tight belts or corsets whenever this is practicable.

Köbner's phenomenon has been invoked to explain the distribution of the eruption on various "sites of election," such as the anterior aspects of the knees, the posterior aspects of the elbows, and over the sacrum. This may well be disputed; so far as the knees are concerned, the suggestion may be valid, but *inter alia* it should be remembered that the scalp is also one of the elective sites, and one has yet to meet the psoriasis patient who emulates one of the athletic feats of Father William.

The Eruption

At the outset one should strip the patient properly, and decide whether the eruption is mild, severe, or grossly exfoliative, and whether it is in the acute, involuting, or chronic stage.

In most cases the lesions consist of circumscribed red areas covered with dry silvery scales; not infrequently each is surrounded by a narrow zone of unaffected integument which is paler than the normal hue of the individual's skin. The lesions vary from a few millimetres in diameter to great plaques involving large areas; sometimes, as they spread, their central portions become clear so that rings are formed. The distribution tends to be symmetrical, and the extensor surfaces are more affected than the flexor. Usually—but not invariably—the exposed areas of the hands and face are not involved.

Certain difficulties in diagnosis may be noted: occasionally the eruption consists of hundreds of small puncta, or of small lesions that are scattered like drops on the skin; if the patient bathes frequently there may be but little scaling. In these cases one usually discovers an aggregation of lesions on the classical sites at the elbows and knees which clinches the diagnosis (Fig. 1).

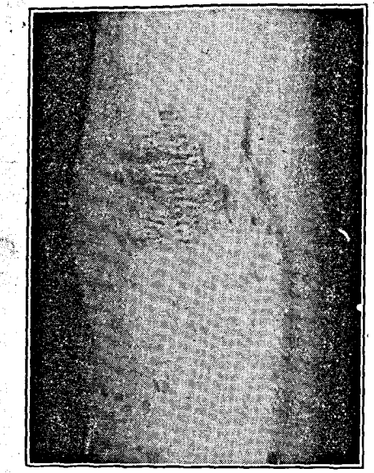

FIG. 1.—Typical psoriasis plaque on the extensor surface of the elbow.

Flexural psoriasis occurring as part of a typical attack gives rise to little difficulty in diagnosis, but occasionally an intractable erythematous eruption develops on a flexural surface, particularly in the crutch, with little or no involvement of the skin of other areas. Unless the area has been made sore by rubbing it has a characteristic dryness which is suspicious. In these cases the scalp should be carefully examined, for here there may be some discrete scaling areas which may confirm one's suspicion of psoriasis.

Psoriasis of the scalp can often be more easily felt than seen : if one rubs one's finger-tips over the head the lesions are firm and hard, so that one notes a sensation akin to that obtained from pressing the fingers across a relief model of a continent studded with low mountains. There are few occasions on which a similar sensation arises from touching the lesions of other maladies ; having noted the distribution one can then turn the hair aside and see the silvery scaling, which can be levelled down without any bleeding or oozing until the last scale of all is removed. The hairs grow freely through the piled-up masses, and the patient can be reassured if she is apprehensive about possible loss of hair, for baldness is not a complication of psoriasis.

In many cases pin-point pitting of the finger-nails—particularly of the third finger—can be noted, but sometimes some or all of the nails of the hands and feet are severely affected (Fig. 2). Usually there are lesions elsewhere on the body, but occasionally only the nails are involved ; diagnosis is then very difficult, but it is worth remembering that, as contrasted with many other forms of onychia, the change is usually first noted in the distal portion of the nails. The affected areas lose their translucency and polish and become white, and the distal part of the nail plate becomes separated from the nail bed by a whitish granular mass. The process slowly extends upwards. Eventually the nails may become discoloured, eroded, and fractured.

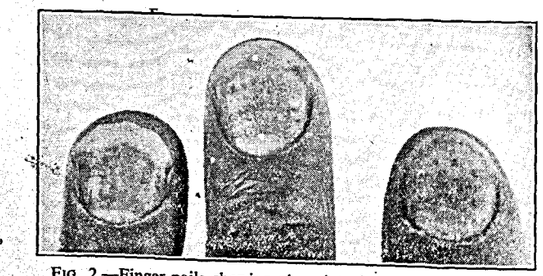

FIG. 2.—Finger-nails showing pin-point pitting; also, on the left, the development of another type of abnormality due to psoriasis at the distal third of the nail.

A Note on Symptomatology

That the lesions of psoriasis do not itch is a well-established and completely fallacious aphorism. Admittedly, in most cases the patient does not suffer from this symptom, but sometimes, particularly in the early stages of a widely efflorescing eruption, the itching may be severe. It seems probable that itching is most often a symptom in those cases in which the eruption develops as a reaction to nervous stress.

FIG. 3.—Arthropathic psoriasis.

Flexural psoriasis involving the vulva may cause pruritus. As already stated, this form of the malady may cause incapacity, particularly in hot climates, because the areas become sore, macerated, and sometimes infected.

Arthropathic psoriasis usually begins with involvement of the joints of the terminal phalanges ; the symptomatology is the same as that of rheumatoid arthritis complicated by the disfigurement—and sometimes the itching—caused by the eruption ; often the psoriasis is intractable (Figs. 3–5).

Treatment

Psoriasis is extremely variable in the severity and frequency of its attacks. Probably many people suffer occasionally from mild degrees of redness and scaliness on the knees and elbows, with some lesions in the scalp, but never experience a widespread attack and never seek medical advice ; others suffer from widespread eruptions occasionally : others, again, experience them frequently. In many cases the eruption may involve a twentieth of the body surface when at the height of its efflorescence : in others, nine-tenths of the surface may be covered and the patient be in jeopardy of developing a generalized exfoliative dermatitis. As already stated, treatment must be adjusted in accordance with the phase and severity of the eruption ; further, there is much more in treating psoriasis than merely ordering appropriate dermatological remedies. One should always attempt to discover the precipitating factor of the attack, in the hope that the patient may be enabled to avoid relapses in the future. Owing to our lack of knowledge, this may be disappointing, but always it is advisable to search for foci of sepsis (which may be treated when the eruption wanes, for it is inadvisable to deal with them during the acute phase). A careful discussion with the patient may reveal psychological factors which demand the assessment of a reliable psychologist.

Of the drugs which may be used for treatment, chrysarobin, dithranol, tar, resorcin, salicylic acid, and ammoniated mercury still hold pride of place. Arsenic is passing through a phase of unpopularity, but sedatives, particularly phenobarbitone, are now prescribed for many cases. Ultraviolet, roentgen, and Grenz rays, and thorium X have their uses. Recently undecylenic acid taken in large doses by the mouth has been advocated by Perlman (1949), but this observation has not been widely confirmed.

FIG. 4.—Arthropathic psoriasis. Note spread of lesions around sites of election on the lumbar area and at the elbows.

FIG. 5.—Arthropathic psoriasis. Note swelling of right hand. In the groins the eruption is affecting the flexures.

For the treatment of chronic lesions on limited areas of the trunk and limbs there is no more satisfactory remedy than the unpopular chrysarobin. Advise the patient to rub the areas gently with ung. chrysarobin, 5%, at night : after the inunction let him leave a thin smear of the ointment on each lesion, and cover it with gauze and a bandage. In the morning the dressing and ointment are removed, and the lesion left untreated through the day. Increase the concentration slowly to 10% or even 15% and persevere with treatment until affected parts are smooth and the surrounding skin slightly inflamed. Then soothe the areas with zinc or cold cream. Some are allergic to chrysarobin, so that treatment should be cautious at first. Warn the patient that the ointment permanently stains garments and sheets a dirty blue shade and that if any reaches his eye it will cause conjunctivitis. Some prefer dithranol to chrysarobin : usually this is employed (with the same precautions) in an ointment of 0.5%–3% concentration, and it is sometimes preferable to use Halden's emulsifying base instead of soft paraffin as a base. Dithranol has most of the disadvantages of chrysarobin, but stains less severely.

The great error that is usually made when dealing with more extensive cases is that, because the patient is not ill in the accepted sense of the word, he is seldom confined to bed. There are always scores of persons attempting to continue at work with widespread psoriasis—wastefully, ineffectively, and messily applying their remedies when opportunity serves—who could be relieved of much distress if their medical attendants would insist that they retired to bed. As a general rule, most persons with efflorescing psoriasis should be confined to bed, kept on a light diet, given small doses of phenobarbitone—e.g., ½ gr. (30 mg.) twice daily—and treated with mild remedies such as calamine liniment or zinc cream, each containing 3%–5% ichthammol. When the psoriasis reaches the chronic stage, or if when the patient first presents himself his eruption is in this stage, more active measures are pursued ; then, under home conditions, he may be kept in bed, given sedatives in mild doses, and twice daily have one of the following ointments well rubbed into his lesions :

℞
Ung. picis liq. ... ...
Ung. hydrarg. nit. dil. ... ... } āā 1 oz.
Ung. acid. salicyl. ... ...
Ung. glycerin. plumb. subacet. ...
M.

℞
Resorcin ... ... 10 gr.
Oil of birch tar ... ... 30 m.
Zinc oxide ... ... 1 dr.
Lanolin ... ... 2 dr.
Soft paraffin ... ... to 1 oz.
M.

℞
Ung. hydrarg. ammon. et pic. carbon. c. acid. salicyl. (*National Formulary*, 1949.)

He should be instructed to have a daily bath, and twice a week should receive autohaemotherapy (5–10 ml.). Lesions in the scalp should be treated by washing the hair twice a week with spiritus saponis kalini and using the following ointment twice daily :

℞
Ammoniated mercury 2%
Liq. picis carbonis 12%
Salicylic acid 2%
Halden's emulsifying base 30%
Water ... ... to 100%
M.

The majority of severe cases will respond to these measures within three or four weeks. Usually the only complication to be feared is that the lesions may extend and alter their character somewhat, and thus a generalized exfoliative dermatitis may develop; this disaster, which is rare, demands admission to hospital under specialist care.

Probably the Goeckerman regime is the most successful routine therapy for hospital use; it depends chiefly on the photosensitizing effect of applications of tar. For the treatment of those who resolutely refuse to retire to bed, Ormsby and Montgomery (1948) have suggested a modification which may appeal to practitioners, and the reader who is interested should obtain the details from their textbook. Very briefly, a 2–4% crude tar paste is applied thickly at night and removed next morning with liquid paraffin. The patient then attends the surgery and receives an adequate exposure to ultra-violet rays, going on to a suitable establishment—or to his home—and having a bath; he may then attend to business. The treatment has to be given daily for 6–8 weeks, and is reinforced by autohaemotherapy, which is given twice weekly on eight occasions.

The clamour for elegant and cosmetic-like local applications is understandable. The formula given above for treatment of the scalp is satisfactory for application—twice daily—to lesions on the body and limbs, but very occasionally enough mercury may be absorbed to cause haemorrhagic colitis. An alternative formula is a modification of ung. cocois co. of the pharmacopoeia of St. John's Hospital for Diseases of the Skin:

℞

Liq. picis carbonis	10%
Hydrarg. ammon.	2%
Salicylic acid	2%
Emulsifying wax	3%
Paraff. mollis flav.	20%
Ol. cocois nuciferae	ad 100%

M.

Some patients prefer to use "paints." Of these, a varnish containing thorium X is the most efficient, but as the thorium X depends for its action on the emission of radiations its use is a matter for special study. "Tar dermament" (Parke, Davis and Co.) or an 8% suspension of crude coal tar in chloroform, applied twice daily, is sometimes satisfactory. Fox suggested a paint containing 10 parts of chrysarobin, the same amount of salicylic acid, 15 parts of ether, and 10 parts of flexible collodion.

In the treatment of flexural psoriasis of the groins and adjacent parts a sitz bath made by adding an ounce of liq. picis carbonis to four pints of hot water, and followed by the application of zinc cream with 4–6% liq. picis carbonis, is satisfactory in the first stages of treatment, and as the condition improves stronger remedies may be employed: chrysarobin and dithranol are usually too irritating to be employed on these areas.

Psoriasis of the nails usually responds best to a combination of *x*-ray treatment locally and arsenic internally. As in other forms of psoriasis, Asiatic pill is probably the best method of administering the drug. (Note here that in all cases arsenic should be employed only in the chronic stage of psoriasis.)

When *x*-ray treatment is not obtainable the nails may be treated by applying dithranol 0.5–1% in Whitfield's ointment twice daily; this stains the nails, and an ointment consisting of equal parts of ung. acid. salicyl. and ung. hydrarg. ammon. dil. may be preferred.

The treatment of arthropathic psoriasis is a matter for a specialist. *X*-ray treatment to the joints usually gives the most satisfactory results.

Conclusion

There is so much to be said about psoriasis that in writing this paper it has been more difficult to know what to omit rather than to decide what to include. I hope that those who have little leisure to read textbooks will find here one or two suggestions which will be helpful in their practices; I would like to suggest to those who have a little more time that they should fill the many gaps in this presentation by reading the chapter on psoriasis in one of the larger textbooks that are now available. But, whatever course the reader takes, there is one final principle concerning the treatment of this malady which must be emphasized; it was formulated many years ago and experience confirms its validity: in all cases treatment should be continued until the last lesion disappears, for if even a few areas remain recurrence will ensue more rapidly than if the patient is encouraged to persevere until his skin regains its normal appearance.

I am indebted to the photographic department of St. Bartholomew's Hospital and Medical College for Figs. 1, 3, 4, and 5.

THE CHILD AND HIS ENVIRONMENT

MATERNITY AND CHILD WELFARE CONFERENCE

The annual conference arranged by the National Association for Maternity and Child Welfare was held at Friends House, London, on the last three days of June. Nearly 100 local health authorities and 50 infant welfare services were represented among the 700 delegates. The general subject was "The Child and His Environment." On the first day addresses were given on various phases of the subject; on the second day the Conference broke up into six groups for separate discussions, and in another plenary session on the third day reports were presented by the leaders of the groups.

The Influences of Heredity

The subject of eugenics and heredity was introduced by Dr. FRASER ROBERTS, of the London School of Hygiene and Tropical Medicine. He said that despite the great reduction in the infant death rate during the last 50 years deaths from two causes—birth injury and congenital malformation—showed no diminution. Congenital malformations were not all due to heredity, but some of them were, and an even higher proportion were due to a combination of hereditary and environmental factors. As conditions improved, and life and health were better preserved, there remained a hard core of really intractable cases largely composed of hereditary disease or undue hereditary susceptibility. While much ill-health of children had been reduced, there was no reason to suppose that club-foot or hare-lip was less common, or that mental deficiency showed any decline in incidence. The proportion of blind children of school age had been much reduced during the last 25 years, but whereas 25 years ago little more than one-third of the blindness was due to congenital and hereditary disease two-thirds of it was now due to such causes.

In a number of simple inherited diseases, each individually rare or very rare, general eugenic measures offered little of value even were it practicable to apply them, but in some cases the chances for further children could be worked out and parents told of the risks. But in many instances the advice given could be encouraging. The people who sought advice were usually conscientious folk who wanted children and had a good home waiting for them, and it was a pleasure to assure them, as one often could, that the risk was very small. Speaking generally, the trouble was not so much that people tended to have too many children as that they tended to have too few. Social measures to encourage parenthood were not outside the realm of practical discussion. If the average age of the mother at the birth of the child were reduced by five years the incidence of mongolism would be cut to less than half, and there would be an appreciable reduction, even if not so striking, in a number of other congenital defects, such as hydrocephalus.

Sometimes a knowledge of genetics could be of direct and positive assistance. The rhesus factor was a case in point. About one child in every 150 was born with haemolytic disease because it had inherited from the father an antigen not present in the mother. Ten years ago at least half these babies died. To-day, thanks to the knowledge of the genetics and serology of the condition, and the preparations for replacement of the baby's blood by donor's blood, the death rate had been cut from one-half to one-tenth.

Pulmonary Tuberculosis

Dr. Fraser Roberts added that under present conditions of life the hereditary constitution was an important factor in determining whether or not a person contracted pulmonary tuberculosis. No family history of tuberculosis, however bad, was a good reason for refraining from having children, though if the prospective parents themselves were affected it might be a different matter. People with a bad family history, however, should be discouraged from entering the tuberculosis nursing service. On the average it was a bad plan for a patient to be nursed by a sister; it was much safer for a wife to nurse her husband. Children likely to be susceptible for genetic reasons should be carefully watched. They formed one group of persons for whom periodical mass radiography was desirable. He noted that in the *British Medical Journal* of June 24 (p. 1487) Dr. W. H. Bradley had advanced the same argument for rheumatic fever. He believed that a considerable proportion of those genetically predisposed could be detected on the basis of family history, and that it was practicable to protect them from the streptococcus that initiated the disease.

The opinion of the group which later discussed this question was that the majority of cases of miliary tuberculosis and tuberculous meningitis in infants were due to contact with infected relatives, usually living in the same house. It was felt that far too little was done to prevent such contacts, and that further priority should be given to infants who were awaiting hospital or sanatorium treatment and were in contact with tuberculous infection in their own homes.

Fundamental Psychological Needs

Dr. EMANUEL MILLER said that the psychological needs of the child varied with each age group. From birth to the weaning period the child needed conditions in which bodily and mental interests were inseparable. The second phase, from weaning to walking, required special attention to the benign acquisition of habits. Where the mother-and-chiid relation was good the training would be easy. Many character peculiarities might grow upon too rigid and too hasty a training regime. The third period, up to talking, was one during which the infant saw persons and things as wholes, and therefore intellectual needs must be safeguarded. The reality and fantasy needs of the child must be encouraged together, so that the child could check its wishes against hard facts.

The group which considered this subject, as reported by Miss DINGWALL, considered that there was far too little breast-feeding in this country. Between 30% and 50% of infants were breast-fed at the beginning, and after a few months the proportion was very much smaller. One of the reasons was the poor propaganda for the breast and the good propaganda for artificial feeding. We had not adopted the American slogan, "Breast-fed is best fed."

Between 70% and 80% of children were born in hospitals or nursing-homes, in many of which there was excessive routine with segregation of mother and child. The child—a tightly wrapped up cocoon—was brought at stated intervals to the mother, who was instructed to feed it. This brought worry and discomfort for the mother, and it was not surprising that there was frequent failure to feed the child successfully. Retraining of midwives, general practitioners, and others so that they understood the psychological significance of feeding was suggested to deal with the problem. The group was glad to learn that at one large teaching hospital undergraduate students were already being trained in the needs of the healthy child, with special attention to the psychological side of feeding and the attitude of the mother both during pregnancy and after the child was born. It was suggested that there might be a rearrangement of hospital routine so that the mother and child relationship was assisted from the very beginning. Training for motherhood should begin long before marriage. There was a place for such training in secondary schools, youth clubs, and elsewhere. The proper place for a child to be born in was not the hospital but, given decent housing conditions, its own home. Mothers of young children should not be encouraged to work away from home. This problem pertained to country districts as well as to towns, although in the country the work tended to be seasonal, and in the towns continuous.

The Delinquent Child

Mrs. DERMOT MORRAH, chairman of London Juvenile Courts, said that she found it difficult to believe that delinquency was a symptom of abnormality, that character was but a product of environment, that the terms "conflict" and "maladjustment" could be substituted for "crime," and that the criminal was a sick person in need of therapy. Most offences were due to bad training and lack of religious and moral background, and consequently to failure in self-control and discipline. Sometimes the psychiatrist's advice at the court was invaluable, and in a difficult case might make all the difference between failure and success; but more often than not the treatment he recommended was not available, and, if it were, goodness only knew whether it would be successful. Quite the most important part of rehabilitation was to enable the child to cure himself; true regeneration was from within. Probation was one of the court's most potent weapons when used judiciously; when used indiscriminately it was a menace. The child must be made to understand that, no matter how much help was given, the ultimate success could depend only on his own personal effort. If the child were excused by reason of his background or his physical defects, the result would be to fill him with self-pity instead of teaching him to face life in a realistic way.

Among other speakers at the Conference were Professor R. S. ILLINGWORTH, of Sheffield University, who dealt with physical development in the first years of life; Dr. JOHN BOWLBY, of the Tavistock Clinic, who discussed parental influence, and Dr. DOROTHY MAKEPEACE, of the Home Office, whose subject was the child in the welfare State.

The closing address was given by Mr. CHUTER EDE, M.P., the Home Secretary, who spoke of the Home Office concern for children who for one reason or another were not in a normal relationship with their environment. The right place for a child to grow up, he said, was in its own home. When, unhappily, this was not possible, the best substitute was the right foster home, carefully selected to suit the child. But some children would have to live for a time in a residential nursery, and individual care was nowhere more important. The routine of the nursery should be such that the child had time to experiment in doing things for himself, but those in charge must make sure that he had his outdoor exercise and proper times for sleep and rest and ate adequate meals.

The Children Act, 1948, said Mr. Ede, was not the end of the story. It opened the way to developments which would go on for a number of years, and the Home Office, local authorities, and voluntary organizations were working in the closest collaboration to this end.

An exhibition of *x*-ray, electro-medical, and other apparatus will be held in conjunction with the Sixth International Congress of Radiology on July 24–28 at the Royal Horticultural Society's Halls, Vincent Square, London, S.W.1. The exhibition is not open to the public, but members of the medical and ancillary professions may obtain tickets on sending a stamped addressed envelope to the Exhibition Manager, International Congress of Radiology, 32, Welbeck Street, London, W.1.

THE LISTER INSTITUTE

Some interesting investigations, especially in the fields of biochemistry and bacteriology, are recorded in the annual report of the governing body of the Lister Institute, of which Sir Henry Dale, O.M., F.R.S., is chairman. The Institute still accommodates the Blood Products Unit, the Blood Group Research Unit, and the Blood Group Reference Laboratory of the Medical Research Council, but the Bacterial Chemistry Unit has been transferred to the Council's new establishment at Mill Hill, and the National Collection of Type Cultures, which has been housed at the Institute for 30 years, has now been installed at the Central Public Health Laboratory, Colindale.

The Blood Products Unit continues to produce dried human plasma and plasma fractions for the Ministry of Health. During the year 18,500 bottles of plasma have been prepared and dried. The plasma fractions prepared and distributed amounted to 900 ampoules of fibrinogen, 3,300 bottles of fibrin foam, 3,800 bottles of thrombin, and 3,700 ampoules of gamma globulin. Half the batch of gamma globulin has been concentrated by drying from the frozen state in bulk, reconstituted in smaller volume, bottled to give 250 mg. in each ampoule, and held as a liquid; the other half has been put in ampoules before drying in the ordinary way, in quantities of 250 mg. A clinical trial will be made to establish a comparison in potency between the material held in the liquid and the dried state. This will be done by the Public Health Laboratory Service.

The Blood Group Reference Laboratory selects, prepares, and supplies blood grouping sera of all kinds to users in Great Britain and abroad. It is stated that there has been a considerable increase in the number of sera examined from cases of suspected immunization by pregnancy and transfusion. Further examples of very rare types of antibody have been detected and the sera containing them made available for use in research.

The Vaccinia Virus

One of the studies undertaken in the bacteriological department of the Institute concerns the properties of vaccinia virus. The influence of B.A.L. (*2,3-dimercaptopropanol*) *on the copper* content of the tissues and on the proliferation of the virus has been particularly studied. Will deprivation of copper interfere *with the proliferation of the virus?* Preliminary experiments indicate that intramuscular injection into rabbits of the maximum tolerated dose of B.A.L. over a period of 10 days significantly increases the urinary excretion and the serum content of copper and reduces the amount of that element in the viscera; but intramuscular and intravenous injections of B.A.L. over this period do not significantly affect the development of lesions of vaccinia. On the other hand, local inunction with B.A.L. ointment has been found to diminish the vaccinal reaction as compared with lesions similarly treated with capsicum ointment and plain lanoline. Inunction with B.A.L. causes a paradoxical local increase in the concentration of copper in the skin, which is presumably bound and is not available to the virus. The histology of these vaccinal lesions is being studied. The *in vitro treatment of vaccinia virus with* B.A.L. reduces the copper content of the virus but does not diminish its infectivity when it is subsequently inoculated in a normal animal or in the "*embryonated*" egg.

Another investigation which is proceeding at the Institute concerns the factors influencing the survival of vaccinia virus under different conditions of storage, such as temperature, type of suspending medium, *p*H, the influence of drying from the frozen state, and the atmosphere in which dried preparations are stored.

Blood Group Lewis

It was reported a year ago that Lewis-positive adult persons are "*non-secretors*" *within the ABO classification.* But a recent study shows that Lewis-positive persons secrete a specific water-soluble gene-product; there are no non-secretors, and all persons secrete one or more of their blood-group factors in a water-soluble form. It is suggested that the Lewis genes and the genes of secretion probably belong to one genetical system. A determination of the precise differences in these closely related gene-products is necessary to the understanding of gene action, and it is hoped to make in this direction a useful contribution to the biochemical aspects of human genetics.

The Institute is also engaged on various nutritional studies, including the effect of streptomycin treatment on the intestinal flora of tuberculous patients and on the nicotinamide status in man. No decisive results can so far be recorded except that during streptomycin administration the intestinal flora is affected significantly in all cases, the coliform bacteria disappearing.

HOW AMERICA FIGHTS CANCER

PUBLICITY AND RESEARCH

The campaign against cancer in the United States is characterized by the briskness which attaches to all American propaganda. Many years ago, when a lecturer to a British audience began by saying, "One in seven of you will die of cancer," this approach was deprecated. The American Cancer Society, however, puts out such slogans as "Every three minutes a cancer patient dies," and argues that it is not wrong to promote fear and disquiet, provided that at the same time a basis for action and a reason for hope are presented.

These slogans do not appear to remain in the memory. After a national advertising campaign only one person in ten interviewed could recall even one slogan; 80% were said to show no morbid reaction to cancer as a result of the propaganda. Of 272 members of the American Board of Psychiatry and Neurology only one-third believed that cancer publicity had increased public anxiety and only 11% that such publicity had done more harm than good.

The American Cancer Society was reorganized five years ago to make a broad national attack on cancer. It has 28 directors-at-large and a similar number of directors for the various *regions, which cover every State.* In 1949 some 200,000 persons died of cancer, and 600,000 were said to be under treatment. A public opinion survey gave 80% of adults as declaring cancer to be the most dangerous disease in the country; 52% had known someone with cancer, and 20% had had it themselves or in their family.

Since the inauguration of the Society the number of cancer detection centres has risen to 251 and of cancer clinics to 570; postgraduate and refresher courses have been established in 51 schools. Pages of the latest report are occupied with "high lights" of the Society's doings. New York City "continues to dramatize the *importance of early detection and to support* cancer research with a total of 64 individual projects under way." In the State of Michigan, 337 women's organizations *helped to make 85,000 dressings* for cancer patients. A mobile diagnostic unit in Kentucky visited 25 counties in mountainous and rural areas and saw 11,612 patients in 744 clinic sessions. In Iowa educational displays were given at 80 county fairs. Every library in the State of Colorado is being converted into a cancer information centre. In Louisiana a total of 12,886 column inches of newspaper space and 40,000 dollars worth of radio time were purchased. In Maine five new airliners carried literature and speakers to the principal towns. In New Mexico some 350 full-blooded Indians were among the thousands attending a cancer film show.

Behind all this far-ranging *publicity the Society is doing a* great deal for research. It has contributed 13 million dollars to a research programme which it has inspired, and which is *being assisted also by the National Cancer Institute,* the Atomic Energy Commission, and private philanthropic organizations. Scientists have been attracted into the field of cancer research by means of fellowships, and generous institutional grants-in-aid have been made. The Society claims—and not without reason—to have put into operation a truly national machine for cancer control based on short-term and long-term research, on education of doctors and laymen, and on service to cancer patients.

Reports of Societies

STREPTOMYCIN IN OTOLARYNGOLOGY

This subject was discussed at the summer meeting of the Sections of Otology and Laryngology of the Royal Society of Medicine, held at Cardiff on July 1.

Professor F. C. ORMEROD reviewed the additional knowledge gained about tuberculosis of the upper air passages during the past 15 years, including its treatment recently by streptomycin. He said that from about 1930 onwards there had undoubtedly been a drop in the incidence of tuberculosis of the larynx and of the upper air passages. At Brompton Hospital in 1929 there were over 300 such cases, but in 1949 *there were only* 23 new patients. Workers in other countries reported a similar decline. The reasons for this fall were a matter of conjecture: one of the main factors might be the *better feeding of the population,* especially in the younger ages; and advances in thoracic surgery had played a great part.

From 1920 down to well in the 'forties the treatment of tuberculosis of the larynx had not changed very much. Reliance was placed on silence, the application of the galvanocautery, and instillation of various drugs. Injections of gold salts and various types of vaccines were tried without any notable effect. *It used to be said that the expectation of life in the case of* laryngeal tuberculosis could be measured in months, except indeed in cases which were successfully treated by collapse therapy of the lungs. Streptomycin was isolated in 1944, and *from about 1947 it began to be used in cases of tuberculosis* of the lung, and in America, where better supplies were available, in some cases of tuberculous laryngitis. In this country *there was difficulty in using it except for research until 1948.* But during the last 18 months or so it had been available for tuberculous laryngitis, and now supplies were such that it could be bought in the open market, and patients could have as much as was necessary.

The Americans, in their first use of it, were a little over-enthusiastic and gave excessive doses. British laryngologists had the benefit of that experience, and, when they started, gave safer doses, with more satisfactory results. Experience, both here and elsewhere, was not yet extensive, and while the literature bristled with articles on the toxicity of streptomycin little was written about its good effects. Many of the cases treated were due to have surgical treatment, and thoracic surgeons now hesitated to operate unless they had the benefit of the "umbrella" *of streptomycin therapy.* Care had to be taken not to present for surgery a patient whose bacilli had become resistant to the effect of streptomycin. Para-aminosalicylic acid (P.A.S.) given concurrently guarded against this, and made it possible to use streptomycin in many cases where otherwise it would be forbidden. He had found that streptomycin in 1 g. daily doses had a rapid effect on dysphagia; within three or four days the patient lost his pain and was able to swallow quite comfortably. There was rapid improvement in the first three weeks, but it might be six weeks or three months before the larynx returned to normal. It was hardly ever necessary to give analgesics, and it was some time since he had had to inject alcohol.

In the Brompton series he described some 34 completed cases. Eighteen *of the patients had returned to normal,* and 12 were very much improved—that is to say, the disease had ceased to be active, though the larynx had not returned to normal. Two further *cases remained quiescent in the sense that the condition,* while not improving, had not got worse.

Toxic Effects of Streptomycin on the Vestibular Nerve

Dr. J. A. B. THOMAS said that, beginning in 1947, streptomycin was given to a number of patients at Brompton Hospital. The patients were examined at monthly intervals, and a final examination was made after completion of treatment. The symptoms and signs of toxicity were vertigo, nystagmus, and changes in the caloric reactions. It was found that patients receiving 2 g. streptomycin a day were four times more likely to become giddy than those receiving 1 g. a day. The giddiness continued severely in two patients who were over 45; others complained of vertigo after sudden movement, but this symptom usually disappeared after a few months. Nausea was less frequently experienced among the lower dosage group. Nystagmus occurred in 14 out of 22 patients taking 2 g. a day, while out of 43 patients taking 1 g. a day only 7 had nystagmus.

It was impossible to obtain a month-by-month picture of the changes in the caloric reaction. Some of the patients were *very ill; some were transferred to sanatoria,* or had operations; but, where possible, an estimation of the caloric response changes was made at the end of the third month. It appeared *that* 1 g. a day given over a long period produced definite vestibular disturbances, and in these cases the absence of response to slight caloric reaction was the earliest and most frequent change. None of the patients complained of loss of hearing, or of tinnitus, and the upper tone limits remained unchanged throughout the treatment.

Discussion had centred on the site of the lesion, and whether there was recovery from the vestibular damage. Unsteadiness was only experienced by these people when walking in total darkness, or with the eyes shut; some of them had difficulty in making sudden changes of posture. The site of the damage was still unidentified; the signs and symptoms were not typical of either a peripheral or a central lesion. Histological changes had been found in animals given large doses of streptomycin, but further pathological study of the human labyrinth was needed. There was some evidence of partial recovery in a few cases examined 18 months or more after cessation of treatment.

Streptomycin in Pulmonary Tuberculosis

Dr. J. R. BIGNALL said that patients whose bacteria developed resistance were the greatest potential source of spread of the disease. When P.A.S. was given concurrently with streptomycin it greatly increased the value of this antibiotic in the treatment of pulmonary tuberculosis, but *resistance* still occurred in a small proportion of cases and limited chemotherapy. The toxic effects of the combined treatment could *not be ignored, and gastro-intestinal symptoms were common.* Vestibular disturbances, rashes, and fever occurred not infrequently. Appetite was disturbed, and reduction of weight might *continue for as long as P.A.S. was given.* A less toxic and cheaper substitute would be welcome.

Streptomycin was of proved value in acute bronchopneumonic and miliary tuberculosis, and in tuberculosis of the trachea and bronchi. Chronic lesions of the lungs, however, were little affected, and cavities seldom closed with rest in bed and chemotherapy alone. The use of streptomycin in the less severe types of pulmonary tuberculosis could be risky.

The sulphones and thiosemicarbazones—the latter were used extensively on the Continent—had not yet been adequately investigated. At present they appeared to possess no advantage over P.A.S., were less effective than streptomycin, and it was possible that bacterial resistance to them might develop. It was doubtful whether at present their use, other than experi*mentally, was justified. The function of* chemotherapy was not to treat far-advanced disease, or to prepare the patient for operation; it was to eradicate the disease at the earliest stage *at which it could be diagnosed and make present treatment* obsolete. That goal was still very far away.

In some general discussion Mr. GAVIN YOUNG said that he was asked to see a patient who was suffering from a laryngeal condition with apparently extensive tuberculous involvement. It was arranged that he should have a course of streptomycin, and when he saw him again six or eight weeks later the condition had cleared, and the larynx had become practically normal except for the thickening of one cord. He thought it advisable to do a biopsy, and an early carcinoma was revealed. This was something to be kept in mind; it presented an unhappy *problem.*

Mr. J. F. LIPSCOMB gave an account of the treatment of 14 cases of laryngeal tuberculosis with streptomycin in 1948–9. Of

these, 13 were improved and eventually entirely relieved of pain. In some cases the larynx became normal; in others there was thickening. One case did not respond even after 29 g. The dosage was 1 g. a day, given as a single injection. The development of resistant organisms in the treatment of laryngeal tuberculosis was very worrying. He thought that if treatment could be concluded within six weeks—preferably four weeks—resistance was less likely to appear.

Mr. F. C. W. CAPPS said he appreciated Dr. Bignall's warning against indiscriminate use of these potent drugs. He asked whether Professor Ormerod would withhold the use of the drug if the patient was improving by ordinary methods. In cases which were improved but were left with the thickening which had been described, could secondary infection from the upper respiratory tract play some part in keeping up the condition? If the tuberculosis was apparently quiescent, was it permissible to deal with an infected tonsil or sinus?

Mr. A. M. ZAMORA said that there was a danger of being intimidated by the scientific work which was being done on toxicity. He pleaded for the laryngologist to have the full use of this valuable drug.

After some further discussion by Mr. MACKENZIE ROSS, Mr. T. BOYLE, Miss DIX, Mr. E. D. D. DAVIS, and others, Professor ORMEROD, in reply, said that the majority of patients of whom he had spoken were ambulatory; they took home a supply of streptomycin in distilled water, and the doctor in charge or the district nurse did the injections. The patients did perfectly well; there was no need for them to be in hospital, and they came up in three weeks for inspection. Some did return after an interval of some months with signs of recurrence. So far these had been but few, but as the treatment was really only 18 months old it was too soon to say very much. The condition in which the lungs were left made it not impossible that the disease would come back and would be difficult to treat because of a possible minor degree of resistance. With regard to early diagnosis, if the idea could be inculcated, especially in the minds of young people, that continuous hoarseness was a dangerous symptom, perhaps these cases would be seen earlier.

BRITISH NEUROLOGICAL SURGEONS

The Society of British Neurological Surgeons held its forty-first meeting at Manchester on May 19 and 20, 1950, under the presidency of Professor Lambert Rogers. There was a large attendance, including visitors from the United States and several European countries who contributed interesting comments to the discussions. These were on a variety of neurosurgical subjects: "The Late Results of Cordotomy," by J. C. White, of Boston; "Suprasellar Meningiomas," by F. C. Grant, of Philadelphia; and "The Localization of Brain Abscess by Electroencephalography," by G. K. Tutton and Mrs. Whittaker. A notable contribution was a preliminary paper by Sir Hugh Cairns and Dr. Honor Smith on the use of intrathecal tuberculin in the treatment of tuberculous meningitis by streptomycin. Exhibitions of Miss Davison's drawings of pathological specimens and operations, of photographs by the hospital's photographic department, and of angiograms of aneurysms and tumours by Dr. Reid were on view in the new neurosurgical operating and *x*-ray block at the Royal Infirmary.

NORTH OF ENGLAND OBSTETRICAL AND GYNAECOLOGICAL SOCIETY

At a meeting held in Newcastle-upon-Tyne on Friday, June 2, 1950, with the president, Mr. H. Harvey Evers, in the chair, Professor E. FARQUHAR MURRAY reported a case of von Recklinghausen's disease associated with pregnancy. Mr. FRANK E. STABLER then described two cases of recovery from acute yellow atrophy of the liver. Both of these patients had been very ill, and each had been treated with large doses of vitamins given intravenously. An intravenous cocktail consisting of normal saline 1 pint (560 ml.), glucose 10%, aneurin 50 mg., nicotinamide 100 mg., and riboflavin 50 mg. had been administered. Three pints a day of this solution and one pint of saline alone were given. Both patients had made most dramatic recoveries. It was interesting to note that a shrunken liver could increase in size with great rapidity, and it was thought that in this condition individual liver cells could shrink and re-expand. Mr. T. G. ROBINSON described an interesting case of extra-ovarian Brenner tumour. This was at first thought to be a fibroid growing from the left broad ligament, but there was no doubt about its pathology after microscopic slides had been examined. The site of the tumour threw an interesting light on the origin and histogenesis of this condition. Mr. F. J. BURKE read a paper describing 585 cases of vaginal hysterectomy.

Nova et Vetera

A MEDICO-HISTORICAL PILGRIMAGE

At a recent meeting of the Scottish Society of the History of Medicine Professor Richard Shryock, of Baltimore, gave an account of the events which led to the foundation of Johns Hopkins University in that city. He traced the varying attitude towards medical education and practice in the United States during the eighteenth and nineteenth centuries, emphasizing the conflicts between utility and culture and, later, between administration and teaching. The difficulty of securing funds for the establishment of universities could not be solved until the captains of industry became convinced of the utility of such institutions. The cultural value of learning did not impress them. The second conflict, which still existed, arose from the fact that administrators ranked more highly than teachers in both salary and prestige. The establishment of Johns Hopkins University was a brave effort to raise the cultural level and to promote learning for its own sake and not merely for the sake of material gain.

Professor Whitfield Bell, of Philadelphia, then read a paper on the life and work of John Morgan, who, after studying in Edinburgh and on the Continent, returned to the U.S.A. full of honours in 1765 and established the first medical school in the University of Pennsylvania.

The Society, whose president is Dr. Douglas Guthrie, made a pilgrimage to the grave of William Cullen at Kirknewton, to the early home of Robert Liston at Ecclesmachan, and to the Preceptory of the Knights of St. John at Torphichen. Dr. William Cullen, who founded the medical school of Glasgow and later succeeded John Gregory as professor of medicine at Edinburgh, had his country residence near Kirknewton. In recent years his tomb was renovated by the Royal College of Physicians of Edinburgh. Liston, the son of the parish minister of Ecclesmachan, attained great distinction as an anatomist and surgeon. While assisting John Barclay in teaching anatomy at Edinburgh he took part in various "resurrectionist" activities. As the present minister, the Rev. R. L. Pinkerton, explained to the Society during the visit to the church, some evidence of his work came to light during structural repairs to the roof of the manse a few years ago. A young workman fell through some decayed timbers above the attic and, to his surprise and horror, found himself in the arms of a skeleton. He fled from the scene and did not stop running until he reached his home at Linlithgow. The skeleton was afterwards decently interred in the churchyard. The final objective of the pilgrims was Torphichen Priory, now scheduled as an Ancient Monument. Although little of the original building remains, the crossing and transepts, surmounted by a bell tower, still represent the Preceptory, which was established in 1124 and became the chief seat of the Knights Hospitallers of St. John in Scotland. In 1547 the building was transferred into the hands of the Government by the last Preceptor, Sir James Sandilands, an ancestor of the present Lord Torphichen.

Correspondence

Stress and the General Adaptation Syndrome

SIR,—May I congratulate Dr. Ff. Roberts (July 8, p. 104) on another of his masterly displays of the clear, logical mind in action? I must confess that although I have read, as they appeared, most of Professor Hans Selye's articles his last effort (June 17, p. 1383) left me in some mental confusion. It was therefore with relief that I read Dr. Roberts's letter, with its clear analysis of the sources of my confusion. I will not anticipate Professor Selye's reply except to remark that probably one reason for some of the lack of clarity was the close condensation of material, which has by now required a large book to embrace it.

I would take this opportunity of enlarging on one of the points brought out in Dr. Roberts's letter. He remarks on the close identity of diseases responsive to cortisone and *x* rays, and that we could not therefore rationally conclude that *x* rays produced their effects through the hypophysis. Incidentally, the relationship is closer than he states, for A.C.T.H. and cortisone do have a definite though transient action on some forms of malignant disease, particularly leukaemia and Hodgkin's disease. To my mind the striking point is that all these diverse therapeutic agents in these diverse diseases are agents capable of diminishing cell proliferation. In a recent short paper in this *Journal* (May 20, p. 1165) I put forward the hypothesis, on the basis of experimental work, that A.C.T.H. might produce its therapeutic effect by damping down mitosis in the affected tissues. Its apparently ubiquitous action therefore depended on one common factor in the pathology of all the conditions responsive to this therapy—i.e., excessive cell proliferation. In putting forward this hypothesis I had also in mind the therapeutic action of ionizing radiations, particularly of *x* rays, in the various skin disorders accompanied by excessive hyperplasia, and in the local treatment of various types of "rheumatic" joint. The anti-mitotic and mutagenic properties of *x* rays are their only biological actions established with certainty and the only basis on which at present we can begin to formulate a mechanism of their therapeutic action. I also had in mind the effective symptomatic treatment of gout with both colchicine and A.C.T.H. The only known biological effect of colchicine is in its powerful anti-mitotic action. The effect of anti-mitotic agents on neoplastic proliferation is not particularly relevant to the present argument, since excessive proliferation is an accepted main feature of its pathology. The fact that cortisone has also some inhibitory effect here does, however, give further support to its role as an anti-mitotic agent. (I would emphasize, however, that there is no present indication that it is of practical clinical value in this respect.)

If this hypothesis can be raised to the level of a theory then it would alter the whole approach to the mechanism of A.C.T.H. and cortisone therapy in these multifarious diseases. All having one factor—i.e., excessive cell proliferation—in common respond symptomatically in varying degrees to any agents capable of depressing mitosis in the particular tissue or tissues concerned in the pathological reaction. A few such important agents have been mentioned, but others will no doubt spring to mind. For instance the therapeutic effect of coal-tar in skin diseases in which excessive epithelial proliferation is a feature probably depends on its local anti-mitotic effect.

I write thus not primarily to air my own pet hypothesis but to show that the therapeutic action of the gluco-corticoids may depend on a mechanism far removed from and not covered by Professor Selye's concept of the general adaptation syndrome. This would not matter except that he has recently built up further support for his concept largely on the basis of the therapeutic effect of these cortical hormones. As far as I understand it the remainder of the argument derives from the pathological effects in rats of large doses of desoxycorticosterone acetate in the presence of excessive tissue sodium, findings which are of great interest, but in isolation could hardly be used as a basis for a firm aetiological approach to a great mass of human disease. No one can deny that the mineralo-corticoids may be concerned in one or all the diseases mentioned in his article, but I do not imagine that Professor Selye himself would have more than tentatively suggested this as an experimental approach if the dramatic effects of A.C.T.H. and 11-oxysteroid therapy had not been revealed.

As Dr. Roberts states, the general adaptation syndrome is a bold attempt at a monistic pathology. We in Sheffield are very interested in the mechanism of the general reaction to injury, for which we still retain the simple work "shock," and we believe that a precise definition of this word will ultimately be possible from systematic studies of the mechanism of this reaction. When these early stages of the reaction to injury (or stress) are more fully understood, it may then be possible to catch a glimmer of the later stages (if any) embraced by Professor Selye's hypothesis. From what we already know I doubt whether Professor Selye's more recent ideas, even born as they are out of prodigious labours, will survive, *in their present form*, for very long. Nevertheless, his own justification that they will stimulate much new and fruitful work will undoubtedly be realized.—I am, etc.,

Sheffield. H. N. GREEN.

Vaccination and Inoculation Certificates

SIR,—The writer, who has recently returned from a world tour, has realized, as the result of somewhat inconvenient personal experiences, the necessity of paying strict attention to the various regulations made by Eastern governments regarding vaccination and inoculations.

Instructions regarding this matter are being constantly altered without notice, and it is time that some uniform system should be evolved. I understand that this is a matter to which W.H.O. is giving some attention. In addition to vaccination some governments insist on protection against yellow fever and typhus. Therefore it is probably safest to be protected against them all. As regards cholera, it should be emphasized that the Egyptian Government lays more stress upon this than any other and may, on occasions, actually segregate a person who is not thus protected. This inoculation must have been performed six days before landing on Egyptian territory. These regulations apply to passengers in transit as well as visitors to Egypt. On the other hand, little or no attention is paid to inoculation against typhoid, but vaccination is considered to be of paramount importance.

Many governments require inoculation and vaccination certificates to be authenticated and stamped by a Government medical officer or medical officer of health. The reason for this is to ensure that the certificate has been issued by a reputable qualified doctor. As it is not always certain at any time which governments do insist upon this authentication, it is in the passenger's interests for all certificates to be officially stamped.

In view of these complications I think it advisable that the B.M.A. secretariat should maintain an up-to-date dossier of information on the requirements of all the various governments. They would then be in a position to advise medical practitioners about the instructions they should give to their patients prior to their departure abroad by sea or by air.

I also suggest that some notice on the lines of my third paragraph should be widely distributed to all doctors for their information.—I am, etc.,

London, W.1. PHILIP MANSON-BAHR.

Intravenous Morphine

SIR,—Morphine is a drug which is usually administered for the rapid alleviation of pain, or because some degree of mental tranquillity is required. The result of the usual subcutaneous injection of morphine is a gamble, as the amount absorbed in a given time depends among other factors on the dose employed, the depth of subcutaneous fat, and the condition of the circulation.

During the "flying bomb" era a robust man of 40 was admitted to hospital under my care suffering from a severe crush injury of the right leg. He was given morphine ¼ gr. (30 mg.) subcutaneously before the leg could be released. About an hour later the debris was removed, and he was carried to an ambulance; as he was still moaning, another half-grain was administered. Owing to road blocks

and the blackout the journey to hospital (of less than a mile) took about an hour, and on admission he was somewhat restless and in obvious pain, so another half-grain of morphine was injected subcutaneously. When I examined him about half an hour after admission the primary shock was apparently subsiding, as his pulse and blood pressure were approximately normal, but his respirations were eight to the minute, and his pupils pin-point. Amputation was performed without the necessity of an anaesthetic, and the patient made an excellent recovery.

In all probability the absorption of an overdose of morphine when the shock subsided did this patient no harm at all, but had he been suffering from a head or chest injury the effects might have been disastrous. The slow and variable absorption of a subcutaneous injection compares unfavourably with intravenous injections, a fact which is demonstrated in the following case.

I was recently asked by a practitioner to see a feeble old man with bronchitis and myocardial degeneration who had a few hours previously strangulated his right inguinal hernia. On examination the patient was vomiting, groaning with pain and anxiety, and the pulse was barely perceptible. The tense and tender hernia was the size of a coconut, and any attempt at manipulation caused further distress and resentment. Obviously he was in no condition to stand a journey to hospital, and still less was he fit for an operation. An intravenous dose of a quarter of a grain of morphine was administered, and within five minutes the patient was comparatively quiet and co-operative and his musculature was relaxed. A determined attempt at taxis was successful, and a welcome gurgle indicated reduction of the bowel. Recovery was uneventful.

Morphine is a potent drug, and its effects should be controlled as far as possible. Intravenous injection guarantees rapidity of effect, which is commensurate with the condition of the patient and the dose administered. It is therefore urged that the controllable intravenous administration should be used, wherever possible, in preference to the usual problematical subcutaneous injection.—I am, etc.,

London, W.1. R. J. MCNEILL LOVE.

D-tubocurarine Salts and Derivatives

SIR,—Your annotation (June 3, p. 1309) pointed out that the dimethyl ether of D-tubocurarine iodide has some slight advantages over the parent phenolic alkaloid when used to produce muscular relaxation. The paper by Dr. H. O. J. Collier and Mr. R. A. Hall in the same issue (p. 1293) contains some significant facts which appear to have been overlooked in your discussion.

The potency of the dimethyl ether is the problem. It is commonly expressed in terms of the potency of the better-known D-tubocurarine chloride. That the ratio:

$$\frac{\text{potency of dimethyl ether salt}}{\text{potency of D-tubocurarine salt}}$$

varies greatly from species to species is not surprising, as the two substances are of different structures, albeit closely related. The ratio also varies within one species when different methods of testing are used to determine potency—e.g., Collier and his colleagues (1948) give the ratio, determined by abolition of the righting reflex in the rat, as 4, whereas they found it to be 2.4 when determined by toxicity. Of more significance, however, is the fact that the ratio appears to vary within species even with the same type of test. The following are examples of the ratio determined by estimation of LD 50 values in the rat by intravenous and intraperitoneal injection:

I.V. Collier, *et al.* (1948)	2.4
I.V. Glock *et al.* (1948)	3
I.P. Marsh *et al.* (1948)	8.4
I.V. Swanson *et al.* (1949)	3.1
I.V. Unpublished	4.68
I.P. „	4.35

The ratio given by Glock and her colleagues was determined by intravenous injection in small rats of 50–100 g. weight: the actual figure obtained was 2.91 with p95 limits of 2.57–3.29. In large rats of approximately 400 g. we obtained a ratio of 4.68 (p95 limits 3.20–6.85). The last ratio quoted above had p95 limits of 3.72–5.08. Unfortunately we did not note the weights of the rats used in this experiment, for at that time we were not aware of the significant difference which exists between the toxicity of both D-tubocurarine and its dimethyl ether in large and small rats, but we are fairly confident that they were on the large side.

The ratio given by Marsh and his colleagues is obviously about twice any of the others. Of course the rats used by different investigators may have been of different sensitivity to the drugs, but it is unlikely that those who got results of the same order—i.e., ratio of 2–4—used the same strain of rats. It is improbable that the difference is due to variation in absorption, because our results were almost the same whether we used the I.V. or I.P. routes of injection (when the rats were of the same size). The more ominous explanation is that the materials used by different investigators may not be the same substance.

In this connexion it may be of value to record a finding made here some years ago. A sample of material reputed to be D-tubocurarine-O-O-dimethyl ether iodide, made by Dr. Dewing, when examined on the isolated rat diaphragm proved to be slightly more than twice as potent as other samples. Chemical and physical analyses failed to distinguish this extra-potent sample. It was prepared by methylating the crude mother liquors, and not in the more usual way of treating crystalline D-tubocurarine chloride.

The molecule of D-tubocurarine (or its dimethyl ether) is large. It consists of two benzyltetrahydroisoquinoline moieties joined by two ether links. There are two asymmetric carbon atoms, of which one is dextro- and the other laevo-rotatory. These two centres of asymmetry permit the existence of four optical isomers—viz., D- and L-tubocurarine and the metho-salts of D- and L-bebeerine (or, synonymously, D- and L-curine). It is, however, possible to construct more than four forms of this molecule using Fisher–Hirschfelder–Taylor atom models. For each of the four enantiomorphs there are at least two forms, since the bonds of the ether oxygen atoms can occupy different spatial positions and so alter the shape of the molecule. These variations would be difficult to detect by ordinary chemical and physical means.

It is imperative that the utmost caution should be exercised when using a derivative of D-tubocurarine like the dimethyl ether because (1) slight alterations in the structure of this complicated molecule may have profound effects on its biological activity; (2) the ratio of potency of any two derivatives is not necessarily the same for all species; and (3) even in the same species and by the same test the reported activity of the (?) dimethyl ether derivative of D-tubocurarine shows wide variation.—We are, etc.,

Domiciliary Care of Premature Babies

SIR,—In recent years much stress has been placed on the care of premature babies, particularly since it has been realized that deaths among these infants are a major factor in the total infant mortality. Great emphasis has been placed rightly on the provision of specialized premature-baby units in hospitals. There are, however, circumstances when a premature baby has to be nursed at home, primarily due to the limited hospital accommodation available. The facilities provided by county borough and county councils for domiciliary care have varied considerably, and it is probably true to say that county councils with widely scattered populations have experienced the greatest difficulty in providing additional care for these babies.

It may therefore be of interest to county councils to outline the scheme introduced by Glamorganshire. The problem has been approached from two aspects: (1) provision of specially trained midwives; and (2) provision of additional equipment. In the training of staff the county council is greatly indebted to the Sorrento premature baby unit at Birmingham, where arrangements have been made for midwives to receive instruction during a month's residence at this unit.

Following very considerable discussion, the special equipment provided is of the simplest type and is enclosed in what appears to be a suitcase (24 in. by 12 in. by 6 in.), but which unfolds to become a draught-proof cot. The cot is reinforced by thin metal sheets and has a washable lining. The contents are as follows:

1 sorbo mattress	2 mucus catheters
3 wool cot-blankets	1 Jacques catheter with graduated pipette for feeding
3 rubber hot-water bottles	8 oz. of olive oil
8 oz. of white lint	3 thermometers (cot, rectal, room)
2 measures for dried milk	6 face-masks
1 liquid measure	
8 oz. of cotton-wool	
1 Belcroy feeder	

It is not suggested that this affords a comprehensive list of requirements for the nursing of a premature baby, but it does form a nucleus of essentials, and, what is of considerable importance in a wide area, it is very easily transportable. It may in fact be regarded largely as first-aid equipment, sufficient to care for a baby who has arrived before the normal preparations have been made.

Having available specially trained staff and having provided additional equipment, there still remained administrative difficulties in putting the scheme into operation. It was not considered feasible that a midwife should be concerned only with premature babies, so it was decided that she should retain a small "normal" midwifery practice, but in addition she would be responsible for the premature births for a wider area within a radius of approximately ten miles from her centre.

When a premature baby is born the attending midwife calls in a colleague who has had the specialized training and who also holds the premature baby outfit. Thereafter the specially trained midwife takes complete charge of the case, mother and baby, under, of course, the direction of the general practitioner whose aid must, by regulation, be sought in the case of a premature birth. Whenever feasible the specially trained midwife is called in to carry out the delivery.

A premature baby requires the attendance of the midwife for longer than the usual 14 days—the duration being decided upon by the progress of the infant, and not by its age or weight. Health visitors are encouraged to pay periodic visits to such infants, and in any case their first visit is not delayed until the midwife has completed her period of responsibility.

In practice the scheme works. Midwives have been most ready to work as a team and have suppressed their natural desire to nurse the premature babies occurring in their own districts. It is to be hoped that in the not too distant future all midwives will receive instruction in the modern methods of care of the premature baby, either in their basic training or in postgraduate courses.

It would be difficult to obtain statistical evidence of the value of the scheme in the reduction of infant mortality, but if in the County of Glamorgan one child is saved each year then it can be regarded as a success.

My thanks are due to Ferris and Co., Ltd., Bristol, for their co-operation in the making of the outfit, and also to Dr. W. E. Thomas, County Medical Officer, for permission to publish this account.

—I am, etc.,

Cardiff. R. T. BEVAN.

Carcinoma of the Stomach

SIR,—I was very interested by Mr. H. C. Edwards's paper on carcinoma of the stomach (April 29, p. 973). In a very general manner most of his conclusions are in agreement with our findings published in 1939. In our book there is to be found a detailed study of the many aspects of the fascinating problem that constitutes on one hand the well-established and rather advanced case of gastric cancer, with its peculiar evolution, sometimes rapid and silent and at others noisy and slow, and on the other hand the initial stages of the disease—i.e., ulceriform cancer, transformed ulcer, gastritis and cancer, etc. Exceptional types described as muco-erosive cancers with slow evolution are worthy of note. In this type the malignancy remains localized in the mucosa, spreading very slowly superficially but not in depth, comparable in some ways to the rodent ulcer of the face.

Mr. Edwards's Case 3 (Plate, Fig. 1b)—"The earliest carcinoma of the stomach that he has ever seen"—although sufficiently recent, appears advanced in comparison with many of our early cases diagnosed as cancers pre-operatively. Although it is difficult to be affirmative from only a low-power magnification, it appears that in this case the muscular layer is already involved by malignancy. I am frankly in disagreement with his statement that the differential diagnosis between a benign and a malignant ulcer of the pyloric antrum is pre-operatively impossible. The diagnosis rests, as is developed in our publications, on perfect radiographs taken at regular intervals combined with the clinical symptomatology. A great degree of suspicion is already given in the first series of radiographs by the radiological signs we have described. At the second series, taken after a three- or four-weeks interval, the suspicion generally becomes a certainty, If necessary a third series is taken. A pathognomic sign of malignancy is, in our opinion, the disappearance of the clinical symptoms with the persistence or increase of the radiological signs. Had there been radiographs taken at more frequent intervals in Mr. Edwards's Cases 4, 6, 7, and 8, it is possible that they would have been diagnosed earlier on. I am of the impression that gastric cancer from its start has a rather slow evolution, or at least many forms of it have.

Mr. Edwards is to be congratulated for the stand he makes regarding radical excision for those cases considered inoperable by others. If the operation is not performed the patient has nothing to gain but a few more months of misery. Taking into account the recent advances in abdominal surgery, every hope for a long and useful life is permissible. No one suffers except the surgical statistics, and the advanced cases of gastric cancer should be included in a different group. I hope that Mr. Edwards will forgive my criticisms, as they come from my deep interest in the subject.—I am, etc.,

Limassol, Cyprus. T. J. PERISTIANY.

Hodgkin's Disease and Pregnancy

SIR,—We were interested to read the correspondence on Hodgkin's disease of pregnancy (May 13, p. 1142; June 3, p. 1322; July 1, p. 47) and would like to quote the following case.

In April, 1949, one of us (J. R. H.) saw a European woman of 25 years who gave a history of nine weeks' amenorrhoea. Pregnancy was diagnosed on examination. It was also noticed that the second and third ribs bulged parasternally, and this area was dull to percussion. The right external jugular vein was filled. Three rubbery glands were felt in the right posterior triangle. The liver edge was palpable, but the spleen was not felt.

She gave a history of having enlarged cervical glands for two years; one of these glands had been taken for biopsy in Europe (result not known). She also said that there had been a shadow in the upper part of the right lung, on x-ray examination. An x-ray film of her chest in April showed a large mediastinal mass. Her blood count was as follows: Hb, 88%; R.B.C., 4.3 million per c.mm.; W.B.C., 5,800 per c.mm. (polymorphs 60%, lymphocytes 34%, eosinophils 2%, monocytes 4%).

A clinical diagnosis of Hodgkin's disease was made. In view of the fact that she had been married only three months and that both she and her husband wanted a child, it was decided to allow the pregnancy to continue. During the course of her pregnancy she developed several brown patches on her right upper arm and right knee. The patches were sharply demarcated, not raised or infiltrated or scaling. They did not disappear on pressure. They were more or less circular in shape and varied in size from ¼ in. to 1 in. in diameter (1.3 to 2.5 cm.).

On August 23 she developed severe pain in the back in the region of the 2nd to 4th ribs posteriorly and down the outside of the right arm. On examination the right biceps reflex was diminished and there was a slight hypoalgesia of the fourth and fifth fingers. It was decided to attempt relief by irradiating the mediastinal mass. The treatment was undertaken by one of us (J. W. W.). After one week's irradiation the pain had completely disappeared, although observation of the mediastinal mass then and during the following

months showed little alteration in size. The mass on screening did not appear to encroach on the brachial plexus.

The remainder of the pregnancy was uneventful except that she remained at the same weight the whole time. Three weeks before term she had a slight loss of blood per vaginam, which did not recur. At term she was delivered normally of an 8 lb. (3.6 kg.) male child, which was weaned from the breast and is now eight months old, weighing 18 lb. (8.2 kg.).

After delivery a large mass of glands appeared on the left side of the neck, rapidly increasing in size. During February and March, 1950, a further course of treatment was given to the mediastinal mass and to the cervical glands. The latter regressed completely, but again there was little observable effect in the mediastinal mass. At the beginning of June, 1950, the pain in the right arm reappeared and a small freely movable gland became palpable on the right side of the neck anteriorly. This is at the moment being irradiated. The mediastinal mass is apparently unchanged. No glands are palpable apart from the small one in the right cervical region.

Two interesting points which this case illustrates are: first, the fact that pregnancy in Hodgkin's disease is usually associated with mediastinal involvement; secondly, that during the whole of the pregnancy no exacerbation of symptoms occurred.—We are, etc.,

Norms of Cerebrospinal Fluid

SIR,—The paper by Mr. W. R. Henderson and Dr. C. G. de Gutiérrez-Mahoney *on cerebrospinal fluid in 302 cases of intracranial tumour, abscess, and subdural haematoma* (June 24, *p. 1461*) *is interesting* in many points. The authors emphasize quite rightly that a pathological cerebrospinal fluid may be only "characteristic" of a tumour, etc., without being "specific," but emphasize that an examination of the fluid as a preliminary investigation has nevertheless its value, in order to confirm or exclude a possible organic disorder of the nervous system. This is a very important point indeed, but I find it rather difficult to agree to their statement that the total protein content of a cerebrospinal fluid may be as high as 60 mg. per 100 ml. According to Mestrezat (1912), one of the pioneers in the field of research on the cerebrospinal fluid, the upper limit of total protein is usually 25 mg. per 100 ml., and only in very exceptional circumstances it may be 30 mg. (but one wonders whether the three persons quoted by him as such exceptions were "normal"). Hewitt (1927) thinks that the normal protein content is about 23 mg. per 100 ml. Lange (1939) and Neel (1939) assume that 25 mg. per 100 ml. is the upper limit, and my own experience agrees with these figures. If one accepts them it will be seen that only very few patients referred to in Table I by Henderson and Gutiérrez-Mahoney had normal cerebrospinal fluids.

It may be worth while to mention on this occasion that the cell content of a normal cerebrospinal fluid is one in 3 c.mm. (Neel), three in 3 c.mm. (Lange). I find that four cells in 3 c.mm. is the upper limit of the norm. Such a low "normality" for total protein and cells is possibly too rigid a measure for the neurologist; for the psychiatrist it is a necessity.—I am, etc.,

Premedication for Gastroscopy

SIR,—The ideal preparation for gastroscopy is a matter about which there are many opinions. For a long time I was in the habit of using morphine 1/6 gr. (11 mg.) one and a half hours before gastroscopy, but for the last 130 cases I have used pethidine 100 mg. with scopolamine 1/150 gr. (0.4 mg.) intramuscularly. (In either case a tablet of "decicain" 50 mg. is given under the tongue half an hour before gastroscopy.)

I have found this latter method of premedication preferable to any other so far tried inasmuch as it produces sufficient sedation and relaxation to make instrumentation generally easy without depriving the patient of the ability to co-operate during endoscopy or rendering him so drowsy afterwards that any untoward post-endoscopy symptoms might be late in appearing. Furthermore it is entirely suitable for out-patients, who can leave the hospital within three hours of gastroscopy.

The number of patients (roughly 5%) in whom oesophageal spasm precludes gastroscopy is about the same in my series whatever method of sedation is used.—I am, etc.,

C. F. J. CROPPER,
Senior Physician.

Ministry of Pensions Hospital, Worcester.

The Dumping Syndrome

SIR,—I have read with very great interest Mr. Thomas O'Neill's communication (*July 1, p. 15*) *on the* "Dumping *Syndrome*," and I would like to endorse his remarks that the condition presents a serious challenge to all who practise the *operation of partial gastrectomy. In the assessment* of cases it is very difficult to differentiate between organic and functional symptoms. I think, however, that no advance can be made until two distinct syndromes are recognized:

1. *An early syndrome*—which occurs during or immediately after a meal and is believed to be mechanical in origin. This rarely follows gastro-enterostomy but is seen in 10% to 15% of cases after gastrectomy. This particular variety of the syndrome may persist for many years and presents the major problem.

2. A delayed syndrome—which occurs during the second or third hours following meals and is considered to be due to and coincident with reactive hypoglycaemia. This is less frequent than the early syndrome and does not present such a problem, as the condition tends to disappear spontaneously. Almost half the patients who exhibit this syndrome after gastrectomy have similar symptoms before operation.

With regard to the operative procedure described by Mr. O'Neill, surely it is the original procedure performed by Hoffmeister in 1908—a valvular anastomosis with a central stoma?

Finally, "dumping" is essentially a radiological term, and I do not think that there is any justifiable pathological basis for its use to describe a clinical syndrome the cause of which is probably not due to any single factor.—I am, etc.,

T. J. BUTLER.

Bristol.

Obstetrical Anaesthesia

SIR,—In regard to Dr. A. H. Morley's letter (July 1, p. 47) in criticism of Professor Jeffcoate's statement that "light chloroform anaesthesia has much to commend it for easy low forceps delivery in domiciliary practice," may I be permitted a few disjointed comments? He asks, "How many expert anaesthetists would choose to administer chloroform for any operative procedure during labour?" My comment would be that I have administered chloroform in all minor and major operative procedures in labour conducted by myself, all in the left lateral position—and a goodly number to wit—and the results show not one single case of primary cardiac failure in the whole series. One case collapsed following a difficult delivery due to the use of pituitary extract, and this was in 1926.

What are the criteria for care in chloroform anaesthesia? Training in the use of the drug, appreciation of any dangers which might occur, and correct treatment when you are unfortunate enough to meet misfortune. What is the alternative to chloroform in the case of the usual domiciliary midwifery where a fire is burning—the fire not only for heating the room—and the practitioner single-handed? Are patients in better condition after ether, can it be used with an open fire, and is it easy to administer single-handed and still conduct a difficult delivery? Trichlorethylene might take its place, but how shall we obtain relaxation, which is surely a necessity if the labour is really difficult and we are to do as little damage as possible? N_2O has the same objection, while thiopentone is surely contra-indicated in this type of work if for only one reason alone—the ease of vomiting occurring with thiopentone, with no warning in patients strongly addicted to this process.

I would commend Dr. Morley's positioning in domiciliary midwifery, particularly in general anaesthesia, as sound and proved by experience. In regard to chloroform in these same conditions, has it not also passed the test of time? It is agreed that the pregnant woman takes chloroform well, and having seen neither cardiac failure nor liver toxicity following the use of this agent in home midwifery I feel we should be careful before we condemn and before we can give the G.P. an agent which is as safe, as easy to give, or as effective. Perhaps Dr. Morley could suggest a simple technique which could replace chloroform in midwifery, and if so we would all be glad to hear from him.—I am, etc.,

J. G. WARNOCK,
Senior Anaesthetist, Tees-side Group.

Middlesbrough.

SIR,—A great deal has been written of late regarding anaesthesia in caesarean section, and both mother and baby have benefited greatly by the strides that have been made in this field. The advent of curare and similar muscular relaxants, with their reluctance to cross the placenta, have greatly decreased the chance of depressing the infant's respirations, by enabling a much lighter plane of anaesthesia to be maintained. Even in the occasional case where mild depression still occurs, the improved methods of resuscitation have greatly lessened the hazard. However, in all the recent literature on the subject we see little emphasis being placed upon the matter of speed in carrying out the operation, and I regard this factor as being of paramount importance.

In this department, which deals with most of the abnormal obstetrics in Herefordshire, our success as borne out by our figures is in my opinion mostly due to a complete understanding and teamwork between obstetrician and anaesthetist. The patient is brought conscious into the theatre, a procedure which in my experience causes no mental disturbance whatever, provided it is not clumsily handled. While the towels are being placed in position the anaesthetist is quietly chatting to the patient and making use of whatever personality he or she may have. When the stage is set, anaesthesia is established with a mixture of thiopentone and "syncurine" intravenously, and controlled respiration is established, using pure oxygen and avoiding any carbon dioxide absorption. The knife, already poised, can make its first incision in about one minute from now, and on the average a loudly complaining infant is handed to the waiting nurse two minutes later. It seems that the infinitesimal quantity of thiopentone that crosses the placenta in these three important minutes is of no significance to the infant. All (except the mother) can now breathe freely, and the second part of the operation can be concluded as a leisurely laparotomy, preferably under cyclopropane, to assist the uterine contraction.

The reasonable operation speed mentioned is not achieved by haste but by wasting no time, and by the avoidance of the following delays: (1) tying-off clamped blood-vessels on the way in; (2) any unnecessary packing; (3) any unnecessary conversation, including detailed lectures and demonstrations to juniors during the vital minutes. This must not be construed as a criticism of surgical technique, but as an attempt to emphasize the vital importance of cutting down to the absolute minimum the time during which an anaesthetic agent is mounting an offensive against a babe unborn.—I am, etc.,

THOMAS F. HEAVEY,
Anaesthetist.

County Hospital, Hereford.

Failed Forceps

SIR,—May I make two comments on Dr. Derek Freeth's interesting paper (July 1, p. 18)?—one in agreement, one not. Dr. Freeth ascribes prolapse after failed forceps to undue stretching of the "uterine supports, particularly Mackenrodt's ligaments," which, he says, "not infrequently . . . remain permanently stretched" so that "prolapse follows." The idea that extrusion of viscera is permitted by the pelvis in virtue of some lesion of the paracervical tissue is, of course, not new. It was put forward by Salmond and Dearnley in 1935,[1] and much earlier by W. E. Fothergill,[2] with whom I had a great battle.[3] The idea, however, is highly imaginary and quite unscientific. It does not fit in with the common occurrence of prolapse latish in life—about 50—the predisposing cause of which certainly is a confinement occurring perhaps twenty-five years before. And am I not right in stating that Mackenrodt's "ligaments" only simulate ligaments in the non-pregnant, and that in late pregnancy all the pelvic visceral connective-tissue thickenings disappear, becoming succulent and loose, thus explaining the mobility of all the pelvic viscera so that the bladder during labour is easily displaced from the pelvis into the lower abdomen?

After forceps delivery under spinal anaesthesia, episiotomy having been performed on one side and perhaps on both, with the patient in the lithotomy position, I have not infrequently seen the cervix presenting as a fringe almost within the now extremely big and even frightening introitus. Next morning, however, the picture is changed. The levator ani muscles, paralysed by the spinal, which after the delivery permitted the introitus to look so terrible, so that at times two fists in apposition could with ease be thrust through into the pelvis, have now regained their tone, and are behaving as in the normal. One advantage of spinal is that these muscles, paralysed, yield during the extraction and thus are less likely to get torn; whereas with most other anaesthetics their resistance to distension is not always in complete abeyance, so that they tear rather than yield.

Inguinal, femoral, obturator, umbilical, lumbar, incisional, and diaphragmatic hernia—not one of these is determined by a relaxation or an undue stretching of the connective tissue attachments of the visceral part involved. When will obstetricians realize that genital prolapse is a hernia?

My other comment is to say how whole-heartedly I endorse Dr. Freeth's plea for the performance of lower segment caesarean section in cases of failed forceps. But here, also, is a fly in the ointment. He appears to base his recommendation on the use of chemotherapy: I do so on the free use of chlorine as a wash and a douche. Semmelweiss cut down the maternal mortality by a half or more by using chlorine, or a solution acting in virtue of it. He did so by making his students wash their hands in such a solution before they examined the patients. I have kept my mortality and morbidity down by thoroughly douching the vagina with chlorine, both in the ward and sometimes again in the theatre before operation; and, after the operation, twice a day for three days and once a day for the rest of the week. Naturally, I use this most effective and precious stuff in my cases of forceps delivery, before and after, voluminously and repeatedly. My results in both cases justified my procedure.

I must cut short my letter. There are two things to say. One, that the advent of chemotherapy, not available when I started, is likely to make obstetricians less strict with their asepsis; and two, that in midwifery with chlorine, and the other usual measures, provided the patient is not already dying and has not some internal lethal state, one can do anything.—I am, etc.,

Dangerous "Prams"

SIR,—I am becoming increasingly concerned about the number of accidents to babies which occur as a result of the construction of the "pram." Mothers are constantly bringing bruised and shaken babies to me because the pram has tipped up with the baby inside. I feel that the very short wheelbase of the pram is the causative factor: very often the wheels actually overlap, and it seems that the more expensive the pram the shorter the wheelbase and the greater consequent liability to accident.

Perhaps it would be going too far to demand a Board of Trade certificate of pavement-worthiness, but I do feel that the safety of our babies should be more adequately considered.—I am, etc.,

DAVID THOMAS.

London, S.W.3.

St. John's Hospital, Lewisham

SIR,—St. John's Hospital, Lewisham, which has been for nearly 70 years a complete general hospital, serving a population of a quarter of a million, is now threatened with dismemberment. This means that St. John's will lose in-patient facilities for six departments of medicine and surgery—viz., gynaecology, dermatology, urology, orthopaedics, E.N.T., and psychiatry; and, in addition, children's beds are to be reduced by over half. Apart from the elimination thereby of its role as a general hospital, its efficiency and ultimate survival are menaced, and the

community will be deprived of that free and alternative choice of opinion and treatment which it has hitherto enjoyed. This step is at complete variance with the promise of the Minister and his instructions to the regional board (R.H.B. (49) 132).

This is no isolated threat, but one that confronts many hospitals of similar size throughout the country. Such hospitals as St. John's have performed useful work to the community because of their completeness. Dismemberment can only be a retrograde step and should be energetically resisted. I urge these hospitals to take action before they are destroyed.—I am, etc.,

London, W.1. JOHN HOWKINS.

POINTS FROM LETTERS

Inoculation and Paraplegia

Dr. C. H. REINHOLD (Colonel, I.M.S., retired) writes: The article and leading article on "Inoculation and Poliomyelitis" in the *Journal* of July 1 reminds me of a parallel case in India fifteen or more years ago, though the victim then was an adult and the inoculation was the prophylactic for rabies. The patient was not mine and I did not see him during the illness, so I do not know all the details, but both he and his wife were treated as a precautionary measure when their dog got rabies and was tended by them both with great devotion. The lady had no ill effects, but her husband developed a paraplegia and was gravely ill for several days and bed-ridden for months. He has made a slow but steady recovery, and can now walk without a stick, though he easily tires, and has put in many years of useful work since. . . . Can this case in any way be squared with the researches recorded in the interesting paper by Professor Bradford Hill and Dr. Knowelden?

Smallpox in the Unvaccinated

Dr. W. A. MACKAY (Southport) writes: With passing years memory and, perchance, mentality depreciate, and I trust I am not doing Dr. J. S. Gemmill (July 8, p. 107) injustice when I demur strongly to his statement "haematemesis at the outset of her illness did not justify a diagnosis of smallpox even to be entertained in the first instance." About 1892, and by the bedside in the Glasgow Smallpox Hospital, Dr. R. S. Thompson taught me that smallpox might have a petechial rash—the variolar triangle with its base across the lower abdomen—and not the usual eruption, and might be accompanied by various bleedings. Further, in French's *Index of Main Symptoms* (third edition, p. 265) malignant variola is noted as a cause of haematemesis.

The General Adaptation Syndrome

Dr. A. WESLEY HILL (Wrexham) writes: One question I should like to ask is, Why is damage divorced from stress and coupled with defence? I think that stress means nothing from the point of view of organized response, apart from the damage it causes. To me stress is a mental concept to which I am comparatively indifferent until it begins to produce in me damage. There appears to me, therefore, no sense in calling stress the interaction between damage and defence . . . it seems to me that the plain biological meaning of stress is that it can cause damage, and that only when it does cause damage does the living organism react as best it can. In the next place I would not include "alarm reaction" and "stage of exhaustion" in the general adaptation syndrome. So far as I can understand the oration, "alarm reaction" is not reaction at all but the biological retreat before a sudden onslaught of damaging stress. It is then that the damage caused by stress takes place, because the organism has not yet arrayed its forces and adapted them to the battle.

Naming of Cancer Hospitals

Dr. BENTLEY PHILLIPS (London, W.1) writes: I should like to bring to your notice on humanitarian grounds the unnecessary anxiety which is bestowed upon patients by bad psychology in the naming of hospitals which specialize in the treatment of neoplastic growths. A highly unpleasant shock is administered to the average patient when told that he or she is being referred to a cancer hospital. The result generally calls for a considerable amount of discussion, "hedging," and reassurance by the doctor referring the case for examination and diagnosis, but in spite of this I am of the opinion that the majority of patients are convinced that the doctor is "breaking it gently" and that in actual fact a death-warrant is being issued. . . . Could not a name such as "radium and *x*-ray hospital," "radiotherapy hospital," or "tumour clinic" be substituted? . . . The real answer to this problem is, of course, better education of the public in order to eradicate the fear of cancer, but until the welcome arrival of that era I contend that it is an unnecessary cruelty to retain the fearsome name "cancer hospital."

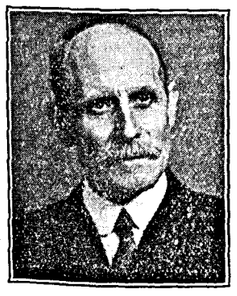
Obituary

H. C. BAZETT, C.B.E., *M.C.*, M.D., F.R.C.S.

Dr. H. C. Bazett, Professor of Physiology at the University of Pennsylvania since 1921, died on July 12 on board the *Queen Mary* bound for Southampton. Dr. Bazett was 65.

Henry Cuthbert Bazett was born at Gravesend in 1885, the son of Dr. Henry Bazett. He was educated at Dover College, at Wadham College, Oxford, and at St. Thomas's Hospital. He took his B.A. in 1908 and graduated B.M., B.Ch. two years later, proceeding D.M. in 1920. He took the F.R.C.S. in 1911. At St. Thomas's Hospital he won the Cheselden Medal, and he was successively house-surgeon, casualty officer, and clinical assistant to the throat and ear department. After completing his next appointment as demonstrator in physiology he won the Radcliffe Travelling Fellowship in 1912 and spent twelve months doing postgraduate work at Harvard. He returned to this country not long before the outbreak of the 1914–18 war and became a demonstrator in pathology at Oxford. Subsequently he served in France with the R.A.M.C. and was awarded the M.C. and three times mentioned in dispatches. He was demobilized with the rank of major and he was also awarded the O.B.E. From 1919 Dr. Bazett was the Christopher Welch lecturer in clinical physiology at Oxford, and then in 1921 he was appointed professor of physiology at Pennsylvania University, the post which he still held at the time of his death.

During the recent war Professor Bazett was given leave of absence and acted as visiting professor of medical research at the University of Toronto from 1941 to 1943. He was in charge of aviation medical research there after the tragic death of Sir Frederick Banting. Professor Bazett was an authority on problems of temperature control and blood circulation. He was himself the subject for much of the detailed work he did on human physiology. When he was studying the control of temperature in relation to changes in the peripheral vessels he often affixed a number of thermocouples to his own arm, each of them being attached to a different galvanometer. He contributed the section on circulation to *Macleod's Physiology in Modern Medicine* in 1938 for the eighth edition and in 1941 for a later edition. He had acted as consultant to the Military Planning Division of the Office of the Quartermaster-General in Washington, and in Canada and the United States he served on a number of important wartime committees on physiological problems. In 1944 he was temporarily attached to the Medical Research Council in this country, and he undertook some special duties for the Admiralty, visiting India in this connexion. He was also at the Royal Aircraft Establishment, Farnborough, for a time, again working on some of the aviation problems which had first engaged his attention at the end of the 1914–18 war. He was awarded the C.B.E. in 1946, and other honours and distinctions came his way in the years immediately following the war.



In 1917 he married Miss Dorothy Rufford Livesey, who survives him with one son and one daughter.

J. G. G. writes: May I add a word of personal appreciation of a man whose friendship I valued highly. I first met Cuthbert Bazett during the retreat from Mons in 1914, and remember well the stimulus that his bright, courageous spirit brought to our tired and dispirited field ambulance. Soon after this, during the fighting on the Aisne, our C.O., the late Colonel G. T. K. Maurice, said of him: "Bazett is the most gallant fellow I have ever met." On a later occasion, in the loose fighting near Béthune, he went out on a bicycle, armed only with a whistle, and collected two fully armed Uhlans who had got cut off behind our front line. He seemed entirely fearless, but never reckless, though sometimes, when trying to follow him on horseback or later when driving with him in his baby Morris car, one was tempted to think otherwise. It was characteristic of him that, in spite of his special surgical qualifications, nothing less than an appendicular abscess could dislodge him from the perilous job of battalion M.O. in front of Ypres. Later in that war he did valuable work on the physiology of flying at high altitudes. His main academic work, the application of physiology to clinical problems, found a fitting culmination in the work he did during the last war in Canada, England, and India. During those years his spirit seemed as young and his mind as active as ever, but physically he was older and felt the strain of long journeys and tiring days. Conversation with Bazett was always stimulating. His mind was teeming with fresh ideas which he never seemed to have quite time to express fully. His views on any subject were always original and worth serious consideration even when they were put forward in a witty phrase or two. He was a wise counsellor whose advice was sought by old and young alike, and the complete sincerity of his nature made his friendship specially valued by his younger colleagues. His was an unusual and altogether delightful character.

EDWIN MATTHEW, M.D., F.R.C.P.Ed.

Dr. Edwin Matthew, who died at his home in Edinburgh on July 7, was appointed to the Moncrieff Arnott chair of clinical medicine in the University of Edinburgh in 1935. A native of Aberdeen, he took his M.A. at the university there in 1899, but thereafter his life was spent in Edinburgh.

At the close of a notable undergraduate career, which included a Vans Dunlop Scholarship, Edwin Matthew graduated M.B., C.M. with first-class honours in 1897, obtaining the much-prized Ettles Scholarship, which is awarded to the best student of the year. After qualification he held the posts of house-physician in Edinburgh Royal Infirmary, under Professor Sir Thomas Fraser, and in the Edinburgh Royal Hospital for Sick Children. He proceeded M.D. in 1908 with the added distinction of a gold medal, and in 1906 he had been elected a Fellow of the Royal College of Physicians of Edinburgh. For nearly 20 years he was physician to Leith Hospital and afterwards physician consultant. He became an assistant physician at the Edinburgh Royal Infirmary in 1909, and physician from 1921 to 1934. Then for a further two years he held the Moncrieff Arnott professorship in clinical medicine, in succession to Professor Edwin Bramwell. For several years he was an examiner in medicine in the University of St. Andrews, and for five years from 1933 he was a member of the General Medical Council.

Matthew was a staunch individualist and a strong upholder of the extramural Edinburgh School of Medicine of the Royal Colleges, giving the systematic lectures on medicine for many years. He possessed a singularly acute mind, with an unusual power of rapid mental assimilation. He once said, not in a boastful spirit but rather as deprecating any personal credit for a natural gift, that on reading once his lecture notes as a student, or a chapter in a book, the contents were fixed in his memory. He was a very successful clinician, with a large following of students, who appreciated the clearness and decisiveness of his teaching. His residents and students knew, often gratefully from practical experience, that they could count upon his support at any time, and that he would never "let them down" if he could possibly avoid it. He was emphatic that every physician should maintain a wide knowledge of general medicine. He was especially interested in the problems of kidney disease and of hypertension, and he inspired the work of many of his assistants in these directions. Matthew had a large private consulting practice in spite of, or perhaps to some extent because of, a dictatorial manner, for his patients recognized his excellence as a physician and his character as a man. He was responsible for numerous acts of generosity, which he tried, often successfully, to conceal.

He is survived by a widow, a daughter, and two sons, one of whom is also a physician.

Dr. JAMES CARSLAW, of Glasgow, died on April 14. For some years he had been living in semi-retirement, though many friends and colleagues still sought his opinion from time to time on particularly obscure cases. Dr. Carslaw was born in 1868, the third son of the late Rev. W. H. Carslaw. He was educated at Larchfield School, Helensburgh, and at Glasgow Academy. At the University of Glasgow he had an exceptional career, graduating M.A. and M.B., C.M. with honours in 1892. He spent a year in the Western Infirmary as a resident, first with Sir William Gairdner and then with Sir Hector Cameron. Thereafter he went to Paisley as assistant to the late Dr. Fraser. Soon, however, his clinical and teaching abilities were recognized by Sir William Gairdner, then regius professor of medicine, and he made Carslaw one of his assistants at the University and in his wards at the Western Infirmary. On Sir William's retirement he became assistant to Professor Ralph Stockman and worked with him until he was given wards of his own in succession to Dr. William McLennan. In the 1914–18 war Dr. Carslaw served as a captain, R.A.M.C., attached to the Scottish General Hospital at Stobhill. In the 1939–45 war he gave help to a number of medical boards, and it was characteristic of the man that he returned to teach at the Western Infirmary where the staff had been much depleted. His mental activity and acute clinical acumen and judgment were greatly admired by all who worked with him then. Tall, and invariably immaculately dressed, Dr. Carslaw had a commanding presence and striking personality. The first impression of austerity was quickly dispelled by his keen yet kindly sense of humour. Painstaking and intensely thorough in all that he did, he demanded a high standard from his staff. He showed an infinite capacity for kindness and generosity to all under his care which endeared him to his colleagues and made him beloved by his patients. Dr. Carslaw's eminence was largely due to his profound knowledge of the art of clinical medicine; a knowledge which he had acquired from his long experience with Sir William Gairdner and from his own acute observation and wide reading. His reputation spread far beyond Scotland, and for many years he was responsible for the organization of postgraduate medical study in Glasgow. He did not write much for the journals, but what he did write was always based on most careful clinical studies. His chief interests lay in disorders of the liver and spleen and of the blood. From his association with Professor Stockman could be traced his great interest in, and knowledge of, the rheumatic diseases. In speech he was slow but to the point, and the

Association of Physicians of Great Britain and Ireland always listened with close attention whenever he spoke. He was a fine physician, and learned in the older and now almost unused medical languages—Latin and Greek. His use and pronunciation of these languages was meticulous, as his staff soon learnt. He belonged to an age of culture which developed the use of the fingers, ears, and eyes to the highest levels of skill; which observed, learned, and thought, and built up a tradition much to be honoured. His widow survives him, and to her and their family the sympathy of all his friends will be extended.—D. S. S.

Dr. HENRY GEORGE BIDDLE, of Stradbroke, Diss, Norfolk, died at his home on June 7 at the age of 83. Dr. Biddle was typical of the old school of family doctor, a beloved friend to his patients and to his colleagues, a genial personality who will always be remembered with affection. Belonging to a family of doctors, he was the son of Dr. Henry Cooper Biddle, of Edmonton. He was educated at Charterhouse and Guy's Hospital, where he qualified in 1892. Before going to Stradbroke in 1913 he was in practice at Broadstairs, and was medical officer to the Whittuck Convalescent Home for Children. He had been a member of the British Medical Association for many years, and in 1922 he was chairman of the South Suffolk Division. Outside his work, lawn tennis was a life-long interest, and first as player and later as an official he was a familiar figure at Suffolk tournaments and county meetings.—W. P. G.

Mr. GEORGE MUNN GRAY, who died in London on June 16, was one of the most distinguished medical men who have ever practised in Nigeria. A graduate of Glasgow University in 1904, he proceeded M.D. in 1909 and took the F.R.C.S. two years later. Soon after joining the West African medical staff he was posted to Southern Nigeria. After serving for two terms there he returned and went into private practice in Lagos, then the capital of Southern Nigeria, where he built a hospital. Gray's success was immediate, and he built up a large practice as his reputation spread throughout Nigeria and the adjoining territories. After the 1914–18 war he took a partner, Mr. Aitken, who unfortunately lost his life whilst bathing in the surf at Lagos about 1930. Gray and Aitken were both skilled and successful surgeons, and the Government of Nigeria recognized this by appointing them consultants and later by taking over the private hospital Gray founded, now known as the Creek Hospital, Lagos. Mr. Gray left Nigeria shortly before the outbreak of war in 1939.

E. C. B. writes: Not only was Gray a most skilled surgeon who will long be remembered by a very large number of grateful patients, including the writer, he was also a most generous and lovable man, and he had hosts of friends in Nigeria and elsewhere. He was a prominent freemason and held high office, being Grand Master of Nigeria at one time. We mourn the loss of a truly great man.

Dr. EDWARD LOUIS VINCENT FITCH, of Cleator Moor, Cumberland, lost his life in a boating accident on June 17. A student of University College, London, and Liverpool University, he took the conjoint diploma in 1938 and was for a time casualty officer at the Royal Infirmary, Preston. Subsequently he was a medical officer with the Friends' Relief Service and with Unrra.

J. S. writes: Dr. Louis Fitch was one of a party bird-watching in a small boat on June 17, when an engine failure led to shipwreck and disaster. Dr. Fitch was able to get ashore, but returned to the boat to rescue others and then lost his life. His manner of dying was in the character of his living. As a practitioner he worked ceaselessly and devoted all his great energy to a people still suffering from the after-effects of pre-war poverty, unemployment, and social neglect. It is gratifying to be able to record that his patients had quickly learned to appreciate and love their new doctor, for Fitch had only been in Cumberland some two or three years. He was a man of wide interests and deep culture: music, literature, and the natural sciences all had their place in his busy life. As a friend he was a great stimulus to all who knew him. Our profession has lost a man who was one of its ornaments, and we, his friends, have suffered a bitter loss.

Dr. WILLIAM HENRY O'GRADY, of Louisburgh, County Mayo, died on June 22 at the age of 66. He was the son of the late William and Mrs. O'Grady of Louisburgh, and he was educated at St. Jarlath's College, Tuam, and Prior Park, Bath. A student at University College, Dublin, and at Edinburgh, he qualified in 1914. He went to Louisburgh as medical officer of health, a post which he held until his death. In addition he was medical officer of health of Clare Island until a year ago. In 1915 he was decorated by the Danish Government for the help and assistance he gave to Danish seamen on Clare Island.

D. F. McC. and C. B. O'H. write: Seldom have we known a man so universally loved and respected as Dr. O'Grady. He was held in the highest esteem by colleagues and patients. He never spoke an unkind word of anybody, and his kindness and charity were unbounded. He was known far beyond the confines of his district, and we all enjoyed his hospitality, his kindly humour, and his fund of anecdotes. On many occasions he risked his life to attend to Clare Island patients in rough seas and gales, though he made little of the risk involved. His chief hobby was his work, but he was also keenly interested in fishing and gardening. He is survived by his wife and his only daughter, to both of whom we offer our sympathy. He was a doctor of the old school, and one whom it will be impossible to replace.

Dr. HENRY JAMES THOMSON, who died suddenly when on holiday at Spey Bay on July 4, was a student at Aberdeen University. He graduated M.B., Ch.B. in 1910, proceeding M.D. in 1924, and took the M.R.C.O.G. in 1933. Soon after qualifying, Dr. Thomson acted as house-surgeon to the late Professor Stevenson. In 1918 he was appointed child-welfare officer to the County of Lanark, the first appointment of this character in Scotland. In the following year an obstetrical service was established in the county, and Dr. Thomson became physician superintendent of this service, a position he held until his death. At the outset the prospects of success were not encouraging, and only six patients were confined in the hospital at Bellshill during the first year. As time went on, however, the women in the area realized how much skilful attention was being offered them, and the numbers increased until over 2,000 confinements a year were conducted at Bellshill alone, while another 1,000 maternity cases were admitted to associated hospitals. The success of this department of public health was due to the foresight and unflagging interest which Dr. Thomson took in the work of the institutions with which he was associated. The welfare of the patients and the nursing staff was his constant consideration. He displayed remarkable judgment in estimating the essential requirements of a rapidly expanding maternity service. He realized that many patients were at a serious disadvantage when they lived in remote parts of the county, and consequently in the year 1932 he instituted a "flying squad" service, this being a pioneer effort in Scotland. By this form of domiciliary treatment he succeeded in further reducing maternal mortality, especially in cases of eclampsia. At the same time Dr. Thomson arranged to supply to practitioners and midwives for the modest sum of 5s. a sterilized obstetrical outfit which was soon being used by everyone engaged in obstetrical practice throughout the county. Dr. Thomson was an able administrator, and he had an extensive knowledge of practical obstetrics. He was called upon, over a period of many years, to deal with the management of the emergencies of midwifery practice. In treating these cases he exercised sound judgment and skilful manipulation. Even when the hospital had attained such proportions that the resident and visiting staff had greatly increased, he continued to take an interest in the clinical work. His death will be mourned by many nurses and house-surgeons, who received from him a training in the essentials of obstetrics that has proved invaluable in practice. The sympathy of his colleagues and friends will be extended to his wife, son, and daughter in their sad loss.—S. J. C.

Medical Notes in Parliament

MEDICAL BILL IN COMMITTEE

The Committee stage of the Medical Bill was begun in the House of Commons on July 14, and when the discussion was adjourned at the end of the sitting the fifteenth of the 36 clauses was under examination and the bulk of the work had been done.

Clause 1 was agreed to, and on Clause 2 Sir HUGH LUCAS-TOOTH moved an amendment to secure that no order should be made requiring a period of intern service as a prerequisite to full registration until the order had been approved by resolutions of both Houses of Parliament.

Mr. ANEURIN BEVAN, Minister of Health, said he would make the orders subject to affirmative resolution by Parliament, instead of using the negative procedure, by moving an amendment at the Report stage.

Mr. BEVAN moved an amendment to subsection (4) providing that

> where, during any period of employment in an approved hospital or institution, an applicant who has been engaged in medicine has also been engaged in surgery or midwifery or both, or an applicant who has been engaged in surgery has also been engaged in midwifery, the period should be apportioned by the body granting the qualifying diploma.

He said that as the clause stood it provided for the way in which a doctor was to have his period of intern service divided into so much time on medicine and surgery, or medicine, surgery, and midwifery. It made no provision for the doctor who engaged in work which combined only medicine and midwifery or surgery and midwifery. The amendment ensured that the same arrangement should operate in all four cases. The difficulty was that it could not be said that the intern was having proper experience if most of it was confined to one specialty, and it was necessary that there should be a proper division of time over the whole of the work in order that he might take full advantage of the intern service. This was the reason they attached such great importance to the inspection of hospitals where the intern service was given. It was essential that the intern's experience should be spread as far as possible and not confined to a group of beds dedicated to only one specialty.

The amendment was agreed to.

Mr. SOMERVILLE HASTINGS moved a new subsection:

> Where physical disability renders an appointment in surgery or midwifery impossible the Council may accept an equivalent period of satisfactory service in medicine or in a health centre in lieu thereof.

Mr. BEVAN said he was prepared to accept this in principle, and it was accordingly withdrawn.

In the general discussion on the Clause, Commander A. H. P. NOBLE expressed anxiety about those whose medical studies had been interrupted by war service and who might otherwise have qualified before the Bill came into force. They were keen to get into practice as soon as possible, and were worried that they might now be held up by an unexpected period in hospital.

Provision for Opting Out

Dr. BARNET STROSS agreed that present-day students were a little disturbed, and he hoped the Minister would give them an opportunity of opting out of this provision. Apart from that, students were being offered full employment at what he hoped would be a suitable rate of remuneration. But he felt it important to remember that not all medical students were alike, and where a man was going into a sister profession, such as physiology, and not intending to practise, he should not have to register fully. Further, it was not possible to get an actual definition of "satisfactory service," and the individual should have a right of appeal against a decision that his service was not satisfactory. Teachers were human beings, and sometimes showed favouritism or bias, and there should be some safeguard for the man who had done his full year.

Mr. H. N. LINSTEAD said that the Minister must make his intentions clear to the profession to remove present misunderstandings.

Dr. A. D. D. BROUGHTON pointed out that the British Medical Students' Association desired that all present medical students should be exempted from the provisions of Clause 1 and Clause 2. He thought this unnecessary, but there should be some right of appeal.

Dr. H. B. W. MORGAN said the grant of a right of appeal to all medical students who were alleged not to have rendered satisfactory service during their intern year was a necessary safeguard so that the student might have the opportunity of answering the case against him. Further, there were not likely to be sufficient hospitals into which these men could go. He asked if they were to be kept waiting for an appointment.

Mr. I. MACLEOD said that when the period of intern service started there would be a wastage for one year at least of general practitioners entering the National Health Service, and he wondered if we could afford this wastage. It might be expedient for a limited period to allow doctors who had completed their training to go into under-doctored areas, or as assistants to group practices—although he admitted the disadvantages of such a course. The question of salaries was extremely important, and there was some anxiety about it. The Goodenough Committee recommended that free board and lodging and something between £75 and £100 should be paid. In terms of the value of money to-day that might be £150 to £200. Even that was considerably below the amount paid to someone holding a house appointment. Nothing would do more to remove uneasiness than a clear statement about salaries. He endorsed the suggestion that those at present engaged in medical training should not have this extra year put on to them.

Mr. SOMERVILLE HASTINGS, as one who had spent the greater part of his life training house-surgeons, said there would be very few cases in which a surgeon or physician in charge would feel justified in saying that a man's service was unsatisfactory, and if the right of appeal were agreed to there would be even fewer. One must remember that if the right of appeal were granted the chief would be put into the witness-box, presumably, and asked all sorts of questions about his house-surgeon, and possibly even submitted to an action for libel. He could remember only one case in which the service of a house-surgeon was really unsatisfactory. He thought the right step would be to let the house-surgeon have another try at another hospital. Even if a house-surgeon had fallen down once, that was not sufficient to prevent his becoming a registered medical practitioner. He hoped that this point would be left as vague as possible, and that it would be for the medical or surgical chief to say whether the service was satisfactory.

Keeping an Even Balance

Mr. BEVAN, replying to the debate, said he would at the outset try to get rid of the idea that the Minister of Health was here accepting responsibility for the content and management of medical education. He was not. That was still being entrusted in part to the Privy Council and in part to the medical corporations, all of them acting jointly, and especially in regard to inspection in later parts of the Bill.

It was necessary to keep an even balance between the legitimate affairs of the medical student and the requirements of the public. In the House of Commons they were the trustees of the public, and their duty was not to let loose upon the community what might be regarded as under-educated doctors, nor to protect individual doctors from what might appear to be hardship. On the other hand, implementing the Goodenough proposals did mean that the State intervened and altered the plans that the private individual made for himself when he intended to go in for medical training. Therefore they must try to mitigate the hardship as much as possible, and see that the arrangements made bore as little harshly upon the citizen as was consistent with the public interest.

In the first place this was not going to be sprung upon the student immediately. It would take between one and two years to make these arrangements, because it would be quite improper for the State to say that a doctor could not be fully registered and enter into general practice unless he had an intern year

in an approved establishment if they had failed to provide such a place for him. They could not fix the period when this would start to operate until they had reviewed the establishments and made these posts available.

They must also see that the hardship was mitigated as much as possible on the financial side. It was therefore proposed to create posts carrying £350 a year for the first six months and £400 a year for the second six months, with a deduction of £100 for board and lodging. He thought the House would agree that those were fairly generous sums.

In reply to a question by Sir HUGH LUCAS-TOOTH, Mr. BEVAN said that there would be no marriage allowances; but he could assure Dr. CHARLES HILL that doctors provisionally registered would be employees of the hospital, and their term of service in the National Health Service would therefore date for superannuation purposes from the beginning of the internship.

Continuing, he said that some people had questioned whether it was fair to a person who had made his plans on one assumption to add another year. But they must start at some point if they were to carry out the recommendations of the Goodenough Committee. The suggestion that they should begin with the student coming in meant that the scheme would not come into full operation for seven or eight years. That was going too far. He hoped he would not be pressed to give concessions on grounds of hardship. Why should the House send out into general practice one who was less well trained than they thought he ought to be? When the date fell, it should fall on all medical students, otherwise some would go through life with a black mark. It would not be wise to invite the medical student, because of some temporary embarrassment, to handicap himself by not having the benefit of the one year.

There was a good deal of anxiety about the "satisfactory service." He was informed that it was similar to the signing of certificates now required to show satisfactory attendance at courses of instruction before a student could sit for an examination. These certificates covered conduct as well as attendance. They represented the opinions of all the people under whom the student had worked. Similarly, certificates of satisfaction would reflect a number of opinions, and there should be no possibility of victimization by a single individual on personal grounds. The certificate itself was given by the licensing body—the medical corporation immediately concerned. There could be no possibility of a superintendent of a hospital who might have developed a "grouch" against an intern reporting on him unsatisfactorily, because he would surely have the collective opinions of all with whom the provisional doctor had worked in the whole of the year. He hoped therefore that he would not be pressed to give a right of appeal. With whom could an appeal lodge? They could not have an appeal against a board of examiners.

When a person reached this stage he was provisionally registered. The intention was not to put up another hoop through which he had to jump; the intention was to give him a year's experience in association with specialists and with a diverse kind of hospital work, so that when he went out into the world he would be a better craftsman. It was intended to be the consummation, as it were, of his general medical training.

Mr. I. J. PITMAN asked if it would be possible for an intern who got an unsatisfactory report to seek another post at which he could have a second year.

Mr. BEVAN replied that there was no reason at all why not. He also said that he could not see how the arrangement for this coming into operation at different times at different places could be made to work, or how it was going to operate with reference to reciprocity with Eire. The present intention was to bring it into operation everywhere at once. The power to vary the period was merely for the purpose of emergency.

In answer to Surgeon Lieutenant-Commander BENNETT, who mentioned the "deviationists" who went into biochemistry and other things, Mr. BEVAN said they could not possibly exempt such men from the intern year because they did not want to practise clinically. They could not frame an Act which would put such people in suspense. They must come down on one side or the other, otherwise they might have some who did and some who did not intend to go into clinical practice, and some who did not but might.

Employment in Health Centres

On Clause 3, in the course of discussion of an amendment moved by Mr. SOMERVILLE HASTINGS but later withdrawn, Mr. BEVAN said that he had accepted with considerable misgivings the provision (inserted in the House of Lords) by which the intern year could be spent in a health centre. It was the hope, though they must keep some sense of proportion about it, that subsequently most general practitioners would be engaged in group practice and would be operating from a building which might be described as a health centre. But health centres could be variously defined. Some of them might merely be associations of general practitioners, and the intention of the Bill was to give the provisionally registered man a year's experience of hospital medicine and not of group general practice. On the other hand there might also be big polyclinic centres in which there was a considerable variety of diagnostic facilities alongside maternity and child-welfare centres, dental and ophthalmic services, and the whole range of personal medical services outside the hospitals. It might be possible to find a health centre of that sort as a place where the year of intern service could be served. But there were none of them at the moment, and it would be a very long time before the country had them, if it ever did. He was extremely doubtful about this proposal, and he hoped that when these institutions came to be approved it would be done with extreme frugality.

The Clause, and Clause 4, relating to the experience required for holders of Commonwealth or foreign diplomas, was agreed to.

Registration

Mr. BEVAN moved on Clause 5 a series of amendments designed to facilitate provisional registration and subsequent consolidation by altering the nomenclature: the amendments were agreed to.

Mr. SOMERVILLE HASTINGS moved to insert the following new subsection:

> A person provisionally registered under this Act shall have all the duties and privileges of a registered medical practitioner but only while serving in an approved hospital or institution as defined in Section 1.

He urged that it should be made clear what a provisionally registered doctor could do. While this man was serving in hospital he should have the full powers and duties of a medical practitioner, particularly in ordering dangerous drugs and in signing death certificates.

Dr. CHARLES HILL emphasized that the intern year must be regarded as an essential part of medical education. To equate the provisionally registered with the permanently registered man, merely leaving an interval of time to pass between them, seemed to suggest that the standard of registration was reached with provisional registration and that the final year was a kind of burden or testing-time imposed by the State. He doubted whether they would be in a position to decide what privileges should go with provisional registration until they saw how the additional year worked.

Mr. BEVAN agreed that unless they were exceedingly careful the intern year would lose its status as the final equipment of the general practitioner. For the purposes of his intern year the man was a fully qualified doctor, but outside it he could not act as a fully qualified practitioner.

The amendment was withdrawn.

In the discussion on the clause as a whole, Dr. CHARLES HILL drew attention to the point that, as it was worded, after passing his examinations the individual was first required to apply for and obtain a post before he could seek provisional registration.

Mr. BEVAN agreed that, especially in the case of a man going in for research and not clinical practice, there was some substance in the argument that his future rights needed some protection. The man ought to be able to complete his training at some future period if he so wished. He would look into the matter to see if this would be covered.

Relations with Ireland

On Clause 6 an amendment was moved by Mr. BEVAN, and agreed to, extending to the Republic of Ireland the same provisions that had been made in respect of health centres in England and Wales.

Surgeon Lieutenant-Commander R. F. B. BENNETT asked for an assurance that the Republic of Ireland would be altering its medical curriculum in step with ours, so that the Clause might have full application.

Mr. A. BLENKINSOP, Parliamentary Secretary to the Ministry of Health, said he understood that was the position. Answering other questions, he said the assumption was—and they had an undertaking that this would in fact be carried out—that there would be provisional registration in Ireland as it would be provided here.

Dr. BARNET STROSS moved amendments to include on the General Medical Council two elected Irish representatives, one resident in the Republic of Ireland and one in Northern Ireland. Dr. A. D. D. BROUGHTON supported the amendments.

Mr. I. MACLEOD opposed the amendments, stating that there was already one representative of the whole of Ireland, and almost the only other example of such agreement was in their rugby football team, which they selected jointly.

Mr. BLENKINSOP said it had always been the case that Ireland had been a unity in respect of medical education. The Republic of Ireland was fully satisfied with the present arrangement.

The amendments were withdrawn, and the Clause agreed to.

Disciplinary Committee of the G.M.C.

On Clause 13, by which it is proposed to transfer the functions of the Council or a Branch Council under Sections 26 and 29 of the Medical Act, 1858, to the newly constituted Medical Disciplinary Committee, Dr. H. B. W. MORGAN moved an amendment, which was negatived, to replace the Disciplinary Committee by a Penal Cases Committee. The G.M.C. should not have powers of discipline and be able to try a man and ruin his career, but, he said, should merely investigate penal cases to discover whether there was a prima facie case to answer.

Dr. CHARLES HILL said that on the contrary the recasting of the disciplinary machinery, and the establishment of a smaller body than the General Medical Council for this purpose, were among the most important parts of the Bill, and should be left untouched. When Dr. MORGAN accused him of speaking against a committee of his own organization he replied that he was expressing the views he held, however they might conflict with those of anybody else, and in his opinion the structure under which the penal cases committee sorted out the complaints against the practitioners, and in addition to which there was a separate body which heard the cases, represented a considerable advance in the technique and methods of the General Medical Council.

In the general discussion on the clause, Mr. J. HAY urged that it was inappropriate that the decisions of the committee, which might result in the barring of a practitioner from carrying out the duties of his profession, should be majority decisions of the members present. The law required the unanimous verdict of 12 people, and it was wrong in his view that a person should be debarred from his profession by a mere majority vote.

Mr. BEVAN said that if the principle of unanimity were introduced, and one person disagreed, the committee could not do its work of protecting the public. If the majority of a man's peers considered him guilty, the principle of unanimity would mean that one person could deny the protection the public ought to have. That tilted the whole balance the other way. He thought the individual was adequately protected. The clause was agreed to.

G.M.C. and Cases with no Complainant

Dr. CHARLES HILL moved to insert the following new subsection:

> For securing that no complaint or information investigated by the Penal Cases Subcommittee, other than a decision in a court of law, shall be referred to the Committee for adjudication unless the circumstances upon which such complaint or information is founded shall have been verified by statutory declaration of the person making the same, or, where such complaint is made or such information submitted by any public department, authority, or other body, by statutory declaration of an officer of such public department, authority, or other body, duly authorized for the purpose.

He said that his purpose was to secure that the almost uniform practice of the G.M.C., that there must be a statement by the complainant, became the uniform practice. He said "almost uniform" because there had grown up in recent years a habit on the part of Government departments, including the Ministry of Health, of not complaining but of sending the papers along in the hope that the G.M.C. might do something about it. All he wanted to secure was that, whether the complainant was an individual body or a Government department, there was a complainant, and that there was a formal complaint which went on to the G.M.C.

Mr. BEVAN said the suggestion meant, for example, that the disciplinary tribunal under the National Health Service could not call the attention of the G.M.C. to evidence placed before it unless it itself made a complaint. That was an exceedingly dangerous thing to suggest. It meant that the disciplinary committee of the Council would be an arbitrator between the doctor and a Government department. It did not follow that the Ministry of Health should come to a conclusion about a doctor at all. It merely meant that, in the exercise of the administrative duties placed upon it by the health statutes, the tribunal had brought to light evidence that would appear, on the surface, to be evidence that the G.M.C. should see in order to make up its mind whether or not it should consider putting its disciplinary machinery into motion. That was reasonable protection for the public.

The National Health Service was concerned with the contractual obligations of a general practitioner, and not with his status as a doctor; that was the concern of the G.M.C. The Minister ought not to be asked to load the case against the general practitioner by so formalizing it as to investigate, for example, a charge of drunkenness arising out of evidence given during a complaint to an executive council, assembling all the papers and evidence, and thus becoming an accuser of the practitioner before the G.M.C. Once they asked a Government department to formalize evidence against a general practitioner they were discriminating against the practitioner in a most dangerous way.

The amendment was still under discussion when the sitting ended, and the proceedings were adjourned until July 21.

Work for Epileptics

Mr. SOMERVILLE HASTINGS asked the Minister of Labour on July 4 what provision he had made for the employment of manual and clerical workers who suffered from epilepsy but were otherwise capable of taking their normal part in industry.

Mr. GEORGE ISAACS replied that sufferers from epilepsy could readily get advice and guidance from disablement resettlement officers, who had been able by special approach to employers to place a considerable number in suitable employment. He added that, to assist in this work, explanatory notes about epilepsy had been issued to employers by the Ministry. A number of the more severe cases had been placed in employment under sheltered conditions in Remploy factories.

B.C.G. Vaccination

Dr. CHARLES HILL asked the Minister of Health on July 6 how many local health authorities were in possession of adequate supplies of B.C.G.; and whether he was satisfied that this method of prevention was being made available on an adequate scale and as rapidly as the paramount necessity of preventing tuberculosis demanded.

Mr. ANEURIN BEVAN replied that 116 out of 145 authorities in England and Wales had so far had arrangements approved for B.C.G. vaccination at the discretion of chest physicians; the vaccine was received as needed, since it could not be stored.

Domiciliary Treatment of Tuberculosis

Dr. CHARLES HILL also asked the Minister whether he would instruct regional hospital boards to arrange for the home treatment of tuberculous patients, for whom there were no sanatorium beds vacant, by making available to them in their homes the services of chest specialists, portable *x*-ray facilities, and any other facilities necessary for adequate and continuous treatment.

Mr. ANEURIN BEVAN said that it was part of the normal work of the boards' chest specialists, with the resources of the hospital service available to them, to take part in the home treatment of tuberculosis patients.

Dr. HILL then pointed out that in only relatively few areas were the resources of the tuberculosis services made available in the homes. Tuberculosis was five times as common among contacts as among the population, and this was an urgent national situation, not only for the sufferers from tuberculosis but for their families as contacts.

Mr. BEVAN said he was well aware of this, and in the next few weeks instructions would be issued dealing with these points (see also *Journal*, July 15, p. 162).

Disinfectants

Dr. CHARLES HILL also asked the Minister of Health on July 6 if he would consult the Medical Research Council with a view to taking steps to ensure that disinfectants produced by manufacturers satisfied minimum standards of efficacy.

Mr. BEVAN replied that he was already in touch with the Medical Research Council, but it was a very difficult and technical subject, and although this matter had now been pursued for nearly five years no standards had yet been achieved.

Clinical Assistantships for G.P.s

Mr. READER HARRIS asked the Minister of Health on July 6 if he was aware that regional hospital boards had not yet begun to offer clinical assistantships to general practitioners, and what action he proposed taking.

Mr. BEVAN said that appointments of this kind had been offered where the needs of the service demanded it.

Mr. SOMERVILLE HASTINGS asked if the Minister realized how important it was from everybody's point of view to keep general practitioners in close contact with their local hospital.

Mr. BEVAN said he was very well aware of that, and part of the difficulty was to try to bring about a reconciliation between the conflicting claims of the G.P. on the one hand and the specialist on the other.

Distinction Awards

Colonel M. STODDART-SCOTT asked the Minister of Health on July 6 how long the committee which dealt with merit awards for medical consultants had been sitting, how many times it had met, who was its chairman, and the salary or fee he had been paid.

Mr. BEVAN replied that the committee was appointed on December 23, 1948. It had held 24 meetings, with Lord Moran of Manton as its chairman. He had received 3,000 guineas for the first year's service, and would receive 2,500 guineas for the second year.

The Services

A Supplement to the *London Gazette* has announced the following awards:

"4 Clasps" to Territorial Efficiency Decoration.—Major (Honorary Colonel) J. C. Alexander, T.D., R.A.M.C.

"3 Clasps" to Territorial Efficiency Decoration.—Colonel J. L. Hamilton, M.C., T.D., late R.A.M.C.

"1st Clasp" to Territorial Efficiency Decoration.—Majors J. Cohen, T.D., and J. B. Mackay, T.D., R.A.M.C.

Territorial Efficiency Decoration and 1st Clasp.—Major (Temporary Lieutenant-Colonel) E. A. Cormack, and Majors R. A. P. Gray and C. H. Imrie, R.A.M.C.

Territorial Efficiency Decoration.—Major (Honorary Lieutenant-Colonel) R. E. Norrish and Major J. B. Schofield, R.A.M.C.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

In Congregation on June 21 the degree of D.Sc. was conferred on Geoffrey Wingfield Harris, M.D.

Professor Homer Smith, of New York University, will deliver a lecture on "Development of Modern Renal Physiology" in the Physiological Laboratory theatre on Monday, July 24, at 5 p.m. The lecture is open without fee to all members of the University.

The following appointments, all from October 1, are announced: *Reader in Clinical Psychology*, D. Russell-Davis, M.D. *University Lecturers in Anatomy*, J. W. Millen, M.D., H. Butler, M.B., B.Chir., and M. Harty, M.B., B.Ch. *University Demonstrators in Anatomy*, W. M. Keynes, M.B., B.Chir., J. D. Lever, M.B., B.Chir., D. Bulmer, M.B., B.Chir., and W. J. St. E. G. Rhys, M.B., B.S.

UNIVERSITY OF GLASGOW

The following degrees were conferred on July 8:

M.D.—[1]L. R. C. Agnew, R. D. C. Brackenridge, [2]*J. C. P. Logan*, D. L. Mackenzie, [1]J. H. Ramage, [1]J. MacK. Sutherland, [3]T. Symington.

CH.M.—R. A. R. Taylor.

M.B., CH.B.—James Adam (Troon), James Adam (Blairgowrie), Elizabeth J. F. Anderson, J. Anderson, T. Anderson, F. A. Arcari, Margaret S. Baillie, W. H. Bain, Mary M. S. Bannatyne, J. Barker, J. R. Barr, T. B. Begg, J. I. Bennet, W. P. Black, N. J. *Blacklock*, I. A. Boyd, Jessie M. McM. Boyd, R. J. I. Boyd, J. P. Boyle, M. T. D. Braide, E. Brookes, W. C. Brown, J. C. Bryce, Isabella R. Buchanan, H. Budge, T. Burnet, J. L. Cameron, D. A. F. Campbell, J. B. Campbell, Margaret R. Campbell, F. J. Cherington, J. A. Clark, Elizabeth J. Coulter, Winifred Coutts, Ann C. Coyle, A. P. Crawley, Margaret W. Devlin, Evelyn J. W. Dobson, W. P. Duguid, A. Edgar, R. F. Edington, B. D. *Fairgrieve*, W. *Ferguson*, A. G. Findlay, F. B. Findlay, I. W. Fingland, W. L. Flanagan, J. G. Fraser, Diana M. Game, I. A. M. Gibb, W. M. Gilmour, Ellen W. Givens, C. Gold, D. P. Gourlay, A. C. Gow, P. A. Graham, A. D. Hally, Katherine M. Harvey, Margaret T. Harvey, J. W. D. Henderson, R. V. Henderson, Eileen E. Hill, Ruby D. McI. Holms, C. C. Hosie, Dorothy W. Hunter, D. C. Hutchison, A. E. Ikomi, Hazel E. Jackson, J. Jamieson, Constance M. Jarvie, B. A. Johnson, H. B. Kennedy, Joyce C. Ker, Elaine H. M. Kerr, Mary C. W. Kerr, W. Lang, Mary R. Lindsay, N. H. Logan, E. O. Lundholm, Helen S. McArdle, Katherine M. McArthur, Mary H. McArthur, J. A. C. MacAuley, Helen M. M. McCallum, I. S. Macdonald, Jessie Macdonald, Margaret M. Macdonald, A. I. Macdougall, Norma M. C. A. McFarlane, T. Macfarlane, D. D. Macfie, Margaret R. MacD. *McGilvary*, D. D. R. *McInroy*, J. Macintyre, K. S. Mackenzie, J. A. McKinnon, W. P. Maclay, Margaret E. Maclean, I. S. McLeish, Elizabeth J. *McLelland*, Aileen C. McMillan, J. McNeill, Mary R. Mactaggart, J. MacVicar, Agnes J. H. McWilliam, Agnes J. H. Malcolm, J. G. Mann, J. P. Masterton, I. D. Melville, R. S. Miller, J. G. Mone, J. D. Murchison, Margaret R. H. Murray, J. W. Nudelman, J. Patterson, R. T. Pettigrew, R. Pringle, E. G. Ramsay, A. M. Rankin, J. P. Reid, T. M. Rein, H. Richmond, A. R. Robertson, I. P. C. Robertson, L. D. S. Rogen, A. A. Schwarz, J. S. Scott, D. A. *Seaton*, D. Sherret, Janet A. Sinclair (neé Kilpatrick), A. C. Smith, G. L. Smith, R. G. Sommerville, D. McD. Sproull, J. H. Stewart, W. N. Stirling, H. M. Strathern, N. W. Struthers, Audrey J. C. Symons, A. M. Thomson, J. Thomson, J. R. Thomson, J. Torley, Julia Torrance, J. D. Tripney, Dorothy M. B. Ward, W. C. Watson, A. W. G. Weir, Jessie M. R. Weir, A. W. O. Williams, R. E. D. Williams, G. Wilson, Helen C. Wright, W. B. *Wright*, R. *O. Wynn*, L. W. McK. Yelland, A. B. Young, N. Young.

[1]With high commendation. [2]With commendation. [3]With honours.

UNIVERSITY OF EDINBURGH

On July 6 the honorary degree of LL.D. was conferred on Professor Robert William Johnstone, Professor Emeritus of Midwifery and Diseases of Women in the University, Honorary Consultant in Obstetrics and Gynaecology to the Royal Infirmary, Edinburgh, and Consultant Adviser in Obstetrics to the Department of Health for Scotland.

UNIVERSITY OF DUBLIN

SCHOOL OF PHYSIC, TRINITY COLLEGE

Frederick Stanley Stewart, M.D., M.R.C.P.I., has been appointed to the Chair of Bacteriology and Preventive Medicine in succession to Professor J. W. Bigger, who retires at the end of September.

Dr. Stewart graduated M.B., B.Ch., B.A.O. at the University of Dublin in 1942 and proceeded M.D. two years later. In 1946 he took the M.R.C.P.I. For seven years he has been Assistant and Lecturer in *Bacteriology* at Trinity College and has published papers on Rh immunization and on the antigenic modification of red cells by periodate.

The following medical degrees, etc., were conferred on July 5:

M.D.—L. A. Kerwood, D. E. Mellon.

M.CH.—D. S. Quill.

M.A.O.—M. T. S. Conradie, H. FitzGibbon, M. Ll. McCauley.

M.B., B.CH., B.A.O.—J. N. Adair, R. A. L. Agnew, T. M. Bamford, Reva Berstock, Germaine H. Boland (formerly Ross), K. F. X. *Bourke*, Doris B. Brownell, S. H. Buchalter, A. M. Cantor, G. Caplin, Anne L. J. Cusack, P. A. H. Davis, K. K. O. Bentsi-Enchill, Renee A. Fleury, Jane C. Gatliff, M. J. H. Hamilton, Mabel M. H. Hodgins, D. A. A. Lane, Sylvia Lath, Phyllis M. Lee, C. D. Levis, J. W. Lewis, W. C. McCord, F. J. McHugh, J. C. McLean, Helen P. Manning, E. A. Martin, R. Nelson, Hilary G. Orr, H. Parsons, Pauline M. Poole, Elinor D. U. Powell, J. A. N. Poynton, V. P. O'Sullivan Quinn, Anna I. Roberts, W. B. Seale, A. A. Sweeney, Annie M. G. Troughton, Mildred Vilensky, Margaret P. Wallace.

LICENCE IN MEDICINE, SURGERY, AND OBSTETRIC SCIENCE.—D. Miller.

UNIVERSITY OF DURHAM

George Algernon Smart, M.D., M.R.C.P., lecturer in medicine in the University of Bristol, has been appointed to the Readership in Medicine at Newcastle.

UNIVERSITY OF LONDON

Professor A. A. Moncrieff has been appointed representative of the University at the sixth International Congress of Paediatrics to be held at Zurich from July 24 to 28.

The following have been appointed, or nominated for appointment or reappointment, as representatives of the University on the governing bodies indicated in parentheses: Dr. R. A. Willis (Royal Cancer Hospital); Professor J. M. Mackintosh (Council of Management, Slough Industrial Health Service, Ltd.); Dr. C. E. Newman (West London Hospital Medical School).

The list of approved institutions for the purposes of the M.D. and M.S. degrees under the revised regulations will be as follows: Charing Cross Hospital and Medical School; Guy's Hospital and Medical School; King's College Hospital and Medical School; London Hospital and Medical College; Middlesex Hospital and Medical School; Royal Dental Hospital of London and School of Dental Surgery; Royal Free Hospital and School of Medicine; St. Bartholomew's Hospital and Medical College; St. George's Hospital and Medical School; St. Mary's Hospital and Medical School; St. Thomas's Hospital and Medical School; University College Hospital and Medical School; Westminster Hospital and Medical School; Hammersmith Hospital and the Postgraduate Medical School of London.

The appointments of house-physician and deputy resident medical officer at St. James's Hospital, Leeds, have been approved for the purposes of the M.D. examination, Branch I.

The Netherne Hospital, Coulsdon, Surrey, and the Belmont Hospital, Sutton, Surrey, have been added to the list of recognized mental hospitals for the M.B., B.S. degrees.

The following candidates have been approved at the examination indicated:

ACADEMIC POSTGRADUATE DIPLOMA IN MEDICAL RADIOLOGY (DIAGNOSIS).—*Part I:* A. K. Banerji, P. Purcell, H. Ward.

The following candidates at the London School of Hygiene and Tropical Medicine have been approved at the examination indicated:

ACADEMIC POSTGRADUATE DIPLOMA IN BACTERIOLOGY.—J. D. Abbott, B. E. Andrews, S. M. H. Bokhari, Naomi Datta, A. D. Evans, C. R. Knappett, G. L. Le Bouvier, Elinor W. McCloy, J. P. P. Mackey, G. B. B. White.

ACADEMIC POSTGRADUATE DIPLOMA IN PUBLIC HEALTH.—K. J. Adams, A. S. Beadel, *H. E. A. Carson, H. D. Conway, P. R. Cooper, D. Crichton, C. C. Draper, J. J. Duffy, *M. Gelfand, F. C. Griggs, Ll. F. Gunaratna, F. J. Ingham, S. I. Kadama, Doreen Landreth-Smith, *M. M. Lewis, Low Chin Seang, Muriel J. Lowe, *R. W. McConnachie, Alison D. McDonald, R. Malan, F. W. Mount, K. C. D. Perera, W. S. Perera, H. T. Phillips, Eileen M. Ring, Lore M. Schulte-Frohlinde, W. D. L. Smith *G. H. Stuart, Ping-Ming Teng, D. A. Thamotheram, J. D. Tonkinson, W. C. Turner, J. M. Urquhart, *P. A. M. van de Linde, P. H. Vernon, J. L. Walsh, F. L. Wheaton, W. A. Young.

*Awarded a Mark of Distinction.

UNIVERSITY OF MANCHESTER

The following candidates have been approved at the examinations indicated:

M.D.—H. J. Beard, D. L. Chadwick (with commendation), H. Lempert, Helen E. Smith, A. B. White.

FINAL M.B., CH.B.—*Old Regulations:* R. M. Ashton, H. G. Fleetwood, Jean M. Halliwell, G. M. Ingall, G. Jessup, B. P. Jones, Margot Nelken, A. Noar. *New Regulations:* B. L. Alexander, R. D. Atherton, W. de C. Baker, Flora M. Bisset-Smith (distinction in surgery), S. M. Broman, P. Burgess, Muriel D. Carr, Barbara M. Couldwell, E. J. Epstein, J. D. Evans, M. C. Flasher, M. Fox, G. Garrett, F. G. Hardman, B. Higgins, S. G. Jeffs, W. Kerns, P. B. Lees, B. J. Leonard, M. A. Lerner, W. H. Lyle, Maria R. Mackay (with honours and distinction in surgery), Nancy Parkin, R. Price, G. V. Purnell, K. L. Purnell, J. Robinson, Dora M. J. Rosbotham, R. Schofield, S. Shubert, Beatrice M. Swift, Hazel W. Symon, G. M. Watson, Sheila M. E. West, A. M. Womack.

DIPLOMA IN PSYCHOLOGICAL MEDICINE.—*Part I:* L. G. Nicol, T. P. Smith.

UNIVERSITY OF LIVERPOOL

The following candidates have been approved at the examinations indicated:

M.D.—A. Ansell, K. Dumbell, T. R. Littler, R. Marcus, P. W. Robertson, G. D. Scarrow.

PH.D.—*In the Faculty of Medicine:* Margaret E. Hayward.

M.RAD.—*Part II (Old Regulations):* J. Ainsworth, Constance M. Davis, G. J. M. Teunon.

M.B., CH.B.—[1] [2]Kathleen Byrne, [1] [2]B. L. Evans, [1] [3]J. P. Stanfield, Rosie Ali, Barbara E. Batty, F. H. Beddow, J. J. Cameron, D. H. Carr, Sheila R. Clarke, S. W. J. Coventry, W. K. Cowan, J. L. Donovan, Joan M. Duncan, Sheila H. E. Fairweather, A. K. Frazer, Lavinia Freeborough, J. N. Gaskell, [4]P. H. Grace, [2]Winifred J. A. Graham, D. R. W. Haddock, Kathleen E. C. Hamilton, Muriel Henshall, Betty E. Hodgkinson, Doreen Jacobs, H. M. Johnson, G. Jones, C. R. Kay, Mimi Keidan, Margery J. King, K. M. Loebenstein, Eileen P. McLeavey, A. C. Macartney, W. Melrose, Jean M. Naylor, E. A. Nieman, J. Parkhouse, Brenda M. Price, Jean A. Raffle, T. D. Reilly, H. Riad, Joan Richardson, Mona V. Rivlin, Blodwen E. J. Roberts, Hilary G. Rubin, Gwendoline D. Salter, R. W. Saul, Beryl M. Sheffield, H. A. D. Shirlaw, R. Steinberg, June Stevenson, J. S. V. Surman, J. Thompson, E. Toke, H. Wilson.

D.P.H.—L. N. Gould, A. Haji Alias, J. T. O'Sullivan, H. N. Singh, L. S. Stephens.

[1]With second-class honours. [2]With distinction in surgery. [3]With distinction in obstetrics and gynaecology.

UNIVERSITY OF SHEFFIELD

At a meeting of the University Council held on July 7 Charles Scott Russell, M.B., Ch.B.Ed., F.R.C.S.Ed., M.R.C.O.G., was appointed to the newly created full-time Chair of Obstetrics and Gynaecology in the University of Sheffield. In 1946 Mr. Russell was appointed Assistant Director in the Department of Obstetrics and Gynaecology of the University of Manchester and resident obstetrician and gynaecologist at St. Mary's Hospitals and in 1949 became Reader in Obstetrics and Gynaecology. Other appointments were made as follows: *Lecturer in Medicine*, W. Whitaker, M.D., M.R.C.P. *Assistant Lecturer in Physiology*, R. Crampton, M.B., Ch.B. *Part-time Lecturer and Clinical Teacher in Chest Diseases*, C. S. Darke, M.D., M.R.C.P. *Part-time Lecturer and Clinical Teacher in Venereal Diseases*, D. J. Campbell, F.R.C.P.Ed., D.P.H.

UNIVERSITY OF BRISTOL

The following candidates have been approved at the examinations indicated:

FINAL M.B., CH.B.—[1]R. J. Ancill, [1] [2]W. A. W. Dutton, [1] [2]M. D. Turner, P. J. D. Benjafield, H. J. Bland, [4]Margaret H. Buston, E. R. Duchesne, F. V. Eastman, Doreen A. Ellis, C. C. Ewing, Z. Fluss, J. C. Gregg, R. Hill, E. A. W. Houghton, G. A. K. M'C. Jahans, Megan, D. M. Johnson, [3]H. I. Leigh, G. Lucas, Jean M. Menzies, G. W. B. Peel, [3]Barbara M. Philpott, L. P. Spence, L. A. D. Tovey, Joan Walker. *Passed in Group II only:* C. E. Dickson, H. Maxwell.

DIPLOMA IN PUBLIC HEALTH *(Part II)*.—A. J. Board, E. L. Fawssett.

DIPLOMA IN PSYCHOLOGICAL MEDICINE *(Part II)*.—M. W. Annear, J. A. Bickford, R. M. Ellison.

[1]With second-class honours. [3]With distinction in obstetrics. [4]With distinction in public health. [4]With distinction in child health.

ROYAL COLLEGE OF SURGEONS IN IRELAND

The following received the Fellowship of the College on July 7:

J. D. Cunningham, J. Conroy, D. J. F. Devane, T. J. Mills, J. P. O'Neill, A. T. S. Paul, D. L. Robinson.

No. 26

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended July 1.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.
Figures of Births and Deaths, and of Deaths recorded under each Infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.
A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1950 (a)	(b)	(c)	(d)	(e)	1949 (Corresponding Week) (a)	(b)	(c)	(d)	(e)

Stillbirths	186	19	22			193	26	29		
Rate per 1,000 total births (including stillborn)			24					28		

* Measles is not notifiable in Scotland, and the returns are therefore an approximation only.
† Deaths from measles and scarlet fever for England and Wales, London (administrative county), will no longer be published.
‡ Includes primary form for England and Wales, London (administrative county), and Northern Ireland.
§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales, London (administrative county), are combined.
‖ Includes puerperal fever for England and Wales and Eire.
¶ Primary pneumonia no longer notifiable in Eire.

EPIDEMIOLOGICAL NOTES

Food-poisoning at Horden

The outbreak of food-poisoning at Horden was briefly reported in these columns last week (July 15, p. 174). At 11 p.m. on Sunday, July 9, the medical officer of health of Easington R.D.C., to whom we are indebted for this information, was told by the senior partner in a practice of five doctors in the village of Horden that a large number of patients had been seen during the week-end complaining of symptoms which were suggestive of food-poisoning. The doctors concerned thought that the food responsible was probably some pork.

Early on Monday, July 10, the whole of the senior sanitary inspector's staff was put to work on the investigation. A rapid survey of 15 households, in which there were 28 patients, showed that the doctors' suspicions were probably correct, and that the vehicle of infection was pork which had been eaten in the form of sandwiches, sausages, pies, pigs' cheek, and also used as an ingredient of pease-pudding. A visit was immediately paid to the butcher's shop by the senior sanitary inspector, who was unfortunately unable to obtain even a fragment of the cooked meat but was able to secure the remainder of the suspected carcass. Portions of this carcass were immediately dispatched to the Public Health Laboratory, Newcastle-upon-Tyne, for bacteriological examination. During the Monday afternoon one specimen of faeces and one specimen of vomit from patients were also sent to the same laboratory. Further specimens were sent on Tuesday. By that afternoon Dr. R. Norton, the bacteriologist, had obtained colonies of organisms, both from the suspected pig carcass and from the faeces and vomit of two patients, which he thought were probably of the salmonella group. On the morning of Wednesday, July 12, he was able to state that these organisms were salmonella and probably of the Newport type. This has since been confirmed. Detailed investigation suggested that the number of persons involved in the outbreak was between 450 and 500. The infected pork in its various forms was on sale throughout Friday and Saturday, July 7 and 8, and the first cases appeared to have been taken ill about midday on Saturday. The interval between consuming the infected food and the onset of symptoms varied considerably, being from 18 to 96 hours.

The predominant symptoms were headache, severe generalized pains, shivering, and sweating, together with pyrexia, followed by vomiting, diarrhoea, and colicky abdominal pains. The duration of the attack also varied, some patients recovering fairly rapidly and returning to work on the morning of Thursday, July 13, while in others the illness lasted several days. Five patients were admitted to the Sunderland Infectious Diseases Hospital.

Subsequent investigation into the history of the infected pig carcass showed that it was received into the Ministry of Food slaughterhouse at Station Town, Wingate, on July 3 as a dressed carcass of sow pig unaccompanied by pluck, stomach, or intestines. The carcass was that of a well-nourished animal, was well bled, and was free of any visible abnormality in the musculature. Lymph glands and serous membranes were normal, but it was observed that the kidneys were paler than usual and there was some superficial scarring of the teats. The carcass had set well, and in the absence of any positive evidence of disease the kidneys and scarred belly tissues were removed and the carcass passed for human consumption. It was then delivered to the butcher the following day.

Between July 4 and 6 he prepared a mould of pig cheek and a quantity of pork pies and pease-pudding, the latter being enriched by pork stock. Approximately 40 lb. of pork sausage was made from one loin, and the two shoulders were boned, boiled, and finally baked for sale in the form of sandwiches. The remainder of the carcass, which involved one loin and both legs, was reserved for manufacture and sale the following week and was in a refrigerator on the premises at the time of the inspector's first visit on July 10.

Later inquiries revealed that the pig had been bought by a local pig-keeper six months previously for breeding purposes. Following the birth of a litter on June 13 the pig suckled its young for two weeks and then gradually went off its food. A veterinary surgeon brought in by the pig-keeper at this stage suspected intestinal obstruction, but in the absence of any appreciable improvement in the animal's condition the owner decided to slaughter it, and on the afternoon of Saturday, July 1, this was done by a local slaughterman, who personally examined the intestines in detail in an effort to trace the suspected obstruction. Under the mistaken impression that the pluck, stomach, and intestines were of no value the owner buried them. According to the statement of the owner, the slaughterman who killed and dressed the animal, and the veterinary surgeon who previously treated it and who saw the carcass, were satisfied that apart from some enlargement of the liver the pluck and intestines were normal in all respects.

All the nine specimens of stools from patients sent to the laboratory on Tuesday, July 11, were reported to be positive, as were also the stools from the five members of the butcher's family and staff. Every member of the latter, with the exception of the butcher himself, had eaten some portion of the infected pork. The positive result from the butcher himself is not easy to explain, but in view of the fact that he handled both the infected carcass and the products therefrom it seems likely that he infected himself from them. At present it is thought that the origin of the outbreak was the infected pig carcass rather than any contamination by a carrier. Further bacteriological investigations, however, are still being carried out on the remains of the pig carcass.

Poliomyelitis

The numbers of notifications of poliomyelitis in the week ended July 8 were: paralytic cases 139 (124), non-paralytic cases 73 (36). Figures for the previous week are given in parentheses. Although the total increase is a considerable one —from 160 to 212—it is largely due to the doubling of the notifications of non-paralytic cases. This suggests that practitioners are being particularly vigilant at the present time. The highest incidence is still in the Midlands, although the figures for Warwickshire have declined a little. The principal increases were in Worcestershire, London, and Lancashire.

Discussion of Table

In *England and Wales* there were increases in the notifications of whooping-cough 174, scarlet fever 112, dysentery 49, and acute poliomyelitis 18; the only decrease of any size was in the incidence of measles 168.

The largest falls in the incidence of measles were Kent 117, Warwickshire 104, Durham 103, and Middlesex 92; the largest rises were Yorkshire West Riding 105 and Lancashire 90. The south-eastern counties, with an increase of 56 notifications, accounted for half the increase in the incidence of scarlet fever. The largest increase in the notifications of whooping-cough was Northumberland 36. There was very little variation in the local returns of diphtheria.

The largest returns of dysentery were Yorkshire West Riding 74 (Bradford C.B. 30, Shipley U.D. 16, Sheffield C.B. 8); Lancashire 48 (Preston C.B. 18, Oldham C.B. 6, Liverpool C.B. 6); Staffordshire 26 (Coseley U.D. 13, Smethwick C.B. 6, Bilston M.B. 6); Durham 23 (Stanley U.D. 13); Surrey 11 (Croydon C.B. 8); and Yorkshire East Riding 10 (Kingston-upon-Hull C.B. 10). The largest outbreak of food-poisoning during the week was in Staffordshire, Wednesbury M.B., where there were 120 notifications.

The largest rise in the notifications of acute poliomyelitis was Staffordshire 9. The largest returns were Warwickshire 47 (Birmingham C.B. 41); Staffordshire 18 (Rowley Regis M.B. 9, Sedgley U.D. 3); London 13 (St. Pancras 3, Woolwich 3); Worcestershire 11 (Halesowen M.B. 5); and Lancashire 11 (Liverpool C.B. 3). Apart from these centres the largest notifications came from Sussex, Brighton C.B. 4, and Middlesex, Uxbridge U.D. 3.

In *Scotland* there were decreases in the notifications of measles 151, whooping-cough 33, and dysentery 15, with increases in the incidence of acute primary pneumonia 35 and acute poliomyelitis 10. The largest returns of dysentery were Glasgow 65, Edinburgh 13, and Dundee 11; each of these cities, in contrast to the trend for the country, showed a slight increase in incidence. The chief feature of the returns for diphtheria was a rise of 8 in Glasgow; only one case was notified in this city in the preceding week. Of the 47 cases of poliomyelitis 27 were notified in Glasgow, 12 more than in the previous week.

In *Eire* a rise of 14 in the notifications of whooping-cough was the largest fluctuation in the trends of infectious diseases. This increase was contributed by the country districts; in Dublin C.B. a decrease of 11 was reported.

In *Northern Ireland* a fall of 17 in the notifications of measles was the only variation of any size in the returns of infectious diseases. This decrease occurred mainly in Belfast C.B. Of the 10 cases of poliomyelitis 8 were notified in Belfast C.B., an increase of 2 over the preceding week.

Week Ending July 8

Notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,031, whooping-cough 3,934, diphtheria 63, measles 8,955, acute pneumonia 281, acute poliomyelitis 212, dysentery 278, paratyphoid fever 15, typhoid fever 2.

Medical News

International Congress of Ophthalmology

The Duke of Gloucester opened the sixteenth International Congress of Ophthalmology in London on July 17, and scientific and social meetings were held throughout the week. Sir Stewart Duke-Elder presided at the opening ceremony, which was attended by over 1,000 ophthalmic surgeons from all over the world. The Gonin Medal, which is awarded at each congress to the individual considered by the International Council of Ophthalmology to have made the greatest contribution to ophthalmology, was presented to Dr. H. Arruga, of Barcelona. Demonstrations of eye operation by television were given by surgeons at Moorfields Eye Hospital. Delegates to the congress made good use of B.M.A. House, where the Great Hall was available as a lounge and social centre. The President and Council of the B.M.A. gave a reception for the delegates on July 19. A report of the scientific meetings will appear in a later issue.

International Federation of Physical Medicine

At a meeting recently held in London it was decided to constitute the International Federation of Physical Medicine. The objects of this body are to promote on an international basis the study and practice of physical medicine, the term being used in the widest sense, and to hold international conferences in this subject. An interim committee was appointed as follows: chairman, Dr. Frank Krusen (Mayo Clinic, U.S.A.); vice-chairman, Dr. Svend Clemmesen (Copenhagen); honorary secretary, Dr. Philippe Bauwens (London); other members: Dr. W. S. Tegner (London) and Dr. Hugh Burt (London). The temporary headquarters of the federation will be in London (c/o The British Association of Physical Medicine, 45, Lincoln's Inn Fields, London, W.C.2), and it is hoped to hold the first congress of the federation in London in July, 1952.

British Surgeon in Turin

At a meeting of the Società Piemontese di Chirurgia on June 24, Mr. W. Alexander Law, of the London Hospital, spoke on "Athroplasty of the Hip" and "Spinal Osteotomy," and operated in the surgical clinic of the University of Turin.

London County Medical Society

There will be no clinical meeting of the London County Medical Society during August. An announcement will be made giving full details of the next clinical meeting.

Smallpox Research Grant

Dr. C. W. Dixon has been awarded a Leverhulme Research Fellowship to study the epidemiology of smallpox and the control of variola minor. Dr. Dixon is lecturer and chief assistant in the department of preventive medicine and public health, Leeds University.

Wills

Major-General Sir Charles Gordon Gordon-Watson, K.B.E., C.M.G., formerly consulting surgeon to St. Bartholomew's Hospital, left £34,122. He left £100 each to St. Bartholomew's Hospital, St. Mark's Hospital, the British Empire Cancer Campaign, the Research Department of the Royal College of Surgeons of England, and the Royal Medical Benevolent Fund. Sir Thomas Houston, of Belfast, the well-known bacteriologist, who left £40,831, bequeathed £1,000 to Queen's University, Belfast, to be used under the direction of the Medical Faculty of the University, and £1,000 to the Royal Victoria Hospital, Belfast, to be devoted to the equipment and furnishing of the laboratory at the Institute of Pathology there. Mr. Herbert Ernest Batten, formerly consulting orthopaedic surgeon to Charing Cross Hospital, left £16,267; Dr. Ludford Cooper, formerly of Rochester, Kent, £34,918, bequeathing £1,000 to St. Bartholomew's Hospital, Rochester; Dr. Robert Walpole Murphy, of Middleton-in-Teesdale, Durham, £15,119; and Dr. John Lawson Dods-Brown, of Wisbech, Cambridgeshire, £6,431.

COMING EVENTS

Banting Memorial Lecture

Dr. Maurice Krahl, of St. Louis, U.S.A., will deliver the Banting Memorial Lecture at the Medical School, University of Birmingham, on Friday, July 28, at 11 a.m. His subject is "Hormonal Regulation of Glucose Utilization by Tissues."

Medico-Legal Society

The Annual General Meeting of the Medico-Legal Society will be held at 26, Portland Place, London, W., on Thursday, July 27, at 8 p.m., when Dr. R. Sessions Hodge will read a paper on "The Hormone Treatment of the Sexual Offender."

Harben Lectures

Sir Leonard G. Parsons, F.R.S., will deliver the Harben Lectures, on "Studies on Child Health," at the Royal Institute of Public Health and Hygiene, 28, Portland Place, London, W., on Monday, Tuesday, and Wednesday, December 11, 12, and 13, at 4.30 p.m. Admission is free, without ticket, but those who wish to attend the lectures should notify the secretary of the institute at the above address.

Refresher Course in Tuberculosis

The Tuberculosis Educational Institute (Tavistock House North, Tavistock Square, London, W.C.) has arranged a refresher course in the pathology and immunology of tuberculosis to be held at the Sir William Dunn School of Pathology, Oxford, on September 19, 20, 21, and 22. The programme is as follows: September 19, 10 a.m., inaugural address by Dr. A. Q. Wells; 10.15 a.m., Dr. W. T. U. Pagel, "Primary Infection—Immunological and Pathological Responses"; 11.45 a.m., Dr. J. W. Clegg, "Superinfection and Reinfection—Pathological Aspects"; 2.30 p.m., Dr. J. W. Crofton, "The Theoretical Basis of Chemotherapy in Tuberculosis." September 20, 10 a.m., Dr. D. Barron Cruickshank, "The Tubercle Bacillus—Clinical Bacteriology and Methods of Demonstration"; 11.45 a.m., Dr. M. Stacey, D.Sc., "The Tubercle Bacillus—Chemical Structure"; 2.30 p.m., Dr. S. Roodhouse Gloyne, "Morbid Anatomy and Bacteriology of Apparently Healed Cavities." September 21, 10 a.m., Dr. V. H. Springett, "Superinfection and Reinfection—Clinical Aspects"; 11.45 a.m., Dr. J. A. H. Wylie, "Relationship of the Reticuloses to Tuberculosis"; 2.30 p.m., Dr. Honor Smith, "Some Effects of Intrathecal Tuberculin in the Streptomycin Treatment of Meningitis"; September 22, 10 a.m., Dr. A. Q. Wells, "Vaccination in Tuberculosis and its Problems—Pathological Aspects"; 11.45 a.m., Dr. I. Mills Hall, "Vaccination in Tuberculosis and its Problems—Clinical Aspects"; 2.30 p.m., Dr. C. M. Fletcher, "Lung Changes Due to Inhalation of Dust." The fee for the course is £5 5s. and for accommodation £4. Remittances should be sent to the secretary of the institute at the above address.

Congress of Cardiology

An International Congress of Cardiology will be held in Paris on September 3–9 under the patronage of the President of the French Republic. It is being organized by the Société Française de Cardiologie on the initiative of the International Committee of Cardiology. Full information may be obtained from the secretary, 19, Rue Hautefeuille, Paris, 6e.

SOCIETIES AND LECTURES

A fee is charged or a ticket is required for attending lectures marked ●. Application should be made first to the institution concerned.

Monday

CAMBRIDGE UNIVERSITY.—At Physiological Laboratory Theatre, Cambridge, July 24, 5 p.m., "*Development of Modern Renal Physiology*," by Professor Homer Smith (New York).

Friday

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES, 11, Chandos Street, Cavendish Square, London, W.—July 28, 7.30 p.m., 29th annual general meeting. "*Random Reflections*," Presidential address by Dr. Robert Lees.

APPOINTMENTS

CULLEN, S. V., M.B., Ch.B., School Medical Officer, Isle of Man.

LEWIS, J. K., M.B., Ch.B., D.A., Consultant Anaesthetist, West Cornwall Clinical Area.

MEREDITH, DAVID ERYL, M.D., M.R.C.P., Consultant Physician to the Clwyd and Deeside Hospitals, North Wales.

NORMAN, A. P., M.B.E., M.D., M.R.C.P., D.C.H., Visiting Physician to Hospital for Sick Children, Great Ormond Street, London, W.C., and Deputy Director of the Institute of Child Health.

ROBSON, T. W., M.B., Ch.B., D.P.H., Medical Officer of Health and School Medical Officer, County Borough of Dewsbury.

SUTHERLAND, MARY, M.R.C.S., L.R.C.P., Orthopaedic Registrar, York County and City Hospital.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Bury.—On July 13, 1950, at The London Hospital, to Sylvia, wife of Dr. J. D. Bury, a son.

Copp.—On July 6, 1950, at Brighton, to Peggy, wife of Dr. T. A. Copp, a daughter.

Crossfield.—On June 1, 1950, at 1015, 7th Avenue West, Calgary, Alberta, Canada, to Isobel, wife of P. O. Crossfield, M.D., M.R.C.P., D.C.H., a daughter—Fiona June.

Elliman.—On July 5, 1950, at St. David's Wing, Royal Northern Hospital, to Hazel (formerly Brown), wife of Dr. H. Elliman, M.D., a daughter.

Hart.—On July 11, 1950, at Westminster Hospital, to Maureen (formerly Tully), wife of Dr. Frank Dudley Hart, a son.

MARRIAGE

Arthurton—Edmonds.—On July 15, 1950, at Banstead, Malcolm William Arthurton, M.R.C.P., to Evelyn Florence Edmonds.

DEATHS

Bazett.—On July 12, 1950, Henry Cuthbert Bazett, C.B.E., M.C., M.D., F.R.C.S., of Philadelphia, U.S.A., aged 65.

Bone.—On July 9, 1950, at Four Winds, Frimley Green, Surrey, Elizabeth Honor Bone, M.D., formerly of 86, Porchester Terrace, London, W.

Dawson.—On July 9, 1950, at Rayleigh, Essex, Reginald Branch Dawson, M.R.C.S., L.R.C.P., late of Leigh-on-Sea.

Dixon.—On June 6, 1950, at Lindo Wing, St. Mary's Hospital, Paddington, London, W., Joyce Dixon, M.B., B.S., aged 28.

Hainsworth.—On July 14, 1950, John William Hainsworth, M.B., Ch.B., of Newcastle-upon-Tyne, late of Greengates, Bradford, aged 83.

Ham.—On July 2, 1950, at Coventry, Constance Irene Ham, M.D., F.R.C.S.Ed.

Hutson.—On March 29, 1950, at Pine Hill, St. Michael, Barbados, B.W.I., Sir John Hutson, O.B.E., V.D., M.B., C.M., D.P.H., aged 91.

Kerr.—On July 13, 1950, at Ardfenaig, Argyll, Neil Thomson Kerr, M.B., C.M.

Lane.—On July 7, 1950, at The London Hospital, Harold Dunmore Lane, M.C., M.R.C.S., L.R.C.P., of 56, London Road, Twickenham, Middlesex.

McGrenahan.—On July 4, 1950, at 6, Cleveland Road, Wolverhampton, William Patrick McGrenahan, L.R.C.P.&S.Ed., L.R.F.P.S.Glas.

McMurdo.—On July 8, 1950, at Addlestone, Surrey, Fergus William Hamilton McMurdo, M.B., Ch.B.

Matthew.—On July 7, 1950, at 9, Walker Street, Edinburgh, Edwin Matthew, M.D., F.R.C.P.Ed.

Mott.—On July 8, 1950, at 5, Wellington Road, Parkstone, Dorset, Raymond Culver Mott, M.B., B.Ch., aged 73.

Naismith.—On July 8, 1950, Robert Turnbull Easton Naismith, M.B., B.S., of Colne House, Slaithwaite, Yorks, aged 54.

O'Grady.—On June 22, 1950, William Henry O'Grady, L.R.C.P.&S.Ed., L.R.F.P.S.Glas., of Tooreen Lodge, Louisburgh, Co. Mayo, aged 66.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Reactions to Pertussis Vaccine

Q.—*In an annotation on "Pertussis Vaccination and Encephalopathy" (January 14, p. 110) you state, ". . . If the child has had previous convulsions or has any reaction to the first injection attempts at vaccination should be abandoned." What constitutes a reaction? I have used two types of combined diphtheria and pertussis vaccine, and with both a fairly high proportion of the children injected showed one or both of the following reactions within six to twelve hours: (1) local swelling and pain at the site of injection; and (2) pyrexia varying from 100° F. (37.9° C.) to 104° F. (40 C.), usually accompanied by no local reaction. In the child with the temperature of 104° F. this temperature was reached six hours after the first injection and did not return to normal for four days. In none of these cases were any nervous symptoms observed. Is a pyrexial reaction after the first injection a contraindication to further injections? If so, is it safe to continue with diphtheria prophylactic alone?*

A.—Reactions to pertussis vaccine may be either local (swelling and pain at the site of injection) or systemic (some degree of pyrexia with general malaise). Local reactions have been quite rare among the large number of children given plain or alum-precipitated pertussis vaccine in the recent trials in this country. Local reactions have been reported more often with the combined diphtheria and pertussis prophylactic, but this type of reaction can usually be minimized by giving the prophylactic intramuscularly or deep into the subcutaneous tissues. The occurrence of a local reaction would not be regarded as a contraindication to further injections. But there is a risk particularly associated with intramuscular injection of the combined vaccine—the rare occurrence of paralysis in the inoculated limb due to poliomyelitis. It might therefore be wise not to use the available combined diphtheria pertussis vaccines during a period when poliomyelitis is occurring in the district. Although the danger of encephalopathy following injections of pertussis vaccine must be extremely small in Britain, it may not be so negligible in countries where various forms of virus encephalitis are endemic. In any case, it is better to avoid giving injections to an infant with a history of recent convulsions, or when a child is teething or is suspected of incubating an infectious disease. A severe systemic and unexplained reaction to a first injection should be regarded as a contraindication to further combined prophylactic inoculations, but small doses of each reagent could be given separately.

Poliomyelitis and Physical Activity

Q.—*It would appear to be important that the physical activity of a child who has possibly been infected with the poliomyelitis virus should be restricted. Does this consideration also apply to mental activity? As it is practically impossible to achieve either of these objects in a young child, say of 4 years, by ordinary means, can some form of sedation be recommended?*

A.—This is an important question which cannot be answered with great confidence. It has been fully confirmed that physical activity of any kind after the onset of the pre-paralytic (meningitic or major) stage of poliomyelitis is highly dangerous, as it seems to render the spinal cord motor cells more vulnerable to the virus. During the epidemic months for poliomyelitis, therefore, minor illnesses in children should be treated carefully by rest in bed with perhaps ½ gr. (32 mg.) of phenobarbitone twice daily to reduce restlessness. Analgesics should also be prescribed if there is pain in the head, limbs, or spine. As the nerve cells concerned with mental activity are little involved in poliomyelitis, it seems unlikely that mental activity is directly harmful, except that in the child excitement leads to all kinds of spontaneous movements, which should be kept minimal.

Another aspect of this question is concerned with the possibility that severe physical activity in a child without symptoms may convert an abortive infection with the virus into a major or paralytic form of the disease. This is specially important in view of the likelihood that most children are infected with the virus during an epidemic even though very few have a recognizable illness. This question, too, cannot be answered with any confidence, but it seems reasonable to advise the parents to take some trouble to reduce the excessive activities indulged in by many children during summer months. A rest in bed after lunch is good for all young children and can be encouraged by ¼ to ½ gr. (16 to 32 mg.) of phenobarbitone. This may add considerably to the resistance of motor nerve cells to the virus of poliomyelitis.

Treatment of Whitlows

Q.—*What is the approved modern treatment for an early whitlow? At what stage should incision be undertaken?*

A.—If by whitlow is meant felon or the infection of a pulp space by trauma, the treatment consists in the intensive use of the antibiotics combined with suitable incision where necessary. Early drainage is more important here than elsewhere in the finger, as tissue tension rises very quickly in the small fascial compartments of the pulp and leads to early spread either to the interphalangeal joint or to the flexor tendon sheath. Incision therefore should not be delayed, even if full penicillin therapy has been instituted previously, unless the signs of inflammation disappear within 24 to 48 hours. A unilateral incision starting ¼ in. (6 mm.) distal to the terminal interphalangeal joint line and extending up just short of the apex of the pulp affords the best drainage. If free pus is obtained counter drainage from the opposite side and a penicillin gauze wick for two to three days is indicated. A horseshoe incision should be avoided except in cases of obvious disease of the terminal phalanx. Immobilization in slight flexion or a digital plaster slab, the avoidance of moist dressings, and the continuation of penicillin therapy constitute the basis of the after-treatment.

Prophylaxis against Syphilis

Q.—*Some textbooks state that the application of 30% calomel ointment more than two hours after an infective coitus may merely delay the development of a primary sore, and modify it to such an extent that the diagnosis may be missed. Is this true? What is the maximum time that should elapse between coitus and adequate prophylaxis? What is the best method of prophylaxis?*

A.—The application of calomel ointment more than two hours after exposure with a person suffering from infectious syphilis may destroy surface spirochaetes and either prevent the development of a chancre or modify it. Spirochaetes may enter the blood stream and lymphatics within a very short time after surface inoculation (perhaps within an hour) so that late local prophylaxis may kill those on the surface but fail to affect those that have penetrated more deeply; as a result the syphilitic infection may be entirely asymptomatic or signs and symptoms may be delayed considerably. Obviously the earlier local prophylaxis is applied the more effective is it likely to be. At no time is it completely effective, but if applied efficiently and within, say, one hour, it should be effective in a high proportion of cases.

The "best" prophylaxis against syphilis is such treatment as has been proved to cure seronegative primary syphilis in a very high proportion of cases—for example, 4 million units of penicillin. However, much less than this often proves effective, and even 200,000 units to 300,000 units taken by mouth within a few hours has been reported as preventing infection. There is little doubt that thorough washing with soap and water immediately after exposure is very effective, otherwise many syphilologists would acquire infection through their hands.

Unilateral Recurrent Irritation of the Tongue

Q.—*I should be grateful for an indication of the possible causation and treatment of unilateral recurrent irritation of the tongue. The condition has been said to be possibly aphthous ulceration, but few textbooks seem to have much detail on the subject. A careful routine physical examination has not revealed any abnormality and I wonder whether the condition is possibly due to some dietary deficiency.*

A.—Unilateral recurrent ulceration or irritation of the tongue suggests a mechanical cause, possibly in the form of repeated traumata from a denture or a tooth. It would be advisable for the patient's dentist to exclude these possibilities. The sore tongue of nutritional deficiency is usually affected symmetrically. Deficiency of several members of the vitamin-B complex is associated with sore tongue; this symptom has been relieved, in different patients, by nicotinic acid, riboflavin, pantothenic acid, "marmite," and injections of liver extract. Thus, even if the clinical phenomena are not characteristic, it is worth giving treatment by the vitamin-B complex a trial. There are a number of ill-understood conditions in which recurrent ulceration of the mouth and tongue have been noted. The condition is sometimes associated with a cyclical granulocytopenia.

Gin and Benedict's Solution

Q.—*A patient who is a severe diabetic, recently stabilized in hospital, is on the following dosage of insulin taken at 8.15 a.m.: 60 units protamine zinc insulin; 40 units soluble insulin. In spite of this, his urine, tested four times daily, showed, on testing with Benedict's solution, light or heavy green or yellow coloration. He is normally abstemious, but a week ago he was persuaded to take two small gins in the evening. His urine the next day showed no reaction with Benedict's solution. Since then he has taken ½ to 1 oz. (14 to 28 ml.) of gin at midday and at 7 p.m., and tests with Benedict's solution have been completely negative. What is the explanation of this phenomenon?*

A.—In order to offer an explanation more information is required about the level of the blood sugar when sugar was being excreted in the urine before the gin was taken and its level now. It is possible, but unlikely, that the blood sugar is now lower than it was, though alcohol is not known to have this effect. The more likely explanation is that the threshold of the kidney is now higher than it was and sugar is not excreted for this reason. Estimations of the blood sugar should be made now in order to ascertain whether it is above the threshold value of 180 mg. per 100 ml.; if it is, the urine tests are now misleading.

Intravenous Salicylates

Q.—*Is intravenous sodium salicylate useful for rheumatism, myalgia, lumbago, etc.? There is a Chinese preparation of sodium salicylate 5%, sodium iodide 5%, in a 20-ml. solution for intravenous injection, and a similar Indian preparation. Both seem to be better than sodium salicylate mixture by mouth. Would it be harmful to continue these injections, and could they be used, say, in acute rheumatic fever?*

A.—The analgesic effect of salicylates in the symptomatic treatment of the conditions named is undoubted. As salicylates are rapidly absorbed from the jejunum nothing is gained by giving them by injection. Repeated injections of sodium salicylate in the high concentrations mentioned will cause sclerosis of the veins. In the treatment of acute rheumatism an adequate blood concentration of salicylates is achieved by regular four-hourly oral therapy. Gastric irritation can nearly always be avoided by diluting the medicine with water and adding sodium bicarbonate, 10 gr. (0.65 g.) to every 20 gr. (1.3 g.) of sodium salicylate. For the very occasional patient who is unable to tolerate the drug by mouth, 1,000 ml. of a 1% solution can be given by slow intravenous drip infusion. The intravenous administration of such large amounts of fluid to patients with an acute rheumatic infection, however, carries with it the danger of overloading the right side of the heart.

Plasma-cell Myeloma

Q.—*What is the treatment and what is the prognosis in a case of plasma-cell myeloma? This was responsible for a pathological fracture of the femur just over a year ago in an elderly woman. Should stilbamidine be given? Is any vitamin therapy likely to be helpful? What other methods of treatment might be tried?*

A.—Plasma-cell myeloma is, in almost every instance, a diffuse neoplastic disease of the bone marrow. An occasional case of a solitary tumour has been reported. It is assumed that the patient in question has the usual type of multiple myelomatosis referred to in the opening sentence. This disease is always fatal, the average period of survival being between two and three years from the first appearance of symptoms. Vitamins have no effect on the course of the disease; stilbamidine and pentamidine have proved disappointing in most cases although they sometimes relieve pain; antimonials, such as "neostibosan," are no more efficacious. If there is an apparently solitary lesion which has led to pathological fracture and is causing pain, local irradiation is most useful, although giving only symptomatic relief. There is no treatment which favourably influences the progress of the disease.

NOTES AND COMMENTS

Intra-articular Injections for Arthritis.—Dr. LESLIE HARTLEY (Camberley) writes: I was very surprised at the answer in "Any Questions?" (May 13, p. 1156) on intra-articular injections for arthritis, and I was very pleased to see Mr. Grant Waugh's comments (July 1, p. 60). As a patient who has been treated for arthritis by this method, the answers I would give are: (1) The results obtained have been excellent in most cases. (2) The technique for the knee-joint is very simple. An injection of 5 ml. of lactic acid (and not 10 to 20 ml. as suggested in the answer) is given into the knee-joint with a No. 20 needle 2 in. long of the same type as used in ophthalmic surgery for a retrobulbar injection, and it is given with the knee in a flexed position. It is not necessary to inject procaine into the skin or into the synovial membrane, as, with a needle of this type, the procedure is practically painless. Actually, each injection is less painful than the previous one, owing to the beneficial effect of the lactic acid on the synovial membrane. (3) Any case of arthritis is likely to benefit, possibly osteoarthritis coming first. It is of particular value in cases of arthritis of the hip and prevents ankylosis of the joint if given in time, but this injection is difficult and requires the skill of an orthopaedic surgeon. (4) The best mixture to use is lactic acid (*p*H 5.4 to 5.8) with or without procaine 2%. Your answer stated that in practice it was of no value except perhaps as a placebo, but I feel that this technique can hardly be compared with some coloured water in a medicine bottle given to quieten a neurasthenic patient. It is not claimed by Mr. Grant Waugh, who has been the pioneer in this work, that it is a cure for arthritis or that its value is anything except local. On the other hand, there are many patients who have been incapacitated or rendered immobile by an arthritic joint which has not responded to rest, heat, etc., but has recovered either partially or fully after six or more weekly injections of lactic acid. It is quite true that after a year or two it may be necessary to have further injections, but, again, any arthritic patient is grateful for any restoration of function, even if it is only temporary, particularly so in a disease like arthritis where nobody can claim any permanent cure; and this applies to the new cortisone, which must be given daily. Finally, your opinion is not shared by our Continental colleagues—otherwise they would not have invited Mr. Grant Waugh to Paris to lecture and to demonstrate his technique to the Académie Nationale de Médecine.

Correction.—Relying upon what is usually a trustworthy source of information, we stated in error in last week's *Journal* that the honorary degree of LL.D. of the University of Liverpool had been bestowed on Dr. E. A. Gregg and Dr. C. O. Stallybrass. The degree conferred was M.D.

REFLECTIONS ON CRIMINAL CONDUCT AND ITS TREATMENT*

BY

Sir DAVID K. HENDERSON, M.D., F.R.C.P.
Professor of Psychiatry, University of Edinburgh

It has seemed to me that the problem of how best to deal with the sick society which exists in our midst to-day has not been discussed comprehensively by anyone who has already given evidence before the Royal Commission. Punishment by any violent and arbitrary method—for example, hanging or flogging—to be administered fairly should be considered in relation to the medical, social, and economic problems which exist. If this is not done then we merely dispose of and deal with a few "tigers" without influencing the tiger problem as a whole. We know that the human race is loaded with imperfections, and in consequence we are not likely to obtain a better-organized society until we have improved the quality of the people who constitute it.

Our mental hospitals and colonies for the mentally defective are crowded to overflowing, and further provision is an urgent necessity. In addition, however, the amount of mental and emotional unrest and instability in the population is increasing rapidly. This is due to the fact, in part at least, that the poorer stocks are increasing while the healthier stocks are tending to diminish, and in consequence a dysgenic situation has arisen whereby the weakly and those potentially liable to mental and nervous upsets are surviving to a much greater age than was the case previously. Socially, the position is complicated by the fact that so many married women are employed in industry. The wastage turnover is high, and leads to unrest, instability, and irritation not only in the factory but in the home. A state of licence and freedom from restraint exists which previously was not the case. The position is complicated by inadequate housing and by the high divorce and illegitimate rate.

Economically, the high cost of living and the state of uncertainty and insecurity in which people live are, I believe, tending to affect the general position and indirectly are influencing the emotional instability which is so prevalent. I believe that it is only by an improvement of the above-mentioned conditions that we are likely to see a better-ordered society. The violent methods of punishment and retribution which have received such universal approval in legal and public circles have little or no constructive value, and make no contribution towards social reformation. The fundamental problem facing everyone interested in human betterment is the improvement of the quality of the race.

*Memorandum submitted to the Royal Commission on Capital Punishment, and published by permission of the Controller of H.M. Stationery Office.

Disorders of Conduct

My interest and experience in relation to the criminal law dealing with persons accused of murder or other serious offences has extended over many years, and has concerned itself essentially with those who, for one reason or another, have been regarded as nervously or mentally abnormal, or at least where doubt has been cast on their sanity. I believe it is generally agreed, medically, that a transitory or more permanent disturbance of the mental faculties of some type or degree plays a significant part in many forms of criminal conduct—for example, murder, suicide, sexual offences, writing threatening letters, fire-raising, etc. Legal and public opinion, however, in judging such offences is apt to adopt a moralistic rather than a medical code and to be sceptical of the findings of the psychiatrist; in consequence, when a medical opinion is submitted it should be stated in terms which can be easily understood and should deal with the actual facts.

Medical theorizing, especially in the witness-box, is as much to be condemned as the hypothetical questions of the lawyer. The estimation and elucidation of a state of nervous or mental disorder—its nature, its severity, its causation and recoverability—is a matter of the greatest complexity which may require repeated examinations, and preferably a period of skilled psychiatric observation, by both doctors and nurses under far better conditions than at present exist. The reason for that statement is because the signs and symptoms of the disorder are so often entirely subjective, and because neither the cell of the accused nor the prison governor's orderly-room or office provides a neutral enough atmosphere for so serious and skilled an examination. Neither the prisoner nor the examining doctor is entirely at his ease.

During the past fifty years our medical knowledge in relation to the various types and categories of nervous and mental illness has been greatly extended, and methods of treatment have been introduced which effect recoveries which border on the miraculous—for example, in syphilitic disorders of the nervous system, pellagra, states of exhaustion and anoxaemia, profound depressive, delusional, and obsessional states. Gaps in our knowledge still exist, but

as our methods of investigation become better defined those gaps should gradually be bridged over, and the how and why of conduct disorder associated with an involvement of the mental faculties may become more fully understood.

One of our great difficulties is that in nervous or mental cases we cannot, except rarely, point to any specific causation as in the case of physical illness. We require to content ourselves with saying that the personality of the individual has become twisted or distorted as the result of a constellation of factors involving the development or lack of development of instinct, hereditary or genetic factors, environmental surroundings, or perhaps more personal matters of a physical or emotional nature. We never can divorce the offence from the life history of the individual. The setting or background in which the crime occurs is an important part of the total picture.

Even with all those points in mind, however, it may still prove extremely difficult to say where sanity ends and insanity begins. The dividing-line is narrow. Sanity and insanity are essentially legal terms which have never been accurately defined. There are many sane persons whose conduct is extremely eccentric and foreign to social custom, whereas there are many technically insane persons whose conduct may never lead them into any serious trouble. In such circumstances we must continue to try to approximate medical and legal opinion, so that, in combination, we can do what is best for the welfare of the individual, whether that involves treatment or punishment.

The legal outlook, in my opinion, is too greatly dominated by an intellectualistic and moralistic point of view, by the concept of reason and free will, and by lack of appreciation of the fact that conduct is motivated by instinctive drives which operate at a much less conscious level. On the other hand, it may be argued that the medical point of view is too liberal-minded, concerns itself too greatly with the individual, and does not fully appreciate its duty to society. But yet it is only by realizing that individualization is the dominant truth of modern medical science, whether applied to disease or to crime, that we look forward more hopefully to the future. The large army of recidivists is the best answer to the arbitrary-sentence methods at present in vogue.

The above general statements may now be applied to the groups of persons with whom I have been particularly concerned : (*a*) those of unsound mind ; (*b*) mental defectives ; (*c*) psychopathic states (character anomalies) ; and (*d*) psychoneuroses.

Persons of Unsound Mind

I am one of those who believe that in cases involving a capital charge the plea of mental disorder in bar of trial or sentence is submitted too frequently. Such a defence is to be deplored in those cases in which there is no special redeeming feature, and when the defence of insanity is really a plea *ad misericordiam* rather than anything else. Doctors and lawyers are equally to blame : doctors because they are too much influenced by sympathy and theory ; lawyers because they have been educated to present every case in as favourable a light as possible. In cases of a less serious type the plea of mental disorder is not submitted often enough, largely because the accused would prefer to serve a defined prison sentence than undergo prolonged treatment in a mental hospital. The danger of such a situation is self-evident, because it is just those cases which merely swell the ranks of the recidivists. Furthermore, it is rare for criminal conduct to be the first sign or indication of mental disorder. The mentally disordered criminal is a person who for years, or months, or weeks beforehand may have given evidence of his mental abnormality, and in numerous cases medical advice may have been sought beforehand. When this has been so it constitutes strong presumptive evidence of the bona fides of the case.

In British courts the method in use of testing the truth of the plea of mental disorder allows both the prosecution and the defence to submit independent medical evidence. There is much to be said in favour of such procedure ; it helps to maintain the liberty and independence of the subject, and as a rule it operates with fairness. Unfortunately in some cases it leads to unseemly wrangling, to a clash of medical opinion, and to a consequent lack of confidence on the part of the public. It was the desire to obviate that state of affairs which led, many years ago, to the introduction of the Briggs Law of Massachusetts. The court appoints a panel of experts to submit a report on the state of mind of the accused, and that report is accessible both to the prosecution and to the defence. It is a method which is worthy of careful consideration. If the panel should fail to agree, then the case goes forward to trial on its merits irrespective of whatever medical evidence there may be.

The M'Naghten Rules

It is cases of psychosis or unsoundness of mind which come into the ambit of the M'Naghten rules. The M'Naghten case is so well known, and the rules have been so fully discussed, that no useful purpose would be served by again considering them in detail. I may, however, be allowed to make certain observations and suggestions. In their day and time the formulation of the M'Naghten rules constituted a definite advance in legal thought and practice ; they set a standard, and they were more or less in conformity with medical knowledge. Now the position has been greatly altered. The M'Naghten rules are no longer in harmony with medical knowledge, and, furthermore, judges themselves vary widely in their interpretation of the rules. This position is greatly to be deplored, because it leads to irritation, which in an indirect way may be vented on the prisoner at the bar. The only way I see of getting round this is by improving the professional training of both the lawyer and the doctor and by the development of medico-legal societies.

In my opinion it is impossible to define degrees of unsoundness of mind—one person is not necessarily more mad than another—but there are many different forms of mental disorder, all of which equally should exonerate a person from a charge of criminal conduct—for example, melancholia, schizophrenia, paranoid states, general paralysis, senile dementia, epilepsy with insanity, and many others. In many of the above cases the individual's mind is sufficiently clear to know what he is doing, but at the same time the true significance of his conduct is not appreciated in relation either to himself or to others. Persons who are proved to be insane in a medical sense are, in my opinion, not legally responsible for the crime which they may commit. I would agree with Lord Justice Clerk Inglis when he said : "In a strictly legal sense there is no insane criminal. Concede insanity and the homicidal act is not criminal. The act of the insane, which in the sane would be criminal, lacks every element of crime."

On the above evidence I believe the M'Naghten rules have introduced a rigid categorizing which may appeal to certain types of mind, but they make the position too academic, and in some respects too easy, so that full effect

is not given to the very special and individual aspects which are present in every case. For instance, most people can understand what is meant by the "nature" of the act, but the "quality" of it can be defined either as synonymous with the physical quality or with the broader concept of "significance." The mentally disordered in many cases realize the physical quality of the act, but they never do realize the full significance of their criminal conduct.

The further moralistic issue of "right and wrong" is hardly ever applicable. In cases in which such a serious issue as capital punishment is involved there is surely little place for rules and formulae, and instead of introducing others, or of adding to or polishing up those already in being, I would suggest that they should be dispensed with altogether. I feel sure that every thoughtful judge who has been trained in criminal law procedure is well qualified to put the issue involved before the jury in such a comprehensive way that every case will be judged on its individual merits rather than in terms of a formula which cannot do complete justice to the individual aspects of each case. It has been said with approval that the M'Naghten rules constitute a yardstick for both judge and jury ; but a yardstick is too rigid an instrument when an individual's life is at stake.

While I have always been greatly impressed by the scrupulous care with which a criminal trial is conducted, and by the fact that almost invariably the prisoner is given the benefit of any doubt which may exist, yet that is not to say that conditions could not be improved. I believe, for instance, that in every case involving capital punishment a psychiatric examination would be advisable, just as it is in cases of attempted suicide : the destructive motive is the same in both instances even though the object may be different.

For those persons who have been adjudged as of unsound mind I would advocate :

1. Care and treatment in a special type of mental hospital independent of a prison regime. Provision should be made whereby every method of psychiatric treatment was readily available. Failing acceptance of the above suggestion, then a modern psychiatric department should be established within the prison system.

2. Parole might be used more frequently.

3. Transfer to civil hospitals should be made more often, and dangerous patients in civil hospitals should be more easily and readily transferred to the prison psychiatric unit.

4. Remedial workshops equipped with modern machinery would be a valuable aid in the rehabilitation of such cases.

5. I would suggest that those cases which require observation and a detailed psychiatric report before trial should be transferred, for the time being, to a suitable psychiatric clinic or to a special ward in a mental hospital.

Mental Deficiency

This condition may be defined as a state of retarded development which has been present from birth or an early age and has prevented the individual from keeping pace with his fellows. It may be of various forms and degrees, which to a certain extent dovetail into one another. It constitutes a serious disorder which for all practical purposes is incurable. But yet, curiously enough, the law refuses (except in the most gross cases) to allow mental deficiency to be utilized as a defence in bar of trial or sentence. In many tragic cases in which I have been willing to certify the prisoner as a mental defective I have been informed that "the prisoner is merely mentally defective" and therefore he must stand his trial in a public court just like anyone else accused of a criminal act. Such an outlook constitutes a grave injustice, and the time is long overdue for a recasting of the criminal law in relation to such persons. A prison sentence, long or short, in such cases has no deterrent or remedial effect ; it merely adds insult to injury, embitters the enfeebled person still further, and renders him more liable to continue in a career of crime rather than to conform to society. Is it not a complete travesty to suggest that persons who can be certified as mentally defective should be allowed to plead to the charge against them, should be considered capable of instructing their defence and of being able to follow the evidence submitted to the court ?

My point of view can be supported by the following cases.

Illustrative Cases

1. An unmarried woman aged 36, who had had two illegitimate children, murdered her third child by drowning shortly after its birth. She was a simple-minded, facile, mentally defective person, who had felt the strain of the childbirth and at the time of the crime was exhausted, sleepless, and distraught. She was subjected to a trial by jury, who found that she had committed the acts charged against her and was mentally defective. The court was then adjourned so that the procurator-fiscal might present a petition for a judicial order committing her to a certified institution.

The necessity for court proceedings under such circumstances seems entirely redundant.

2. An unmarried woman aged 24 murdered her newly born baby by inserting scissors or other sharp instrument into the mouth and throat of the child. The prisoner when 7 years old had already been certified as a mental defective. My examination showed her to be a feeble-minded person with marked intellectual and emotional impairment. As, however, she was "merely feeble-minded," she was regarded as fit to plead, and was tried in the usual manner. It was in this case that the Lord Justice Clerk (Aitchison) made the scathing comment: "If the law had kept pace with medical practice this prosecution would never have arisen. On the medical evidence this woman should never have been brought to trial." The opinion of the Lord Justice Clerk may not have conformed to the letter of the law, but it showed humanity and understanding.

3. An unmarried woman aged 36 cut the neck of her newly born child. The prisoner was a simple-minded, facile person who had not had sufficient realization or understanding to make any preparation for the birth of the child. After the fatal act she was quite unmoved by the tragic situation in which she was placed. The case went to trial and eventually the advocate-depute accepted a plea of culpable homicide to which she pleaded guilty. In this case the Lord Justice Clerk (Aitchison) took the view that she had already been three months in prison and that she could now be safely looked after in her father's home. She was accordingly discharged.

These cases illustrate the unfortunate and pitiful state which still exists. The legal procedure in such cases is antiquated and chaotic, and should be brought more into harmony not only with medical but with public opinion.

My contention is that mental deficiency of whatsoever degree should be regarded as an adequate defence in bar of trial or sentence, and that mentally defective persons who have committed criminal acts should be cared for under hospital or colony conditions until they can be discharged with benefit to themselves and with safety to the public.

Suitable provision for such cases is an urgent necessity, but at present we have neither the buildings nor the necessary medical or nursing personnel to cope with them. I do not ask for leniency in relation to them, but for greater understanding. It should always be remembered that they are mentally defective, that mental defect is one of the most prolific factors in criminal conduct, and that repetition of the offence is frequent. In consequence a return

to social and family life should always be regarded with meticulous care, and should not be considered advisable until a sense of social responsibility has been built up.

Psychopathic States (Character Anomalies)

The individuals who form this group constitute the biggest, most serious, and most controversial medico-legal and social problem. They are social misfits in every sense of the term, persons who have never been able to adapt themselves satisfactorily to their fellow man and appear to be entirely lacking in altruistic feeling. Their life histories are illuminating, and show how, from a tender age and from a variety of causes, they have proved a problem to themselves as well as to the world at large. They are the "sports" of the human race. The more I see of them or read about them or deal with them, the more confirmed I become that they are persons who have failed in the psycho-biological development. Such a failure may not be due to any fault in their environment or education, although that possibility should always be considered, but it is essentially constitutional, something which is inborn, something which is akin to the lack of intellectual development which characterizes the mental defective.

Irrespective of all the efforts which are made to assist them, often from their earliest days, they remain at an immature, individualistic, egocentric level. On this account they fail to appreciate reality; they are fickle, changeable, lack persistence of effort, and are unable to profit by experience or punishment. They are dangerous when frustrated. They are devoid of affection, are cold, heartless, callous, cynical, and show a lack of judgment and forethought which is almost beyond belief. They may be adult in years, but emotionally they remain as dangerous children whose conduct may revert to a primitive subhuman level. Neville Heath and John George Haigh are extreme examples.

On the surface they can behave as ordinary, likeable, attractive human beings, but they harbour in their inner depths instinctive forces which on occasions overwhelm them. In conversation and under controlled conditions no special flaw may be discovered to enable medical certification to be effected; it is impossible in such cases to define sanity or insanity, but it is surely obvious to everyone that we are dealing with conduct abnormality of such a degree and type as to constitute the greatest potential danger to the individual and his victim. They are in the most deplorable of all conditions—not sane enough to be at large and not insane enough (in terms of certifiability) to be suitable for Bedlam.

If our ethical code feels justified in sending them to the gallows then let it be so, but at the same time let us clearly understand that such persons are driven by what may be called their collective unconscious to deeds of violence which are as uncontrollable as a tidal wave. Are we justified, in such circumstances, in attempting to control the conduct of our fellow men by imposing capital punishment in the case of those we do not fully understand? I doubt whether we are. We merely add something to the satisfaction of the murderer, and, paradoxically enough, capital punishment may, instead of deterring others, encourage them to follow the same course.

This was the type of case which Lord Alness had in mind when he promulgated the doctrine of limited or modified responsibility which has been generally accepted by our Scottish courts. May I remind you of Lord Alness's words: "Formerly there were only two classes of prisoner—those who were completely responsible and those who were completely irresponsible. Our law has now come to recognize in murder cases a third class—those who, while they do not merit the description of being insane, are nevertheless in such a condition as to reduce their act from murder to culpable homicide. . . . There must be a weakness or aberration of mind; there must be some form of unsoundness; there must be a mind so affected that responsibility is diminished from full responsibility to partial responsibility; the prisoner in question must only be partially responsible for his action." That is an admirable statement, one to which I can heartily subscribe, and which meets the situation in most such cases. I believe it could be applied with justice to a much wider range of cases—for example, assault, sexual offences, and so on.

During the next fifteen years no capital sentence was carried out in Scotland, and, so far as I know, during that period the homicide rate in Scotland did not increase. While I agree with the position taken by Lord Alness, yet this does not mean that I believe that such cases should be treated more leniently. On the contrary, I believe they should be treated not necessarily with greater severity but under more specialized conditions and for such time as to prevent a possible recurrence of the offence. My plea is for an indeterminate sentence until a sense of social responsibility becomes established. Furthermore, they require to be cared for in a special institution or colony such as has been established in Denmark at Herstedvester, near Copenhagen (see Appendix).

Psychoneuroses

The persons who constitute the various clinical groupings of the psychoneurotic state are those who, while suffering from a vast number of nervous symptoms, are at the same time able to conduct their lives at a reasonable level and even continue at their work. Their number is legion, but their involvement in criminal conduct is comparatively infrequent. For the most part they seem able to exercise sufficient control and understanding whereby in time of stress or conflict they are able to go to someone for help, or else develop in themselves ways and means by which their emotions or disturbing thoughts are kept in check.

It is, however, important to understand that all the vagaries of conduct exhibited by the hysteric, the neurasthenic, the anxiety state, or the obsessive-compulsive are conditions which are not mere foolishness and something which the individual can control. Such states are the result of inner conflicts and emotional disturbances which are overpowering. The medical profession generally subscribe to the view that the signs and symptoms constituting the conduct disorder of the psychoneurotic are determined at a subconscious or unconscious level and are the result of the constant conflict which exists between the good and the evil, between one's conscience and one's instincts. When such conflicts can be resolved the patient may lead a moderately happy and contented life, but otherwise nervous fears, strange thoughts, compulsive acts, may take the field in an attempt, distorted though it may be, to bring matters to a solution. There are some who are willing to go so far as to say that all criminal acts must be determined on the basis of conflict, and that therefore the criminal person should be regarded as a sick person and not as a delinquent. That, however, is an extreme view and one which, in the present state of our knowledge, would not gain general acceptance. I would rather put it in this way—that the conflict which produces criminal acts in the case of delinquents is very much the same type as that which produces psychoneuroses. The problem may be the same, but the reaction is different, depending upon the structure or make-up of the individual. I have never known a pure obsessive-compulsive state lead to a homicidal attack, but sexual offences are not uncommon.

Conclusion

In summing up the whole of this discussion I would like to say emphatically that I do not believe that medical men, whether psychiatrists or not, have ever wished to take over the functions of judge and jury, or even unduly to influence them in relation to any opinion they may come to. We wish to work in association with the law, because we believe we are able to make some contribution, small though it may be, to the elucidation and understanding of criminal conduct. We are primarily interested in doing everything we can to benefit, to care for, and even in some instances to cure the person affected, but we are likewise concerned with the welfare of society and the preservation of the lieges, and are as anxious as anyone else to live with a sense of security.

I would advocate that the legal and medical professions, so specially concerned in dealing with the disordered group of humanity, should be willing to appreciate each other's point of view and thus avoid scathing comment and criticism, especially in a court of law. It is the purpose of all engaged in the difficult task of estimating human conduct to do what we can to help those who have been unable to help themselves. Great advances can be made if together we are determined to understand and investigate more thoroughly the causes of criminal conduct and how they can be eliminated. Fundamentally this would take us back to a consideration of genetic and environmental factors—for example, housing, education, marriage, and so on—but, while such preventive and eugenic measures should be kept in mind, yet in practice we should, within our prison and legal system if thought advisable, build up an organization whereby the mind and spirit of the offender will come in for consideration to a far greater extent than previously. The essentials are:

1. Good psychiatric units, where satisfactory examination and observation can be carried out previous to trial, and where suitable cases could have adequate treatment after trial.

2. A well-qualified medical and nursing personnel, who, along with social workers and those with an aptitude for research, might bring an investigative spirit to bear on this most difficult problem.

3. An efficient aftercare organization.

4. Discharge to be determined on the basis of social stability. An elastic scale might be devised with minimum and maximum periods—but personal preference is for the introduction of an indeterminate sentence.

5. A special colony establishment under psychiatric control for psychopathic states; the improvement of working conditions and the use of modern machinery.

6. A judiciary imbued with a remedial outlook and able to think in terms of illness and disease which may be entirely subjective.

7. Modesty on the part of the psychiatrist in relation to his ability to attain cures in the case of individuals who are so grossly and seriously involved.

APPENDIX

I have prepared a short abstract of an article by Dr. G. K. Sturup on the treatment of psychopathic criminals in Denmark. Dr. Sturup is the medical superintendent of the Herstedvester Institution.

The Danish Criminal Law (1930) does not utilize the M'Naghten rules, but states that no person who has committed a crime shall be subject to any punishment if, at the time of the deed, he was irresponsible on account of insanity or a similar condition of mind, or a high degree of mental deficiency. Those cases may be admitted to ordinary mental hospitals.

Herstedvester was established in 1933. There is accommodation for 180 males and 20 females. The period of detention is indefinite. The institution is neither a hospital nor a prison. It is described as a unique social-psychiatric department. Its problem is twofold: to effect satisfactory preventive detention, and to treat patients according to their psychical needs so that they may return to a normal life: detention is described not as punishment but as a security measure.

The majority of the patients are relapsed criminals who have committed serious offences—for example, murder, robbery, incendiarism, rape, indecency to boys or girls—or drug addicts. The detainees vary in age from 18 to 70 years.

The same court which has passed sentence decides whether the detainee may be released, and release is always on a parole basis. Supervision while on parole is effected by officers specially trained by the institution.

There is very close co-operation between the court and the psychiatrist. The medical superintendent is counsellor to the Ministry of Justice, and thus is able to assist or advise every prison medical officer in difficult cases.

In addition to the main institution, a farm near Copenhagen has been developed as a market garden with accommodation for 20 detainees. Some of these detainees have been castrated, because it is believed that after such treatment those guilty of repeated sexual offences can be released on parole with much greater safety.

The staff consists of psychiatrists, nurses, teachers, a sociologist, and warders who have been trained in mental hospitals. Careful medical and social histories of each patient are compiled, and treatment of all kinds is utilized. Trades and occupations such as gardening, printing, bookbinding, joinery, toymaking, and tailoring are engaged in. The detainees work an eight-hour day, and are paid 10 kr. a week; some earn more. They are allowed to spend half the amount they earn, and the remainder is saved until release is effected.

There is a lively club life, with sport, stamp-collecting, chess, and bridge. Study circles are formed, and in certain subjects correspondence courses are available.

It is asserted that 50% of the detainees go back to normal life in the community. Sturup believes his results can be improved upon.

Speaking at a scientific meeting of the Zoological Society of London on June 13 Dr. J. F. G. Wheeler gave an account of some poisonous fish and said that these were of two types, those which when eaten were followed by internal disorders, and those bearing spines capable of causing poisoned wounds. The first type presented a curiously baffling subject of investigation because the symptoms were not manifested until the cause had disappeared. In the Tropics fish-poisoning was a matter of economic importance. In Mauritius a large number of fishes, especially red fishes, were suspected of poisonous qualities and barred from the markets. According to the account of Charles Grant, published in 1801, fish-poisoning caused the failure of Admiral Boscawen's invasion of Mauritius in 1748. Some of the earlier Dutch seamen calling there referred to poisoning by fish but others mentioned eating fish reported to be poisonous without suffering any ill-effects. With the possibility of fishery development on the vast ocean banks like the Saya de Malha, the assertion that 80% of the fishes caught there belonged to a species (*Lutianus civis* C & V.—locally called Vara Vara) known to be poisonous was not encouraging and called for investigation. In the course of a two-year Fisheries Survey the scientists and crew of "M.F.R.V. No. 1," now renamed *Research*, have discounted these legends.

REACTIONS PRODUCED BY ARTHROPODS DIRECTLY INJURIOUS TO THE SKIN OF MAN*

BY

R. M. GORDON, M.D., Sc.D., F.R.C.P.

Professor of Entomology and Parasitology, University of Liverpool

During the past few years my colleagues and I have been investigating the reactions shown by the mammalian host to the bites and stings of certain tropical and non-tropical arthropods (Gordon and Crewe, 1948; Crewe and Gordon, 1949), and since these reactions are often, although by no means always, confined to the skin we thought it might be of interest to present some of our findings. Before doing so, however, it is necessary to emphasize the fact that we have studied only a few representative species of medically harmful arthropods, and it would therefore be unwise to draw any far-reaching conclusions from such limited data.

Our observations suggest that the pathogenic effects produced by arthropods directly injurious to man fall into certain well-defined groups and can usually be classified in one of four categories: (1) lesions due to mechanical trauma; (2) lesions due to secondary infections; (3) lesions due to the injection of substances which are normally harmless, but to which the host has become sensitized as a result of previous exposure; and (4) lesions due to the injection of directly injurious substances. Although these pathogenic effects are considered separately, they may, and often do, occur in conjunction—a fact which is sometimes overlooked by the clinicians.

Lesions Due to Mechanical Trauma

In the case of the puncture or abrasion made by a blood-sucking arthropod, the extent of the lesion produced will depend on the size and nature of the insect's mouth-parts and the manner in which they are used. Some blood-sucking insects, such as the mosquito, with long and delicate mouth-parts, may feed with the proboscis in the lumen of a capillary; whereas the proboscis of larger flies, such as the tsetse (*Glossina* sp.), are too bulky to enter the lumen and are used to suck up the blood which results from the repeated laceration of small subcutaneous vessels. It is, of course, obvious that the large and relatively clumsy skin-piercing organs of some of the "horse-flies" or "clegs" (*Tabanidae*) will produce a more extensive wound than will the small and delicate mouth-parts of the midges (*Culicoides*); but the difference in the final result is not so great as might be expected, since both insects tend to probe the tissues until a pool of blood, more than sufficient for their purpose, has been produced. From the clinician's point of view, however, it would seem that the uncomplicated trauma produced by any type of blood-sucking arthropod is seldom severe enough to cause any serious disturbance in the host.

When, however, the parasitic arthropod extends its activities from blood-sucking to tissue invasion the resultant trauma may be more extensive. Thus, in the Tropics, myiasis caused by the larvae of certain flies, such as the "Berne fly" (*Dermatobia hominis*), may result in the deep invasion of the subcutaneous tissue by a number of larvae, each of which is more than 1 in. (2.5 cm.) in length, while the invasion of the turbinal mucous membrane, or even of the frontal sinuses, by the so-called "screw-worm" larvae of other flies, such as *Cochliomyia* sp. or *Chrysomyia* sp., may produce even more serious injury: extensive invasions by such large arthropods are obviously not only painful but are bound to interfere seriously with health.

On the other hand, the invasion of the host's tissues by a parasite so minute as *Sarcoptes scabiei*, and one which never penetrates below the stratum corneum, cannot be regarded as causing any serious mechanical trauma, and the extensive lesions sometimes associated with its presence must be ascribed to some other cause. Between these extremes there are a host of tissue-invading parasites, mostly larvae of two-winged flies which in the Tropics and, more rarely, in this country cause varying degrees of mechanical trauma in the tissues of their host.

As already mentioned, a few species of myiasis-causing larvae may produce serious lesions, but with these exceptions, and in the absence of complications, most of the tissue-invading arthropods, so long as they confine themselves to the tissues of their normal host, seldom produce a degree of trauma sufficient to interfere with general health. Occasionally, of course, an invading parasite finds itself in the tissues of the wrong host, as happens in the case of the so-called "larva migrans," and in such instances both parasite and host may behave abnormally. In this case the lesion was probably caused by the larva of an ankylostome normally parasitic in dogs in the Tropics; but almost precisely similar lesions occur in this country after the penetration of the human skin by the larva of the warble fly (*Hypoderma* sp.), the usual host of which is cattle, or by the larva of the bot-fly (*Gasterophilus* sp.), which is normally parasitic in equines.

Lesions Due to Secondary Infections

It has been shown that the larvae of a few, mainly tropical, species of two-winged flies (Diptera) may produce considerable mechanical trauma. Usually, however, the most serious results of myiasis are those which follow the subsequent invasion by bacteria of the wound previously made by the parasite, and the term "myiasis" generally conjures up a picture of a septic lesion for the cause of which bacteria are more responsible than Diptera.

It sometimes happens that such organisms are introduced by the parasite when piercing the skin, but it seems to be more usual for them to gain access after the abrasion has been made, and such abrasions do not appear to be any more prone to infection than similar lesions caused by other means. In any case, lesions due to secondary infections can scarcely be regarded as being the responsibility of "arthropods directly injurious to the skin of man," and I therefore propose to pass on to my next category.

Lesions Due to Injection of Normally Harmless Substances into a Previously Sensitized Host

The picture which we have just presented of a more or less trivial traumatic injury which may or may not be followed by a more serious bacterial infection is often thought to be further complicated by the injection by the parasite of a substance inimical to the host, the responsible substance usually being thought to be derived from the salivary glands of the parasite, although some workers believe that it originates from some other part of the insect's digestive tract.

*Read in opening a discussion at a combined meeting of the Sections of Dermatology and Tropical Medicine at the Annual Meeting of the British Medical Association, Liverpool, 1950.

Our own observations do not support this view; they suggest, rather, that only a very limited number of parasitic arthropods secrete a substance of a toxic nature, and when this does occur, as sometimes happens in the case of mosquito bites, the reaction produced is delayed and trivial and never results in the immediate well-marked weal so often associated with the bites of parasitic arthropods.

My colleagues and I have fed a varied assortment of blood-sucking creatures on human volunteers, and, so long as these volunteers have never previously been exposed to the bites of the particular kind of arthropod under investigation, either no reaction has occurred or it has been so slight as to be negligible so far as the clinician is concerned. Of course, it is difficult to ensure that the individual has never previously been exposed to any particular parasite; but this difficulty can be overcome by importing tropical insects, such as the tsetse-fly, and by feeding them on persons who have never visited the Tropics.

As regards the source of the irritating substance, we have been able to show that, in the case of the tsetse-fly at any rate, it must be derived from the salivary glands. This fact has been demonstrated by removing the salivary glands from the living insect and then feeding it on a person who is known to react violently to the bite of the normal insect. In these circumstances the fly feeds to repletion but the host shows no subsequent reaction.

I have just mentioned that persons living in this country and not previously exposed to the bites of the tsetse show no reaction when these insects are fed on them for the first time; the question now arises of what happens if you continue to feed tsetse-flies on such persons. We can answer that question, so far as our observations have gone, by saying that if the flies continue to be fed on such an individual at regular intervals he will remain free from any reaction, but that if the flies are fed at irregular intervals the majority of individuals on whom the flies are fed develop a reaction which may or may not be severe in character.

So far my remarks have been concerned mainly with the tsetse-fly, but we have repeated some of these observations on persons exposed to the bites of mosquitoes, sand-flies (*Phlebotomus* sp.), midges (*Culicoides* sp.), and bed-bugs, and the results obtained have been similar to those following tsetse-fly bites. In addition, we have been able to confirm that these reactions are often highly specific, and that persons who react to one species of insect do not necessarily react in a similar manner when bitten by a different species, although both may be so closely related as to belong to the same genus. These findings may explain why it is not unusual to encounter persons who state that, although they sometimes react violently to flea-bites, at other times they remain unaffected, or that they react to the bites of mosquitoes in one part of the country but not in another.

As regards desensitization, we have not carried out any experiments on the value of antigens prepared from the insects responsible for the reaction, but we have been able to show that, in persons who have become sensitized to the bites of mosquitoes, the reaction diminishes after continued regular exposure, and that this desensitization is usually specific, so that the person who has been desensitized to the bites of one group of mosquitoes, such as the culicines, may still be sensitive to the bites of another group, such as the anophelines.

Perhaps I might summarize the conclusions arrived at by my colleagues and myself concerning parasitic arthropods by saying that, like poor relations, they try to get as much food and shelter as they can from their host, but are scrupulously careful to avoid causing him any unnecessary pain or inconvenience, since the results of such actions are usually detrimental not only to the host but also to the parasite.

It is true that the observations which I have described refer only to a limited number of common parasites; but, so far as those are concerned, it seems reasonable to consider that any immediate and severe reaction associated with their bite or with their invasion of the tissues is due to previous sensitization on the part of the host and not to the injection of any poisonous or toxic substance by the parasite.

Lesions Due to Injection of Directly Injurious Substances

The association between man and arthropod so far considered has been that of host and parasite, and we have shown that, since it is always to the disadvantage of the parasite to cause any serious injury to its host, most of the injuries resulting from this association have been in the nature of accidents caused by secondary infections or following the injection by the parasite of a normally harmless substance into a previously sensitized host. On the other hand, certain arthropods which are non-parasitic and in no way dependent on man for their existence have developed weapons of offence, in the form of secretions which they use to kill or paralyse their prey, while others have developed defensive secretions which they use to protect themselves from interference. These offensive and defensive secretions resemble each other in many respects, and in some instances are used for dual purposes; but generally they differ in their virulence.

In the case of arthropods, such as scorpions and spiders, which have developed predatory habits and which secrete poison that is to be used to kill or paralyse their normal prey, the venom secreted is usually of a high virulence and when injected into man may produce serious general as well as local effects. In the case of other venomous arthropods, such as bees, which have not developed predatory habits, the venom secreted is not intended to kill but merely to produce a sufficiently quick and painful reaction to deter the intruder from any further interference; and in such instances the poison, although quick-acting, is usually of a milder character, the reaction produced tending to remain localized. It must not be forgotten, however, that the stings or bites of usually only moderately poisonous arthropods may take on a serious aspect if inflicted on a previously sensitized person, in whom the result of even a single sting may be followed by severe and sometimes fatal consequences.

The literature concerning the venom of scorpions and bees contains a great number—in the case of bee-venom one might term it a vast number—of papers dealing with the chemical structure and physiological effect of these poisons, together with an almost equally large literature describing the clinical manifestations which have been observed to follow the stings of these creatures; but there seems to be no account of the histological lesions produced. As my colleagues and I wished to compare these lesions with those produced by blood-sucking insects, we undertook a limited number of experiments in which a scorpion or bee was allowed to sting a guinea-pig, the tissues being removed from different animals at various times after the infliction of the sting and then sectioned and examined.

The results of this investigation showed, as might be expected, that, whereas the uncomplicated bites of blood-sucking insects never cause any inflammation and are comparable to the injury which might result from the probing of a surgical needle beneath the skin, the stings of scorpions and of bees result in a very marked inflammation. In the case of the bee, the sections showed oedema, marked cellular infiltration, and some necrosis of the underlying muscle layer, which was followed within 24 hours by a walling-off of the damaged tissue by a palisade of inflammatory cells. In the case of the scorpion sting, the reaction was somewhat similar, though more severe, and was associated with an extensive coagulative necrosis of the underlying muscle.

"Immunity"

There remains one aspect of the association between the skin-piercing arthropod and its host to which, so far, no reference has been made. It is not unusual to encounter individuals who declare that a particular venomous arthropod, such as a bee, will not sting them, or that certain blood-sucking fleas or flies do not bite them. The first group of persons seem to depend for their immunity on their power to handle particular arthropods—in this case bees—without alarming them. The second group is more difficult to explain; unquestionably there are persons who are not so attractive to lice or mosquitoes as their less fortunate fellows, but in our experience such cases are rare, and we have not yet encountered a case of complete immunity.

Pepys—you may remember—declared that while at Portsmouth he shared a bed with a certain Dr. Clarke, and that the fleas bit the doctor but not the diarist, a happening which seems to have pleased the latter "mightily." Pepys's statement can never now be substantiated, but we have carried out a number of experiments in which persons who stated that they were seldom bitten by mosquitoes, together with controls claiming no such privilege, introduced their hands and forearms into a large cage containing many hungry mosquitoes. The cage was arranged in such a way that, though the observer could see what was going on inside, the persons volunteering for the experiment could not. Under these conditions the results of individual experiments were always similar; the persons claiming immunity continued to maintain that they were not being bitten, but the impartial observer recorded in his notebook that the mosquitoes were unimpressed by such an assertion and were biting the "immunes" as readily as the "non-immunes."

It would seem, therefore, that the majority of individuals who believe that they are relatively immune from the bites of a particular species of insect are mistaken, and that their apparent immunity is the result of their failure to notice the insect during the time that it is biting. This failure is due either to the individual's not having become sensitized to the species in question, or because, although previously sensitized, he has become desensitized as a result of regular and prolonged exposure.

Summary

The pathological effects produced by arthropods directly injurious to man—as distinct from those which as transmitters of diseases are regarded as indirectly injurious—can usually be classified in one of four categories.

1. Lesions due to mechanical trauma, in which the damage done is usually severe only when it is caused by certain of the larger species of myiasis-producing larvae or when an abnormal host is attacked.

2. Lesions due to secondary infections—these include the more serious effects of myiasis which follow the infection by bacteria of wounds previously made by invading arthropods.

3. Lesions due to the injection of substances which are normally harmless but to which the host has become sensitized as a result of previous exposure. Recent research suggests that any immediate and severe reaction associated with the bite of parasitic arthropods or with their invasion of the tissues is due to previous sensitization of the host. Such reactions are usually highly specific.

4. Lesions due to injection of directly injurious substances. Certain predatory arthropods, such as scorpions and spiders, secrete venom usually of high virulence which, when injected into mammals, causes both generalized symptoms and an extensive coagulative necrosis of the underlying muscle. In the case of non-predatory insects, such as bees, the reaction tends to be mild and to remain localized.

DIVISION OF POPLITEAL VEIN IN THE TREATMENT OF SO-CALLED VARICOSE ULCERATION*

BY

GUNNAR BAUER, M.D.

Chief Surgeon to the General Hospital, Mariestad, Sweden

Non-specific ulcers of the lower leg have for a long time been termed varicose ulcers, evidently because varices of the subcutaneous veins were thought to be the cause of the ulcer formation. To-day, however, we know that this is only part of the truth and that the root of this evil goes much deeper. Knowledge of the normal and pathological physiology of the veins of the lower extremity has made very considerable progress during the past decade. Modern investigation tends to regard the entire vascular system of the leg as one system, similar to a U-shaped communicating glass vessel. The aorta and the large arteries form one branch of the vessel, the capillaries the bottom, and the large vein trunks and the vena cava the other branch. Being completely filled with fluid, this system is in perfect hydrostatic equilibrium. If a quantity of blood is introduced into one side of the system, as is the case each time the heart stroke pours blood into the aorta, an equal amount of blood flows out of the other end of the system, from the vena cava into the right side of the heart. This explains how the venous blood is made to return from the lower extremity irrespective of the body's position.

However, when the body is brought into the vertical position another factor is added. It is a well-known fact that in this position, because of the action of gravity, a large quantity of blood assembles in the lower parts of the leg. To explain this it is necessary to remember that the human U-shapel vessel, unlike those made of glass, does not have rigid and impermeable walls. Instead, the blood vessels, especially the veins, have elastic coats which are apt to give way under high pressure. The lumen widens and an ever-increasing amount of blood can accumulate. After some time a condition of pronounced venous stasis is created.

To get rid of this surplus of blood the healthy human being is in possession of a highly efficient auxiliary

*Read in opening a discussion in the Section of Surgery at the Annual Meeting of the British Medical Association, Liverpool, 1950.

mechanism, consisting of the action of the muscle masses of the calf. When these muscles contract, as in walking, they act as a sort of peripheral heart, squeezing considerable amounts of blood from the lower leg up into the popliteal and femoral veins. From there the blood cannot return because of the action of the valves in these large veins.

It is not difficult to imagine what would happen if those important valves for one reason or another were no longer able to function properly. The blood that was squeezed out of the lower leg would return the moment the muscles relaxed, and no amount of walking or muscle movements would be able to rid the lower leg of stagnating blood. The venous stasis would steadily increase and oedema would soon begin to develop. If prolonged for weeks or years, graver tissue changes, such as induration and even ulceration, would set in, and, as a result of anoxaemia, there would be aching or pain.

It is impossible not to be struck by the fact that the pathological changes just described constitute the exact image of what is to be observed in cases of lower-leg ulcers. An ulcer is hardly ever found quite alone. It is nearly always accompanied by chronic pitting oedema and by large areas of brawny and indurated skin, and the patient generally complains of a dull aching or bursting pain whenever the leg is in the vertical position. In fact, these symptoms constitute the components of what may be called the "lower-leg-stasis syndrome."

The grave circulatory disturbances evidently underlying this syndrome caused me and my co-workers, about four years ago, to start an investigation into the conditions prevailing in the large deep veins of the entire leg. The results of this work have been described in detail elsewhere (Bauer, 1948, 1950a). Using a special phlebographic technique in which the contrast was introduced into the proximal end of the femoral vein, a large series of cases was studied. In practically all cases with a pronounced stasis syndrome the femoral and popliteal veins were found to be in a pathological condition, the main feature of which consisted in the complete, or nearly complete, absence of normally functioning valves.

The aetiological factor in many cases was found to be a previous deep venous thrombosis. When a vein trunk is recanalized after having been obliterated by thrombotic clots, the result is a thick-walled rigid tube without even traces of valves. In an even larger group, however, the valvular insufficiency was caused by phlebosclerotic or similar changes, and might be called idiopathic.

The conclusion was reached that the stasis was caused by this pathological condition of the valves. Later experience from several hundred cases entirely corroborated this view.

Treatment of Venous Overloading

The main problem when trying to devise a suitable therapy appeared to us to be this: in what way would it be possible to assist the action of the peripheral heart, or, in other words, by what action could we prevent the blood that is squeezed out from the lower leg by muscular contraction from flowing back again?

It seemed to us that if the large avalvular vein trunk was permanently blocked at its lower end, in the popliteal region, this would prevent the possibility of back-flow. Division of the popliteal vein was performed in a few cases, and the results were encouraging. The patients improved, and it could be demonstrated radiographically that after operation the calf-muscle contractions drove the blood through numerous fine-calibred channels into the muscle veins of the thigh, and that no back-flow occurred.

It thus appeared as if a suitable form of treatment might be within reach, and ligation and division of the popliteal vein was taken up as a routine procedure and has remained so for more than three years.

Indications for Popliteal-vein Division

At the Mariestad Hospital, up to the time of writing, 245 popliteal-vein divisions have been performed in cases of proved valvular incompetence. The symptoms present at the time of operation are given in Table I. It will be

TABLE I.—*Leg Symptoms in 245 Patients Before Popliteal-vein Division*

Symptom	No. of Cases in which Present
Bursting pain	243
Oedema	244
Induration	236
Open ulceration	180
History of repeated ulceration but no ulcers open at the moment	33

seen that pain, oedema, and indurative skin changes were present in practically all the cases, and that open ulcers or a history of repeated ulceration were observed in seven-eighths of the patients.

During the first year of this work all cases were examined by retrograde phlebography before being subjected to popliteal-vein division, because a need for further study was felt. To-day we feel convinced that in practically all cases with a clear-cut stasis syndrome there is also deep valvular insufficiency, and we do not hesitate to operate on the strength of an ordinary careful clinical examination alone, without recourse to phlebography.

In a fair number of cases there will be found, in addition to the typical syndrome, the well-known signs of incompetence of the great saphenous vein or of incompetence of one or two of the large communicating veins arising out of the depths in the lower third of the thigh. In these cases there is every indication to divide and inject or strip these veins as well. It is our belief that no good can possibly come from any vein with a retrograde blood-flow, and it has been our practice for a long time to deal with these veins at the same time as we are doing the popliteal-vein division. We have seen no harm arise from this.

Now and then there come under observation borderline cases in which some of the components of the syndrome are not very well marked and in which, at the same time, a large, tortuous, and incompetent great saphenous vein is demonstrated. In such cases the question may arise whether the lower-leg changes are caused by the saphenous alone or whether there may not, in addition, be a deep insufficiency. In these circumstances phlebography is indicated. The examination should, however, not be done by puncture of the femoral vein. It is much easier to introduce the contrast medium *via* the saphenous vein. This vein must in any case be exposed at its upper end and tied. After tying the lower ligature, but before applying the upper one, the needle of a syringe containing 20 ml. of diodone ("diodrast") (35%) is introduced into the saphenous vein. Before injecting, it is absolutely necessary to make sure that the valves in the superficial femoral vein, if any, are closed at the moment when the dye runs into the vein. According to our experience this can best be done, and the most uniform results obtained, if the foot

end of the operating table upon which the patient lies is suddenly lowered to 45 degrees or more. Then, but not until then, should the injection be made, occupying about thirty seconds. At the end of that period the *x*-ray exposure is made.

If with this technique the contrast medium is seen to have run down into the femoral vein and to have passed the knee level, indications for popliteal vein division are present. If, on the other hand, this technique is not strictly followed, the contrast medium, which is heavier than the blood, may sometimes be observed to trickle downwards for some distance, even in persons in whom there exists no valvular incompetence. Instances are known in which this phenomenon has caused some observers to doubt the value of the method.

At this point it should be mentioned that we have devised a method to make absolutely sure, on the operating table and before actually dividing the popliteal vein, that the femoral vein is incompetent. After exposing the popliteal vein a loosely tied ligature or a clamp is applied on the distal end of the exposed vein. After that, we insert in the vein, proximal to the ligature, the needle of a manometer similar to that used in lumbar puncture but with a much longer glass tube. The foot end of the table is then slowly lowered to 45 degrees. If blood enters the glass tube and rises to a level of 40 to 60 cm., which, incidentally, corresponds to the level of the patient's heart, this is a sure sign that the femoral valves are incompetent.

Results

There were no post-operative deaths among the 245 cases operated upon. No complications were observed, with the exception of slight wound haematomas in five cases. In no case was there any demonstrable harm to the circulation in the lower leg as the result of the operation.

A marked improvement was observed in all the patients. The aching or bursting pain was relieved almost at once. The ulcers generally healed in a shorter time than might have been expected with conservative treatment.

Follow-up Examination

It is a well-known fact that patients with leg ulcers nearly always show a considerable improvement after an interval of hospital care, whatever treatment is given. The utmost care must therefore be exercised when the effect of an additional new form of therapy is to be evaluated. A considerable period of time, preferably several years, must be allowed to pass before final judgment can be pronounced.

In the Mariestad Hospital material only one patient has been observed for more than three years and only 55 have passed the two-year mark. Nevertheless, in order to obtain a preliminary idea of what may be expected after popliteal-vein division, follow-up studies were made of all those cases, 196 in number, in which the time of observation was at least six months. It was found very informative not merely to examine all the patients at a given date but also to follow the course of their illness in detail from the time of operation up to the present (Table II).

TABLE II.—*Post-operative Course After Popliteal-vein Division in 196 Cases. Time of Observation: Six Months to Three Years*

	No. of Cases
Uneventful post-operative course. Steady progress towards complete recovery	165 (84%)
Intervals of recurrence	31 (16%)

In 165 patients the post-operative course was entirely uneventful. These patients were relieved from their previous bursting pain and enjoyed instead an unaccustomed feeling of lightness and comfort in their legs. They had, as a rule, no demonstrable oedema; in a few cases there were at times traces of it in the evening. In all cases the ulcers had completely healed, and remained healed, often leaving no traces. The indurative changes showed considerable regression and in many cases had entirely disappeared. In short, there existed in this group a steady progress towards what looked like complete recovery.

In 31 cases the post-operative course was disturbed by shorter or longer periods of recurrence. These cases were made the object of careful analysis in order to ascertain why recurrence had occurred and how it might be avoided (Table III).

TABLE III.—*Recurrence of Leg Symptoms After Popliteal-vein Division in 31 Cases*

Reason for Recurrence	No. of Cases
Persisting insufficient venous channels	18
Superimposed arterial disease	11
Other reasons	2

It was observed that in not a single case had the major stasis phenomena returned. All of the 31 cases were free from the bursting pain they had had before operation, and with very few exceptions the oedema of the whole lower leg also failed to return. Ulcers, on the other hand, had reappeared at the old site or in a new place.

Upon careful examination the reason for recurrence in 18 cases was found to be the existence of *untreated venous channels showing signs of evident insufficiency*. In some cases these had been overlooked at the time of the operation on the popliteal vein. In another group, with incompetence of the great saphenous vein, this had been noted from the beginning, but no treatment had been instituted because, during the first period of popliteal treatment, some doubt was felt about the wisdom of dividing both the popliteal and the great saphenous veins at the same time. Out of the 18 patients in this group, seven were healed after division of the great saphenous vein and six after leaking communicating veins in the lower third of the thigh had been dealt with. In four patients improved bandaging was sufficient to secure a good result, while one patient remains unhealed.

In another group of 11 patients a very interesting reason for the recurrence of the ulceration was found—namely, *superimposed arterial disease*. In these cases examination showed that the popliteal division had eliminated the previous symptoms of venous stasis and that the recurrence of ulceration was instead caused by obliterative changes in the major arteries of the lower leg, generally at about mid-calf level or higher. A characteristic feature of these cases was the extreme painfulness of the ulcers. While there was none of the old aching all over the lower part of the leg, which had been most pronounced in the daytime, there was a sharp pain, especially marked at night. These ulcers were also found to be extraordinarily slow in healing. The blood pressure in general showed a considerable increase and the pulse in the dorsalis pedis artery was absent. A more detailed report of this condition, which hitherto does not seem to have been sufficiently taken into consideration, has been given elsewhere (Bauer, 1950b).

Treatment with antispasmodic drugs had a favourable effect in two cases only. One patient was healed after repeated sympathetic blocking. In six cases lumbar sympathectomy resulted in very rapid healing. This operation is probably the treatment of choice.

Post-operative Treatment

This report must not be concluded without a few words on the importance of careful after-treatment. It must be remembered that after popliteal-vein division the blood that is being squeezed out of the lower leg by muscular contractions has to find its way to the thigh through a number of rather fine-calibred veins passing the knee level. Until these veins have enlarged and become fully capable of taking over the entire blood flow there is the risk that some blood may be forced from the depth, through incompetent communicating veins, into the surface veins of the lower leg. To counteract this it is necessary to keep the subcutaneous veins in a state of compression for some time. It is our custom to make all patients wear some kind of supporting bandage for at least two months after the operation. After that time a large proportion of them have been allowed to discard these bandages. Others are instructed to wear them whenever the day's work involves much standing or walking. A small proportion do not seem able to carry on without continuous support.

Summary

So-called varicose ulceration is nearly always found to be connected with chronic oedema, indurative skin changes, and bursting pain. Together, these components form what may be termed the lower-leg-stasis syndrome.

The erect position in man causes a certain amount of venous overloading in the lower parts of the leg. In healthy individuals this superfluous blood is easily removed by contractions of the calf muscles, which act as a peripheral heart. This mechanism postulates normal functioning of the valves in the femoral and popliteal veins.

In patients with the lower-leg-stasis syndrome it has been demonstrated that the above-mentioned large veins are incompetent, their valves having been destroyed by previous thrombosis or by phlebosclerotic processes. In such cases superfluous blood cannot be effectively removed by contraction of calf muscles, every relaxation of these muscles being immediately followed by a back-flow of blood down the valveless main trunk. This results in permanent venous stasis, and in due time is followed by pain and tissue changes.

A remedy for this condition has been devised at the Mariestad Hospital in the form of blocking of the main deep trunk in the popliteal region. After this operation the calf-muscle contractions drive the blood through numerous fine-calibred channels into the muscle veins of the thigh, and no back-flow can occur.

Popliteal-vein division has been performed 245 times. The operation seems to be entirely free from risk. There were no deaths and no complications. The immediate results were favourable. The post-operative observation time is too short to allow a final evaluation of the late results to be made. However, a follow-up examination of 196 cases after six months to three years showed that 165 patients (84%) remained healed and without stasis symptoms. In 31 patients (16%) intervals with recurring symptoms were observed.

TOXIC EFFECTS IN ANIMALS AND MAN AFTER TETRAETHYLAMMONIUM BROMIDE

BY

ALEXANDER J. P. GRAHAM, M.B., B.S., F.R.C.S.

(From the Wilkie Surgical Research Laboratory, Department of Surgery, University of Edinburgh, and the Royal Infirmary of Edinburgh)

Tetraethylammonium bromide (T.E.A.B.) is a quaternary ammonium compound introduced into medical investigation as a vasodilator. It acts by blocking the transmission of vasoconstrictor impulses in autonomic ganglia, and has been used in cases of peripheral vascular disease to assess the capacity for vasodilatation.

Dangerous reactions following its administration have been reported, but do not appear to be sufficiently appreciated. During the course of recent experimental investigations on the action of this drug in animals and man certain toxic effects were observed.

In Animals

During an investigation of changes in peripheral blood pressure following arterial ligation in dogs a 10% solution of T.E.A.B. in doses of 2.5 mg./kg. was given intramuscularly and repeated half-hourly for two and a half to five hours. Preliminary trials had shown that with the animal supine this dosage was just insufficient to cause a fall of blood pressure of more than 10 mm. Hg. Total doses administered before toxic effects developed ranged from 100 to 240 mg., depending on the weight of the animal. For a man weighing 70 kg., doses over similar periods would be 475–1,200 mg. The usual single intravenous dose in man is 400–500 mg. (Boyd *et al.*, 1948). Other doses recommended in the literature are 4–7 mg./kg. (Birchall *et al.*, 1947) and 4–6 mg./kg. (Hayward, 1948), whereas Berry *et al.* (1946) have used 20 mg./kg. intravenously to a total of 1–1.2 g. Therefore although the individual dose per kilogram used in this experiment was well on the safe side, the sum of the half-hourly doses was two or three times that usually given.

In 7 out of 20 dogs toxic effects were noted. The first signs of these appeared after T.E.A.B. had been given for a period of two to three and a half hours: paralysis of intercostal breathing developed, and respiration continued with irregular diaphragmatic movements of diminished strength and frequency. Prominent features were bradycardia and hypertensive change with increased pulse rate—characteristics of the effect of anoxia in dogs. Cyanosis was also apparent. In two animals, when T.E.A.B. was stopped a gradual return to the previous state occurred over a period of one to one and a half hours. The remaining five died. In three of them normal respirations almost ceased, an anoxic hypertensive state followed, and death occurred 15, 20, and 60 minutes later respectively; during this time the few respiratory efforts were feeble and jerky in nature and entirely diaphragmatic, but as a result of movements of the heart some diffusion of air in and out of the lungs occurred. In the other two a slow rise in systemic blood pressure and in pulse pressure was followed by sudden respiratory failure and death. At post-mortem examination the only positive finding was gross dilatation of the heart and large veins.

In Man

Seven subjects undergoing investigation (Burt and Graham, 1950) were given T.E.A.B. intravenously in doses of 250–500 mg. in two to four minutes. In six no abnormal reactions occurred. The remaining subject, a healthy woman aged 22, developed paralysis of curariform type after being given 300 mg. of T.E.A.B. intravenously over two minutes. The pulse rate immediately rose from 70 to 80. After 15 minutes she became drowsy, was unable to speak or to raise her upper eyelids, and showed loss of power in neck and arm muscles with periodic twitchings of limb muscles. There was paralysis of intercostal respiration; diaphragmatic respiratory movements increased in magnitude, affecting blood-flow tracing in the foot, and the respiratory rate rose from 18 to 30 a minute. The skin colour remained good. The drowsiness deepened into a state in which there was no response to questions or commands. When the eyelids were lifted up the pupils were found to be moderately dilated with loss of light reflex, and both eyes rolled irregularly. During this time the blood pressure rose from 126/86 to 136/90, and there was a rise both in blood flow and in skin temperature in the hand, and a transient but not marked rise in the foot. An hour after injection the subject could partly open her eyes, and after tilting her head backwards could count fingers. Power of hand muscles and of speech was returning, though cerebration was still very slow. Two hours after injection walking was possible. There were no further after-effects.

Discussion

Previous reports of toxic effects following the use of tetraethylammonium compounds suggest that these are similar in man and in animals. Marshall (1912, 1913) demonstrated the curariform actions of the quaternary ammonium salts in animals. Birchall *et al.* (1947) produced alarming curariform effects in man with doses of 32 mg./kg. of tetraethylammonium chloride. Artificial respiration was required to compensate for the intercostal nerve paralysis and insufficient diaphragmatic breathing. Asthmatic subjects seem particularly prone to respiratory distress after the administration of T.E.A.B.

Schwartz (1949) found that asthma was aggravated in four out of seven cases; one subject "became pulseless, gasped for breath a few times, stopped breathing, became unconscious," and died after only 230 mg. of T.E.A.B. Schwartz believed that the most likely explanation was "a sudden excessive hypotension due either to lowering of the blood pressure or to ventricular fibrillation analogous to the paroxysmal tachycardia" observed by Friedlich *et al.* (1948). Their case was also an asthmatic, and developed ineffectual gasping respiration of an alarming nature, followed by hyperventilation. However, the mode of death in the case reported by Schwartz is similar to that of the animals in the present report, which is attributed to respiratory failure.

Although Lyons *et al.* (1947) believe that large doses of T.E.A.B. cause death from central respiratory depression without curariform paralysis of respiratory muscles, the evidence presented above suggests that the latter effect is the more common. The close similarity between the toxic effects of T.E.A.B. in animals and those in man has not been sufficiently stressed, and indicates that curariform paralysis is a danger to which both are prone.

Summary

Toxic effects in animals and man following the administration of tetraethylammonium bromide are reported. Out of 20 dogs to which T.E.A.B. was administered in large doses seven died—five from curariform paralysis of intercostal and diaphragmatic muscles, and two probably from central respiratory paralysis. A similar but not fatal curariform paralysis in man is reported.

THE MANAGEMENT OF HEAD INJURIES FROM THE ANAESTHETIST'S POINT OF VIEW

BY

R. BRYCE-SMITH, M.A., B.M., B.Ch., D.A.

First Assistant, Nuffield Department of Anaesthetics, University of Oxford

The anaesthetist has much to contribute to the care of the unconscious patient, no matter what the cause may be. In respect of their management, patients suffering from barbiturate poisoning, poliomyelitis, and acute head injuries have much in common, though the last group provides the greatest variety of problems.

Factors Against a Clear Airway

The maintenance of a clear airway is the immediate consideration, since this may be menaced by any of four factors or by a combination of them.

1. *Depression of Reflexes.*—Quite apart from the fact that in any unconscious patient the tongue may fall back and cause a respiratory obstruction above the glottis, a head injury may be severe enough to obtund reflexes essential to life. If the cough reflex is in abeyance the trachea is no longer protected from invasion by foreign bodies.

2. *Gastric Motility.*—War injuries repeatedly showed that injury reduces gastric motility, and as a result the stomach will retain its contents for many hours afterwards (Macintosh, 1949). Since so many head injuries occur on the roads after "closing-time," a full stomach must be expected. If the patient remains conscious this offers no danger to life, but in one whose reflexes are depressed, as a result of either a head injury or a general anaesthetic, vomiting may lead to a fatal respiratory obstruction.

Case 1.—A man aged 69 was admitted to hospital with a compound fracture of the frontal bones, the result of being knocked off his bicycle. In the casualty department he was deeply unconscious, but his general condition was satisfactory and his airway good. He was therefore sent direct to a ward. After he had been lifted into bed it was noticed that his respiration was stertorous. He was then slightly cyanosed and his pulse rapid and feeble. An anaesthetist was called, but by this time respiration had stopped. A laryngoscopic examination revealed a considerable quantity of stomach contents in the pharynx and trachea. This was aspirated immediately and artificial respiration started, but the patient died within ten minutes. At necropsy the lungs were found to be full of vomitus.

3. *The Direct Results of Injury.*—These include fractures of the mandible, which make it difficult to retain the tongue forward, and bleeding from the mouth, nose, tongue, or from the base of the skull. In an unconscious patient particularly, these can lead to a serious respiratory obstruction.

4. *Pulmonary Oedema of Central Origin.*—Although this complication is more common some days after injury it may develop almost immediately, and it is most frequently associated with injury to the mid-brain. Experimentally, the condition, which resembles the pulmonary oedema of heart failure, has been reproduced in animals by the injection of fibrinogen into the fourth ventricle. Cameron (1948) reports that at necropsy pulmonary oedema was found in 67% of patients with non-traumatic intracranial haemorrhages and in 63% of patients with fractured skulls. He believes that the condition is due to a disturbance of intracranial pressure.

The treatment of the patient unconscious as a result of a head injury is important, for not only may it be life-saving but it may also influence the later management of such cases.

Immediate Treatment

A stomach tube should be passed at the earliest possible moment. There is no justification for not doing this, for even if the stomach is empty no harm can result. The procedure may be of inestimable value, particularly when the patient is to be moved any distance, short or long, for during transit skilled attention and facilities for treatment are unlikely to be at hand.

An adequate airway may be maintained by (*a*) posture, (*b*) manual control of the jaw and tongue, or (*c*) artificial airways; but even an endotracheal tube is not foolproof unless properly supervised; nor, unless a means of suction is at hand, can it overcome the respiratory embarrassment caused by excessive bronchial secretion or blood. Case 2 illustrates four undesirable sequelae of intubation in an attempt to ensure an airway.

Case 2.—A man aged 42 was found unconscious on the roadside after a motor-cycle accident. He was taken to the local cottage hospital, where he was intubated through the mouth with a No. 8 Magill tube before being transferred to a larger centre. When I first saw this patient, 14 hours after injury, his respirations were rapid and stertorous, and he was slightly cyanosed. Respiratory obstruction was suggested by indrawing of the chest wall on inspiration, and this was confirmed by the character of the breath sounds through the tube, which showed that the latter was not fulfilling its function. The tube was therefore removed, and under direct vision a quantity of thick purulent mucus was aspirated from the pharynx and trachea. The cords were seen to be ulcerated and there was a gross tracheitis. Forty-eight hours later the patient died, and at necropsy the ulceration of the posterior borders of both cords was confirmed and a tracheitis which amounted to frank ulceration extended to the carina. The trachea was full of purulent mucus.

Examination of the endotracheal tube after its removal showed that it was so long that the tip must have entered a bronchus: this was not diagnosed during life, as the clinical picture was complicated by multiple fractured ribs. The lumen of the tube was greatly reduced by mucopus, which had become so inspissated and adherent to the inner wall of the tube that it could not be removed by aspiration. A transverse marking on the concave border of the tube was probably the result of repeated kinking caused by movement of the patient's head during the ambulance journey. Finally, the severity of the tracheitis suggested that the irritation might be chemical rather than mechanical, and suspicion became a strong probability when the fumes of formalin detected by the nose were strong enough to cause lacrimation.

Despite its limitations, I believe that an endotracheal tube may be recommended as a means of retaining an airway, provided that the dangers are fully recognized, and provided that a proper airway cannot be maintained by simpler measures—that is, manual control, a Waters airway, or correct posture. The last-named is, in any case, of the greatest importance. The supine position must be condemned not only because it permits the tongue and jaw to fall back and occlude the pharynx but also because the direction of the trachea prevents drainage of secretions from the lungs and encourages blood and vomit to run down the respiratory tract. The presence of an endotracheal tube does not prevent this, since it does not occlude the glottic opening in the deeply unconscious patient, whose cords may be widely separated. Thus the semi-prone or "tonsil" position with a head-down tilt should be adopted, for this encourages drainage from the trachea, prevents the inhalation of foreign bodies, and allows the jaw and tongue to hang forwards (Macintosh and Bannister, 1947).

Management in the Later Stages

This period starts as soon as the patient is in bed in a ward and continues until consciousness is regained. Once more the overriding consideration is that of maintaining an airway, because even a minor degree of obstruction, if allowed to persist, may lead to pulmonary oedema and cardiac failure (Macintosh and Mushin, 1946). It is well known that an endotracheal tube will cause ulceration of the cords and trachea if left *in situ* for a long time. What period may elapse before harm results is unpredictable, but I consider that twenty-four hours should be regarded as the time limit. It is therefore essential to make an assessment of the probable period of unconsciousness as early as possible. This estimate may be wide of the mark, but an opinion should be formed whether the patient is likely to regain consciousness in a few days or only after a matter of weeks.

In cases of prolonged unconsciousness an endotracheal tube is out of the question, and with the best will in the world manual control of the jaws is inefficient, especially as this duty is commonly relegated to a junior nurse. Further, the longer the patient remains unable to clear his own secretions by coughing, the more essential does it become to remove them by other means. Pharyngeal toilet alone can never be completely effective, and, since repeated intubation is both undesirable and impracticable, an early tracheotomy is indicated.

Tracheotomy

Not many years ago oxygen was administered, not for any therapeutic value, but as an inevitable last rite to the dying. To-day tracheotomy is regarded in much the same light, and the advantages it has to offer are never seen, because more often than not the operation is performed on a moribund patient. A timely tracheotomy, in fact, ensures a safe airway and a ready access for tracheo-bronchial toilet, without which the patient will assuredly die from a combination of asphyxia and lung infection. A minor operation in the hands of a competent surgeon, tracheotomy is a small price to pay for the

advantages it bestows. To regard tracheotomy as too drastic an undertaking shows a failure to appreciate the gravity of the issues at stake. All too frequently patients with head injuries die, not from their primary injury, but from a chest complication which might have been avoided altogether, or at least mitigated, if efficient bronchial drainage had been established early.

A tracheotomy by itself is not sufficient. It must be combined with frequent changes of posture, at least hourly, to allow secretions from the various lobes of the lungs to drain into the more accessible bronchi or trachea, from which they may be removed by suction. A warning is necessary if a tracheotomy is considered only after an endotracheal tube has been in place for a long time. If there is any degree of tracheitis or ulceration of the cords there is a risk that the tracheotomy wound may become infected, and this in turn will lead to fibrosis, and possibly to stenosis of the glottis and a permanent tracheostomy.

Case 3.—A man aged 28 was admitted to hospital with a severe head injury as a result of a road accident. He was intubated soon after arrival, and except for short intervals the tube remained in position for four days. By this time his cords were ulcerated and an attempt was made to maintain an airway by a relay of nurses holding his lower jaw forward. After three days a tracheotomy was performed. A clear airway was assured, and the patient, though remaining unconscious, was kept free from lung complications for a whole year. The improvement of his cerebral condition was slight, but as the cough reflex returned an attempt was made to close the tracheotomy; this had to be abandoned because of a complete stenosis of the glottis. The criticism here is not that a tracheotomy was performed but that it was performed too late.

Bronchoscopy is a valuable manœuvre, and should be performed if there is evidence of atelectasis or if secretions cannot be removed by "blind" aspiration. The importance of early bronchoscopy must be stressed, for it will be of little value if withheld until secondary changes appear in the lungs as the result of infection or obstruction of the bronchi. By itself it is only a temporary measure, and must therefore be used as an adjunct to the general treatment already described.

The previous cases show the pitfalls which abound for those concerned with the management of the unconscious patient. Case 4 is included, therefore, to show how satisfactory the result may be when the treatment as advocated in this paper is followed and is instituted at the correct time.

Case 4.—A man aged 66 was admitted to hospital after a fall from his bicycle. He was unconscious and a diagnosis of subdural haemorrhage was made. In spite of a decompression he remained unconscious. Twelve days after the accident, during which time he had become increasingly "chesty," he developed a left lower lobe atelectasis. The temperature rose to 101° F. (38.3° C.), pulse to 110, and respirations to 30. He was slightly cyanosed. Bronchoscopy was performed and a quantity of mucopus was aspirated, mainly from the left side. A tracheotomy was performed the same day, and a further quantity of mucopus was removed. Changes of posture to encourage drainage from the lungs were made more frequently, and on the following day the temperature had fallen to 99° F. (37.2° C.), the pulse to 90, and the respirations to 25. Six weeks after injury the patient was co-operative and making a good recovery. The cough reflex had returned and the tracheotomy was therefore closed.

CONGENITAL ATRESIA OF THE OESOPHAGUS

BY

R. H. R. BELSEY, M.S., F.R.C.S.
Consultant Thoracic Surgeon, Frenchay Hospital, Bristol

AND

C. P. DONNISON, M.D., M.R.C.P.
Consultant Paediatrician, Cheltenham General, Eye, and Children's Hospital

Congenital atresia of the oesophagus is commoner than is generally realized, and if recognized early can be amenable to surgical treatment. The condition is very readily overlooked, but if the possibility is borne in mind it can be diagnosed without difficulty. The purpose of this article is to report a series of cases in support of these statements and to describe the technique of treatment that has been carried out at the Department of Thoracic Surgery of the Frenchay Hospital.

Incidence

The incidence of congenital atresia of the oesophagus has been stated to be about 1 in 2,500 births (Franklin, 1947; Grey Turner, 1949). In our experience the incidence is much greater than this, presumably because many cases are not recognized and deaths are regarded as having been due to atelectasis or pneumonia.

One of us is a consultant paediatrician to a clinical area with a population of about 100,000 in which there are approximately 2,000 births annually. He has seen five cases during the course of two years. The first was in May, 1948, and the patient was 6 days old and very ill with pneumonia, which terminated fatally before surgical treatment could be arranged. The diagnosis was confirmed at necropsy. The remaining cases are described below, being Nos. 2, 4, 7, and 10.

The incidence of cases in this clinical area in which the diagnosis was confirmed was thus 1 in 800 births. It is not to be assumed that all such cases were referred for consultation or that they were diagnosed if so referred. Hence it is reasonably certain that the incidence is distinctly greater than 1 in 800. There is no justification for believing there may be a special incidence of the condition in the area where these observations were made. No epidemic of rubella or other disease that might cause it has been recognized and there has been no undue incidence of other congenital abnormalities.

It is easy to understand how the condition can be overlooked. It presents no easily recognized signs. The infant brings up some frothy mucus during the first day or two of life. Attempts at feeding lead to regurgitation, choking, and probably cyanosis. These events in a newly born infant may call for no special concern on the part of the nurse. By the third day chest symptoms are developing which are attributed to infection, and all further feeding difficulties and respiratory distress are attributed to pneumonia. This terminates fatally when the infant is about a week old, and the cause of death seems obvious. If a necropsy is performed the oesophageal condition is very easily overlooked.

In our cases we have noticed that the condition is often associated with atelectasis, particularly of an upper lobe. The reason for this is not altogether clear, but it may arise from inhalation of saliva, the right upper lobe being a common site for any inhalation phenomenon. Inhalation of feeds is not necessarily an explanation, since in two cases the atelectasis had been recognized before any feeds were given. This may explain why some cases are overlooked. The atelectasis is recognized, and is regarded as the explanation of the infant's condition. The oesophagus is not examined.

We want to emphasize that congenital atresia of the oesophagus probably has an incidence comparable to that of congenital heart disease. Unlike the latter condition, no infant can survive without the prompt aid of the surgeon. Early diagnosis is essential, and if this is to be achieved it is imperative that all concerned with the care of infants during the first few days of life should be aware of the condition and understand when its presence should be suspected.

Pathology

In most cases the anatomical abnormality conforms to the pattern described by Vogt (1929) as Type 3 (b). There is a complete and considerable gap in the intrathoracic oesophagus; the upper segment ends blindly at the level of the superior thoracic inlet, is dilated, and is often densely adherent to the posterior wall of the trachea. The lower segment is narrow and poorly developed, and opens into the posterior wall of the trachea by a vertical slit just above the bifurcation. Rarely, the lower segment is deficient or entirely absent, and there is no tracheo-oesophageal fistula (Vogt Type 2). The extent of the defect in the viscus varies from a thin mucosal obstructing web to complete absence. The position of the tracheo-oesophageal fistula is also variable, and may involve the upper segment or, occasionally, both segments. Cases of tracheo-oesophageal fistula without atresia have been described.

Other congenital abnormalities may be present, but these are rarely incompatible with life. In our own cases the commonest coexisting abnormality has been multiple accessory auricles.

Clinical Manifestations

Most articles published on this condition give rather inadequate descriptions of the clinical manifestations and describe as the typical symptom attacks of cyanosis and choking on attempting to feed. We venture to suggest that this is comparable to describing faecal vomiting as the typical symptom of intestinal obstruction. Feeding these infants is bound to lead rapidly to inhalation pneumonia, and we consider that it is most desirable, and often possible, to recognize the condition before any feeding is attempted. Such recognition before feeding would be achieved more often if midwives and nurses were aware of the condition.

A characteristic feature in most cases is that these infants bring up froth. This has not received adequate recognition in the literature. Many infants will produce some bubbly mucus for a few hours after birth. In contrast the infant with oesophageal atresia brings up a froth comprised of rather smaller bubbles, and this continues or increases. Occasionally the froth is bile-stained. Any infant that is bringing up frothy mucus 24 hours after birth should be investigated for possible oesophageal atresia. Furthermore, no feed should be given until this condition has been excluded by passage of a catheter into the stomach.

Respiratory distress and signs of atelectasis may present themselves before a feed is given. The infant's condition may then be attributed to the atelectasis, which is thought to be an explanation for the subsequent developments. Any infant that is reasonably mature and for no adequate reason presents signs of atelectasis should have a catheter passed into the stomach to exclude possible oesophageal atresia.

A further important sign of the condition is a distended and tympanitic abdomen; the distension, moreover, tends to increase whenever the infant cries or strains. In most cases a lower oesophageal segment is present and communicates with the trachea through a fistula situated just above the bifurcation. Any rise in the intrathoracic pressure forces air through the fistula into the lower oesophagus and thence into the stomach. In the rare case of complete atresia, in which no tracheo-oesophageal fistula is present, the abdomen is dull and no gas can be demonstrated in the intestines on *x*-ray examination.

In every case the infant must be carefully examined for other congenital abnormalities.

Diagnosis

Once suspected, the diagnosis can be quickly and easily confirmed by passing an adult-size rubber catheter into the upper oesophagus. An obstruction is encountered 3 to 3½ in. (7.5 to 8.8 cm.) from the gums. If a thin catheter is passed it may coil up in the blind oesophageal pouch and give the impression that it is passing into the stomach. If an obstruction is suspected all feeds by mouth are withheld, and 15,000 units of penicillin are given by injection immediately, and repeated three-hourly. Survival of the infant is dependent upon early diagnosis, early admission to hospital, and early operation before the lethal complications of the condition have supervened.

A trained nurse armed with a catheter and some means of applying suction—a rubber-bulb Dakin syringe is probably the best, as it can be used with one hand—should accompany the infant to hospital in the ambulance, so that the pharynx can be kept clear of mucus.

On admission to hospital penicillin administration is continued, and mucus is aspirated from the pharynx as quickly as it accumulates. If the lungs are wet and the infant cannot be induced to cough by passing the aspirating catheter down to the epiglottis, postural drainage is employed by placing the infant in the face-down head-low position and gently slapping it on the back.

As the emphasis is on quick diagnosis and early operation to restore bowel continuity, it is questionable whether any time should be devoted to attempts at restoring fluid balance by giving subcutaneous salines, unless the infant is remarkably dehydrated. In our experience this is unusual in the first three days of life.

Without delay an antero-posterior film of the chest and abdomen is taken to reveal the extent of the pulmonary atelectasis and to confirm the presence of gas in the intestine. If no gas is present the inference is that there is no tracheo-oesophageal fistula, and in all probability the lower segment is deficient or absent. In these circumstances immediate restoration of bowel continuity is probably impossible and the surgical treatment has to be modified. The catheter is again passed into the upper oesophagus, and 0.5 ml. of iodized oil is injected and its progress viewed under the fluorescent screen. It is unnecessary and dangerous to inject larger quantities. Barium must never be used owing to the risk of its entry into the lungs. After antero-posterior and lateral radiographs have been taken, the iodized oil is immediately aspirated again.

The radiological confirmation of the diagnosis by the method outlined should be undertaken only in the unit where surgical treatment can follow immediately. It cannot be stressed too often that this condition is an acute surgical emergency, and any step that may delay operation should be avoided; this applies especially to the repetition of diagnostic procedures in the various hospitals through

which the infant may pass before reaching the operating theatre.

No case is too hopeless for operation, but we have reason to believe that some cases are never referred to the surgeon, "because they appear moribund." The worse the condition of the infant the greater the indication for immediate action.

Treatment

Chemotherapy, pharyngeal aspiration, and postural drainage are continued while the above investigations are being carried out. A slow-drip blood transfusion is begun and an injection of atropine given. The infant's colour and general condition will probably have improved since admission as a result of the removal of secretions from the air passages.

The success of surgical treatment depends to a large extent on the skill of the anaesthetist, who should preferably have special experience of both thoracic surgery and anaesthesia in infants.

The technique of the operation performed in this unit differs in detail from the procedure normally adopted. Under intratracheal ether anaesthesia the fifth rib on the right side is resected subperiosteally and the right pleural cavity is widely opened. The mediastinal pleura is incised, the azygos vein is ligated and divided, and the upper and lower oesophageal segments are identified and dissected from the surrounding mediastinal structures. The upper segment may be densely adherent to the posterior wall of the trachea. The lower segment is divided close to the trachea and the fistula closed. The next step is of great importance: the upper end of the lower oesophageal segment derives some or all of its blood supply from the trachea, and after closure of the fistula cyanosis of the cut end of the oesophagus is usually present. Even though it increases the gap between the two oesophageal segments and renders the subsequent anastomosis more difficult, the cyanotic tissue must be trimmed back until free bleeding from the cut edge is seen. Omission of this step was probably responsible for the breakdown of the anastomosis and the death of three infants in this series.

The blind upper segment is opened, drawn down to the shortened lower segment, and an end-to-end anastomosis performed with one row of interrupted 45-gauge stainless-steel-wire sutures. The mediastinal pleura is not sutured. The lung is re-expanded by the anaesthetist and the chest closed without drainage. During the operation 200 to 300 ml. of blood is given and the drip continued with N/5 saline for the next 12 hours. The infant is placed in an oxygen tent. The pharynx is aspirated frequently to remove excess mucus and to stimulate the infant to cough.

No gastrostomy or jejunostomy is performed. Feeding by mouth begins 24 hours after operation, and ½-oz. (14-ml.) feeds of sterile water are given every two hours.

In those rare cases in which no tracheo-oesophageal fistula is present and the lower segment is deficient the operative technique is modified. The blind upper segment is brought out to the surface on the left side of the neck and is opened to allow buccal secretions to escape, to prevent their aspiration into the lungs. The deficient lower oesophageal segment is dissected free from the mediastinum and pushed down into the peritoneal cavity; the oesophageal diaphragmatic hiatus is then closed. The abdomen is opened, and, after freeing the upper half of the stomach by division of the left gastric artery and gastro-splenic omentum, the lower stump of the oesophagus is brought to the surface as a gastrostomy. An immediate cervical oesophago-gastric anastomosis is not attempted, but the procedure is deferred till a later date.

Results of Treatment

The many surgeons in this country now interested in this problem almost certainly have a few successes to their credit, and the time has come for the pooling of information regarding not only the survivors but the failures as well, to stimulate physicians and midwives to consider the diagnosis earlier and to take the necessary steps to have it confirmed.

Ten cases have been treated surgically in this unit. Of these patients five are alive and well and five died after operation. There have been two deaths in the last seven cases. In all instances a right transpleural thoracotomy was performed under intratracheal ether anaesthesia; in nine the fistula was closed and bowel continuity restored by an end-to-end anastomosis; in the remaining case no anastomosis was possible, owing to the absence of the lower oesophageal segment, and the infant is thriving on gastrostomy feeds pending a cervical oesophago-gastric anastomosis at a later date. No late complications have been encountered in the survivors.

A brief review of the fatal cases is instructive. One infant, in whom the diagnosis was not made till the fifth day of life, when bilateral bronchopneumonia was already present, died 12 hours after the operation from the lung infection. Another patient, a puny premature infant of 4 lb. (1.8 kg.), 2 days old and almost moribund on admission, died 10 hours after operation from extensive pulmonary atelectasis, which, after recovery from anaesthesia, developed owing to the infant's inability to cough. This infant might have been saved by bronchoscopy.

The three remaining patients all died of infection resulting directly from a leak at or near the site of the anastomosis. In none of these three was the blood supply to the lower segment safeguarded by trimming back the cyanotic upper end. In the light of our more recent experience it is not unreasonable to assume that these three might well have survived if this most important factor had received due consideration.

Case Records

Case 1.—A male infant 5 days old was admitted on October 18, 1946. Since birth there had been regurgitation, frothing, and cyanosis. His general condition was very poor, with evidence of bilateral bronchopneumonia. Gas was present in the bowel. Operation was carried out immediately without blood transfusion. The fistula was closed and an end-to-end anastomosis done. He was dyspnoeic and cyanosed for a considerable time during induction of anaesthesia and died 12 hours after operation from bronchopneumonia.

Case 2.—A male infant 5 days old was admitted on June 28, 1948, with a similar history. His general condition was poor; the lungs were very wet; the right upper lobe was collapsed; and the abdomen was distended with gas. Immediate operation was performed, with blood transfusion. The fistula was closed and end-to-end anastomosis done without trimming back the ischaemic lower segment. Evidence of a leak at the anastomosis appeared two days after operation. Gastrostomy and drainage of right pleura by intercostal catheter were carried out. He died on the eighteenth post-operative day with bronchopneumonia, undrained loculated basal empyema, oesophago-pleural fistula, patent ductus, and patent foramen ovale.

Case 3.—A male infant 4 days old was admitted on December 1, 1948. He had had cyanosis and regurgitation since birth and his general condition was poor. The right middle lobe was collapsed, and gas was present in the bowel. Blood transfusion and immediate operation were performed, with closure of the fistula and end-to-end anastomosis. The infant died on the fifth post-operative day with tension pyopneumothorax due to a leak at the anastomosis. The ischaemic lower segment of the oesophagus was not trimmed back in this case.

Case 4.—A male infant aged 2 days, admitted on December 18, 1948. No feeds had been given owing to frothing since birth. The right upper lobe was collapsed and the abdomen distended with gas. His general condition was fairly good. Blood transfusion and immediate operation were done; the fistula was closed and end-to-end anastomosis performed after resecting the upper centimetre of the lower segment. Convalescence was uneventful. He was fed by mouth from the second post-operative day. A post-operative barium swallow showed a well-functioning anastomosis.

Case 5.—A male infant 3 days old was admitted on April 24, 1949, with a characteristic history. He was very dehydrated, his general condition was poor, and he was passing no urine. The right upper lobe was collapsed and the abdomen distended. Blood transfusion and operation were carried out, the fistula was closed, and end-to-end anastomosis performed with great difficulty, as the upper segment was very short and only just reached the apex of the chest. The lower segment was cyanosed, but had it been resected the gap could not have been bridged. There was evidence of a leak on the fifth post-operative day; the empyema was drained and gastroscopy performed. He died on the ninth post-operative day from suppurative pericarditis.

Case 6.—A male infant 2 days old was admitted on August 29, 1949. No feeds had been given on the first day owing to frothing. On the second day two feeds were given and both were regurgitated; cyanosis was present after the second. His general condition was good. The lungs were dry and there was no gas in the intestines. Blood transfusion and operation were performed: no fistula was present and no anastomosis was possible, as the lower segment was deficient and extended only 2 cm. above the diaphragm. The chest was closed and cervical oesophagostomy and gastrostomy were performed. Convalescence was uneventful. The infant is now thriving on gastrostomy feeds; for restoration of bowel continuity later.

Case 7.—A female infant 2 days old was admitted on September 18, 1949. She frothed copiously two hours after delivery and her lungs were very wet. All feeds were returned, but there was no cyanosis. The right upper lobe was collapsed, and the bowel contained gas. Blood transfusion and operation were performed, the fistula was closed, and end-to-end anastomosis made. Convalescence was uneventful. Mouth-feeding began on the second post-operative day. The infant is now progressing normally.

Case 8 (Figs. 1 and 2).—A male infant 3 days old was admitted on October 2, 1949. Frothing, regurgitation, and cyanosis had been present since birth. The diagnosis was missed at one hospital owing to the use of a fine catheter, which coiled up in the oesophagus. The lungs were wet, and the abdomen distended with gas. Blood transfusion and operation were performed; the fistula was closed and end-to-end anastomosis performed with difficulty, as the upper segment was short and the gap to be bridged was formidable; nevertheless the lower segment was trimmed back and a satisfactory anastomosis finally achieved. Convalescence was normal. Mouth-feeding was started on the second post-operative day. The infant is now well and is feeding normally.

Case 9.—A female infant, admitted when 7 days old, had vomited every feed since birth. There had been frequent attacks of cyanosis, and frothing was continuous. She was very dehydrated, but the lungs were wet. Admission to hospital had been delayed "because the infant appeared to be moribund." The abdomen was distended. The birth weight was 6 lb. (2.7 kg.), and at the time of operation was 3½ lb. (1.6 kg.). Blood transfusion and operation were performed, with closure of the fistula and end-to-end anastomosis after

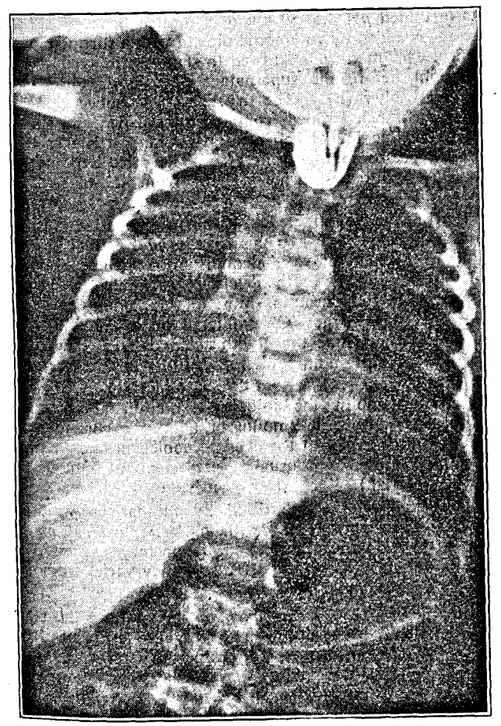

FIG. 1.—Case 8. Pre-operative film showing very short upper segment outlined with lipiodol, and pressure of gas in intestines.

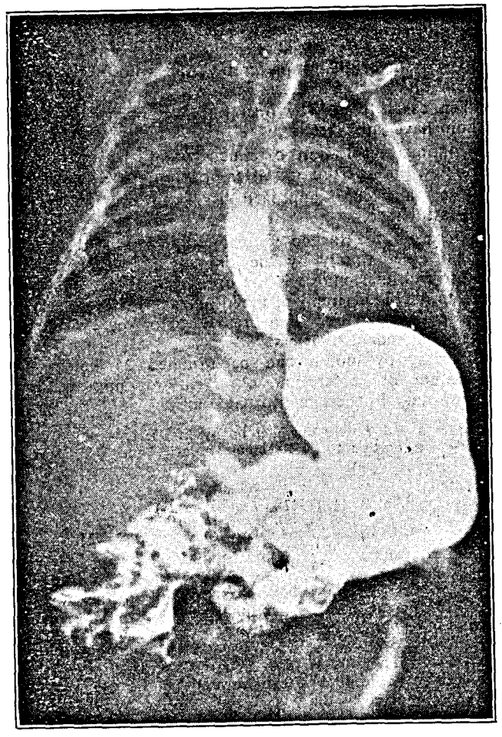

FIG. 2.—Case 8. Barium swallow five weeks after operation.

trimming back the lower segment. Mouth-feeding began on the second post-operative day, and convalescence was uneventful.

Case 10.—A female infant was admitted on February 5, 1950, when 2 days old. Pregnancy had been terminated at 38 weeks owing to severe pre-eclamptic toxaemia. Birth weight: 4 lb. 11 oz. (2.1·kg.); on admission 4 lb. 4 oz. (1.9 kg.). The lungs were wet; there was no cough reflex; and she was cyanosed and frothing. The case had been diagnosed elsewhere as "atelectasis of the left lower lobe," and a tracheal catheter had been passed for aspiration. Mucus aspirated from the pharynx was blood-stained. Blood transfusion and operation were performed; the fistula was closed and end-to-end anastomosis done after trimming back the lower segment. Her post-operative condition was satisfactory at first, but the cough reflex never returned, and she died 12 hours later with atelectasis of both lungs. Both bronchi were full of blood clot and mucus.

Conclusions

Congenital atresia of the oesophagus is commoner than is generally realized, the incidence probably being at least 1 in 800 births. Cases are missed clinically or at necropsy because they are considered to have developed pneumonia or to have atelectasis.

Diagnosis is easy once the condition is suspected. An infant that brings up an undue amount of mucus, particularly as a fine froth, for several hours after birth should be suspected of atresia, and such an infant *should not be fed by mouth until the condition has been excluded.* Diagnosis can easily be confirmed by passage of a medium-sized rubber catheter.

Operation holds out good prospects of cure if these cases are diagnosed early and operated upon promptly. Operation is hardly worth attempting unless there is available an anaesthetist with special experience in connexion with thoracic surgery, and preferably one who has made a special study of anaesthesia in infancy.

Ten cases treated by operation are recorded, five of whom have survived.

Continual aspiration of mucus from the mouth and pharynx, both before and after operation, is necessary.

The transpleural approach has been used in all five successful cases.

Closure of the tracheo-oesophageal fistula and restoration of bowel continuity by the simplest form of one-layer end-to-end anastomosis is the operation of choice. Attention to the blood supply of the lower segment should reduce considerably the risk of a breakdown of the anastomosis and its attendant disasters.

Feeding by mouth can be resumed 24 hours after operation, or earlier, and a gastrostomy appears to be unnecessary in the uncomplicated case.

Cases 3 and 7 were operated on by Mr. J. L. Griffith, second surgeon to the South-west Regional Thoracic Unit.

Revised salary scales have been agreed for senior nursing staff in general and fever hospitals and sanatoria. The new scales are part of the general review of nurses' salaries which has been proceeding for some time, and they have retrospective effect from February 1, 1949. The new scales cover all senior staff in these hospitals except tutorial grades, which are now being considered by the Nurses and Midwives Whitley Council. The scales for senior staff in mental and maternity hospitals are also under consideration.

REVIEW OF ONE YEAR'S WORK IN WATFORD PREGNANCY DIAGNOSTIC CENTRE

BY

H. SCHWABACHER, M.R.C.S.

(From the N.W.M.R.H.B., Group 9 Laboratory, Watford)

The Watford Pregnancy Diagnosis Laboratory at Shrodells Hospital, Willow Lane, Watford, was set up in 1949, and was equipped to undertake the Hogben test for pregnancy. This particular test was chosen because it is more reliable, more economical, and more easily adapted for routine work than any other method.

The main requirement for reliable results by the Hogben method is that the test animals (*Xenopus laevis*) are in good condition before being used. The routine followed at Watford is almost identical to that published by Landgrebe and Hobson (1949). When the animals are thought to be suitable they are first tested by the administration of 70 i.u. of chorionic gonadotropin. Only those which respond are used for pregnancy diagnosis. For this purpose a dry stable extract of chorionic gonadotropin was made by a modification of the Katzman and Doisy method (1931).

Preparation of Extract of Chorionic Gonadotropin

All urines yielding a positive Hogben reaction are pooled and filtered the day after receipt. To every litre of urine (A) (acidified *p*H 4.5) 50 ml. of saturated benzoic acid in acetone is added by volumetric pipette with a stirring movement. This mixture is allowed to stand in the refrigerator overnight before the supernatant fluid is decanted into another beaker (B). The dry deposit is collected on a Buchner funnel, scraped from the filter paper, and stored under acetone in the refrigerator. Fluid in beaker B is again processed as the urine (A). The dried deposits are pooled—30 litres of urine yielding from 1.5 to 6 g. of powder.

The powder is extracted with three consecutive amounts of 100 ml. of water. To this slightly acid extract (C) are added 3 volumes of 95% alcohol and 1 volume of ether (diethyl ether); it is then left in the refrigerator for 18 hours. After decanting most of the alcohol and ether the remaining extract (C) is filtered on a small Buchner funnel, washed three times with acetone, dried quickly in warm air, placed in ampoules, sealed off, and stored in the refrigerator.

Before attempting the biological standardization, one can estimate the probable amount of chorionic gonadotropin per mg., assuming that the original pooled urine contained 20 i.u. per ml. (It is usual to extract about 80% of the active material.)

This powder is standardized by comparison with the international standard powder, using *Xenopus laevis* as test animal (Landgrebe, 1948), and its potency expressed in international units per mg. The potency varies from 100 to 400 i.u. per mg.

Number of Tests Undertaken in 1949.—Once the stock of *Xenopus laevis* reached 200 tested animals, urines from Hertfordshire were accepted. Specimens from London and the South of England were taken as the number of tested animals increased. In February, 41 specimens were received, while the peak number handled was 522 in October; 3,724 tests were performed throughout the year.

Technique of Test

The chorionic gonadotropin was extracted from the urine according to Scott's method (1940). Half of the eluted gonadotropin—that is, 2.5 ml.—was injected into one toad; the other half was kept at 2° C. overnight and injected into a second toad if the first had failed to ovulate after 18 hours.

Over a series of 103 specimens it had been noticed that, when two toads were injected with the extract on the same day, only in three cases did one toad ovulate without the other responding. Hence it was decided to inject the second toad only if the first had yielded a negative result after 18 hours. On the evidence obtained from the Pregnancy Diagnostic Centre, Edinburgh, about 50% of our tests would be positive, and we were thus able to increase the possible number of tests undertaken with the same number of test animals by 25%. Table I demonstrates that on 55 occasions out of a total of 1,220 tests the *first injected* toad yielded a false result when "read" at 18 hours, in that it had failed to ovulate until 24 to 48 hours, or failed to ovulate at all, whereas the *second toad,* inoculated with the same extract a day later, yielded a positive result.

TABLE I.—*Demonstrating the Need to Inject a Second Animal When the First Animal Failed to React*

No. of Cases	Delayed or Negative Reaction in Toad I		Positive Reaction in Toad II from Identical Extract
	No Reaction After 48 Hours	Positive Reaction within 18 to 48 Hours	Positive Reaction within 18 Hours
55 (4·5% out of 1,220 tested)	35 (63·6%) 2·86%	20 (36·4%) 1·64%	55 (100%) 4·5%

The recording of delayed positive or false negative results is being continued, as it is thought we may have here a means of evaluating the sensitivity of the animals in our colony.

Distribution of Toad Population in the Tanks.—Negative reactors (A) are placed in tanks (A1) and positive reactors (B) in tanks (B1) until there are 50 animals in each tank. These animals are rested for one month. Toads from tank A1 are used for the fresh tests, and are rested in tank A2 or tank B2. All A3 toads (reacting negatively to three injections) are tested by injection of 70 i.u. of extract. We have had to reject 2.7% of our toads. Thus the subnormally reacting toads are continually being excluded from use. "Positive" toads in B tanks are used regularly for the second injection of a negative Hogben reaction.

An Analysis of the Tests Undertaken

We have recently attempted to encourage the doctors to fill in the data asked for on our request forms by refusing to submit the result of the Hogben test until they return the amended form. We now receive a wealth of information.

In Table II are shown the reasons for which the urines were sent to our laboratory for test.

TABLE II.—*Reasons for Submitting Urine for the 3,724 Hogben Tests Performed*

Clinical Condition	
Abortion	12·6%
Hydatidiform mole	5·7%
Abnormal implantation	1·9%
Tuberculosis (pulmonary)	1·5%
Assumed to be normal pregnancies	39·6%
Menopause	9·5%
Fibroid or tumour	3·2%
Unmarried mother	3·9%
Testicular carcinoma	0·33%
Hormonal amenorrhoea (i.e., obesity, anaemia, etc.)	6·4%
Heart lesions	0·07%
No information given	15·3%
	100·00%

Confirmation of Laboratory Findings

Printed cards, asking whether the Hogben reaction agreed with clinical findings, are posted two months after the Hogben test is carried out. This enables the practitioner to report to us with certainty.

False positive Hogben reactions do not occur. The animal cannot ovulate unless it is injected with the active substance. When, at our request, the doctors were asked to investigate the laboratory's two false positive reports, it was elicited that the patients had concealed their abortion (Table III, D).

TABLE III.—*Interesting Cases*

Group	Evidence			
	Histological Report	Ref.	Hogben Test	Doctors' Confirmation
A. Testicular	Teratoma	557	−	
	Seminoma	562	−	
	Malignant	2,560	+	
B. Pregnancy with menstruation	Confinement May	2,159	+1/10	Pregnant
	Menstruation August to October	2,728	+1/10	
C. Pregnancy with *delayed* Hogben reaction	L.M.P. 10 weeks	1,099,	−,	*X*-ray foetal parts present
	,, 12 ,,	1,291	−	
	,, 20 ,,			
	L.M.P. 8 weeks	796	−	
	,, 10	1,163	−	
	,, 11 5/7 weeks	1,360	+	
	L.M.P. 5 weeks	Edinburgh	−	
	,, 9 ,,	,,	−	
	,, 11 ,,	2,151	+	
D. Pregnancy		891	+	Neg. reinvestigated; patient had aborted
		1,386	+	Neg. reinvestigated; patient had aborted

False negative Hogben reactions may occur when the chorionic gonadotropin in the urine is deficient because the urine has been sent too early, or the urine is not a concentrated specimen—that is, of too low a specific gravity—or if the patient is a poor secretor or excretor, or destruction of the chorionic gonadotropin by an unknown factor has occurred.

Owing to the small number of tests undertaken and to the insufficient confirmatory returns in 1949, figures for the evaluation of the accuracy of the work at Watford will be pooled with this year's results and published in the report for 1950.

Some interesting cases are recorded in Table III. There has been only one case of testicular carcinoma: this we were able to confirm (Group A). Group B represents one patient in whom we were able to allay the fear of malignancy and predict a second conception within three months of delivery of a first baby. The three cases in Group C in which the Hogben test became positive two months after probable conception are examples of failure to send early morning specimens of urine of high specific gravity.

Case of Hydatidiform Mole

This case is recorded (Table IV) by permission of Professor F. J. Browne.

According to dates, this patient was 8 to 10 weeks pregnant when first seen, yet the uterus showed a four-months pregnancy. The uterus failed to increase in size during the four weeks of the investigation.

TABLE IV.—*Hogben Tests in a Case of Hydatidiform Mole*

20	138	4041	10/1/50	—	
21	26 days	4258	30/1/50	—	

One millilitre of cerebrospinal fluid was negative to a Friedman test on November 30. A larger volume, 8 ml., injected on January 3, 1950, produced a strongly positive Friedman reaction. It is emphasized that it is *unnecessary to use cerebrospinal fluid* for confirmation of hydatidiform mole. A few years ago, to end the habitual procedure of spinal puncture, the Usher Institute, Edinburgh, refused to accept specimens of cerebrospinal fluid.

Pre-operative urine on December 1 yielded a positive Hogben reaction in a dilution of 1 in 500. Tests repeated 28 and 32 days later reacted only in a dilution of 1 in 10. In view of the lessening of chorionic gonadotropin, the absence of evidence of foetal parts by x-ray examination, and the fundus of fourth-month pregnancy it was decided to empty the uterus. This was accomplished by the vaginal route on January 4, 1950.

Twenty specimens of urine were collected in the course of six days, in the hope of detecting the point at which chorionic gonadotropin was no longer being excreted. The test remained positive up to the fifth post-operative day. During this time no specimen caused a reaction in a dilution of 1 in 10. From the sixth post-operative day the test became negative.

Summary

A description is given of the preparation and standardization of chorionic gonadotropin from urine.

The method of using and resting the Watford colony of tested *Xenopus laevis* is recorded.

Some interesting cases are reviewed.

I wish to express gratitude to Dr. F. W. Landgrebe, of the Usher Institute, Edinburgh, for all the helpful interest he has taken in the Watford Pregnancy Diagnostic Centre.

The Minister of Health recently received a deputation from the Socialist Medical Association, when tuberculosis and its treatment under the National Health Service were discussed. The deputation put forward a number of proposals. The Minister in reply drew attention to the progress already achieved and indicated the lines along which he hoped there would be further advance.

USE OF THE MALE BRITISH TOAD AS A PREGNANCY TEST ANIMAL

BY

J. F. D. FRAZER, B.M., B.Ch.

AND

F. X. WOHLZOGEN, M.D.Vienna

(From the Department of Physiology, St. Mary's Hospital Medical School, London)

In the last four years various workers have successfully used male toads of numerous species in the Galli Mainini pregnancy test (Galli Mainini, 1947, 1948; Houssay, 1947). It was decided to investigate the possibility of using the British species (*Bufo bufo*) as a pregnancy test animal.

Method

Two male toads of over 15 g. weight each have 1 ml. of filtered first morning urine injected into the dorsal lymph sac. The toad's cloacal urine is taken at the time of injection. and the absence of spermatozoa is checked. Further samples are taken three to six hours later, and the presence of spermatozoa in any of these is regarded as a positive result (see Fig.). If no sperms can be detected in either toad's cloacal urine six hours after injection the result is negative.

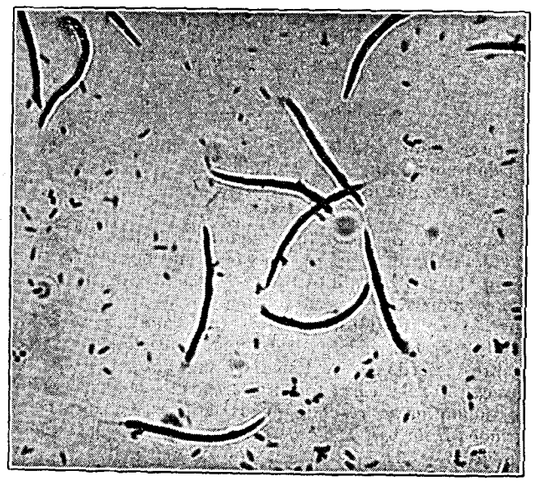

FIG. 1.—Toad spermatozoa (*Bufo bufo*) (× 1,000). The thick black lines are the heads of the sperms, the tails being much finer. The usual debris found in these smears is also present. (Stained Giemsa.)

The toad's urine is collected by means of a fine glass pipette of 1 mm. diameter inserted into the cloaca and moved gently backwards and forwards. This can be examined, unstained, under a low-power microscope (⅔ in.—16 mm.).

Toads can be reused after one week, but no toad should be used for more than four tests, as the reaction is then less prompt, is less pronounced, and sometimes fails altogether.

Results

Eight consecutive tests on 80 pairs of toads gave 53 positive and 27 negative results. Of the 53 positives, 51 were confirmed clinically as pregnancy, one as hydatidiform mole, and one as a chorionepithelioma of the testis. Of the 27 negatives, 26 were subsequently proved clinically not to be pregnant. The one false negative was an early pregnancy of less than six weeks which a few days later became a threatened abortion.

Discussion

A suitable quantity for injection was 1 ml. of first morning urine, this being the most concentrated specimen of the day. Positives could then be obtained when afternoon specimens gave negative results. Some of Klopper and Frank's (1949) false negatives may be due to this, despite the injection of 2 ml. a toad. Cerquiglini's (1948) injection of 10 ml. a toad is far too much for toads around 20 g. in weight.

The weight of the toads should be over 15 g. This was shown by analysis of the first 25 positive tests (see Table). Of the toads heavier than 15 g. 97% were positive after six hours, while only 75% of the lighter toads were then positive.

TABLE.—*Difference in Response Between Light and Heavy Toads*

Time in Hours	No. of Toads First Giving Positive Result	
	Over 15 g.	15 g. or Less
After 2	24	5
,, 4	7	6
,, 6	2	1
,, 24	1	2
Not in 24	0	2

Pairs of toads are used for every test, and the result is regarded as positive even if only one responds. Thus in our series of 53 positive tests (that is, 106 toads), three toads gave a negative result. With single toads the accuracy would then have been 97%, but the use of pairs brings it to over 99.9%.

In considering the stage of pregnancy after which the toad test becomes positive one has to realize that this, as well as the Aschheim–Zondek, Friedman, and Hogben tests, is essentially a test for gonadotrophins; so the result will depend on the concentration of gonadotrophins excreted in the urine. In normal pregnancy the urinary gonadotrophin level shows a marked rise about the fourth to sixth weeks; before this time it is generally too low for there to be sufficient gonadotrophin in the injection mass to produce a positive result in the various biological pregnancy tests.

As the thresholds of different test animals—mice, rabbits, *Xenopus*, *Bufo*—are not the same, and as in various tests different amounts of urine are injected, it is obvious that not all of the pregnancy tests will become positive at the same time. It has been tentatively put forward (Frazer and Wohlzogen, 1949), and since confirmed (Frazer and Wohlzogen, 1950), that in the British toad the threshold (ED 50) is about 8 i.u. for standard chorionic gonadotrophin. Despite the results of Bach and Szmuk (1949) on frogs, this threshold in *B. bufo* has not varied significantly at different times of the year in toads kept in a warmed animal-house. Use of the same standard gonadotrophin has shown a threshold for the Friedman test of 15 i.u. approximately; for the Aschheim–Zondek 10 i.u. approximately, and for the *Xenopus* 70 i.u. approximately (Frazer and Wohlzogen, unpublished). With the usual amounts of urine injected in these tests—namely, Friedman 15 ml., Aschheim–Zondek 2 ml., *Xenopus* 7 ml., and *B. bufo* 1 ml.—this means roughly that the gonadotrophin levels above which positive results are obtained with unconcentrated urine will be: Friedman, 1 i.u./ml.; Aschheim–Zondek, 5 i.u./ml.; *B. bufo*, 8 i.u./ml.; and *Xenopus*, 10 i.u./ml.

From this it becomes apparent that the Friedman test will give a positive result earlier in pregnancy than the others. The toad test, however, can be brought up to the same level of sensitivity as the Friedman test by concentrating the urinary gonadotrophins eight times by the method of Scott (1940).

Conclusion

The series of positive results with unconcentrated morning urine were obtained from cases ranging from the fourth week (eight cases) to the seventh month of pregnancy. Over this period there would seem to be no bar to the use of the toad test; but when negative results are obtained in what may be the third to sixth weeks of pregnancy it would be advisable, for 100% accuracy, either to concentrate the urine eightfold or tenfold and repeat the test, or to perform a Friedman test. If neither is feasible the test should be repeated after a fortnight. Which alternative is adopted may depend upon the laboratory facilities available.

Summary

The use of the male British toad (*Bufo bufo*) for pregnancy tests is described. In a series of 80 consecutive cases no false positive and only one false negative result was obtained.

The results are discussed, and suggestions are made for the assessment of the results of pregnancy tests in what may be the first six weeks of pregnancy.

Medical Memoranda

Inversion of the Uterus

Inversion of the uterus is a very rare condition. The incidence is variously estimated at figures varying between 1 in 16,000 and 1 in 200,000 deliveries. The most searching article on the subject is that written by P. Das (1940). He studied the literature from the earliest times and found records of 391 cases, of which 297 were puerperal. I have found references to a further 122 cases in the journals available to me, while many more are to be found in the *Index Medicus*.

Case Report

The patient, aged 34, was in her fourth pregnancy. Her last menstruation was on October 10, 1946, and her expected date of confinement was July 28, 1947. Her three previous pregnancies had gone to term and her labours had been rapid —the longest three hours. All the children are alive and in good health. Throughout pregnancy she was very well and had no abnormalities of any kind.

Two weeks before her expected date she felt crampy pains which she attributed to indigestion. These persisted for about 24 hours, when they became stronger and were followed by a "show," after which delivery was accomplished in about 50 minutes. The perineum was intact. The third stage was completed in 20 minutes, with a total blood loss of about 10 oz. (284 ml.).

One hour after delivery the uterus was firmly contracted, and as there had been no loss of blood I left the house. The nurse was called away to another case about an hour later. When she left, the uterus was still firm and no bleeding had occurred. About 30 minutes after her departure the patient felt the need to micturate, and having no bedpan raised herself on to the chamber pot. During the act she "felt something come down" in the vagina, and, finding a mass at the vulva, lay down and sent for me.

On arrival about 10 minutes later the inverted fundus was visible at the vulva, the tubal ostia showing clearly. Only slight oozing was occurring from the placental site. Her pulse was 92. The vulva and fundus were liberally swabbed with "dettol" (20%). Vaginal examination confirmed that the uterus was inverted. The loose cuff of the dilated cervix was palpable. The uterus was reinverted by gentle pressure with a sterile pad. Morphine, ¼ gr. (16 mg.), and ergometrine, 0.5 mg., were given and a course of sulphathiazole was ordered. Her pulse rate was now 80.

Throughout the puerperium her temperature did not rise above 98° F. (36.7° C.) nor the pulse rate above 88. The patient was allowed up on the twelfth day and has been free of symptoms since. She carries out her household duties every day.

Acquired Sensitivity to Thiopentone

The following case illustrates how individual requirements for thiopentone can vary from time to time.

CASE REPORT

A woman aged 64 was to be operated on for acute intestinal obstruction. Her general condition was poor, she was ill-nourished, and had been vomiting for 24 hours, though cyanosis and jaundice were not present and she did not look anaemic. Her blood pressure was 180/100 mm. Hg, and pulse 100. Atropine sulphate, 1/100 gr. (0.65 mg.), and morphine sulphate, 1/6 gr. (11 mg.), were given one hour before operation and she was induced with 12 mg. of curare and 0.3 mg. of thiopentone. Slight respiratory depression for about 10 minutes followed this, but no apnoea. Anaesthesia was maintained with cyclopropane and oxygen, and 3 mg. of curare was given after half an hour. A volvulus of the pelvic colon was found and resected, leaving a left inguinal colostomy. The operation lasted 65 minutes, and at the end the patient had completely recovered her cough reflex.

Failure of the colostomy to close necessitated another operation six weeks later. Her general condition had by now greatly improved. Premedication was given as before. After an initial dose of 0.2 g. of thiopentone she became apnoeic, and artificial respiration with oxygen, using a Coxeter-Mushin absorber, was undertaken. The surgeon at this stage commented on the satisfactory relaxation. The absorber was cut out of the circuit periodically lest the washing out of alveolar CO_2 had been serving to maintain the apnoea. After 20 minutes she was intubated orally and the pharynx packed without any sign of resistance from the patient. Later 3 ml. of nikethamide and 1.5 ml. of picrotoxin were given intravenously with no response.

After 50 minutes' apnoea spontaneous respiration began, and at the end of the operation, which lasted one hour, she was breathing normally. Consciousness was regained an hour later, and apart from mild bronchitis she made an uneventful recovery.

COMMENT

The altered response of this patient to thiopentone points to some change having occurred in her detoxicating powers.

Thiopentone detoxication is imperfectly understood (Hewer, 1948), but the drug is believed to be broken down quickly in the tissues generally (Adams, 1944). The role of the liver in this process is very debatable, and, while some hold that it plays a major part (Shideman and Kelly, 1947a, 1947b; Shideman, 1948, 1949; Walker and Wynn-Parry, 1949), Richards and Appel (1941), Lundy (1942), and Scheifley (1946) do not believe that liver damage prolongs thiopentone anaesthesia. Liver and kidney function tests done on the day after the second operation revealed gross dysfunction, and there were persistently high quantities of urobilin in the urine.

The patient was also grossly deficient in vitamin C. While this deficiency prolongs pentobarbitone ("nembutal") narcosis, of which thiopentone is the sulphur analogue, Adriani (1946) denies that it plays any part in the detoxication of thiopentone.

Fears that thiopentone administration might have a deleterious effect on patients undergoing sulphonamide therapy were abandoned after the experience gained in the last war (Adams, 1944). Nevertheless, it may be mentioned that in my case 21 g. of sulphadiazine had been administered two weeks previous to the second operation, and that a course of succinylsulphathiazole was started 24 hours before it. The precise bearing of this on the course of events is a matter for speculation.

Shortly before her discharge from hospital the patient informed us of her intention to resume the "injections for the blood," which she had been having thrice weekly prior to admission. Blood examination at that time showed: red cells, 1,430,000; white cells, 2,000; Hb, 40%; the stained film being typical of pernicious anaemia. Her first operation being a night emergency, no pre-operative blood examination was feasible, and her satisfactory post-operative course gave no indication for haematological investigation.

On incubating thiopentone with blood at body temperature, Richards (1947a, 1947b) found a decrease in potency which did not occur when plasma was substituted for whole blood. This suggests that some enzyme in the red cells is capable of detoxicating thiopentone. In my case the deficiency in the red cells due to anaemia at the time of the second anaesthetic would mean loss of this enzyme and could account, at least in part, for the altered response to the drug.

Liver deficiency could have been secondary to the gross degree of anaemia that developed during the six weeks' abstinence from liver extract, and could have been a manifestation of anoxia. Thus the "acquired sensitivity" to thiopentone can be attributed to a combination of gross anaemia and liver damage.

I am indebted to Mr. A. M. Abrahams and Dr. J. B. Hargreaves for permission to publish this case, and I would be interested to hear of any similar cases.

TUMOUR FORMATION

Studies on Tumour Formation. By the late G. W. deP. Nicholson, M.A., M.B., B.Ch. (Pp. 637; 183 figures. 63s.) London: Butterworth. 1950.

Between 1921 and 1938 the late Professor G. W. Nicholson wrote a series of articles on tumour formation for the *Guy's Hospital Reports*. These are collected together and published in chronological sequence in this volume, which, as Professor R. A. Willis says in the foreword, "is a fitting memorial to a great man who was too little known in his lifetime."

It is regrettable that Nicholson's published work was not more widely read in his lifetime. This was to a large extent due to his strong aversion to the public exposition of his views and his disinclination to oversimplify his writings. His literary style was entirely his own, and this volume carries so deep and accurate an impression of his personality that, in order to give the prospective reader some idea of the scope and quality of the work, it is necessary to say something of the author himself.

Nicholson was first and foremost a general biologist with a passionate interest in microscopic structure and the broad problems of growth and development. With this background he was led, in the genial atmosphere of the Guy's Medical School, to the study of tumour formation, and to this problem he unselfishly devoted his life and energies. Others have followed or are following this trail, but Nicholson's writings and teaching had a unique quality which was to a large extent the outcome of his early training in the humanities. He brought to the study of biology the fruits of an arduous Continental schooling in the classics and a long period of rigid training in formal logic and Germanic philosophy. As he reached maturity and his experience of the structure and behaviour of tumours ripened, his deductions were the outcome of intellectual integrity, an uncommon degree of independence and impartiality of thought, and fierce intolerance of dogma which provoked him in his published work to outspoken and almost pungent criticism.

Although the last chapter of this volume was published twelve years ago, Nicholson's deductions with regard to the fundamental nature of tumour formation have not been outdated by modern discoveries. Close analysis of his evidence led him to believe that in structure, function, and manner of growth tumours "do not differ essentially from other tissues and obey the laws of growth that govern their behaviour." With regard to causation, he concluded that two basic factors were concerned—an external stimulus (factor of realization), and an intrinsic cellular reaction, which he concluded must be "essentially natural, biological, and entirely physiological." He was not greatly concerned with the external stimulus, the carcinogen, or, as he called it, the "cause of cancer in the medical sense." He believed that we understand as much about this aspect of causation as we do about infection. He was almost entirely preoccupied with the living reacting cell, and the growing modern tendency to investigate the biochemistry of the growing cell supports his belief.

Of the twenty chapters in the book six deal with specific but debatable subjects in tumour pathology, such as the hypernephromata, the mixed tumours, the teratomata, and the heterotopic tumours. In each case, although the basic significance of observed structure is fully examined, the tumour in question is used to illustrate general principles or to stress the futility of some theory or hypothesis which professes to "explain" its origin. The hypotheses of Cohnheim, Grawitz, and Wilms are dealt with in turn, gently at first, then with a gradually rising crescendo of less and less restrained criticism.

The remaining chapters are on the application of biological principles to the general pathology of tumour formation, and of these Chapter XI (Causation: Reaction and Environment), Chapter XIII (Somatic Development and Tumour Formation), and Chapter XX (Induction and Determination) should be read by every serious student of the subject.

To read this book demands patience and concentration. As the author's arguments are unfolded the reader is likely to meet with some rude shocks to one or other of his cherished beliefs. He may sometimes be annoyed, but he will far more often be amused. He will certainly be made to think, and it is very probable that he will never again say that "tumours are autonomous."

GEOFFREY HADFIELD.

TEXTBOOK OF RADIOTHERAPY

A Short Textbook of Radiotherapy for Technicians and Students. With a supplementary Chapter for the Dermatologist. By J. Walter, M.A., B.M., M.R.C.P., D.M.R.E., and H. Miller, M.A., Ph.D., F.Inst.P. Foreword by J. L. A. Grant, *M.C.*, F.R.C.S.Ed., F.F.R., D.M.R.E. (Pp. 444; 199 illustrations. £1 8s.) London: J. and A. Churchill. 1950.

When a book covers the intricacies of modern physics, deals with cancer from a medical point of view, and is on a subject, radiotherapy, which many doctors shy away from, it is clearly a delicate task to be lucid for girls of School Certificate standard who will have to use the book for technical examinations. This book is written for radiographers and student radiographers, and whether the authors have succeeded entirely in their aim cannot be easily decided by anyone familiar with the technical terms. For instance, will the average radiographer be confused by two different applications of the word "normal" occurring on the same page? Only the reader for whom it is designed can answer these questions properly. In the opinion of the reviewer the authors have succeeded admirably in their aim and, moreover, produced a book which will serve for medical students as an introduction to a subject which is something of a mystery to them. Physics, radium, radon, and high-voltage radiation, together with super-voltage apparatus and radioactive isotopes, are some of the non-biological ingredients, while accounts of theories of cancer development, spread of cancer, biological action of radiation, and effects of *x*-ray treatment are some of the biological ingredients. The fruit of the cake consists of accounts of various diseases coming within the scope of radiotherapy and of the methods employed in dealing with them, together with a section on protection from radiation. The whole is liberally decorated with diagrams and photographs which are clear in their application, and the last two-thirds is spiced with quotations and footnotes which show the derivation of some medical words.

Inevitably the readers for whom it is intended are destined to suffer from some mental indigestion, but the authors have done well in making the cake appetising and attractive, considering all the ingredients necessitated by the examinations which radiographers must take in therapy. Any radiotherapist could criticize some points, but all will agree that it fills well a need for which no other book is available.

FRANK ELLIS.

A GREAT WORKER IN PUBLIC HEALTH

Selected Papers of Haven Emerson, A.M., M.D., D.S.M. Published on the occasion of his 75th birthday, October 19, 1949, by the W. K. Kellogg Foundation, Battle Creek, Michigan. (Pp. 507. $3.)

On October 19, 1949, Haven Emerson, one of America's greatest practitioners of public health, celebrated his 75th birthday. The occasion was marked by the most sincere expressions of appreciation from his many friends and colleagues and by the publication of thirty-five well-selected papers from more than one hundred and fifty written by him during his long life.

He is not the first great worker in the field of public health to have forsaken a most promising career as a physician for the less obvious attractions of preventive medicine and to have distinguished himself subsequently in epidemiology and medical administration. His rarity lies not only in his clear and able scientific work but in his constant awareness of its deeper social significance.

This book can be recommended to readers in Britain on three accounts. First, such papers as that on "The Prevention of Heart Disease" and "The Place of Mental Hygiene in the Public Health Movement" are as worthy of study now as when they were written. Secondly, many papers are concerned with the relation to each other of voluntary and official bodies and their proper place in the promotion of community health. These are the considered opinions of a man of great intelligence and experience, and should be closely examined at this critical time in the development of our health services. Thirdly, those interested in the growth to maturity of the human personality will find fascination in the study of these papers, taken as they are chronologically, and representative of the main stages in the life of an outstanding man.

J. M. MACKINTOSH.

ASPECTS OF UROLOGY

Essential Urology. By Fletcher H. Colby, M.D. (Pp. 580; 342 figures. £3 1s. 6d.) London: Baillière, Tindall and Cox. 1950.

The title of this work is apt to mislead. To most people the essentials of any specialty are those broad principles which should guide the medical man in his practice of it and should form a sound basis for diagnosis and treatment. But in this work the emphasis is on the embryology, anatomy, physiology, and pathology of the genito-urinary organs. The author considers that methods of treatment change so rapidly and are so soon out of date that it is difficult to include them in a book meant primarily for students. But, although he does not claim that this book is a comprehensive work on genito-urinary surgery, and discusses treatment only secondarily, he throws light on many of the practical problems with which the genito-urinary surgeon is concerned. For example, the book includes an excellent table which allows the reader to see at a glance the respective advantages and disadvantages of the various methods of carrying out prostatectomy. It also gives statistical data by which the mortality rate, and therefore the risks attached to these operations, can be assessed. The book can therefore be looked upon as being an excellent means of supplementing other reading on this subject. It can claim to deal with essentials in so far as anatomy, physiology, and pathology are the foundation subjects on which all surgery rests. Like almost all medical works coming from the U.S.A., this book is very well illustrated.

KENNETH WALKER.

BOOKS RECEIVED

Review is not precluded by notice here of books recently received

Human Sex Anatomy. By R. L. Dickinson, M.D., F.A.C.S. 2nd ed. (Pp. 145. 76s. 6d.) London: Baillière, Tindall and Cox. 1949.

Domestic Science and Dietetics. Choice of Careers: New Series No. 13. (Pp. 40. 9d.) London: H.M.S.O. 1950.

BRITISH MEDICAL JOURNAL
LONDON
SATURDAY AUGUST 5 1950

THE CAUSES OF DELINQUENCY

In the opening pages of this issue we publish the memorandum submitted to the Royal Commission on Capital Punishment by Sir David Henderson, who from his great experience suggests certain lines of treatment for "sick society." Sir David, like many others, thinks that the state of uncertainty and insecurity in which people live is an important cause of the prevalent emotional instability. Certainly the post-war increase in juvenile delinquency, to which we have already referred once before this year,[1] has disturbed public opinion and has led to a number of investigations, published and unpublished, into its possible causes. Of these the most elaborate and most recent is that carried out by Mr. D. H. Stott with the assistance of the Carnegie United Kingdom Trust.[2] His plan was to take up residence at an approved school as an apparent member of the staff and to make an intensive study of 100 youths during the time that each remained at the school. The age of his subjects varied from 15 to 18 years, and their ability from that of a high-grade defective to that of an average grammar-school pupil. The majority were persistent offenders and had made at least "three previous court appearances." Stott's method was to collect all available information about the previous history of each youth and about the conditions prevailing in his home, and then to amass detailed records, for the most part in non-technical language, by means of interviews, unobtrusive observation, and reports from his colleagues on the staff. His results are presented in the shape of informal case-histories; and a bird's-eye view is given in one huge frequency table, showing how often each important feature was noted in each individual. The raw material, including as it does numerous verbatim records, constitutes an unusually valuable mine of data for the patient reader, but it might perhaps have gained a little in intelligibility had the details been arranged or classified in accordance with some regular scheme. Stott discards "psychiatric categories" and dispenses with psychological tests, except for a preliminary application of the matrix test of intelligence. He defends his procedure by contending that "a delinquent act is not a fortuitous episode, but the outcome of many emotional cross-currents, which can only be demonstrated by a full and continuous description of each case." The conclusion which he finally reaches is that "delinquent breakdown is an escape from an emotional situation which (for the particular individual with the various conditionings of his background) becomes, temporarily at least, unbearable." This intolerable emotional situation arises almost always within the lad's own home and "centres round his relationships with his parents."

Within this general picture Stott found it possible to distinguish five main motives for juvenile crime. The most frequent, present in more than half his cases, is that which he calls "avoidance-excitement"—"the lad throws himself into a round of escapades to keep at bay an anxiety too poignant to be faced." The second, almost equally common, is "spite or retaliation," usually directed against the parents. In nearly half the cases he discerned a third "co-operating motive"—an attempt, often quite deliberate, to secure removal from home. In a smaller number of cases the delinquent behaviour began as a somewhat perverse method of attracting the notice of unaffectionate parents and "testing their loyalty." The last motive, found in about one case in five, was that of "compensating for inferiority." His classification, it may be noted, is based on types of reaction rather than on types of person, and the author's insistence on this is one of the most welcome features of this report. As so many investigators have emphasized, delinquency, like other forms of maladjustment, is to be explained not in terms of any simple cause, such as heredity, innate constitution, or economic or social handicaps, but rather as the result of a prolonged dynamic interaction between an individual personality on the one hand and environmental circumstances on the other. This insistence on the complexity of the causes of delinquency comes out clearly in his discussion of the influence of the cinema. Stott notes that film-going, as the most readily available channel for what he terms "avoidance-excitement," provided the favourite form of entertainment for nearly all the youths he had under observation. It is from the cinema that they have obtained the chief means of "emotional education." Sometimes its influence has proved beneficial, since it can "perform the function of catharsis, and at the same time keep them out of mischief." The worst that can be said of "the gangster and the gay-life film" is that it sets a low standard of social behaviour and may occasionally "determine the form of the delinquent breakdown." It is interesting to note that much the same conclusion has been reached by the recent inquiries among delinquent youths carried out by the Departmental Committee on Children and the Cinema.[3]

If any one cause is to be singled out as all-important, Stott believes it is the conditions in the home. "The problem of delinquency is in great measure the problem of the unsatisfactory family." However, before his

[1] Leading article in the *British Medical Journal*, 1950, 1, 590.
[2] *Delinquency and Human Nature*, Carnegie United Kingdom Trust, 1950.
[3] *Report of the Departmental Committee on Children and the Cinema*, 1950, London: H.M.S.O.

wider generalizations are accepted, two limitations in his survey must be borne in mind. First, the youths who provided the material for his study can scarcely be regarded as forming a random or typical sample of juvenile offenders. Those committed to an approved school are a specially selected group. "The vast majority of the boys," Stott writes, "had been removed from their homes as a measure of despair." It is therefore not surprising to find that in almost every one of his cases a dominant part was played by the unsatisfactory home conditions and lack of adequate parental care and discipline. Secondly, it is not known how frequently the same kind of conditions prevail among law-abiding youths drawn from the same social classes. In planning his investigation Stott decided to dispense with what he calls "the standard modern technique" of comparing a typical sample of the delinquent population with a parallel sample of non-delinquents. This omission he defends by insisting on "the probable inconclusiveness of the control-group technique": of itself, he says, it cannot directly reveal the line of causation. That may be true; but the inclusion of a control group can certainly help to verify inferences about the probable nature of causes deduced on other grounds. Every psychological observer can cite instances in which non-delinquent youngsters have been brought up in homes where the emotional situation has become intolerable. Many react not by delinquency but by neurotic breakdown. As Sir David Henderson states in his memorandum, "the conflict which produces criminal acts in the case of delinquents is very much the same type as that which produces psychoneuroses." It seems very probable, therefore, that some additional condition may be present, either in the boy or in his social circumstances, which leads to a breakdown in some cases and not in others, and which, in a certain proportion of the former, causes that breakdown to assume the form of criminal outbreaks.

Stott considers that many of his cases, judged by present-day psychiatric standards, would probably be diagnosed by medical investigators as "psychopathic personalities." Sir David Henderson considers that the individuals in this group are a most serious problem, but Stott believes that the label "psychopathic personality" is apt to be misleading. He cites instances in which the diagnoses offered by psychiatrists contradicted each other or in which their prognoses were not borne out by the after history of his cases, and he deprecates the tendency of current psychiatric teaching to encourage the "psychologically minded parent" to suppose that the inevitable naughtiness of his child may be symptomatic of some incipient "mental abnormality." He believes that all this results from the fact that "some schools of psychology have yielded to the temptation of generalizing wholesale from the pathological to the normal." We ought, he argues, to begin with the study of the normal mind before we turn to the delinquent. The prevalence of crime is sufficient evidence of the unsatisfactory condition of the psychology of crime, and this, in his opinion, is due not so much to any intrinsic difficulty of the subject but to "that disease of modern psychology—the classic separation between theory and practice." On the one hand, there is the psychiatrist daily engaged in clinical work, working with "concepts of a crude pre-scientific character"; on the other, the academic psychologist, "well versed in general principles and the methodology of research," but engaged on little else but intelligence testing. The cure is for theorist and practitioner to come together, each profiting by the experience of the other. Stott concludes his report with suggestions for future research. In the past the most substantial contributions to the study of delinquency have been made by those psychologists who were in a position to combine the statistical method with the case-study method. His own inquiries have admirably demonstrated the value of the case-study method. But, as he himself points out, "the total number of cases so studied remains insufficient to demonstrate any convincing association," and what is now most urgently needed is a broader co-operative inquiry, using both the theoretical and the practical approach, and extensive enough to permit "a statistical validation of the hypotheses already advanced."

PUBLIC HEALTH DISPUTE

The negotiations on revised salary scales, which have been conducted through Whitley machinery for the last four months, have broken down, and the matter has been referred to arbitration. Discussions began on March 16, public health medical officers being represented by the staff side of Committee C of the Medical Whitley Functional Council under the chairmanship of Dr. Metcalfe Brown. The management side comprises representatives of the associations of local authorities, and an observer from the Ministry of Health and from the Department of Health for Scotland.

The new salary scales were first formulated over eighteen months ago.[1] Under them the range of maximum salaries for medical officers of health varies from £2,400 a year where the population does not exceed 100,000 to £3,600 where the population exceeds 750,000. Senior medical officers who are in charge of services or departments such as school-health and mental-health services would receive maximum salaries, also related to size of population, ranging from £2,160 to £2,520. These salary scales were formulated in terms of the 1939 value of money and include a betterment factor of 20%, which has not been finally agreed.

[1] *British Medical Journal Supplement*, 1949, 1, 45.

The management side of the Whitley Council has countered these claims with proposals of its own. The arithmetical difference between the claims of the two sides is not known, but agreement has not been obtained. On July 24 the staff side therefore intimated their desire to refer the matter to arbitration, and the management side concurred. The dispute will be reported to the Ministry of Labour for reference to the industrial court under the Industrial Courts Act of 1919. A satisfactory feature of the conflict is that resort to arbitration has been agreed by the two sides and has not been demanded by one alone, as it could be under the National Arbitration Tribunal (Defence) Regulations of 1940. The terms in which the dispute will be taken to the industrial court have not yet been agreed between the two parties, but presumably the court's decision will be binding on both.

The necessity for more attractive salary scales for medical officers in the public health service has become increasingly obvious since the Health Service started. Medical men and women now take up public health work with a reluctance that is bound to be detrimental to the efficiency and development of the country's preventive medical services. Again, the Health Service has provided opportunities for remuneration which, though unsatisfactory to many, yet seem attractive to the absurdly underpaid workers in the public health services. The "wage freeze" still remains the Government's policy, but clearly it cannot be allowed to jeopardize the safety of the country's health. Whatever view the industrial court may take—and comment would be out of place, for the matter is now *sub judice*—the Government cannot allow the present drift away from public health work to continue.

THE MEDICAL ACT, 1950

The Medical Act, 1950, received the Royal Assent on July 28. The main purpose of the Bill, which was first considered in the House of Lords on April 18, was to give effect to the Government's acceptance of certain recommendations put forward by Sir William Goodenough's Committee in 1944. The General Medical Council in the first instance drafted a non-controversial Bill which provided for the "intern year" and for a number of amendments to its own disciplinary procedure. The two most important changes proposed were the establishment of a disciplinary committee and the granting of the right of appeal. It was generally felt that the opportunity might be taken to introduce further changes, so the British Medical Association, the Medical Defence Union, and the other defence societies prepared in 1947 recommendations for submission to the G.M.C. A number of conferences followed, and the draft Bill was passed to the Ministry of Health. There were prolonged and useful discussions between representatives of the Ministry, the Association, and the defence societies. The draft Bill as finally revised then had to wait some months before there was a prospect of legislation. When it did reach the House of Lords a number of constructive amendments were adopted. Lord Addison introduced the Bill, and valuable contributions were made by his noble colleagues to the debates on the Second Reading, in Committee, and on the report stage.[1] In the House of Commons[2] the Minister of Health was open to argument, and the medical members there effected other amendments and obtained a number of important assurances. The Bill was entirely a non-party measure, and both medical Lords and medical Members of Parliament showed their anxiety to improve the standards of medical education and to fortify the General Medical Council in its disciplinary functions.

In its first six clauses the Act provides for the "Good-enough year." After securing a registrable qualification a student will be obliged, from a day to be appointed, to spend a period to be prescribed in a resident appointment at an approved hospital or institution.

It will probably be a year, or even two years, before an "appointed day" can be set with the assurance that there will be places available for every medical student who qualifies. The period to be prescribed, probably 12 months as it was in the original Bill, is now to be decided by the G.M.C., subject to the approval of the Privy Council. Once these points have been settled the newly qualified man or woman must first of all seek and obtain an appointment. He or she has then to submit to the Registrar of the G.M.C. evidence of appointment, evidence of qualification—and five guineas—to secure "provisional registration." Full registration will follow on presenting to the Registrar a certificate of satisfactory service duly completed—and six guineas. Until the newly qualified are fully registered they will not be at liberty to practise other than in an "approved appointment." Subject to certain safeguards, approved appointments may at some future date include appointments at suitable health centres. These appointments are intended to be an extension of the period of medical education, though they will carry a rate of remuneration of £350 a year for the first six months and £400 a year for the second six months. The scope of the work that can be undertaken by a provisionally registered practitioner will depend on rules to be laid down by the Privy Council. It is anticipated that anyone provisionally registered will be authorized to sign death certificates and to prescribe dangerous drugs. Reciprocal arrangements with the Republic of Ireland have been negotiated, and it seems that similar arrangements may be made with, for example, New South Wales, the Union of South Africa, and other countries.

[1] *British Medical Journal*, April 29, 1950, p. 1011; May 13, p. 1146; May 27, p. 1275.
[2] Ibid., July 8, 1950, p. 112; July 22, p. 223; July 29, p. 302.
[3] Ibid., 1949, 1, 1144.

New powers have now been given to the G.M.C. to inspect the medical tuition afforded to students at medical schools. This, too, is in accordance with the recommendations of the Goodenough Committee. Hitherto the Council has only had power to "listen in" at examinations. The visitors appointed for this purpose are expected to work harmoniously with the visitors who conduct an inspection of hospitals from time to time on behalf of the University authorities. In this way the G.M.C. will exercise a closer supervision over the work and instruction of medical students.

In 1945 the Representative Body adopted a motion by Hendon that it was necessary to examine and report on the composition and procedure of the G.M.C. The new Act does increase the number of directly elected representatives. The present Council consists of 39 members, including seven elected by the rank and file of the profession. The remainder are the nominees of the Privy Council, the Universities, the Royal Colleges (now including the Royal College of Obstetricians and Gynaecologists), and the Licensing Corporations. The new Council is to have 11 elected members—an increase of four—out of a total of 47. It is now obligatory to appoint three lay members. Lay members will not receive any fees but will be granted the usual travelling and other expenses. This gets over the difficulty of lay members who are M.P.s holding offices of profit under the Crown.

The disciplinary machinery of the G.M.C. has often been criticized by the legal profession and by doctors. The medical defence societies have long had prepared a whole series of recommendations for the improvement of this machinery. Not all their proposals have been accepted, but some of the more important ones are incorporated in the Act, and others are likely to find their way into the new Rules of Procedure. In future, complaints will in the main be the subject of a statutory declaration. The Ministry of Health still reserves its right in certain special circumstances to inform the G.M.C. of the facts disclosed at an inquiry under the National Health Service Acts. The Minister, however, has given an undertaking that when a doctor is acquitted by the Tribunal no documents on the case will be sent to the G.M.C. Witnesses can be subpoenaed in future, and to them, as to others giving evidence, the oath may be administered. Doctors, and others, will be entitled to be legally or otherwise represented if they so choose. The new Disciplinary Committee is to consist of 18 members and the President, though for most cases only nine members will sit. Six of the 18 and two of the nine acting in this capacity are to be directly elected members; five will form a quorum. Only a simple majority is required for any decision (which might mean a majority of three to two), and a respondent, when a charge is not proved, is now entitled to a verdict of "Not Guilty." The Disciplinary Committee is to sit with a legal assessor, and if he gives any ruling the parties to the case are entitled to be made aware of that ruling. Any member of the Council (except the President) who takes part in a preliminary review of a case by the Penal Cases Committee is precluded from serving on the Disciplinary Committee when that same case is under inquiry. Most important of all, there will in future be an appeal from a decision of the G.M.C. to erase the name of a practitioner from the *Register*. This appeal will be to the Judicial Committee of the Privy Council and must be entered within 28 days. The G.M.C. may appear as a respondent, and the appeal can rest on points of law or on points of fact.

There is a minor though important provision raising from £20 to £500 the fine that may be imposed, under Section 40 of the Medical Act, 1858, on a person who wilfully and falsely holds himself out to be a registered medical practitioner. In this regard it may be said that the clarification of the law suggested by the Lord Chief Justice in the Lufting case[3] has not been effected. In general, however, though not all that has been sought has been conceded, the Medical Act, 1950, makes a number of substantial and welcome changes. In future the G.M.C. will be possessed of wider powers, improved machinery, and a better status, all serving to ensure the continued and enhanced confidence of the profession and the public alike.

VARICOSE ULCERATION

A condition such as varicose ulceration, the incidence of which in Great Britain has been estimated to be in the region of five per thousand of the population,[1] certainly merits the most serious and conscientious attention of general practitioners and surgeons alike. Knowledge of the aetiology of this condition and sound understanding of the proper methods of treatment have been slowly and painfully acquired, and gradual progress has been made. The underlying mechanism of varicose ulceration is certainly more complex than was formerly believed, and sometimes exponents of one or other theory and practice have been guilty of over-simplification of this problem. It is true to say that few things are either as good or as bad as they at first seem, and this is a valid comment on many of the methods of operative treatment of this condition which have gradually come into vogue.

Few with experience of this problem will now dispute that most cases of so-called varicose ulceration are due to a previous deep venous thrombosis. For this reason it should be obvious that the prevention and early treatment of cases of deep thrombosis are of the greatest importance, and in this direction surgeons have made much progress, though it would be rash to suggest that the thrombosis problem is near to solution. It is at least possible that a few of the most recently introduced measures, and especially the sometimes indiscriminate use of deep-vein ligation in cases of acute thrombosis, may lead to later leg troubles, but it would take ten years or more to justify such a prediction.

During the last few years the increasing use of phlebographic investigation of the veins of the legs, and the less extensive practice of venous-pressure studies, have modified some earlier conceptions of valvular damage in the deep vessels. There is now ample evidence of the serious structural damage which a deep thrombosis may inflict, and the regurgitant venous flow which results from valvular incompetence in the deep veins has been clearly demonstrated. Homans[2] first suggested the use of femoral- and iliac-vein interruption in these cases, and several other surgeons have undertaken careful studies of femoral-vein ligation.[3-7] It has been difficult to assess the true value of these procedures, for no properly controlled trial has been described which will enable an independent and more sceptical observer to judge the importance of the many accessory influences to which such cases have been subjected. Mahorner,[8] writing from great experience, has expressed strong doubts about some of the reported results of vein ligation.

Failure to relieve the ulceration and related symptoms by superficial femoral-vein ligation can in certain cases be ascribed to the presence of other incompetent main channels and to tributaries which continue to "feed" the ligated vessel at a lower level. In a paper which he read at the recent Annual Meeting of the B.M.A. at Liverpool and which is published in this issue, Dr. Gunnar Bauer discusses this problem and makes the reasonable suggestion that the main vessels should be divided in the popliteal region, where by-passing can less readily occur. Though this seems a logical step, it might be wise to add that there is perhaps some danger of being a little too logical and of regarding this as simply a mechanical and hydrostatic problem. With earlier experiences of femoral-vein ligation before us it would be altogether premature to try to assess the value of this new operation so soon. In one respect at least popliteal-vein ligation offers special advantage, for it seems to provide immediate relief from the distressing bursting pain of which many patients complain. This type of pain is, however, often relieved by the support given by an efficient bandage, and it would be wise to try the effect of a well-applied bandage before deciding to tie the popliteal vein. Dr. Bauer mentions a test of femoral-vein incompetence which can be performed on the operating table, but it should be remembered that in the resting patient the pressure in a dependent vein, whether normal or abnormal, will represent the hydrostatic pressure exerted by a column of blood extending up to heart level. The measurement of pressure in the popliteal vein on the operating table is therefore of doubtful significance. On the other hand, White and Warren[9] have shown the value of the walking venous-pressure test, and Walker[10] has confirmed their observations on patients with the syndrome of lower-leg stasis. Dr. Bauer, who has done much to advance knowledge of early thrombotic processes, rightly regards the operation of popliteal-vein ligation as merely one weapon to be used in concert with other methods; it does not supersede the well-tried and more conservative forms of treatment.

Popliteal-vein ligation should be submitted to a fully controlled investigation in this country, and surgeons who are too busy to study their results, or unable to provide their patients with adequate supporting bandages and detailed aftercare, should not in the meantime be tempted to use it indiscriminately. The proper application of supporting bandages is a technique which not many have mastered, but one which brings the patient great benefit. At the discussion which took place after Dr. Bauer had presented his paper Mr. Dickson Wright referred to the need for a missionary zeal in dealing with cases of varicose ulceration. This advice, from one who has for many years emphasized the benefits of a more conservative regime than is sometimes practised to-day, should be heeded.

CARDIAC ARREST DURING ANAESTHESIA

The experienced anaesthetist nowadays hardly ever meets with a case of cardiac arrest during anaesthesia. Though this emergency is rare, its treatment is now clear: immediate cardiac massage offers the only hope of re-starting the heart. But the patient will survive only if the heart is re-started before anoxia has caused irreversible damage to the brain. If there is damage but the patient survives, various nervous lesions may be left. Even in cases of apparent recovery mental changes may be a late result.

Courville[1] has already pointed this out in an important book. He recorded in it reports of a number of cases all of which showed the effects of cerebral damage as a consequence of anoxia. They ranged from death to the mildest mental changes, some appearing long after the incident. Another case of the latter type, so often missed, has recently been put on record by Turner.[2] The patient, a healthy young man of 29, was to have a submucous resection of the nasal septum. Cyclopropane was administered, and then, perhaps unwisely, 2 ml. of 1-in-1,000 adrenaline solution was injected into the submucous tissues. The heart promptly stopped but was re-started after a subcostal incision had been made and massage carried out. Not until the third day did consciousness return, and not until the tenth day did the patient become correctly orientated. A year later he showed signs suggestive of a mild frontal-lobe syndrome with distinct personality changes. After two years had elapsed he appeared to have made a good recovery, but amnesia for twelve hours before and four days after the incident remained. Anaesthetists should study this case and others like it described in Courville's book. Fortunately those methods of using nitrous oxide whereby the patient is "blacked out" are now outmoded, and recently described methods[3 4] of using this gas indicate the importance of suitable and sufficient supplementary drugs.

If the patient's heart stops during anaesthesia speed in performing cardiac massage is essential for success. The emergency demands heroic treatment, and tardiness due to diffidence or ignorance in these circumstances may cost the patient, at worst, his life or, at best, his senses.

REFRESHER COURSE FOR GENERAL PRACTITIONERS

THE FAILING HEART

BY

K. SHIRLEY SMITH, M.D., F.R.C.P.

Physician, and Physician in Charge of Cardiac Department, Charing Cross Hospital

While dyspnoea is constantly present in heart failure, the symptoms and signs as a whole vary according to the cause of the failure. Thus heart failure in mitral stenosis is very different clinically from that in hypertensive disease. The recognition of these divergences and of their importance dates from the improved methods of determining circulation time and cardiac output during the past 20 years; moreover, the better understanding of the circulatory derangements in the various syndromes of failure has led to a more discriminating therapy. Although digitalis still holds an honoured place as a specific cardiac remedy, it is by no means in every case the most important, or even an advisable, medicament. For these reasons it will be best here to consider first the recognition of heart failure in general and in its various forms; the basic principles of prevention and treatment will then be reviewed. Each important syndrome of failure in relation to its cause will be considered and its treatment and management described. The various forms of acute failure, such as occur in cardiac infarction, diphtheria, and pulmonary embolism, will not be dealt with.

Recognition of Early Heart Failure

Breathlessness on exertion is the most constant indication of diminishing cardiac reserve, although this symptom obviously has many other possible organic causes, notably diseases of the lungs. But it may also derive from disorders of function such as the effort syndrome. When difficulty is encountered in distinguishing an organic from a functional dyspnoea the following points in symptomatology will help: breathlessness due to disease of the heart will be proportionate to the amount of exertion and may be accompanied by cyanosis; it will be constant from day to day and the patient will often claim that he feels quite well when the symptom is not being produced. Shortness of breath due to functional causes (e.g., in effort syndrome and sighing breathing, or suspirious) varies greatly from day to day and even from hour to hour, bearing no precise relation to the degree of effort; and, apart from this symptom, the patient has other complaints, often numerous, such as dizziness, "nerves," and insomnia.

The failing heart usually implies a diminishing cardiac output, and thus a reduced blood supply to muscles and vital organs. Physical weakness and disinclination for activity result. Sleep may become disturbed from no obvious cause, and the patient may have found benefit from using extra pillows. Cough is not uncommon, particularly on lying down at night. This symptom and paroxysmal nocturnal dyspnoea will be referred to later in the section on left ventricular failure. Instrumental or other special methods of investigation find little application in the diagnosis of cardiac failure, but radiographs will reveal engorgement of the branches of the pulmonary artery when the left ventricle is failing and at a time when there may be no other manifestation except paroxysmal dyspnoea. Some enlargement of the heart will be found in almost every case in which dyspnoea is of cardiac origin.

While in adults the first signs of congestive failure are rales at the bases of the lungs and oedema at the feet, in children the most important indication is the respiratory rate. This has been pointed out by Taussig, who states that when the rate exceeds 30 a minute the liver begins to enlarge. She draws the inference that rales at the bases in children cannot be taken as being due to failure unless a rapid respiration rate and hepatic engorgement coexist.

Treatment of Early Heart Failure

When the cardiac reserve is waning but before congestion has developed, adjustments in the regime and mode of life are of greater importance than medicines. The first requirement is to lessen the work of the heart. The obvious means of doing this is by curtailing the patient's daily activities and increasing his hours of rest, both at night and in the daytime. A laborious occupation must be discontinued and lighter work sought. If insomnia impairs the night's rest a sedative at bedtime, such as phenobarbitone 1 gr. (65 mg.) or sodium amytal 2 gr. (130 mg.) should be given. At this stage digitalis therapy is not required. The work of the digestive system may be lessened by avoidance of heavy meals. A search for contributory causes of overburdening of the heart should be made, and, if found, remedied. Thus coughing should be checked by a codeine linctus. Obesity, which is a common and sometimes heavy burden for the damaged heart, should be corrected by adjustments of diet—chiefly the restriction of starchy foods and the avoidance of fat, fried foods, and sugary foods.

Infections, and particularly those of the respiratory tract, are often immediate causes of heart failure. As shown below, this is especially the case when chronic pulmonary disease overburdens the right heart; but it is also true in other forms of heart disease, and many a patient with advanced hypertension or mitral stenosis holds his own until an attack of bronchitis or influenza ushers in heart failure with increasing breathlessness, which may be paroxysmal. This serious consequence is attributable to toxaemia, the strain of coughing, and the heightened metabolism in feverish illnesses. For these reasons persons with heart disease should do their best to avoid contact with colds or influenza, and if such infections are contracted they should be treated with especial care: anything more than a slight cold will necessitate confinement to the house or perhaps to bed. The infection itself will need prompt treatment according to its nature, and, particularly, measures should be taken for the relief of cough.

Anaemia is a frequent additional burden on the heart, because in this condition there is a great increase in the output and therefore in the work of the organ. If anaemia exists, prompt steps should be taken to determine its nature by blood examination and the appropriate remedy—iron or liver extract—administered. The repair of anaemia may so greatly lessen the work of the heart that failure is averted.

Use of Digitalis

If, in spite of the adjustments of regime and the lightening of the work of the heart, congestive failure develops,

the use of digitalis becomes necessary. Digitalis is then of value irrespective of the cause of the failure, of the rhythm of the heart, the level of the blood pressure, and the presence or otherwise of mitral or aortic lesions. This drug, however, cannot be effectively administered unless the facts concerning excretion and action are known. The body can eliminate about 20 minims (1.2 ml.) of the tincture or 2 gr. (130 mg.) of the leaf preparation in 24 hours; only when the daily dosage exceeds these amounts does digitalis begin to accumulate in the body. When a certain concentration is reached in the body the dyspnoea of heart failure is relieved, diuresis sets in, and the discomforts due to oedema of the legs and engorgement of the liver disappear. Digitalization is the process of securing this beneficial result while avoiding toxic symptoms due to overdosage; these are headache, nausea, vomiting, and slowing of the heart with pairing of the beats.

The quantity of digitalis necessary to bring about digitalization in a patient of 10 st. (63.5 kg.) weight is about 20 ml. of the tincture or 30 gr. (2 g.) of digitalis folia. For lighter patients less will be needed in proportion, and for heavier patients more. The digitalizing total may be given in divided doses over a period of 24 hours (rapid digitalization); thus an initial dose of 90 minims (5.4 ml.) of the tincture could be followed by 60 minims (3.6 ml.) after six hours, and 30 minims (1.8 ml.) six hours later, and thereafter 20 minims (1.2 ml.) thrice daily, this amount being increased or diminished. Sometimes in very rapid fibrillation with a heart rate of 150 a minute or more, or when a speedy result is essential, "digoxin" may be used in doses of 1.5 mg. orally or 1 mg. intravenously. These doses will produce full effects in six and two hours respectively, but they must never be given if the patient has been taking digitalis during the previous 10 days.

In general, these very rapid methods of digitalization are not necessary, and satisfactory effects upon congestive failure are produced in several days by the use of an initial dose of 6 gr. (0.4 g.) of the leaf followed by 3 gr. (0.2 g.) at six-hourly intervals, until the symptoms of dyspnoea and congestion are alleviated or toxic symptoms are produced, when the administration should be stopped for 12 hours and continued subsequently at a dose of, say, 2 gr. twice or thrice daily. Thereafter a maintenance dose of digitalis must be determined; this may range from 2 gr. of the leaf thrice daily to 1 gr. daily.

Treatment of Left Ventricular Failure

This is a very common form of heart failure, because the chief causes—namely, hypertensive disease and aortic valve disease—occur so frequently. The patient becomes aware of breathlessness on exertion, perhaps slight, and then experiences a paroxysm of dyspnoea which usually wakens him from sleep. The distress may be short-lived, so that sleep is soon resumed, or it may become a protracted struggle to breathe, lasting for an hour or more. For this disorder morphine is a sovereign remedy and should be given subcutaneously in doses of ¼ to ¼ gr. (16–22 mg.), repeated in half an hour if necessary. The patient should be propped up well with a back rest or pillows in bed or in an arm-chair. The latter is especially helpful in severe cases, as the dependent posture of the legs slows venous return and helps to lower the pressure in the right auricle; in the overloaded heart this results in an augmented cardiac output, so that pulmonary congestion is relieved. If, in spite of the use of morphine, dyspnoea persists or pulmonary oedema or Cheyne-Stokes breathing appears, an intravenous injection of theophylline ethylenediamine ("cardophylin") should be given—0.48 g. in 10 ml. of distilled water, administered slowly. Some patients with failure of this kind who have high blood pressure and distended veins with normal rhythm respond more dramatically to venesection than to any other procedure. This may be carried out either by slitting the antecubital vein direct through the skin with a sharp scalpel or by introducing a wide-bore Record needle or French's needle into the vein. In either case, after 15 to 20 oz. (420–570 ml.) of blood has been withdrawn, a pad and firm bandage are applied and the arm allowed to lie in a horizontal position.

In some patients with left ventricular failure there is, in addition to the usual features, conspicuous bronchospasm aggravating the respiratory distress. The safest means of treating this will be by the oral or, if necessary, intravenous administration of one or other of the theophylline derivatives, such as cardophylin or "monotheamin." Ephedrine and adrenaline are, in general, contraindicated in heart failure owing to their liabilty to increase the work of the heart; however, if the measures mentioned above fail to relieve bronchial spasm a subcutaneous injection of adrenaline hydrochloride, not exceeding 4 minims (0.25 ml.) in a 1 in 1,000 solution, might be tried.

When pulmonary oedema develops and is not quickly relieved by the methods described above, oxygen administration should be started without delay. The method of choice is the transparent oxygen tent which forms a canopy over the head of the bed. There must be no open fire in the room if this method is used, owing to risk of explosion.

Episodes of paroxysmal dyspnoea are due to failure of the left ventricle to discharge fully its contents, so that blood begins to accumulate in the left auricle and the pulmonary circulation. The attack should be a signal for a thorough review of the patient's mode of life, the state of the heart, and the general condition. Rest in bed is ordered for a week or two, the patient being placed on a light diet with no added salt; the intake of fluids during the latter part of the day is avoided so far as is possible. If oedema exists three or four injections of 2 ml. mercurial diuretic are given intramuscularly or intravenously at four-day intervals. Even if there is no oedema one or two such injections may help to relieve paroxysmal dyspnoea. Apart from the longer-term measures, one of the best preventives for nocturnal dyspnoea is a draught containing chloral hydrate 10 gr. (0.65 g.), with nepenthe 20 minims (1.2 ml.), given at night. In chronic left ventricular failure, digitalization, preferably by one of the slower methods described above, is often of value, and may bring good results when other therapy has failed. Large doses in hypertensive disease may induce auricular fibrillation.

Heart Failure in Chronic Rheumatic Heart Disease

Heart failure in mitral stenosis is compatible with a longer tenure of life than failure in any other chronic heart disease. I have records of a patient whom I have seen in failure at intervals during eight years, and it is not uncommon for failure to recur at intervals for four or five years. Failure in these patients is ushered in often by bronchitis or other respiratory tract infection, or sometimes by physical strain; fibrillation may make its appearance at this time or it may have existed previously. It is particularly in failure associated with fibrillation of rheumatic origin that digitalis effects its most brilliant results, and the rapid digitalization method, with massive or intravenous dosage, finds its chief application when such failure has developed suddenly with a very high heart rate.

Digitalization will be employed in conjunction with mercurial diuretics. Venesection is not advisable in these

patients. On account of the vascular engorgement and the oedema of the lungs, oxygen administration will often be of value in the initial stages of treatment of severe failure. Pulmonary infarction (generally due to embolism) is perhaps commoner in this variety of failure than in any other; pleural pain, sudden dyspnoea, or jaundice otherwise unexplained should arouse suspicion of this complication, which should be treated with morphine injection and oxygen therapy.

The Failing Heart in Chronic Pulmonary Disease

This form of failure, usually following long-standing bronchitis and emphysema, is one in which the cardiac output is substantially more than normal. Recognition of this fact is fundamental in treatment, because the raised output is a compensation for the reduced oxygenating power of the lungs. Any treatment, such as venesection, that depletes blood volume will be detrimental. For the reason that it may lessen cardiac output by lowering venous pressure, full digitalization may be prejudicial to these patients.

Failure in patients with chronic pulmonary disease most commonly develops in the winter months, and the first cold or foggy spell of the autumn reduces many of these patients to a serious condition in a few days. Such breakdown is due principally to recrudescence of infection in the respiratory tract. The lung symptoms become worse, with severe dyspnoea, wheezing, and cough; cyanosis deepens, while the cervical veins and liver become engorged; headache and mental confusion develop. This is one of the few forms of heart failure in which pyrexia may coexist, but fever is not always present. Normal rhythm may be maintained or fibrillation may supervene.

Treatment is based upon the existence of cyanosis and infection: oxygen therapy should be instituted at an early stage and maintained for days or a week or two, and at the same time penicillin treatment (200,000 units I.M. every six hours, or "prolopen" 1 ml. daily) should be started, whether or not obvious infection or fever exists. Sulphadimidine may be employed in addition. The necessity for immediate effective treatment in these cases makes it impracticable to await sputum examinations and tests of penicillin sensitivity of suspected causal organisms. The measures described will often retrieve situations that are well judged to be desperate.

Digitalis may be employed at a later stage, but only in moderate dosage, such as tab. digitalis folia 2 gr. twice or thrice daily. Morphine, if it is used, should be given in small doses and in conjunction with atropine. A few injections of mercurial diuretic should be given if oedema is more than slight. While salt should be restricted, too great a reduction of fluid intake should not be made, three pints (1.7 l.) in the 24 hours being a suitable quantity.

Some Less Common Forms of Failure

In thyrotoxic heart disease, heart failure develops only after many years, and generally only when no adequate treatment has been given for the thyroid disorder. Indeed, by the time heart failure sets in evidence of active thyrotoxicosis may be lacking; the ruins of the cardiac structure and its chaotic function are the relics of a fire that is smouldering or extinct. Such patients have hearts that are enlarged and fibrillating rapidly; they often have hypertension; the evidences of failure point to both ventricles, so that there is often pulmonary oedema and hydrothorax, while the liver and the cervical veins are engorged. The usual regime of bed-rest and fluid and salt restriction is necessary, coupled with digitalization, which should be by fairly rapid oral methods. If swift control is gained by these methods it is an indication that little or no thyroid influence remains. Sometimes digitalis alone fails to control the heart rate, and success following the simultaneous administration of Lugol's iodine points to persisting thyrotoxicosis. In this case the treatment of failure must be followed by the treatment of the thyrotoxicosis either by operation or by methyl or propyl thiouracil.

Failure develops often in later middle life among patients who have severe thoracic deformity. In these cases cervical venous engorgement may be masked and hepatic engorgement may be difficult to assess. Increasing dyspnoea and oedema of the legs, with signs of pulmonary oedema, are the important indications. Treatment will be based on the general lines already described in conjunction with digitalization that is not too rapid. The evidences of right ventricular failure ultimately predominate and call for oxygen therapy, and the antibiotics if respiratory tract infection is suspected.

Treatment of Advanced Chronic Failure with Anasarca

This condition may be the final stage of failure due to any cause. The duration of life must in any case be short, and the aim of treatment is to secure comfort by dispersing the accumulation of fluid. In the first place salt intake must be reduced to less than 0.5 g. daily, milk being restricted and salt-free bread and margarine being used. Fluids are cut down to 25–30 oz. (0.7–0.8 l.) in the 24 hours. Any accumulation of fluid in the pleural cavities must be removed. If the legs have become greatly swollen with fluid and mercurial diuretics are diminishing in effect, then drainage of the legs by Southey's tubes is called for. It is often found that removal of fluid collections by these various means allows some restoration of cardiac function. Thus kidney function is improved and the mercurial diuretics regain their efficacy. Slowly the longer-term measures of salt restriction take effect and the patient may ultimately be quite rid of the oedema. He thus may become able to leave his bed by day and sleep undisturbed at night. Measures of this kind may be effective also in the even more intractable cases where there is recurrent ascites due to chronic congestive changes in the liver. Fluid accumulation may by these means be confined to the abdomen and the intervals between paracenteses be considerably lengthened. Mercurial diuretics function well when given intraperitoneally, and 1.5 ml. in 10 ml. normal saline introduced at the conclusion of tapping will sometimes produce a better result than intramuscular injection in disorders of this kind.

Dr. I. C. Fang, of the World Health Organization, has recently gone to Bangkok, where he will temporarily direct W.H.O. health activities in the Western Pacific. A regional organization, grouping all countries in that area, is to be established early next year. It is expected that the regional committee of W.H.O. member States in the Western Pacific will hold its first meeting in February or March to recommend the permanent location of the regional office, designate a director, and outline health campaigns needed in the various countries. Several international health programmes are now under way in the Western Pacific region: they include W.H.O. nursing, sanitation, hospital, and tuberculosis services in China, and joint W.H.O./Unicef programmes for mother and child health in Sarawak, Brunei, North Borneo, Hong Kong, and South Korea, as well as B.C.G. vaccination campaigns against tuberculosis in Singapore, Malaya, Formosa, and the Philippines. It is expected that the temporary W.H.O. office will be in Hong Kong until a permanent site is approved by the United Nations.

INTERNATIONAL CONGRESS OF OPHTHALMOLOGY

MEETING IN LONDON

The 16th International Congress of Ophthalmology, attended by over 1,000 members representing 64 nations, was opened by the Duke of Gloucester on July 17 at Friends House, Euston Road, London. His Royal Highness delivered a message of good will to the assembly from their Majesties the King and Queen, who had graciously consented to be patrons of the Congress.

Professor J. W. NORDENSON (Stockholm), the president of the International Council of Ophthalmology, stressed the importance of these gatherings, which enabled experiences to be pooled and misunderstandings smoothed away. He also paid generous tribute to the services rendered by Great Britain, not only in the organization of previous international congresses, but in scientific and clinical discovery as well.

Inaugural addresses were delivered by Dr. EDWARD HARTMANN (Europe), Dr. JOHN H. DUNNINGTON (North America), Professor R. ARGAÑARAZ (South America), Sir JAMSHEDJI DUGGAN (Asia), Dr. ABDEL FATTAH EL TOBGY (Africa), and Dr. J. RINGLAND ANDERSON (Australasia). Professor Nordenson then presented the Gonin Medal to Dr. H. ARRUGA (Barcelona) for his outstanding services to ophthalmology. Since the opening of the Congress Dr. Arruga has also been created a count, and he and Sir Stewart Duke-Elder have both received Honorary Fellowships of the Royal College of Surgeons of Edinburgh.

Presidential Address

The chairman of the Congress, Sir STEWART DUKE-ELDER, in his opening address said that modern ophthalmic surgery was now two centuries old and dated from the achievement of that great Frenchman Jacob Daviel, oculist to Louis XV, who introduced his operation for cataract in 1747 and communicated his method to the Academy in Paris in 1752. This year also marked the centenary of ophthalmology as an independent specialty within the larger kingdom of Medicine, owing to the genius of Herman von Helmholtz, who first demonstrated his ophthalmoscope to the Physical Society of Berlin on December 6, 1850. The new world opened by Helmholtz was explored with enthusiastic zeal: it must indeed have been exciting living at a time when within a few years so many things no one had even dreamed of were disclosed, when, almost every few months, a new disease was discovered and described. There was the work of Bowman and others on the minute anatomy of the eye, of Donders on refraction and the prescribing of spectacles, and of a host of others on new techniques in surgery—all within the first decade after the ophthalmoscope was introduced.

In the hundred years which had followed, they had been reaping the fruitful harvest of this prodigal sowing, consolidating and expanding, but adding little that was fundamentally new and revolutionary. Improvements and intricacies of techniques had been added one to the other: von Graefe's iridectomy for glaucoma had evolved into a dozen drainage operations, and Daviel's extraction of cataract was to-day transformed. The only great revolutionary concept that had been added to the techniques of surgery was the treatment of detachment of the retina by Jules Gonin, whose memory they were proud to honour.

They had surely reached the stage when the ophthalmoscope and the microscope had revealed most of their secrets; for revolutionary new advances they required revolutionary new techniques. Virchow's theory of cellular pathology wherein the cell was taken as a unit had moulded pathological thought for 100 years. But to-day they could go further: they could leave the world of cells and enter the world of atoms and molecules. From the structural point of view the electron-microscope was opening out a new and more intimate universe within the cell. From the functional point of view they could follow metabolic processes through all their intricacies by means of radioactive elements.

The first great revolutionary victory had already been won. It was now possible to overcome a great number of infective organisms—not by their mass slaughter by antiseptics but by interfering with their intimate metabolism by penicillin and other antibiotics. Ophthalmology was leaving its first century of adolescence and entering its second century—its adult life.

Bowman Memorial Service

On Sunday, July 16, the day before the Congress began, a short religious service, at which the Venerable the Archdeacon of Hampstead officiated, was held in St. James's Church, Piccadilly. Professor J. W. NORDENSON paid tribute to the memory of Sir William Bowman, founder of the Ophthalmological Society of the United Kingdom, and afterwards laid a wreath at the Bowman memorial tablet. Sir STEWART DUKE-ELDER thanked Professor Nordenson for his gesture of sympathetic understanding, and referred to the warmth of Sir William Bowman's personality, as well as to his achievements in the realm of ophthalmology.

Scientific Activities

"The role of the sympathetic nervous system in the genesis of vascular hypertension and its effect upon the eye" and "The clinical and social aspects of heredity in ophthalmology" were subjects to each of which one whole morning was devoted.

At the other six scientific sessions three halls had to be used concurrently for the presentation of 131 papers on other subjects, including detachment of the retina, choroido-retinal degeneration, the pathology of the aqueous humour, corneal grafting, radiotherapy, glaucoma, the technique of cataract extraction, electroretinography, and aniseikonia.

Retrolental Fibroplasia

Special interest was aroused by a paper on retrolental fibroplasia by A. B. REESE and F. BLODI (U.S.A.), who showed slides demonstrating the presence of angioplastic tissue in the retina of affected babies during the active stage, which lasted for about ten weeks. Haemangiomata of the skin were found in about 18% of the cases. Apart from the fact that nearly all the babies affected by retrolental fibroplasia were premature, the aetiology of this disease remained unsolved. The ocular manifestations were only one aspect of a systemic malady; associated changes had been found in many other organs and tissues. Slight exophthalmia had occurred initially in some of the more severe cases. In a fully developed case the anterior chamber was shallow; the iris was atrophic and partially adherent to a lens progressively opaque. Until the cataracts had become dense, irregular masses of connective tissue were visible in the vitreous chamber.

Dr. Reese's statistics underlined the increased incidence of retrolental fibroplasia in the United States since 1943, so that to-day it would appear that a premature baby with a birth-weight of less than 4 lb. had a 1 in 14 chance of being afflicted with the disease. This risk was doubled when the birth-weight was less than 3 lb.

Professor A. FRANCESCHETTI (Geneva) and his assistant, Dr. J. D. BLUM, both testified to the rarity of retrolental fibroplasia in Switzerland, and Professor Franceschetti wondered whether wrong classification might partly account for the discrepancy. He suggested that the term "hyaloretinal dysplasia" might well be adopted to embrace this and kindred diseases. Dr. REESE maintained, however, that in the compilation of his figures he had been careful not to include cases of persistent posterior vascular sheath, congenital falciform fold, and other conditions likely to simulate certain phases of retrolental fibroplasia.

[Evidently the incidence of retrolental fibroplasia varies in different countries, but this disease is not as rare in Great Britain as it appears to be in Switzerland. At the Hospital for Sick Children, Great Ormond Street, and at other hospitals, the reporter has seen at least 25 cases within the last year. Inquiry among several British colleagues, although not yet

documented by statistics, shows that the incidence of retrolental fibroplasia has risen to a disquieting level, so that the task of prevention is becoming urgent.]

Ocular Effects of Hypertension

Professor F. H. ADLER (Philadelphia), who opened the discussion on "The role of the sympathetic nervous system in the genesis of vascular hypertension and its effect upon the eye," emphasized that stenosis of the arterioles was a cardinal fact in hypertension, but he went on to insist that the main problem was to explain the reason for this vasoconstriction. Did it arise from direct intervention of the nerve supply to these vessels, or was it an effect of some chemical substance? If the latter supposition was true, did the humoral agent exert immediate action upon the vessel walls, or did it influence the vascular calibre through the medium of the medullary vasomotor centre?

According to Professor Adler, the role of the sympathetic nervous system was secondary, and the known facts indicated that a humoral substance acting upon the vessel walls must be the explanation in a typical case of arterial hypertension. He asked, Why, then, did sympathectomy ever produce good results? Elimination of "pressure peaks" was the reason. When the average level of arterial pressure was higher than normal, vasoconstrictor impulses were apt to produce a disproportionate increase in peripheral resistance. Thus arose the threat of a vascular crisis, which might produce retinal damage or fatally interfere with the brain. The cardiovascular system could sometimes adapt itself to pressure levels far beyond normal limits, but sudden increments were less likely to be tolerated. At any rate the nervous control of vessels within the eyeball was not abolished by operations upon the sympathetic system. Therefore the benefit undoubtedly conferred by such treatment upon some cases of hypertensive retinopathy must be attributed not to any action upon the blood vessels of the retina but rather to a flattening of the peripheral resistance peaks elsewhere in the body.

Continuing the discussion, Dr. S. SCHIFF-WERTHEIMER (Paris) also recognized the basic role of peripheral resistance, but drew attention to the multiplicity of the factors concerned in the regulation of blood pressure. They had to bear in mind not only such obvious influences as the cardiac thrust, the blood volume, the recoil of the great vessels, and the resistance of the distal arterioles, but also nervous regulation, both central and peripheral, together with the incalculable effects of the endocrine system. Dr. Schiff-Wertheimer said that she believed there was a reversible and an irreversible phase of hypertension, although admittedly there was no abrupt line of cleavage between the two. Ophthalmoscopy might supply a clue to differential diagnosis, but prognostication founded mainly upon this mode of examination often proved fallacious. She agreed with Professor Adler's contention that sympathectomy did not augment the calibre of the retinal arteries, but claimed that the operation usually mitigated retinal damage in so far as it might be due to abnormal capillary permeability.

Mr. HEDLEY ATKINS (London) pointed out that the patients with hypertension were as numerous as those affected by cancer, and that the vascular changes found were the results and not the causes of raised pressure. He regarded the retinal changes found in malignant hypertension as images or heralds of pathological processes in the kidneys. Patients with this severe form of the disease were as a rule comparatively young. Shortness of breath, intellectual decline, and irascibility were characteristic manifestations, and many patients complained mainly of headache, which was particularly severe after a sleep. Drugs might relieve such headaches, but lasting relief was unlikely without operation.

The difficulties attending comparison of various surgeons' results were stressed by Mr. Atkins. So much depended upon individual selection of cases, although most authorities agreed that the prospect of benefit faded when they operated upon patients more than 55 years old. He surveyed the main surgical methods, but himself favoured the Smithwick procedure, which was less mutilating than some of the rival operations. Charts illustrating the favourable effect of this operation upon certain cases were shown.

Dr. A. J. BEDELL (U.S.A.) pointed out that most hypertensives displayed no changes in the fundus. This generalization was based upon the study of more than 2,500 fundus photographs. Nor was it correct to assume, as did many observers, that an increased reflex along the retinal arteries was pathognomonic of raised pressure. Another consideration to be borne in mind was the capacity of the retina to absorb haemorrhages and exudates, whether the patient was being treated or not. Naturally they would be replaced by other exudates and haemorrhages in many instances, but that tendency might be modified by rest in bed. In other words, recumbency rather than any particular operation might well deserve the credit in certain alleged surgical cures.

Dr. I. S. TASSMAN (U.S.A.) emphasized the importance of emotion, especially anxiety, apprehension, or anger, as factors modifying the blood pressure. Various material factors, proved by experiment to have an effect upon the pressure, were in their turn subject to the influence of emotion, under the everchanging conditions of life outside the laboratory. Such influence would often be mediated through the thalamus. Dr. P. BAILLIART (Paris) maintained that the actual calibre of the vessels was less important than the permeability and degree of fragility manifested by their walls.

Heredity in Ophthalmology

Professor LAURENCE H. SNYDER (U.S.A.), who opened the discussion on heredity, insisted upon the need for thoroughly investigating the family history before making decisions about genetic disease. Nor should the observer's attention be confined to families exhibiting a high incidence of the particular abnormality. Sporadic cases often illuminated the problem of inheritance so long as they remembered that sporadic instances might be fortuitous. This speaker also mentioned the problem of genetic carriers. He dwelt upon the fact that genetic influences could be profoundly modified by environment, and vice versa. Thus the distinction between inherited and non-inherited congenital defects was far less rigid than was formerly supposed. Another interesting aspect of the subject considered by Professor Snyder was the part played by enzymes in the fulfilment of pathological changes hinging upon a faulty gene.

Miss IDA MANN (London and Perth, Australia) also spoke of the intimate relationship obtaining between hereditary and environmental factors, and she suggested the subdivision of congenital ocular defects into four groups: (1) dependent upon the parents' genetic constitution, (2) due to gene mutation, and therefore transmissible but not inherited, (3) due to some genetic factor activated by an environmental influence, and (4) entirely attributable to environment. Miss Mann proceeded to describe some of her own experimental work on the transmission of ocular and other defects in mice and rats. She emphasized the importance of such work as a means of interpreting lesions found in human subjects. Recent statistics showed an enormous increase in the proportion of cases of blindness due to congenital defects of the eye. Many of these abnormalities could be prevented by making parents aware of the facts, and especially the fact of "anticipation," in Nettleship's sense of that word.

Professor A. FRANCESCHETTI's remarks were founded upon work done with his colleagues D. Klein, S. Forni, and J. Babel at Geneva. He discussed a number of inherited fundus diseases, particularly those which attacked the macula. The relationship of cutaneous dystrophy and choroido-retinal degeneration was also considered.

Demonstrations

Clinical demonstrations interspersed with sightseeing tours during the week preceding the Congress were organized by Dr. G. I. SCOTT (Edinburgh) and by groups of English ophthalmologists. During the Congress week members were free to visit the Institute of Ophthalmology in Judd Street, where the departments of pathology, medical illustration, physiology, and chemistry were on view. Special physiological and pathological demonstrations were arranged there during each afternoon. Operative sessions, orthoptic work, and demonstrations in radiotherapy, physiotherapy, and colour television were also placed on the programme, and the Association of Dispensing Opticians staged a show of artificial-eye fitting, including the "mobileye," a prosthesis used in conjunction with the Hamblin-Cutler implant. Contact lens manufacture and fitting were also demonstrated.

Films and Exhibitions

Only a few years ago the ophthalmological film was a rarity, but this branch of activity has now leapt far ahead. Over 60 items had been selected for display, so that six sessions in the auditorium of the Wellcome Research Institution were required for this exceedingly popular part of the programme.

A whole week might profitably have been spent upon the superb clinico-pathological display set out in the Wellcome Research Institution, but there were, in addition to that, other treasures, including historical books, early operating instruments, and spectacles. A number of beautiful histological specimens were on view, the principles of illumination were exhibited, and an excellent museum of social and industrial ophthalmology had been assembled in the London School of Hygiene and Tropical Medicine. The display of work done by blind people showed the variety of occupations that can be successfully followed without the aid of vision.

A skilfully planned array of ophthalmological and surgical instruments, books, and drugs was on view at the St. Pancras Town Hall.

Ancillary Societies

At a scientific session of the International Association for the Prevention of Blindness, under the presidency of Dr. P. BAILLIART (Paris), reports upon "nomenclature and classification of the causes of blindness" were submitted by several delegates. The International Organization against Trachoma held a discussion on the initial signs of trachoma, which was opened by the president, Mr. A. F. MACCALLAN (London). Eight other papers were read.

Social and Other Events

The Old Library in B.M.A. House, Tavistock Square, was used as the registration office for the Congress, and an information bureau was set up in the Hastings Hall. On July 17 a reception and dance were held at Grosvenor House. His Majesty's Government arranged a reception at the Tate Gallery on July 18, when visitors were welcomed by the Right Honourable Aneurin Bevan, M.P., Minister of Health. On July 19 receptions were given by the Royal College of Surgeons, the British Medical Association, and the Royal Society of Medicine. Sir CECIL WAKELEY, P.R.C.S., conferred the Honorary Fellowship of the College upon Dr. PAUL BAILLIART (Paris) and Dr. DERRICK T. VAIL (Chicago, Illinois) during the reception at the Royal College of Surgeons. On the eve of the Congress the president and council of the Royal College of Surgeons had entertained the International Council of Ophthalmology to dinner in the council room of the College.

The chief guests at the official banquet of the Congress, held at Grosvenor House on July 20, were His Excellency Lewis W. Douglas, the American Ambassador, and Mrs. Douglas. Mr. M. H. WHITING, president of the Ophthalmological Society of the United Kingdom, presented the Nettleship Medal to Dr. A. J. BALLANTYNE (Glasgow) at Apothecaries' Hall, where some of the senior visitors were entertained to dinner by the officers of the Ophthalmological Society, the Ophthalmic Section of the Royal Society of Medicine, and the Faculty of Ophthalmologists.

Closing Ceremony

At the closing ceremony Professor NORDENSON generously praised the ophthalmologists of Great Britain for the success of the Congress and the warmth of the welcome extended to visitors from other countries. He suggested that it would be inadvisable at this stage to decide where the 1954 Congress should be held. The venue should be left for later decision by the International Council. Closing speeches were made by Professor L. GUGLIANETTI (Europe), Dr. G. STUART RAMSAY (North America), Professor M. E. ALVARO (South America), Dr. N. F. AYBERK (Asia), Dr. R. C. J. MEYER (Africa), and Dr. W. J. HOPE-ROBERTSON (Australasia).

Sir STEWART DUKE-ELDER, the chairman of the present Congress, emphasized the value of friendships formed and strengthened at these gatherings of colleagues from all over the world. He also expressed his warm gratitude to Professor Nordenson, whom he has succeeded as president of the International Council; to Professor H. Ehlers (Copenhagen), whose position as honorary secretary of the International Council now passes to Dr. E. Hartmann (Paris); to Mr. F. W. Law, secretary-general of the present Congress; to all the many helpers and promoters of Congress activities; and to the guests, with their wives and associates.

DEVELOPMENT OF RENAL PHYSIOLOGY

MEETING OF THE RENAL ASSOCIATION

The Renal Association held a special meeting at the house of the Ciba Foundation, London, on July 15 to hear an address on the development of renal physiology by Dr. HOMER SMITH. The president of the association, Dr. A. A. OSMAN, was in the chair.

Dr. Homer Smith said it was a special pleasure to him that the first time he addressed a scientific meeting in England he should be speaking to the Renal Association and that it should be in London, the home of Cushny and Starling. Dr. Smith remarked that Cushny had come into renal physiology "via the gastro-intestinal tract" through his work on magnesium sulphate, which led him to renal catharsis. Cushny remained in London until 1916, when he went to Edinburgh, where he occupied the chair of pharmacology until his death in 1927. He was very much influenced by Starling, who, Dr. Smith remarked, had left a tradition of ultra-filtration which he applied to the capillary bed throughout the body. Starling had bequeathed problems which were far from being resolved to-day and which were as important as the simple concepts that he had left in physiology: no one had had a greater influence since Harvey, except Claude Bernard.

Cushny's Theory

In Edinburgh Cushny studied the literature on the kidney, mainly German and French, and he found a "wrangle of two great views"—those of ultra-filtration and tubular absorption and of tubular excretion. Out of the mélange of conflicting ideas Cushny wrote his *Modern Theory of Renal Secretion*. The experimental era in renal physiology had not yet arrived, and Cushny had approached the matter mainly from the analytic standpoint. He called it the "modern theory," because he said it was not the work of one man but of many. Dr. Smith remarked that on the subject of tubular excretion Cushny might be accused of a historical prejudice. He used the expression: "Renal physiology is the one last relic of vitalism. . . ." Having taken his stand against tubular excretion, Cushny proceeded on the basis of ultra-filtration and tubular reabsorption, and he was faced with the complicated nature of the reabsorbate. There were so many substances that if they were each reabsorbed separately it would again look like exercise of "free will" by the cells—which Cushny would not accept. He therefore stated that both filtration and reabsorption were due to blind physical force and that an "ideal fluid" was reabsorbed without discrimination to maintain the blood in that constancy of composition which Bernard had emphasized.

Cushny was the first to apply modern physico-chemical thinking to the kidney. In 1917 Richards went to France. After the war he met Cushny in Sir Henry Dale's laboratory, and after he returned to the United States he began with Schmidt his classical experiments on the amphibian kidney.

The Glomerular Fluid

Dr. Smith discussed the analysis of the glomerular and tubular fluid obtained by Chambers's microdissection pipette by Richards, Walker, Bordley, R. C. Bradley, Bott, and Westfall. It was found that the capsular fluid was an ultrafiltrate, that glucose was reabsorbed in the proximal tubule and not the distal, and that the distal tubule was concerned with chloride reabsorption, ammonia excretion, *p*H, and hypotonic urine formation.

There was lacking, however, a standard of reference to indicate the degree of water reabsorption. In 1926 Marshall and Grafflin began their studies of the aglomerular fish kidney, and showed that its blood supply was venous in nature—a counterpart of the renal portal system—that there was no glomerulus and the structure resembled the proximal tubule in man.

Inulin Clearance

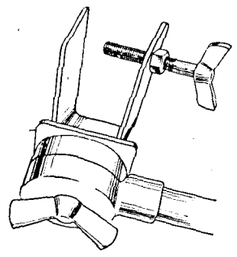
By now a standard of reference was available in inulin, a polysaccharide with a large molecular weight (5,200). Dr. Smith mentioned that, although the human kidney was not comparable in certain respects with that of the dog, he thought the laboratory experience with inulin was such that it must be trusted as a clinical standard. Inulin gave an identifiable clearance rate, and from the time of its introduction proper experiments began on tubular reabsorption and excretion. Shannon's study on glucose was the first to show a maximal rate in tubular transport. This maximum rate (T*m*) was subsequently determined for a number of other substances—vitamin C, various amino-acids, sulphates, phosphates, creatine, uric acid. Clinically this knowledge was useful, but most interesting was the implication of the possibility of complete clearance.

Dr. Smith remarked that Cushny would not have believed that the normal renal filtration rate per day was 180 litres: this contained 1,200 g. of sodium chloride (or nearly 3 lb.), excretion being regulated to within ± 1 g. a day—an indication of the importance of the kidney in relation to body fluids—400 g. of sodium bicarbonate and 190 of glucose.

Section of the vasomotor nerves had no effect on the renal blood flow. Discussing the question of how the blood flow in the kidney is regulated, Dr. Smith remarked on the constancy of this blood flow and of the filtration rate, and suggested that the next chapter in the history of renal physiology would be headed "Glomerular–tubular balance."

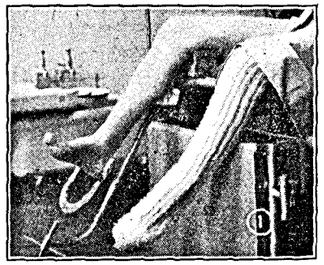
Sodium Excretion

Dr. Smith then discussed sodium excretion in relation to glomerular–tubular balance. He recalled that some years ago it had been postulated that water reabsorption was carried out in two phases, obligatory and facultative, the obligatory absorption taking place in the proximal tubule and the facultative in the distal. In maximum water diuresis about 15% of the filtered water was available for excretion. In extreme osmotic diuresis 60% of water was excreted, although sodium chloride continued to be reabsorbed. It appeared that reabsorption of sodium was independent of the reabsorption of water and that it was an active process. First the sodium chloride was absorbed and then the water diffused back to maintain the osmotic pressure of the urine at approximately that of plasma.



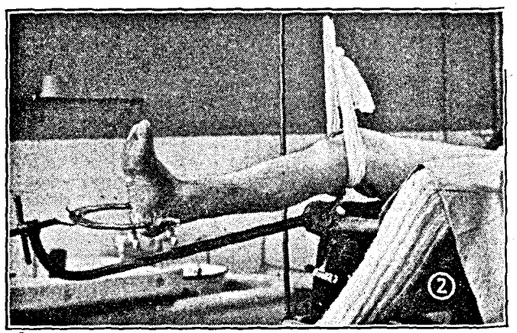
Dr. Smith said that the thin segment consisted of very flat epithelium; many investigators thought that its function was to act as an "osmotic dialyzer." In the distal system the reabsorption of sodium chloride at least appeared to be limited by a critical constant comparable with the constants for glucose and other substances in the proximal system.

In general Merrill's theory of the genesis of oedema in chronic congestive heart failure was supported by recent studies. But it must be recognized that the tubular reabsorption of sodium was importantly influenced by adrenal cortical hormones and other factors. Finally the speaker stressed that modern methods of renal measurement were not suitable for general clinical use. The most valuable clinical method of assessment remained the urea clearance.



Preparations and Appliances

TREATMENT OF FRACTURES OF TIBIA AND FIBULA



Dr. P. R. SONDHI, Worcester Royal Infirmary, writes: In the treatment of these fractures, with current methods of traction apparatus, it has always been a handicap to apply a plaster-of-Paris cast in two stages. This usually involves handling of the leg by porters and nursing staff while the plaster is being completed. Owing to this uncertain and variable traction, angulation or even shortening can occur.

If a swivel apparatus (see Diagram) is attached to the table end of the Watson-Jones apparatus, traction can be applied with the knee held at any angle. Traction can be done with the knee at right-angles (Fig. 1) and the whole apparatus swung round to the position of slight flexion at the knee, when post reduction radiographs can be taken (Fig. 2). The knee is supported during this manœuvre by a sling and the hip is raised from the table by a sandbag. Counter-traction is applied by raising the foot of the table. The whole leg and the fractures are thus held in a fixed position in which the cast can be applied in one stage.

Another suggested use for this apparatus is that the traction can be applied to the

fracture with the knee in slight flexion in cases where it is not desirable or practicable to have the knee in 90 degrees flexion, such as in fracture with ankylosis of the knee. It can also be of use in compound fractures, as the leg is held in a fixed position for towelling and surgical toilet.

The Ministry of Health has sent a circular to superintendents of certified institutions saying that the Railway Executive will allow reduced fares for visitors to patients at hospitals that accommodate mainly long-stay cases. Particulars of the scheme can be obtained from the secretary of the Passenger Committee, Railway Executive, 203, Eversholt Street, London, N.W.1.

ONE HUNDRED AND EIGHTEENTH ANNUAL MEETING

of the

British Medical Association

HELD AT LIVERPOOL AND SOUTHPORT
JULY, 1950

THE SECTIONS

SUMMARY OF PROCEEDINGS

SECTION OF MEDICINE

Thursday, July 20

Pharmacology of Antihistamine Compounds

With Professor ROBERT PLATT (Manchester), a vice-president, in the chair, Professor J. H. BURN (Oxford) opened the discussion on the pharmacological action of antihistamine compounds. He pointed out that many of the substances used medicinally as analgesics and as spasmolytics had common properties, among which was included the ability to act like quinidine on the heart.

During the last war work had been carried out to find substances to replace quinidine. These substances had been tested to assess their ability to reduce the maximum rate at which rabbit's auricle could follow electrical stimulants. It had been found that various local analgesics, including procaine, amethocaine, and cocaine, had an action similar to quinidine, and it had then been discovered that spasmolytics such as atropine, papaverine, and "trasentin" also had such action, as did the analgesic pethidine. "Anthisan" had been found to be twice as active as quinidine. It also had the properties of the other substances; as an analgesic it was not as good as pethidine, though it was more active than aspirin. "Benadryl" had the same effect.

Once these properties had been established it would be expected that the action of these various drugs would merge into one another. From this knowledge, certain practical consequences were to be anticipated. Benadryl, like atropine, might cause drying of the mouth, and like pethidine mental confusion; indeed, all the antihistamine drugs had such side-effects. They had properties like those of hyoscine, which could control sea sickness. In a single-dose experiment on aviators at Randolph Field it had been shown that benadryl and "dramamine" prevented air sickness, though hyoscine was slightly better, failures with benadryl being 30.7%, dramamine 28.7%, and hyoscine 19%.

It was known that atropine might abort a common cold by drying up secretion; so would the antihistamine drugs. One would therefore expect that, just as quinidine would help to restore normal rhythm in the case of auricular fibrillation, so would the antihistamine drugs, and there was no doubt that benadryl gave great benefit in cases of myotonia. One would also expect that, just as procaine had been used successfully to relieve bronchial spasm, pethidine must be even more effective. The basis of these common properties was that these substances had a depressing effect on acetylcholine, histamine, and adrenaline—the substances that controlled activity locally in many tissues.

Professor D. M. DUNLOP (Edinburgh) recorded the clinical results which he had found in treating patients with antihistamine drugs. The drugs were excreted in the urine unchanged, and therefore the administration had to be continued indefinitely, since histamine was continually produced in the body. Most of the cases he had treated were given doses of anthisan varying from 100 mg. to 250 mg. three times a day. He had treated 350 cases, and in 138 (55%) there had been side-effects—mild and passing off within 48 hours in 65, more severe in 60, and severe enough to stop the drug in 13. These symptoms consisted of sleepiness in 58, more persistent sleepiness in 51, nausea in 14, dizziness in 11, dryness of the mouth in 10, feeling of tension in 10, vomiting in 5, diarrhoea in 3, headache in 3, and collapse from hypotension in 1.

He found the best use of the drugs in the treatment of urticaria and angioneurotic oedema, over 80% of the cases being controlled by the drugs, provided the dosage was adequate and properly spaced. They prevented irritation but had no effect on established lesions, though they prevented new ones from occurring. They were effective in uses of urticaria resulting from sensitization to penicillin and streptomycin. While they removed the skin irritation in serum sensitization, they had no effect on the fever and arthralgia of that condition.

In hay-fever anthisan gave relief in 55% of 36 cases, and significant relief in a further 31%. It was certainly far more satisfactory than long desensitization with a specific protein. The results in perennial vasomotor rhinitis were less impressive, but definite. Complete relief was obtained in 54% of 35 cases, with significant relief in a further 34%. He had found antihistamines disappointing in asthma.

In 47 patients with carcinoma of the breast having the same dose of deep *x*-ray therapy who had developed radiation sickness, he had found that 17 patients treated with anthisan did worse than 15 having no treatment and 15 with dummy tablets. He had found benefit from anthisan in cases of liver sensitivity, insulin sensitivity, pruritus, intermittent hydrarthrosis, and paralysis agitans, but no benefit in periarteritis nodosa, dermatomyositis, migraine, allergic purpura, and acute nephritis.

It had no effect on the gastric secretion of hydrochloric acid. It appears, therefore, that antihistamine drugs found their main clinical application in those states characterized by superficial vascular phenomena. The newer antihistamines, though of greater potency and more satisfactory because of increased duration of action or a lowered incidence of side-effects, had so far made no material addition to the list of disorders amenable to this form of treatment. There seemed to be no benefit to be obtained in the deep visceral allergies.

Dr. LESLIE GAY (Johns Hopkins University, Baltimore) recorded the results of his observations with beta-dimethylaminoethyl benzohydryl ether 8-chlorotheophyllinate (dramamine). The investigation was promoted by the observation that in a pregnant woman with urticaria, who had suffered all her life from car sickness, it was possible to control the car sickness at will. A placebo failed repeatedly, but dramamine gave complete relief if she took 50 mg. a few minutes before she boarded a car. Other victims of car sickness, without exception, had been completely freed of discomfort, provided the drug was taken just before exposure to the motion of the vehicle.

Sixty patients who had developed sea sickness on crossing the Atlantic had had the condition controlled by dramamine. Investigation was therefore carried out on a crossing of the Atlantic by troopship in bad weather. There were 1,366 soldiers on board, and the drug was given in a dosage of 50–100 mg. every six hours orally or rectally. It had been effective both prophylactically and therapeutically, and no untoward side-effects had been observed by the investigators. In 319 soldiers treated therapeutically there had been failure in only 8, and in 124 treated prophylactically failure in only 2, compared with the failure in 38 out of 59 treated therapeutically with a placebo, and 35 out of 123 given a placebo prophylactically. It was the only drug which would relieve the condition once the symptoms had developed.

It had been shown in another investigation that among 210 sufferers from sea sickness 204 had been completely relieved; out of 52 with air sickness 51 had been relieved; and out of 59 with car sickness 54 had been relieved: making a total of complete relief in 309 out of 321 patients. There had been partial relief in 6 and failure in 6, while reactions had occurred in 37.

An investigation had then been carried out to determine the effect of dramamine on marksmanship. Ninety-six marines

had been divided into two groups by random selection as to firing ability and as to positive history of motion sickness. Dramamine had had no effect on marksmanship.

Further investigations had been carried out by commercial air lines in the United States. One line in one month had had 270 cases of air sickness among 3,528 passengers. The symptom of sweating occurred in 155 cases and had been relieved by dramamine in 125; nausea had been relieved in 163 out of 207 patients, and vomiting in 66 out of 111. The principal side-effect appeared to be drowsiness, which had occurred in 3.7% of the patients!

Intercarotid injection of di-isopropyl fluorophosphate (D.F.P.), a drug which destroyed cholinesterase and permitted accumulation of acetylcholine, caused "adversive syndrome" in rabbits. Within a minute of injection there was marked constriction of the pupil on the operated side. The head was turned away from that side and the animal was compelled to circle on four legs in the direction opposite to the injected side. The injection of 5 mg./kg. of dramamine intravenously immediately corrected this turning effect. It had also been found that dramamine prevented the epileptic seizures which occurred in rabbits after injection of D.F.P.

He suggested that the effectiveness of dramamine was due to the vasodilator effect of this drug. Nearly all other antihistamines had a vasoconstrictor effect. The vasodilator action was probably produced by the 8-chlorotheophyllin part of the molecule. Dramamine was also found to be effective in the nausea of pregnancy, following vestibular operations, and in radiation sickness.

Professor PLATT said he thought the evidence in favour of the antihistamines in acute nephritis was most unconvincing, and pointed out that the course of this disease was very variable.

Professor BURN, while admitting that dramamine was effective against sea sickness, said that there had not been a controlled experiment to show that it was more effective than hyoscine. Dr. GAY pointed out that this was hardly practicable, since hyoscine was too toxic to give continually over a period of 14 days. He asked why, if such a dramatic response as had been obtained with dramamine was possible with hyoscine—a drug which had been known for a large number of years—it had not been already reported.

Vitamin B_{12}

Dr. J. F. WILKINSON (Manchester) reviewed the present state of knowledge about vitamin B_{12}. It was found in liver, kidney, milk, and the grasses, and contained about 4% of cobalt. Used in adequate dosage of 60 μg. initially, followed by 40 μg. weekly until the blood count returned to normal, and then 20 μg. fortnightly or monthly, it usually caused a good initial response as judged by the reticulocyte count and the subsequent return of the blood to normal. In all cases the bone marrow showed a rapid change in the course of two days from megaloblastic hyperplasia to the normoblastic condition seen in a properly treated case of pernicious anaemia. Since 1948 he had treated 170 patients with pernicious anaemia or subacute combined degeneration of the cord for periods of more than six months. Of these 136 remained well, with normal counts. But the following were exceptions: 28 (16%) had subsequently shown falls in the red blood cells after 3–4 months' treatment on a dosage of 20–40 μg. at weekly intervals in 7, and at fortnightly intervals in 21. Two had given poor response on 40 μg. weekly and had been put back on to liver extracts. Three others had responded very slowly—one taking seven weeks to reach 4,000,000 red cells per c.mm. at 80 μg. weekly; another seven months to remain at over 4,000,000 on 20 μg., and the third three months to reach 4,300,000 before falling again, although he had responded to larger doses. Increasing the dosage in some of these cases had improved the counts.

Vitamin B_{12}, like liver extracts, seemed to reverse in the early stages the neurological symptoms and signs produced by folic acid therapy. Nutritional megaloblastic anaemias seen in the Southern States of America and in Cuba and India appeared to respond well to vitamin B_{12}; but macrocytic anaemias of pregnancy, idiopathic steatorrhoea, and sprue, which did not respond to liver extracts, were usually also refractory to vitamin B_{12}.

He thought that vitamin B_{12} was as efficient as, if not better than, highly potent liver extracts in the treatment of pernicious anaemia and subacute combined degeneration of the cord. But there was more than one factor concerned in the true story of the mechanism of the megaloblastic anaemias; vitamin B_{12} was certainly not *the* factor and not the only one.

Dr. D. RIDING (Runcorn) suggested that in man the normal requirements of vitamin B_{12} were met by bacterial synthesis in the colon. The only foods in which it was found were meat, liver, herring, and egg yolk. Therefore only meat and fish eaters, and possibly young suckling mammals, derived vitamin B_{12} from food. The vegetable-eating populations of many parts of the world must derive their requirements from some other source.

To reproduce in laboratory culture media the conditions maintained in the caecum was obviously impossible. It was likely that in the great symbiotic conglomeration of faecal organisms there must be very many types capable of synthesizing vitamin B_{12}.

Normal gastric juice contained a non-dialysable heat-labile substance which combined with vitamin B_{12} to form a complex which was non-dialysable and not dissociated by dialysis. Vitamin B_{12} in this combination was not available to micro-organisms but was released by heat, whereupon it was again microbiologically active. It was probable that this "inhibitor" was the intrinsic factor of Castle or an important component thereof. In all specimens of human gastric juice which had been examined where free HCl was present, this intrinsic factor had been found in large quantities. The only instances where there was no inhibitor were cases of known pernicious anaemia. It was interesting that some animals did not possess this intrinsic factor. The dog and the pig had it, whereas the horse, calf, and sheep did not.

Vitamin B_{12} given orally to cases of pernicious anaemia in relapse produced a response, so it was possible for man to utilize this vitamin orally without the intervention of intrinsic factor. Could it be that in the carnivora and omnivora, depending as they did on ingested meat for a partial supply of vitamin B_{12}, intrinsic factor acted as a protective mechanism? The combination of vitamin B_{12} with intrinsic factor to form a complex not available to micro-organisms might also prevent destruction of the red substance by the alkaline digestive juices of the upper intestine.

SECTIONS OF SURGERY AND OF PATHOLOGY AND BACTERIOLOGY

Thursday, July 20

Renal Failure

With the president of the Section of Surgery, Professor CHARLES WELLS (Liverpool), in the chair, the combined meeting was opened by Mr. RALPH SHACKMAN (London), who explained that the views he would express were not necessarily those of Professor Ian Aird, for whom he was deputizing. He first mentioned the various types of renal failure, and said that he did not intend to deal with the post-renal obstructive variety. After reviewing certain pertinent points in the anatomy and physiology of the kidney, he described the functions of the various parts of the nephron and the factors influencing them, pointing out that renal failure might be due either to failure of glomerular filtration or to tubular dysfunction. The effects of systemic hypotension were not altogether predictable; glomerular filtration could be maintained under conditions of unusually low blood pressure by various adjustments in the intrarenal vascular mechanism. Changes in the calibre of the efferent arterioles might affect not only the glomerular filtration but also the function of the tubules. Tubular dysfunction was associated with water intoxication, retention of tissue metabolites, and potassium poisoning; the mechanism of this type of failure was probably more complex than it appeared to be. In the early stages of tubular dysfunction the patient could be regarded as virtually having had a bilateral nephrectomy; in the later stages the polyuria, loss of potassium ions, and *p*H imbalance could cause very severe symptoms. The possible role of the pituitary, adrenal, and parathyroid glands could not as yet be properly assessed. Among the several clinical conditions in which renal failure occurred, Mr. Shackman mentioned oliguria following surgical operations, renal failure associated with gastro-intestinal bleeding, and renal failure after biliary surgery. The first type was incompletely understood; the second type, while chiefly due to absorption of breakdown products from the bowel, was also due to other factors; and the last type, following biliary surgery, might be due to the effects of an unknown toxin and/or peripheral circulatory failure. He concluded with a few words on treatment and said that, although the Borst method was not well tolerated by patients after operations, he believed that Bull, Joekes, and Lowe had made a considerable contribution to our understanding of the proper management of renal failure.

Histological Changes

Professor J. H. DIBLE (London) said that he proposed to confine his remarks to intrarenal causes of renal failure and to concentrate on the histological changes in the kidney. He emphasized the difficulty of obtaining pathological material in the first stages and of assessing the early changes; the results of animal experimental work were not strictly analogous. Though there was no profound significance in the finding, he had found it useful to differentiate between cases of tubular necrosis without pigmentation and those with this change. He thought that there was little or no evidence of glomerular damage and that the condition was chiefly due to tubular failure, the earliest evidence of which was the presence of hyaline material in the medullary and second convoluted tubules. At an even earlier stage there was congestion of the kidney; after 30 hours the hyaline casts appeared, and, in those cases showing pigmentation, pigment appeared after 40 hours. Tubular "blockage" was not evident at this early stage. Between the fourth and sixth days inflammatory changes appeared, and regeneration of the collecting tubules was also obvious. Inflammatory changes and tubulo-venous lesions were, however, secondary events, but they were possibly more marked in the pigmented cases. Later still there was oedema and fibrosis of the medulla, with widely dilated tubules containing flattened epithelium. Professor Dible said that it remained to be decided whether the renal lesions were primary or secondary in nature, but anuria was present before the development of the lesions. The powers of recovery of the kidney, though remarkable, were slow; even with the best treatment some patients did not recover. This was an unsolved problem worthy of the closest consideration. He concluded on a provocative note by offering alternative explanations of the changes so that others would criticize them, and he mentioned cortical ischaemia, obstruction to glomerular filtration, the absorption of toxic substances from the filtrate, a mechanism due to changes in the marginal zone, and, finally, an obstructive lesion lower in the nephron.

Dr. E. M. DARMADY (Portsmouth) said that though oliguria and anuria might have many causes there was great similarity in the histological changes. Some 60 different precipitating factors had been listed, and he himself divided them into seven groups, though some conditions could be placed in more than one group. Of the theories put forward to explain the condition he felt that tubular blockage should be ruled out for three reasons: casts were often minimal or absent; the glomeruli were not dilated; and there was no dilatation of the tubules above or below the casts. He had studied the dissected tubules by the method of Oliver and had been struck by the fact that the casts did not seem to have damaged the related lining of the tubules; he therefore discarded the idea that the casts were nephrotoxic. Dr. Darmady showed a series of slides demonstrating tubular "bursts" with resultant leakage of protein; the nephron seemed to be damaged at many points throughout its course. He thought the shunt theory was not entirely tenable, as was shown by the oxygen extraction studies of Bull. Further, the condition had been produced experimentally by neurogenic stimuli which, it had been shown, were incapable of sustaining the shunt. The pituitary-adrenal mechanism deserved fuller attention, and the general adaptation syndrome of Selye might provide some explanation of the changes seen.

Acute Tubular Necrosis

Dr. G. M. BULL (London) said that with Drs. A. M. Joekes and K. G. Lowe he had investigated 50 patients suffering from acute tubular necrosis of differing cause. These causes ranged from the purely toxic to the purely ischaemic. He and his colleagues had shown that the clinical course was largely predictable and could be divided into four phases: onset, anuric or oliguric, early diuretic, and late diuretic. They had not investigated the first phase, but the work of van Slyke and others made it clear that the reduction of renal blood flow was the most important factor at this stage and its correction called for blood, plasma, or saline tranfusion. In toxic cases, on the other hand, there was probably no significant initial reduction in blood flow; preventive measures and the use of specific antidotes were indicated. In the second phase blood flow might be under 5% of normal; studies by means of renal vein catheterization showed that this was mechanically induced, was not due to a shunt, and was not relieved by splanchnic block. Glomerular filtration was virtually absent at this stage, and there was no renal excretion of water or of sodium, chloride, and potassium ions, or of the end-products of nitrogen metabolism. For these reasons water intake should be 1 litre a day; no minerals should be given, and the diet should be protein-free and of high calorie content. In the anuric phase potassium intoxication was second only to water as a cause of death. On this type of diet the blood urea rose at about a third of the rate that occurred on a protein-free low-calorie diet, and potassium release from the tissues was inhibited. The early diuretic phase was characterized by returning blood flow and increasing glomerular filtration rate and urine flow, with continued poor tubule function. The urine passed was only a slightly modified glomerular filtrate. Water loss could be measured and corrected. The sodium and chloride loss could be predicted because the urine concentration of these substances was approximately half that in the plasma, but the potassium loss was not easily predicted. In practice it was found that once the urine volume exceeded 1 litre a day a diet consisting largely of fruit would maintain adequate potassium levels. The keynote of this stage was adequate mineral replacement. On the average this phase persisted for as long as the anuric or oliguric phase preceding it; for this reason mineral replacement should be continued for this time. Concluding with a few words on dialysis, Dr. Bull said that he had experience of this method. It was theoretically sound, but in practice extremely difficult, requiring a large and experienced team. He believed that with conservative management the mortality of uncomplicated acute tubular necrosis need not exceed 5–10%.

Steps in Treatment

Mr. RONALD W. REID (Colchester) acknowledged the great help given by Dr. Bull and his co-workers. The two main functions of the kidney were, first, the excretion of water and waste products and, secondly, the maintenance of the *milieu intérieure*. Both functions must be clearly remembered in planning treatment lest this should tend to restore one function and to embarrass the other. The first step was, where possible, to remove the cause, and in many general surgical cases this meant the relief of obstruction in the urinary tract; the second step was to correct anaemia, restore blood volume and blood pressure, and so ensure a normal circulation. He agreed with the early limitation of fluid. In the later stages he preferred to use Ringer's solution for fluid replacement, but he thought the use of sodium sulphate a dangerous procedure. Oedema in the kidney could have a serious effect. In two recent cases he had, among other measures, undertaken renal decapsulation. In both of these cases much fluid, containing urea, had drained from the flank wounds; in one case there had been as much as 1,200 ml. He confirmed the great difficulties and dangers of peritoneal dialysis, but by the use of a plasma substitute in the peritoneal wash there was less danger of over-hydrating or dehydrating the patient.

In the subsequent discussion Mr. L. R. BROSTER (London) said that his particular problem had been in adreno-cortical cases. Laboratory control was difficult. Dr. Bull had shown a number of beautiful charts, but he felt that few surgeons

would be able to avail themselves of such expert facilities. Professor CHARLES WELLS referred to the work going on in the Liverpool area, where they had been chiefly concerned in trying to avoid these troubles. He spoke of the use of an adrenaline drip in certain operation cases, and said he would like to know the answers to several problems. What was the mechanism of this condition? When did it occur? How much time had one in which to remedy the early stage of onset? From the remarks made by Dr. Bull and others he presumed that they should not make use of spinal analgesia and splanchnic block in the treatment of the early case. Professor H. L. SHEEHAN (Liverpool) said he had been greatly impressed by Dr. Bull's work and he thought that in it lay their only real hope in treatment. He disagreed with Dr. Darmady's views about cast obstruction; he also had noted damage in relation to the casts (perhaps only five or six cells of the tubule). He believed that there was no connexion between the initial cortical ischaemia and the later changes in the tubules. Mr. R. MARCUS (Liverpool) spoke of the immediate effects on renal function of relieving urinary obstruction, and he demonstrated this by reference to some intravenous pyelograms, one of which had been taken on the operating table just after an enlarged prostate gland had been removed.

Dr. GEORGE DISCOMBE (London) said that they had to consider first the patient with urinary obstruction; secondly, the surgical patient with impaired kidneys who was faced with a severe operation; and, lastly, the patient with established uraemia due to one of the many causes already mentioned. His chief concern had been the last two groups, and in the second group he would emphasize the great importance of keeping the haemoglobin level high and of assuring a correct acid-base balance. At the Central Middlesex Hospital they had seen a number of post-abortive cases and they had had the benefit of Dr. Bull's advice and experience. He had no doubt of the value of the method described by Dr. Bull, for the cases recovered much more readily than his previous experience would have led him to expect. Good results were the rule rather than the exception. Dr. W. N. LEAK (Winsford) recalled that he had been told by a missionary doctor in Formosa some 30 years ago that it was their practice to decapsulate the kidneys in cases of acute nephritis. It had seemed to him that Professor Dible's slides had demonstrated the picture of a pressure necrosis.

Professor WELLS, from the chair, then called on the opening speakers to reply. Dr. BULL said that some speakers had expressed concern about laboratory facilities, but the method of treatment he had described could be carried out with the minimum of laboratory control, or even with no laboratory control at all. In reply to a question about how he had demonstrated changes in the renal blood flow he referred to a method of catheterizing the right renal vein and the various tests they had done. The available evidence suggested that there was no shunt in the stage they had investigated, for the blood in the renal vein was more venous, rather than more arterial as might have been expected. Dr. DARMADY, in reply to Professor Wells's question about how much time there was to treat the early stage, thought that there was probably about eight hours in which to do this. He pointed out that casts tended to occur in one nephron and not in others, while tubular "bursts" might occur anywhere. Casts also tended to occur lower down in the tubules because of greater concentration there. Professor DIBLE said that there were really two main types of tubular necrosis: those cases due to exogenous causes and those due to endogenous ones. He thought that one could not reconcile the cortical changes with a pressure lesion, and this was confirmed by the apparently normal condition of the glomeruli. He agreed with Professor Sheehan that the casts were by no means static and developed with the passage of time. The most remarkable thing of all was that the damage done in such a short space of time persisted and, in some cases, might never recover at all. Mr. SHACKMAN, in conclusion, said that the common factor to both glomeruli and tubules was the blood supply going to the whole nephron, and it was here that they must look for the cause of the condition. Discussing the question of pressure necrosis, he quoted a case in which he had had evidence that the intrarenal pressure was not high. He agreed that prevention was of paramount importance.

SECTION OF CHILD HEALTH

Thursday, July 20

Breast-feeding

The president, Professor NORMAN B. CAPON (Liverpool), took the chair and conveyed the apologies of Mr. E. C. Fahmy (Edinburgh) for unavoidable absence. Dr. F. CHARLOTTE NAISH (York) outlined the history of breast-feeding over the centuries. She drew attention to the varying influence of fashion. Continuity of supervision was the key to successful breast-feeding, and the study of breast-feeding problems was the duty of the general practitioner. Utilizing their opportunities for controlled experiments, the paediatricians had done much to emphasize the importance of breast-feeding. The general practitioner was in a position to see other issues: the emotional integration of the mother that resulted from success with feeding; the success of breast-feeding resulting from increased care of the emotional stability of expectant and nursing mothers; and the resultant improved health of the children.

There could be no questioning the value of antenatal care. Breasts should be examined as a routine at the time of first and subsequent examinations. No comment should be made at the time of the first antenatal examination, as it was not possible to foretell the degree of success which would attend breast-feeding. Fashion determined views on when the newborn baby should be first put to the breast.

For treatment of congestion of the breast Dr. Naish advocated reducing both the time between feeds and the time spent at each feed. Finger-tip massage to the periphery of the breast was valuable where congestion was severe. It was possible that the massage stimulated the "draught" just as the butting of the lactating sheep's udder by lambs might stimulate the "letting down." In Dr. Naish's experience the reduction in secretion which frequently took place in the third week was a feature common to mothers not getting adequate supervision. To obviate it post-natal visits should be made by the family doctor until the end of the fifth week. Where a decline in the volume of milk occurred, immediate resort should be made to complementary feeding, which was best explained to mothers as a form of "topping up," possibly required only temporarily.

The need was for the organization of all looking after the mother with the object of favouring continuity of supervision, and full co-operation between the health services, the obstetrician, and paediatrician, and, of first importance, the family doctor, whose key position must receive full recognition. The family doctor could carry out infant welfare within the ambit of his general practice.

Mr. K. C. RICHARDSON (London) then discussed the structural basis of milk discharge. He pointed out the need to distinguish between milk secretion and milk discharge. In the cow at the time of milking the milk pressure rose—the so-called "let-down." Where this did not occur, less than half the expected yield was obtained, only the cisterns and large ducts being emptied. The rise in milk pressure was due to activity of contractile tissue in the mammae initiated by a neurohormonal mechanism. Experimental evidence justified the belief that nervous reflexes from stimulation of the nipple and breast were transmitted to the posterior pituitary and led to discharge of oxytocin. A contraction resulted independent of smooth muscle surrounding the major ducts. Animal experiments had shown that oxytocin and other substances such as acetylcholine acted specifically on the contractile tissue in the absence of a motor-nerve supply and under conditions of constant blood pressure. Many accounts referred to the contractile tissue as smooth muscle intermingled with the mammary glandular units. There were, however, contractile myo-epithelial cells between the secretory epithelium and the basement membrane. Mr. Richardson showed interesting slides of goat and human material which, by means of a new method of silver impregnation applied to thick sections, clearly demonstrated the presence of myo-epithelial cells. The orientation of the cells was consistent with the assumption that they squeezed the distended alveoli and shortened the ducts so that they were held open.

He said it was not known whether myo-epithelium was innervated and so possessed a neural as well as a hormonal response. The sensory innervation of the breast and udder had not been sufficiently studied. The effect on the neuro-hormonal mechanism of milk discharge by stimuli from the skin surface and from the cerebral cortex was established, but knowledge was lacking whether filling of the breast influenced the mechanism.

Breast Tension

Dr. H. K. WALLER (Tunbridge Wells) said that security of lactation depended on regular emptying of the breast from the time secretion began. Failures resulted from insufficient regard to the condition of the breasts. He discouraged too hasty conclusions about the relation of failure of milk secretion to such factors as nervous upset and a return to domestic responsibilities. The relation between failure to secrete and excessive milk retention required prior consideration. It was known that involution tended to follow gross overloading of the breasts, and it was possible that distension might give rise to injury and irreversible interference with the function of the secretory cells. Among causes of incomplete emptying of the breasts were a yield in excess of the infant's requirements, lack of strength or of inclination to feed on the part of the baby, and nipples so adherent to deeper structures that effective suckling was impossible.

Discussing reflex stimulation, he suggested that the fact that milk might leak periodically between feeds was possible evidence that milk secretion was stimulated in part by milk tension reaching a certain level. He deprecated the use of rules intended for general application; submitted a plea for more objective study; asked for more help from the anatomist and the physiologist; and asked that obstetricians should realize that breast-feeding cannot be firmly established in the first two weeks of life.

The president, Professor CAPON, said that, while the part psychology played in normal breast-feeding must be respected, study must remain objective. Dr. D. CRADDOCK (Clare) considered that in general practice manual expression need not start before the 36th week of pregnancy, and that some practitioners had not the time to continue supervision for five weeks after the baby was born. Dr. K. M. HIRST (London), referring to a remark by Dr. Naish on co-operation, said it was the duty of the health visitor to visit as soon as possible after the attendance of the doctor or midwife had ceased, and thereafter as frequently as circumstances permitted. Dr. P. D. MOSS (Liverpool) gave self-demand feeding as a means of overcoming the tendency for hospital sisters temporarily to possess infants to the partial exclusion of the mothers. Dr. MARGARET M. FISHER (Luanshya, Northern Rhodesia), speaking as a mother, suggested that hospital routine allowed the mother little rest and that the baby should not be continuously at her bedside. Midwives and mothers-in-law were described by Dr. G. CATHERINE EVANS (Herne Bay) as inclined to have a discouraging influence on breast-feeding. This view, so far as midwives were concerned, was not shared by Dr. ALAN BARKER (Whitstable), who regretted the tendency for early discharge from hospital.

Professor W. S. CRAIG (Leeds) urged that antenatal care should have as one object the discouragement of weaning decided on without professional advice. The expectant mother should have impressed upon her that the doctor, health visitor, and midwife were there to maintain continuity of supervision and to advise if feeding difficulties arose at any time in infancy.

Speaking as an obstetrician Mr. A. H. HOLMES (St. Asaph) attributed many difficulties in breast-feeding to the attitude of the general practitioner, and expressed doubts about the value of stilboestrol in cases of breast congestion. Dr. J. D. HAY (Liverpool) spoke of experience of self-demand feeding at a maternity hospital. Four months' experience had been encouraging. The procedure was practicable and was appreciated by the mothers. Supervision of feeding was less close, but the nursing staff was less overworked.

Replying to points raised in discussion, Dr. NAISH shared doubts expressed about the use of stilboestrol. She urged that management of breast-feeding should not be determined by strict adherence to theories of rigid regimentation or of self-demand. Dr. WALLER described the use of stilboestrol as valuable and justifiable if carefully studied and if the nursing staff was carefully trained.

SECTION OF DERMATOLOGY

Thursday, July 20

Chemotherapy of Venereal Diseases

With the president, Dr. R. STOPFORD-TAYLOR (Liverpool), in the chair, Dr. ROBERT LEES (Manchester) opened a discussion on chemotherapy of venereal diseases, its uses and abuses. He said that the use of penicillin and sulphonamides was advocated in the treatment of gonorrhoea, but reliable tests to establish diagnosis and cure were essential. Streptomycin was preferable if coincident syphilis was suspected. Empirical treatment and neglect of ancillary treatment were common abuses, and overdosage with penicillin might conceal syphilis. He did not approve of penicillin by mouth as a prophylactic against venereal disease.

In cases of early syphilis penicillin alone might be curative, but the amount of drug and the duration of administration required were unknown. A common practice was to combine the use of penicillin, bismuth, and arsphenamines. A treatment schedule suggested had two phases: (*a*) a very intensive attack, lasting two to three weeks, with penicillin, bismuth, and arsphenamine; and (*b*) a prolonged phase—e.g., for six months—with arsenicals and bismuth. The place of penicillin in the treatment of late syphilis was still undetermined. It was valuable in syphilis of the central nervous system and might be useful in the treatment of cardiovascular lesions. For the latter, caution and the proper preparation of the patient by slow-acting drugs were advocated. Congenital syphilis could be prevented completely by antenatal treatment, which should consist of penicillin and bismuth, but not arsenicals. Special technique was needed for lesions such as interstitial keratitis.

Some abuses in the treatment of syphilis were: (1) overdosage, especially of cases of congenital syphilis and of latent cases with "fixed" positive serum reactions; (2) undertreatment of early syphilis, often without established diagnosis; (3) local applications of penicillin; and (4) treatment of healthy persons wrongly suspected of having syphilis.

Dr. SYDNEY M. LAIRD (Ipswich) said that chemotherapy represented a fundamental advance over the symptomatic treatments of earlier centuries. The principles of treatment were essentially the same irrespective of the particular chemotherapeutic drug. Three important factors were the virulence of the organism, the natural defensive powers of the patient, and the efficacy of the drug. The last depended on the sensitivity of the pathogenic organism and the tissue level of the drug which could be established at the site of infection. The combined use of chemotherapeutic agents might sometimes be advantageous. Accurate bacteriological diagnosis before treatment and adequate follow-up were essential.

In gonorrhoea one injection of penicillin was usually adequate for the uncomplicated case. In complicated cases longer chemotherapy and local treatment were required. Penicillin had established its place in the treatment of all stages of syphilis and with few exceptions should replace the arsphenamines. Bismuth compounds should be combined with it in all stages. In late syphilis treatment with bismuth should precede penicillin to reduce the risk of Herxheimer reaction and therapeutic paradox.

Dr. DOUGLAS J. CAMPBELL (Sheffield) thought that there was more rapid clearance and a higher rate of cure with the early pattern of treatment of gonorrhoea in the male with 100,000 units of penicillin than with the modern dosage of 300,000 units of procaine penicillin with 2% aluminium stearate. To avoid masking syphilis in cases of gonorrhoea dosage of penicillin should be either low or very high. The toxic effects of arsenic were overemphasized. Streptomycin, which was effective in non-venereal urethritis, was not as good as penicillin in the treatment of gonorrhoea. He had found the antihistamine drugs of some use in the treatment of interstitial keratitis.

Interference with Immunity

Dr. ARTHUR S. WIGFIELD (Worcester) emphasized that the relatively short six-weeks combined course of treatment with N.A.B., bismuth, and penicillin as prescribed in Liverpool carried less than a 2% failure rate. With this yardstick it was not necessary to treat hundreds of cases of early syphilis with newer and more intensive methods. Three failures should be sufficient to condemn a course. Intensive initial treatment interfered with immunity to syphilis. Clinical relapses following penicillin therapy alone occurred within the first nine months of the disease. He considered that the masking of syphilis by penicillin was less of a danger than was generally believed.

Dr. D. I. WILLIAMS (London) spoke on the value of B.A.L. in the treatment of arsenical and other metallic poisonings and especially of exfoliative dermatitis. The drug should be administered early; the necessary dosage was not yet settled. It should not be employed where there was any liver damage. There was a high incidence of sensitization to the drug. It was difficult to assess the published results, but they were certainly encouraging. He felt that B.A.L. should be given to all cases of arsenical intoxication except the mildest.

Dr. P. B. MUMFORD (Manchester) thought arsenical dermatitis was now rarely seen. The procaine employed with penicillin might cause sensitization reactions. Dr. A. O. FERGUSSON ROSS (Liverpool) referred to the early work with penicillin in the treatment of cases of secondary syphilis in Liverpool. He stressed the importance of care in the use of penicillin in late syphilis. Without preliminary medication it was dangerous in cardiovascular syphilis.

Colonel CLIFFORD MORGAN (U.S. Army) gave figures indicating the reduction in the incidence of venereal disease in the army in Europe. There was danger from concealed cases. Use was being made of the Career Guidance Council. Dr. J. T. INGRAM (Leeds) thought the development of some immunity in the patient was important. Penicillin was withheld until the middle of the period of treatment. Dr. A. MURRAY STUART (Portsmouth) thought that wives of men infected with gonorrhoea should be treated without waiting for confirmation of the diagnosis. He had found calcium thiosulphate of value in treating the toxic effects of arsenic. Dr. DONALD R. HUGGINS (Port of Spain, Trinidad) said that an effective short course of treatment for syphilis was essential to deal with the problem in the West Indies. Dr. J. P. G. ROGERSON (Shrewsbury) drew attention to the difficulties of the problem in small country communities. Patients could attend for treatment only once a week, because of distances and for economic reasons. He saw very little arsenical dermatitis.

The openers replied briefly to the points raised.

SECTIONS OF DISEASES OF THE CHEST AND TUBERCULOSIS AND OF PREVENTIVE MEDICINE

Thursday, July 20

Care of the Tuberculous Patient in the Home

With the president of the Section of Preventive Medicine, Professor W. M. FRAZER (Liverpool), in the chair, Professor F. R. G. HEAF (Cardiff) opened a discussion on the care of the tuberculous in the home. He drew attention to the lack of institutional facilities for the treatment of tuberculosis; the result of this was that 137,000 patients had to be treated in their own homes. The curative aspects of domiciliary treatment could be divided into two parts—pre-sanatorium and post-sanatorium. The success of pre-sanatorium treatment depended on the home conditions: when these were poor domiciliary treatment should not be attempted. Such patients should have priority for admission to a sanatorium. There must be co-operation between the chest physician and the general practitioner, and together they should teach the patient the importance of rest. The three essentials for successful domiciliary treatment were freedom from financial anxiety, facilities for rest, and a co-operative patient. Sympathetic help from the local health authority was also important. It had to be recognized that domiciliary treatment cost money, though it was cheaper than sanatorium treatment. A good ambulance service was necessary, and also a home-help service and facilities for occupational therapy. Active domiciliary treatment threw a great burden on the chest clinic, and the physician would need additional staff. Hospital beds for the treatment of complications were a necessity. Existing schemes proved that active domiciliary treatment could be successful. Collapse therapy should be used with care, and streptomycin should not be employed indiscriminately, because of the danger of spread of resistant organisms. An exception might be made in cases of tuberculous laryngitis with dysphagia and tuberculous tracheobronchitis. All general practitioners should consult the chest physician before giving streptomycin to their patients. During the pre-sanatorium period preventive measures should be instituted, and the education of the family was essential. Contacts should be examined and Mantoux-negative children vaccinated with B.C.G.

In the post-sanatorium period it was necessary to help the patient adapt himself to the change of environment from the sanatorium to the home. Prevention of the spread of infection and rehabilitation were the main objectives. The experience of village settlements, where serious tuberculosis in children is rare, showed that spread could be prevented.

Financial assistance and the finding of suitable occupations, including sheltered employment, were essential. Some of the money which would have been spent on these patients in hospital might be used to provide domiciliary treatment. But the spending of this money was the concern of the hospital board, and the local health authority was often disinclined to accept the financial burden which proper aftercare arrangements entailed. The reunion of the tuberculosis services was as essential to the anti-tuberculosis campaign as the provision of more nurses. Treatment must not be divided from prevention and aftercare, and hospital boards and local health authorities should find some means of co-operation, such as by the formation of local joint tuberculosis panels. Better still, the Act should be amended to provide a unified tuberculosis authority.

The Work of the Chest Clinic

Dr. R. GRENVILLE-MATHERS (Harrow, late of Wallasey) said that the chest clinic was now the major centre for the treatment of the tuberculous. Only selected cases suitable for active treatment should be admitted to the sanatorium, but there was a need for places where precautionary measures could be taught to other patients and where the deteriorating chronic patient could be looked after. Proper selection of patients would solve the sanatorium bed problem. There were dangers in instituting collapse therapy at home. In Wallasey the aim had been to put the available sanatorium beds to their maximum use. Patients were admitted for collapse therapy and discharged as soon as this was established, to continue their treatment at home. The co-operation of the general practitioners was secured, and by these means domiciliary treatment was successful if the home conditions were good. Mothers and housewives were unsuitable for home treatment. Home helps were required, but many patients were unable to afford the charge made by the local authority, and this penalized the patient who was having home treatment. The patient with a persistently positive sputum presented a major problem. Village settlements had pointed the way by showing that such a patient was not a danger if suitable conditions were provided. In the North Wirral area sputum-positive patients were given immediate priority for rehousing, and they were carefully trained in hygienic precautions and found suitable employment. A resettlement clinic which was attended by an officer from the Ministry of Labour had the task of selecting a suitable job for the patient, consideration being given both to his or her point of view of health and to the prevention of spread of the disease. Sixty-five per cent. of the children notified to this clinic had no known contact, showing that it was the unknown case of tuberculosis which was the danger.

Integration of the Tuberculosis Services

Dr. W. D. GRAY (Liverpool) said that the clinic physician was responsible for the care at home of all tuberculous persons, before and after sanatorium treatment. He must know the home, and the family must be treated as a whole and contacts examined and re-examined. Co-operation with the general practitioners was essential, but tuberculosis was not a well-taught subject in medical schools and some doctors did not realize the importance of rest. Many patients did very well when they were able to rest at home, but, especially in industrial areas, accommodation for urgent cases and patients from poor homes was needed. Housewives were unable to rest at home, and the majority of families could not afford the local authority's charges for home help. Housing policy must be used in a preventive way. In the North Liverpool area, with a population of 300,000, there were 1,895 adult patients: 140 were awaiting admission to hospital, and of these 82 were able to rest in bed in a separate room (this included married couples who shared a room), 5 were able to rest in a room shared with others, 35 were unable to rest, and 28 were unwilling to rest. In the same area 51 patients were deteriorating at home, 302 were ambulant but unfit for work, 58 were fit but unemployed, and 920 were working. Diagnosis and treatment and prevention and aftercare should not be separated. Beds should be allocated on an agreed plan between sanatorium and clinic, taking into consideration social as well as medical needs. Sympathetic attention should be given to each individual case—every patient could be helped, although not all could be treated.

In the subsequent discussion Dr. L. M. JOHNSTON (Wallasey) mentioned the dangers of tobacco-smoking. Dr. E. G. SITA-LUMSDEN (Southend-on-Sea) advocated postural retention for patients having home treatment and the greater use of open-air shelters. Dr. J. K. B. WADDINGTON (Liverpool) mentioned the gulf between the general practitioner and the specialist service. The chest clinic should maintain contact with the practitioner and preach the gospel to him. Dr. J. GREENWOOD WILSON (Cardiff) stressed the need for amending legislation to provide free home helps for the tuberculous. He said that some local authorities had lost the use of occupational therapy workshops in hospitals taken over by the hospital boards and that some patients abused housing priority. Dr. O. F. FRAZER (Liverpool) said that streptomycin should not be given to the patient who was likely to have surgical treatment, and he warned against its indiscriminate use in the home. P.A.S. was comparatively harmless. Dr. WATSON (Chester) thought that the great importance of preventive work in tuberculosis should be reflected in the grading of physicians engaged in such work. Dr. J. L. LIVINGSTONE (London) suggested that the matrons of teaching hospitals should be instructed, possibly by a booklet, in the very small risk attached to nursing tuberculosis. Nevertheless the conditions of nursing in some hospital wards for advanced cases still needed improvement. Dr. C. H. C. TOUSSAINT (London) mentioned the importance of the work of the welfare officer, who could help the patient undergoing domiciliary treatment to have an easy mind. In the home postural treatment and absolute rest were the most successful measures. He supported Dr. Johnston in a dislike of tobacco.

SECTION OF GERIATRICS

Thursday, July 20

Activity in Advancing Years

With Dr. C. O. STALLYBRASS, the president, in the chair, the theme of activity in advancing years was introduced by Dr. MARJORY W. WARREN (London), who contrasted the results of continued inactivity of body and mind with those of activity. She emphasized both physical and psychological aspects, mentioning stiffness of joints, contractures, and flexion deformities of limbs and neck, as well as the mental atrophy which is so often found. Much incontinence could be attributed to actual laziness and bad habits. The diagnosis of senility or simple old age should be avoided at all costs, since it could hide a multitude of physical and mental lesions. At the end of her talk Dr. Warren showed a film illustrating her methods of rehabilitation in cases of hemiplegia and of double amputation through the thighs.

Mr. J. P. HERON (Liverpool) spoke on the orthopaedic aspect of activity for the aged. He urged the need to conserve and increase all bodily function as much as possible. The less limbs were immobilized by plaster the better. As for the use of skin traction in fracture treatment, it gave poor results. He emphasized the need for planned treatment from the first time of seeing the patient. Consultation with the anaesthetist before operation was often more helpful than the opinion of the physician. Curare could be of great value in producing muscle relaxation for surgery. It was of great importance to start mobilization of the patient as well as of the affected limb soon after operation. Manipulation was best performed under a general anaesthetic, not too much being attempted at one session. Mr. Heron ended his talk with a brief survey of common orthopaedic complaints met with in elderly patients, together with practical points concerning their management.

Dr. TREVOR H. HOWELL (London) spoke on the need to analyse the various kinds of pain which might be found in elderly patients suffering from different types of arthritis. He distinguished between synovial pain, capsular pain, and pain secondary to muscle spasm. The first would usually respond to tetraethylammonium bromide or methonium compounds, and was described as general, diffuse, and throbbing, with exacerbations. The second was sharp, stabbing, and localized in character. It could be relieved for a time by accurate injection with a local analgesic. The third, also sharp and stabbing, was associated with muscle spasm which could be relaxed by 0.5 mg. of neostigmine intramuscularly.

Dr. S. R. HIRSCH (Brussels) gave an account of the newer conceptions of arteriosclerosis. He pointed out how the clinical and pathological aspects differed and how the experimental approach had not yet met the needs of the clinician. After summarizing the aetiological factors, Dr. Hirsch mentioned the vasomotor and haemodynamic results of ischaemia, congestion, and tension, which might be clinically silent although pathologically established. He ended with a plea for the establishment of an investigation into the early signs and symptoms, so that prevention might be attempted for a disease which had no effective form of treatment. "This is the scourge of contemporary humanity," was his conclusion.

Dr. ROBERT M. EVANS (Liverpool) spoke on the subject of pulmonary fibrosis as a cause of diminished activity among the elderly. Chronic bronchitis, old tuberculosis, or bronchiectasis in this age group all had this factor in common. The main symptom was dyspnoea, to which wheezing, cough, and the onset of congestive heart failure were added. In the aged, hypertrophy of the right ventricle was prevented by coronary insufficiency. Hence prevention was essential as early as possible. Removal from known aetiological factors, depression of cough, and removal of irritants to the pharynx were all needed. It was necessary to cut short all attacks of bronchitis by antibiotics and antispasmodics before more damage to the lung took place. Too much rest in bed should be avoided or lung bases would get clogged with sticky mucus.

Dr. LOUIS CARP (New York) gave a most interesting address on operative mortality in geriatric surgery. He emphasized the need for the surgeon to be a good doctor as well as technically expert. After describing the work of the Goldwater Memorial Hospital in New York, he showed how the operative mortality in various clinics ranged from 7% to 17% according to the amount of emergency work undertaken. In his unit half the cases needed emergency surgery, and these cases had a 39% mortality during the past five years. Surgery of election showed this rate diminished very considerably. Bronchopneumonia, pulmonary oedema, and peritonitis were the chief fatal complications, with pyelonephritis as a main contributory cause. Dr. Carp emphasized the need for planned procedure and careful preparation before operation. Nitrogen imbalance, fluid lack, and anaemia in particular required special study. After a survey of the common surgical conditions which prevailed and the technical measures needed, he stressed the importance of early ambulation and the limitation of sedation. Finally, there was the need for a proper psychological approach to the patient, which could result in co-operation instead of fear, nervousness, and resistance.

SECTION OF MEDICAL GENETICS

Thursday, July 20

Genetics and Medical Practice

After taking the chair, the president, Dr. C. P. BLACKER, said that this first meeting devoted to medical genetics in the history of B.M.A. Annual Conferences owed its inception to Professor Arnold Sorsby. Owing to other commitments Professor Sorsby was unfortunately unable to attend, but he had sent a letter of good wishes.

Professor L. S. PENROSE (London), opening the discussion on the contribution of genetics to medical practice, said he thought the contribution of genetics was real though of limited usefulness. There were, however, two fields in which it was of especial value. One was serology and the other pathological chemistry. He looked forward to the time when the treatment of metabolic disorders would be helped by the application of genetic knowledge. He did not consider that there was much hope of reducing the number of bad genes in the population, but said that guidance on having children could be useful in individual cases. The most important task for the immediate future was the study of relatively common, and therefore important, conditions in whose causation a hereditary contribution was important. He stressed the need for ascertaining the morbidity rates by sex, age, etc., as the all-important prerequisite.

This was illustrated by studies on peptic ulcer and mammary cancer, in which the necessary basic figures for the population were first obtained. It could then be seen that the rate among brothers of sufferers from the first condition and among female relatives of sufferers from the second were about doubled as compared with rates in the general population.

Tests for Paternity

Dr. R. R. RACE (London) then discussed practical aspects of blood-group genetics. He mentioned the genetic simplicity of the subject and said that there were now eight independent systems of blood groups. The gene and the antigen might be almost the same thing, and the ultimate contribution to pure genetic theory might be great. He outlined the story of haemolytic disease and deplored the fact that girls were still, at least recently, being given transfusions or injections of whole blood in the attempt to protect against measles, without rhesus testing. The chance of a single incompatible transfusion or injection immunizing the patient permanently was 50%, and those so immunized stood a high chance of losing their first and subsequent babies if, as would be usual, they married an Rh-positive man.

On the subject of exclusion of paternity, he said that this country was very backward in its appreciation of the new knowledge. In Denmark the number officially tested was now 20,000. It was a great pity that Lord Merthyr's admirable Bill became a war casualty. It was now possible to exclude 62% of wrongful paternities, and in his experience half the paternities attributed were wrong. As 7,200 affiliation orders were made in a year and 2,000 men went to prison for non-payment, he thought that preventable injustice was being inflicted on a large scale. The majority of suspected mixings of babies at maternity hospitals could be cleared up by serological methods.

Genetic Clinic

Dr. J. A. FRASER ROBERTS (London) described a genetic clinic organized in connexion with the Institute of Child Health of the University of London, and held once a month at the Hospital for Sick Children, Great Ormond Street. Patients were referred by the physicians and surgeons to the hospital. While the proportion of the population needing genetic advice might be small, the numbers in any large city would be considerable.

Cases should be referred by the family doctor or a specialist, and all necessary investigations should already have been carried out. One man could give reasonable advice over the whole field except for genetic advice on mental disease (not mental deficiency), which should be provided by a psychiatrist who was also a geneticist. The chances should be explained, but the decision left to the persons concerned. In his experience it was possible to give advice adequate for the patient's needs in the great majority of instances. Much of the work consisted in reassuring those who had little to fear.

The discussion was summed up by Professor F. A. E. CREW, F.R.S. (Edinburgh), who on the basis of his long experience in genetics contrasted the work of the plant and animal breeder with that among human beings. He stressed the fact that at a genetic clinic the real patient was the unborn child. The doctor could not escape having the power to influence conduct, and this must be increasingly based on exact knowledge. He devoted his concluding remarks to the serious genetic implications of the use of radiation in industry and medicine. These beneficent activities could not only hurt individuals but were potent in regard to the well-being of future generations. Here was a new field of mutational prophylaxis which was to be based on genetic knowledge.

In the discussion that followed, Dr. WILLIAM N. PICKLES (Aysgarth) said that the general practitioner who had been long in one district saw clearly the baneful trend of hereditary disease—not of rare diseases such as had been mentioned that morning, but of common conditions such as hypertension and glycosuria. He described a remarkable family which contained 62 members of whom 23 had had rheumatic fever or unmistakable signs of mitral disease. It was for the G.P. to provide facts of this sort and for others more skilled to give advice on them. He pleaded for a greater interest in genetics by G.P.s and a close liaison between them and the geneticist.

Dr. MURIEL BARTON HALL (Liverpool) mentioned the difficulty in routine clinical practice of making use in the genetic field of relevant material which presented itself.

Dr. N. S. BARNETT (Liverpool) asked whether it was possible, if the "undesirable" type—for example, the achondroplastic dwarf—were allowed to breed and rebreed, that by mutation a type might emerge superior to the previously accepted standard of "fitness." Dr. FRASER ROBERTS said that there was little chance of this.

The president, Dr. BLACKER, and Professor CREW remarked on the general agreement among those present in their approach to these problems. This new Section had been inaugurated with some diffidence, but could look forward to a useful future.

SECTION OF NEUROLOGY

Thursday, July 20

The Diagnosis and Treatment of Pain in the Upper Limb

With the president, Sir HUGH CAIRNS, in the chair, Dr. M. J. MCARDLE (London) opened the session by referring to the considerable advances in knowledge of this subject during the last ten years. The diagnosis of "brachial neuritis" was rarely made to-day. In 1938 frequent reference was made to the scalenus syndrome as a cause of pain in the arm, but recently this had received less attention. The lesson had been drawn from our knowledge of lumbar disk lesions as a cause of sciatica, and greater interest was now taken in cervical disk lesions producing cervical root irritation. Practically all cases of pain in the arm were included under the following headings: disk root lesions, costoclavicular syndrome, acroparaesthesia, and fibrositis. Cervical root pain was of a constant character, being a nagging severe pain not intensified by abduction of the arm. There was tenderness of the muscles supplied by the affected root. Objective signs of a root lesion would be found on careful examination: objective sensory signs were minimal and motor changes were diagnostically the most useful.

Prolapsed cervical disks were usually those between the fifth and sixth or sixth and seventh vertebrae. Lateral flexion of the neck towards the side of the lesion might exaggerate the pain. Dr. McArdle referred to the small "neurocentral" joints whose importance had recently been emphasized by Dr. James Bull, and said that osteophyte formation from these joints, when arthritic, could compress and irritate a cervical root in its foramen. A prolapsed disk and an osteophyte were not very easy to differentiate as a cause of root pain. A sudden onset of symptoms favoured a disk lesion, and slow changes

osteoarthritis. *X*-ray examination might reveal the osteophyte formation. The differentiation was not very important, as treatment was the same. Diffuse osteoarthritis of the cervical spine did not commonly produce root irritability. Pressure at the cervico-brachial junction was the most controversial aspect of the subject. If there were no vasomotor changes it was not very easy to diagnose. "Proximal thenar atrophy" was sometimes caused by such pressure. Unaccustomed physical strain, such as the carrying of heavy weights, might produce temporary symptoms. Recent investigations had shown that costoclavicular compression (compression of the subclavian artery and the brachial plexus between the clavicle and the first rib) was impossible if there was no gross structural abnormality.

Acroparaesthesia was most often seen in women between the ages of 40 and 50 years and commonly woke them at night by intense burning sensations in the hands and arms, sometimes paroxysmal in character, and there was usually an unpleasant aching pain as well. Manual work during the day appeared to be a provocative factor. The syndrome ran a chronic fluctuating course from a few months to thirty years. It was very unusual in men. Dr. McArdle considered that the paraesthesia was due to nerve compression of some kind occurring at varying sites. Sometimes it was a median nerve compression in the carpal tunnel. He had had a dozen suspected cases of this in which surgical decompression of the median nerves had given uniformly good results. In other cases the ulnar nerve might be involved, and yet others were of very obscure aetiology. Our views in five to ten years' time would be very different from those of to-day.

Cervical Disk Lesions

Dr. M. KREMER (London) considered that in most cases symptoms due to a cervical disk lesion were insidious in onset. Sometimes a history of an antecedent stiff neck was obtained, but this was not common—not as common as the history of lumbago preceding sciatica. The root pain from a cervical disk lesion generally began at the root of the neck and spread laterally either anteriorly or posteriorly to the axillary fold, then down either the anterior or posterior aspect of the arm to the elbow. The pain usually paused for a time at the elbow. Very rarely the pain extended further below the wrist and into the fingers. The affected muscles became very tender. In left-sided cases coronary pain was sometimes simulated. Muscular spasm occurred in some cases. The head might be tilted towards the shoulder on the affected side. As a result of spasm and immobilization the condition of "frozen shoulder" might develop. By the time pain had reached the wrist paraesthesia had usually developed in the fingers. Sensory changes resulted in difficulties in picking up small objects. A visible flabbiness or atonia was often seen in affected muscles and there might be reflex losses. Some objective signs would invariably be found after a few weeks in all these cases of root lesion. The pain was of a very severe character. It was worse at night. Sleep might become impossible. Additional pain was caused by putting strains on muscles in spasm. Movements of the neck are commonly restricted. Patients would often seem to "turn in one piece." Even in the early stages of root lesions some pathognostic signs were generally to be found. For example, pressure vertically downwards on the head might produce root pain. In contrast, traction under the chin might give great relief; this was a most useful sign.

Dr. Kremer emphasized the importance of conservatism in treatment. More than 90% of cases became well spontaneously in six to ten weeks. The keynote of treatment was rest in bed. The three-quarters sitting position, properly supported, was best, though lying flat suited some patients better. Sandbags might be necessary to keep the head still, and the affected limb must be fully supported. Analgesic drugs should be freely given to relieve pain where necessary. The object was to secure complete rest in bed by obtaining relief of all pain by appropriate drugs. Manipulation under general anaesthesia was dangerous. The use of a neck-sling, with extension, was valuable for the relief of pain in some cases. If necessary a plastic or leather collar for the neck could be fitted, or, alternatively, a temporary collar could be made by the patient himself from a sheet of 1-in. orthopaedic rubber. Only a very small percentage of cases required operative treatment. Dr. Kremer referred to neuralgic amyotrophy as another cause of pain in the arm in young adults. Severe pain at the root of the neck and around the shoulder was present for 10 to 20 days. Then weakening and wasting of the affected muscles became noticeable. Later the pain disappeared, and recovery, partial or complete, slowly took place.

Radiological Features

Dr. J. W. D. BULL (London) described the radiological anatomy of the cervical spine, with particular reference to the structures bordering on the exit foramina of the vertebrae. He pointed out the importance of the small neurocentral joints which lay on the lateral aspects of the bodies of the third to seventh cervical vertebrae only; they also formed the anterior border of the exit foramina. He showed how in cases of cervical disk degeneration these joints often showed signs of arthritis and osteophyte formation encroaching on the exit foramen. He felt that this feature was one of the factors in the production of brachial neuralgia. He stressed the puzzling absence of symptoms in some cases with marked radiological abnormalities and referred to our ignorance of many other factors concerned in causing root pains in the arm. He expressed the view—and other speakers agreed—that myelography was unnecessary in the diagnosis of cervical disk lesions.

Mr. W. R. HENDERSON (Leeds) said that an important point in the diagnosis of cervical disk lesions was that only one root was affected. He agreed that the treatment was mainly conservative and operation rarely needed. He spoke of the dangers of manipulation. Such treatment might occasionally result in sudden improvement but sometimes made the symptoms worse. Operative treatment was essential if there was compression of the spinal cord. Spinal tumour was an occasional cause of pain in the arm. Such tumours were generally extradural, benign, and removable if diagnosed early enough. Root pains from such tumours usually occurred over the shoulder and down the arm. There might, however, be very little root pain, and this added to the risk of misdiagnosis. There was a danger of overlooking the presence of removable tumours by considering prolapse of cervical disk as the cause in all cases of cervical root pain.

Mr. D. LLOYD GRIFFITHS (Manchester) spoke from the standpoint of the orthopaedic surgeon and stressed that the commonest cause of pain down the arm was something wrong with the shoulder. Among his cases, only one in five of pain in the arm was due to a cervical disk. The disk syndrome was easily recognizable, as was the shoulder syndrome. There were some cases, however, that could be very difficult to diagnose. The pains from a shoulder lesion were from soft tissues, the capsule, and surrounding tendons. In such cases not only might "frozen shoulder" develop but also "frozen hand," and after the pain had disappeared movements remained restricted. Many cases of rheumatoid arthritis in middle age began with pain in the neck and down the arm. In normal people the costoclavicular syndrome was of no importance, but it became very important when a large cervical rib was present. Unlike the lumbar region, in the cervical region osteoarthritis in the spine was common in cases of cervical disk lesions. Mr. Griffiths disagreed with Dr. Kremer and considered that a plaster-of-Paris jacket to fix the neck was more important than rest in bed. It could relieve pain dramatically. Lastly, referred pain—such as that of cardiac disease—should not be forgotten.

Mr. D. M. MORRISSEY (Birmingham) spoke of the costoclavicular or thoracic inlet syndrome. He considered that the loss of supraclavicular hollowing was a sign of a falling clavicle. This was particularly important in cases of cervical rib, which might become very prominent. He agreed with other speakers that alteration in the pulse volume was of little significance. Except in rare cases conservative treatment gave the best results. Nearly all patients recovered spontaneously. Operation might be required if a cervical rib gave rise to severe symptoms.

The Care of Paraplegics

In the afternoon the Section visited the spinal injury unit at the Southport Promenade Hospital. Mr. A. SUTCLIFFE KERR (Liverpool), in a preliminary address, stated that it was now not enough to keep all paraplegics alive. They must be rehabilitated

sufficiently to be able to go home. The treatment of their cases could be put in three categories: care of the renal tract, of the skin, and of the patient's mental outlook. A keen nursing staff was necessary. In the early stages paraplegics had to be turned every two hours to reduce the risk of bedsores. They might have to be nursed on their faces for long periods. Rehabilitation consisted largely in developing the muscles of the upper trunk and arms: these could largely replace those of the legs in relearning to walk. In the treatment of bedsores already present Mr. Kerr advised bland, not sticky, dressings, the excision of sloughs, and the use of full-thickness pedicle skin grafts where necessary. Stiff joints were a handicap, and joints should be kept healthy by physiotherapy. Mr. Kerr stressed that every patient with a lesion at the tenth dorsal segment or below should be able to walk. Spastic paraplegics were less easy to rehabilitate. It was important to have a resettlement unit in connexion with a spinal injury centre. Mr. J. COSBIE ROSS (Liverpool) and others spoke on the urological problems in paraplegics; in the relief of chronic retention of urine bladder-neck resection had important possibilities. Apparatus of an original character for training patients to walk was demonstrated.

SECTION OF RADIOLOGY

Thursday, July 20

Some Aspects of Bronchiectasis

With Dr. P. H. WHITAKER (Liverpool), a vice-president, in the chair, Dr. J. C. H. MACKENZIE (Leicester), opened the discussion on bronchiectasis, which, he said, was defined as a condition with dilatation of the bronchi. With the introduction of iodized oil as a contrast medium it had become possible to confirm the diagnosis during life.

In the medical literature there were no statistics of the incidence of this disease in a community. The figures from the Leicester Isolation Hospital and Chest Unit showed that the greatest incidence occurred up to the age of 15 years, and that the incidence in females was greater, particularly up to the age of 10. There was good co-operation between the Leicester chest unit and the Leicester City school medical service, and the figures for bronchiectasis among the school population in the city could be considered reliable. These cases of bronchiectasis were proved by bronchograms. The incidence was 2.9 per 1,000 school-children. The speaker suggested that the incidence would vary between communities, depending on social factors, the efficiency with which T.B.-positive cases were isolated from children, and the efficiency of chemotherapeutics and antibiotics.

The aetiological factors were mechanical forces—from traction and from distension from secretory pressure—and infection. Lander and Davidson had shown that traction forces within a collapsed segment produced dilatation of the bronchi, and they suggested that bronchiectasis was reversible. Lander in 1946 further suggested that in an incomplete bronchial stenosis the collapse was peripherally situated and the bronchus dilated, but that in complete obstruction dilatation might occur from secretory pressure. Infections which produced dilatation of the bronchi could be acute, subacute, or chronic. Acute destruction of the lung tissue occurred in Friedländer's pneumonia—non-specific suppurative pneumonitis and viral diseases associated with secondary infection. The subacute destructive changes occurred in tuberculosis when the upper lobes were particularly involved. The bulk of cases of bronchiectasis were chronic and invariably began with atelectasis of the lower lobes, either from an inflammatory cause or from glandular pressure, particularly tuberculous hilar adenitis. Bronchiectasis, however, did not necessarily follow atelectasis.

Pathological Changes

Dr. F. WHITWELL (Liverpool) said that his material had been collected from surgically resected lungs for bronchiectasis. He divided his cases into three main groups. First, the disease occurred in young people, usually following previous respiratory infections—particularly whooping-cough and measles. Here there were thickened, inflamed bronchi surrounded by zones of chronic interstitial pneumonia. No epithelial ulceration had been observed. These changes produced a compression of the bronchi and bronchioles from outside. The absence of alveolar filling and mucous plugs suggested that collapse was unimportant in the causation of bronchiectasis, and that the changes of importance were a peripheral bronchial obstruction.

In the second category was the saccular type of bronchiectasis, occurring in older people, usually without any previous respiratory infection. Sections showed an obvious saccule, which had a fibrous wall and was lined by metaplasic squamous epithelium. This was surrounded by normal alveoli, while the draining bronchus showed superficial bronchial inflammation with polypoid changes. These produced partial obstruction but no destruction of the bronchial wall. The third group of cases showed evidence of collapse with generalized bronchiectasis. The cause was enlarged hilar masses, usually tuberculous glands.

Lung Function

Dr. F. J. PRIME (Liverpool) described studies of lung function in a series of cases of bronchiectasis of varying severity in adults. The cases fell into two groups. In one function was but little affected: vital capacity, total lung capacity, and residual air were normal, but some degree of dysfunction was apparent in a reduced breathing reserve and minimal suboxygenation of the arterial blood. In the second group all measurements were grossly abnormal. Severe emphysema, shown by a high ratio of residual air to total lung capacity, was present in all, together with gross defects of intrapulmonary mixing of inspired with lung air. All the findings were such as would be expected from spreading fibrosis, with the production of focal or generalized emphysema.

In the general discussion the chairman, Dr. P. H. WHITAKER, said that in cases of bronchiectasis most of the damage was done in childhood, and early recognition of the disease was essential. Professor A. S. JOHNSTONE (Leeds) referred to the irregularity and kinking that might occur in the bronchi and bronchioles in an otherwise normal bronchogram, and suggested that these might be due to early bronchiectatic changes. Dr. R. J. KEATING (Wirral) noted that all cases of bronchiectasis did not fit into the groups that had been described, and suggested that a possible vascular disturbance might be associated. Dr. K. D. F. MORLE (Liverpool) referred to cases of reversible bronchiectasis which he had noted in healthy adults. These would appear to follow a segmental pneumonitis: bronchographic studies disclosed that return to normal occurred in from 10 days to 6 months. Mr. L. G. CRUIKSHANK (Leicester), Dr. J. E. WALLACE (Bognor Regis), Dr. R. FAWCITT (Ulverston), Dr. W. S. HOLDEN (Liverpool), Dr. G. B. LOCKE (Manchester), Dr. J. A. ROSS (Liverpool), and Dr. J. S. FULTON (Liverpool) also joined in the discussion. Replies were given by the opening speakers.

SECTIONS OF OTO-RHINO-LARYNGOLOGY AND RADIOLOGY

Thursday, July 20

Carcinoma of the Larynx

With the president of the Section of Oto-rhino-laryngology, Mr. I. SIMSON HALL (Edinburgh), in the chair, Dr. M. LEDERMAN (London) opened the discussion. Laryngeal cancer, he said, could be subdivided into supraglottic, glottic, and subglottic forms. The old classification into intrinsic and extrinsic groups should be abandoned. Of the radiotherapeutic methods of treatment available, external radiation by teleradium or high-voltage *x*-ray therapy was to be preferred, particularly the former if available. Radiation might be used for curative or palliative purposes or as a pre- or post-operative measure. The palliative value of radiotherapy was considerable. Pre- and post-operative radiation should be used with discretion.

Supraglottic tumours should be treated by radiotherapy, and subglottic tumours should be treated surgically. Radiotherapy should be used for all cases of glottic tumours suitable for laryngo-fissure, partial laryngectomy, or laryngectomy in which the cord was still mobile. Surgery should be reserved for cases unsuitable for curative radiotherapy—that is, the more advanced, recurrent, or complicated cases. If the primary lesion was to be treated by radiation and nodes were present, these should be treated in the same way. If the primary lesion was healed and operable nodes appeared, block dissection should be performed. Inoperable nodes should receive palliative radiotherapy. "Prophylactic" irradiation of the neck was indicated for all supraglottic tumours. The results of teleradium treatment at the Royal Cancer Hospital, London, were as follows: 5-year survivals—operable cases, 16 out of 23 (70%); all cases, 18 out of 56 (32%). 3-year survivals—operable cases, 30 out of 46 (65%); all cases, 35 out of 96 (35%).

The discussion was continued by Mr. C. P. WILSON (London), who said that the factors to be considered in deciding upon the best method of treatment in intrinsic carcinoma of the larynx were the site of origin and extent of the growth, the mobility of the cord, the histological features, and the type of patient. The methods of treatment available were radiotherapeutic, limited surgical removal, radical surgical removal, and palliative treatment only. Early growths—with a rigid regard for the definition of an early growth—gave equally good results whether treated by radiotherapy or limited surgical removal by the laryngo-fissure route. Choice would depend upon the facilities available, the histological features, and the circumstances of the patient. More extensive unilateral growths were best treated by radiotherapy. Growths of the commissure should be treated by radiotherapy rather than by limited surgical removal. Growths with fixation of the cords were better treated by radical surgery than by radiotherapy. Advanced growths should be treated by radical surgery in comparatively fit patients and by palliative measures in the old and infirm. Subglottic and supraglottic growths were both less favourable than glottic growths for treatment either by surgery or by radiotherapy; if comparatively early, radiotherapy might be the better, but if there was fixation of the cord, or if the growth was of an extensive nature, radical surgery offered a more favourable prognosis. If the growth was of a well-differentiated keratinizing type there should be a bias in favour of surgery, but if the growth was of a non-keratinizing undifferentiated type the bias should be in favour of radiotherapy.

Recurrence after previous limited surgery or radiotherapy should be treated by radical surgery or palliative means alone. A second course of radiotherapy should be given only rarely. If glands were present the results were likely to be poor whatever treatment was adopted. If they were of differentiated type and were amenable to radical surgical removal this should be done, otherwise only radiotherapy or palliative treatment should be given.

Radiological Examination of the Larynx

Dr. J. J. STEVENSON (London) said that a thorough radiological examination of the larynx was not one which was carried out in many hospitals in this country. While it was a time-consuming investigation requiring a special technique, the information gathered from it did supplement that obtained by clinical methods. It was often helpful in determining the site of origin of a tumour, thus influencing the method of treatment and the prognosis. The extent, and particularly the lower borders, of laryngeal tumours were very difficult to assess by any other means. Indirect laryngoscopy sometimes failed to show subglottic extension of laryngeal growths which could be easily demonstrated by radiography. This method was also of help in assessing the nature of the tumour—as in the case of involvement of the epiglottis. To discover whether the growth was ulcerating, infiltrating, or proliferating was useful in planning the management of the case. The propagation of the tumour could be appreciated in most cases of spread into the pre-epiglottic space or into the pharynx. Finally, in cases subjected to radiotherapy it provided an objective record of the patients' response to treatment.

Dr. Stevenson said that his practice in all cases of carcinoma of the larynx was to take soft-tissue lateral radiographs and antero-posterior tomographs. Two lateral views were taken, one during normal respiration and one during phonation: as well as showing the topography, these helped to show the mobility of the laryngeal structures.

Mr. TERENCE CAWTHORNE (London) said that he regarded it as very satisfactory that surgeons and radiologists were in such close agreement about the treatment of this condition. He also referred to Dr. Constance Wood's work for the Medical Research Council and her successful results in the treatment of carcinoma of the larynx. Lieutenant-Colonel D. MACD. FRASER (Liverpool) asked how big a disability a total laryngectomy was to a labouring man who had to use considerable energy. Dr. S. C. SEN (New Delhi) asked whether the Coutard method of protracted treatment, as against high-intensity treatment, was still in favour amongst radiotherapists.

Combination of Surgery and Radiotherapy

The chairman, Mr. I. SIMSON HALL (Edinburgh), said that no surgical operation on the larynx was performed in his clinic between 1932 and 1942. The five-year recovery rate was 20%, *x*-ray therapy alone being used. This convinced him of the necessity for combining surgery with radiotherapy. Dr. J. S. FULTON (Liverpool), president of the Section of Radiology, said that he thought that the subject had been most adequately covered by the opening speakers. He was very much against the use of the single-dose method of radiation in the treatment of any form of cancer. He recommended continuous radiation for seven to ten days. He considered that radiation was not a successful method after surgery. In his opinion the discomfort caused to the patient by radiotherapy was much exaggerated.

Mr. WILSON, in replying, stressed that there was no conflict between laryngologists and radiotherapists. He thought that radiation was quite useless in the treatment of hyperkeratosis. He disagreed with Dr. Lederman that supraglottic tumours were not removable surgically. The modern operation of laryngectomy allowed even a labourer to do almost anything except swim. Dr. LEDERMAN also spoke in reply. He said that Coutard's method of low dosage had been almost universally abandoned.

Intestinal Parasites of Man in Great Britain

With Professor R. M. GORDON (Liverpool) in the chair, Professor J. J. C. BUCKLEY (London) spoke on helminthic infections of man in Great Britain. He said that on account of the climate and geographical position Britain's human helminthological fauna was restricted to relatively few of the 120-odd species known to occur in man. Those which did occur could be divided into those for which man was the normal host and those which were normally parasites of domesticated animals—e.g., dog and sheep—and which occurred in man only accidentally. Most of the "accidental" parasites came from the dog because it was a privileged household pet. They belonged mostly to the tapeworm family, and it should be recognized that tapeworms in dogs were dangerous and should be removed. *Dipylidium caninum* (which could be recognized by its segments) might be regarded as a trivial danger, but *Taenia multiceps* and *T. serialis* were more serious. The most dangerous of all was *Echinococcus granulosus*, which was easily overlooked in dogs, being very small, and which produced hydatid cysts if the eggs were swallowed. Fortunately human infections were now rare.

The "normal" parasites of man included four nematodes. Of these *Ascaris lumbricoides* and *Trichuris trichiura* were rarely important in Britain. *Enterobius vermicularis* (although in one sense it passed a "hand-to-mouth" existence) was very common. Recently it had been shown that the infection could be continued in the same host by a method named "retrofection," wherein eggs (scattered in the perianal region by the migrating female threadworm) hatched into larvae, which crawled back through the anus into the original host and attained maturity in the caecum. *Trichinella spiralis* had attracted attention during the war because of several outbreaks in widely separated localities in England and Wales. A pre-war survey had shown subclinical infection in only 2 out of 200 human diaphragms examined at necropsy, but a

survey made later in the war revealed trichiniasis in 10.8%. Women were infected more often than men.

The human tapeworms in Great Britain included *Taenia solium* and *T. saginata*, the latter appearing in beef as *Cysticercus bovis*. Routine meat inspection at abattoirs had shown a marked increase in the frequency of *C. bovis* in meat. A similar increase had been recorded from Denmark, and there it was accompanied by a rising incidence of the tapeworm in man. The general experience in Denmark had shown that meat inspection does not prevent transmission of the infection to human beings, since the cysts are often few and are easily overlooked. The other human tapeworm, *T. saginata*, which was derived from pigs, was fortunately now rare, partly because of efficient meat inspection, and partly because of the improved methods of keeping and feeding pigs.

Dr. C. A. HOARE (London) spoke on amoebiasis in Great Britain. His paper was published in full in last week's *Journal* (July 29, p. 238).

Treatment of Intestinal Helminths

Dr. R. F. VERE-HODGE (Tisbury, Wilts) spoke on the treatment of intestinal helminths. Before treatment a careful examination should be made to exclude debilitated subjects, the dose should not be repeated within ten days to avoid accumulation of the drug, and in children it was best to err on the side of underdosage. The commonest infestation was by threadworms. Treatment by gentian violet was usually effective, but relapse or reinfection often occurred. Younger children must be treated with quassia enemata on alternate days, probably for a month. In Britain ascaris never occurred in such overwhelming numbers as in China, where one patient might harbour as many as 2,000 worms. Santonin, being non-toxic, was the best drug to give, provided that oils, fats, and alkalis were avoided. A second treatment, 4–7 days later might be necessary. The treatment of taenia was often difficult and uncertain. He recommended fluid diet and purgation for two days, then a dose of 90 min. (5.3 ml.) of liquid extract of male fern, followed half an hour later by magnesium sulphate. Carbon tetrachloride was also effective, but might be toxic. Hexylresorcinol was non-toxic but not very effective. For hookworm he recommended tetrachlorethylene plus oil of chenopodium. Strongyloides was usually resistant to treatment, but methylene blue had given promising results in a small series of cases.

Mr. R. B. GRIFFITHS (Liverpool) spoke on the incidence of *Cysticercus bovis* in Great Britain. Apparently this had recently become more common, and in 1949 routine inspection at the abattoirs had shown that 1.6 to 4.2% of the cattle slaughtered might contain it. It must be recognized that inspection at the abattoir could not detect all cases of infection, and the housewife must constitute a second line of defence by insisting on the thorough cooking of all meat. Apparently women were more liable to infections derived from meat than men were. The problem was of appreciable financial as well as medical importance, and a careful inquiry into the means of improving preventive measures to protect cattle from this infection would be well worth while.

Infestation in Children

Dr. R. C. MACKEITH (London) described the case of an infant with an ocular infection by *Enterobius vermicularis*. He also described a survey of the faeces of 142 children in London which showed 4 infected with *E. vermicularis* (perianal smears detected many other cases), 1 with *Trichuris trichiura*, 9 with *Giardia lamblia*, 1 with *Chilomastix mesnili*, 12 with *Entamoeba coli*, 3 with *Endolimax nana*, and 10 with *Blastocystis hominis*. Many of these infections occurred in the same patients. Other speakers in the discussion included Dr. L. E. NAPIER (London), Colonel W. H. HARGREAVES (London), Brigadier J. S. K. BOYD (London), Mr. P. L. LEROUX (London), and Dr. A. R. D. ADAMS (Liverpool). It was agreed that the higher rate of infections from meat among women was probably due to the contamination of the hands, though in some cases during the war trichiniasis had been contracted by eating raw sausages. In most cases *G. lamblia* was non-pathogenic, but many of the speakers considered that it might cause a peculiar chronic diarrhoea in certain patients.

SECTION OF ORTHOPAEDICS

Thursday, July 20

Treatment of the Short Leg

With the president, Dr. BRYAN L. MCFARLAND (Liverpool), in the chair, Mr. GORONWY E. THOMAS (Liverpool) opened a discussion on treatment of the short leg. Having described the common methods of alleviation by alteration to footwear and noting the possibility of disguising a very short limb within an extension prosthesis, Mr. Thomas reviewed methods of surgical correction either by lengthening the affected limb or by shortening the normal one. During the growth period of the *long* limb, operations could be performed for arresting growth by interfering with the epiphysial line by either permanent ablation (epiphysiodesis) or temporary interference by *stapling*; after the period of growth, shortening osteotomies, generally femoral, could be performed. The optimum period for the former was between the years of 8 and 11, and for osteotomy after the age of 12. He drew attention to the risks of operation, particularly of the ablation type, during the growth period, for late deformity had been reported in from 10% to 20% of cases. Discussing operations for the *short* leg, he said that sympathectomy to improve its vascularity and therefore its growth was unreliable and the improvement insignificant. When growth had ceased, lengthening of the short leg by osteotomy and distraction of either the femur or of the tibia and fibula was a procedure of complexity, and there were not unimportant possibilities of complications. The whole problem was difficult of decision, for, while leg shortening of the normal limb was less complicated and demanded a shorter period in hospital, it had the material disadvantage of general reduction in stature.

Mr. F. G. ALLAN (Birmingham), speaking about leg lengthening, discussed the problem on the basis of 101 cases. The tibia and fibula had been lengthened in 54 and the femur in 47, the largest number in the former group being for poliomyelitis and in the latter for shortening due to tuberculosis of the hip. The surgical technique and the complex apparatus used were described. Mr. Allan emphasized the necessity for a three-point hold above and below the step-cut osteotomies of the tibia and fibula, each comprising two *transfixion pins* and plaster-of-Paris. In the femur the maintenance of alignment was more difficult. The principles of the method were absolute fixation of the fragments, and completely controlled distraction, which was carried out very slowly. The possible complications included traction lesions in nerves, fracture of one or other of the step-cut osteotomies, mal-union, delayed union, weakness of lengthened muscles, osteomyelitis, traumatic arthritis, late fracture, pressure or stretch necrosis of skin, and circulatory disturbances.

Mr. A. L. EYRE-BROOK (Bristol), discussing surgical shortening, said that epiphysial arrest was more readily within the scope of the average surgeon and had few risks. Post-operative deformity had been a cause of criticism of the procedure, but he felt that this was minimized by greater thoroughness in the process of ablation of the epiphysial line. Besides the insertion of grafts across each side of the epiphyses, above and below the knee, it was necessary to excise a large section of the epiphysial cartilage between the grafts. Surgical shortening was the preferable approach to all patients in the older age group with the exception of a small number who were unwilling or who could ill afford to sacrifice any height. It was a safe procedure, quick in its results. It was best done in the femur, and as much as 4 in. (10 cm.) of shortening could thus be obtained with full return of knee movements and muscular control within three to five months.

In the subsequent discussion, Mr. H. OSMOND-CLARKE (London) noted the possibilities which were being explored in Sweden to improve the vascularity of the short limb, and therefore growth, by the production of an arteriovenous fistula with ligation of the main vein on the proximal side. He also stated that insufficient attention was being paid to the psychological problems of the patient in whom shortening a normal limb was contemplated. While in the adult this could be decided by the individual more readily, surgeons were assuming a very serious responsibility in committing a child to a future of psychological stress associated with shortened stature.

Mr. D. WAINWRIGHT (Newcastle, Staffs) described an elongating Thomas splint on which the limb was supported during bone lengthening of the femur, for which he advocated an oblique osteotomy from the region of the lesser trochanter downwards and outwards. Mr. H. J. SEDDON (London) and Mr. B. L. MCFARLAND, the president, both stressed the importance of segregating such cases in the hands of a few people prepared to master the complex technique involved.

Acute Osteomyelitis

Professor WALTER MERCER (Edinburgh) noted the beneficial effect which the use of modern chemotherapeutic drugs had had on acute osteomyelitis. There were still the problems of early diagnosis, the best use of penicillin, and the indications for surgery. The responsibility of general practitioners was very great in the early recognition of osteomyelitis, for the cure of the disease depended on the start of antibiotic treatment within five days of onset. After that, abscess formation occurred in spite of penicillin, and after ten days all cases required some intervention. The significant symptom was pain and the conspicuous sign was bone tenderness. Radiographs at this stage were valueless.

In treatment, the penicillin blood level must never fall below 0.1 unit per ml. It was necessary to give a large initial dose of 200,000 units followed by 50,000 units three-hourly in order to ensure that organisms shut away in the dense bony tissues were dealt with. He was also satisfied with giving daily injections of 300,000 units of procaine penicillin and 100,000 units of sodium penicillin with aluminium stearate in arachis oil. He did not approve of the fantastic high dosage sometimes given. It had been suggested that the bactericidal effect might be reduced thus. Penicillin-resistant organisms, of which there were between 5% and 10%, detected after 48–72 hours' treatment might require "aureomycin," with a dose of 10–60 mg. per kilogram body weight orally per day.

This treatment still necessitated immobilization of the limb, general supportive measures, and, if abscesses developed, their prompt evacuation. In such cases after ten days operation was almost always necessary—drilling of the bone and primary closure, penicillin being instilled into the wound.

Mr. DENIS BROWNE (London) agreed that early operation should be avoided, and advocated the aspiration of abscess. Mr. F. C. DWYER (Liverpool) felt that it was better if in doubt to open the medullary cavity rather than wait for destruction.

Hidden Dislocations

Mr. H. OSMOND-CLARKE (London) discussed a group of injuries the diagnosis of which might readily be missed unless care was exercised to temper the evidence of radiography by proper use of clinical acumen. Most frank dislocations were easy to recognize, but there were some which might escape notice until the time for successful treatment by simple means had passed. Among such lesions were persistent dislocation of slight degree and lesions of the deep joints. Some dislocations reduced spontaneously but left important soft-tissue damage—particularly, for example, in the ankle after a rupture of the external lateral ligaments and resulting inversion subluxation; in the knee with rupture of the collateral ligaments; and in the neck, where subluxation might be shown only when the neck was in forward flexion. Such cases were often being diagnosed for a long period after injury as hysterical. If they were recognized early, adequate immobilization would produce a stable joint. If clinical signs suggested these more serious lesions, a negative *x*-ray examination should be checked repeatedly. The question was asked whether simple plaster immobilization was adequate for the treatment of a complete ligament rupture at the knee. Mr. Osmond-Clarke agreed that, based upon one reported group of 60 cases of internal lateral ligament rupture, these should always be explored surgically.

Supracondylar Fracture of the Humerus

Mr. F. W. HOLDSWORTH (Sheffield), discussing supracondylar fracture of the humerus, mainly in children, remarked on the anxiety which had affected most surgeons because of the possibility of late deformity and loss of movement. He noted the difficulties of accurate reduction. They had tended to lead surgeons in America to perform open operation, and in Britain to carry out repeated manipulations. Discussing particularly transverse fractures, he noted that the most difficult to reduce was that through the condyles, in which reduction was often a matter of obtaining a knife-edge balance. Stability was almost impossible without some rotatory deformity. Some of the worst results were achieved by open operation and fixation.

The speaker had recently reviewed a considerable group of old cases, and his conclusion was that these fractures gave good results regularly by a single manipulation, with maximal correction, the use of collar-and-cuff fixation, and then gradual mobilization. Some degree of displacement after manipulation need not cause any great anxiety for the ultimate result. No advantage was obtained by the use of posterior plaster supports. A year must pass before assessment was possible. But he had found that the anterior spike from the upper fragment, which was due to the stabilizing rotatory displacement, was of no importance, for it was lost by remoulding later, and this process also tended to bring the lower articular surface of the humerus into normal alignment. In adults, T-shaped fractures also did not need absolute anatomical reduction.

Ischaemic contractures were always due to arterial damage at the time of injury, and required exploration of the artery. Fractures with displacement of the capitellum required operative replacement of the fragment and simple immobilization with the elbow in extension and pronation without internal fixation. Fractures of the internal condyle required no special treatment unless incarcerated within the joint.

Trochanteric Fractures of the Femur

Mr. NORMAN W. ROBERTS (Liverpool) discussed the results of 50 cases of trochanteric fracture of the femur, of which 35 had received operative reduction and fixation with a two-piece nail plate. There was no operative mortality. The method gave at least as good results as conservative treatment by immobilization and traction in bed, and at the same time gave these results with a shorter period in hospital and an easier convalescence. He did not operate on all such cases, for there were some which were entirely stable and did well by conservative means. The average age of his patients was 62, but he had operated on a certain number of young people. A particular indication was in pregnant women, where early activity was essential. There were certain types of subtrochanteric fracture where the nail plate provided a very satisfactory alternative to the less desirable Küntscher nail. He emphasized the need to impact the fracture in all cases when applying the device.

Clinical Demonstration

A clinical meeting was held at the Royal Infirmary, Liverpool, on Friday, July 21, at which the president, Mr. B. L. MCFARLAND, presented a case of arthroplasty of the knee for ankylosis. He mentioned the technical difficulties which distortion of bony outline caused. Cases were shown in which patellectomy had been done for recurrent dislocation, and in which plastic reconstruction of the quadriceps had realigned the pull on the tibia (the point of the procedure being that such patellae were always degenerate). He also demonstrated the first case of congenital pseudarthrosis of the tibia on which he had operated, 17 years ago, by his "by-pass" method of bone grafting. The growth of the tibia and remoulding from the original deformity to a straight bone were remarkable.

Mr. F. C. DWYER (Liverpool) presented cases of transplantation of the ulnar nerve, including two cases of leprosy in which fibrotic shortening of the nerve had occurred. He also demonstrated a case of Madelung's deformity due to traumatic arrest of growth.

Mr. P. B. MORONEY (Liverpool) presented an example of "railings" fracture. These injuries, he pointed out, occurred in children who fell from railings and twisted their lower legs into severe adduction at the ankle, the lower epiphysial plate being split by the "anvil" action of the astragalus, producing premature fusion and severe late varus deformity. Correction by osteotomy was performed.

Mr. R. P. OSBORNE (Liverpool) showed cases of leg lengthening.

SECTION OF SURGERY

Friday, July 21

Burns

With the president, Professor CHARLES WELLS (Liverpool), in the chair, the meeting was opened by Mr. ROWLAND P. OSBORNE (Liverpool), who said that, as he had been working in co-operation with Mr. J. P. Reidy at Stoke Mandeville, it was his purpose to deal with the treatment up to the skin-grafting stage and to leave Mr. Reidy to continue from that point. Mr. Osborne began by emphasizing the very great importance of preventive measures and the need for special precautions in the case of children and epileptics. The use of fireguards and the proper placing of electric fires could do much to prevent the distressing incidence of burns. Turning to the question of burns centres, Mr. Osborne said he did not think it would be an economic or practicable proposition to establish many big centres, but he believed that by the simple modification of existing ward accommodation much could be done to provide proper dressing-rooms without sacrifice of too much space.

Mr. Osborne first discussed the problems of local treatment. In the initial process of cleansing the burnt area nothing should be applied which would damage the remaining epithelial elements. The first-aid dressing should consist in the application of the cleanest material available, and clothing should not be cut away. When the patient had reached hospital it was often best to delay the local treatment for some time in those cases requiring urgent and extensive resuscitation. It was their practice to undertake the first dressing in the theatre with full aseptic ritual and under general anaesthesia. The area was gently cleansed with a 1% "cetavlon" solution, and they then generally preferred the use of a Bunyan-Stannard envelope for limb burns, or, alternatively, the use of penicillin cream containing 400 units per gramme. In the latter instance the application of some pressure to the dressing was of importance, but it was not always easy to do this properly, and elevation of the limb was a simpler way of checking oedema. The speaker did not favour the use of plaster-of-Paris other than as a means of lightly splinting the limbs in children. Where dressings were used they should be applied with the greatest care and so fixed that they could remain securely in place for a long time; generally they were not disturbed for 10–14 days, and the only indications for changing them before this were: (1) because the dressing had shifted; (2) because exudate had soaked through and provided a passage for infection, or (3) because of fever, pain, or severe constitutional disturbance. Many superficial burns would be healed or nearly healed after 14 days, and in areas of full-thickness burn sloughs should then be removed and early grafting undertaken. Mr. Osborne referred to the importance of having a clean and flat granulating area to graft on, but he emphasized that it was sometimes justifiable and imperative to apply "postage-stamp" grafts to an infected area, and in any case they always used these "postage stamps" rather than sheets of skin. Concluding his discussion of local treatment, he referred to the use of saline baths, a method which was applicable only where expense was no object and a big team was available, and he stressed the need for careful bacteriological examinations and sensitivity tests, so that bacteriostatic and antibiotic agents could be intelligently used. He also mentioned the early excision of localized deep burns. In referring to the problems of general care, the speaker said that time would not permit more than a brief survey of circulatory restoration, the avoidance and control of anaemia, and the difficulties of correcting those profound metabolic disturbances which occurred in severe cases. Attention to the latter two factors, in particular, was an essential prerequisite to control of infection.

Skin Grafting

The discussion was continued by Mr. J. P. REIDY (London and Stoke Mandeville), who considered the patient from the stage when his burn was ready for the application of skin. Early skin cover of areas of deep loss reduced toxaemia, promoted healing, and restored function. Autogenous grafting of "postage stamps" cut from a thin sheet of skin was the most certain and economical method. Pinch grafts certainly had no place in treatment, for they were less likely to take and could leave a most unsightly donor area which was of no further use for provision of skin. Mr. Reidy said that, although homogenous grafts were able to survive only for a short time, homogenous grafting was of the greatest value as a temporary measure in many cases in which more than 40% of the body area had been burned. He then referred to the "high priority areas"—eyelids, hands, and flexures—all of which should be grafted at the earliest possible moment. In the case of the hand it was absolutely essential to maintain it in a position of function while healing occurred. Donor areas should be chosen with great care, and every effort should be made to use the maximum amount of each donor site in the most economical manner possible. Mr. Reidy concluded his remarks on early grafting by brief reference to the causes of failure and the occasional value of refrigerated grafts. On the subject of later repair he referred to the use of Wolfe grafts and flaps and to the problems of keloid scarring, illustrating his points by reference to a number of photographs.

Treatment by Exposure

Mr. A. B. WALLACE (Edinburgh) described the problems of controlled fluid replacement and his own method of treatment by exposure. He referred to the significance of pallor, thirst, and restlessness as evidence of incipient oligaemic shock, and explained the principles and methods of fluid replacement. In his own unit they had prepared tables which gave detailed guidance in this therapy at different ages and in burns of different extent, and these formulae gave considerable help to the junior medical and nursing staff in the care of the case. Mr. Wallace said that he was a great believer in keeping the burnt surface dry, and, having found that burns treated by pressure were much more readily healed when they remained dry, he was emboldened to try the treatment of cases by exposure to the air of the ward. After a careful ritual cleansing essentially similar to that mentioned by Mr. Osborne (although often conducted under premedication only), the burnt area was liberally insufflated with penicillin-lactose powder. This insufflation was continued four-hourly in the ward until the area was crusted over; this usually took 48 to 72 hours. He had used this method initially in children, and he emphasized the freedom from pain, marked lack of constitutional disturbance, low fever, and good progress. Although these surfaces were exposed to the full bacterial contamination of a general ward he had not had a case of infection with a β-haemolytic streptococcus, proteus, or *Ps. pyocyanea* in two years, and this was despite the fact that Petri dishes exposed in the ward were liberally contaminated by these organisms. Mr. Wallace illustrated the application of this method in various cases and concluded by showing a coloured film on exposure treatment of a superficial burn of the perineum and buttocks.

Dr. HERBERT M. BATTINGER (Gary, Indiana) said that as he was in such considerable measure of agreement with the two opening speakers he did not propose to burden the meeting with his full paper. He then selected the more important points for elaboration and said that he was a firm believer in the proper use of pressure dressings and elevation of the affected part. It was his practice to give one part of blood to every two parts of plasma in the early treatment, and he rarely gave much intravenous fluid after the first 36 hours. Dressings were left for 12 to 14 days, and he then performed a delayed excision of the sloughs and grafting, or else applied pressure dressings for a few more days if it was a superficial burn which had not yet healed. He believed in using sheets of skin and had not tried "postage-stamp" grafts. He referred to the use of high-calorie and high-protein diets, the administration of vitamins, and the need for keeping the haemoglobin at not less than 85%. Commenting on the exposure method of treatment, he said that this was new to him, and, although he was quite impressed, he felt that the superficial burns shown in Mr. Wallace's film might have healed equally well under any application, even cabbage leaves.

In the general discussion Mr. JOHN A. SHEPHERD (Liverpool) mentioned the dangers of morphine in some of these cases, the importance of avoiding all sticky dressings, and the treatment of shock. In the latter connexion he believed that there was a great danger in using such tables of fluid replacement as Mr. Wallace had mentioned. He also thought that laboratory investigation with haematocrit readings was often difficult, and he preferred to rely on clinical judgment in giving his intravenous fluids. Mr. R. S. MURLEY (London) said that, as one who had been privileged to see Mr. Wallace's patients in the Edinburgh Children's Hospital, he would like to underline various points in this method. Many who had neither seen nor tried it were far too ready to condemn this very simple and eminently satisfactory method. He could confirm the remarkable general well-being of these patients and the absence of infection. Although some had said that this was a method which was likely to be difficult to apply in adult cases or in deep burns, he did not believe that this was so. In wartime, or in the treatment of large numbers of cases, the method would certainly be of the greatest value. Mr. Murley said that he could not agree with Mr. Shepherd's remarks about judging fluid therapy on clinical grounds: it was necessary to have some basic plan of campaign if one was to avoid doing great harm to some of these patients.

Treatment of Severe Burns

Miss ISABELLA FORSHALL (Liverpool) said that she was disappointed that none of the opening speakers had shown a picture of a really severe burn, and she would have liked to hear more about the burnt hand. She wondered whether the results with exposure were really much better than they had formerly obtained with tannic acid and other similar agents. It had seemed to her that relatively inefficiently cut skin grafts of varying thickness took better than carefully cut ones. Mr. R. B. WELBOURN (Liverpool) said that Mr. Osborne did not seem to regard infection as a major problem. He would like to know if the opener agreed with the practice of grafting on an infected surface to save time. He thought that somebody should emphasize the dangers of serum jaundice, for the previous speakers had all spoken of using plasma and had not mentioned the possibility of this serious complication. Surely plasma substitutes were advisable. Finally, he was not clear whether Mr. Wallace applied dressings after grafting.

The chairman, before calling on the first two speakers to reply, asked Mr. Wallace to answer some of these questions. Mr. WALLACE regretted that he had shown no severe cases, for he had a number of photographs of such cases with him and had been unable to show them in the short time available. He went on to describe some of the methods, such as the use of a special bed, by which he had treated very extensive burns by the exposure method. He completely disagreed with Miss Forshall about tannic acid and gentian violet, both of which damaged the burnt area, while the latter was a protoplasmic poison which delayed healing. In reply to Mr. Welbourn, he stated that he treated his cases after grafting in an orthodox manner. Mr. REIDY, in reply, said that he strongly disagreed with Mr. Shepherd's remarks about basing fluid therapy on clinical impression, though he agreed with his comments on the dangers of morphine. It was naturally justifiable to graft on an infected area provided that infection had been properly reduced beforehand. Miss Forshall had said that grafts of varying thickness might take better, but he did not know how she had formed this impression, since thin grafts of even thickness certainly took much better. He always cut his grafts with a Humby knife and had given up use of the dermatome for this purpose. He had not said more about burnt hands because he had purposely limited his remarks to the underlying principles of maintaining function, since in other respects there were few fundamental differences in treatment. Like Mr. Wallace, he could only mention tannic acid in order to condemn it.

Mr. OSBORNE pointed out that it had been hoped to get Sir Archibald McIndoe to open this discussion, and he regretted that the meeting had not had the privilege of hearing him. Mr. Osborne thought a basic plan of fluid therapy was quite essential. Haematocrit readings were not really so difficult, especially if one used capillary blood, as was the practice at Birmingham. A previous speaker had said that anaemia could be entirely prevented, but this was certainly not true, since it was, unfortunately, an inevitable development in severe burns and could be corrected only by frequent transfusions of fresh blood. In burns of the hand the important points were early movement, early removal of sloughs, and early grafting. He thought that the patient's own work was altogether preferable to remedial occupational therapy. Contrary to Mr. Welbourn's remarks, he did regard infection as a major problem: it was exceedingly difficult to render a surface sterile and almost impossible to keep it so, but luckily one could graft successfully without eradicating all infection. He concluded by showing pictures of some massive burns and briefly mentioned a useful method of applying alternate strips of autogenous and homogenous skin grafts in such cases. The latter method had been developed by Mr. L. M. Rouillard at St. Albans.

The chairman, Professor WELLS, then thanked the opening speakers for their contribution to what had been a very interesting and valuable discussion, and he especially thanked Dr. Herbert Battinger for having come so far for this meeting and for having been so courteous and considerate in cutting his paper down to an absolute minimum.

SECTION OF CHILD HEALTH

Friday, July 21

Epidemiology in Relation to Child Health

After thanking officers of the Section for their assistance, the president, Professor NORMAN B. CAPON (Liverpool), invited Dr. WILFRID SHELDON (London) to take the chair. Professor S. G. GRAHAM (Glasgow) opened the discussion with a paper on infection in the maternity hospital. He pointed out that the behaviour of infection in the newly born differed from that in older children and adults. The incidence of infection in the newly born was difficult to assess, but there was reason to believe it was highest in teaching hospitals, where premature deaths were more frequent. Necropsies revealed that approximately only 50% of infections were detected during life by experienced clinicians. Endogenous infection might explain the greater liability of the small premature infant to develop infection. Approximately 25% of the neonatal mortality was associated with infection. Professor Graham stated that the increase in institutional midwifery coupled with the failure of hospital construction to keep pace with demands made for greater risk of infection. The risks were less, and the possibility of epidemics did not exist in domiciliary practice. The greatest hazard in hospital arose from the herding of infants in ill-equipped and poorly ventilated rooms.

Neonatal Infections

Neonatal infections in a nursery were all potentially dangerous. In general, conjunctivitis, pemphigus, and thrush did not contribute materially to the neonatal death rate. Some sticky eyes were sterile, but *Staphylococcus albus* was frequently found and was probably pathogenic. Thrush was almost endemic in many nurseries, and had increased in frequency, though there had been no corresponding increase in monilia infection among mothers. Among major infections the aetiology of epidemic diarrhoea remained uncertain. Incrimination of special types of *Bact. coli* awaited final proof or disproof. Treatment of serious infections was on the whole unsatisfactory. Despite conflicting reports concerning their value, there was a place for the sulphonamides and penicillin, and there was justification for believing that there was a future for "aureomycin" and "chloromycetin." There was need to differentiate the so-called pneumonia arising from the aspiration of irritant amniotic fluids and the infective pneumonia of bacterial origin. A rigid regime designed to prevent the spread of infection constituted the essence of treatment. The prevention of prematurity required further study, and attention must be focused on social factors which contributed to the major problem of infection in the newly born.

Tuberculosis in the Home

Introducing Dr. W. N. PICKLES (Aysgarth), the chairman congratulated him on the honorary degree of D.Sc. recently conferred on him by the University of Leeds. Dr. Pickles's paper dealt with infection in the private house. In vivid terms he described instances known to him personally of tuberculous infection contracted by infants and children from relatives and elders in the household. He made a moving appeal for full appreciation by doctor and public that tuberculosis was our most important infectious disease. He reinforced his argument by contrasting the great care exercised in isolating scarlet fever, and by illustrating from records compiled during a long experience of general practice the providentially small death rate arising from the exanthemata and other diseases of an infectious nature.

Dr. Pickles gave it as his conviction that infectious diseases other than tuberculosis were introduced to the home by the school-child, and the method of transmission was usually by droplet infection. During the war evacuation was instrumental in bringing infection into rural reception areas, but not on the scale anticipated by many. Measles and chicken-pox were easily traced to their source in country districts, and Dr. Pickles suggested that in contradistinction to whooping-cough they need not occasion too much concern. Poliomyelitis he described as a seemingly insoluble problem of the future. Tuberculosis was the infectious disease of first importance; it should, with a view to control, have reserved for it their main resources and hospital beds.

Infection in the Hospital Ward

Dr. R. McL. TODD (Liverpool) discussed infection in the hospital ward. In his introduction he referred to reports on the subject published by the Medical Research Council (1944) and the British Paediatric Association (Watkins, 1949). Cross-infection was commonest in wards admitting infants of less than 12 months of age. Spread was by contact, droplet infection, or infected dust. Ideally every child admitted to a children's hospital should be isolated until proved non-infectious.

Dr. Todd outlined the procedures followed and the results obtained in 1949 in controlling infection at Alder Hey Hospital, which admitted infants and children up to the age of 15 years suffering from medical and surgical conditions, acute and long-term. Some wards were open: others were of the cubicle type. The average number of beds occupied was 586. In the open wards there were outbreaks of dysentery (61), measles (11), and chicken-pox (7). Medical wards in which Sonne dysentery developed were closed for all admissions until three negative rectal swabs had been obtained from all patients. When measles occurred all patients were given serum (if available), and until the end of the quarantine period only patients with a history of measles were admitted. In the cubicle wards some babies admitted for other symptoms developed diarrhoea and vomiting. The isolation of α and β coli proved a valuable indication of cross-infection. Instances were described of infection following intravenous infusions.

Summarizing, Dr. Todd gave the following as factors affecting the incidence of hospital infection and cross-infection: ward architecture; the standard and adequacy of nursing service throughout the 24 hours; methods of food preparation; aseptic technique; standards of toilet and hygiene; and ward cleaning procedures. There was reason to believe that vacuum cleaners used where floors were not oiled were as effective in reducing the spread of infection as the method of oiling floors and using sweeping brushes.

Infections in Nurseries

Dr. K. M. HIRST (London) continued the discussion with a contribution on infections in nurseries. She referred to the two principal groups of infections—respiratory catarrh and intestinal infection. The incidence of respiratory catarrh among children attending day nurseries was higher than that among children of comparable age not attending nurseries. Symptoms occurred at all ages but especially in children between the ages of 2 and 3 years. Spread of respiratory infection in nurseries could not be wholly prevented if the children were to lead a normal life. Little was known concerning the long-term significance of those minor respiratory conditions which might in any event be contracted during school life but which in nurseries developed earlier. There was a need for a follow-up of nursery children, and in particular of those children who had not stayed the course and had attended for only a short period.

Discussing intestinal infections, Dr. Hirst advocated the exclusion of young babies from nurseries because of the potential danger of enteritis. Food-poisoning was relatively uncommon. Many nurseries suffered from such disadvantages as lack of sink provision, a poor hot-water supply, inadequate draining and drying facilities, and domestic workers who required constant close supervision. For the washing of dishes and cutlery satisfactory results were obtained with the use of detergents followed by immersion in really hot water. The use of hypochlorites required care in the matter of "dosage." Sonne dysentery was the source of greatest trouble and was liable to involve the staff. Trial of chemoprophylaxis was justifiable where medical examination could be maintained and where laboratory services were available. The susceptibility of young members of staff entailed the close supervision of their general state of health. The risk of infection was such that it should be taken into consideration when nursery policy was being formulated.

A paper on infections in schools was given by Dr. J. C. RYLE (Shrewsbury). The conditions he described consisted of a group of specific infections, and a larger group of non-specific infections, including influenza and tonsillitis. Virus influenza had an average attack rate of 4% per term. Streptococcal infections had an attack rate of 6.4% and a high carrier rate. Influenza and streptococcal infections accounted for 40% of non-specific infections in school. Common colds accounted for 50%. The remaining 10% was generally diagnosed as P.U.O. and was composed of several entities which included abortive forms of virus diseases (glandular fever, poliomyelitis, and probably infective hepatitis), which played a small but important part.

Routine Preventive Measures

General discussion of the papers was opened by Dr. W. E. CROSBIE (Liverpool), who stressed two aspects of cross-infection in hospital—routine procedures to prevent spread of unrecognized infection and steps to control spread of manifest infection. Essentials of routine were adequate ventilation, avoidance of overcrowding, and medical examination on admission, with special attention to cases off the waiting-list. Manifest infection called for removal of the patient, search for carriers, and ascertainment (with immunization where applicable) of susceptibles. An appointment system reduced spread of infection. Administrative and medical staff should recognize the key importance of nursing staff. Dr. J. D. HAY (Liverpool) supported earlier views concerning the limited value of hypochlorites as sterilizing agents. Dr. G. SLOT (London) urged that sight be not lost of the social background to the subjects under discussion. Many children had no bed to themselves. He referred to the sense of false security arising from faulty mask technique in hospital. Considering visitation of patients, Professor CAPON asked for common-sense consideration of a child's human needs. Professor WILFRID GAISFORD (Manchester) gave the retention of babies with their mothers in lying-in wards as a method of reducing infection. He favoured the immunization at an early age of all infants against pertussis, and advocated sulphonamide therapy in appropriate daily doses in the winter as a form of prophylaxis against respiratory infection in infancy.

Dr. WILFRID SHELDON (London) spoke of his conviction that the incidence of infection was not increased where visitors to hospitals were allowed. He deprecated the unnecessary retention in hospital of healthy children, and urged that patients and relatives be educated into an understanding of higher hygienic standards. Accepting that a case might exist for day nurseries at the present time, Dr. Sheldon submitted that they should not be continued a day longer than absolutely necessary.

SECTION OF GERIATRICS

Friday, July 21

Hospital and General Practitioner

With Dr. MARJORY W. WARREN, a vice-president, in the chair, Dr. C. T. ANDREWS (Truro) opened the discussion on linkage between the hospital service and the general practitioner in the care of the aged sick. The problem of co-ordination was difficult, he said, because of the increase in the aged section of the population, the inadequate hospital accommodation, strain on the general practitioner, and various social problems. He showed that 41% of all hospital patients in Cornwall on a certain day were over 60 years old. Many old folk should be treated in their own homes rather than in hospital beds, which were over twice as costly to maintain as in 1939. Co-ordination between general practitioners and hospital was needed at three levels. First, in the geriatric unit and its long-stay annexe; secondly, at the cottage hospital, where doctors could care for their own aged patients with consultant advice; and, finally, by domiciliary consultations with the geriatric team, assisted by the district nurse and the home help. It was essential to bring together all the different social and medical agencies interested in the welfare of the old person. This could best be done at first on a voluntary basis.

Dr. VISCHER (Basle) described the post-mortem findings on 1,836 aged subjects from his hospital. Omitting cancer from his survey, he found that 99% of the cases had some degree of arteriosclerosis. This affected the aorta in 94%, the coronary arteries in 86%, and the circle of Willis in 71%. The main renal vessels were involved in fewer than half the subjects. Over a quarter showed myocardial fibrosis, and 9% died with coronary thrombosis. There was softening of the brain in 29% as a contributory factor. Emphysema grew more frequent with advancing years, but hypertrophy of the right ventricle in such cases was less marked as age increased. Gastric ulcers were more frequent than duodenal ones, but not related to age. Enlargement of the prostate, however, was commoner in older people than in those aged about 60. Pulmonary tuberculosis was not rare in the aged. The incidence of bronchopneumonia far outweighed that of any other pulmonary disease and was a frequent cause of death.

Dr. I. HARRIS (Bootle) spoke as a general practitioner. Formerly, he said, it had been quite easy to get an elderly patient into hospital. Now it was very difficult, as the gap left by removal of the relieving officer had never been filled. General practitioners had no contact with hospital management committees, and there seemed to be nobody whose duty it was to be responsible for hospital admissions. He advocated the creation of a senior geriatric medical officer at regional level. There should be more domiciliary consultations and mobile physiotherapy and mobile pathology services. The general practitioners were too busy to devote enough time to treating elderly patients and keeping them out of hospital. Pressure by relatives, need for laundry facilities, and so on tended to increase the calls for hospital admission of many aged persons who were sick.

Dr. A. FRANKLIN (Garston) contrasted the differences between urban and rural practice as regards the elderly patient. Difficulty over hospital admissions had begun in crowded town districts when the National Health Service had started. There were more idle, lonely, and unwanted old folk in the cities, while agricultural workers continued at their wonted work and play long after 65. More co-ordination of hospital services, consultants, district nurses, and welfare services was essential on the domiciliary front, and physiotherapy should be easily available. Only by early hospital treatment could the burden on the relatives of an old person be lessened.

Dr. E. L. ROBERTS (Formby) said there was a financial inducement for relatives to get aged people into hospital, and this also added to their reluctance to have them back again. More hostels were badly needed to ease the younger generation's plight of being tied to their houses. Otherwise hospital beds would be blocked by old people unable to return home.

Dr. K. B. GIBSON (Liverpool) thought that the general practitioner was now isolated from the hospitals, so that the profession was divided into two parts. Geriatrics must lead against this situation and bring doctors from hospitals out to meet the general practitioners in clinics and domiciliary visits. They should also take them into hospitals to help as clinical assistants and part-time medical officers to the great benefit of both parties. There was room for general practitioners here, since geriatric units did not recruit medical staff easily.

More Hostels Needed

At Fleetwood Road Hospital, Southport, in the afternoon, Dr. W. E. FITZ-GERALD, the medical officer of health, advocated a service for the elderly like that now existing for children. Remarking on the preponderance of women in the older section of the population, he mentioned the need for more ground-floor accommodation. Hostels were badly needed, preferably with a sick-bay provided. In Southport the district nurses spent half their time attending to old people, and admission to hospital was not easy. Hence efforts must begin in the home of the patient. After mentioning the local activities to help the aged sick, Dr. Fitz-Gerald urged the special allocation of hospital beds to meet the problem which had arisen.

Dr. P. Y. LYLE (Southport) likened the geriatric specialist to the general of an army. His headquarters were the geriatric unit; his weapons were the new methods of treatment and rehabilitation; his army was composed of general practitioners, nurses, home helps, welfare workers, and the relatives of the patient. Only by good staff work and deploying his forces to the best advantage could he successfully attack the troubles of old age.

After the welfare officer (Mr. Sinnert), a health visitor (Mrs. Brown), and a voluntary social worker (Mrs. Spilsbury) had described the work which they were doing in the town and its evident success, Dr. JEANIE F. WISHART spoke. She outlined the hospital arrangements for the local aged sick and the measures taken to select cases for admission to various units. Acute cases were taken at once to general hospitals to avoid delay in waiting for a bed. It was often difficult to get relatives to receive rehabilitated cases home again, and beds were blocked for lack of hostel accommodation suitable for frail ambulant patients.

SECTION OF NEUROLOGY

Friday, July 21

The Treatment of Parkinsonism

With Dr. S. P. MEADOWS, a vice-president, in the chair, Dr. HUGH GARLAND (Leeds) opened the session by saying that the Parkinsonian syndrome was first described by Parkinson in 1817, in the first account of paralysis agitans. This disease, a degenerative disorder, appeared most often in the presenium. Recent work had shown the importance of the genetic factor. Other causes for Parkinsonism were encephalitis lethargica, cerebral arteriosclerosis, neurosyphilis, and, occasionally, head injury, carbon-monoxide poisoning, and manganese poisoning. The syndrome had been reported as having appeared suddenly after an emotional shock. Dr. Garland outlined the many drugs used in the treatment of the syndrome, over the years, with little evidence of efficacy. He thought that "artane" was now the most popular. He considered the attitude of doctor and family to the patient to be of great importance. Deep *x*-ray therapy was useful in correcting sialorrhoea. Oculogyric crises, so troublesome in chronic Parkinsonism, appear sometimes to be influenced by environment, and Dr. Garland had obtained temporary good results by electric convulsion therapy.

Dr. G. E. SMYTH (Manchester) said that palliative drug treatment did not have a prolonged effect. He considered physiotherapy of the greatest importance in treatment, drug treatment coming second. He had found artane produced troublesome mental confusion in some cases.

Dr. DENIS LEIGH (London) stressed the need for objective tests and standards in assessing results of treatment. He described electromyographic and other experimental methods he had used for this purpose. He found it necessary, however, to come back to an assessment of the patient's subjective symptoms and changes. He considered artane the most effective of

the modern drugs. Dr. Leigh then spoke at length of the psychological strains and stresses of the patient with Parkinsonism in relation to his environment.

Doubts about Surgical Treatment

Sir GEOFFREY JEFFERSON (Manchester) discussed the recent attempts to relieve the tremor of Parkinsonism by surgery. He was doubtful of its value. The desiderata for operation were as follows: (1) the disease must be predominantly or wholly unilateral; (2) not, or very slowly, progressive; (3) the chief disturbance must be tremor; (4) the tremor must be so severe as to be disabling; and (5) patients must not be over 55 years.

These conditions, said Sir Geoffrey Jefferson, removed 95% of cases. The three operations at present used were, first, division of pyramidal tract on the affected side at C_2 level; secondly, ablation of cortical area 6; and, thirdly, division of the anterior limb of the internal capsule by a transventricular approach. Sir Geoffrey Jefferson found the high published mortality rate of the operations inexplicable. There was much evidence of a considerable risk of focal epilepsy after removing area 6. The published figures showed that after division of the pyramidal tract in 25% of cases there was a complete hemiplegia still present one year later. In one series of 55 cases of cordotomy there was reported worth-while relief in 15 cases. Sir Geoffrey Jefferson quoted Klemme's figures for the operation of removal of area 6. Out of 100 cases 17 died—too high a figure in the speaker's opinion—and relief of tremor was reported in 45. Myers had reported good results with his difficult operation of division of the internal capsule. Sir Geoffrey Jefferson deprecated the inaccurate publicity recently given to the treatment of Parkinsonism by surgery; he emphasized that there could be no surgical "cure" for this disease.

Sir HENRY COHEN (Liverpool) was surprised at the statements that sustained drug treatment was of no value in Parkinsonism. He had many patients benefiting from large doses of stramonium regularly administered. He emphasized the activity of the infection in many chronic post-encephalitic cases and felt that future antibiotic treatment might bring an advance.

SECTION OF OTO-RHINO-LARYNGOLOGY

Friday, July 21

Deafness in Children

With the president, Mr. I. SIMSON HALL (Edinburgh), in the chair, Mr. R. R. SIMPSON (Hull) opened the discussion on deafness in children. He said he proposed to deal only with deafness as it occurred in school-children. This was a problem which otologists should be able to solve, though, of course, they could not eliminate hereditary congenital deaf-mutism nor prevent the onset of otosclerosis in the older school-child. There remained the large problem of deafness in children due to Eustachian tube obstruction and to chronic otitis media.

It was not always easy for parents to realize that a child was deaf, and it was often the school-teacher who first suggested that the child's hearing should be examined. In this connexion the speaker regretted the change of status and importance under the new Health Service of the school clinic, for in his opinion a follow-up of suspected cases of deafness could not now be so effectively done as it was under the former school medical service. Before the war he and Dr. Ritchie Rodger, working in the school clinics in Hull, believed that they had largely eliminated chronic otitis media among the school population. The method adopted in Hull was worth recording. All the school children in the city were inspected by the school doctors, and if any ear disorder was discovered the child was referred to one of four well-equipped clinics for examination by an ear specialist. After this examination treatment was ordered or operation advised. The "follow-up" system was excellent, and no case was allowed to become chronic. Otorrhoea was quickly spotted in the schools and the child referred to one of the ear clinics. The condition quickly cleared up under treatment or after a mastoid operation. In this way the child's hearing was saved. After this scheme had worked for a year the number of cases of chronic otorrhoea among school-children was reduced by 66%.

Mr. Simpson said there were three causes of deafness due to Eustachian tube obstruction in children—adenoids, sinusitis, and nasal allergy. Here again the school medical service did invaluable service in the early recognition of these cases. In his opinion adenoids had not been satisfactorily removed in a case of deafness unless the fossa of Rosenmüller was palpated by the gloved finger. In deafness due to sinusitis he adopted a conservative outlook. Mr. Simpson said he was surprised at the relatively few children who were certifiable as "partially deaf." He had fitted such children with a Medresco hearing-aid, and they remained at an ordinary school. The children under 14 used their aids only in school, but those over 14 were allowed to have their aids at home; this was to try to ensure that reasonable care was taken of the aids.

Value of Hearing-aids

Mr. J. H. OTTY (Bradford) gave details of his experience in the fitting of children of school age with the Medresco hearing-aid. Some 50 children had been fitted with the aids. Their ages ranged from 5 to 14 years of age. There was universal agreement among parents and teachers about the very real benefit that followed from the use of an aid. All the children showed pleasure in using it. There was a brightening of the expression in many of the partially deaf, who heard without strain for the first time. Again, there was almost universal improvement in the individual voice production. The teachers' impressions were that the children were more ready to take an active part in class lessons, and their attention was more easily sustained for longer periods. It was important that the partially deaf children should be sought out early so that they might be fitted with aids. In many cases, by so doing, they should be able to continue in normal schools. Practically all cases were fitted with individually moulded inserts for the receivers, and there had been little difficulty with their retention. The children readily learnt to adjust the volume control of the instrument and were very sensitive to defects in the instrument or batteries.

Dr. T. S. LITTLER (London) said that the steps to be taken to ensure the maximum articulation efficiency in the use of a hearing-aid would be as follows: (1) The output of the hearing-aid should be arranged so that it was never likely to exceed the maximum comfortable intensity under the conditions of use. (2) The listening positions should be arranged so that there was a minimum amount of reverberant sound and noise—i.e., by the closest proximity to the teacher and by the disposition of acoustic absorbents to reduce the effect of multi-reflective sound paths. The floors of rooms should in addition be covered by soft surfaces to reduce shuffling and impact noises. (3) The acoustic amplification of the hearing-aids should be as free from peaky responses as possible, otherwise the tolerance range was likely to be seriously affected in cases of severe nerve deafness, and the range of steady speech was likely to exceed the normal 30 decibels.

It was most desirable that a child should have a course of instruction in the manipulation of the hearing-aid, so as to use it with the maximum efficiency. Since the alleviation of deafness by the use of a hearing-aid could never restore articulation to normal it was extremely important that the child should receive a good training in lip-reading; many speech sounds which were difficult to distinguish by hearing were among those which were easy to recognize by lip-reading. So far as the constructional side was concerned, the single unit, or monopack, hearing-aid was probably the most satisfactory for children. The disadvantages of extra running costs due to battery consumption were more than outweighed by the simplicity, extra comfort, and minimization of lead breakages. Wherever possible a moulded insert should be provided, and there should be periodical checks with the supply of a new insert whenever there was any indication of an acoustic leak, with the accompaniment of inferior response or likelihood of howling. It would appear that as the use of hearing-aids in normal schools became more widespread the importance of binaural listening, refinement of response, and other improvements would receive more attention. There should therefore

be a possibility that ultimately any intelligent partially deaf child should be able to take his place alongside his hearing fellows.

Importance of Early Ascertainment

In the ensuing discussion Mr. T. E. CAWTHORNE (London) said it had been noted that some 6% of school-children were hard of hearing in one or both ears, and it was probable that about ½% were permanently hard of hearing in both ears. It was of the utmost importance that any impairment of hearing should be discovered at the earliest possible moment—often no easy matter—so that appropriate remedial or educational measures could be quickly instituted. It was always sad to see a child whose mental development, education, and speech had all been retarded because of unsuspected deafness. It was gratifying to know that the Medresco aid had proved so helpful in children. Sometimes in very deaf children the use of an aid, though it might not help in comprehending speech, resulted in an improvement in the speaking voice. In this connexion it was of fundamental importance to ensure that a deaf child always understood the meaning of any word it was asked to try to repeat. Mr. J. E. G. MCGIBBON (Liverpool) said he had found deep *x* rays of some value in the prevention of recurrent attacks of otitis. He preferred *x* rays to radium from experience in the R.A.F. Mr. R. F. J. MARTIN (Liverpool) stressed the importance of Eustachian obstruction by adenoids as a major cause of deafness in children. The operative removal must be adequate, particularly from the fossae of Rosenmüller. No mention had been made of secretory deafness. He aspirated the viscous fluid from the tympanum in such cases by means of a short-bevel lumbar-puncture needle mounted on a special type of haemorrhoid syringe.

Mr. T. A. CLARKE (Canterbury) was disappointed to learn from Mr. Otty how small a percentage of children in deaf schools were fitted successfully with hearing-aids. In his experience a much larger percentage were helped. He was disappointed also to hear the opinion expressed that mental defect was common in addition to the hearing defect; this was contrary to the teaching long given by otologists. He thought that the necessarily slow tempo of education in special schools accounted for the difficulty in transferring such children, helped by hearing-aids, to ordinary schools. The Ministry of Health should make clear to the public that the supply of hearing-aids was inadequate, and that educational and employment requirements must be met first. The Association could do a very great service to the deaf—children and adults—by encouraging the training and employment of more lip-reading instructors. Colonel J. P. J. JENKINS (Pontypool) said that as a general practitioner he had found that the mothers would not bring their children regularly for treatment. They were not prepared to wait for hours in overcrowded surgeries for treatment lasting only a few minutes. Therefore facilities should be provided for treatment in centres equipped with a trained staff. Mr. G. A. MOULDEN (Birkenhead) was surprised at the omission to mention catarrhal otitis media with effusion as a cause of deafness in children. Hoople had recently made a plea for better teaching about this condition, stressing the difficulty of diagnosis by inspection alone. He (Mr. Moulden) would like to stress the value of tympanic aspiration; if the condition was left untreated or did not resolve spontaneously deafness developed.

Mr. J. C. MCFARLAND (Liverpool) had had disappointing results from irradiation. He found that otologists were asked to make very few domiciliary visits: it was surely important that cases of acute otitis media should be seen early, so that myringotomy should, if necessary, be done before chemotherapy was begun. Mr. I. SIMSON HALL asked if it was possible to decide by an audiogram whether a child should go to a special or an ordinary school. In Edinburgh every possible acute case was admitted to hospital. At least 91% were cured by conservative treatment inside 12 weeks, and of the residue 89% were then cured by simple operative measures.

Mr. SIMPSON, in reply, said that the answer to Colonel Jenkins's problem was efficient school treatment centres, and he thought the Ministry should re-establish them. In his estimate 1% of children referred for deafness in Hull were partially, and 0.1% totally, deaf. He agreed that for the partially deaf training in the use of an aid and return to a normal school produced much better speech in the child. He agreed with Mr. Clarke's figure of 25% fitted with aids, and said that even toddlers had been successfully fitted. Mr. OTTY, in reply, said he wished to stress the importance of lip-reading instruction. He thought that the old school medical service should be re-established by the hospitals. He had found the incidence of recurrent otitis to be reduced by irradiation. Dr. LITTLER, in reply, said that a hearing-aid should be fitted at as early an age as possible, provided no distress was caused. This could best be assured by keeping output at a low level. Two devices were being experimented with, known as "peak limiting" and "automatic volume control." These aimed at restricting speech reception to the tolerance range. The child should sit as near the teacher as possible, but screening devices should be avoided, as they tended to put the child in a special "compartment."

Correspondence

Infection by Syringes

SIR,—I was very glad to see the paper by Drs. R. J. Evans and E. T. C. Spooner (July 22, p. 185), pointing out the danger inherent in one of the common methods of mass inoculation. In your annotation on the subject (p. 204) you suggest two possible improvements, neither of which seems very good.

May I bring to your notice another method which is simple and effective? This is not a new method, for it has been used for half a century. Instead of changing the syringe and/or the needle for each inoculation, the same syringe and the same needle can be used throughout the series of inoculations. The syringe is sterilized immediately before each inoculation by four or five successive fillings and emptyings with liquid paraffin at 130° C. If a fine needle is being used through which the oil will not rapidly pass it is better to remove the needle and then sterilize the barrel of the syringe with the hot oil. The needle is then replaced and can be held in the hot oil for 15 to 30 seconds, or the hot oil can be drawn through and expelled several times.

If great speed of inoculation is desired two syringes can be used, and an assistant sterilizes one while the other is being used. Another advantage of this method is that the needles are always oily, so that they do not rust and remain sharp for a long time.

As I have said, the method is not new. It was devised by Sir Almroth Wright in the early days of this century and was used by him and his pupils (of whom I have the honour to be one) ever since as the standard method employed in the Inoculation Department of St. Mary's Hospital. In that one institution close on one million inoculations have been given with syringes sterilized by hot oil, and there have been no disasters. The method is described in Wright's book[1] on the technique of the teat and capillary glass tube, and more recently the merits of the method have been pointed out by K. B. Rogers.[2]

I have myself used this method of sterilizing syringes for inoculation since I entered Wright's laboratory in 1906, and I still use it. I cannot remember in that 44 years septic complications in any of the thousands of patients I have inoculated.

If it is desired to use a syringe containing many doses of the vaccine or toxoid I would suggest that this can still, with the aid of a hot-oil bath, be done safely and simply. Instead of removing the needle and thereby infecting the syringe, the needle is merely dipped into hot oil for about 10 seconds. The oil could for this purpose be at a higher temperature than could safely be used to sterilize Record syringes, and temperatures of 150° or 160° C. could be employed. The water in the needle would boil, and any pathogenic organism likely to have infected

the needle would be destroyed. At the same time the needle is oily, so that it goes through the skin more easily and remains sharp for a long time.—I am, etc.,

London, W.1. ALEXANDER FLEMING.

SIR,—I have read with great interest the article on this subject by Drs. R. J. Evans and E. T. C. Spooner (July 22, p. 185). By a curious coincidence I have recently referred to the same problem in an article in the *Medical Officer* (July 15, p. 29), the point there being prevention of the possible transference of the virus of poliomyelitis from one individual to another. Without then having the benefit of the experiences described by the above workers, I suggested the following: (1) Only the amount of material required for one injection should be drawn up into the syringe. (2) Obviously a sterile needle is used for each case. (3) After discharging the contents, the plunger should be kept pressed firmly home until the needle is withdrawn from the arm.

I was not apparently far wrong, with the exception of the possibility of fluid being sucked up the bore of the needle in the act of removal from the syringe, owing to the vacuum created when disconnecting the boss.

Here, then, is a further suggestion. Slightly more fluid is drawn up into the syringe than is required for the injection. The correct amount having been inoculated (when convenient subcutaneously, to avoid built-up pressure from muscular contraction) the syringe and needle are withdrawn and the remainder of the fluid is expelled through the needle before removal of the latter from the syringe for changing. I think that the syringe should have a plunger which fits perfectly, like the good old "agla" once supplied by Burroughs Wellcome and Co., and it should be slightly stiff in operation. Further, pressure of the thumb or palm of the hand should be maintained evenly on the plunger during removal of the needle from the arm. Most of the pitfalls should be covered by this procedure.

Short of sterilizing numerous syringes, which is difficult in mass immunization, this is the most watertight technique that I can envisage. I would be glad to hear what Drs. Evans and Spooner think of this as the best compromise.—I am, etc.,

London, S.E.5. GUY BOUSFIELD.

SIR,—I have read with considerable interest the paper by Drs. R. J. Evans and E. T. C. Spooner on this subject (July 22, p. 185), and noted that, though using a bacteriological method, they confirmed my findings which were published in the *British Medical Journal* in 1946.[1]

I continued my investigations and published the results in the *Journal of the Royal Army Medical Corps* in 1946.[2] This further work made it clear that the pumping action on removing a needle from a syringe was of considerable importance, particularly with the large "Army" fitting. I found that with a Record fitting contamination with red cells occurred in 14% of instances after an intramuscular injection, whereas with an "Army" fitting it occurred in 47% of instances. As Evans and Spooner, using a very sensitive bacteriological method, have found contamination of the syringe in 81% of injections with a Record fitting, presumably if the experiments were repeated using their method contamination with an "Army" fitting would be almost 100%.

Syringe contamination would certainly seem to be an important factor in the transmission of infective hepatitis and possibly other diseases during mass inoculation in the Forces. It would be a pity to discard the "Army" fitting on this account alone, as the larger joint is much more convenient than the Record fitting—the needle does not tend to slip from the syringe, and one can use a large aspirating needle on the syringe with a good deal more security. In my opinion the "Army" fitting would be mechanically more satisfactory than the Record fitting for general use.

I suggested a simple method by which contamination of the syringe could be avoided during an intramuscular injection. In brief, this consists in interposing a removable tap between the needle and the syringe; when the injection is given the tap is turned off, the needle withdrawn from the tissues, and the tap and the needle removed for sterilizing. A further tap and needle can then be applied to the syringe for the next injection. This method has the great advantage that the needle and tap can be rinsed and dropped in a boiling sterilizer, to be sterilized in the minimum of time, unlike syringes, which are liable to breakage by unskilled personnel. I carried out a series of 99 intramuscular injections using this technique, and on microscopical examination for red cells I was unable to detect contamination of the syringe in a single instance. It would be interesting if this work could be repeated using Evans and Spooner's bacteriological technique; if the safety of the method is confirmed I think it might well be adopted during mass inoculations. The taps could be mass produced at a comparatively small cost: only about half a dozen would be required for each operator.

Incidentally, the author of your annotation on syringe sterility in the same issue of the *Journal* (p. 204) scarcely does me justice when he states:

"Hughes concluded that the pressure produced, especially by a rapid injection into contracted muscle, may force a little fluid back into the nozzle of the syringe. No suggestion is offered in his paper that any other mechanism may be concerned."

I would draw his attention to the final paragraph of my paper, published in the *Journal* in 1946, which is as follows:

"The limited number of investigations carried out suggests that contamination occurs as follows. A small amount of fluid is forced back into the needle after the injection, or traces of blood are left on the tip of the needle when it is withdrawn; this blood tends to spread slowly along the needle, and on removing the latter from the syringe the needle contents are aspirated, leaving a contaminated drop of fluid on the tip of the syringe. This drop contaminates the next injection, despite the changing of the needle."

If he still doubts whether I mentioned the importance of aspiration of fluid from the needle when it is removed from the syringe, I would refer him to my paper in the *Journal of the Royal Army Medical Corps*.[2]—I am, etc.,

Liverpool. ROBERT HUGHES.

Haemorrhage from Peptic Ulcer

SIR,—The discrepancy between mortality figures in haematemesis and melaena given in the *Journal* of July 15 by Drs. C. D. Needham and J. A. McConachie (p. 133) from the Aberdeen Royal Infirmary and by Drs. A. G. Ogilvie and I. O. B. Spencer (p. 138) from the Royal Victoria Infirmary, Newcastle-upon-Tyne, is so great that a further comment on them may not be out of place. There will probably be general agreement with the statement of Needham and McConachie that their mortality rate of 13.9% for 476 cases corresponds to results obtained for a similar period in most general hospitals. The achievement of Avery Jones[1] (7.8% mortality in 615 cases) shows clearly how large is the room for improvement, but I submit that the very low mortality claim by Ogilvie and Spencer (2.4% in 170 cases) may be misleading.

To begin with, the total number with which these authors deal is relatively small—they work out at two patients per month, while general physicians in hospitals of comparable size where no restriction is placed on admission of such cases will often handle many times that number. This low turn-over suggests that only a small proportion of cases of haematemesis and melaena occurring in the populous area of Newcastle-upon-Tyne found their way into the Royal Victoria Infirmary, probably because of needs for teaching students. The figures given by Ogilvie and Spencer bear out the idea that such a selection was indeed made, because they show that only 16% of their patients were over 60 years of age, most of these between 60 and 70, whereas the records of Needham and McConachie, Avery Jones[1] from the Central Middlesex Hospital, and Baker[2] from the Selly Oak Hospital, Birmingham, dealt with about 30% of patients over 60, a heavy proportion of whom were over 70.

Without knowing what happened to the other patients with bleeding peptic ulcers in Newcastle-upon-Tyne, it is difficult to accept Ogilvie and Spencer's mortality figures at their face value.

On the larger issue, haemorrhage from peptic ulcers ceased some time ago to be solely the preoccupation of physicians, and now even the most conservative recognize that surgery has a place in the treatment of that emergency. Few will be found to subscribe to the idea that all, or even the majority of, cases of such haemorrhage should be operated on as a matter of course, and the balance of present-day opinion inclines to the view that there is a definite, though not very large, percentage of cases in whom operation would be a life-saving measure.

Most clinicians now feel that an emergency operation should be offered to some of the patients in whom severe haemorrhage recurs after admission to hospital. Obviously a number of such patients will not be fit for operation for a variety of reasons, while others may refuse surgical aid, and the crux of the matter is to balance in the remainder the probability of death without and with operation. The problem would be easy if only there were a way of divining whether bleeding comes from an opening in a sizeable artery, often eroded tangentially in the floor of a chronic ulcer, because it is then that an imminent threat to life exists. Few will disagree that in such instances an operation, preferably a partial gastrectomy, should be performed.

In the various series of cases of haematemesis and melaena recorded I have yet to find a reference to the type of patient who is admitted—sometimes shocked, sometimes in a fair condition—who in spite of recognized treatment continues to lose ground in a rather insidious way. The blood count of such patients goes on dropping to a level far below that for which haemodilution would account; frequently they do not vomit or pass melaena stools, and one must assume that in them continued seepage of blood into the bowel is taking place. I am sure others will recognize in that description a large group of cases whose place is between those who go all one way and give rise to little anxiety and, at the other extreme, those in whom a sharp recurrent haemorrhage gives clear warning of impending disaster. The patients in this middle group often benefit from blood transfusion, and with experienced management they will rarely need an operation.

This letter is not the place for giving an account of the routine treatment of haemorrhage from peptic ulcers adopted in the hospital at which I work—this has been done already by Baker in his report—but one of the points I insist on in my patients is the avoidance of any aperients or enemata in the first week after admission, or even longer if melaena continues. I have found from prolonged observation that, as in typhoid, constipated patients with haematemesis or melaena rarely die. I feel that injudicious stimulation of the bowel in a precariously balanced patient may start bleeding again. It is true that an occasional subject has to pay for my view with faecal impaction, but, while this may give rise to considerable discomfort, it can be relatively easily relieved and does not endanger life.

Finally, those charged with the care of patients suffering from haematemesis and melaena will agree with the views expressed in your leading article (p. 153) that there is a real need for further clinical studies of this serious and all too commonplace problem.—I am, etc.,

Birmingham. A. M. NUSSEY.

Abortion

SIR,—We should like to offer the following comments on the review of 2,665 cases of abortion by Mr. Albert Davis (July 15, p. 123). He suggests that the frequent finding of organisms such as *Staphylococcus albus* and diphtheroids is indicative of active infection.

In the former London County Council puerperal sepsis unit at the North-western Hospital, Hampstead, a strict bacteriological survey of all cases of post-abortal sepsis was carried out between 1937 and 1946, and the infecting organisms were classified as follows:

Infecting organism	Cases	Percentage
Haemolytic streptococcus	134*	13.9
Staphylococcus pyogenes	110	11.4
Bact. coli	239	24.8
Other aerobes	119	12.3
Cl. welchii	190	19.7
Anaerobic streptococci	125	12.9
Bact. pseudonecrophorum		
Negative cultures	48	5
Total cases	965	100

* 60 strains (45%) belonged to group A.

While a series of 50 consecutive cases of abortion are not strictly comparable with cases of definite sepsis, nevertheless we did not consider that the presence of organisms such as *Bact. coli, Cl. welchii*, anaerobic streptococci, or coagulase-negative staphylococci was always associated with clinical signs of infection, although putrefying products of conception may certainly encourage their proliferation.

The greatest difficulty in the bacteriological assessment of these cases is the determination of the pathogenicity and invasiveness of the various organisms found on cervical culture. The wide variation in the toxigenicity of *Cl. welchii* strains has been emphasized in a previous study.[1] Experience has shown also that the finding of coagulase-positive staphylococci on cervical culture carries with it a considerable chance of pyaemia, whereas coagulase-negative organisms can be disregarded.—We are, etc.,

SIR,—In his interesting report on abortion Mr. Albert Davis (July 15, p. 123) describes a method of causing the uterus to empty itself while the cervical canal is distended by a Hegar's dilator. Ten units of oxytocin are injected into the uterus. Since I have seen severe and prolonged circulatory collapse following the administration of ten or even five units of "pitocin," I am prompted to ask if the risk of this alarming complication is justified in order to achieve a more or less bloodless evacuation of the uterus.—I am, etc.,

Birmingham. HUGH C. MCLAREN.

D-tubocurarine Salts and Derivatives

SIR,—The letter from Drs. G. A. Mogey and J. W. Trevan (July 22, p. 216) rightly calls attention to the need for exercising caution in using derivatives of D-tubocurarine. The variation in the relative potencies of D-tubocurarine and its dimethyl ether from species to species is, as the writers point out, not surprising, nor indeed are the variations observed with different methods of testing and modes of administration; for it would be very unusual if a phenol and its methyl ether were absorbed and metabolized in precisely the same way.

The experiments carried out by Dr. H. O. J. Collier and Mr. R. A. Hall (June 3, p. 1293) were designed to show whether dimethyl tubocurarine differed in any important respect from D-tubocurarine. The results obtained with different species of animals were important because they indicated that the relative potencies of the two substances varied from species to species, suggesting that there might also be a difference in the relative potencies of the two substances in humans. Such a difference was in fact found, and was favourable to dimethyl tubocurarine, which, according to Drs. H. B. Wilson, H. E. Gordon, and A. W. Raffan (June 3, p. 1296) and Pelikan, Sadove, and Unna,[1] is two to two and a half times as potent as D-tubocurarine in humans. The pharmacological investigation showed furthermore that for equipotent doses in the cat less histamine was released by dimethyl tubocurarine than by D-tubocurarine and that there was less paralysis of the autonomic ganglia. Further, in the rabbit and the rat there was less paralysis of respiration by dimethyl tubocurarine than by

equipotent doses of D-tubocurarine. Far from being a more dangerous drug than D-tubocurarine, dimethyl tubocurarine clearly has several desirable properties not shared by D-tubocurarine.

The conclusion to be drawn from the results quoted by Drs. Mogey and Trevan is presumably that, whatever the methods used by research workers in evaluating a new drug, the potency and toxicity of any particular sample of that drug must be determined relative to that of a standard specimen of the substance, ideally a chemically pure specimen. This is of course the procedure followed with D-tubocurarine, every batch of which must be approved by the Ministry of Health following a direct comparison with a standard preparation of D-tubocurarine chloride kept in the National Institute for Medical Research. The reason is that D-tubocurarine is a "therapeutic substance the purity or potency of which cannot be adequately tested by chemical means'" and thus falls within the scope of the Therapeutic Substances Act, 1925, to which it was made subject by the Therapeutic Substances (Amendment) Regulations, 1948. Drs. Mogey and Trevan have indicated how difficult it is to prepare a chemically pure specimen of such a complex substance as D-tubocurarine, which may exist in a large number of different enantiomorphic forms. These considerations apply equally to dimethyl tubocurarine, although in preparing it from tubocurarine by methylation the number of enantiomorphs present would tend to be reduced and would certainly not be increased. In any event, no reputable manufacturer would attempt to prepare dimethyl tubocurarine iodide for clinical use by methylation of crude mother liquors.

Drs. Mogey and Trevan draw attention to the variations obtained by different workers in values for the ratio:

$$\frac{\text{potency of dimethyl tubocurarine salt}}{\text{potency of D-tubocurarine salt}}$$

Reference to Table I in the paper of Collier and Hall indicates that only two seriously aberrant values are found among the total of 19. One of these, the value of 5 in man, was obtained by Marsh, Sleeth, and Tucker[2] in a single volunteer, and it would be reasonable to discount it. The other, a figure of 8, obtained in the rat by Marsh and his colleagues, would appear to be anomalous. The rat appears to be the only animal in which such an anomaly has occurred. It so happens that in these laboratories the rat has been regularly used for assaying the potency of dimethyl tubocurarine since 1948. Results with consecutive samples have been very uniform in this animal, and nothing resembling the results of Marsh and his colleagues has come to light.

The fears expressed by Drs. Mogey and Trevan that different batches of dimethyl tubocurarine iodide may vary widely in potency and toxicity should be dispelled by the information that dimethyl tubocurarine iodide, like D-tubocurarine chloride, now falls within the scope of the Therapeutic Substances Act, 1925. The provisions applicable to this substance are contained in part III of the ninth schedule in the Regulations of 1948, and the licensing authority has tested and approved all the material recently made available to clinicians. Moreover, the potency of recent batches has been compared with that of a standard preparation of the dimethyl ether kept at the National Institute for Medical Research, so that the misgivings expressed by your correspondents have been anticipated and no clinician need feel that he is running unnecessary risk in using dimethyl tubocurarine in preference to D-tubocurarine.—I am, etc.,

Vascular Changes in Diabetes

SIR,—Dr. Elliott P. Joslin (May 13, p. 1095) demonstrates the formidable incidence of peripheral vascular disease in young diabetics, and Dr. Cecilia Shiskin (June 24, p. 1490) and Dr. R. D. Lawrence (July 8, p. 107) consider the possibility (I like to think probability) of a common factor causing both diabetes and vascular damage; this awaits further research, but there is another aspect on which I should like to invite opinion. Vascular disease is believed to be a degenerative process which affects diabetics and non-diabetics; in the former there is a heavier incidence and earlier onset. May this be due to malnutrition of the peripheral tissues, including the vascular system? Perhaps this factor makes gangrene of the toes so much more common in diabetics than in non-diabetics with arteriosclerosis. The diabetes is usually mild and stable in these cases, the blood sugar being easily kept within orthodox limits with small doses of insulin, yet gangrene, superficial or deep, develops in one toe after another. Dr. Lawrence points out that no diabetic has a normal sugar metabolism. Certainly the injection of insulin, which is absorbed into the blood stream regardless of the prevailing glucose level, is a clumsy substitute for the delicate mechanism by which it is secreted normally in response to a rise in the blood sugar. It seems possible that injected insulin needs a greater "head" of sugar in the blood than that found in the normal person in order to carry out the anabolic process of promoting the storage and utilization of glucose.

The fear that a persistent high blood sugar is harmful has overshadowed our thought and practice; I suggest that it is not the high blood sugar *per se* which brings disaster to the untreated diabetic, but rather starvation in its widest sense. Two observations illustrate my point. First the dramatic improvement in the general health, strength, and weight of a diabetic as soon as he begins insulin and long before the blood sugar levels become normal; and secondly an observation on the nutrition of the muscles. The diabetic before he begins insulin experiences an aching and weakness of the great muscles of the thighs—e.g., on going upstairs. The diabetic on insulin develops exactly the same weakness and aching if, for example, in the course of a long walk hypoglycaemia develops. In both cases the sugar metabolism is at fault and the muscles are deprived of fuel.

Dr. Joslin's observation that on the whole the better controlled patients resist longer the onset of vascular complications is not incompatible with this suggestion, since the badly controlled probably have insufficient insulin for their metabolic needs; but the fortunate few, who escape vascular complications after more than 20 years, are by no means those who adhere to a strict regime, weighing their food and testing their urine, but often lead a full free life, taking exercise, food, anxiety, and hard work as it comes.

The practical application is to endorse and underline the doctrine that a persistently low blood sugar is more dangerous to diabetics than a persistently high one. Should we set the optimum in routine blood sugar estimations, four hours after meals, at a higher level than that of a normal person—perhaps at above the renal threshold of 180 mg. per 100 ml. ?—I am, etc.,

Hove, 3. G. M. WAUCHOPE.

Rectal Thiopentone in Children

SIR,—On reading Dr. John Lorber's article on this subject (July 1, p. 21), I was struck by his omission to lay sufficient stress on the potential hazards of this method. The technique described is so simple that physicians using it for diagnostic procedures may be tempted to employ this method where no trained anaesthetist is available or present. Such a course should under no circumstances be contemplated, as considerable respiratory depression may ensue from the dosage the author recommends, and as there is no evidence that the drug given by the rectal route will be less liable to predispose to laryngospasm than when given intravenously.

In that connexion I also notice that Dr. Lorber fails to mention a laryngoscope and endotracheal tubes as accessories which should be available whenever thiopentone is being given by whatever route. Indeed, it appears likely that the patient who had "severe spasm of coughing and temporary cyanosis" may have suffered from a mild attack of laryngospasm, which fortunately resolved spontaneously. Atropine is by no means infallible in preventing such an occurrence, although it will markedly lessen the vagal hypersensitivity induced by thiopentone.

This and the other case of aspiration of vomitus constitute 3% of the whole series, and any one of these two cases may have had serious consequences. Thus one cannot fail to wonder whether the risk involved is not too high a price to pay in order to obtain sedation for diagnostic procedures.—I am, etc.,

University of Illinois, Chicago, U.S.A. GORDON M. WYANT.

Intermittent Dosage with Streptomycin

SIR,—I have read with interest the article "Intermittent Dosage in the Treatment of Pulmonary Tuberculosis with Streptomycin" (May 27, p. 1224) and also the leading article entitled "Streptomycin Resistance of Tubercle Bacilli" (p. 1245).

Reports of this kind ably presented by the Medical Research Council are eagerly awaited and usually put into effect in this country. In view of this I would like to draw attention to a principal finding in the above article—"It is concluded that one gramme of streptomycin a day in a single injection, without intermission of treatment, is the most satisfactory way of giving the drug in pulmonary tuberculosis." The continued existence of a streptomycin-resistant organism depends on possibly two factors—an inherent and an acquired or environmental factor, which latter is dependent on a low peak concentration of streptomycin. The four dosage groups employed in this case in an attempt to avoid or delay the emergence of predominantly streptomycin-resistant tubercle bacilli in the treatment of the disease have been all of relatively bacteriostatic, not bactericidal, regimes. The use of a higher single dosage of streptomycin given twice weekly and its bactericidal effect on the life cycles of the tubercle bacilli and their mutants have not, in this case, been considered.

The coexistent use with streptomycin of a synergistic drug such as P.A.S. to prevent the formation of streptomycin-resistant mutants is plausible, but it seems that a fundamental factor is being ignored when the dosage of streptomycin given does not prevent, indeed is conducive to, the formation of a streptomycin-resistant from a previously streptomycin-sensitive tuberculous organism, irrespective of its inherent property.—I am, etc.,

Adelaide, South Australia. R. MUNRO FORD.

Domiciliary Treatment of Tuberculosis

SIR,—Under the subheading "Doctors' Ignorance," in the account of the meeting of the Sections of Diseases of the Chest and Tuberculosis and of Preventive Medicine at the Annual Meeting of the B.M.A. in Liverpool, Dr. W. D. Gray is reported in the *Liverpool Echo* (July 20) as having expressed the following opinion: "There is a deplorable ignorance among general practitioners about the first principles of treatment in tuberculosis."

We feel that Dr. Gray should seek the hospitality of your columns to substantiate or withdraw this serious charge, which, to our knowledge, has already caused considerable concern among patients.—We are, etc.,

R. FITZGERALD, P. T. GARRY,
M. J. O'DONNELL, T. A. JERMY,
T. A. G. HUDSON, JAMES BINNIE,
C. A. L. KELLY, E. V. O'RIORDAN,
T. J. COAKLEY, J. V. COGHLAN.

∴ A letter from Dr. W. D. Gray is published below.—ED., *B.M.J.*

SIR,—In my address to the Sections of Diseases of the Chest and Tuberculosis and of Preventive Medicine at the Annual Meeting of the B.M.A. in Liverpool I complained of the ignorance about principles of treatment of tuberculosis shown by some general practitioners. This I attributed to faulty education in our medical schools, where many students are trained without ever entering a sanatorium or chest clinic for instruction. My charge was that some general practitioners do not seem to realize that it is more important for the tuberculous case to rest in bed while awaiting admission to sanatorium than it is for him to seek fresh air by walking in the park. I complained that some doctors told the patients to go out, when I had told them to stay in bed. I also referred to some general practitioners prescribing streptomycin and P.A.S. indiscriminately, without consulting the tuberculosis officer or chest physician. This was also mentioned by Professor F. R. G. Heaf.

The press excerpt from my address did not report that I said: "There are many general practitioners with whom it is a pleasure to work, however, and they make the care of the tuberculous at home much easier for the clinic physician. Close co-operation is essential for success." I fully realize the difficulties of the busy general practitioner in any industrial city, and my aim in mentioning these points was solely to stress the need of closer co-operation between specialist and general practitioner in the home treatment of the tuberculous.—I am, etc.,

Liverpool. WILLIAM D. GRAY.

Stevens–Johnson Syndrome

SIR,—In view of the recent paper by Dr. Bernard A. Thomas on this subject (June 17, p. 1393), the following case may be of interest.

A married woman aged 31 years came to the surgery on May 20 complaining of the sixth attack of a condition which appeared as blistering of the lower lip and hands and intense itching of the eyes and vulva. She stated that she had been exceptionally healthy until February, 1949, when she had her first attack, which was sudden in onset. The attacks invariably started with an eruption on her lip, which symptom was the last to disappear after the attack had subsided. The blisters on her hands appeared two or three days after the lip eruption. This was the first time in which the eyes or genitals were affected.

Her temperature was normal. There was slight injection of the conjunctiva, one fairly large bulla on the lower lip, and several smaller blisters on the inside of the lower lip. The dorsum of the hands was covered with small clear blisters. The palms and palmar aspect of the fingers were covered with closely set erythema iris macules, which did not subsequently progress to bulla formation. There were a few scattered macules on either forearm which did not form bullae. Desquamation took place in from 10 to 14 days. The blood Wassermann reaction was negative. There was mild secondary anaemia. The urine was normal. Fluid from the blisters yielded no organisms. No history of allergy or susceptibility to sulphonamides or other drugs could be elicited.

This appears to be a mild case of erythema exudativum multiforme (Hebra). A point about it seems to be that the attacks are increasing in severity gradually, since this is the first time in which the conjunctivae were involved even mildly. The normal temperature is also unusual.—I am, etc.,

Tullow, Co. Carlow. J. B. MAHER.

R.A.M.C. Roll of Honour

SIR,—May I crave the hospitality of your columns to inform your readers that the Roll of Honour of all ranks of the R.A.M.C. who gave their lives during the Second World War (September 3, 1939–May 8, 1946) is now complete, and copies have been sent to all the next-of-kin with whom we have been able to get into touch. I shall be glad to send a copy to any who, owing to a change of address or other cause, may not have received the original notice. Application should be made to me at R.A.M.C. War Memorial Fund, 34, Victoria Street, S.W.1.

The Roll is included in an illustrated booklet describing our Book of Remembrance, the Memorial Window, and other Corps Memorials in Westminster Abbey and its precincts, and will be sent to any of your readers who are kind enough to send a donation to our fund, which is devoted to helping all ranks of the R.A.M.C. who took part in the war, and their families.—I am, etc.,

London, S.W.1. R. E. BARNSLEY,
Major-General.

Obituary

IVOR I. PRICE, M.B., F.R.C.S.

Mr. I. I. Price, senior consultant surgeon to the Whittington Hospital, London, died on July 24, 1950, at the age of 46.

Ivor Isaac Price was educated at Daventry Foundation School and entered King's College Hospital Medical School in 1920. He had a most distinguished student career and won many awards, among them the Alfred Hughes Memorial Prize and the Senior Scholarship. He took the conjoint diploma in 1925 and graduated M.B., B.S. in 1926. After holding resident appointments at King's College Hospital and Queen Mary's Hospital for the East End he was appointed medical superintendent at the Seamen's Hospital, Tilbury. He became a Fellow of the Royal College of Surgeons in 1928, and in 1929 he entered the London municipal hospital service, where his outstanding surgical skill and judgment brought him rapid advancement. He served in several surgical posts in L.C.C. hospitals, and in 1938 was appointed senior resident surgeon and deputy medical superintendent at St. Mary Islington Hospital. Here he soon built up a reputation as an able general surgeon, widely respected by the general practitioners of the district and by the large numbers of patients who had reason to be grateful for his skill and kindness. His experience covered almost every field of surgery, and he published papers on several subjects in this *Journal* and elsewhere, but he developed a special interest in gastro-enterology.

In the L.C.C. hospital service he was one of the pioneers of gastroscopy, at which he became highly skilled. As an operator he was quick, yet gentle and meticulous, and he had special success with patients whom many would regard as poor operative risks. He was a scrupulously conscientious surgeon, avid for work, and was seen at his best in his handling of the patient with post-operative complications. Those who worked with him will always be grateful for the way in which he rallied to their support when problems arose, and he was especially beloved by the nursing staff. He was an accomplished clinical teacher, and many candidates for the F.R.C.S. examination will remember the bedside classes which he so ably conducted for the Fellowship of Postgraduate Medicine.

In 1947 Mr. Price was appointed surgeon specialist by the London County Council. Unhappily it was about this time that he suffered the first symptoms of heart disease, and in the following year he had two attacks of coronary thrombosis. He returned to duty early in 1949 and took up his operative work again. With the reorganization of his hospital under the National Health Service and its amalgamation with the two adjacent hospitals to form the Whittington Hospital, he became surgical director of the newly established gastro-enterological unit. Despite recurrent anginal attacks he was courageously taking an increasingly heavy share of the arduous surgical work of this unit, when he suffered his third and fatal attack of coronary thrombosis. Though his determination to return to active surgical work probably shortened his life, all who knew him will realize how characteristic was his decision to carry on to the end. He leaves a widow and one young son.—A. L. J.

Sir JOHN HUTSON died at his home in Pine Hills, Barbados, British West Indies, on March 29 at the age of 91. The son of the late Archdeacon Hutson, he was one of three brothers, each of whom held distinguished positions in the Colonial Empire. His eldest brother, Sir A. Hutson, was a Colonial Governor, while his other brother was Bishop of Antigua and Archbishop of the West Indies. John Hutson was educated at Lodge School, Codrington College, and Edinburgh University, where he graduated M.B., C.M. in 1883. He took the Cambridge D.P.H. in 1905. Returning to Barbados, he joined the staff of the General Hospital there, and he served as public health inspector and poor law inspector for a time. Subsequently he was appointed chief medical officer when that office was created. He was appointed a member of the Legislative Council in 1920, and served on the Education Board and on the Executive Committee. He represented Barbados at the coronation of King George VI, and until he resigned the presidency of the Legislative Council he was chairman of the local branch of the Empire Parliamentary Association. Sir John Hutson, who was knighted in 1943, had been a member of the British Medical Association for over sixty years, and he represented the Branch at the annual meetings at Portsmouth in 1923 and at Eastbourne in 1931. He was president of the Barbados Branch in 1929–30 and then from 1932 to 1938. He was one of the Branch's keenest and most hard-working members, and the sympathy of all his colleagues and friends will be extended to Lady Hutson, who survives him.—A. P. M.

Medico-Legal

TRESPASS AND ASSAULT

A recent report in these columns entitled "Trespass by a House-surgeon" (July 15, p. 171) has prompted the council of the Medical Defence Union to remind practitioners again of the need to obtain proper consent in writing from patients or their relatives when any operative treatment is recommended.

This case has emphasized another point. It is also essential to make it clear that, when a patient is admitted to hospital for operative treatment, the operation proposed will not necessarily be performed by any particular surgeon, who may have seen the patient previously, or under whose name he is admitted.

So that practitioners will be provided with adequate legal authority and protection to avoid the risk of their subsequent appearance in the Courts on a charge of trespass or assault, the council of the M.D.U. has had prepared a number of model forms. These forms of consent, reproduced below, are considered appropriate by the solicitors to the M.D.U.

Consent by Patient

I ..... of .....
hereby consent to undergo the operation of .....
the effect and nature of which have been explained to me.

I also consent to such further or alternative operative measures as may be found to be necessary during the course of such operation and to the administration of a local or other anaesthetic for the purpose of the same.

I understand an assurance has not been given that the operation will be performed by a particular surgeon.

Dated this ..... day of .....

(Signed)

Consent by Relatives

I ..... of .....
the ..... of the above named .....hereby also consent to such operation.

Dated this ..... day of .....

(Signed)

(The formula of consent by the spouse or near relative, although not strictly necessary in law, may save trouble afterwards.)

Consent for Minor

I ..... of .....
hereby consent to the submission of my child .....
to the operation of ..... the effect and nature of which have been explained to me.

I also *consent* to such further or alternative operative measures as may be found to be necessary during the course of such operation and to the administration of a local or other anaesthetic for the purpose of the same.

I understand that an assurance has not been given that the operation will be performed by a particular surgeon.

Dated this ..... day of .....

(Signed)

Consent for E.C.T.

I ..... of .....
hereby consent to the administration of convulsive therapy, the effect and nature of which have been explained to me. Notwithstanding the fact that there are certain risks of injury inherent in the treatment, I request you to administer the same to me and I accept any risk attaching to such administration.

I understand that an assurance has not been given that the treatment will be administered by a particular practitioner.

Dated this ..... day of .....

(Signed)

Medical Notes in Parliament

ROYAL ASSENT TO THE MEDICAL BILL

The Medical Bill became an Act of Parliament on July 28. The amendments made in its passage through the House of Commons were agreed to by the House of Lords on July 26, and on the 28th, the day Parliament rose for the summer recess, the Royal Assent was signified to it and a number of other Acts by commission.

Tuberculosis in Scotland

MRS. JEAN MANN asked the Secretary of State for Scotland on July 25 what consideration he had given to the report of the Scottish Committee on Tuberculosis Service in Scotland; and if he would make a statement on the recommendation of crisis expansion of tuberculosis service.

Miss HERBISON, the Under-Secretary, replied that with his officers the Secretary of State had been studying carefully this report, but had found in it no recommendation for the expansion of facilities which had not already been considered, while most of the recommendations had been tried with varying degrees of success. In the last two years more than 300 additional beds had been brought into use for respiratory tuberculosis, many of them in infectious-diseases and general hospitals: This process he proposed to continue, especially in general hospitals where nursing staffs were strongest.

Mrs. MANN said that not all the recommendations published in the *British Medical Journal* [of July 8] had been tried—notably the ones that beds in infectious-diseases hospitals should be used, and that patients should have treatment in their own homes.

Miss HERBISON said that was quite wrong. Already, as she had pointed out, there were 300 beds, most of them coming from infectious-diseases hospitals; and certain steps in the direction of domiciliary treatment had been taken in the auxiliary services.

Sir DAVID ROBERTSON said there were only 10 beds for tuberculosis patients in the county of Caithness, and a large number of sufferers were walking about in great danger for whom accommodation could be found.

Mr. ELLIOT asked if recent figures showed a rise or fall in the trend of notifications, and if the number of deaths—which was recently notable—continued, or was it slacking off.

Miss HERBISON said the number of notifications for the whole of Scotland had gone down slightly. In the number of deaths in the 16 principal towns in Scotland there had been about a 20% decrease during the last year.

Dr. CHARLES HILL pointed out that there were 1,000 beds available in Switzerland for the treatment of tuberculosis, and suggested the restoration of the scheme by which public money was made available to enable persons to obtain treatment in Switzerland.

Mr. JOHN HYND said the question whether Swiss treatment was suitable for all these cases should be seriously considered before the taxpayer was involved in any considerable expenditure.

Mr. ELLIOT said it was a case of relieving the overloaded bed system in this country.

Miss HERBISON said that she could give no information on the subject of Swiss sanatoria.

Replying to Mr. CARMICHAEL, Miss HERBISON stated that Glasgow's waiting-list of tuberculosis patients at June 30 this year showed an improvement of 205 compared with last year.

Treatment in Switzerland

Miss WARD asked the Minister of Health on July 27 whether, in view of a recent decision to accommodate tuberculous patients in general hospitals, he would introduce legislation to enable him to subsidize tuberculous patients recommended by local authorities for treatment in Switzerland. Lord MALCOLM DOUGLAS-HAMILTON also asked the Minister whether, in view of the increase in pulmonary tuberculosis in Great Britain, he would take steps to provide funds to enable tuberculosis patients in the lower income groups to undergo sanatorium treatment in Switzerland, as was at present done by Holland, and as was formerly done by our own local authorities prior to 1939.

Mr. BEVAN said that he could not undertake in present circumstances to add to the cost of the Health Service as proposed; but he had recommended to hospital authorities action for making the best use of their own resources.

Empty Beds

Mr. MARPLES asked how many beds which were suitable for tuberculous patients were empty; and how many could be used if there were staff available.

Mr. BEVAN said that hospital returns at December 31 last showed that approximately 5,000 such beds had been unoccupied on that date, of which about 4,000 stood closed for lack of staff.

Chest Physicians' Contracts

Mr. KABERRY asked the Minister of Health on July 27 why the Leeds Regional Hospital Board continued to delay the presentation of contracts to chest physicians within that region; why the board could not now define the point of entry to the salary scale proposed by the board for each chest physician within that region, and pay forthwith all arrears of salary from July 5, 1948.

Mr. BEVAN said that action by the board must await settlement of the general question of the basis of employment of these officers, which was under discussion with the local authority associations and the medical profession.

Sanitary-Inspector Students

Mr. KING asked the Minister of Health on July 27 if he was aware that ex-Service students recruited into and educated for sanitary inspectorship under his department's health training scheme were finding it difficult to obtain employment in their profession; and what steps he proposed to see that they were absorbed into the profession.

Mr. BEVAN said he was aware that some students had not found immediate employment. Appointments of sanitary inspectors were made by local authorities. He was accordingly in no position to ensure the employment as such of any person. Employing authorities must advertise vacancies, and he was sure they might be relied on to give due consideration to applications from ex-Service men.

Mental Officers' Retirement

Mr. RANKIN asked the Secretary of State for Scotland on July 25 if he would state the reasons for the decision of the Western Regional Board to enforce the retirement of all officers in their asylums and mental institutions who had reached the age of 60 years.

Miss HERBISON, the Under-Secretary, replied that she was informed by the Western Regional Hospital Board that they had taken no such decision, and that in fact many mental health officers over the age of 60 were employed in the region.

Doctors' Prescription

Mr. DRIBERG asked the Minister of Health on July 27 if he would investigate the circumstances in which a general practitioner, of whose identity he had been informed, had been notified that he should not have prescribed charcoal biscuits for a patient and that the cost of this medicament was to be deducted from his remuneration; and if he would make a statement.

Mr. BEVAN said the regulations provided a proper procedure for determining whether doubtful substances were drugs in the circumstances of a particular case and for the recovery from the general practitioner of the cost of any substances prescribed which were not drugs. Charcoal biscuits were normally regarded as food, and as such should not be prescribed at the cost of the National Health Service.

Mr. GEOFFREY COOPER asked the Minister of Health on July 28 whether, having regard to the views of the Cohen Committee on Prescribing that preparations advertised direct to the public should not be prescribed under the National Health Service, he would assist doctors by providing them with a list of equivalent preparations; and if he would forbid the use of such advertised proprietary medicines under the Service.

Mr. BEVAN said a list of official counterparts of proprietary preparations was given in the *National Formulary*. Doctors had already been asked not to order proprietary preparations where the alternative standard drug could be ordered without detriment to the patient's condition.

Bone Induction Hearing-aids

Mr. LESLIE HALE asked the Minister of Health on July 27 on what date it was proposed that a bone induction hearing-aid would be available for distribution under the provisions of the National Health Service.

Mr. BEVAN said that trials of a modified aid were now being arranged, but it was too early to say when supplies would be available generally.

Suture Needles

Lady TWEEDSMUIR asked the Minister of Health on July 27 whether, in view of the acute shortage of surgical suture needles in Aberdeen, Edinburgh, and Glasgow, he would assist manufacturers to increase supplies as a matter of urgency.

Mr. BLENKINSOP, the Parliamentary Secretary, said the Minister had been taking steps to assist the manufacturers to increase supplies.

Surgical Appliance Contracts

Mr. OSBORNE asked the Minister of Pensions on July 25 if he would permit pensioners to purchase surgical boots from any supplier provided they were prepared to pay the extra cost of better-quality boots; and if he would make a statement on the conference about this subject recently held at Blackpool with representatives of the Surgical Instrument Makers' Association.

Mr. MARQUAND said the surgical boots supplied by his Department were made from best-quality materials requiring a high standard of workmanship. He was satisfied that the requirements of war pensioners were fully safeguarded by the terms of the manufacturers' contracts and by technical inspection. His Department had made contracts for the supply of surgical boots and appliances with 713 firms throughout the country at prices which were considered by them reasonable and fair. A minority of contractors had refused the terms offered by his Department, but he hoped that they would reopen negotiations. He was not prepared to enter into contracts at excessive prices.

Lieutenant-Colonel KINGSMILL asked the Minister of Pensions how many contracts to date for the year 1951 had been placed for surgical boots and appliances with the co-operative societies; and how many through the Surgical Instrument Manufacturers' Association.

Mr. MARQUAND said that for the year 1950–1 contracts had so far been placed with 36 co-operative societies. He had not a complete list of members of the Surgical Instrument Manufacturers' Association, but, of 94 members who were known to be suppliers of surgical boots and appliances, contracts had been placed with 55 and negotiations were proceeding with 18 others.

Smallpox

Mr. VIANT asked the Minister of Health on July 24 what was the definition of a smallpox-infected country; and whether any part of Great Britain was smallpox-infected at the present time.

Mr. BEVAN said the International Sanitary Conventions did not define a smallpox-infected country. No part of Great Britain was infected at the present time.

Lingfield Epileptic Colony

Brigadier MACKESON asked the Minister of Health on July 27 if he would make a statement on the death of Winton Hogben at Lingfield Epileptic Colony, and if he had taken steps to ensure that supervision had been improved.

Mr. BEVAN replied that he had no jurisdiction over this voluntary institution, but he understood that the medical superintendent felt there had been inadequate supervision of this patient and had strengthened the rules governing supervision of patients in bathrooms.

R.A.M.C. Pay and Conditions

Major NIALL MACPHERSON asked the Secretary of State for War on July 27 what was the present deficiency of regular commissioned specialists in all branches of medicine and surgery on the basis of existing establishment of the Royal Army Medical Corps; to what extent the deficiency was being made up by civilian specialists; and what steps he was taking to overcome the shortage of regular specialists at an early date; and also what was the present deficiency of permanent and short-service regular qualified doctors in the Royal Army Medical Corps on the basis of present establishment; and what was the total deficiency after taking into account National Service doctors; and what steps he was taking to overcome the shortage.

Mr. STRACHEY said that the deficiency of regular, including regular short-service, doctors was 381. This figure included 13 specialists. Taking into account National Service doctors the total deficiency was 265, which included 115 specialists. With a view to overcoming these shortages an examination of the rates of pay of doctors and specialists was being carried out. Sixty-six civilian medical practitioners and 10 civilian specialists had been employed, and 49 medical officers, including 12 specialists, had been given type "B" commissions for one or two years or had been granted special deferments. Conditions for short-service commissions for women doctors would shortly be promulgated, and proposals were now under discussion for reopening short-service commissions for specialists which were calculated to attract highly qualified doctors from civil life.

Major MACPHERSON asked if the Secretary of State for War would now bring the emoluments of qualified doctors and specialists serving on regular commissions in the R.A.M.C into line with those applying under the National Health Service.

Mr. STRACHEY said the rates of pay of medical officers and specialists in the R.A.M.C. were now being examined. Account would be taken of the average earnings of doctors under the National Health Service.

Major MACPHERSON further asked what was the present scale of pay and allowances offered to specialists attached to the R.A.M.C. in a civilian capacity, for home and overseas service respectively.

Mr. STRACHEY replied that civilian specialists serving at home were paid £1,300 or £1,600 a year according to experience and qualifications. Abroad they were paid £1,800 or £2,200 a year and received an outfit allowance and a local allowance varying from £25 to £425 a year according to the station and whether they were married or single. These allowances were common to all Civil Servants of comparable grades. Free sing

accommodation and, in certain stations, free messing were also provided.

Employment of German Doctors

Mr. SORENSEN asked the Secretary of State for the Colonies on July 26 why medical practitioners with German qualifications were allowed to practise in Tanganyika and the Cameroons but not in the Gold Coast, Nigeria, and other Colonies; and, in view of the great need of doctors in all the Colonies not being likely to be met for a long time, whether he would take action to secure the fuller services of German medical practitioners, dentists, and similar professional men.

Mr. GRIFFITHS said there were no special rules about German qualifications as such. In most Colonial territories doctors from outside who wished to practise were required by law to have qualifications recognized by the General Medical Council in the United Kingdom. The law in the former mandated territories, however, gave the local authorities discretion to register practitioners with other qualifications. The recruitment of foreigners for the Government medical services in the Colonies was obviously not free from difficulty, but in fact a number of foreign doctors and dentists had been appointed during the last two or three years. Most of them had obtained British registration.

Pneumoconiosis

Mr. PATON asked the Minister of National Insurance on July 25 if she proposed to amend the relevant regulations to bring within the scope of the Industrial Injuries Act all foundry workers who suffered from a pneumoconiotic condition as a result of being engaged in any process in or around a foundry.

Dr. EDITH SUMMERSKILL said pneumoconiosis was already prescribed in respect of a number of foundry processes where medical evidence indicated there was a risk of contracting the disease, and she was not considering an extension of the scope of the regulations.

Mr. PATON said there was a great deal of evidence of the spread of pneumoconiosis and silicosis in processes other than those prescribed by the regulations. Would it not be simpler and more just if, instead of having to prescribe processes, the basis for eligibility were to be made the existence of the disease in a foundry worker.

Dr. SUMMERSKILL said she was prepared to examine that.

Mr. AWBERY asked what procedure was adopted before a disease was regarded as an industrial disease and was liable to be brought under the Industrial Injuries Act.

Dr. SUMMERSKILL said they had to have convincing medical evidence before it could be attributed to the process.

Whiter Bread

Mr. WEBB, Minister of Food, announced in reply to questions by Wing Commander BULLUS and Dr. STROSS on July 24 that it had been decided to reduce to 80% the extraction rate of flour used for the national loaf. This would be made up of home-milled national flour with a rate of 81%, and a proportion of imported flour with a lower rate. This change, which would take effect on Sunday, August 27, would enable the public to get a whiter and more generally acceptable loaf while still meeting the standards recommended by the Post-War Loaf Conference. It would also add to the quality and quantity of supplies of animal feeding-stuffs.

Dr. STROSS said the 85% extraction rate, together with the high consumption of liquid milk, was responsible in the main for the continuously improving conditions in the health of the nation, and asked the Minister to state now that he did not contemplate any further degradation of that standard.

Mr. WEBB said this was their decision. They had decided that it was possible to reduce the extraction rate at this point because of the high nutritional value of the extra amounts of other kinds of food which they were now able to supply.

Dr. STROSS asked the Minister what was the iron content of wheaten flour at the rates of extraction 85%, 80%, and 72%.

Mr. WEBB said that depended on the grists (the mixtures of wheat). But typical figures for 85%, 80%, and 72% extraction rates were 2.1, 1.65, and 1.25 mg. per 100 g. of flour.

Universities and Colleges

UNIVERSITY OF OXFORD

In Congregation on July 25 a formal welcome was addressed to the International Congress of Anatomists being held at Oxford. The honorary degree of D.C.L. was conferred on Viscount Addison, P.C., M.D., F.R.C.S., Lord Privy Seal, and the honorary degree of D.Sc. on Professor G. W. Corner, director of the Carnegie Institute of Embryology, Professor M. W. Woerdeman, Professor of Anatomy at Amsterdam, and Mr. L. S. B. Leakey, Curator of the Coryndon Museum, Nairobi.

In a Congregation held on July 15 the following degrees were conferred:

D.M.—*W. D. Brinton.

B.M.—D. J. Goldsmid, C. N. Watson, J. D. Cairns, G. C. R. Morris, J. Taylor, J. G. Armstrong, J. M. L. Gilks, G. E. D. Morrhall, W. W. Slack, W. A. Openshaw, J. R. W. Gleave, R. F. Brown, M. J. Evans, J. L. Galbraith, Mrs. Margaret E. H. Warwick, Margery P. S. Woolf, *M. J. Rosenthall, *Jean M. Shanks, *Anne S. Fowkes.

*In absence.

ROYAL COLLEGE OF PHYSICIANS OF LONDON

At a quarterly comitia of the Royal College of Physicians of London held on July 27, with the President, Dr. W. Russell Brain, in the chair, the following Fellows were elected officers for the ensuing year: *Censors*, J. F. Smith, A. H. Douthwaite, F. J. Nattrass, K. E. Harris; *Treasurer*, W. G. Barnard; *Registrar*, Sir Harold Boldero; *Harveian Librarian*, E. C. Dodds, F.R.S.; *Assistant Registrar*, M. I. A. Hunter.

Sir Archibald Gray was appointed Harveian Orator and Dr. D. H. Brinton Bradshaw Lecturer, both for 1951. The following Lecturers were also appointed: Lumleian (1951), Sir Adolphe Abrahams; Goulstonian (1951), Dr. H. J. Anderson; Oliver-Sharpey (1951), Professor K. J. Franklin; Milroy (1951), Dr. J. C. Broom; Croonian (1952), Dr. E. B. Strauss; FitzPatrick (1951), Dr. W. Brockbank; Mitchell (1951), Dr. W. E. Lloyd.

The President, Dr. Russell Brain, was elected the College representative on the General Medical Council and on the governing body of the British Postgraduate Medical Federation.

The Bisset Hawkins Medal was awarded to Sir Wilson Jameson in recognition of his services in promoting public health during the past ten years while he was Chief Medical Officer of the Ministry of Health.

The Gilbert Blane Gold Medal for 1950 was awarded to Surgeon Commander E. B. Martin, R.N., and the Murchison Scholarship to Dr. J. C. Mitchell.

The appointments of Dr. W. D. W. Brooks as a member of the Prophit Committee, Dr. Alice Stewart as a member of the Rheumatic Fever Committee, and Dr. Mildred Creak as a member of the Psychological Medicine Committee were confirmed.

The following having satisfied the Censors' Board were elected Members of the College: E. M. Backett, M.B., J. C. Batten, M.B., J. S. K. Boyd, M.D., E. G. Brownell, M.D., A. W. Capon, M.B., T. Chelvarajah, L.M.S., P. R. Clay, B.M., Betty L. Coles, M.B., D. H. Collins, M.D., A. E. Doyle, M.B., R. L. Eakin, M.B., W. J. D. Eberlie, M.B., R. Fife, M.B., T. R. L. Finnegan, M.B., W. Fox, M.B., E. N. Gauld, M.B., S. B. Hall, M.D., A. C. Hayton, M.B., J. B. Holroyd, M.B., G. Howells, M.B., M. C. Joseph, M.B., W. A. E. Karunaratne, M.D., S. E. Large, M.B., Major, R.A.M.C., G. L. McDonald, M.B., C. McIver, M.B., H. W. Matthews, M.B., Lieutenant, R.A.M.C., W. R. May, M.B., S. S. Meighan, jun., M.B., J. S. Menzies, M.D., A. W. N. Oatway, M.B., Margaret M. O'Hare, M.B., L. I. Phillips, M.B., Muriel E. Port, M.B., G. S. Ratnavale, M.B., B. Stone, M.B., T. J. Thomson, M.B., W. J. Walkden, M.B., A. P. Waterson, M.B., J. A. Waycott, M.B., R. G. Welch, M.B., E. Williams, M.B.

Licences to practise were conferred upon 107 candidates (including 15 women) who have passed the final examination in Medicine, Surgery, and Midwifery of the Conjoint Board and who have complied with the necessary by-laws: K. R. Aberdour, D. Abse, Lilian E. Ackermann, Sheleagh E. Aldersmith, R. J. Ancill, M. J. Argyrides, B. H. Bass, W. H. G. Batham, Barbara E. Batty, H. H. G. Bell, J. C. Betts, Hyla M. Birks, F. R. Brearley, J. M. Brown, B. H. Burne, G. E. H. Callebaut, T. H. Christie, D. J. Coleman, H. G. Cooper, H. D. Cullimore, H. J. B. Day, A. R. de C. Deacock, J. C. Dilley, P. Dinmore, W. A. W. Dutton, M. A. Ebrahim, H. B. Eckstein, J. A. Eddington, P. C. Fleming, R. Fleming, J. H. G. Ford, N. S. Galbraith, L. E. Garrett, Angela M. Geere, R. E. Gibson, A. L. A. Gill, S. C. Gomez, J. Gower, B. P. Green, J. L. Griffiths, R. Hart, R. F. Harvey, C. McL. Hewat, R. Hill, R. Hinchcliffe, E. R. Heuhns, Anne Isaac, G. Jessup, P. E. E. Kann, F. M. Kinsman,

S. F. Knipe, S. S. Lazarus, D. Lennie, H. E. Lewis, J. A. F. Lord, J. W. McCloy, R. F. McKnight, Sheina A. Maclean, M. K. Mason, Jennie C. Maurice-Jones, W. C. Mok, R. D. Morbey, Ann E. Morgan, A. H. Mortimer, G. M. Murphy, R. N. Nauth-Misir, T. O. O. Ogunlesi, D. W. Orton, E. M. Orton, Kathleen M. Parker, J. W. Parkin, J. A. Pedler, L. H. Pell, J. E. H. Pendower, Joan K. Perkins, D. A. Plomer, A. J. Redenham, G. D. Rees, Alison M. Richardson, E. H. Roffey, I. M. Rosen, N. L. Rowe, K. E. K. Rowson, Hilary G. Rubin, P. W. Ruggles, P. S. B. Russell, M. R. Salkind, Gwendoline D. Salter, D. I. Segall, H. Silver, P. R. Stevens, E. Stokoe, D. T. I. Stuttaford, G. C. Swain, D. R. *Sweetnam*, Gwendolyn R. Tapp, I. O. Taylor, W. C. T. Thomas, G. W. Thorpe, J. G. Turner, W. J. A. H. Turner, J. M. Walker, H. B. G. Webb, J. A. Williams, K. G. Williams, R. I. J. Williams, D. Wiseman.

Diplomas in Medical Radio-Diagnosis, in Medical Radiotherapy, in Laryngology and Otology, in Psychological Medicine, in Anaesthetics, in Tropical Medicine and Hygiene, and in Child Health were granted, jointly with the Royal College of Surgeons of England, to the successful candidates whose names are printed below in the report of the meeting of the Royal College of Surgeons of England.

Other diplomas were granted, jointly with the Royal College of Surgeons of England, as follows:

DIPLOMA IN PUBLIC HEALTH.—N. J. Caldwell, M. J. Collins, R. E. C. Copithorne, Audrey T. Evans, K. C. Mackenzie, N. Newman, J. O'Callaghan, R. O'Farrell.

DIPLOMA IN OPHTHALMOLOGY.—M. Alimuddin, H. L. Backhouse, R. H. Baird, J. C. Bass, Fiona M. Bennett, W. G. C. Craigen, R. P. Dhanda, D. B. Dunlop, R. Ebenezer, R. F. Elliott, Nora M. English, B. Ibrahim, B. U. Killen, Ella I. Mackinnon, S. Prakash, P. K. Rai Chaudhuri, A. V. *Rajagopal*, J. P. *Robinson*, T. R. Sakhuja, J. H. Scott, K.-Y. Sun.

DIPLOMA IN OPHTHALMIC MEDICINE AND SURGERY.—P. H. Ball, R. N. Bulsara, R. B. W. A. Cole, P. C. Ghosh, Margaret M. Harley, M. C. Head, Anna J. Kesson, J. M. McKeogh, R. A. Morris, D. J. O'Connor, J. Ll. J. Phillips, D. Plum, T. F. Roche, F. Saif, L. F. Samut, A. G. Shanks, J. R. C. Spicer, H. S. Sweet, D. S. Thomson, Ll. M. Weerekoon.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

At a meeting of the Council of the Royal College of Surgeons of England held on July 13, Sir Cecil Wakeley was re-elected President for the ensuing year, and Professor Ernest Finch and Mr. P. H. Mitchiner were elected vice-presidents.

Mr. A. Hedley Whyte, Mr. E. W. Riches, Sir Arthur Porritt, and Professor A. M. Claye were admitted as Members of the Council.

Professors and Lecturers for the ensuing year were appointed as follows:

Hunterian Professors.—Mr. A. W. Allen, one lecture on modern trends in colonic surgery; Mr. R. T. Johnson, one lecture on carotid ligation for intracranial aneurysms; review of 100 cases; Professor Milroy A. Paul, one lecture on the blood and lymph pathways in the spermatic cord; Mr. A. *Wilfrid Adams*, one lecture on the range and results of transurethral surgery; Mr. Denis J. Browne, one lecture on congenital deformities of mechanical origin, their pathology and treatment; Mr. Harvey Jackson, one lecture on tumours of the orbit; Mr. F. G. Hollands, one lecture on malignant disease of the urinary bladder; Mr. P. G. L. Essex-Lopresti, one lecture on fractures of the os calcis; Mr. J. C. Goligher, one lecture on the functional results following sphincter-saving excisions of the rectum; Mr. C. A. R. Schulenburg, one lecture on adamantinoma; Mr. B. N. Brooke, one lecture on the surgery of ulcerative colitis; Mr. Arthur Naylor, one lecture on brachial neuritis, with particular reference to lesions of the cervical intervertebral disks; Mr. R. P. Jepson, one lecture on a clinical and physiological study of 200 cases of severe Raynaud's phenomenon.

Arris and Gale Lecturers.—Professor J. M. Yoffey, one lecture in the form of a film of the lymphatic system; Mr. J. B. *Kinmonth*, one lecture on surgical physiology of large arteries, with particular reference to traumatic spasm; Mr. W. J. Dempster, one lecture on some problems involved in homotransplantation of tissues, with particular reference to skin.

Erasmus Wilson Demonstrators.—Mr. C. E. Shattock, two demonstrations; Mr. P. H. Mitchiner, two demonstrations; Mr. L. W. Proger, two demonstrations.

Arnott Demonstrators.—Mr. R. J. Last, two demonstrations; Dr. F. S. Gorrill, two demonstrations; Dr. H. D. Ross, two demonstrations, with a discussion of the pathology of reactive and neoplastic changes in synovial tissues, illustrated by specimens from the museum.

Professor David Slome, Professor of Applied Physiology, was also appointed as Bernhard Baron Research Professor.

The Macloghlin Scholarship for 1950 was awarded to John Julius Fryatt of Lewes County School.

Diplomas of Fellowship were awarded as follows: W. E. Wimberger, N. T. Holden, J. B. David, S. H. Janikoun, R. P. Crick, J. D. Randall, G. H. D. Channing, J. G. Craddock, W. Sewell, R. O. Wheeler, R. S. Henderson, J. G. Stubbs, A. J. Evans, L. R. McLaren, D. T. R. Evans, P. R. *Sondhi*, O. M. Jonathan, A. M. B. Tompkin, R. H. Maudsley, H. O. Williams, J. P. Hopewell, J. D. Trethowan, R. H. Sewell, R. R. Burn, J. E. L. Price, C. G. Attenborough, G. S. Yeoh, D. A. Bailey, J. Upsdell, C. W. Graham-Stewart, L. T. Cotton, K. D. Roberts, L. F. Tinckler, N. C. D. Pizey, A. J. Ruzicka, E. J. Newton, K. K. Ghosh, D. F. de S. Goonawardena, A. Hirtstein, A. B. May, R. V. Singh, M. D. Gelfand, T. M. Hennebry, K. W. B. Rostron, G. S. M. Wilson, A. F. Marshall, E. Hoffmann, B. M. Pujari, O. H. Schneider, S. E. Seneviratne, A. Ashworth, J. L. Bignell, A. T. S. Paul, M. A. Sadek, P. K. Chatterjea, A. M. M. Farag, J. M. Jalundhwala, W. Paterson, H. J. Richards, P. Sivasubramaniam, D. S. Chapman, I. A. Lester, J. F. *McInerney*, P. W. E. Moore, C. A. Simmons, H. F. Smith, J. H. Cloke, B. S. Crawford, G. M. Goodson, G. W. H. James, P. N. S. Jayaswal, T. P. Leadman, N. C. Mackillop, A. W. Middleton, J. H. Shelswell, I. B. Taylor, J. H. Brown, M. D. Cremin, T. G. Crombie, D. P. Greaves, M. H. M. Harrison, S. J. *Hersch*, J. R. Heseltine, A. A. Jefferson, P. Jewsbury, A. U. Khan, R. Merryweather, A. G. Quinlan, F. G. Smiddy, J. W. Sutherland, W. L. Thompson, R. G. Turner, R. M. T. Walker-Brash, T. J. Wilmot, K. C. Wybar, R. E. Aitken, D. M. Bell, A. R. Cockerell, L. A. Eckert, B. Hurst, C. H. Kinder, W. L. F. Utley, R. G. Webb, B. N. Catchpole, W. D. Corfield, D. A. Gibson, J. Hankinson, I. A. McDonald, R. G. C. MacLaren, D. E. Savage, R. H. C. *Robins*, M. S. Strong.

A Diploma of Membership was awarded to Robert Foster McKnight (St. Thomas's Hospital).

Dr. George Edward was appointed Frederick Hewitt Lecturer.

J. C. Nicholson, D. Blatchley, A. G. Shields, and H. R. Sheppard were elected Fellows of the Faculty of Anaesthetists.

Diplomas were granted, jointly with the Royal College of *Physicians* of London, to the following successful candidates:

DIPLOMA IN MEDICAL RADIO-DIAGNOSIS.—Violet Auld, E. A. Beetles, H. S. Bennett, N. N. Blaxland, D. J. Chapman, H. Clain, D. Cockcroft, W. J. J. Czyzewski, I. O. Faiman, S. Ghose, D. T. Glass, G. L. Hardman, R. T. Hastings-James, V. Hay-Bolton, R. M. Hector, K. E. Hodge, F. H. Howarth, D. C. Light, M. J. Lochrin, J. K. McCabe, R. P. C. MacDonald, E. V. M. Medill, I. R. Moyle, A. H. R. Muir, J. J. O'Connell, S. N. Prasad, L. L. Ralph, J. A. Rankin, D. F. Reynolds, K. A. Rowley, M. G. Scott, D. Sircar, W. H. Smith, R. F. Stubbs, G. J. MacA. Teunon, T. F. Thomas, W. R. R. Thursfield, E. A. Waldron, D. A. H. Walton, H. B. Ll. Williams, A. R. C. Young.

DIPLOMA IN MEDICAL RADIOTHERAPY.—J. Ackerley, F. Batley, F. M. Benton, L. G. Capra, P. K. Dutt, A. J. H. *Henning*, Dorothy M. E. McGuire, I. McHattie, P. K. Mookherjee, Dorothy J. D. Smith, J. E. Stapleton.

DIPLOMA IN LARYNGOLOGY AND OTOLOGY.—N. Ahmad, M. Amjad Ali, C. R. Black, A. C. Camm, A. R. Curtis, H. A. Fraser, D. S. Gideon, B. S. Hilliar, H. M. Mann, G. S. Ramachandran, V. Rasanayagam, M. Shawaf, M. S. Strong.

DIPLOMA IN PSYCHOLOGICAL MEDICINE.—M. W. *Annear*, A. L. Galea, M. M. Glatt, E. L. Ives, S. F. Lindsay, S. J. Rydlewski, A. R. Samuel, J. E. G. Vincenzi, J. H. S. Whyte, G. M. Woddis.

DIPLOMA IN ANAESTHETICS.—R. C. Allison, W. E. Arnold, D. A. N. Barran, J. K. Black, H. R. Blades, S. O. Bramwell, C. P. Brown, D. H. P. Cope, Sheila A. Costello, A. S. Crawford, Celia M. Davies, P. S. Dearden, J. W. Dundee, D. A. Forbes, Marion G. Foster, F. N. Gabali, R. Ghose, C. M. H. *Gunaratne*, W. S. Hart, E. H. Hopkinson, R. A. House, Evelyn M. Lafferty, R. E. Lee, Mair Llewelyn, N. G. Marshall, D. Matheson, C. J. J. Morkane, T. P. Murray, Barabara M. Parker, Cynthia M. Parrott, K. A. S. M. A. Quader, D. E. G. Sayers, W. M. Smeeton, A. E. Smith, D. I. H. Smith, W. J. Tyson, A. B. Ward.

DIPLOMA IN TROPICAL MEDICINE AND HYGIENE.—S. H. Shah.

DIPLOMA IN CHILD HEALTH.—Edith J. R. Parfit, K. Prabhakar.

Regulations were approved for the award of the James Berry Prize endowed by Lady Berry.

The award of the Mackenzie Mackinnon Research Fellowship to Mr. R. S. Murley was reported.

The following hospitals were recognized under paragraph 23 of the Fellowship regulations: Beckett Hospital, Barnsley (resident surgical officer); Clatterbridge General Hospital, Bebington (resident surgical officer, first and second house-surgeons); Royal Victoria Hospital, Dover (senior house-surgeon); City General Hospital, Stoke-on-Trent (surgical registrar, first and second and third house-surgeons, ear, nose, and throat registrar).

The National Association for Mental Health has published the proceedings of the conference on "Mental Health and the Family" held on March 23–24 this year. The proceedings are obtainable for 5s. from the association at Maurice Craig House, 39, Queen Anne Street, London, W.1.

No. 28

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended July 15.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1950 (a)	(b)	(c)	(d)	(e)	1949 (Corresponding Week) (a)	(b)	(c)	(d)	(e)

Stillbirths	153	21	25			185	26	34		
Rate per 1,000 total births (including stillborn)			28					33		

* Measles is not notifiable in Scotland, and the returns are therefore an approximation only.

† Deaths from measles and scarlet fever for England and Wales, London (administrative county), will no longer be published.

‡ Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales, London (administrative county), are combined.

‖ Includes puerperal fever for England and Wales and Eire.

¶ Primary pneumonia no longer notifiable in Eire.

EPIDEMIOLOGICAL NOTES

Poliomyelitis

Notifications of poliomyelitis in the week ended July 22 were: paralytic cases 189 (152); non-paralytic 71 (60); total 260 (212). The figures for the previous week are shown in parentheses. London had 20 more cases than last week, Warwick 5 more, Stafford 3 more, Essex 3 more, Worcester 2 more, and Lancaster 2 more. Four counties together contributed 46% (119 cases) of the total notifications for the week under review—namely, Warwick 43, London 28, Lancaster 24, Stafford 24. Most of the increase in notifications for the week ended July 22 were in areas where the disease was already present, and there is no evidence of any considerable spread elsewhere.

Anthrax in Cattle

An outbreak of anthrax in cattle has occurred at Holme Pastures, Sutton-on-Trent, Nottinghamshire. Nine cattle have died, but at the time of going to press the cause of death has not been bacteriologically proved in all cases. The outbreak is regarded as exceptionally severe.

Discussion of Table

In *England and Wales* there were increases in the notifications of measles 340, whooping-cough 183, scarlet fever 144, acute pneumonia 34, while the only decreases were dysentery 56, and diphtheria 13. Large changes in the trend of measles were recorded in only a few counties; the largest rises were Lancashire 329, Yorkshire West Riding, 141, Dorset 66; and the largest falls were Middlesex 118 and Hertfordshire 77. Most of the increase in the incidence of scarlet fever occurred in the southern section of the country; in London and the south-east counties the notifications were 73 more than in the preceding week.

The chief features of the returns for diphtheria were an increase of 5 notifications in Lancashire and a decrease of 7 in Durham. The largest increases of whooping-cough were in Nottinghamshire 55, Lancashire 49, and Sussex 42, while the only large decrease was 71 in Durham. The fall in notifications of dysentery was due to the experience in Lancashire, where 55 fewer cases were recorded than in the preceding week. The largest returns for dysentery were Lancashire 83 (Preston C.B. 26, Oldham C.B. 12, Royton U.D. 8); Yorkshire West Riding 36 (Bradford C.B. 10); London 19; Northumberland 16 (Newcastle-upon-Tyne C.B. 12).

The notifications of poliomyelitis were the same as in the preceding week. The largest centres of infection were Warwickshire 38 (Birmingham C.B. 29, Sutton Coldfield M.B. 4); Lancashire 22 (Liverpool C.B. 9); Staffordshire 21 (Rowley Regis M.B. 4, Sedgley U.D. 5); Northumberland 16 (Newcastle-upon-Tyne C.B. 8); Worcestershire 11 (Halesowen M.B. 4); Yorkshire West Riding 11; Essex 10; Gloucestershire 9 (Cheltenham M.B. 4); London 8; Middlesex 7; Nottinghamshire 6; Leicestershire 5 (Leicester C.B. 5); Durham 5; Carmarthenshire 5.

The only large outbreak of food-poisoning notified during the week was in Durham, Easington R.D., with 249 cases.

In *Scotland* there were decreases in notifications of measles 127, whooping-cough 41, scarlet fever 26, acute primary pneumonia 19, while the only increase of any size was 7 for acute poliomyelitis. The fall in the incidence of scarlet fever occurred in the Western area. Although the number of notifications of dysentery were the same as in the preceding week, an increase of 20 was recorded in the Western area due to outbreaks in Dumfries 16 and Kilmarnock 10. The other important returns for dysentery were Glasgow 33 (a decrease of 9), Edinburgh 10, and Dundee 8. The largest returns for acute poliomyelitis were Glasgow 15, Fife county 7, Lanark county 5, Renfrew county 4.

In *Eire* an increase of 102 occurred in the notifications of measles and a decrease of 23 was recorded for whooping-cough. The largest returns for measles were Dublin C.B. 124; Dublin, Dublin South R.D. 48; Meath, Dunslaughlin R.D. 33.

In *Northern Ireland* there were decreases in measles 37, scarlet fever 23, whooping-cough 19.

Statistical Review, 1948

Part I (Medical) of the Registrar-General's *Statistical Review for 1948* records that the crude death rate during the year was 11.0, the lowest ever recorded in England and Wales, and 0.4 below the previous lowest rate recorded in 1930. The infant mortality was 34 per 1,000 related live births and was the lowest ever recorded, being 7 below the previous low level of 1947. Cancer accounted for 16.9% of all deaths compared with 15.1% in 1947. Deaths from coronary disease and angina pectoris showed a further substantial increase, and, even allowing for the change in the age and sex distribution of the population, mortality from this cause has practically been doubled in the last ten years.

Infant Mortality

Provisional figures for the second quarter of this year show that both stillbirths and infant mortality were lowest on record for a June quarter in England and Wales. Stillbirths were 22.5 per 1,000 total births. Infant mortality was 28 per 1,000 related live births, compared with 30 in the June quarter of 1949, and 50 in the same quarter of 1938.

Week Ending July 22

The notifications of infectious diseases in England and Wales during the week included scarlet fever 1,153, whooping-cough 3,881, diphtheria 46, measles 8,754, acute pneumonia 293, acute poliomyelitis 260, dysentery 166, paratyphoid 5, typhoid fever 6.

Medical News

Miners' Welfare Commission

The Minister of Fuel and Power has reappointed the Miners' Welfare Commission in accordance with the Coal Industry Nationalization Act of 1946. Viscount Hyndley is chairman. The only medical member is Dr. S. W. Fisher, H.M. Principal Medical Inspector of Mines. Professor E. L. Collis, formerly Talbot Professor of Preventive Medicine in the University of Wales and H.M. Medical Inspector of Factories, has resigned after serving on the commission for over 30 years.

First Prize for Film

The film "The Treatment of Infections of the Hand" was shown at the film section of the International Medical Congress at Verona and awarded first prize. It demonstrates the methods taught in Professor R. S. Pilcher's department at University College Hospital, and was produced under the auspices of the B.M.A. Glaxo Laboratories, Ltd., sponsored the film, and it was produced by the Realist Film Unit, Ltd. A note on it appeared in the *Supplement* of July 29 (p. 71).

Joseph Goldberger Award for 1950

Dr. Fuller Albright, associate professor of medicine at Harvard Medical School, is to receive the Joseph Goldberger Award in Clinical Nutrition for his work on mineral and human metabolism. The award, which is made annually by the American Medical Association, consists of a gold medal and $1,000.

Food Production

The Royal Society of Arts is to award a prize of £500 and a gold medal for a new and outstanding means of promoting the production or the economic utilization of food in Britain. The society gives as examples of its objective: a scheme for encouraging a return to the land; a system to ensure the marketing of perishable food, such as fish or vegetables, in better condition. The prize is given as part of the society's celebrations for the Festival of Britain. Entries must be received by March 1, and the award will be made on May 1, 1951.

Princess Tsahai Memorial Hospital

The Princess Tsahai Memorial Hospital, which has been built at Addis Ababa, will soon be engaging staff. Applications for the post of principal physician should be addressed to the honorary secretary, Miss E. Sylvia Pankhurst, 3, Charteris Road, Woodford Green, Essex.

COMING EVENTS

First-aid and Home-nursing Course

A plan for civil defence having been put into operation by the authorities, the St. John Ambulance Brigade will hold an Intensive First-aid and Home-nursing Course at St. John House, 15–16, Collingham Gardens, London, S.W.5, on September 2 for two weeks. The first week will be on first aid and the second on home nursing, including an examination in each subject after the week's lectures. Anyone is eligible, without obligation, to join the Brigade, and the successful candidate will receive the St. John Ambulance Association certificate. The course will be under the direction of a Brigade county surgeon, and there will be a resident S.R.N. tutor to instruct in home nursing and practical first aid. For further details apply to the Warden at the address above.

Institute of Ophthalmology

The academic year 1950–1 of the Institute of Ophthalmology (University of London) (Judd Street, London, W.C.) will be inaugurated on Wednesday, October 4, at 4.30 p.m., with an address by Dr. W. Russell Brain, President of the Royal College of Physicians of London. The annual dinner of the institute will be held at Claridges Hotel, Brook Street, London, W., at 7.30 p.m. the same day. Past students of the institute and of Moorfields Westminster and Central Eye Hospital are invited to both these functions. Tickets for the annual dinner are 25s. each and may be obtained on application to the secretary of the institute at the above address.

SOCIETIES AND LECTURES

A fee is charged or a ticket is required for attending lectures marked ●. Application should be made first to the institution concerned.

Tuesday

EDINBURGH POSTGRADUATE BOARD FOR MEDICINE.—At University New Buildings (Anatomy Lecture Theatre), Edinburgh, August 8, 3.30 p.m., "*Development of Modern Renal Physiology*," by Professor Homer W. Smith (New York).

APPOINTMENTS

FISHER, R. E. W., M.B., B.Ch., D.P.H., D.I.H., Chief Medical Officer, South Eastern Area Gas Board.

NEILL, G. A. W., M.D., D.P.H., Barrister-at-law, Medical Officer of Health, County Borough of Barnsley.

PULLAN, J. M., M.Chir., F.R.C.S., Part-time Consultant Surgeon, St. Thomas's Hospital, London, S.E.

BIRTHS, MARRIAGES, AND DEATHS

BIRTH

Keeling Roberts.—On July 21, 1950, at The Crescent, Wem, Shropshire, to Margaret (formerly Mayhew) and John Keeling Roberts, M.R.C.S., L.R.C.P., the gift of a son, a brother for Alison—Christopher Stuart.

MARRIAGE

Bailey—Simpson.—On July 26, 1950, at West Kirk, Greenock, John Oswald Bailey, Berrow Court, Edgbaston, Birmingham, to Catherine Gilray Simpson, M.B., Ch.B., D.P.H.

DEATHS

Daniel.—On July 28, 1950, at Gilcroft, Checkendon, Oxfordshire, Peter Lewis Daniel, F.R.C.S., late of 1a, Upper Wimpole Street, London, W.

Hughes.—On July 28, 1950, at Pembury Hospital, Kent, Ernest Cranmer Hughes, O.B.E., M.Ch., F.R.C.S., aged 71.

Jamieson.—On July 23, 1950, at 43, George Square, Edinburgh, John Boyd Jamieson, T.D., M.D., F.R.C.S.Ed.

Kennard.—On July 24, 1950, Douglas Frederick Kennard, *L.R.C.P.Ed.*, of Clacton-on-Sea, late of Spitalfields.

Laidlaw.—On July 27, 1950, at 40, Sherbrooke Avenue, Glasgow, Marion Wylie Laidlaw, M.B., Ch.B., wife of Dr. Stuart I. A. Laidlaw, Medical Officer of Health for Glasgow.

Moir.—On July 25, 1950, at Lloran Lodge, Combs, Chapel-en-le-Frith, Edward Moir, L.S.A., D.A.

Solly.—On July 26, 1950, at a Harrogate nursing-home, Ernest Solly, *M.B.*, F.R.C.S., of Strathlea, Coldbath Road, Harrogate, aged 87.

Ward.—On July 30, 1950, at the Manor House, Shelsley Beauchamp, Bernard Joseph Ward, F.R.C.S.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Chondromalacia of the Patella

Q.—*Is chondromalacia of the patella a toxic, nutritional, or vascular disease? What can be done in treatment to prevent pain and destructive changes in the joint?*

A.—Chondromalacia of the patella is characterized by roughening or fibrillation of the articular cartilage of the patella, the joint being otherwise normal. The condition not infrequently begins in young persons. The cause is unknown. Some authorities have attributed it to injury, but others have denied that injury is a significant factor. Clinically, there is aching in the front of the knee, a tendency to recurrent mild effusions, and crepitus in the patello-femoral compartment on movement. In the early stages the bone is not affected and the radiographic appearances are normal. The course is variable. In mild cases the condition is not necessarily progressive; but there is always a risk of the later development of osteoarthritis.

The problem of treatment is difficult. In mild cases radical measures do not seem justified, and resort is usually had to rest (as in a plaster cylinder) or to physiotherapy in the form of short-wave diathermy and muscle development exercises. But when the early development of progressive and painful degenerative arthritis is suspected excision of the patella is probably the wisest course, even in relatively young subjects. Attempts have been made to restore a smooth patellar articular surface by paring away the fibrillated cartilage, but the operation is unlikely to give permanent relief and cannot be recommended. No form of medication—whether it be systemic or by intra-articular injection—can be expected to be of benefit.

Subacute Combined Degeneration

Q.—*In "Any Questions?" of December 31, 1949 (p. 1539), the treatment for subacute combined degeneration was given as "an intensive initial course of liver injections . . . and then two or three times weekly until the condition is much improved." Is there any indication when the patient is getting too much? On the other hand, should the injections be continued for a year or longer at two or three times a week? The case I have in mind is a man of 78 who has been having liver injections for macrocytic anaemia about once a month for the last eight years. During the last year a certain degree of optic atrophy has developed in one eye, with paraesthesia of the feet and other signs. In the last two months there has been some improvement under more intensive treatment. The blood count, which eight years ago was down to 1,500,000, now and for the last few years remains fairly steady at a little over four million, and the red cells are normal in appearance.*

A.—There is no danger of giving too much liver therapy in the treatment of subacute combined degeneration of the spinal cord; the only exception to this is in the small minority of patients who develop sensitivity to liver extracts. In the case mentioned, neurological symptoms have apparently appeared during treatment of the macrocytic anaemia while the blood count was around four million. Optic atrophy is a recognized but rare complication of pernicious anaemia (*Brain*, 1940, **63**, 225), and may well be so caused in the case described. The development of neurological symptoms indicates that the dosage of liver extract was inadequate or that the liver preparation used was not fully active, and the clinical response which has occurred with more intensive treatment suggests that the former alternative is correct. The intensive treatment should be continued in view of the presence of optic atrophy and could be supplemented with proteolysed liver by mouth in a dose of 1 oz. twice daily. Visual impairment due to optic atrophy complicating pernicious anaemia usually improves with adequate liver treatment. Vitamin B_{12} has now been shown to be effective in the treatment of pernicious anaemia and of subacute combined degeneration, and this substance in a dosage of 40 μg. twice a week by injection could be given as an alternative to liver injections.

Delayed Reaction to Midge-bites

Q.—*Is there any means of desensitizing a patient who suffers severe and prolonged irritation and swelling following midge- and gnat-bites?*

A.—Severe prolonged irritation and swelling following midge- and gnat-bites is presumably the "delayed" type of reaction which comes on about 24 hours after being bitten and which often lasts some days, and not the "immediate" urticarial type of reaction which comes on in about 30 minutes and is usually of comparatively short duration. Work on similar reactions from mosquito-bites suggests that so far as these delayed reactions are concerned specific desensitization should greatly reduce the inconvenience caused (Heilesen, B., *Acta Allergologica*, 1949, **2**, 245 (in English)). An extract from midges and gnats for specific desensitization can be obtained from commercial firms; the dosage and the details of administration vary according to the particular preparation employed. (See also article by Professor R. M. Gordon at p. 316.)

Hyperpiesis and Albuminuria

Q.—*What investigations are called for, what is the treatment, and what is the likely prognosis in a case of hyperpiesis with paroxysmal albuminuria? The patient is a man of 39, and his blood pressure, which is now 210/140 mm. Hg, has risen gradually since he was first examined six months ago. He complains of severe headaches and occasional vomiting, and during these attacks his urine is loaded with albumin. In the worst of his attacks there was a small retinal exudate. Transient improvement follows venesection or rest in bed for a few weeks. What is the cause of the albuminuria in a case of this kind? Is this the sort of case in which sympathectomy should be considered?*

A.—The albuminuria is a reflection of episodes of extreme hypertension, and is a result rather than a cause of the patient's illness. The diagnosis may well be malignant hypertension, although chronic nephritis is possible. Lumbodorsal sympathectomy should certainly be considered. Preliminary investigations should include renal function tests, examination of urine deposits, intravenous or retrograde pyelography, and perhaps a sedation test, in which the effect on the blood pressure of 3 gr. (0.2 g.) of sodium amytal repeated hourly for three doses is determined. If the results of the renal function tests are fairly good, malignant or severe essential hypertension is the probable diagnosis. Paroxysmal hypertension from pheochromocytoma of the adrenal medulla should be excluded by means of the histamine, tetraethylammonium, and benzodioxine tests, details of which need not be given here. If there is serious impairment of renal function, chronic nephritis is probably responsible for the hypertension, in which case little can be done. Acute episodes of extreme hypertension, headache, and vomiting should be treated with rest in bed, sedatives, and a low sodium diet, whatever the aetiology. Venesection is not advised.

Haemospermia

Q.—*What are the possible causes of haemospermia in a patient aged 58? He is married and free from venereal disease; his occupation necessitates absence from home for regular periods of four months, during which time he is absolutely continent. The condition has occurred three times in the last four years. Can anything be done about it, beyond increased exercise and avoidance of "pelvic congestion"?*

A.—Slight enlargement and congestion of the prostate and a mild vesiculitis are probably the most frequent causes of haemospermia in a patient of this age. However, haemospermia often occurs without any cause being discovered for it, and for lack of any other explanation it is attributed to congestion of the genital tract. Provided that genital tuberculosis and any

form of growth have been excluded (and these are comparatively uncommon explanations) the condition is of no importance. Nothing can be done for it beyond trying a period of sexual continence, and in this case the patient has been continent for over four months without result. He should be told, therefore, not to bother about his condition, which will eventually clear up.

Chronic Pancreatitis and Carcinoma

Q.—*(1) What are the possible causes of death in chronic pancreatitis with an indeterminate type of diabetic blood-sugar curve and in the absence of jaundice or ketosis? (2) Is chronic pancreatitis ever the result of chronic malnutrition, and is it ever regarded as a precancerous condition? (3) How many cases of carcinoma of the pancreas with or without chronic pancreatitis have been reported as dying from spontaneous hypoglycaemia? (4) Do you know of any cases of chronic pancreatitis associated with carcinoma of the pancreas with a diabetic type of blood-sugar curve dying from spontaneous hypoglycaemia while the patient was on ordinary diet and not having insulin?*

A.—(1) A chronic pancreatitis causes loss of weight and energy. Patients lose strength fairly quickly and usually die of an intercurrent disease. The details given in this case are insufficient to make a diagnosis of pancreatitis. A hard tumour in the region of the pancreas is always suggestive, and a barium meal should be given to exclude a tumour in the stomach. An enlarged and hard liver may be present, and secondary metastatic deposits should be sought for. An estimation of the total amount of fat excreted in the stools per day should be made when a diet containing 100 g. of fat is eaten for three days. The presence of undigested meat fibres in the stools should be looked for when the patient is eating meat. An estimation of the diastase in the urine may be useful. Since the sugar tolerance is said to be low the possibility of a bronzed diabetes should be considered. A small portion of the skin should be removed and stained for iron.

(2) The cause of chronic pancreatitis is quite unknown, but it is more likely that it has been responsible for the chronic malnutrition than that the latter has caused the chronic pancreatitis. A carcinoma may arise as a result of the chronic inflammatory condition.

(3) Neither chronic pancreatitis nor carcinoma of the acinous portion of the pancreas causes spontaneous hypoglycaemia. But a carcinoma of the islets of Langerhans is a well-known cause of the condition. Secondary deposits of the islet tumour occur in the liver, and in the end lead to death in hypoglycaemia.

(4) No. Patients with a sugar-tolerance curve suggesting a slight diminution of sugar tolerance sometimes have symptoms of hypoglycaemia, but these are usually very mild and death is most unlikely to occur from this cause. These mild symptoms of hypoglycaemia are not necessarily associated with a chronic pancreatitis or with carcinoma of the pancreas.

Climate and Rheumatoid Arthritis

Q.—*Are there any statistics showing the incidence of rheumatoid arthritis according to climate? During twenty years of practice in the Tropics, in Malaya and India, although mild joint affections were extremely common, I doubt if I ever saw in an Asiatic patient a typical case of rheumatoid arthritis.*

A.—There are no statistics showing the incidence of true rheumatoid arthritis in the Tropics, but it is commonly believed to be rare, though infective arthritis, which may be difficult to distinguish from true rheumatoid arthritis, is a common complication of some tropical diseases. Gonorrhoeal arthritis is said to be common in Nigeria, India, and China, and may be difficult to differentiate. Dr. Julia Morgan, who was associate professor of medicine at Shantung in China, mentions a list of tropical diseases associated with arthritis and others in which arthralgia is common, and says that among natives in the Gulf of Guinea "rheumatic arthritis" is said to be the commonest joint disease (Comroe's *Arthritis and Allied Conditions*, 1944, London). Pemberton states that he had several patients from Arizona, which has a hot dry climate and is generally considered to be favourable for chronic arthritics. There is some evidence that humidity may be more important than temperature and that fluctuations in temperature and humidity, such as are common in Britain, may have an even greater effect.

Lemon Juice and Calcium

Q.—*It is commonly believed among Colonial peoples that lemon juice, when used freely, produces a diminution in the calcium content of the body, especially of the bones. Is there any foundation for this belief?*

A.—Theoretically the organic acids in lemon juice—for example, citric acid—might be expected to precipitate calcium in the gut and hinder its absorption. From a practical point of view, however, there is no evidence that fruit juices, even in large amounts, interfere with the absorption of calcium. After all, relatively large amounts of citrate are added to infants' milk to render it more easily digestible, yet it does not produce rickets in these infants. The acid reaction of the small intestine, from which calcium is absorbed, is probably sufficient to prevent the formation of insoluble calcium salts. It has been found that calcium is quite well absorbed, except at critical levels of vitamin-D intake, even when relatively insoluble compounds are administered, such as calcium silicate.

Insulin Ointment

Q.—*What is the best base or bases for insulin ointment?*

A.—Experiments on the administration of insulin in various ointment bases have proved that this method is valueless.

NOTES AND COMMENTS

Tennis and Golfer's Elbow.—Dr. J. H. CYRIAX (*London*) *writes:* Your expert ("Any Questions?" July 15, p. 177) is mistaken in regarding tennis and golfer's elbow as identical. "*Tennis elbow*" is the term widely adopted for chronic strain of the extensor tendon at the lateral humeral epicondyle; it was first named "lawn-tennis elbow" by Major in 1883. By contrast, golfer's elbow occurs at the medial humeral epicondyle as the result of strain of the common flexor tendon. The distinction has a practical importance, for the usual type of tennis elbow is quickly cured by manipulation (Mills, 1928), whereas the only way to secure swift recovery from a golfer's elbow is adequate deep massage (Cyriax, 1947).

Corrections

Mr. MALCOLM DONALDSON (London, W.1) writes: Since my recent visit to America I realize that I used the wrong term in speaking of "tumour clinics" in the second paragraph of my article on "Education of the Public Concerning Cancer" (July 1, p. 35). The clinics at which the patients without any symptoms are examined are, as a rule, called "detection clinics," and the term "tumour clinic" is generally used to mean a weekly consultation of the staff to see all new cases of cancer in order to plan treatment.

Mr. H. J. SEDDON writes from the Royal National Orthopaedic Hospital, Stanmore: May I correct a small but significant slip in your report (July 29, p. 293) of the meeting of the Section of Orthopaedics held at Liverpool on July 19? The mobilizing apparatus used for patients confined to bed for long periods, which has the effect of minimizing skeletal decalcification, is described as if I had invented it. This is not so; both at the meeting and in the MS. of my paper I said that we owed this most valuable innovation to my friend and colleague, Mr. E. J. Nangle.

HUMANISM, HISTORY, AND NATURAL SCIENCE IN MEDICINE*

BY

F. M. R. WALSHE, M.D., D.Sc., F.R.C.P., F.R.S.

Physician to University College Hospital; Physician to the National Hospital for Nervous Diseases, Queen Square, London

The Linacre Lectureship, to which the Master and Fellows of St. John's College have done me the honour to call me, is, I believe, the oldest medical lecture foundation in this country. It has a tradition all its own in that it was one of the academic activities that survived the greedy spoliations of this University by Henry the Eighth that Latimer was to deplore in 1550, and again because its founder, Thomas Linacre, has a great place in our history, not only as a physician and the translator of the works of Galen from their original tongue but also as the principal restorer of the knowledge of Greek in this country.

In this work of restoration he was one of that small group of English humanists which included Grocyn, Lily, Colet, and Thomas More, who shed such lustre upon English learning in their time; one of whom, Thomas More, was to catch the imagination of all Christendom in his day as the living embodiment of all that was best in Christian Humanism; an ideal by which he lived and, in the manner of his death, endorsed.

What perspectives of opportunity, therefore, this lecture must conjure up in the heart and mind of anyone possessed of imagination and called upon to take his place in the long sequence of Linacre lecturers.

It would be vain for me to hope to rise to the height of this opportunity. I can but do my best to set out in their relevance to medicine three themes which come naturally to the mind in the contemplation of Linacre's life and circle. They are Humanism, History, and Natural Science.

For my shortcomings in a journey that will take me beyond the confines of medicine, as we ordinarily think of it, I ask your charity. And if I venture upon this task, it is not with the hope of completing it, but out of the conviction that to rebuild a bridge between medicine and the humanities is a pressing need; that this building can be done only from the side of medicine; and that someone must make a start if medicine is not to lapse into a mere congeries of techniques, to fail in coherence on its theoretical side, and to suffer the loss of its traditional values. Linacre was a bridge-builder between the ancient world of Hellas and Tudor England. It is not unfitting, therefore, that the Linacre lecturer of to-day should, in however humble a fashion, seek also to be a bridge-builder.

I shall not be derogating from Linacre's just place in history when I submit that perhaps his chief claim to enduring renown amongst us was his reintroduction of Greek to England. He was already an accomplished Greek scholar when, almost by chance as it might seem, he turned aside in his Italian journey to visit Padua, then a foremost centre of medical learning and of philosophy. There with a remarkable celerity he graduated as a doctor of medicine. Upon his return to England the Universities of Cambridge and Oxford hastened to confer upon him the like degree, with an easy liberality that must excite the puzzled envy of the present generation.

I am not enough of a historian to know precisely what could have been the course of the studies so speedily accomplished, but we learn that he defended his thesis with skill and applause against all comers, that within a few years of his return to his native land he had been appointed physician to that formidable patient King Henry the Eighth, and had embarked upon his famous translations of Galen, about which, were I strictly faithful to the provisions of his foundation, I should now be discoursing to you. One of his last acts was to found these lectures, expressing in his Deed of Gift the wish that they should "redound to the glory of God, the true art of medicine, the relief of the fallen, and the increase of the realm." I take leave to say, even in this bleak age of the spirit in which we live, that no nobler ideal of the vocation of the true physician could be proposed.

In a Harveian Oration before the Royal College of Physicians in 1948 I ventured to submit the claim of medicine to a place as of right within the body of the natural sciences. It is not my purpose to-day to reiterate this claim, but rather to propose to you that in its nature and aim medicine transcends the natural sciences; that medicine has in it an element also that properly belongs to the discipline of historical science, and that, ranging high above these, it has, at its best, qualities of humanism that the natural sciences, at least, can scarcely claim. Humanism, History, and Natural Science therefore are, I submit, the elements which medicine, worthily conceived and practised, integrates, or seeks to integrate, into a harmonious whole.

*The Linacre Lecture delivered to the Master and Fellows of St. John's College, Cambridge, on May 6.

Humanism

In his attractive seventeenth-century phraseology Hobbes reminds us that "the Light of Humane minds is Perspicuous Words, but by exact definitions first snuffed, and purged from ambiguity," and there can be few terms in respect of which this process is more necessary than the one now in question—namely, Humanism. Aristotle provided the first apology for an intellectual and secular humanism in his *Ethics*. Boethius, in his *Consolations of Philosophy*, gave us an early and familiar apology for a truly Christian humanism; and since his day, and particularly during the Italian Renaissance from the time of Petrarch onwards, ideals of humanism, secular and 'Christian, have been many.

In our own time and country Pater and Housman have expounded their views on the subject, and have written of a humanism in which the cultivation of the mind, of an intellectual excellence, is an end in itself.

But it seems to me that the humanism which a Linacre lecturer must put before you must be the Christian ideal and not the purely secular one, though this undeniably has its own intrinsic excellence. With the narrowest of all conceptions of humanism, that which equates it with a classical education, I am certainly not now concerned. Nor do I adopt any of the definitions given in that impressive shorter dictionary which emanates from another seat of learning than this.

Let me say, more positively, to what I do refer by the term "humanism." The Christian world inherited from the ancient world an idea and an ideal of culture which had three aspects: a speculative aspect, the ideal of truth, *veritas*; a moral aspect, the ideal of virtue, *virtus*; and an oratorical and literary aspect, *eloquentia*. And, since we are the agents of thought, speech, and action, this ideal may properly be called humanism.

Here is a humanism that strives for intellectual excellence, on the speculative side for the perfection of the lower reason which is ordered knowledge, *scientia*, and for that of the higher reason which is wisdom, *sapientia*, by which we are enabled to place knowledge in the whole framework of life; while, on the moral side, it includes practical wisdom—that is, prudence. Aristotle in his *Ethics* points out that science deals with things that are of necessity and with universals, while prudence deals with the affairs of men and not with universals only but with particulars. Thus it demands experience.

In the application of science to the practice of medicine the physician needs practical as well as speculative wisdom. He must be governed in his actions by a wise regard for the whole welfare of each patient individually. This regard is the peculiar, the essential, act of the virtue called prudence, which transcends natural science and comes within the category of moral excellence—ethics.

Finally, a complete humanism demands also the literary quality of eloquence: lucidity and conciseness of language and the skilled use of analogy and metaphor, which is what the mediaevals spoke of as rhetoric.

This is the humanism we see so beautifully exemplified in the life of Linacre's youngest and most famous pupil, Sir Thomas More, the patron saint of humanism. To whomsoever may not have read them I recommend the biography of More, and the smaller volume upon More's place in English literature and history, written with such insight by the late Professor R. W. Chambers, himself a rare humanist; works which have done so much to clear away those mists of provincialism and prejudice that have blinded the eyes of so many writers on More.

More's humanism had an eager zest for the things of the mind and a fine sense of proportion—"nothing too much"; a clear sense of the limitations of the State when viewed against the natural rights of the human person, and the courage to resist tyranny in the State; a clear and unfailing vision of what lay beyond finite values; and the grace to look beyond these to the hope of a greater experience in another sphere of existence. Here, then, is the humanism I should like you to associate with your thought of Linacre and of the practice of medicine. It is all implicit in the terms of this lecture foundation, drawn up by him in his last years and already quoted.

This occasion therefore seems to me one singularly appropriate for an exposition of medicine, not primarily as a theoretical and practical activity within the realm of natural science, but as an activity whose full scope and final end transcend natural science. With this confession of faith I turn to my second theme—namely, the relation of medicine to historical science.

Relation of Medicine to Historical Science

Medicine to-day carries the wounds of much ruthless administrative planning, but what she most needs is some intellectual organization from within, and as part of this it is important that we should ourselves undertake some analysis of her relations to the disciplines under which her activities are subsumed.

In a recently published book, *The Concept of Mind*, the Wayneflete Professor of Metaphysical Philosophy in the University of Oxford, Professor Gilbert Ryle, writes that medicine is but "the name of a somewhat arbitrary consortium of more or less loosely connected enquiries and techniques, a consortium that neither has, nor needs, a logically trim statement of programme."

This is surely an erroneous notion of the nature and methods of medicine, lacking both in historical sense and philosophical comprehension. Yet it is significant that such a definition should find serious utterance, and that in Professor Ryle's mind—if indeed I may apply this term to the neural dispositions of an avowedly anti-intellectualist philosopher—medicine is, as it were, comparable to a travelling country dealer's horse and van, wandering the countryside from farmhouse to cottage, with its odd assortment of wares, chosen in a spirit of opportunism, casually thrown together and having no other relationship than that of contiguity.

Yet, however apt the analogy, the light of common sense shows us that even the travelling dealer has a unity of method and purpose, capable of and needing that logical statement of programme that Professor Ryle to medicine, either as a possession or as a requirement it has seemed worth while to cite this pronouncement because it hints at what may, even now, be the medicine by many others, even within its own ranks, have not given serious thought to its history and philosophy. Who can doubt that the mushroom growth of specialisms, especially therapeutic specialisms, in medicine is a its disintegration as a body of ordered knowledge by men alert to lift their minds out of the mass of This state of affairs is justification enough for an to subsume medicine under the notions of history natural science, for now, more than ever, some principles must be impressed upon those who wish thought and practice in the medicine of the future.

In discussing in what sense medicine may within the discipline of historical science

also, that what is known as psychological medicine belongs primarily to this discipline and not to that of natural science. In doing so, I begin to tread upon dangerous ground, knowing full well that many rhetorical land-mines may be expected to go up noisily and dustily in my track as I proceed upon my hazardous way. Nevertheless, someone must clear the ground if it is to be made fertile soil for the growth of clear and coherent notions in psychological medicine.

Those who are acquainted with Collingwood's stimulating work entitled *The Idea of History*, or with Whitehead's *Modes of Thought*, where the same thesis is briefly expounded, will know something of the argument I shall try to develop, but to many within the ranks of medicine this will be unfamiliar and it is to them primarily that I address my thesis.

History in Medicine

We are prone to take it for granted that our activities in medicine are all to be subsumed under the heading of scientific theory and practice on the one hand, and that of purely empirical and traditional arts on the other. However, in the primary and essential process of eliciting what we call the history of an illness, our activities do not come within any of these categories. We are in fact seeking to collect a record of past events that for us are not sense data, but things that have happened not under our eyes; things that, more often than not, we cannot submit to any process of scientific verification. This record we proceed to subject to a process of critical thought. From its items we select, discard, and assemble in the light of our previous experience; and the final product of our activity is the sublimation of a certain kind of evidence from one source and of a critical study of it from another. Also, since the evidence we thus collect includes not only events that have happened to the patient but, in addition, actions that he has performed, there appears a new element not encountered in natural science—namely, human action. Between a simple event and a human action a distinction has to be made. In short, what we call "the history" in clinical medicine is not a mere chronicle of events, subjected to no analysis or interpretation, but it is a true exercise in historical method, as I shall seek to define this. This is not yet to assert that we are historians in the sense commonly understood by historians, but that we are using their method, which is not the method of natural science.

Distinction Between Natural and Historical Science

Let me briefly elaborate the distinction that I wish to make between natural and historical science, but although I begin from Collingwood's conception of history I shall allow myself the liberty of differing somewhat from him as to his application of this conception to psychological factors in medicine.

The prime method of natural science is the observation of events, the flux of which forms a moving spectacle before us, with such verifications and repetitions of this observation as sound factual conclusions may demand. Under the term "observation" I include the method of controlled experiment which Bacon has spoken of as "putting nature to the question." Having observed these events as particulars we then seek to determine the patterns and sequences in which they fall, and from these to make the generalizations that we speak of as laws of nature. The historian, on the other hand, is not concerned with events which he can only infer, nor does he seek to make generalizations, or to propound universals. He is concerned with events that lie in the past, though they may have their consequences in the present, which have not the quality of sense data as these are understood in natural science. His evidence is the written and archaeological record, to which he applies a critical judgment based on his experience, using those processes of selection and assembly that I have spoken of as of the essence of clinical history taking. To his final conclusion there go the same two elements that we have seen in the clinical history. In both historical science, as the historical expert conceives this, and in taking a clinical history there is a subject–object composition.

Now the historian regards his task as concerned not with simple events as such, but with events as determined by, and expressive of, human thought—that is, with human actions—and his quest is to uncover the motive forces which, for him, are the inside of the event. Events are not spectacles which he observes and seeks to classify, but something that he seeks to go behind so that he may uncover the human thoughts and motives, conscious and unconscious, that they express.

Collingwood gives a simple example that may make this distinction clearer to those who are not familiar with it. He says, "When a scientist asks, 'Why did that piece of litmus paper turn pink?' he means, 'On what occasions do pieces of litmus paper turn pink?' When a historian asks, 'Why did Brutus stab Caesar?' he means, 'What did Brutus think which made him decide to stab Caesar?' The cause of the event for him means the thought in the mind of the person by whose agency the event came about: and this is not something other than the event, it is the inside of the event itself."

It is the function of the natural scientist to ask the first kind of question, but that of the historian to ask the second kind; and, having asked it, he does not proceed to formulate general laws or to indulge in predictions, and in this also he differs from the natural scientist.

The True Historical Method

We come now to consider the relevance of all this to medicine. It is clear that the historian does not regard sequences or patterns of simple events as part of the historical process as he conceives this. Therefore, much of what we elicit and interpret in the taking of a "clinical history" is not history in this general sense, though, I submit, the method we have used is in fact the true historical method.

Yet, as every physician knows from his experience, the elements of "event" and of "human action" do enter into the development and behaviour of bodily illness: there is action and reaction between mind and body, and both contribute to the sum which is presented for elucidation. This is true not only of what I shall continue to call the "history" of the illness, it is true also of the clinical picture presented to our direct observation. I submit, therefore, that even in the apparently and exclusively somatic illness we cannot confine ourselves wholly to the methods of natural science but must take account also of the historical method. Further, owing to the common incompleteness of the data of observation presented to us, we have to read them in the context of the clinical history. Thus the methods of natural and of historical science are closely interwoven in our activities.

Every physician, and especially every teacher of medicine, knows that what is called "history taking" is a task calling for experience and critical thinking, and that it cannot be learned with the ease to which the techniques of clinical examination often lend themselves. This is in

*The Linacre Lecture was delivered in the Hall of St. John's College, Cambridge, on June 9, 1950.

accord with what, following Collingwood, we have said of the nature of historical evidence, and of its criticism, selection, and assembly in the writing of history : a complex intellectual exercise in which the evidence is given life and meaning by the historian's own contribution of thought and knowledge. Therefore, we need not be surprised that the young student so often gives us those flat and incoherent chronicles, thickly sown with irrelevances, that are too frequently allowed to pass muster as medical histories.

History and Psychology

It is when we come to consider psychological medicine, and what we may term psychologically determined illness, that the analogy between medicine and history leaps to the eye. Here, I submit, we are truly within the realm of historical science as the historian strictly defines it. Psychology, or the science of human nature, as our eighteenth-century philosophers were wont to call it, has since their time sought assiduously to establish itself as a discipline within the field of the natural sciences, and has claimed to use their methods.

In the case of psychological medicine, or psychopathology, this claim has been eloquently stated by Bernard Hart in his Goulstonian Lectures of 1926. He regards the data of the psychologist in medicine as strictly comparable in character to those of natural science, and goes on to say that a scientific concept "must explain the observed facts, and must be capable of verification by repeated reference to experience and experiment." These postulates he clearly believes to be fulfilled in psychological medicine. Yet surely the aim of psychological medicine is the discerning and unravelling of the mental processes, conscious and unconscious, that lie behind the "observed facts," which are in their origin and nature merely derivative phenomena and of infinite variability and unpredictability. The essential data in psychology, as we find it in medicine, are the mental processes behind the façade of the so-called "observed facts." It is surely a *non sequitur* to invoke the canons of natural science in this situation. The postulates propounded by Hart are not, and cannot be, fulfilled by psychological medicine, and it is meaningless to speak of "verification by repeated reference to experience and experiment" in this connexion. Elsewhere in the lecture he says that "the introduction of purpose removes psychology from the mechanistic sciences, but this does not justify its removal from the whole field of science." Here Hart seems almost trembling on the brink of awareness that psychology does not belong to natural science. However, he goes on to place it with biology. Yet the word "purpose" is not unequivocal, for teleology in biology is not the "purpose" that determines human actions. Such are the pitfalls of linguistics.

It is of course virtually impossible to generalize about psychology as we find it in medicine to-day, because it has no unity of method or of concept, and it continues to be regarded by its exponents as "scientific" in so loose and undefined a way that the adjective has no clear connotation. Nevertheless, countless expositions make it certain that it is natural science which the psychologist has in mind when he uses the term.

Of its possible relation to historical science we find no word in the superabundant writings on psychological medicine. Even that most lucid and philosophic critic of Freudian method, psychology, and philosophy, Maritain, in his attempt to assess and orient them, shows no realization of the possibility that much of the difficulty in determining their status would be resolved if they were measured against the standards and methods of history and not against those of natural science.

Yet how far removed from the methods of natural science are the Freudian psychology and philosophy Maritain indicates in the following verdict : "It is in the techniques of interpretation (that is, of dreams and free association), and especially in the use of symbolism, that Freud and his disciples have been led to the profusion of the arbitrary, of obsessional dogmatism, and of pedantry."

Even in the latest review of the development of psychological medicine by Rickman it is stated that the unravelling of the meaning of dreams is "the main tool of research," and the concepts derived from the use of this tool are spoken of as within the realm of "scientific thought," though what order of science we are not told.

An Illusion

For any who may still cherish the illusion that Freudian psychology has any discoverable relation to natural science in its methods or concepts, a careful reading of Rickman's article, "The Development of Psychological Medicine," should prove an effective remedy.

The fact surely is that the psychologist in medicine is not primarily concerned with events, nor does he use the sense data that are the material of natural science, but his first concern is the application, more or less imperfect, of the historical method to the fragmentary and fugitive records of human thinking and action which he can glimpse in his patient's mental past. It is upon this application that all depends.

The springs of human action which are his quest are not data of observation amenable to experimental control or classification. If they are to be revealed at all it is only by the method of historical thinking in which the inquirer collects his record of evidence, subjects it to critical assessment and selective assembly, and then formulates conclusions that have the duality of origin I have already proposed for the ordinary clinical history.

In this process he aims to understand the mental activities underlying the concrete situation he is studying, and he can do this effectually only by rethinking or reliving these activities in his mind and in the context of his own knowledge. The medical psychologist's problem is a concrete historical one and does not and cannot lead to the formulations of universals, for there is no blue print, no master key, to the springs of human thoughts and actions, applicable to all persons at all times and in all circumstances, and no natural laws for the human mind as natural laws are generally conceived.

We may therefore conclude that the steady endeavour of two centuries to fit psychology within the realm of the natural sciences is based upon a false analogy, to which the very term "human nature" lends colour. This analogy has gravely retarded the growth of a true science of psychology under the aegis of history.

In medicine the easy illusion that they are natural scientists, using the methods of natural science, has not saved medical psychologists from wandering within a labyrinth of conflicting speculations and methods, blown about by every wind of doctrine ; from exotic symbolist systems on the one hand to extremes of anti-intellectualism on the other, and through the latter to a new psychiatry which in effect dementalizes mind and seeks to account for its activities in terms of "nerve nets," "reverberating circuits," and "feedback mechanisms" in the cerebral cortex—that is, to provide physiological accounts of mental activities and in so doing to leave no room for psychology.

Wanderings of Psychological Medicine

This constant wavering of psychological theory in medicine between allegory and machinery, and of psychological practice between the exegesis of dreams and what in a barbarous neologism is called "psycho-surgery," does not allow a resting-place for the psychology of the modern psychiatrist within the confines of any known scientific discipline. It has become a chaos of conflicting allegorical systems, of pseudomysticism, and of "hit or miss" mutilations of the brain that have no ascertained scientific basis.

Surely, in such a situation, the claim to come within the realm of natural science is revealed as no more than the overt expression of unconscious yearnings to acquire some sort of academic prestige within the world of ordered knowledge. These wanderings of psychological medicine in the wilderness, not yet ended, always recall to my mind the title of one of Captain Marryat's stories for boys, *Japhet in Search of a Father*.

Yet, despite this profoundly unsatisfactory situation, there are of course sage medical psychologists who do use the historical method in its strictness, though they may not know it for such. When these men do turn to physical methods of treatment they remain fully aware that these have no scientific basis, but are wholly empirical procedures acting in unknown fashion but having the possibilities of pragmatic justification in particular instances. Nevertheless, it is surely clear that the hope of an advance towards coherence and scientific status for psychological medicine would be immeasurably increased if its exponents thought out the nature of their subject and became aware of the scientific discipline to which it should be affiliated—that of historical science.

If there be a body of psychological knowledge within the bounds of natural science it is that physiological psychology which has sense data to observe and classify in the forms of nervous and muscular activity which are the physical expression of current mental causes. Of such a physiological psychology there is a distinguished school in this university, but its aims, methods, and results in no way resemble those of the so-called medical psychology which shares with it little but the substantive common to their names.

It would be over-sanguine to look for a ready assent from the psychologist in medicine to a proposition so contrary to all he has hitherto believed regarding the nature of his activities and their place in the body of science. Yet it may be that the moment will arrive in which he is found willing to turn to some epistemological contemplation of his special body of knowledge and theory. The need is surely urgent, for there is a place for a scientific psychology in medicine under the aegis of historical science, a discipline as worthy of our esteem as that of natural science. To seek to remove psychological medicine from the one domain to the other is not to derogate from its status and importance.

Yet the historical method has its own ideals of truth ; and the realization of these is not compatible with intellectual submission to fixed symbolic systems in the interpretation of human action. Such lesser loyalties have no place in any scientific discipline, and with their advent there creep in, as attendant evils, myth and pseudomysticism, an obsessional dogmatism, and a sacerdotalism of outlook that have always been the greatest enemies of science.

The medical psychologist must be elective if he is to preserve his intellectual freedom and integrity, and in the interpretation of human records which are the essential data of his study his own knowledge and critical insight must be the dominant instruments.

A Dissent

Before I leave this subject I venture to make one dissent from Collingwood's view of the proper task of psychology. He says : "In realizing its own rationality mind also realizes the presence in itself of elements that are not rational. . . . These irrational elements are the subject matter of psychology. They are the blind forces and activities in us that are part of human life as it consciously experiences itself, but are not parts of the historical process : sensation as distinct from thought, feelings as distinct from conceptions, appetite as distinct from will. Their importance to us consists in the fact that they form the proximate environment in which our reason lives, as our physiological organism is the proximate environment in which they live. They are the basis of our rational life, though no part of it. Our reason discovers them, but in studying them it is not studying itself."

Yet surely reason does not work in an emotional vacuum, and in studying human actions it is impossible to separate, save by the process of abstraction, the emotional from the rational elements in our actions and their motive forces. And if history is the study of the concrete, this abstraction cannot be made save for purposes of discourse and logical analysis. I venture to submit, therefore, that we cannot regard psychology as concerned solely with the irrational in us, or allow that the latter is not involved in the historical process which it is the psychologist's business to study.

Conclusion

I believe, then, that history and natural science are recurrent themes, closely interwoven in medicine, not always recognized by us as such as we pursue our activities, but always present. I believe, too, that we shall think more clearly if we know that this is so.

At least those of us who teach medicine, and bear responsibility for the future of medicine, should have some awareness of the nature of our subject. In his book, *The Idea of the Universe*, Collingwood, whom I have quoted so often, observes that "a man who has never reflected upon the principles of his work has not achieved a grown-up man's attitude towards it ; a scientist who has never philosophized about his science can never be more than a second-hand, imitative journeyman scientist. A man who has never enjoyed a certain type of experience cannot reflect upon it."

These thoughts must be my justification for the excursion I have made this afternoon upon territory which the physician will enter with diffidence and tread with circumspection, yet the physician is the man best placed to reflect upon his experience and to philosophize upon it.

This foundation of Linacre's has seemed to me an admirable opportunity for such reflection, and I venture to think that he might not altogether disapprove the intention which informs my lecture, though he might well have thought less highly of its realization.

In conclusion, although the occasion that calls us together is not the only Foundation we owe to Linacre's concern for the advancement of medicine, it is the only one which has been consistently devoted to humanist and academic themes and ends.

To use the brief recurrent occasions which this lecture affords us amidst the press of material preoccupations in order to dwell upon these values and purposes is not mere escapism. It should be refreshment.

Doubtless the cynic will think and say otherwise, but cynicism is too often only the threadbare cloak for timidity in the face of threats to our traditional values. The idealist, as he looks at the world around him, which he has so little

share in moulding, need not feel ashamed if he continues to cherish and to advocate his ideals.

Only such an ideal of humanism as I have sketched, with its emphasis upon practical wisdom, and such reflections upon the nature of our activities as I have so imperfectly put before you, can save the loss of our traditional values and keep us aware of the nature of what we are thinking and doing. Yet, whatever be true of the latter, there can be no doubting that the practice of medicine flourishes most when doctors think most highly of their functions; when they remember that prudence governs the employment of science, and that in the last resort they are concerned with the ultimate particular thing, the human person, whom science by itself is inadequate to comprehend.

INSULIN-INDUCED SKELETAL ABNORMALITIES IN DEVELOPING CHICKENS*

BY

P. K. DURAISWAMI, M.S., M.Ch.Orth., F.R.C.S.
Research Fellow, Department of Orthopaedic Surgery, University of Liverpool

According to C. S. Stockard (1912) developmental anomalies of various types and degrees cause "the death of about 23% of the human race before or shortly after the time of birth and handicap(s) a certain proportion of the survivors throughout their lives." During the last few decades the discovery of genetic factors leading to malformations has attracted a great deal of attention, while research in the field of environmental teratogenic factors has lagged behind.

There exists a widespread belief among laymen as well as among physicians that single and multiple congenital malformations are always the result of changes in the germplasm—in other words, they are genetically determined and hereditary. I do not, for a moment, minimize the role of genetic factors in the causation of congenital anomalies, but it has been shown in recent years that developmental processes can be altered by environmental disturbances as well as by abnormal genes. It will be of great interest to the geneticist to know that types of congenital malformations which are sometimes genetically determined, such as microphthalmos, cleft palate, and certain skeletal abnormalities, can be produced in the offspring not only by maternal nutritional deficiencies and by roentgen irradiation, but also, at least in some animals, by the deliberate introduction of certain substances during embryonic growth.

New momentum to this line of thought has been given by the valuable epidemiological observations first made by Gregg in Australia in 1941. Since then evidence has accumulated that the contraction of rubella by the mother early in pregnancy is related to the development of congenital anomalies like cataract, heart disease, and deafmutism in the offspring. This has naturally raised the question whether other infectious diseases, particularly those due to a virus, such as mumps, measles, and chickenpox, may cause similar defects. It may easily be that the more severe infectious diseases contracted during pregnancy are prone to result in abortion or miscarriage, whereas comparatively milder ones like rubella can give rise to congenital anomalies in the foetus without jeopardizing its life.

In 1943, while investigating the role of glycogen granules in hypertrophic cartilage cells during endochondral ossification, I made an accidental observation as a result of which I became interested in the insulin-induced skeletal abnormalities in developing chick embryos. In the course of a series of experiments I introduced 5 units of insulin into hens' eggs at various intervals after the beginning of incubation and noticed that some of the chicks showed *x*-ray appearances resembling osteogenesis imperfecta in the human, that some had developed abnormalities of the spinal column like spina bifida, with partial or complete suppression of development of some vertebrae, while others showed deformities in the limbs. I have observed that "synthalin," too, can induce certain skeletal deformities when injected in the same way, and an account of these deformities will be given in a separate paper. Unfortunately my investigations were interrupted during the war, and for one reason or another I could not renew my experimental work until I came to Liverpool in October, 1947.

Material and Method

My experiments have been conducted mostly with eggs from brown leghorn matings. I have used a simple apparatus not only for testing the fertility of an egg before injection but also for transilluminating it while drilling a hole into the shell and injecting into the yolk. In this way I have avoided injuring the embryo and the chorionic blood vessels. A fine dental drill held in a small chuck has been used to make a hole in the egg-shell, which has been sterilized with spirit. A tuberculin syringe fitted with the finest hypodermic needle ¼ in. (1.9 cm.) long has been found most suitable for making the injections. This length of needle enables one to inject into the yolk.

In my experiments I have used crystalline insulin dissolved in distilled water and made up to a strength of 40 units in each millilitre. The doses given varied from 0.05 to 6 units at different intervals after the beginning of incubation. Calculated on the basis of the human dose, 6 units to a developing chick embryo may appear to be distinctly excessive. But Riddle (1923) and others have shown that birds are highly resistant to insulin and can therefore survive a dose of insulin 30 times as strong as that which would kill a rabbit. Whenever the volume of the solution injected has exceeded 0.05 ml. an additional hole has been drilled into the egg-shell in the region of the air sac in order to prevent undue increase of pressure inside the egg. I should perhaps make it perfectly clear, at this stage, that only one injection of insulin is given into the egg, and no more either during the remaining period of incubation or after hatching.

After making the injection the needle is carefully removed without injuring the embryo or the chorionic blood vessels, and the holes are sealed and the egg returned to the incubator. By the same technique control eggs have been injected with the same quantities of physiological saline and incubated in the same incubator. Embryos have been removed at varying intervals before hatching for histological and other investigations. All chicks which survived 14 days after the beginning of incubation and those that hatched out alive either by themselves or with help, as in the case of deformed ones, have been *x*-rayed. All the live chickens, insulin-treated as well as the controls, have been fed on a nutritious diet rich in vitamins and reared under conditions equal in every way. It should be noted here that nearly all the insulin-treated chickens are smaller and more delicate than the controls, so that they have to be reared with special care.

*Based on a paper read at the Liverpool Medical Institution on January 19, 1950.

Observations

I do not propose to enter here into a detailed discussion on the histological, biochemical, and other aspects of the problem, which will be dealt with later, but rather to give a preliminary survey of the more important observations that have so far been made.

Insulin-induced Skeletal Abnormalities

Day of Injection after Starting of Incubation	Part of Body *Primarily* Affected by Insulin
0–2nd day	Vertebral column
3rd day	Claws
4th and 5th days	Limbs; beak
6th day	Hip (congenital dislocation of hip)
3rd to 6th days (high doses of insulin)	Generalized developmental disturbance of bone resembling osteogenesis imperfecta

FIG. 2.—Spina bifida in an embryo treated with insulin 24 hours after incubation and removed from the shell alive on the 20th day of incubation.

Broadly speaking, insulin seems to affect primarily the part or organ which is in the most active stage of development or differentiation at the time of injection, though the growth of the embryo as a whole is retarded to a degree varying with the dose of insulin. The accompanying Table and Fig. 1 give some idea of the type of deformity that has been induced by insulin in relation to the time of injection after the starting of incubation of the egg. If it is remembered that during the development of the limb bud it is the distal part that first shoots out, as it were, from the side of the trunk, then it is easy

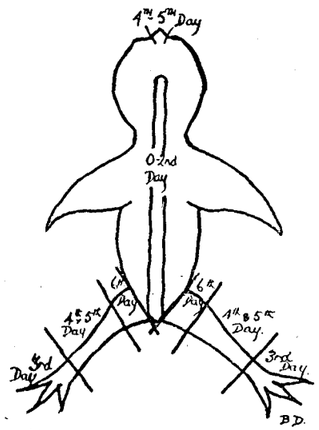

FIG. 1.—Diagram illustrating the type of deformity induced by insulin in relation to the time of injection into the egg after incubation.

FIG. 3.—Divarication of claws. Note the arched upper beak ("parrot beak"). (20-day-old embryo treated with insulin on the third day of incubation.)

FIG. 4.—Adduction deformity of the claws resembling clubfoot in a 20-day-old embryo treated with insulin on the third day of incubation.

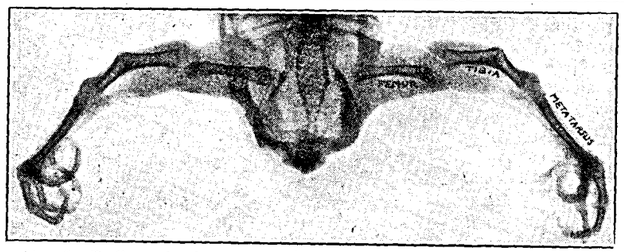

FIG. 5.—Radiograph of a 3-weeks-old chicken with bilateral dislocation of the knee. Note the pathological fractures of both tibiae and the marked buttressing of the concavities of the bowed bones by subperiosteal new bone. (Injection of insulin into the egg on the fourth day.)

to understand the significance of Fig. 1. Within the range of 0.05 to 6 units of insulin that I have injected, both the incidence and the severity of the deformities seem to increase with the dose of the hormone. Figs. 2–11 illustrate the various abnormalities, with appropriate controls for comparison. A generalized developmental disturbance of bone resembling osteogenesis imperfecta has been induced by injecting high doses of insulin between the third and the sixth day of incubation.

FIG. 6.—Deformity of the limbs as seen in arthrogryposis in a 20-day-old embryo treated with insulin on the fifth day. Note the "parrot beak."

Ossification in the Chick

As the process of ossification in the long bones of birds differs in certain essential respects from that of mammals, it is necessary to outline briefly the normal process of ossification in the chick before considering the abnormalities in ossification induced by insulin. Ossification of a long bone in the chick comprises the following four stages :

1. *Formation of Perichondral (Periosteal) Bone.*—The perichondrium deposits a layer of bone on the surface of the cartilage near its centre, thus forming a bony ring, which gradually lengthens into a hollow cylinder by extending towards the ends of the cartilage. This is illustrated in Fig. 12. The perichondral bone is naturally thickest in the centre of the shaft and tapers towards the extremity of the cartilages.

2. *Absorption of Cartilage.*—The matrix softens in the centre of the shaft, and the cartilage is replaced by the fundamental tissue of the marrow. This process extends towards the ends and is faster in the region of the cartilage subjacent to the perichondral bone than in the centre. In this way there remain two terminal cone-shaped cartilages, and the ends of the cones project into the marrow cavity.

3. *Calcification of Cartilage.*—Salts of lime are deposited in the matrix of the cartilage at the ends of the marrow cavity.

4. *Endochondral Ossification.*—Osteoblasts within the marrow cavity deposit bone on the inner surface of the perichondral bone.

It is worthy of note that in birds there is no independent epiphysial centre of ossification in the long bones such as exists in mammals. The ends of the bones remain cartilaginous and provide for growth in length. Growth in diameter of the bones takes place from the periosteum, and is accompanied by enlargement of the marrow cavity owing to simultaneous absorption of bone from within. It is thus obvious that in time all the endochondral bone is removed from the shaft, though some may remain in the spongy ends.

FIG. 7.—Generalized developmental disturbance of bone resembling the "prenatal type" of osteogenesis imperfecta with marked stunting in growth (compare with Fig. 8 on the same scale). Note the deformities of the limbs and beak. (20-day-old embryo treated with a high dose (5 units) of insulin on the fifth day of incubation.)

Effect of Insulin on Ossification

We may now see how insulin interferes with the normal process of ossification by comparing the photographs of

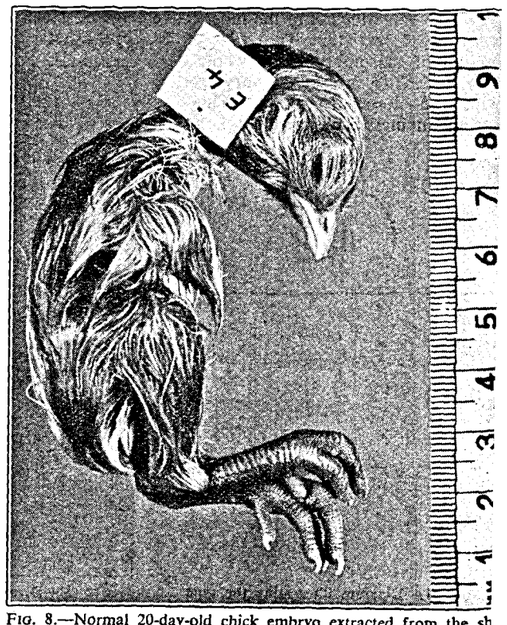

FIG. 8.—Normal 20-day-old chick embryo extracted from the sh before hatching.

FIG. 9.—Radiograph of the skeleton of the same embryo as in Fig. 7 (× 2). Note the deformities of the various bones due to pathological fracture and bending (mollities). Observe the defective ossification and also lack of development of several vertebrae in the distal part of the vertebral column.

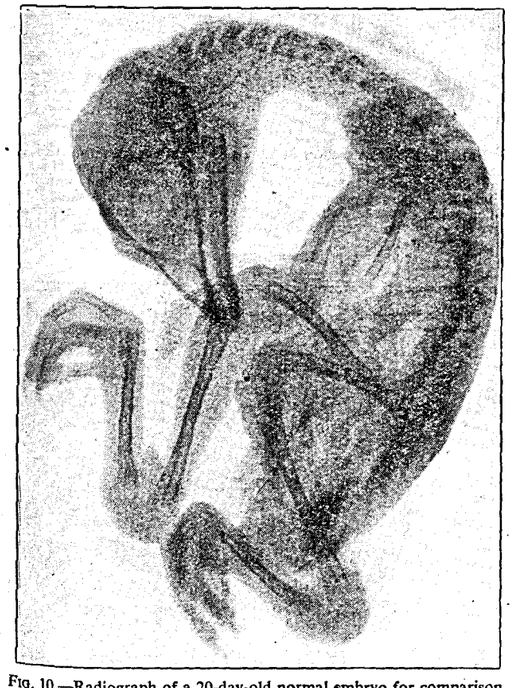

FIG. 10.—Radiograph of a 20-day-old normal embryo for comparison with Fig. 9.

enlarged mid-sagittal sections of the tibiae taken from insulin-treated and normal chick embryos of corresponding ages. The possible mechanism of action of insulin is discussed below.

Fig. 13 shows a mid-sagittal section of the tibia from a 20-day-old insulin-treated embryo, and Fig. 12 represents a mid-sagittal section of the proximal half of the tibia from a 20-day-old control embryo for comparison. The special features to be noted in the case of the insulin-treated one are the deformity, the pathological fracture, the stunted growth, and the lack of subperichondral ossification as compared with the corresponding control. Fig. 7 is a photograph of a 20-day-old excessively stunted chick embryo, showing evidence of a generalized developmental disturbance of bone resembling osteogenesis imperfecta ("prenatal type"), while Fig. 9 is a radiograph of the same embryo showing the various deformed bones and pathological fractures.

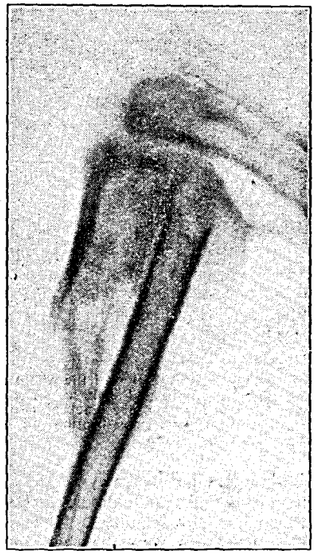

FIG. 11.—Radiograph of pathological fracture of the left tibia in a 5-months-old cockerel with insulin-induced osteogenesis imperfecta (resembling "post-natal type").

The occurrence of a pathological fracture at the distal third of the tibia has been noted with great regularity in such chicks. It may be recalled that this is the favourite site for pseudarthrosis in children. Fig. 11 shows the radiograph of a pathological fracture of the left tibia in a 5-months-old cockerel with insulin-induced osteogenesis imperfecta ("post-natal type").

Deformities of the Beak and other Malformations

A highly arched upper beak was often associated with the limb deformities, and, much less commonly, a short upper beak and crossing of the beaks were observed. Apart from the skeletal abnormalities, I have noticed only

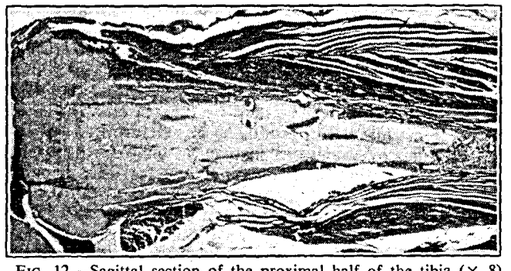

FIG. 12.—Sagittal section of the proximal half of the tibia (× 8) of a normal 20-day-old embryo stained with haematoxylin and eosin. Note that the subperichondral bone is thickest in the centre and tapers towards the extremities. (The perichondrium, together with the subperichondral bone, was partially detached from the proximal cone-shaped cartilage of the tibia during preparation of the section.)

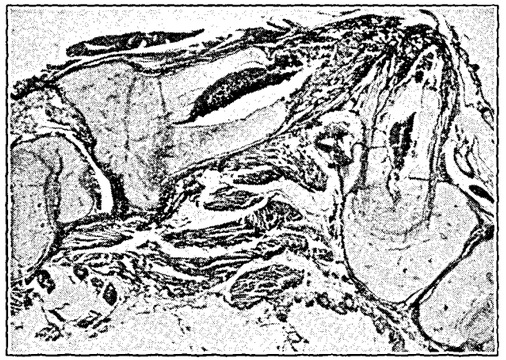

FIG. 13.—Sagittal section of the whole of the tibia (× 7.5) from a 20-day-old insulin-treated embryo. The pathological fracture, the deformity of the tibia, the thickening of the periosteum, and the defective subperiosteal ossification all suggest the condition of osteogenesis imperfecta.

certain anomalies of the eyes such as anophthalmos, microphthalmos, and buphthalmos, the last-named almost always accompanied by blindness. It is interesting to note that all the malformations that have been induced by insulin in my experiments so far have been confined to the skeleton and the eyes. The reasons for this selective action of insulin are given below.

Discussion

The question naturally arises whether these deformities are due to the trauma caused by the injection or to any specific action of insulin. Saline in quantities very much larger than the volumes of insulin solution has been injected into hundreds of control eggs and no deformities have resulted; and injections of parathormone (up to 5 units), calciferol (up to 2,000 i.u.), and radioactive phosphorus (up to 20 microcuries) have been made, also without any resulting deformities. Insulin inactivated by the methyl-alcohol-hydrochloric method of Charles and Scott (1931) has been injected and no deformities have appeared, whereas, when inactivated insulin was reactivated by alkali and then injected the deformities have occurred. I am satisfied, therefore, that the possible trauma of injection is not a factor in causing the abnormalities and that insulin has, in fact, a very specific effect.

There are further reasons for holding this view on the specificity of insulin. Insulin, if injected during the first week of incubation, produces a definite hypoglycaemia which persists till about the twelfth day of incubation (blood sugar estimated by the Hagedorn–Jensen method). Insulin-treated embryos which survive seem to recover normal blood-sugar levels from their own resources between the twelfth and the fourteenth day after the beginning of incubation. This may be the reason why I have so far not succeeded in producing any deformity by injecting even up to 6 units of insulin on or after the twelfth day of incubation. The explanation for this apparent discrepancy may very well lie in the experimental observations made by Idzumi (1924), Murray (1926), and Potvin and Aron (1927), indicating that the embryonic liver in the chick begins to store glycogen in appreciable quantities on or about the eleventh day of incubation, and it is only thereafter that the carbohydrate metabolism is controlled by interaction of the various hormones concerned. Presumably this unchecked insulin hypoglycaemia until about the twelfth day of incubation could result in damage to embryonic cells which, according to Needham (1926), almost exclusively metabolize glucose during the early developmental stage of the embryo. It is generally recognized that insulin enables the tissues to utilize glucose, but, if the

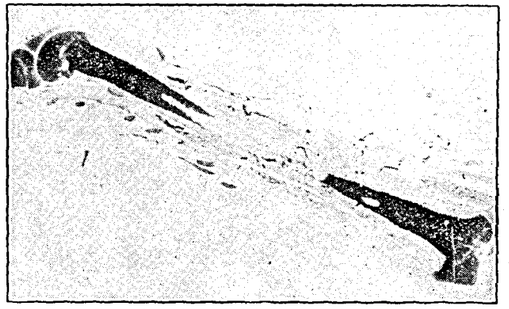

FIG. 14.—Sagittal section of tibia (× 7) of a normal 12-day-old embryo stained with toluidine blue. The cartilaginous core of the tibia has been stained deeply by this selective stain, whereas all the rest of the tissues in the section, including subperichondral bone, appear faintly tinted. The unstained area between the cones of cartilage in the middle of the bone represents the newly forming marrow cavity.

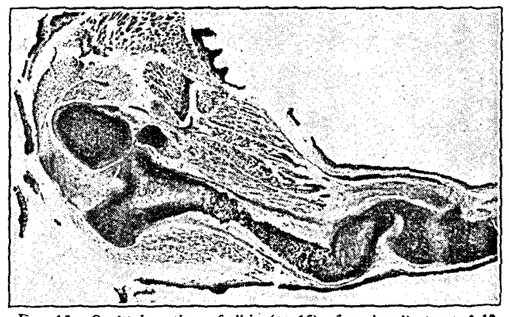

FIG. 15.—Sagittal section of tibia (× 15) of an insulin-treated 12-day-old embryo stained with toluidine blue. Note the marked stunting and deformity of the tibia as compared with the normal in Fig. 14. There is no marrow cavity, the whole sagittal section being filled with cartilage, which has, however, been stained much less intensely by the specific stain owing to poor chondroitin-sulphuric acid content in cartilage cells, many of which show degenerative changes as seen in Figs. 18 and 19.

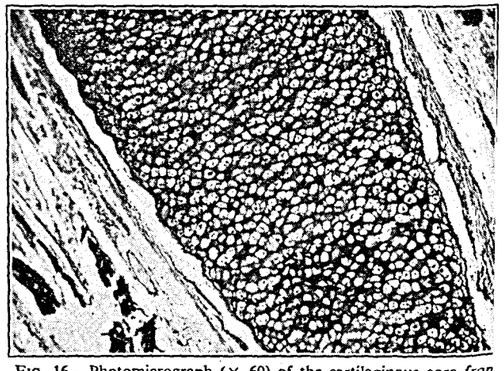

FIG. 16.—Photomicrograph (× 60) of the cartilaginous core from the tibia of a normal 10-day-old embryo stained with toluidine blue Cartilage cells are stained deeply by this special stain and appea normal.

FIG. 17.—Same as Fig. 16 (× 450).

FIG. 18.—Photomicrograph (× 60) of the cartilaginous core from the tibia of an insulin-treated 10-day-old embryo stained with toluidine blue. Note the moth-eaten appearance of the cartilaginous core and the debris of disintegrating nuclei of degenerated cells.

FIG. 19.—Same as Fig. 18 (× 450).

blood sugar is persistently low and glycogen is not stored in the liver during the early stages of development, then it is easy to understand how cellular metabolism will continue to be abnormal as long as the hypoglycaemia lasts.

Needham (1926) has also observed that in the early stages of development in the chick there is a larger proportion of glucose not accounted for by glycogen or free glucose than at any other time. According to him this combined glucose is probably a "mucoprotein glucose," and its importance in the early stages may be correlated with the primitive gelatinous intercellular matrix in which embryonic cells at that time grow and migrate. It is known that cartilage and parts of the eye such as the cornea, vitreous humour, and the sclera, which has a special inner layer of hyaline cartilage in birds, are all rich in substances of the mucoprotein (glycoprotein) type, and it is significant that the insulin-induced abnormalities that I have observed so far have been confined to the skeleton and the eyes.

With a view to the investigation of the effect of insulin treatment on the mucoprotein content of developing cartilage I have employed Lison's histochemical technique for localizing the chondromucoid, which contains chondroitin sulphuric acid, by staining with a basic metachromatic aniline dye such as toluidine blue. Lison (1935) has presented evidence that the metachromatic reaction is specific for chondroitin-sulphuric acid, the affinity of which for the dye is so great that even in very high dilutions (approximately 1 in 250,000) the chondromucoid is stained deeply while the other tissues are faintly tinted by the dye. The contrast between the arresting red-violet of the chondroitin-sulphuric acid and the faint blue colour of the surrounding tissues facilitates a comparative analysis of the distribution and the amount of the chondroitin-sulphuric acid in the cartilaginous skeletons of the insulin-treated and control chick embryos of corresponding ages.

By employing this technique I have observed that there is not only very marked stunting of the cartilaginous skeleton in the insulin-treated chick embryos as compared with the controls, but also the cartilage cells in the former show varying degrees of degeneration and exhibit less affinity for the dye owing to a low chondroitin-sulphuric acid content (Figs. 14–19). It is suggested that such degenerative changes in the cartilaginous skeleton may be followed by deformities, defective ossification, and pathological fractures which may be caused by the vigorous embryonic movements that can be observed from an early period of development, and thus may eventually result in a condition resembling osteogenesis imperfecta.

As mentioned at the beginning of this paper, several nutritional deficiencies have been shown to give rise to congenital malformations. Ivanovsky (1923), in a report on the physical modifications of the population of Russia under famine, remarks: "The number of children either prematurely born or stillborn, monsters, and children with different anomalies considerably increased during the famine." In India and Japan stillbirths, premature deliveries, and congenital malformations have often been reported to be the result of maternal vitamin-B deficiency. Byerly and his co-workers (1935) obtained short-legged embryos from eggs of chickens on a deficiency diet whose effects were reversed by wheat-germ, liver, and whey. Romanoff and Bauernfeind (1942) demonstrated that riboflavin deficiency gave rise to short-legged embryos. Couch and his co-workers (1948) obtained similar abnormalities with eggs from biotin-deficient hens.

It was reported by Warkany and Nelson (1940) that female rats reared and bred on a diet deficient in riboflavin gave birth to offspring a third of which had congenital skeletal abnormalities. The malformations consisted of shortening of the mandible, tibia, fibula, radius, and ulna. Histological examinations revealed that not only osseous but also cartilaginous and pre-cartilaginous structures were deformed in a manner similar to the insulin-induced deformities. It is interesting to note that the tibiae were affected in a high proportion of the deformed offspring as in the case of insulin-induced skeletal deformities. When riboflavin was added to the maternal diet no abnormal young rats were obtained. This new knowledge in the field of nutrition deserves special attention, since it demonstrates the effect of vitamin deficiencies upon the earliest processes of growth and differentiation.

It is well known that the yellow enzyme (containing riboflavin), coenzyme I, and coenzyme II (containing nicotinamide) participate in the breakdown of carbohydrates in the tissues. Spratt (1949) has presented experimental evidence for the existence of the typical phosphorylating system in the early chick embryo. One can therefore anticipate that deficiency of phosphorylating enzymes, produced by lack of vitamin-B complex, may induce malformations in the same way as insulin hypoglycaemia can,

by causing disturbances to cellular carbohydrate metabolism at critical periods during development. Further, I have experimental proof that insulin-induced deformities can be prevented to a remarkable extent by injecting nicotinamide and riboflavin into eggs along with insulin, and details of this work will be given in another paper dealing with the preventive aspect of the problem.

Summary

Though genetic factors play an important part in the causation of congenital anomalies, it has been shown in recent years that certain environmental factors can interfere with the normal developmental processes in the embryo.

An account of the skeletal abnormalities induced by insulin has been given.

It has been suggested that unchecked insulin hypoglycaemia during the early stages of development may adversely affect the development of the cartilaginous skeleton and of the eyes by depriving them of their essential constituent mucoprotein to varying degrees.

This experimental research has been conducted in the Department of Orthopaedic Surgery, University of Liverpool, with the aid of a scholarship granted by the Government of India till October, 1949, and thereafter with a Fellowship awarded by the University of Liverpool, and my grateful acknowledgments are extended to them. I wish to thank Mr. Bryan McFarland, director of orthopaedic studies, and his assistant, Mr. G. V. Osborne, for providing the facilities for carrying out this research; Sir Edward and Lady Mellanby for their helpful criticism; Dr. C. A. St. Hill and Miss M. Lichfield for the histological sections; Mr. W. Lee for the photographs and photomicrographs; Miss B. Duckworth for the drawing; and Burroughs Wellcome Ltd. for a supply of crystalline insulin.

The booklet *Notes on the Diagnosis of Occupational Diseases Prescribed under the National Insurance (Industrial Injuries) Act* is now obtainable by medical practitioners from H.M.S.O. or through any bookseller for 1s. 6d. An earlier edition was issued in 1948 to those medical practitioners to whom claimants to industrial insurance benefit on account of prescribed occupational diseases were being referred for initial diagnosis. Notes on pneumoconiosis and byssinosis have now been added to the booklet.

MORTALITY FROM AND RISK OF GASTRIC CARCINOMA AMONG PATIENTS WITH PERNICIOUS ANAEMIA*

BY

JOHANNES MOSBECH, M.B., B.S.

AND

AAGE VIDEBAEK, M.D.

(From the Bispebjerg Hospital, Medical Department B, Copenhagen, and the University Institute of Human Genetics, Copenhagen)

The introduction of concentrated preparations of liver and stomach in the treatment of pernicious anaemia (Minot and Murphy, 1926) has changed completely the prognosis of this complaint. The disease, which previously had followed a capricious but usually rapidly fatal course, could now be kept under control, so that as a rule the patients enjoyed a long period of freedom from symptoms with full working capacity.

It is now possible, with more than 20 years' experience of this treatment, to evaluate the prognosis of the disease under the radically altered conditions. While studying for a different purpose a group of patients suffering from pernicious anaemia we arrived at results which differ in several respects from those previously reported and which we therefore feel justified in publishing.

Present Investigations

The series comprises a fairly large number of patients treated for pernicious anaemia at the Bispebjerg Hospital, Medical Department B, during the period 1928 to 1949. A few foreigners and provincials have been omitted. All the case records were reviewed and the diagnoses confirmed according to the following criteria: a characteristic clinical picture, typical blood findings (megalocytic, hyperchromic anaemia, anisocytosis, leucopenia, increase in reticulocytes following specific therapy), and achlorhydria refractory to histamine.

In cases in which the diagnosis had been made before admission to hospital, data regarding the earliest clinical

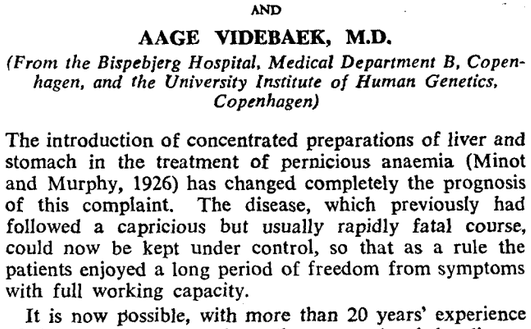

FIG. 1.—Age distribution of 219 females and 82 males suffering from pernicious anaemia. (Age when the disease was diagnosed.)

symptoms and blood findings were sought for confirmation. It was decided to leave out one case of megalocytic anaemia in a pregnant woman and two cases in which specific treatment was suspended at the recommendation of the department, since the blood findings were atypical; one of them has been symptom-free without treatment for 2½ years, but contact with the other has been lost.

Thus curtailed, the series comprises 301 patients—219 females (72.7%) and 82 males (27.3%). Fig. 1 shows the age of the patients when the diagnosis was made (average: females 59.1, males 56.4 years).

Table I groups the series according to the length of the follow-up period, and gives the number of deceased patients within each group.

TABLE I.—*Follow-up Period in 301 Cases of Pernicious Anaemia*

Follow-up Period (Years)	Females		Males	
	Cases	Deaths	Cases	Deaths
1–5	45	32	24	12
6–10 ..	72	26	22	9
11–15 ..	51	16	17	5
16–20 ..	39	7	13	5
21–25 ..	12	2	6	1
Total ..	219	83	82	32

Mortality Among Pernicious Anaemia Patients

The average follow-up period was 10.5 years (10.3 years for males and 10.7 for females), the study being concluded on June 1, 1949. By that time 83 of the 219 females and 32 of the 82 males had died.

On the basis of the mortality among the population of Copenhagen during the period 1935–9, it would be expected that, of 301 individuals of the same age and sex distribution and followed up for the same length of time as the patients with pernicious anaemia, 89 females and 28 males would die. It is evident from Table II that the actual findings are in perfect accordance with the expected deaths, and that in the present series the mortality did not exceed what is normal.

Males	32	28
Total	115	117

Prognosis

For the purpose of adjudging the actual prognosis in cases of pernicious anaemia the authors chose a follow-up period of 10 years, including in this group only those patients whose disease was diagnosed prior to 1940. This group comprises 222 patients (168 females and 54 males). A total of 51 females and 17 males died during the follow-up period. On the basis of the ordinary mortality it was calculated that, among a population of the same age and sex distribution as the 222 patients, 50 females and 13 males would be expected to die in the course of 10 years.

Figs. 2 and 3 show the survivors among the females and males, respectively, with pernicious anaemia followed up for a minimum of 10 years, and also the survivors among a population of the same age and sex distribution. It is clear from the diagrams that, so far as the females are concerned, the mortality of patients with treated pernicious anaemia is the same as that of the average population. The apparently high mortality among the males (Fig. 3) proves, upon statistical calculation, to be within the error of the mean, due perhaps to chance in this small series of males. In other words, in the present series the life expectancy among the female patients is the same as among normal females; in the case of the males there is a slightly higher, but not significantly excessive, mortality.

In contrast to these findings, Jörgensen (1949), in his series of 148 females and 58 males suffering from pernicious anaemia, found the mortality in the females to be 13% and in the males 107% above the normal. He is of the opinion that this high mortality is due entirely to inadequate treatment. The difference in his mortality rate from that of the present series may be due to the fact that our patients were treated largely with the same preparation ("exopylorin," medicinalco), whereas Jörgensen's patients had undergone various treatments. In addition, a large number of our patients have been examined at intervals for years because of the particular interest devoted to pernicious anaemia in the department.

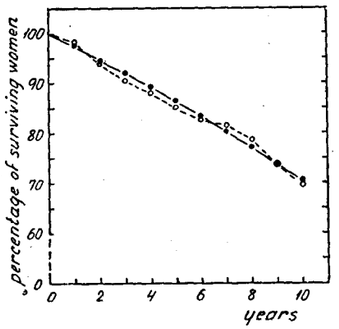

FIG. 2.—Percentage of survivors among 168 females suffering from pernicious anaemia (O- - -O) as compared with the calculated mortality among a corresponding population (●——●).

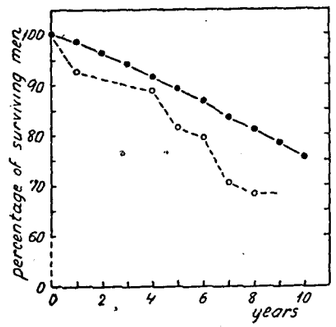

FIG. 3.—Percentage of survivors among 54 males suffering from pernicious anaemia (O- - -O) as compared with the calculated mortality among a corresponding population (●——●).

Causes of Death among Pernicious Anaemia Patients

Up to June 1, 1949, 115 (83 females and 32 males) out of the 301 patients had died. Table III shows the way in which the causes of death were ascertained.

TABLE III.—*Sources of the Cause of Death in 115 Cases of Pernicious Anaemia*

	Cause of Death Confirmed by		
	Case Record and Necropsy	Case Record Without Necropsy	Death Certificate
Females ..	13	36	34
Males	7	12	13
Total ..	20	48	47

Sixty-eight patients (49 females and 19 males) died in hospital. In the case of 13 females and 7 males the cause of death was confirmed by necropsy. Forty-seven patients died in their homes, and the cause of death was derived from the death certificates. In cases in which the latter mentioned carcinoma, further details regarding the diagnosis were obtained from the family doctor or the hospital department concerned.

*This investigation was supported by a grant from the Division of Research Grants and Fellowships of the National Institutes of Health, U.S. Public Health Service.

Total	83	32	115

The causes of death in the 115 cases of pernicious anaemia are listed in Table IV. Pernicious anaemia appears to have been the immediate cause of death in only the three cases given. Two of these patients were senile females who were admitted to hospital in a state of severe anaemia, and both were so debilitated that adequate therapy proved of no avail. The third patient refused treatment, and died in his home from severe anaemia a fortnight after discharge from hospital.

In this connexion it might be interesting to call attention to a study from the Simpson Memorial Institute published by Sturgis (1939). Analysing the causes of death in 150 cases of treated pernicious anaemia dying within the first 10 years after the introduction of liver therapy, he arrived at the result that half the patients died from anaemia (particularly myelopathic manifestations with sphincter disturbances) and the other half from irrelevant causes. In the present series myelopathic symptoms did not constitute the cause of death in any case.

Gastric Carcinoma in Pernicious Anaemia Patients

Thirteen females and eight males died from carcinoma (Table IV). On the basis of the mortality from carcinoma among the population of Copenhagen, 1935–9, it may be calculated that, among 301 individuals of the same age and sex distribution and followed up for the same length of time as the anaemic subjects, 6 males and 15 females would be expected to die from carcinoma (Table V). In

TABLE V.—*Number of Deaths From Carcinoma Among the Series of 301 Cases of Pernicious Anaemia as compared with the Number of Expected Cancer Deaths*

	No. of Patients	Deaths from Cancer	
		Actual	Expected
Females	219	13	15
Males	82	8	6
Total	301	21	21

other words, the mortality from carcinoma among the present series was not excessive.

It is striking that no fewer than 8 out of 83 females (10%) and 6 out of 32 males (19%) died from carcinoma of the stomach. In addition, the series includes a man who underwent operation for gastric carcinoma and who six months later is still surviving in a debilitated state. Details of the 15 cases of gastric carcinoma are given in Table VI.

Of the females, four died in hospital and were examined at necropsy, but microscopical examination was performed

TABLE VI.—*Fifteen Cases of Gastric Carcinoma Occurring Among 301 Patients Suffering From Pernicious Anaemia*

Case	Sex and Age	Duration of Pernicious Anaemia Before Gastric Carcinoma was Diagnosed (Years)	Site of Tumour in Stomach	Microscopical Examination
1	F 60	3	Ulcerated tumour occupying entire pyloric area (necropsy)	Papilliferous carcinoma
2	F 71	1	Large tumour occupying distal half of stomach (*x*-ray)	Not performed
3	F 72	2	Flat tumour, size of child's hand, on posterior wall of stomach, 6-7 cm. from pylorus (necropsy)	,, ,,
4	F 72	1	Firm and nodular tumour, size of goose's egg, occupying entire pyloric antrum (necropsy)	,, ,,
5	F 75	15	Entire pyloric area tapers into fine irregular canal (tumour of pylorus) (*x*-ray)	,, ,,
6	F 58	9	Irregular, large filling defects on middle of lesser curvature, reaching to and involving entire cardia (*x*-ray)	,, ,,
7	F 68	17	From fundus a large irregular filling defect extends 8–10 cm. into body (*x*-ray, operation)	,, ,,
8	F 68	4	Ulcerating carcinoma, size of an orange, on middle of lesser curvature (necropsy)	,, ,,
9	M 48	19	Nodular tumour, size of closed fist, on middle of lesser curvature (operation)	Adenocarcinoma
10	M 66	13	Circular carcinoma, size of closed fist, in area of pyloric antrum (operation)	Adenocarcinoma with solid areas
11	M 68	8	Diffuse infiltration of entire stomach (necropsy)	Solid, scirrhous, diffuse carcinoma
12	M 70	7	Firm tumour, size of half-crown, on middle of greater curvature (necropsy)	Adenocarcinoma
13	M 57	5	*X*-ray: pyloric tumour. Operation revealed cicatricial stenosis. Five years later entire stomach was involved in diffuse scirrhous infiltration (operation and *x*-ray)	Not performed
14	M 61	7	Circular constriction of middle area of body which shows irregular, sharp contours. Fundus and pylorus normal (*x*-ray)	,, ,,
15	M 57	14	Operation revealed an ulcerated tumour, size of palm of hand	Adenocarcinoma

in only one case. Four died in their homes, the diagnoses having been confirmed by characteristic *x*-ray findings, occult bleeding, and the clinical course of the disorder. So far as the males are concerned, histological verification was available from operation or necropsy specimens in five cases. In two cases the diagnoses were substantiated by typical *x*-ray findings. The age stated in the table refers to the age when the diagnosis of carcinoma was made, and, since the patients usually die from carcinoma within the first year (the longest interval in this series being 18 months), the age at diagnosis accords fairly well with the age at death.

All the patients were examined radiologically. Five (one female and four males) underwent operations; necropsy was performed in six instances (four females and two males).

On the average, pernicious anaemia was of eight years' standing (seven years for females and ten years for males) when gastric carcinoma was diagnosed, the average age when the carcinoma was diagnosed being 68 years for the eight females and 61 years for the seven males. This difference in age is not statistically significant, but in all probability it is real, since Jörgensen found a corresponding sex difference in his series.

On the basis of the ordinary mortality from gastric carcinoma among the population, corresponding as regards sex and age to the 301 cases of pernicious anaemia and followed up for the same length of time, it may be calculated that 3.5 females and 1.7 males should have died from

TABLE VII.—*Incidence of Gastric Carcinoma Among 301 Cases of Pernicious Anaemia as Compared with the Expected Incidence in a Corresponding Normal Population*

	No. of Patients	Cases of Gastric Carcinoma	
		Occurring	Expected
Females	219	8 (4%)	3·5 (1·6%)
Males	82	7 (9%)	1·7 (2·1%)
Total	301	15 (5%)	5·2 (1·7%)

gastric carcinoma at the end of the follow-up period. *Table VII* gives the cases of gastric carcinoma occurring in the present series as compared with the expected incidence.

The number of patients dying from gastric carcinoma in the present series has thus far exceeded the expected deaths. The difference is significant for females as well as for males. It strikes one that the increased incidence of gastric carcinoma does not involve a corresponding increase in the incidence of total carcinoma.

Previous workers (Jenner, 1939; Waldenström, 1945; Kaplan and Rigler, 1945, 1947; Bourne, 1948) have called attention to the particular predisposition to gastric carcinoma among patients suffering from pernicious anaemia. This finding was recently confirmed by Jörgensen, who emphasized that the increase in the incidence of gastric carcinoma among patients suffering from pernicious anaemia was more marked among males than among females, an observation which accords with the findings in the present series. It is difficult to explain this male preponderance. The data available in our series afforded no evidence that the male patients developing gastric carcinoma were alcohol addicts.

Attempts have been made to explain the high incidence of gastric carcinoma in association with pernicious anaemia as being the result of the pathological changes found in the stomach in the latter condition. It has been pointed out by Meulengracht (1939) that patients with pernicious anaemia are affected with atrophic gastritis, localized primarily to the fundal area, whereas the mucosa of the distal part of the stomach is comparatively intact. If this gastritis were the precursor of gastric carcinoma, such carcinoma would be expected to develop by preference in the fundal area or at least in the proximal part of the body.

According to Torgersen (1944) gastric carcinoma in pernicious anaemia is in the great majority of cases localized to the fundus and to the proximal part of the body. In contrast, gastric carcinoma in a non-selected material was found to be situated in the pylorus and pyloric antrum in 50 to 60% of the cases. Torgersen's series comprises 106 cases of pernicious anaemia coexisting with gastric carcinoma (90 from the literature and 16 of his own). According to the description, in only two of his own cases was the carcinoma unmistakably in the fundus, whereas in seven it was in the body and in seven in the pylorus.

There seems to be some incongruity between Torgersen's observations in his own cases and the conclusion which he claims to be able to draw from earlier reports. The earlier reports of gastric carcinoma in association with pernicious anaemia have usually been of single cases or of groups comprising only a few patients. Among a somewhat larger series (Table VIII), the one reported by Strandell and Jansson (1937) is worth mentioning. Among 686 cases of pernicious anaemia they found 21 of gastric carcinoma in the following sites: nine in the pylorus, four in the fundus, and eight in the body of the stomach.

TABLE VIII.—*Site of Gastric Carcinoma Occurring in 85 Cases of Pernicious Anaemia*

	Pylorus and Antrum	Body	Fundus	Diffuse
Jenner (1939)	3	2	1	1
Strandell and Jansson (1937)	9	8	4	
Washburn and Rozendaal (1938)	4	2	3	
Torgersen (1944)	7	7	2	
Doehring and Eusterman (1942)	8	4	3	2
Present series	5	6	2	2
Total	36	29	15	5

Among 906 cases of pernicious anaemia Washburn and Rozendaal (1938) found gastric carcinoma in nine—three were in the fundus, two in the body, and four in the pylorus.

Jenner (1939), studying 181 cases of pernicious anaemia, found among them seven cases of gastric carcinoma. In one case the fundal area was definitely the site of the tumour; in two cases the site was probably the body; in three it was natural to interpret the tumour as being in the pylorus; and in the last case the growth was without doubt a scirrhus involving the entire stomach.

Doehring and Eusterman (1942) found 17 instances of gastric carcinoma among 1,014 patients suffering from pernicious anaemia. Eight were situated in the distal third of the stomach, four in the middle third, and three in the proximal third; two cases involved the entire stomach. These authors concluded that the site of gastric carcinoma in patients suffering from pernicious anaemia did not differ from that found normally.

The reported cases of gastric carcinoma in the presence of pernicious anaemia therefore fail to afford evidence that the growths in these patients are situated by preference in the fundal area or in the proximal part of the body.

The present series includes five cases of pyloric carcinoma, six of the body, and two of the fundus; in two instances the entire stomach was involved. Accordingly, this group does not confirm the theory that gastric carcinoma in the presence of pernicious anaemia should be localized by preference to the fundus.

The reason for the particular predisposition to gastric carcinoma among patients suffering from pernicious anaemia remains unelucidated. Possibly the explanation is that both pernicious anaemia and gastric carcinoma result from achlorhydria. If so, it is not unnatural that the two conditions should at times coexist. There is perhaps a question of inherited factors, since achlorhydria, an almost invariable sign of both lesions, occurs with particular frequency in families affected with pernicious anaemia.

A wide study of the familial occurrence of achlorhydria, pernicious anaemia, and gastric carcinoma may help in elucidating the relationship between these lesions. Investigations along these lines are being carried out.

Summary

A total of 219 females and 82 males who received treatment for pernicious anaemia at the Bispebjerg Hospital, Medical Department B, Copenhagen, during the period January, 1928, to June, 1949, have been studied. Of these, 83 females and 32 males have died. The expected number of deaths is 89 females and 28 males.

Two hundred and twenty-two patients have been followed up for more than ten years. Female patients with pernicious anaemia have the same chances of survival as normal females, whereas there is a slightly but not significantly higher mortality among the males.

The causes of death are tabulated. Twenty-one patients died from carcinoma, a figure which corresponds to the expected number of cancer deaths. Among this group, however, no fewer than eight females and six males died from gastric carcinoma. The expected number of deaths from carcinoma in all sites is 15, from gastric carcinoma only 5, so that the excessive mortality from gastric carcinoma is statistically significant.

It is found that patients suffering from pernicious anaemia do not develop their gastric carcinoma in the fundus and upper part of the body of the stomach, where the pathological changes characteristic of pernicious anaemia are localized. Possibly the explanation is that both pernicious anaemia and gastric carcinoma result from achlorhydria.

HAEMOLYTIC STREPTOCOCCAL GANGRENE OF BREAST SUCCESSFULLY TREATED WITH STREPTOMYCIN

BY

R. MARCUS, M.D., Ch.M., F.R.C.S.

(From the Department of Surgery, University of Liverpool)

Haemolytic streptococcal gangrene was first accurately described by Meleney (1924). In almost all cases there is an initial lesion which may escape the patient's notice. The limbs are affected more commonly than any other part of the body, as they are exposed to injury. The disease may occur in the scrotum (Marcus, 1949) and rarely on the trunk. Its clinical course is characterized by very rapid development. Within twenty-four hours the affected part becomes markedly swollen and shows all the signs of a rapidly spreading inflammation. In a day or two blisters and bullae begin to form and then the skin becomes frankly gangrenous. The condition is due to the haemolytic streptococcus, which can be obtained by culturing the discharge aerobically or anaerobically. Other organisms, such as *Staphylococcus aureus, Pseudomonas pyocyanea, Bact. coli, Proteus vulgaris, Streptococcus faecalis,* and diphtheroids may occur as secondary invaders.

Meleney (1924) recommends incision as far as the extension of the subcutaneous necrosis, but not further, as incisions in the zone of cellulitis may be harmful. The gangrenous skin should be excised as soon as the line of demarcation has developed and removal can be adopted without causing much bleeding. Amputation is rarely necessary, as the infection is superficial in most cases and can usually be combated by superficial incisions.

Penicillin and the sulphonamides have proved of value in haemolytic streptococcal infections, and in many cases render incisions unnecessary. The following two cases may be of interest, as these drugs failed to prevent the infection spreading, but when used with streptomycin localization occurred within a few hours.

Case 1

A married woman aged 57 was admitted for investigation for Cushing's syndrome. She had a small infected area on the left breast, for which she was given 100,000 units of penicillin daily. The inflammation extended by 1½ in. (3.8 cm.) in 24 hours and discharged copiously. When seen five days later the skin of the breast, except for the nipple and areola, was gangrenous (Fig. 1). The spreading margin extended upwards towards the clavicle, and was painful and vesiculated. Sulphatriad, 1 g. thrice daily, was given for 48 hours.

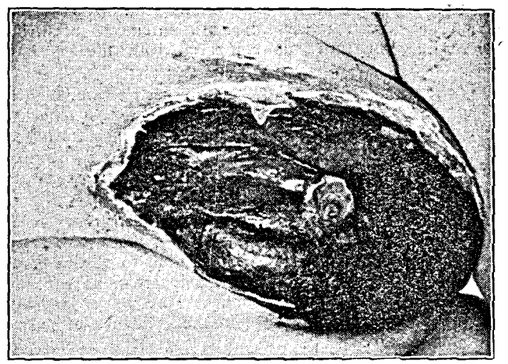

FIG. 1.—Case 1. Before streptomycin. The skin of the breast is gangrenous, and the gangrenous process is extending by 1½ in. daily.

Culture on February 16 showed: haemolytic streptococcus sensitive to 1/16 unit of penicillin per ml. and 8 units of streptomycin per ml.; *Staph. aureus* sensitive to 32 units of penicillin per ml. and 2 units of streptomycin per ml. Streptomycin, 0.5 g. six-hourly, was given—total 6 g.

The general condition improved within 12 hours. The tenderness was lessened, the spreading process was arrested, and the gangrenous skin showed a line of demarcation. *Culture:* haemolytic streptococci sensitive to 1/16 unit of penicillin per ml. and 8 units of streptomycin per ml.; *Staph. aureus* resistant to at least 32 units of penicillin per ml. and sensitive to 4 units of streptomycin per ml.

On February 18 the bacteriological findings and sensitivity to penicillin and streptomycin were unaltered. About three-quarters of the gangrenous skin had separated, and this was easily cut away with scissors, leaving a remarkably clean granulating surface. The remainder of the skin was removed next day without causing much bleeding; the nipple and areola were left intact. A small area below the nipple was affected more deeply than the remainder of the breast and contained a slough about ¾ in. (1.9 cm.) long. Culture from this region grew *Proteus vulgaris.*

On February 23 healing began, and granulations were healthy except for a small area below the nipple. Culture from this region grew *Proteus vulgaris* resistant to at least 32 units of penicillin. On March 23 postage-stamp Thiersch grafts were applied to the granulating surface. By April 1 most of the grafts had taken successfully and healing proceeded rapidly. The raw area had completely epithelized by April 18.

Comment on Case 1

The haemolytic streptococcus isolated was of Lancefield Group A. It was not completely eliminated from the margin of the gangrenous area during the period streptomycin was given. After the gangrenous skin had been removed the organisms were not found in repeated cultures from the margin of the granulating tissue. As the skin was not viable when streptomycin treatment was initiated it is not surprising that the organisms were not eliminated until the affected area was excised.

Case 2

A married woman aged 64 had a radical mastectomy for carcinoma of the breast. The wound had been sutured without tension. Five days after operation she was toxic and had severe pain in the wound. There was a small area of erythema with a vesicular centre in the outer part of the wound. She was given 500,000 units of penicillin intramuscularly daily and 1 g. of sulphadimidine three times a day.

When seen 14 hours later the temperature was 103° F. (39.4° C.), pulse 180. The outer part of the incision showed a gangrenous area, undermining of the skin, and gross oedema. While being examined the margin was seen extending. The discharge from the wound was copious and foul-smelling. Culture from the margin grew anaerobic haemolytic streptococci sensitive to one unit of streptomycin per ml., *Staph. albus (coagulase-negative),* and an organism of *Bacillus subtilis* group. Streptomycin, 0.5 g. six-hourly, was given—total 6 g. Sulphadimidine was discontinued, as this caused vomiting.

Next day her general condition improved considerably; the tenderness was much less and the spreading margin was arrested. The following day the gangrenous skin showed a line of demarcation and was excised (Fig. 2). Cultures grew

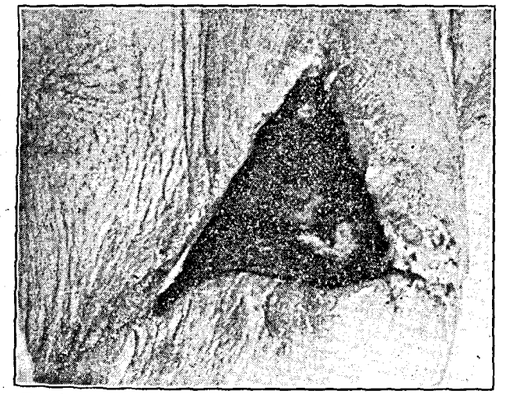

FIG. 2.—Case 2. Two days after receiving streptomycin. The gangrenous skin showed a line of demarcation and was excised. The sutures have been removed and the remainder of the incision has healed. Pain and oedema were markedly decreased.

anaerobic haemolytic streptococci, non-haemolytic streptococci, and an organism of *B. subtilis* group. A week later the wound was dry and healthy. Closure was carried out with interrupted sutures, and a small stab drain was inserted into the dead space below the suture line.

Discussion

Meleney (1933) classified the various types of infectious gangrene of the skin as acute and chronic. The acute forms are represented by gas gangrene and haemolytic streptococcal gangrene; the chronic forms include ecthyma (gangrenous *impetigo*), anaerobic gangrene, fuso-spirochaetal gangrene, and progressive bacterial synergic gangrene. The last-named condition is due to a symbiotic infection by a non-haemolytic *Staph. aureus* (Brewer and Meleney, 1926; Meleney, 1931, 1933, 1935). There are a few reports of successful treatment of post-operative progressive bacterial synergic gangrene with penicillin (Grimshaw and Stent, 1945; Meleney *et al.*, 1945; Clarke, 1947). In successful cases the inflammation, induration, oedema, and pain around the wound resolve and healing occurs rapidly, or after skin-grafting. Failing a satisfactory response excision of the wound is necessary before the condition is finally controlled (Meleney *et al.*, 1945).

Haemolytic streptococcal gangrene has been described as phlegmonous or gangrenous erysipelas, but should not be confused with erysipelas, which is also caused by the haemolytic streptococcus. Lymphangitis and lymphadenitis are rare, though phlebitis is fairly common in the former condition. In erysipelas, organisms may be cultivated at and beyond the spreading margin but not in the centre. The reverse is the case in haemolytic streptococcal gangrene. There may be a wide zone of sterile oedema beyond the limits of necrosis.

The synergic effect of penicillin, streptomycin, and the sulphonamides is of value when one drug alone fails to arrest the gangrenous process. This synergic effect has been noted in other infections (Redewill and Potter, 1948; Wells and Marcus, 1949; Bigger and Daly, 1949). The response to this form of treatment in the above two cases was dramatic. Within a few hours there was demonstrable improvement in the local and general condition of the patients. The spreading process was arrested and separation of the gangrenous skin began before completing streptomycin therapy. In both cases incisions as recommended by Meleney (1924) were not necessary.

The morbidity resulting from anaerobic streptococcal gangrene may be decreased by early recognition of the condition and by giving streptomycin before the gangrenous process is extensive. Incisions and skin-grafting will then be unnecessary. It is questionable whether secondary sutures are as valuble as skin-grafting. The undermining of the skin results in a dead space which cannot be easily obliterated by sutures.

Summary

Two cases of streptococcal gangrene of the breast are described. Penicillin and the sulphonamides by themselves failed to prevent the infection spreading, but when used together with streptomycin this was localized within a few hours.

Grateful thanks are due to Professor C. A. Wells and Mr. H. Hughes, who entrusted me with the care of their patients. I also thank Professor A. W. Downie and Dr. T. Black for the bacteriological investigations and sensitivity tests, and Mr. W. Lee, of the Central Photographic Department, University of Liverpool, for the illustrations. The streptomycin used for Case 1 was supplied by the Medical Research Council.

Normally claims for sickness benefit must be made within three days of the beginning of an illness, but when a person has never claimed sickness benefit before there will be no penalty so long as the claim is made within 21 days of the beginning of the illness. This is the main effect of provisional regulations made by the Minister of National Insurance, Dr. Edith Summerskill, which came into force on July 19. The regulations also enable delay in making a claim to be automatically excused during a period in hospital up to a maximum of three months. There is no change in the general rule that sickness benefit cannot be paid for more than three days before the claim is received at the local National Insurance office unless good cause for the delay is shown. The new regulations, however, allow late claims to be accepted without inquiry into the reason in special circumstances where difficulty has been experienced by insured persons.

RHEUMATIC HEART DISEASE IN SERVICE PENSIONERS

A REVIEW OF 318 CASES

BY

RONALD HARTLEY, M.R.C.P.

Physician to the Miller General Hospital and to the Dreadnought Hospital for Seamen

During the 1939–45 war cardiologists recorded their experience in the diagnosis of early chronic rheumatic heart disease in recruits. In spite of excellent work by medical boards, backed by specialist opinion, a small proportion of men with this condition were accepted for service. This paper reports the subsequent course of 318 such men re-examined after discharge while drawing disability pensions. In only one of these had the opinion of a cardiologist been taken before entry. The age at diagnosis varied from 18 to 50, and it may be presumed that the disease was already present on entry, for all had well-established valvular disease at the time of diagnosis. The lesions present are shown in Table I. In only five cases had an apical systolic murmur been noted on entry. In view of the fact that many hundreds of men with incidental systolic murmurs were accepted for service on specialist advice it is apparent that clinically the problem of distinguishing incidental from organic systolic murmurs has been largely solved. At the time of invaliding three of these five had mitral stenosis and aortic incompetence and two had mitral stenosis only. Seven other men had hypertension in addition to the valvular lesion.

TABLE I.—*Incidence of Clinical Valvular Disease Found in 318 Men at Time of Diagnosis*

Mitral stenosis	82 (25·7%)
Aortic incompetence	77 (24·2%)
Mitral stenosis and aortic incompetence	127 (39·9%)
Aortic stenosis and incompetence	19 (5·9%)
Mitral stenosis, aortic incompetence, and aortic stenosis	13 (4·0%)

After the 1914–18 war Grant (1933) analysed 736 cases invalided with valvular heart disease, and his figures show aortic lesions in nearly 60%, compared with 74% in this series. Both these figures were high and do not represent the true incidence of aortic valvular involvement, for aortic valvular disease is more readily missed than mitral valvular disease in routine examination, and so those with aortic lesions are more likely to enter the Forces, yet rheumatic aortic lesions are far commoner than is generally realized.

A history of previous rheumatic infection was obtained in only 37% in this series—a low figure; 100 men reported an attack of rheumatic fever, 15 of chorea, and 3 of both diseases.

Medical boards were much influenced by such a history, and many men were referred to cardiologists for this reason alone. This largely explains the low percentage of positive histories in this valvular series.

The features leading to diagnosis are given in Table II.

TABLE II.—*Features Leading to Diagnosis in 318 Men With Chronic Rheumatic Heart Disease*

Rheumatic fever	98 (31%)
Dyspnoea on effort	73 (23%)
No symptoms. Discovered at routine examination	104 (33%)
Haemoptysis	17
Anxiety state	7
Onset of auricular fibrillation	5
Mass radiography	5
Bacterial endocarditis	4
Congestive cardiac failure	1
Paroxysmal tachycardia	1
Embolic phenomena	1
Angina of effort	2

Cases with Recurrence of Rheumatic Fever.—The expected recurrence rate of rheumatic fever at the age of 20–25 is approximately 5% (Wilson, 1940). A Service rate of 31% is very high. Although a few men were under active service conditions when they had their relapse, most admitted that they were in good billets. It was apparently the open-air life and exposure to chill during training that brought about so many relapses. There was an increased liability to relapse in those who had had a previous known attack. In this group 51% relapsed within two years of enlistment, while only 13% served over five years. The valve affected in the 98 patients who developed acute rheumatic fever in the Service was the aortic in 35 (36%), the mitral in 18 (18%), and the combined lesion in 45 (46%). This is surprising, but the figures are hardly adequate for definite conclusions to be drawn. A previous rheumatic history was recorded in 50% of these men. There was no difference in the age at relapse between those with such a history and those without it.

Cases Reporting with Dyspnoea.—Only 27.4% of these men had a previous rheumatic history. The age at which the symptom appeared is that which would be expected from present knowledge of the natural history of the disease. There is no evidence that it was precipitated prematurely by the vigorous Service training. In this group 42% reported dyspnoea within two years of enlistment, while 27% served over five years.

Cases Diagnosed on Routine Examination.—A previous rheumatic history was recorded in 31%. The diagnosis in 16 was made at the demobilization examination. The percentage of men with a cardiac neurosis superimposed upon their disability is high. This is due to a failure on the part of doctors to explain the condition to the patient at the first diagnosis. Too often a man's sole knowledge about a cardiac affection is derived from the more sensational novels and films. Among the 104 men diagnosed on routine examination, all denying dyspnoea prior to diagnosis, over 80% claimed the advent of their symptoms within six months of diagnosis. This is due to two facts: first, the development of cardiac neurosis, and, secondly, the over-restriction of activities. All 104 had done their full Army training—the majority one battle course and a high percentage two or more such courses—yet they had no dyspnoea until they were told to go carefully. Lack of training alone may account for this symptom. A history of collapse or heart failure during exercise was not found among these 104 men or among the 73 reporting with dyspnoea.

Cases with Haemoptysis.—The percentage presenting with an initial haemoptysis was small—17 men (5.3%). In most cases there was prolonged dyspnoea as a result of work in full kit or wearing gas masks before haemorrhage occurred. The great importance of haemoptysis as a symptom of mitral stenosis does not seem to be fully appreciated. Often there was considerable delay while lung investigations were carried out and before the correct diagnosis was made. Five men entered sanatoria; one of these had four postero-anterior *x*-ray plates of the chest taken before the true condition was recognized.

Cases with Bacterial Endocarditis.—The percentage of men with subacute bacterial endocarditis in this series is low and many must have died from the disease before the introduction of penicillin. Those who survived were permanently disabled and none were fit for work.

Discussion

That most of the 318 cases could have been diagnosed before entry is without question. Twelve admitted that they were rejected as volunteers and later were accepted as conscripts. One man was invalided from the Guards and then joined the Royal Air Force. These keen men persevered until they had their own way, and came to no harm while doing excellent service.

Failure to carry out a full clinical cardiac examination such as recommended by Parkinson and Hartley (1946) accounted for most acceptances. In many men auscultation failed to reveal the mitral diastolic or presystolic murmur with the patient in the standing position, when these conditions were obvious with the man lying in the left lateral position after exertion. In the same way many aortic diastolic murmurs could be heard only when the breath was held at the end of full expiration with the patient sitting. But there is often a silent period in the natural history of rheumatic fever when no murmurs may be present, and in the absence of radiological enlargement a positive diagnosis is impossible. The early diastolic murmur of aortic incompetence may be difficult to hear unless there is absolute quiet, and many boards did not work under such ideal conditions. Boards were handicapped by the absence of facilities for routine radioscopy and so depended entirely on the clinical findings.

More attention might have been paid to the apex beat. The apex beat as a physical sign has two components—position and type of impulse. The position is defined as the furthermost point outwards and downwards at which the impulse raises the examining finger. This point is an extremely accurate guide to the left cardiac border, except in those with a broad chest and those with a vertical heart. Normally the position lies within the mid-clavicular line. Among these 318 men both position and character were normal in only 20. In 154 the position was normal but the type of impulse was diagnostic: mitral stenosis gives a sudden impulse, aortic incompetence a forcible one. Over 200 normal young Naval officers were examined as a control, and in none was the type of impulse abnormal, while in only two was the position beyond the mid-clavicular line. These were both broad short men, and the coincidence of the apex beat as defined above with the radiological left border of the heart was confirmed in these officers.

Radiology

The radiological findings of established chronic rheumatic heart disease are well known, and the use of mass radiography in the future will ensure that most men with the disease will not be accepted for military service (Maclean and Rogen, 1949). It will not exclude all. The limitation of mass radiography in heart disease is that the postero-anterior film only is taken, whereas the earliest change in mitral stenosis is enlargement of the left auricle, shown in the right oblique position with barium in the oesophagus.

Parkinson and Hartley (1946) found this to be the only certain *x*-ray change in 74% of 104 symptomless recruits with presystolic murmurs, while in 13% there was no change in the size or shape of the heart. The same observers could find no change in the heart's appearance in 16% of 202 men with symptomless rheumatic aortic incompetence. Full-plate radiographs, usually only postero-anterior, were taken of 264 men in this series at the time of the first diagnosis. Of these, 215 hearts (81.4%) were reported as enlarged, while 44 (16.6%) were reported as normal. The valvular lesions found in these 44 men are shown in Table III. The high percentage of radiographs reported to be normal in this series is discouraging, for if enlargement is not detected on the full-size plate it is unlikely to be recognized on the miniature film. Five more (1.9%) were diagnosed on mass radiography. Three of these had mitral stenosis, one aortic incompetence, and one both.

TABLE III.—*Valvular Lesion in 44 Men Whose Postero-anterior Film Was Reported as Normal at the Time of Clinical Diagnosis*

Mitral stenosis	8
Aortic incompetence	13
Mitral stenosis and aortic incompetence	19
Mitral stenosis, aortic incompetence, and aortic stenosis	2
Aortic incompetence and stenosis	2

It is during the silent period of the disease that radiology is the only method of detection. Wilson (1940) says that, in her patients, while the auscultatory signs of cardiac involvement might disappear or become uncharacteristic during the course of the disease, cardiac enlargement was demonstrable at all times. Hartley (1948) has pointed out that aortic incompetence may cause enlargement before the aortic diastolic murmur is heard, while, as Parkinson (1949) has emphasized, the *x*-ray appearance often suggests further auscultation, with positive results.

It has always been well known that the patient with a chronic rheumatic heart fares badly in the armed Forces. He should not be accepted, as it is impossible to foresee which case will deteriorate and which will not.

The figures in Table I show that men with chronic rheumatic heart disease who are accepted for the Forces fall mainly into three groups from the medical point of view.

In the first group there occurred during service some incident of the rheumatic disease which might be expected to affect permanently the natural history of the disease in that man. Such incidences are the recurrence of rheumatic fever, auricular fibrillation, bacterial endocarditis, heart failure, angina of effort, or embolic phenomena. In all these cases, although such complications might have occurred in civilian life, the prognosis has been made worse. Hence a permanent increase in the disability must be accepted as a medical fact. Of the 318 men 34% are found in this group.

In the second group fall those men whose initial symptoms occurred during service, but in whom there was no specific incident that might be expected to influence the ultimate prognosis. Dyspnoea was the main symptom. Haemoptysis in 17 cannot be said to have done any permanent damage. Paroxysmal tachycardia is a disorder of function only. Nearly 29% fell in this second category. The presenting symptom can in no way be associated medically with military service, for between the ages of 20 and 30 the onset of symptoms is to be expected.

The remaining third of the cases had no symptoms before the diagnosis at routine examination. Over 80% of these developed dyspnoea within six months of this knowledge. It would appear that Service life with daily exercise improved their condition, and allowed them to exert themselves more than they would have been able to do otherwise.

It was the overrestriction of their activities, together with inadequate knowledge of their own condition, that precipitated symptoms.

Summary

Of the 318 men drawing disability pensions for chronic rheumatic heart disease who were re-examined, 74% had an aortic-valve lesion.

Only five men had an apical systolic murmur on entry, and the conclusion is drawn that the many hundreds of men accepted with incidental apical systolic murmurs were correctly assessed and so provide remarkably few of the cases here examined.

Most of the cases (87%) were revealed in three main ways—31% had a recurrence of rheumatic fever, 23% developed dyspnoea, and 33% were discovered on routine examination. These three groups of cases are discussed in detail.

The reasons why medical boards failed to diagnose and exclude these cases from service are discussed, with special reference to the importance of the position and type of the apex beat in diagnosis.

Increased disablement from a purely medical point of view occurred in only 34% of the total. It was caused by recurrent rheumatic fever, bacterial endocarditis, auricular fibrillation, angina of effort, and the occurrence of emboli or cardiac failure.

The importance of radiological examination of the heart and the potential value of mass radiography are discussed.

I wish to thank Sir John Parkinson for his helpful criticism. My thanks are also due to Dr. F. T. Rees, Director-General of Medical Services, Ministry of Pensions, for permission to publish this article, which does not necessarily represent the view of that Ministry.

DECAMETHONIUM IODIDE AS A CURARIZING AGENT IN GENERAL ANAESTHESIA

BY

A. R. ELLERKER, L.M.S.S.A.

Late Anaesthetic Registrar, Selly Oak Hospital

The following series of 208 cases in which decamethonium iodide (C10) was used as a curarizing agent, in conjunction with most general anaesthetic agents, may prove of interest to those who are not convinced of its value as a substitute for D-tubocurarine chloride.

C10 is the decane derivative of bistrimethylammonium iodide. It is a white crystalline water-soluble salt, which forms a stable neutral solution. On intravenous injection both in experimental animals and in human beings it produces a neuromuscular block with little or no effect on the autonomic ganglia. The fact that it is cheap to synthesize and mixes readily with thiopentone sodium, together with its curarizing properties, makes it an even more attractive proposition.

Clinical Series

In all the 208 cases, with the exception of those in which caesarean section was performed, premedication with "omnopon," ½ gr. (22 mg.), or morphine, ¼ gr. (16 mg.), and hyoscine, 1/150 gr. (0.43 mg.), or atropine, 1/100 gr. (0.65 mg.), was carried out between 30 and 60 minutes before operation, and anaesthesia was induced with thiopentone sodium in doses varying from 0.4 to 1 g. For the caesarean sections premedication was carried out with atropine, 1/100 gr., and induction with cyclopropane and oxygen. The ages of the patients ranged from 12 to 79 years. The following are the operations for which the method was used.

Operation	No.
Oesophagoscopy	10
Bronchoscopy	5
Tonsillectomy	18
Mastoidectomy	10
Thyroidectomy	8
Dental operations	20
Facial and neck operations	13
Upper abdominal operations (including gastrectomy, gastro-jejunostomy, perforated peptic ulcers, cholecystectomy)	14
Laparotomy (appendicectomy, colostomy, excision of colon, etc.)	9
Herniorrhaphy	21
Prostatectomy	10
Nephrectomy	4
Anal and rectal operations	12
Thoracic sympathectomy	4
Caesarean section	13
Mastectomy	3
Amputation of leg	3
Laminectomy	10
Orthopaedic, unclassified	11
Unclassified, miscellaneous	10

Administration and Results

C10 may be injected intravenously either as a mixture with thiopentone sodium or by itself. Dosages of from 2 to 5 mg. have been used on different cases, and to produce full muscular relaxation an initial dose of 4 mg. was found to be the best. This produced excellent relaxation of the abdominal musculature for as long as 25 minutes, but also brought about apnoea due to respiratory paralysis for five to ten minutes after the full effect was obtained, which was usually some three to five minutes after the original injection.

Experiments carried out on the conscious patient by Organe, Paton, and Zaimis (1949) indicated that with a dose of 3 mg. of C10 the respiratory musculature was not in any way affected. It has been found here, however, that even with this dose there was apnoea for one to three minutes, while adequate abdominal relaxation was not always obtained. In this respect it differs from D-tubocurarine chloride, which does not always produce respiratory arrest with an equivalent dosage.

Repeated doses have not the cumulative effect that D-tubocurarine chloride has, and a maximum of 15 mg. of C10 has been given without ill effects, recovery taking place as after a single dose.

Continuous or intermittent injections of a thiopentone C10 mixture have been used with success in most of the herniorrhaphies and in a large number of the intraperitoneal operations, but the resulting apnoea makes it desirable to intubate these patients and to keep them well oxygenated.

The experimental work of Young (1949) on near-term guinea-pigs and rabbits suggests that C10 does not pass the placental barrier, and clinical trials by Organe (1949) indicate that this is so. In the 13 caesarean sections in this series, using doses of 2 to 3 mg. injected 10 to 15 minutes before delivery, we have found that the infant was definitely more flaccid and reluctant to breathe than after cyclopropane, oxygen, ether, or gas-oxygen-ether anaesthesia. It would seem, then, that C10 does cross the placenta into the foetal circulation, although more slowly and in smaller quantities than D-tubocurarine chloride. Recovery of muscle tone in these babies is fairly rapid.

Side-effects.—No deleterious side-effects were noted in any of these cases. One death occurred at the end of a partial gastrectomy for uncontrollable haematemesis. This patient was not, however, in the best condition, and some difficulty was experienced in keeping him oxygenated. *Post-mortem* examination revealed bilateral basal pneumonitis, with a large amount of purulent exudate and an advanced degree of myocardial degeneration.

Discussion and Conclusions

The use of C10 in short operations is clearly indicated to avoid the respiratory depression so often seen after the use of D-tubocurarine chloride. In all cases in which intubation is necessary or desirable C10 facilitates the passage of a Magill intratracheal tube without producing complete abdominal relaxation, which is so often unnecessary in E.N.T., orthopaedic, and other classes of operation.

It may be used in conjunction with D-tubocurarine chloride to produce short-term relaxation of the abdominal muscles when the peritoneum is being closed and it is undesirable to give another dose of D-tubocurarine chloride because of its long action and cumulative effect. Full respiratory excursions will then be established before the patient returns to the ward.

Antagonist.—Pentamethonium iodide, or C5, is the antidote to C10. Hewer *et al.* (1949) have reported its effects. It acts by producing a block of the autonomic ganglia, and would seem to be contraindicated in major surgery. It may produce a profound fall in blood pressure, and the patient may collapse in a very alarming manner. No opportunity has arisen and no attempt been made to use this substance here.

My thanks are due to Dr. T. H. Hobbes, the senior anaesthetist, for his help.

Medical Memoranda

Volvulus of the Small Intestine

The following case illustrates the difficulty of diagnosis of volvulus of the small intestine. This difficulty is present not only before operation but when the abdomen has been opened. The aetiology of the condition is obscure, and in the case described an adhesion was present round which the gut appeared to have pivoted. This has been described in other cases, but the operator is likely to find no obvious cause whatever.

CASE REPORT

A storekeeper aged 53 was admitted to hospital complaining of acute abdominal pain 1 in. (2.5 cm.) to the left of the umbilicus two days previously. Before this he had always been quite well. There was continuous dull abdominal pain with exacerbations of acute colic. The bowels had been absolutely confined and no flatus passed. Vomiting began a few hours after the onset of pain and had continued.

On admission he had an ashen appearance. His tongue was dry and furred. His temperature and pulse were normal. The abdomen was tympanitic and a little distended but with no real rigidity. No free fluid was discovered and there were no localizing signs of any sort to assist diagnosis. He was vomiting brownish fluid but there was no faecal change in the vomit. Enemas were returned unchanged. Borborygmi were heard over the large intestine. A diagnosis was made of small-bowel obstruction probably due to strangulation by band or internal hernia.

At operation there was a little free fluid and the whole small intestine presented moderately distended and markedly congested but not "plum coloured." In the left hypochondrium a band 3/16 in. (0.5 cm.) in diameter and extending from the splenic flexure downwards and inwards was found to be attached to the middle of the mesentery. This band was part of numerous adhesions tying the whole colon from caecum to sigmoid to the anterior peritoneum. The small intestine was free of adhesions. The large intestine was moderately and normally distended. Round the band was wrapped a loop of small intestine which was more obviously affected than the rest, as it was plum coloured and more distended. The band was divided and the small loop began to recover in appearance. At first it was thought that the cause of the obstruction had been discovered and dealt with, but the poor condition of the whole small intestine raised doubts, and, on feeling round the abdomen, the typical "band" caused by the twisted mesenteric root was felt and the volvulus diagnosed. The small intestine was eventrated, the 180-degrees twist that was present was untwisted, and the abdomen closed. The patient made an uninterrupted recovery.

A. J. HOBSON, F.R.C.S.

Aplastic Anaemia Complicating Miliary Tuberculosis

In the following case complete aplasia of the bone marrow developed. This seems to be an unusual complication and the clinical findings are worth recording.

CASE REPORT

The patient, a man aged 41, was healthy until March, 1949. His initial symptoms were non-specific—namely, lassitude, anorexia, and headaches. In June, 1949, he had a severe epistaxis and bleeding from the gums. He was admitted to hospital on August 4. There was no family history of tuberculosis.

On examination he was obviously very ill. He complained of a sore throat. The fauces were injected but not ulcerated. Pallor was pronounced without any evidence of icterus. The superficial lymphatic glands were not enlarged. His temperature was 101.6° F. (38.7° C.) on admission, and a remittent pyrexia, fluctuating between 100 and 103.2° F. (37.8 and 39.6° C.), persisted until the day before death. The pulse was 120. A loud systolic murmur was audible at the mitral area. The blood pressure was 145/80. No abnormal signs were elicited in the lungs. The spleen was enlarged to ½ in. (1.2 cm.) below the umbilicus, and the liver was enlarged 2 in. (5 cm.) below the costal margin.

The urine was normal. A blood count showed: haemoglobin, 36%; red cells, 1,510,000; C.I., 1.2; white cells, 1,200. No primitive cells were seen in the film. The red cells showed anisocytosis and poikilocytosis. Aerobic blood culture was negative. Examination of the sternal marrow smears revealed no primitive cells of either the myeloid or erythrocyte series. The film was diagnostic of aplasia of the bone marrow.

A radiograph of the chest showed a resolving area of consolidation in the left mid-zone. The remainder of the lung fields was clear. There was no enlargement of the mediastinal lymph nodes and no mottling. The patient died on August 21, 17 days after admission.

Permission for a necropsy could not be obtained, but the spleen was removed. This viscus was grossly enlarged and the histological examination showed multiple areas of necrosis with a slight mononuclear reaction around the margins. With Ziehl-Neelsen's stain lesions were seen to contain acid-fast bacilli. The picture was that of an atypical miliary tuberculosis.

COMMENT

There are several features of unusual interest in this case. Aplasia of the bone marrow was caused by an overwhelming toxaemia with a very low resistance. The absence of chest symptoms and minimal radiological findings are very difficult to explain in a case of generalized miliary tuberculosis. The primary focus was probably extrapulmonary. The gross splenomegaly was due to numerous tubercles and there was no evidence of splenic panhaematopenia. The miliary tuberculosis was not seriously considered in the differential diagnosis. Aleukaemic leukaemia was excluded by the marrow findings.

Septicaemia due to an anaerobic organism was the tentative diagnosis.

My thanks are due to Professor J. H. Biggart for his report on the histological section of the spleen, to Dr. M. G. Nelson for the report on the marrow smears, to Dr. C. R. Murdock for the report on the blood, and to Dr. H. B. McDowell for the report on the radiographs.

Treatment of Typhoid Carrier with Penicillin and Sulphamerazine

The successful treatment of a typhoid carrier, who had resisted combined sulphonamide–penicillin and caronamide, and choramphenicol, was eventually achieved by sulphamerazine and penicillin in dosage similar to that employed in our earlier case (Rumball and Moore, 1949).

CASE REPORT

A boy aged 9 contracted typhoid fever in Egypt in July, 1948, and came under our care six months later as a chronic persistent and profuse faecal carrier. His agglutinations were: typhoid O, 1 in 20; typhoid H, 1 in 250; and typhoid Vi, 1 in 10 standard agglutination and 1 in 20 partial agglutination. *In vitro* sensitivity tests showed: sulphathiazole—insensitive at 25 mg. per 100 ml., sensitive at 50 mg.; penicillin—insensitive at 1 unit per ml., sensitive at 5 units; sulphathiazole and penicillin combined—no demonstrable increase in sensitivity.

Over a period of nine days beginning on February 12, 1949, 19,000,000 units of crystalline penicillin, 75 g. of caronamide, and 39.75 g. of sulphatriad were given. Serum penicillin assay showed a range of 0.08 to 0.3 unit per ml., and sulphonamide concentration from 9.2 to 18 mg. per 100 ml., these levels being obtained immediately before the four-hourly doses of the combined drugs. A scanty growth of *Salmonella typhi* continued throughout treatment, but a profuse growth returned within a few days afterwards, even though the patient's serum on February 18 had inhibited the isolated organism.

Chloramphenicol was considered as a second method of treatment, based on the findings of Smadel *et al.* (1948), Woodward *et al.* (1948), and Murgatroyd (1949) that this drug was active in the acute disease, though at the time no literature was available regarding its effectiveness against the carrier state. The isolated organism was found to be extremely sensitive *in vitro* to chloramphenicol at a dilution of 2.5 mg. per ml. A course of treatment, using 0.25 g. of chloramphenicol four-hourly for seven days, to a total of 10.5 g., was therefore given from April 12 to 18. This dosage, equivalent to 10 mg. per kg. body weight, was based on half the adult dose given in acute cases. Positive stool cultures were obtained consistently during and after this course. A further course, using a threefold increase in dose to a total of 32.25 g., was given from April 25 to May 2, and was also unsuccessful. During the latter course serum sensitivity levels from 0.02 to 0.04 mg. of chloramphenicol per ml. were obtained, and faeces were negative. Apparently inhibition of the organism occurred while there was a high concentration of the drug in the bowel, but with the cessation of treatment the organism reappeared in profusion. In view of the outbreak of typhoid fever in Crowthorne, Berkshire, at the time (April, 1949) the unsuccessful use of the drug in this particular carrier was regarded as an important though disappointing clinical result.

Finally a 10-day course of 29.5 g. of sulphamerazine and 32,200,000 units of penicillin, comparable to that successful in our earlier case, was given in May, during which serum penicillin levels rose to 1 unit per ml., sulphamerazine concentration ranged from 15.8 to 36 mg. per 100 ml., and the patient's serum inhibited the organism in dilutions of 1 in 16. Faeces became negative early in this course of treatment and have remained negative consistently throughout the nine months' follow-up. The Vi titre had also returned to negative. Cure is therefore presumed probable.

COMMENT

It is stressed that cure of a second case with this method warrants no special claim being made of its superior value over other reported successful methods of treatment, but this case again serves to impress the fact that high and sustained blood levels are essential for success. In this case repeated failure with other methods, and success with the third course of treatment, may also be explained on the findings of Fry *et al.* (1948) that intermittent courses of treatment may be more successful than a continuous attack. The advent of chloramphenicol has considerably reduced the clinical complications and hastened recovery in acute cases of typhoid, in which the organism is more accessible to its action, but the treatment of the carrier state is a very different problem. Before abandoning hope in the treatment of carriers it is considered that the combined use of penicillin and sulphamerazine is worth a trial.

Since submitting this article a chronic urinary and faecal carrier of *Salmonella kottbus* has come under our care. Treatment similar to that detailed above was successful. *Salm. kottbus* belongs to the food-poisoning group of organisms. A summary of the case history is appended.

A 21-year-old aircraft hand was notified to us from a military hospital, to which he was admitted in December, 1949, suffering from diarrhoea and vomiting. His stools and urine gave a pure growth of *Salm. kottbus*. He was transferred to our care on January 31, 1950, symptomless and well. The organism was isolated and found to be sensitive to chloramphenicol, and a course of 25 g. was given. Subsequent cultures showed that the urinary infection had been eradicated, but the bowel infection persisted. At the end of February he was given a seven-day course of penicillin, 400,000 units four-hourly, night and day, together with a course of 27 g. of sulphamerazine. On completion of this the faeces were free from *Salm. kottbus*. He has remained under bacteriological surveillance, and during the three months since completing treatment both stools and urine remain free from *Salm. kottbus* infection. This case demonstrates the susceptibility of urinary infection to chloramphenicol and the resistance of bowel infection, which, however, responded to combined sulphamerazine and penicillin.

Our thanks are due to Air Marshal Sir P. C. Livingston, Director-General of Medical Services, for permission to publish these cases, and to Air Vice-Marshal T. C. Morton, consultant in pathology and tropical medicine, for advice and assistance in the bacteriology of the cases.

The British Standards Institution has issued a draft British Standard for linen textiles for use by local authorities and hospitals. The draft is being circulated to interested organizations so that they may comment on it before August 15. It is based on proposals made by the Local Authority Standards Advisory Committee in collaboration with the Hospital Equipment Standards Advisory Committee.

Reviews

UROLOGY

Essentials of Urology. By J. C. Ainsworth-Davis, M.A., M.D., B.Ch.(Cantab), F.R.C.S., F.R.C.S.Ed. (Pp. 734; illustrated. £2 10s.) Oxford: Blackwell Scientific Publications.

Urology has established itself now as a specialty, and many new textbooks are being published. Some are written by single authors and others by teams of contributors. One misses in the composite works what may be called the personal touch. While they are excellent books of reference, they do not reveal so clearly, as does a book by a single writer, which of the various alternatives described is likely to be the best method of treatment in a given case. Mr. Ainsworth-Davis does not derive sufficient profit from this advantage enjoyed by the single author. He gives an excellent description of the various alternative operations that may be carried out, but he keeps too far in the background and does not tell us enough of his own personal experience of them. Otherwise his book is to be highly recommended. The text is concise and clear, the accounts of after-treatment are excellent, and the diagrams and plates of an exceptionally high order. The general surgeon and postgraduate student could not have a better account of urology than what this book gives them. It is to be hoped that in a second edition the author will be a little less modest and let us know more of his own experience of the operations he so clearly describes.

KENNETH WALKER.

PRINCIPLES OF INDUSTRIAL HEALTH

Industrial Health. By R. Passmore, M.A., D.M., F.R.S.Ed., and Catherine N. Swanston, M.R.C.S., L.R.C.P., D.P.H., D.I.H. Foreword by Professor F. A. E. Crew, F.R.S. (Pp. 110. 4s. 6d.) Edinburgh: E. and S. Livingstone. 1950.

This book is labelled an introduction for students. It is far more. It is a concise, readable—if elementary—account of the principles of industrial health. The writers have drawn on their practical experience in presenting their material, and doctors and industrial nurses, managers and foremen, could all find valuable information here.

After describing the distribution of the working population in this country and the special occupational problems of young and old, the writers discuss methods of assessing the health of working communities. A good short account of the main factors in the physical environment follows. Despite the steady improvement over many years in physical working conditions, it is pointed out that improvement in psychological and social environment has not kept pace, and that in consequence "many are working at three-quarters pressure only." The writers discuss these psychological and social factors and their effect on working efficiency. Chapters on industrial accidents and occupational diseases are included. They are sound, except for the account of the pneumoconioses, which is somewhat muddled and may confuse the reader. Short chapters follow on legislation and on the responsibility of management for health in industry, and the functions in this field of such industrial experts as the personnel manager, the safety officer, and other technical staff.

More and more are doctors being asked to undertake duties in factories and among working groups. If their time is to be used to the full they require some special training. This little book would provide an excellent accompaniment to any short course, and it would alone provide the general practitioner with a useful introduction to medical work in industry.

R. E. LANE.

DRUGS AND TREATMENT

A Concise Applied Pharmacology and Therapeutics. By F. G. Hobart, Ph.C., and G. Melton, M.D., M.R.C.P. With a foreword by Sir Adolphe Abrahams, O.B.E., M.A., M.D., F.R.C.P. Third edition. (Pp. 234. £1 1s.) London: Leonard Hill Ltd. 1949.

The appearance of the third edition of this book indicates that it has been found useful. Since one of its authors is a pharmacist, the publication contains much information required by the practising physician which is not of interest to the student approaching pharmacology in its early stages. The student is then chiefly concerned with understanding the mechanism of the action of drugs and has not yet come to face the practical difficulties of nomenclature, for example. The practising physician, on the other hand, will value a book which begins with a list of proprietary drugs and their definitions or non-proprietary equivalents. For him it is obviously a valuable and handy book of reference.

J. H. BURN.

MARMALADE AND MATERIALISM

A Doctor Digresses. By Kenneth M. Walker, M.A., M.B., B.Ch., F.R.C.S. (Pp. 207. 10s. 6d.) London: Jonathan Cape. 1950.

"If those of you who have brought their Bibles with them will turn to the Book of Leviticus . . ." Thus Kenneth Walker began his 9 a.m. lecture on gonorrhoea twenty-five years ago, and we amiably concluded that the lecturer had wit, style, and an interest in religion. These qualities have remained with him, and in this book he displays them yet again. The book is in truth a series of essays on such subjects as health, the patient, psychosomatic medicine, Western psychology, and Eastern philosophy—a continuing skein through them being skilfully woven by Marmalade, his cat, and Bonnington, an *alter ego* : Marmalade stands for elegance, for grace, and for non-attachment, while Bonnington holds fast to scientific materialism.

Pandit Nehru said recently that the man without internal conflict is a lunatic, and in our author there is a healthy schism between Kenneth, the artist, and Walker, the surgeon, which is scarcely resolved by "K. W.," the well-known medical philosopher. The philosopher tries hard to be eclectic in his approach to authority, but those who have read his other books will know that his heart is with Whitehead against Russell, with Jung against Freud, with Sherrington against Watson, with free will against determinism, with spirit against corpus, with physicians against specialists—in short, with Marmalade against Bonnington. This book adds little to our knowledge of the author's philosophy; but for the interested layman it provides stimulating and even exciting reading, and there are few medical readers who will not find here a new idea well conceived and finely phrased, or an old concept freshly illuminated. If Mr. Walker had given his book an index, it would have been a kindness to reviewers and at the same time have provided a silent testimony to the remarkable range of his

reading and to the extent of his learning. Now and again, however, he is uncritical in his acceptance of authority, as when he fails to examine the statement that nine out of ten of the persons attending the Peckham Health Centre were in a state of ill-health.

He tells us that this book rose phoenix-like from the ashes of a burnt manuscript, an ambitious work entitled "The Philosophy of Medicine." As he watched the flames destroy the result of a year's labour he consoled himself with the reflection that the philosophic method had no place in medicine, which required only careful observation and experiment. This is Walker writing, for nothing is more apparent in the practice of medicine to-day than that it lacks a coherent philosophy. "K. W." should try again.

D. V. HUBBLE.

FANCY FREE

Adaptation. Edited by John Romano, M.D. (Pp. 113. 16s.) Ithaca, New York: Cornell University Press. London: Geoffrey Cumberlege. 1949.

This volume consists of the papers read at the "Dedicatory Program" of the psychiatric unit at the Rochester School of Medicine and Dentistry. A brief editorial introduction is followed by five variations on themes suggested by the title. They are composed respectively by distinguished professors of zoology, physiology, psychobiology, psychiatry, and anthropology, the theme of "adaptation" being chosen on the grounds that it was a concept "central" to them all.

It is impossible to summarize the contents, since the contributors have let their fancy roam with fluent zest. The action of enzymes, the work of Pavlov and Sherrington, the views of sundry philosophers, the behaviour of wild rats and of neurotic goats, the result of a Gallup Poll (published in the *Ladies' Home Journal*) on the belief in the existence of God, the revelations of Freud, and many other matters—all find a place.

It is as if each professor had been set a question in some nightmare examination, "Write down what you know and interests you in not more than 22 pages"; but none complain, and only one seems to ask rather plaintively what it is all about. And who would not be puzzled, for example, about whether it is remarkable or only to be expected that elephants should have legs thick enough to support their weight? If they hadn't—but that is too easy: the elephant —and what else?—does not arise, or falls flat.

DESMOND CURRAN.

In *Energy and Matter* (Staples Press, 10s. 6d.) Dr. R. L. Worrall endeavours to give in a short space an account in simple language of the development of modern physics. He begins with a rapid review of the rise of physical science from the days of Aristotle to the present time. Such a review must of necessity be limited to the main positions taken up by the great physicists upon whose discoveries progress is dependent, and the author has wisely expressed their views in terms used by the discoverers themselves. Even if this method involves a certain degree of discontinuity, it provides a series of solid foundations the veracity of which can scarcely be questioned. Whether the reader who is not already familiar with the conceptions of modern physics will be able to grasp their meaning is an open question, but at least he will have the opportunity of a rapid review of the problems. The author has evidently read very widely, and it is a remarkable achievement to have compressed so much in so short a space. The absence of mathematical terms and symbols will certainly be appreciated by the readers for whom the book is intended.

BRITISH MEDICAL JOURNAL
LONDON
SATURDAY AUGUST 12 1950

NON-PULMONARY TUBERCULOSIS

At a time when the incidence of most of the common infectious diseases in Great Britain is declining rapidly, more and more attention is being directed to the continued high mortality from tuberculosis. Unfortunately our knowledge of several factors in the aetiology of this disease is still deficient, and no reliable records are available even for the morbidity rate. Public health interest is centred mainly in pulmonary tuberculosis, and the importance of the non-pulmonary form in causing sickness, deformity, and prolonged invalidity in those who escape death tends to be overlooked. The publication, therefore, of a report[1] to the Medical Research Council on non-pulmonary tuberculosis is to be welcomed, for the committee of experts responsible for planning the investigation, under the chairmanship of Dr. G. S. Wilson, have produced a very informative document. Apart from the intrinsic value of its contents, the report affords an admirable example of what can be achieved by group research. All the investigations were carried out on material obtained in their day-to-day work by hospital pathologists, public health bacteriologists, and tuberculosis officers working according to an agreed plan. The inquiry took its origin at a conference that was called by the Medical Research Council to discuss whether any light could be thrown on the reasons for the increased mortality from tuberculosis during the first two years of the war.[2] The delegates from England, Wales, and Scotland who attended decided to restrict their investigations to non-pulmonary tuberculosis and to organize their work for each country separately. The general plan was for pathologists in hospitals to collect suitable material taken during life or after death and to send it to bacteriologists, working usually in public health laboratories, for determination of the type—human or bovine—of the infecting organism. As soon as this had been done, the tuberculosis officer or medical superintendent was asked to provide information on the patient's occupation, change of address within the preceding five years, number of persons in the home, exposure to contact with tuberculous patients, and the milk supply before and during the war. The report is in two sections, the first concerns England, the second Wales. The inquiries in these two countries were carried out in 1943, 1944, and the first nine months of 1945. It is presumed that the Scottish report will be published later.

In England tubercle bacilli were cultivated from a total of 994 patients; of these, 733 (73.7%) were shown to be infected with the human and 261 (26.3%) with the bovine type. An attempt made to compare the distribution of the human and bovine types according to the age, sex, occupation, address of the patient, and other factors proved difficult for two reasons. First, no figures were available for the true morbidity of non-pulmonary tuberculosis in different parts of the country, so that all conclusions had to be based on the proportions of the two types in different regions; and, since a high bovine–human ratio in one region compared with a low ratio in another might mean either that there was a greater risk of infection with the bovine or a smaller risk of infection with the human type, it was impossible to estimate the real risk of infection with the bovine type in the two regions. Secondly, though the information obtained by the collecting pathologists on the age and sex of the patients and the site of the disease was practically complete, details provided by the tuberculosis officer or medical superintendent about the patients' environment were less satisfactory. Much of the information asked for could not be obtained, partly for reasons connected with the war; and some of it, derived by postal or delegated questionaries, was manifestly so unreliable that it had to be discarded.

Analysis of the figures according to the site of disease showed that the bovine type of bacillus was responsible for approximately 28% of all cases of meningitis, 57% of cases of cervical glandular tuberculosis, 10% of cases of bone and joint disease, and 22% of cases of genito-urinary disease. In all these groups the proportion of bovine-type infections was higher in children than in adults. This was in accord with previous experience: but in contrast with previous experience it was found that the highest proportion of infections with the bovine type was no longer in the 0–4 age group, but in the 5–9 age group. The reason for this change is supposed to be twofold. Owing to the gradual replacement of raw by heat-treated milk for infant feeding during the past 25 years or so the relative risk of infection with the bovine type in the first year or two of life is less than it used to be. On the other hand, the introduction of the milk-in-schools scheme has resulted in a greater relative risk of infection with the bovine type among school-children, many of whom receive milk now who before would have had none at all. Though it is true that most school milk is either heat-treated or comes from T.T. or attested herds, in the early days of the scheme much ordinary raw milk was supplied, and even

[1] *J. Hyg., Camb.*, 1949, **47**, 337.
[2] *Report of the Committee on Tuberculosis in War-time*, Spec. Rep. Ser. med. Res. Coun., Lond., 1942, No. 246. H.M.S.O., London.

at the present time probably about 10% of schools—though a lower percentage of school-children—are still provided with potentially dangerous milk. Further analyses revealed that adult females who developed non-pulmonary tuberculosis were almost twice as liable as adult males to be infected with the bovine type; that 30% of all cases of infection with the bovine type were in persons over 15 years of age; that 87% of patients infected with the bovine type gave a history of drinking raw milk as against 53% of those infected with the human type; and that the lowest proportions of bovine-type infections occurred in the London, North-East, and South-East regions, and the highest in the North-Midland and North-West regions, where tuberculosis in cattle is known to be particularly prevalent. By applying the proportions for the different ages and the two sexes to the recorded deaths from the different forms of non-pulmonary tuberculosis it is calculated that 1,300 persons died in England during the year 1944 from infection of bovine origin.

The investigation in Wales was carried out on a smaller scale. The proportion of infections with the bovine type was found to be lower than in England. Strains of tubercle bacilli were cultured from 112 patients, of which 17%, as compared with the English figure of 26%, proved to belong to the bovine type. How much of this difference is to be attributed to the higher proportion of attested herds in Wales, to the relatively large number of cases of meningitis examined, and to the possibly greater risk of infection with the human type, it is impossible to say. If the figures for England and Wales are combined it may be said that about 24% of all cases of non-pulmonary tuberculosis were due to infection with the bovine type of tubercle bacillus, and that in 1944 approximately 1,350 persons died from non-pulmonary tuberculosis of bovine origin. Previous estimates of this nature have been criticized because they were based on material drawn from selected areas which were not necessarily representative of the country as a whole. No such criticism can be made of the present report. Material was drawn from all parts of the country, and, though not exactly the same proportion of samples from each form of the disease was examined in each region, the authors have, by standardizing the age and sex distribution and by working out alternative arithmetic means, provided figures more reliable than any previously collected. There can be no doubt from their analysis that a large number of deaths, and presumably a still larger number of cases of non-pulmonary tuberculosis, are occurring each year which might be prevented by adequate heat treatment of the milk supply. The Government now have the power of compulsory pasteurization; it is to be hoped that they will soon use it.

FOETAL PATHOLOGY

The pathology of the foetus is a relatively unexplored subject, though as long ago as 1892 Ballantyne, of Edinburgh,[1] made what now appears a notable beginning to the solution of some of its problems with his book *The Diseases and Deformities of the Foetus*, which he styled "an attempt towards a system of antenatal pathology." The foetus, Ballantyne showed, is by no means exempt from the ordinary diseases of adult life, though its response to any particular stimulus may be very different from the more familiar happenings in the adult. But, in addition, the foetus has its own diseases, though for obvious reasons the pathologist has little opportunity to study these in the post-mortem room. Outstanding among these specifically foetal conditions are the "malformations"—the end-results of abnormal developmental processes. In recent years advances in embryology have greatly aided the study of these conditions. Descriptive embryology has provided the "time-table" of normal embryonic development, thus helping to define the period during which the disturbance responsible for a particular malformation must have occurred. At the same time those working in the field of experimental embryology, using the easily manipulable embryos of amphibia, have demonstrated that many of the spontaneously occurring foetal abnormalities can be caused by simple mechanical interference with the developing embryo. Huxley and de Beer[2] have given an account of experiments of this nature, which of course have not provided evidence about the aetiology of spontaneously occurring developmental abnormalities in the human but have merely illustrated the mechanism which has brought about the final results. Indeed, the importance of environmental causes of human malformations has received little emphasis, and from published surveys[3 4] of the work on this subject it might be concluded that inherent defects—that is, genetic abnormalities—are the cause of nearly all congenital malformations. It is of interest that a minor developmental abnormality—brachydactyly—was the first example of Mendelian inheritance demonstrated to occur in man.

This emphasis on the importance of genetic factors in the causation of developmental abnormalities does not come solely from clinical studies. In 1929 Bagg[5] was able to produce, by subjecting parent mice to *x* rays, a strain of animals with familial malformations, including clubfoot, syndactylism, hypodactylism, and congenital "amputation," all presumably due to induced genetic mutations. However, the association of developmental abnormalities—such as cataract, cardiac septal defects, patent ductus arteriosus, deaf mutism, and microcephaly—with epidemics of German measles, noted in Australia by Gregg[6] in 1941 and later clearly attributed to maternal infection in the early months of pregnancy,[7] demonstrates clearly enough that genetic factors cannot always be invoked as the cause of such abnormalities. Other environmental factors, too, such as deficient diets, have been found experimentally to cause developmental abnormalities, and the relative aetiological importance of heredity and environment therefore still remains to be determined. Experimental work in this field is full of interest and should be rewarding, for from the study of the factors, inherent or environmental, which cause malformations in the human some information may be obtained about why such factors should affect the particular tissues concerned. Hitherto the difficulty has been to find a precise agent with which to influence the developing embryo. But in the chick embryo at least this difficulty has been overcome, and in an interesting paper appearing elsewhere in this issue Mr. P. K. Duraiswami describes how the injection of insulin into the yolks of developing hens' eggs gives rise to a number of developmental abnormalities, including spina bifida, abnormalities of limbs and beak, eye changes, and certain skeletal defects which can be compared to osteogenesis imperfecta.

Limb changes resembling those noted by Duraiswami have been described in the offspring of rats reared on a diet deficient in riboflavin,[8] and it is interesting that he found the administration of nicotinamide and riboflavin largely prevented the abnormal development. From the clinical standpoint it is clear that a number of bone defects are "developmental." While there is good evidence that genetic factors are concerned in the causation of a few of these—such as osteogenesis imperfecta, osteopetrosis, multiple exostoses, and achondroplasia—there are many others whose aetiology is unknown. It is significant, therefore, that bone appears as the outstandingly susceptible tissue in these examples of experimentally induced abnormalities, and that such "physiological" factors as blood sugar, hormones, and vitamins appear to control the normal development of this tissue. Without fuller information it is not possible to judge how closely the condition of the bones in Mr. Duraiswami's experimental animals resembles human oesteogenesis imperfecta, or to suggest how the mechanism of calcification is so grossly disturbed, but it is quite certain that the study of these and other experimentally induced developmental abnormalities of the skeleton is important.

PERNICIOUS ANAEMIA AND GASTRIC CARCINOMA

In the last five years much evidence has been brought forward to suggest that carcinoma of the stomach is a complication of pernicious anaemia. Bourne[1] examined 15 unselected cases and found symptomless carcinoma in three. Wilkinson[2] reported on the causes of death in the 301 patients who died out of the 1,480 patients with pernicious anaemia which he had treated since 1929. He found that 70 died of cancer and that of these the site of the growth was in the stomach in 28. It is impressive that the proportion of cancers which were located in the stomach was twice as high as that which occurs generally, but it is not possible to determine from the evidence whether the unexpectedly large figure was due to an abnormally high incidence of gastric cancer or to a low incidence of other forms. Drs. Johannes Mosbech and Aage Videbaek, in Copenhagen, now demonstrate in a paper published in this issue that carcinoma of the stomach does in fact develop in patients with pernicious anaemia about three times as often as in other subjects. Their series consists of 301 patients. It is not large, but all the patients have been followed up—the longest for 21 years—and 115 deaths have been observed. Results of treatment were so successful that only three deaths could be directly attributed to pernicious anaemia; and the actual number of deaths attributed to other diseases was slightly less than would be expected in the same number of normal inhabitants of Copenhagen (in a group of appropriate age and sex composition) observed for the same number of years. The only exception to this good prognosis was the increased risk of developing carcinoma of the stomach: 15 cases occurred, significantly higher than the expected 5.

Now that the risk is recognized, the important question is how the knowledge can be used to the advantage of patients with pernicious anaemia. Diagnosis must be early if there is to be any chance of treating gastric cancer successfully, and the advisability of regular and frequent barium-meal examinations must be considered. It is, however, doubtful whether many investigations are justified. Jennings[3] has pointed out that the annual risk of a man in his fifties developing gastric cancer is 1 in 1,000, and, even if the risk in a selected group were twice or three times that figure, routine barium-meal examinations would bring few cases to light. It would, of course, be a different matter if a group could be defined in which the annual risk was as high as 1 or 2%: Jennings has suggested that patients with pernicious anaemia might constitute such a group in the first few years following diagnosis, but Mosbech and Videbaek's data do not support his hypothesis. On the contrary, in their series the risk was practically constant at all stages after diagnosis. Why the two diseases are associated is not known. Pernicious anaemia is constantly, and gastric carcinoma is frequently, associated with atrophy of the gastric mucosa, and it is tempting to ascribe the carcinoma to the atrophy. Torgersen[4] has claimed to find evidence for this, in that the growths associated with pernicious anaemia have mostly been

located near the fundus of the stomach, in the area mainly affected by the mucosal atrophy of pernicious anaemia. Mosbech and Videbaek found the contrary, and they also reached a different conclusion from a review of the literature. In their experience the commonest site for gastric carcinoma was the pyloric antrum, both in patients with pernicious anaemia and in all others. It would therefore seem that mucosal atrophy is not in itself a sufficient explanation, and that the reason for the association must be sought in the disturbed physiology which underlies the development of pernicious anaemia.

THE PRE-THROMBOTIC STATE

Although thrombosis and embolism occur in relatively few patients after operations these complications may be crippling or fatal, and methods for the prevention and treatment of thrombo-embolic disease have been extensively studied. Many of the treatments suggested, such as the use of anticoagulant drugs and ligation of the femoral veins or inferior vena cava, are potentially dangerous and cannot be applied indiscriminately. The selection of patients for treatment is therefore important, and many workers have attempted to find tests to diagnose a "pre-thrombotic state" and to distinguish those patients in whom intravascular thrombosis may occur. All of these tests presuppose that some alteration in the coagulability of the blood is an important factor in thrombosis. This assumption is reasonable, because changes in the blood which might facilitate coagulation are commonly found in patients after operation.[1-4] In 1940 Bergquist[5] suggested that the whole-blood clotting time was shorter than normal in some cases of thrombosis, but in 1945 he reported that the shortening was not constant and the test was, in his view, of no value.[6] Cummine and Lyons[7] reinvestigated the test in 1948, using the capillary tubing method with capillary blood at room temperature. They found that in patients who developed thrombosis the clotting time fell below a critical level of 4–5 minutes just before the onset of thrombosis. In addition they suggested that the fibrinogen in these patients was altered to a form, "fibrinogen B," which was clotted non-specifically by substances other than thrombin, of which naphthoquinone is one. In a series of 550 surgical patients there were 20 in whom the whole-blood clotting time was shortened and the fibrinogen-B test positive. Of these patients, twelve who received no anticoagulant therapy developed thrombosis and eight who had anticoagulant therapy did not develop thrombosis. These findings are clear cut and convincing, but they have not been supported by subsequent work. In 1949 Dunn, Jackson, and Lyons[8] showed that the fibrinogen-B test was positive in many patients who never developed thrombosis, and other workers have found that the capillary clotting time as used by Cummine and Lyons gives variable and unreliable results.[9 10]

A different approach to the problem was followed by Ochsner and his colleagues,[11] who suggest that a decrease in antithrombin combined with an increase in prothrombin may predispose to thrombosis. This combination of pathological findings was found in 30 out of 200 surgical patients. Of these 30 patients 16 developed thrombosis, whereas only one out of the remaining 170 patients showed any evidence of thrombosis. The authors suggest the use of α-tocopherol in the treatment of incipient thrombosis because this substance causes a rise in blood antithrombin. These results are promising, but it will be necessary to await their confirmation before applying them in practice.

EXPROPRIATION OF PRIZE FUND

The National Health Service Act of 1946 gave the Minister of Health power to take over certain hospital endowment funds, and under these provisions he has appropriated the Sanderson-Wells Nurses Prize fund, which was founded by Mr. T. H. Sanderson-Wells, who was for many years honorary surgeon to the Weymouth and District Hospital and is now living in retirement. The securities which formed the endowment were vested in trustees through a trust deed. The annual value of the prize is said to have been about £30. On July 5, 1948, the Minister of Health appropriated the securities at a capital value of about £714. The trustees were not consulted and did not give their consent. The income balance of about £50 standing in the current account was transferred to the Minister through the Bank of England on January 1, 1949. In reply to a Parliamentary question by Sir Ernest Graham-Little, Mr. Bevan stated[1] in October last year that the Sanderson-Wells Nurses Prize fund did not still exist as a separate unit. Mr. Bevan added that he had asked the West Dorset Management Committee to have regard to the objects of the fund in administering the sums received from time to time from the Central Hospital Endowments Fund. Later asked[2] what sum had been allocated from the Central Fund to this prize fund, Mr. Bevan pointed out that the prize fund no longer existed, "and there can therefore be no question of allocation of funds to it." He repeated that the management committee had been asked to bear in mind the objects of the old prize fund, and for the time being they were awarding an annual prize of £5. He had asked them to review the matter in the light of the considerable sums they had received from the Central Fund. As a result of the exertions of Mr. Sanderson-Wells and others an allotment of £19 was subsequently made by the West Dorset Hospital Endowment Committee.

Apart from the fact that the nurses are considerably worse off financially since the Minister appropriated the fund, it is questionable whether he had the right to take it over at all. In Section 7 (10) of the Act the expression "endowment" is defined as "property held by the governing body of the hospital or by trustees solely for the purposes of that hospital." It seems hardly possible that those who framed the Act intended the words "solely for the purposes of that hospital" to cover an endowment made solely for the purpose of a nurses' prize fund. Again, the annual income of the fund is said to be slightly over £25, yet this sum is apparently not being awarded as a prize. Under Section 7 (7) of the Act an obligation is put on the Minister to secure, "so far as is reasonably practicable, that the objects of the endowment and the observance of any conditions attaching thereto . . . are not prejudiced by the provision of this section." The object of this endowment was to provide an annual prize worth about £25–£30, and it would appear to have been prejudiced by the Minister's action, for the sums paid out have been very much smaller, while the value of the securities has probably not depreciated much, if at all.

The Minister is in a very strong position, for in order to challenge Mr. Bevan's actions Mr. Sanderson-Wells or someone else would need to undertake long and expensive litigation in the courts. The Government puts an intolerable burden on private citizens when it passes Acts which are so loosely worded that their provisions appear to be in contradiction to the actions taken under them by a Minister. It would seem to be desirable that cases such as this should be taken to the courts, as the *Law Journal* has suggested,[3] at the expense of the State.

POST-TUBERCULOUS MIDDLE LOBE SYNDROME

An important consequence of tuberculous adenitis may be stenosis of the bronchus of the middle lobe of the right lung. In a review of this relatively common condition Brock[1] has described the occurrence and behaviour of tuberculous lymphadenitis within the lungs and mediastinum. A primary tuberculous focus in the lung is accompanied by enlarged glands at the hilum, which are closely related to the bronchi and may obstruct them or cause ulceration. The middle-lobe bronchus is especially vulnerable, since it and its two branches are long and narrow and are surrounded by glands which drain the middle and the lower lobes. A mass of glands may cause complete bronchial obstruction if it is large or if it occurs in childhood when the bronchi are soft. Such an adenitis may resolve completely, and the effects be only temporary, even if the primary infection occurs in adult life. On the other hand, in the presence of secondary infection bronchiectatic changes will occur and be permanent even when the obstruction subsides. Alternatively, a caseous gland may ulcerate into the bronchus. Its contents, or granulation tissue, may again cause obstruction, or even be coughed up. Caseous tissue often calcifies, and if this happens at a later stage a broncholith or pneumolith will be formed. The contracture caused through healing of the ulcerated bronchus leads to a partial or complete fibrous stricture. Such pathological processes may involve the middle lobe bronchus before it branches or its lateral segment only, and the same changes may take place coincidentally in the cardiac segment of the right lower lobe or the anterior segment of the upper lobe. It is important to recognize these late secondary manifestations as sequelae of tuberculous disease. Each may eventually be complicated by a more or less severe degree of pyogenic infection, and it is usually only when this occurs, which may not be for many years, that the lesion becomes clinically evident. Bronchiectasis is accompanied by pulmonary fibrosis. Fibrosis may also occur beyond a stricture, but distension with mucus or pus is more common, resulting in an abscess or a pyocele. A very severe infection may be associated with the presence of a broncholith. Suppuration may spread to the pleura, other pulmonary lobes, or even more distantly.

This syndrome usually appears in late middle life, the "cancer age," even though the primary lesion occurred in childhood. The sexes are equally susceptible. The symptoms are the result of infection. A pneumonitis may resolve or be followed by an empyema, lung abscess, or by recurrent attacks at the same site. General malaise or unexplained pyrexia may be due to the chronic infection. Cough and sputum suggest bronchiectasis. Haemoptysis is common, and may be repeated and copious, but it is seldom the only symptom. The signs may be very suggestive of bronchial carcinoma. Although a lower-lobe carcinoma may spread to involve the middle-lobe bronchus, and although this bronchus may be compressed by a mediastinal mass of glands, carcinoma of the middle-lobe bronchus itself is very rare. When it does occur it lies peripherally, whereas a post-tuberculous stenosis affects the proximal part of the bronchus: if the exact anatomical location of the lesion is investigated—a lateral radiograph is essential—this diagnostic pitfall will be avoided. Further valuable confirmation of the originally tuberculous cause is afforded by radiological evidence of calcification, either of the primary focus or especially of the gland at the site of the stenosis. Calcification which changes position in successive films indicates a broncholith.

Accurate diagnosis is the first step to treatment. It is clear that radical treatment is often unnecessary, since the disease may remain latent for many years and attacks of inflammation usually subside. In young persons especially surgery is to be avoided, for the tuberculous process may still be active. Operation is necessary if broncholiths or pneumoliths are present, and is indicated if there is a total or subtotal bronchial obstruction; this can best be demonstrated by bronchography. Excision is the treatment for chronic abscess, but not for bronchiectasis unless there is much purulent sputum. During the operation bronchial occlusion is essential. A middle lobectomy is the manœuvre of choice, but technical difficulties sometimes necessitate removal of the lower lobe as well. Brock operated on 18 of the 60 patients in his series.

The half-yearly indexes to Vol. 1 of the *Journal* and the *Supplement* for 1950 are now being sent to members who receive them regularly and to subscribers. Members who have not previously asked for the indexes to be sent regularly to them can obtain copies, post free, on application to the Publishing Manager, B.M.A. House, Tavistock Square, London, W.C.1. Those wishing to receive the indexes regularly as published should intimate this.

REFRESHER COURSE FOR GENERAL PRACTITIONERS

SULPHONAMIDE THERAPY

BY

D. M. DUNLOP, B.A., M.D., F.R.C.P. F.R.C.P.Ed.

Professor of Therapeutics and Clinical Medicine, Edinburgh University

Indications for Use

The pre-eminent place of sulphonamides in the treatment of many infections has been usurped by penicillin. Their prerogatives indeed are likely to be curtailed still further when the newer antibiotics come into more general use. Nevertheless, they still have a wide application in therapeutics: they are the drugs of choice in meningococcal meningitis, since penicillin passes the blood-brain barrier uncertainly and with difficulty, and in dysenteric and coliform infections, which are unaffected by penicillin; they are almost as effective as penicillin in pneumococcal pneumonia and erysipelas, in which their use is preferable because of their relative cheapness and the convenience of their oral administration; they have been superseded by penicillin in gonococcal and staphylococcal infections and to some extent in streptococcal infections, particularly in septicaemias, except in those cases in which the organism has proved to be penicillin-resistant. When a purulent complication has occurred sulphonamides are ineffective.

The evidence favouring the employment of sulphonamides to prevent the respiratory complications of measles, common colds, and influenza, and for the prophylaxis of the complications of scarlet fever, is in my opinion insufficient to justify their routine use for such purposes. There is considerable statistical evidence that their prophylactic use in daily doses of 0.5 g. for long periods is of value in preventing the recurrences of acute rheumatism, even though sulphonamides are useless in the treatment of the established condition. There seems to be little danger in giving such small doses even for years; nevertheless, further controlled studies must be undertaken before this form of treatment can be recommended in general practice.

Experience gained in the recent war seems to indicate that the use of crystalline sulphonamides and of sulphonamide ointments as topical agents is not very successful in the treatment of infected wounds or in infections of the skin and mucous membranes. Moreover, the prolonged use of sulphonamide creams and ointments often results in severe and intractable forms of sensitization dermatitis. The routine use of sulphonamides as topical agents is therefore to be discouraged, except in the form of eye-drops for the treatment of conjunctivitis, corneal ulcers, and blepharitis, and to prevent infection after injuries to the eye. Even here a mild chronic blepharitis may result from the use of sulphacetamide.

In summary, then, the main indications for sulphonamide therapy to-day are in the treatment of meningococcal, coliform, and dysenteric infections; lobar pneumonia; erysipelas; certain infections of the eye; and in infections due to haemolytic streptococci, gonococci, and staphylococci when these have proved resistant to penicillin.

Absorption, Fate, and Action

When sulphonamides are swallowed they are absorbed to a greater or less extent from the small intestine. Some preparations are completely absorbed, others are hardly absorbed at all. When they are absorbed they become rapidly distributed among all the body fluids, though their concentration in milk is too low to affect a suckling baby. The amino-nitrogen in these compounds is partly acetylated in the body—the degree of acetylation varying according to the preparation used. The acetylated form has no therapeutic effect. A mixture of the free drug and acetyl compound is excreted in high concentration in the urine, but about 30% of the sulphonamide is destroyed in the body.

The concentrations of sulphonamides in the blood (5 to 15 mg. per 100 ml.) which are obtained by therapeutic doses do not kill organisms but inhibit their growth so that they are dealt with by the ordinary defence mechanisms. Their action is due to their inhibiting effect on the metabolism of *p*-aminobenzoic acid, which is required by many species of organism as a growth factor.

Preparations and Choice of Drug

There are numerous official preparations of sulphonamides, many of which are marketed by manufacturers under an astounding variety of names, one of the few undesirable expressions of the inventive genius of the great pharmaceutical firms. The practitioner may well be bewildered by the number of preparations at his disposal and doubtful about which drug to use in any given circumstance and how to use it to the best advantage. Many of the sulphonamides differ only very slightly from one another, and it is more important to know how to use a few properly than to be continually changing to an unfamiliar preparation because of some slight advantage it may be reputed to possess. Actually only three or at most four preparations need be employed; one or possibly two for general infections; one for intestinal infections; and one for application to the eye.

The following are brief notes on the main attributes of the more important sulphonamides.

Sulphanilamide (*B.P.*) is the active principle of the original sulphamidochrysoidin ("prontosil red") introduced by Domagk in 1935. It is rapidly and completely absorbed and quickly excreted. It is relatively soluble so that it does not produce renal complications, though in other respects it is more toxic than the newer sulphonamides and less therapeutically active, having no effect on pneumococcal infections. Its prescription is now seldom indicated.

Sulphapyridine—the famous "M. and B. 693"—has been omitted from the 1948 *British Pharmacopoeia* because of the severe toxic effects it produces, particularly nausea and vomiting. There is nothing it can do that modern sulphonamides cannot do better, and it should never be prescribed nowadays.

Sulphathiazole (*B.P.*) and *Sulphadiazine* (*B.P.*) closely resemble each other. They are both highly active and are rapidly absorbed and excreted, so that they have to be given at short intervals in high dosage to maintain adequate blood concentrations. Both drugs and their acetyl derivatives are relatively insoluble in acid urine. Sulphadiazine is rather less toxic than sulphathiazole, and of the two is probably the preferable drug.

Sulphadimidine ("sulphamezathine") and *Sulphamerazine* (*U.S.P.*) have almost identical qualities. I am prejudiced in favour of the former—possibly on account of its British origins.

Sulphadimidine is more rapidly and completely absorbed than sulphadiazine, so that with equal oral doses sulphadimidine attains a blood concentration approximately twice that of sulphadiazine. It is also more slowly excreted, so that it may be given in smaller amounts and less frequently. The acetylated and free forms of sulphadimidine are more soluble than sulphadiazine in neutral and acid urine, and are thus much less apt to give rise to renal complications, though in other respects the two drugs have approximately the same degree of toxicity. Thus, sulphadimidine is probably the best sulphonamide for routine use, though, as it is possibly a little less active than sulphadiazine, the latter may remain the preferable drug in severe meningococcal meningitis.

Sulphadiazine and sulphadimidine are insufficiently soluble for parenteral administration except in the form of their *sodium salts*. Such solutions are strongly alkaline and should be administered only intravenously. Ampoules containing 1 g. of dry powder are available, and the contents should be dissolved in 10 ml. of normal saline. An excellent alternative is "soluthiazole," which is supplied in rubber-capped bottles ready for use; 5 ml. are equivalent to 1 g. of sulphathiazole. It is a neutral solution and so can be given intramuscularly as well as intravenously—a considerable advantage where babies are concerned. It is seldom necessary to give the drugs parenterally except in very severe infections when it is desirable to obtain rapidly a high concentration of sulphonamide in the blood, or when the patient is comatose and unable to swallow, or when intense vomiting prevents absorption.

Sulphatriad, a combination of sulphathiazole, sulphadiazine, and sulphamerazine, is recommended on the principle that if two or more sulphonamides are administered in combination the therapeutic actions of the different compounds are additive but their solubilities remain independent of each other. Accordingly, it is possible to obtain a high blood concentration without the risk of renal complications. Since we have in sulphadimidine a powerful and relatively soluble sulphonamide it seems superfluous to use sulphatriad, which is also more costly.

Sulphacetamide (*B.P.*) yields a very soluble and almost neutral sodium salt (sulphacetamide sodium *B.P.*) which can be used as eye-drops in concentrations up to 30%.

Sulphaguanidine (*B.P.*), *Succinylsulphathiazole* (*B.P.*), and *Phthalylsulphathiazole*, though soluble in the intestinal contents, are all relatively poorly absorbed, thus permitting them to exert their bacteriostatic action in the intestinal tract. Hence their only use is for intestinal infections, particularly dysenteric infections, and for treatment before and after operations on the colon. All three are non-toxic, but succinylsulphathiazole and phthalylsulphathiazole are absorbed even less than sulphaguanidine and are therefore preferable to it. There is some slight evidence that succinylsulphathiazole is superior to phthalylsulphathiazole in acute dysentery and for the elimination of the carrier state.

From what has been said it would seem that the following four sulphonamides are probably the drugs of choice: sulphadimidine for lobar pneumonia, erysipelas, and coliform infections; sulphadiazine and its sodium salt for meningococcal meningitis; succinylsulphathiazole for intestinal infections; and sodium sulphacetamide for infections of the eye.

Administration and Dosage

Sulphonamides are marketed in tablet form, each of which contains 0.5 g. (7½ gr.). The tablets should be broken into small fragments and swallowed with 2–3 oz. (57–85 ml.) of milk or water. The drugs should be given in full dosage or not at all. The only exception to this rule is in infections of the urinary tract (see below). Full dosage should be maintained till the treatment is stopped. The administration of sulphonamides should seldom be continued for longer than seven days and never for more than ten days. It is always advisable to give an initial "loading dose." Children tolerate the drugs well and require a larger dose than might be expected on a purely weight basis. Over the age of 12 they can be given the full adult dose; between 3 and 12, two-thirds of it; between 1 and 3, one-third; and under 1, one-sixth.

In *lobar pneumonia* and *erysipelas* a "loading dose" of 3 g. of sulphadimidine should be given, followed by 1 g. six-hourly till the temperature has been normal for two or three days.

In *coliform urinary infections*, owing to the fact that sulphonamides are concentrated by the kidneys in their passage from the blood into the urine, it is unnecessary to give the large doses required in other diseases. A "loading dose" of 2 g. of sulphadimidine should be given, followed by 0.5 g. six-hourly.

In *meningococcal infections*, in view of their serious nature, the "loading dose" of sulphonamide should be given intravenously in the form of at least 1 g. of sodium sulphadiazine. The injection should be made slowly. Thereafter 2 g. of sulphadiazine should be given orally followed by 1.5 g. every four hours. Treatment should be terminated only when the cerebrospinal fluid has been sterile for some days and all physical signs are in abeyance. This usually involves the administration of sulphadiazine for seven or eight days. As dehydration is common in cerebrospinal fever, and as there is a real danger of renal complications when sulphadiazine is used under such circumstances, every effort must be made to maintain an adequate fluid intake, if necessary by the use of parenteral fluids. As sulphadiazine is much more soluble in an alkaline medium an attempt must be made to render the urine alkaline by the administration of a mixture containing 20 gr. (1.3 g.) each of potassium citrate and sodium bicarbonate—the frequency of dosage being determined by the reaction of the urine to litmus.

In *acute bacillary dysentery* succinylsulphathiazole can be given in massive doses with complete safety, since little is absorbed into the blood. At least 3 g. should be given four times a day and continued for some days after the stools have become normal. Prolonged treatment, which is perfectly safe with this drug, may be necessary in the eradication of the convalescent and chronic carrier state. The drug has been recommended in idiopathic ulcerative colitis, but in my experience is of little or no value.

In *infections and injuries of the eyes* sulphacetamide sodium is used as eye-drops, though penicillin is more effective in severe infections such as ophthalmia neonatorum. In the treatment of acute conjunctivitis and in the prophylaxis of ocular infections after injuries a few drops of a 10% solution are instilled every two hours. An ointment containing 5% of the drug may be smeared along the roots of the lashes three times a day in the treatment of blepharitis.

Toxic Effects

When modern sulphonamides are properly used toxic effects should be rare, and virtually confined to those few

patients who have become sensitized to the drugs or who have an idiosyncrasy to them.

Some malaise and loss of appetite are not uncommon as the result of sulphonamide therapy, but the distressing vomiting so common after the use of sulphapyridine is seldom produced by the more modern drugs.

A harmless cyanosis due to methaemoglobin was often encountered during treatment with sulphanilamide but is rarely occasioned by the drugs which have been recommended. Very exceptionally, sulphaemoglobinaemia develops, accompanied by cyanosis, shallow respirations, and a rapid pulse of poor quality. I have seen this complication on only one occasion. A slow recovery usually occurs when the drug is withdrawn. Sulphaemoglobinaemia is probably due to absorption of sulphides from the large bowel, and, as this is facilitated by fluid colonic contents, the use of saline purges is inadvisable in conjunction with sulphonamide therapy.

Sensitization phenomena, taking the form of a drug fever with or without a skin rash—usually a widespread rose-red maculo-papular rash which fades on pressure—may occur in a previously sensitized individual after a single dose of sulphonamide or may appear from the fifth day of treatment onwards. In the latter case, when there is only a fever and no rash, it may be difficult to distinguish this toxic manifestation from a recrudescence of the disease. When these sensitization phenomena occur or are suspected it is wise to stop sulphonamide therapy and to change to penicillin or one of the other antibiotics if further treatment is indicated. Sensitization to sulphonamides is common and serious enough to render it highly undesirable to resort to sulphonamide treatment for every minor infection which may occur in practice.

Owing to the low solubility of sulphadiazine and especially of its acetyl derivative the risk of microscopic or gross haematuria and ultimately anuria may be considerable following its use under conditions which reduce the output of urine, such as an inadequate fluid intake, vomiting, diarrhoea, or excessive sweating. These renal complications may be prevented by ensuring a fluid intake of at least five pints (2.8 litres) and preferably six pints (3.4 litres) a day, sufficient to maintain a urinary output of not less than 50 oz. (1.4 litres), and by rendering the urine alkaline. The occurrence of a microscopic haematuria is a warning signal to institute prompt preventive measures. Provided the urinary output is normal the discovery of crystals of the drug in urine which has stood for some time is of no significance. The development of anuria calls for immediate cessation of sulphonamide therapy and for forcing oral and parenteral fluids. If this is not rapidly successful specialist aid should be sought and a trial made of ureteric catheterization. Sulphadimidine practically never gives rise to these renal complications.

Blood dyscrasias are rare after sulphonamide treatment unless it is prolonged beyond ten days, or unless previous sensitization phenomena have been disregarded. They include purpura, haemolytic anaemia, aplastic anaemia, and agranulocytosis. The occurrence of these disorders is an absolute indication to stop treatment.

A few cases of peripheral neuritis have been reported following sulphonamide therapy.

The Nursing Appointments Service of the Ministry of Labour and National Service has been reorganized. One result is that there will be 135 offices of the Ministry instead of 33 where nurses and midwives and would-be nurses and midwives can receive advice about these careers and any help they may want in obtaining posts.

INTERNATIONAL CONGRESS OF RADIOLOGY

MEETING IN LONDON

The Sixth International Congress of Radiology, attended by 2,700 members from 54 countries, was opened by the EARL OF ATHLONE, chancellor of the University of London, on July 24 at the Central Hall, Westminster. Dr. RALSTON PATERSON was invested with the insignia of office as president of the Congress, and gave an address in which he pictured the evolution of radiology from its troglodytic days in beetle-infested basements to its modern status as a mature science helping medicine in diagnosis and treatment. On the evening of the same day British Radiology gave a dinner at the Guildhall to over 600 guests from many countries. The Lord Mayor of London and Vice-Admiral Earl Mountbatten of Burma were the guests of honour, and the latter, in proposing the toast of Radiology, referred to the advanced course in radiological defence and atomic medicine given to civilians and members of the Services at the Royal Naval Medical School at Alverstoke.

The scientific meetings took place in three main groups: (1) General Congress Symposia, four in number; (2) a series of symposia in each of the four main subdivisions of radiology—radiodiagnosis, radiotherapy, radiobiology, and radiophysics; (3) meetings of all four sections, with the addition of electrology, at which more than 300 papers were delivered.

General Congress Symposia

A symposium on supervoltage radiotherapy was held on July 25 at which Dr. R. S. STONE (U.S.A.) evaluated the late effects of the use of radiation in excess of 1,000 kV. There were definite advantages, although the relatively high incidence of deep fibrosis of tissues counselled caution. Dr. O. DAHL (Norway) described the 1,500 kV generator at Bergen, and discussed the factors influencing the choice of voltage and the engineering problems involved. Professor B. W. WINDEYER, the chairman, pointed out that, in the range of one to four million volts, therapy has now emerged from the technically experimental stage and is available for clinical evaluation. Advantages to be derived and problems of organization were discussed.

On the following day Sir STANFORD CADE (London) opened a symposium on radiological achievements (1937–50) with a review of the clinical aspects of radiodiagnosis and radiotherapy, and marked the recent milestones of progress. Dr. EDITH QUIMBY (U.S.A.) pointed out the need for a unified and adequate system of dosimetry for high energy radiations now being developed. She described some instruments designed to meet special problems in this field. Dr. A. LACASSAGNE (France) dealt with the advances in the understanding of the actions of radiation on living tissues, in the physio-chemical mechanism of direct and indirect radiation, and with some aspects of cytoplasmic changes in the cell. Dr. ROSS GOLDING (U.S.A.) reviewed advances in gastro-intestinal radiology, with particular emphasis on the radiology of the small intestine and the use of the Miller–Abbott tube. Gall-bladder radiology had been improved by the introduction of a new opaque medium. Dr. P. FARINAS (Cuba) also discussed opaque media, while Dr. K. LINDBLOM (Sweden) considered the use of water-soluble iodine compounds in the study of trauma to joint-cartilages and other structures. Dr. J. LAWRENCE (U.S.A.) outlined the present status of treatment with radioisotopes of iodine and phosphorus. Dr. RALSTON PATERSON (Manchester) dealt with advances in clinical radiotherapy (1937–50).

Mass radiology of the chest was discussed on July 27. Professor M. DE ABREU (Brazil) traced the development of his work from the earliest attempt at fluorography in 1923 to the final methods presented in 1936. Problems relating to the efficient employment of 180 units operating in Brazil were discussed. He gave some details of the chest diagnostic service which works alongside the mass survey for the further assessment of abnormal shadows. He touched upon the social implications of mass radiology. Dr. A. C. CHRISTIE (U.S.A.), who is ill and whose paper was read by Dr. Orndoff, outlined the development of mass radiology in U.S.A.; it was first applied on a large scale to the examination of the U.S. Army and Navy, when 15 million recruits were seen during five years, 1940–5. Dr. A. NELSON (Sweden) surveyed the progress in technical developments of mass radiography, especially improvements in brilliance of screens, the employment of mirrors instead of lenses, and the use of automatic exposure timers to ensure uniformity of image density. Dr. P. KERLEY (London) compared the present position of mass miniature radiography with that of B.C.G. inoculation. There were not yet figures to prove that mass radiography on a national scale was justified, although the statistics for selected groups showed the method to be of value.

On July 28 radiation hazards were discussed. Professor ROBLEY EVANS (U.S.A.) presented the quantitative aspects of chronic radium and mesothorium poisoning in a series of 24 men exposed for many years to luminous paint. New methods of *in vivo* estimation of these elements have been devised. Studies are still proceeding, but it appears that the figure of 0.1 μg. of radium as a maximum permissible dose may have a much larger safety factor than was once supposed. Dr. A. BRUES and Dr. S. WARREN (U.S.A.) considered various types of radiation hazards and their control. Professor W. V. MAYNEORD (London) described some of the hazards associated with the use of radioactive isotopes and high energy sources of radiation, such as the 30 meV synchrotron in clinical practice, with methods of controlling them.

Radiodiagnosis

At a symposium on angiocardiography papers ranged over technique and clinical applications, a notable contribution being by Dr. C. WEGELIUS and Dr. J. LYND (Finland) describing apparatus for taking serial radiographs at speeds of up to 12 per second synchronously in two planes, with concurrent electrocardiograms. The films illustrated were impressive for their clarity and degree of contrast. Dr. G. JONSSON (Sweden) stressed the value of selective visualization of the abnormal area and described his method of passing a catheter directly into the aorta. Dr. R. N. COOLEY (U.S.A.) and Dr. T. HILLS discussed the technical requirements in the visualization of congenital defects causing cyanosis, and features of practical importance in the selection of patients for surgical treatment were emphasized.

In a discussion on the small intestine Dr. E. A. ZIMMER (Switzerland) described a contrast preparation which tended to excite slight motor activity and thus gave a more rapid transit through the small bowel, so that it could be examined in one hour; the illustration showed a very satisfactory delineation of the mucosal folds in all its parts. In discussing the significance of meteorism Dr. K. ANDERSON (Denmark) gave his reasons for regarding the interchange of gases between bowel and blood stream as proceeding by diffusion. Tests showed that in mechanical ileus gas accumulated proximally to the obstruction and was mainly due to swallowed air. In a closed loop gas formation does not occur. Dr. FRIMANN-DAHL (Norway) dealt with the early diagnosis of strangulation. Strangulation often excites little output of fluid, and few levels are visible on the plain film. An important diagnostic feature is the presence of a tumour-like opacity due to the matted and incarcerated coils. Dr. F. R. BERRIDGE described changes in the small bowel in subjects suffering from calorie deficiency. Delay in transit, with widening of intestinal calibre and loss of mucosal pattern, were noted, with segmentation of the barium column as seen in the sprue syndrome. The small intestine enema by direct intubation was described by Dr. A. LURAO (Italy), and Professor R. PREVOT (Germany) dealt with the diagnosis of inflammatory conditions.

Under the heading of arthrography the value of the injection of water-soluble contrast media into the joint was discussed by Dr. K. LINDBLOM (Sweden) with reference to the menisci of the knee-joint, by Dr. C. H. NELSON as applied to the shoulder-joints, and by Dr. F. NORGAARD (Denmark) in the diagnosis of lesions of the temporo-mandibular joints. Dr. P. HAUCH (Canada) compared the value of injected oxygen as against "diodrast" or vacuolization in the diagnosis of knee-joint derangements. Professor A. LEB (Austria) showed angiograms of the vessels around joints in rheumatoid arthritis, and demonstrated narrowing of the small vessels and stasis in the veins.

Bone changes in the leukaemias of children were discussed by Dr. J. A. SOTO (Uruguay). Dr. L. DREY (Israel) presented a case of Cooley's anaemia having widespread skeletal changes. Drs. LEFEBVRE, J. LERIQUE, and P. BERTRAND (France) presented a large number of examples of leukaemic bone changes, and Dr. U. COCCHI (Switzerland) dealt with the osseous lesion of lymphosarcoma, myelomatosis, and osteomyelosclerosis.

Radiotherapy

Contributions to a symposium on the presentation of results in the treatment of cancer came from Professor J. HEYMAN (Sweden), Dr. H. F. DORN (U.S.A.), Mr. J. W. BOAG, Dr. P. F. DENOIX (France), Dr. J. CLEMMESON (Denmark), and Professor R. MACWHIRTER. There was general agreement that the present lack of uniformity in methods of presenting results reduced the value of the contributions made by the various workers in cancer therapy. Suggestions for standard methods were put forward by Boag and Denoix. Heyman outlined the more important criteria of cure upon which agreement should be reached. Clemmeson and MacWhirter drew attention to W.H.O. as an appropriate body with which a liaison might be reached, and it was proposed on behalf of the British delegation that an International Committee for standardization of method be set up.

On July 25 the use of radioactive isotopes in therapy was discussed.

Radioiodine (I^{131}) is now emerging from the experimental stage in the treatment of thyrotoxicosis in selected cases, and has proved of value in both primary and metastatic thyroid carcinoma. Radiophosphorus (P^{32}) has proved beneficial in the treatment of polycythaemia vera and in the chronic leukaemias. These points were made in contributions by Mr. G. W. BLOMFIELD, Dr. J. G. HAMILTON (U.S.A.), and Dr. L. O. JACOBSON (U.S.A.). Dr. S. M. SEIDLIN (U.S.A.) gave his experience of cases of metastatic thyroid carcinoma treated with I^{131}, while Professor D. W. SMITHERS remarked that many applications of artificial isotopes, in both treatment and diagnosis, were being tried, but that experience had been short in this country as compared with the U.S.A. He had obtained interesting results in plotting the spread of breast cancer; and in many other fields, such as the rate of absorption of Na^{24} from the bladder, work was in progress.

On July 27 Professor G. E. BERVEN (Sweden) outlined the method used at the Radiumhemmet for treating breast cancer, and gave reasons for the use of pre-operative as well as post-operative irradiation. His figures gave 81.5% five-year cures when no glands were found, and 48.6% five-year cures when glands were involved. He pressed for a committee to standardize rules for presenting results along the lines suggested by Heyman. Professor J. MAISIN and Dr. E. PLUYGRES (Belgium) treated operable cases by radium implant, employing 125–135 mg. of radium for five days. Ten-year survival rates in Steinthals type I and II were 35.8%. Professor M. PONZIO (Italy) reviewed the present position of treatment of cancer of the breast as presented by the literature, and felt that medium tension *x*-ray therapy was still superior to other methods of irradiation. He did not think that there had been any remarkable progress within recent years. Dr. U. V. PORTMAN (U.S.A.) presented a method of classifying types of breast cancer based on clinical and pathological assessment of their extent. Dr. M. LENZ (U.S.A.) made comparison between cases receiving surgical treatment with pre- or post-operative irradiation, and those receiving irradiation only, in various types of breast cancer seen between 1930 and 1942.

In a symposium on radiotherapy of cancer of the larynx Dr. F. BACLESSE (France) described his results in the treatment of cancer of the vestibule, of the glottis, and of the subglottis. He outlined the treatment employed at the Fondation Curie. Mr. V. E. NEGUS dealt with the criteria upon which the employment of surgery, surgery and irradiation, or irradiation alone should rest. Professor A. ZUPRINGER (Switzerland)

considered that satisfactory cure rates were possible by *x* rays, but that tissue reaction in relation to the distribution of dosage was of major importance and still not adequately worked out. He had had promising results when giving the dose in two parts separated by a space of 30 days. Dr. F. E. LEBORGNE (Uruguay) was convinced that *x* rays were in most cases the best form of treatment but advocated the irradiation of minimal areas, not attempting to include lymphatic channels in one treatment. Dr. J. NIELSEN (Denmark) gave statistics for treatment of 115 cases of intralaryngeal cancer. All cases were subjected to fractionated therapy. In cord cases, functional results were excellent. Overall there had been a 57% five-year cure rate.

Radiobiology

The emphasis in the earlier part of a meeting on histology was upon the cellular reaction to radiation, Dr. S. WARREN (U.S.A.) dealing with the general aspects of biological response, and Dr. G. GRICOUROFF (France) with the problem presented by cells which resist radiation action and retain both their viability and mobility, and consequently their capacity for producing new growth. Dr. GLUCKSMAN described the action of radiation in promoting differentiation and so inducing a process by which some malignant cells can be rendered non-viable, although they are not "immediately" destroyed. This process can be followed by the examination of serial biopsies of tumours under treatment, and has a prognostic value. Dr. PALMIERI (Italy) showed that even after the death of the "organism as a whole" there is a short period during which cells still "react" to radiation. The last paper, by Dr. WEST (U.S.A.), dealt with the systemic enzyme changes induced by radiation therapy of malignant tumours, and this contribution produced a lively discussion.

This subject led on to the following day's symposium on radiation chemistry, which centred chiefly on the problems connected with the formation of active radicals within the substance of, and in the neighbourhood of, living cells. Contributors were Dr. M. BURTON (U.S.A.), Dr. P. BONET-MAURY (France), Dr. F. S. DAINTON, Dr. W. M. DALE, and Dr. W. MINDON (Switzerland).

The effect of irradiation and of chemical agents in the production of chromosome changes and in the induction of mutations was the principal subject of another symposium. Similarities and differences between the chemical and radiological changes were discussed by Dr. C. E. FORD and Dr. C. AUERBACH, while Dr. G. BONNIER (Sweden) attributed to indirect chemical change, caused by irradiation, the discrepancy between calculated values for mutations at zero dose and those found in controls. Work by Dr. T. C. CARTER on whole-body irradiation of mice served mainly to demonstrate that a high spontaneous mutation rate existed. A paper by Dr. A. H. SPARROW and Dr. L. F. NIMS (U.S.A.), which was read by the latter, dealt with the cytochemical approach to the understanding of irradiation effects, and included a discussion of desoxy-pentose nucleic acid concentration and of oxygen tension.

A final discussion reviewed the mode of action of ionizing radiations and the many ways in which biological changes might be induced in living cells, especially with changes in their chemical environment. This was the main theme of the papers of Dr. A. FORSSBERG (Sweden) and of Dr. LATARJET (France), while Dr. L. H. GRAY dealt with the influence of radiation quality on the biological response, both for the single ionization and for the integrated result of many ionizations. Dr. A. HOLLAENDER (U.S.A.) described changes in biological response induced by the association of infra-red (heat), light, and ultrasonics with *x*-ray irradiation. Striking modifications of radiosensitivity were observed, although singly these agents had no effect. Dr. B. RAJEWSKY (Germany) discussed the limitations of the target theory. Dr. J. READ presented results from his work upon the roots of *Vicia faba*, which showed that increase of oxygen tension within the cell markedly increased the biological response to *x*-ray dosage.

Radiophysics

Dr. D. W. FRY described the linear electron accelerator and emphasized its suitability in the production of *x* rays in the 3–20 meV region. Experience gained has been applied to the production of a suitable design of apparatus for therapeutic use. A paper by Dr. C. A. TOBIAS, Dr. H. O. ANGER, and Dr. J. H. LAWRENCE (U.S.A.) described experiments on mice using the 184-in. cyclotron built by E. O. Lawrence and his associates. At 190 meV deuterons had a range of approximately 15 cm. in soft tissues. Their ionization intensity is maximal at about 0.7 cm. before the end of their track, and this is approximately four times that on entry. Heavy dosage is thus possible at depth without skin overdosage. Experiments suggested that a useful therapeutic field existed for these high-speed particles. Dr. J. G. TRUMP (U.S.A.) outlined recent research with electrostatic accelerators in the energy range up to 4 meV.

At a symposium on radiological units the difficulty presented by the inadequacy of the "r" unit when high energy radiations were being used was the theme of most speakers. Professor W. V. MAYNEORD suggested the retention of the "r" unit for energies up to 5 meV, but advocated a unit based upon energy absorbed per unit mass of material for radiations of higher energy. This was in line with the views expressed by Dr. LAURISTON TAYLOR (U.S.A.) and Dr. M. FRILLEY (France). Professor R. SIEVERT (Sweden) was more doubtful of the value of an energy unit, and raised the possibility of utilizing certain phenomena which occurred in a vacuum chamber as a possible starting point in the search for a suitable unit.

Treatment was the subject in this section on July 27, when Dr. S. BRENNER (Sweden) described the activities of the Institute of Radiophysics in Stockholm. Constant check is kept upon the output of tubes in the Radiumhemmet by taking measurements in about 15% of all treatments. Drs. H. E. JOHNS and E. K. DERBY (Canada) described the physical aspects of treatment with *x* rays generated by the 22 meV betatron. Dr. L. F. LAMMERTON pointed out the difficulty of attempts to apply a standard system of dosage measurement to many conditions of treatment. An instrument of recent design was presented which enabled the depth dose within a field of any size or shape to be rapidly estimated. Dr. W. J. MEREDITH discussed problems of dosage estimation when using radium implants, and referred to the value of radiography in this connexion. Dr. F. W. SPIERS dealt with the discontinuities in dosage caused by the presence of bone and air-containing tissues, and described attempts to calculate dosage modifications. Dosage variations within bone were discussed. The effects of heterogeneous tissue were much less in evidence when higher energy ranges were used. Dr. W. C. WILSON gave an account of the development of the physical aspects of teleradium therapy since 1937, and gave some description of apparatus and techniques employed.

A symposium was also held on the production and physical properties of radioisotopes, when the production and distribution of radioisotopes in Oakridge, U.S.A., Chalk River, Canada, and Harwell, Great Britain, were discussed respectively by Dr. P. AEBERSOLD, Dr. A. J. CIPRIANI, and Dr. H. SELIGMAN. Methods of standardization were presented, and the steps taken to safeguard those handling radioactive material were described. Emphasis in the clinical use of isotopes has shifted somewhat from therapeutic to diagnostic applications. Dr. L. D. MARINELLI (U.S.A.) described investigation of the ionization which took place in air around beta-ray emitting sources.

Exhibitions

The largest technical exhibition of *x*-ray plant and equipment ever to be held in Britain filled both of the Royal Horticultural Halls. Manufacturers from many countries were represented. The Science Museum in South Kensington arranged a historical exhibit, including a copy of Roentgen's original description of his discovery in 1895 and a print taken by him of his wife's hand. In the main meeting-place of the Congress at the Central Hall was an impressive display of radiographs and of photographs of machines and apparatus.

Reports on Protection and Radiological Units

During the closing ceremony on July 28, Sir ERNEST ROCK CARLING, chairman of the International Committee on Radiological Protection, read a summary of the committee's report, in which it was recommended that the tolerance dose for workers continuously employed in radiological departments should be reduced to 0.5 r per week. Dr. LAURISTON TAYLOR, secretary of the International Committee on Radiological Units, in summarizing its report, said that for radiations of higher energies than 5 meV the "r" unit should be replaced by one based upon energy absorbed per unit mass of tissue.

The next Congress will be held in Copenhagen in 1953.

STREPTOMYCIN IN THE TREATMENT OF TUBERCULOUS MENINGITIS

Streptomycin trials have been in progress for some time in 25 hospitals, under the guidance of the Medical Research Council, and the Ministry of Health recently held a conference of interested workers to discuss the records of 369 patients with bacteriologically proved meningitis, with or without generalized miliary tuberculosis, who had been under observation for from 10 to 22 months. The Ministry has now issued the following report of their general conclusions.

General Results

There appears to be a belief prevalent amongst medical practitioners that streptomycin treatment does no more than prolong life or produce "recovery" as a physical and mental wreck. This is not true. It seems a better representation of the facts to say that, provided skilful treatment was given *early in the disease*, some 40% of patients made a complete recovery, except in some instances for minor disabilities which at the time of assessment did not interfere with their leading a normal life. Medical practitioners who have doubts about the efficacy of treatment would probably have better impressions if they were to take the opportunity of visiting some of the special units treating these patients and seeing for themselves. They will be welcomed at these units. Before the introduction of streptomycin treatment, proved cases of tuberculous meningitis were inevitably fatal with no indisputable evidence in support of alleged exceptions. In the series under review about 1 patient in 4 survived. More precisely, a mortality of well-nigh 100% was reduced to 71.4%, and to 50.7% for early cases. Of those who survived 31% had normal cerebrospinal fluid and approximately 89% were clinically fit and well. Approximately 40% of the early cases survived and were clinically fit and well. In all, 104 of the 369 patients survived.

The 104 survivors were followed up at the end of a further year, giving observation periods varying from 22 to 33 months. All were still alive. Eighty-eight were clinically fit and well, 59 (57%) had normal C.S.F. Of the 16 not fit and well 6 were under age 4 and described as "mentally retarded"—a condition on which it is perhaps unwise yet to make a definite pronouncement; 2 were suffering from genito-urinary tuberculosis; 8 had been "unfit" at the assessment a year previously and included 3 with bone or joint tuberculosis, 1 with optic atrophy registered as a blind person, 2 paralysed and incontinent, 2 "emotionally unstable," one of them being also deaf.

At the end of 22 months the overall survival percentage was 27 for meningitis alone and 17 for meningitis complicated by generalized miliary tuberculosis. Amongst those patients who were observed for longer periods there was no fall in those percentages. For early cases of meningitis there were 48% of survivors at 16 months and at 2½ years, but for advanced cases only 12% at 13 months and only 10% at 2½ years. This emphasizes the importance of prompt diagnosis and treatment.

Methods of Treatment

Only exceptionally did a patient suffering from meningitis respond satisfactorily to intramuscular treatment alone; that occurrence was even more rare with miliary tuberculosis plus meningitis. Intrathecal treatment accompanying intramuscular treatment gave appreciably poorer results when it was given on 50% or less of the intramuscular treatment days in a given period than it did if given more intensively. The general trend of results within homogeneous clinical groups seems to be towards better chances of survival with more intensive intrathecal courses. This assumes, however, concurrent intramuscular treatment for at least two-thirds of the days in a given period. There is no unequivocal evidence on the optimum level of intensity of intrathecal treatment above 75% of the days in a given period. The best results were obtained in patients with early meningitis. Early diagnosis and prompt treatment are of the first importance.

In patients suffering from miliary tuberculosis without meningitis, examination of the cerebrospinal fluid at the commencement of, and at intervals during, streptomycin treatment is important. One-third of the cases of miliary tuberculosis so treated developed meningitis during treatment, and about one-fifth died following it. Meningitis can develop as late as the seventh month of a course of treatment for miliary tuberculosis, and some workers have reported even later onsets in cases not in the series reviewed. There was no evidence that "prophylactic" intrathecal treatment prevented the occurrence of meningitis in patients during the course of their treatment for miliary tuberculosis, and what little evidence there was seemed to incline in the direction that it did not.

Assessment of Results

There is a good deal of difficulty in comparing the results obtained by different observers owing to differing conceptions of what constitutes a normal cerebrospinal fluid. Accounts given should state clearly what is the definition adopted in terms of cerebrospinal fluid cells, protein, and sugar. In the series under review the reports given by the hospitals were all compared with a severe standard of normality—namely, per ml. of cerebrospinal fluid; cells not more than 4; protein not more than 40 mg.; sugar not less than 45 mg. During the period of observation there was no instance of relapse in a patient whose cerebrospinal fluid had attained to that standard and who was at the same time clinically fit and well. Further investigation is, however, needed into the possibility of relapse after longer periods, to distinguish relapse from reinfection, and the possibility of tuberculous lesions arising later elsewhere in the body.

Although it was stated in general terms that recovered patients were mentally normal, rather backward, etc., there would be great advantage in recording detailed psychometric assessments, and their value would be enhanced if there were appended any information derived from school medical records or other sources about the mental condition prior to the onset of illness. Vestibular function and deafness should also be investigated and recorded in relation to recovered patients.

Laboratory Findings

Bacteriological proof is of the first importance in assessing results. It does not seem to be fully realized that on occasions this may be obtained only after a large series of negatives over a long period before eventually a positive is obtained. The most extreme example in the series was a patient who had 61 negative reports in the course of about 10 months before a positive was obtained in the 62nd. The attempt to obtain bacteriological proof should not be too readily abandoned. The larger the volume of a sample of cerebrospinal fluid it is possible to send to the bacteriologist for examination the greater is the likelihood of his being able to obtain a positive result.

The importance of precise quantitative estimates of the cerebrospinal fluid sugar content as a guide in assessing progress is becoming increasingly recognized. It is less well recognized that, whilst cerebrospinal fluid examinations are necessary at intervals to assess progress, it is also necessary, if there is to be research into the relative efficacy of different treatment regimes, to make cerebrospinal fluid examinations at certain definite stages. These are: before and after proposed dates of commencing and ending treatment, on discharge, in the earlier follow-up examinations, and from time to time in the later ones.

There will always be a proportion of patients for whom it is not possible to secure consent to a post-mortem examination, but for research to be of real value necropsy of 100% of the patients who die should be the aim.

Future Research

Apart from the investigation of results over the extended observation periods now in progress, it is hoped to organize further more intensive investigation by selected hospitals into aspects of streptomycin therapy which the recent analysis either failed to clarify sufficiently or revealed as matters which needed special study. With the general release of streptomycin to all practitioners and hospitals there has been a considerable decline in the number of patients admitted for treatment to the selected hospitals participating in this investigation. In order that research may be carried out on the relative merits of different modes of employment of streptomycin in patients clinically comparable, adequate numbers are needed. The greater the number of patients available the more speedily can an answer be found leading to yet better results and the preservation of useful human lives. It is most necessary therefore to give the selected hospitals the opportunity for admitting these patients if they have accommodation available.

EPSOM COLLEGE

The ninety-seventh annual general meeting of the governors of Epsom College was held at 49, Bedford Square, London, W.C., on July 7, with Dr. Harold Spitta, the chairman of the council, in the chair. The results of the last election of pensioners and foundation scholars were announced by the chairman. Dr. Spitta reported that the progress of the school had continued to be most satisfactory. Rises in costs had forced the council to raise the fees from Michaelmas, 1950, and to make a charge for stationery and the use of books. The council intended to appeal for funds with which to make lasting improvements to the school in commemoration of the centenary of the college and its Royal Medical Foundation. The following eight members of the council were re-elected for a further period of three years: Miss Janet K. Aitken, Sir Ernest Goodhart, Mr. J. W. Horsford Hodgson, Mr. Frederick G. C. Morris, Sir Cosmo Parkinson, Mr. Cyril J. Parton, Dr. Harold Spitta, and Mr. B. N. Wallis, F.R.S. Colonel Norman C. King, Mr. H. H. Rew, and Mr. H. A. Deeker were reappointed auditors for the ensuing year. A cordial vote of thanks was passed to all honorary local secretaries, the British Medical Association and its Charities Committee, numerous panel committees, and the editors of the *British Medical Journal*, the *Lancet*, and the *Medical World*, through whose generosity and help the funds of the college and its Royal Medical Foundation have benefited during the past year.

The Ministry of Health states that the Prison Commission recently approached the Minister of Health about the psychiatric treatment of offenders serving short sentences. Such treatment may be incomplete when the offender is discharged, and if not continued any benefit from it is likely to be lost. But if arrangements could be made for the treatment to be given by a regional hospital board psychiatrist while the offender is in prison it would probably often be possible to continue it after discharge. The Minister does not object to arrangements being made by regional hospital boards and local prisons for consultants to treat prisoners serving short sentences with a view to continuing the treatment if necessary after discharge from prison. Conversely, prison medical officers who have psychiatric qualifications could assist at regional hospital board clinics. The Minister considers this proposal to be an important social service which should be developed where possible, and hopes that any approach made by local prison authorities will be sympathetically considered.

Correspondence

Residual Insecticides in Assam

SIR,—Dr. D. M. Bertram has recorded the results of an inquiry into the relative efficacy of D.D.T. and benzene hexachloride ("gammexane") in the control of *Anopheles minimus* in Assam (May 20, p. 1200). He reached the conclusion that many anophelines landing on walls treated with D.D.T. were stimulated rather than killed, and though the numbers caught in treated houses were materially reduced the anopheline mosquito population able to bite was not materially changed.

My colleague Dr. Alan Gilroy, also working in Assam on *A. minimus*, has asked me to report the following findings, which do not support Dr. Bertram's conclusion. The technique of treatment and checking was as described by Dr. Bertram. D.D.T. was applied at 45 and 90 mg. per sq. ft. (929 sq. cm.), B.H.C. at 10 mg. of the gamma isomer per sq. ft. Dead mosquitoes were counted on floor sheets, and traps containing mosquitoes which had tried to emerge were removed and kept under cool conditions for 24 hours' observation, others being substituted in the huts. Results at one month are summarized below.

Treatment	Mosquitoes Collected			Mosquitoes in Traps Surviving 24 Hours
	Dead on Floor	In Trap		
		Dead	Alive	
(*a*) All mosquitoes:				
B.H.C.	134	144	777	66
D.D.T. 45 mg. ..	13	44	361	47
D.D.T. 90 mg. ..	3	41	245	7
(*b*) Anophelines only:				
B.H.C.	50	59	104	8
D.D.T. 45 mg. ..	5	33	56	2
D.D.T. 90 mg. ..	0	19	37	2

The anophelines included 135 *A. minimus* and 17 *A. leucosphyrus*, none of which survived 24 hours.

The figures show no material survival following contact with D.D.T. in excess of that following contact with B.H.C. Care was taken to prevent contamination of cages, a possible cause of mortality. If it occurred it is not likely to have exceeded the contamination of the cages from huts treated with B.H.C. in which the survival rate is greater than reported by Dr. Bertram.

In my opinion both of these insecticides may be of great value in Assam, and ultimately it might prove desirable to alternate them. It would be regrettable if either of them were to be condemned without very full trial and independent repetition of work to confirm results, such as is now being made in the case of Muirhead Thomson's work on D.D.T. in the control of *A. gambiae* in Africa.—I am, etc.,

London, W.C.1. G. MACDONALD.

Haemorrhage from Peptic Ulcer

SIR,—Your two articles by Drs. C. D. Needham and J. A. McConachie and by Drs. A. G. Ogilvie and I. O. B. Spencer (July 15, pp. 133 and 138) provide further useful data on the mortality from bleeding peptic ulcer and its response to treatment. But the only indication that Drs. Needham and McConachie give of the treatment employed in their cases is that it was the usual routine conservative regime employed in medical wards. But, Sir, may I urge that there is no usual routine? Opinion has been divided between the extremes of those who feed and those who starve their patients, and those who transfuse on the least provocation and those who transfuse only when the late manifestations of exsanguination supervene. May I ask, therefore, Drs. Needham and McConachie to state whether their patients were starved or fed, and if fed when and on what? May I also ask whether their patients were transfused; if so, on what indications and how much? I ask this, Sir, because I think we still have much to learn about the medical treatment of bleeding ulcer, and we can all learn if we are in full possession of the facts.—I am, etc.,

London, W.2. G. W. PICKERING.

*** The reply of Drs. Needham and McConachie to Professor Pickering's inquiry appears below.—ED., *B.M.J.*

SIR,—We are grateful for this opportunity to reply to Professor G. W. Pickering's letter. We would suggest that for some years past it has not been usual to treat haematemesis by either starvation or full immediate feeding. The "usual routine conservative regime" employed in the Aberdeen Royal Infirmary lay somewhere between those extremes—viz., fluids by mouth from the time of admission (2–5 oz. = 57–142 ml. of half-normal saline or of half-strength milk hourly or two-hourly), going on to thickened feeds the second day, and small amounts of pounded-chicken type of solids on the third day. Minor differences existed between the three medical units concerned, but the most "cautious" and the most "liberal" feeding wards showed the same mortality, which was slightly higher than that in the "intermediate" feeding ward, which, however, seemed to have dealt with a smaller proportion of severe cases. The appended table gives details of the blood transfused.

		Not Transfused	Transfused	
			Number	Average Amount of Blood per Patient Transfused (M.R.C. Bottles)
Fatal ..	Recurrent	3	48	4·9
	Non-recurrent	3	12	
Survived	Recurrent	14	59	4·5
	Non-recurrent	288	49	2·4
Total		308	168	4·08

The indications for giving blood can best be estimated from the numbers transfused and the amount of blood used. There was never any hard-and-fast policy laid down on this point, but blood was not withheld until severe exsanguination was evident.—We are, etc.,

Aberdeen. C. D. NEEDHAM. J. A. MCCONACHIE.

Anaesthesia in Heart Surgery

SIR,—Dr. D. C. Devitt (July 29, p. 295) is of course absolutely correct in stressing the importance of smooth induction of anaesthesia and of adequate oxygenation in patients who are to be the subjects of cardiac surgery. I believe, however, that his objections to the use of thiopentone for this purpose are not necessarily valid.

It may be of interest if I describe briefly the method that I and my colleagues at Guy's Hospital have found useful in anaesthetizing Mr. R. C. Brock's cases of mitral valvulotomy (we were not concerned in Case 6 of the series described in the article published in your issue of June 3). Preliminary medication is with papaveretum ("omnopon") and scopolamine, and the patient sucks an amethocaine tablet for fifteen minutes before coming to the anaesthetic room. The larynx is then anaesthetized with 2% "butyn" or amethocaine, as if for bronchoscopy, and 5% thiopentone is injected very slowly—the slowness being of great importance—until the patient is unconscious and the jaw relaxed. The dose required to produce this effect is not greater than 0.5 g., and is sometimes less than this. The largest possible cuffed endotracheal tube is then passed under direct vision, and anaesthesia continued with ether and oxygen only.

When using this method we have always found induction to be smooth and free from untoward incidents. Provided that the thiopentone is really injected slowly, significant circulatory depression does not seem to occur, and I know of no quicker or more certain way of gaining complete control of the situation.

I agree with Dr. Devitt in his reluctance to use cyclopropane in cases of mitral stenosis, where there is always a considerable element of myocardial insufficiency. I have no such reluctance, however, in the cases of congenital heart disease which I anaesthetize, for in these the heart muscle appears usually to be extraordinarily healthy. The technique of induction in children suffering from these conditions is different from that for adults. Premedication is by pentobarbitone sodium, administered orally, and atropine, and anaesthesia is induced with cyclopropane and ether by means of a facepiece to a sufficient depth for the passage of a tube by direct vision.—I am, etc.,

London, S.E.1. E. H. RINK.

Treatment of Painful Amputation Stumps

SIR,—After reading the article by Drs. W. Ritchie Russell and J. M. K. Spalding (July 8, p. 68) we think it worth while to mention a form of treatment now under trial at Queen Mary's Hospital, Roehampton.

The treatment consists in infiltrating the painful area with a local anaesthetic of prolonged action, in this case "prolongal" benzocaine, which is 2% benzocaine in urethane. This preparation was devised by Dr. Rappaport and was kindly supplied to us by the manufacturers, Messrs. Zori, of Tel Aviv. After injection urethane is absorbed and benzocaine, being insoluble in water, is precipitated in the tissues in the form of tiny crystals. These crystals persist in the tissues for about four to five weeks and are very slowly absorbed. The pain-killing effect, however, in most cases seems to last much longer.

The injection is performed under general anaesthesia, as there is a period of initial pain which we try to avoid, and, furthermore, a psychological effect is also achieved. In most of our cases other forms of treatment have been tried and failed to bring about an improvement.

So far the results have been very encouraging, provided the cases were well selected, and the relief from pain is sometimes quite dramatic. The selection of cases is most important. The pain has to be due to local causes if the treatment is to be successful. No improvement can be expected if the pain is of psychoneurotic origin.

The number of cases treated is still small and the period of observation too short to draw any valid conclusions, but we hope to be able to report further details and results when a larger series of cases has been treated and observed.—We are, etc.,

Queen Mary's (Rochampton) Hospital, London, S.W.15. M. VITALI. J. KOHN.

Treatment by Mechanical Vibration

SIR,—In 1949 I wrote pointing out to you that mechanical vibrations had been used for many years prior to Dr. Ritchie Russell and that they were of value in other painful conditions beside amputation stumps, but that there was a danger to the operator. This last point has been conceded in Dr. Russell's report (July 8, p. 68). It is amusing to find in the book by Dr. James Ross (then assistant physician to the Manchester Royal Infirmary) called *Diseases of the Nervous System*, published by J. and A. Churchill in 1885, a reference to "mechanical vibrations" from which I send a quotation:

"Some years ago Dr. Mortimer Granville was led to try the effects of rapidly tapping the skin over the fifth nerve in a case of fascial neuralgia by means of a Bennet's percussion hammer, using the pleximeter as a shield. The results were so encouraging that he gradually extended the application of mechanical vibrations as a therapeutic remedy to various other nervous diseases. With the view of better regulating the number and strength of the blows which can be delivered in a given time, Dr. Granville had an instrument constructed which he names 'percuteur.' The newest and most efficient is worked by electricity. . . . Dr. Granville believes that by its use he can relieve neuralgia in a considerable number of cases."

—I am, etc.,

Crisis in Tuberculosis

SIR,—The recent memorandum on tuberculosis from the Ministry of Health to regional hospital boards and local authorities (July 15, p. 162) will be welcomed by all who strive for the welfare of the consumptive patient. The declaration (though long overdue) that "many more beds must be made available quickly," and that the Minister "deems it necessary to augment the insufficient resources of sanatoria and tuberculosis hospitals by using a proportion of beds in general hospitals for tuberculosis cases," suggests that the tuberculous patient may perhaps eventually receive a fair share of the medical resources of this nation.

Most chest physicians will agree with the recommendation to use beds pre-eminently for recoverable cases, and to expedite the "turn-over" of cases in hospital beds. It is surprising to find that an official document which advocates such formerly heterodox practices as this, as well as the active treatment of tuberculosis cases in their homes, nevertheless clings to the idea of "central oversight of admissions and discharges by headquarters medical staff." Throughout the country to-day waiting-lists are longest where this rigid bureaucratic control is imposed, and the most successful improvisations and bed economy are to be found where each chest physician has his own direct charge of hospital beds, no matter how few.

If indeed beds are to be made available quickly it is of paramount importance that general hospitals shall open their doors not primarily to relieve central waiting-lists but to help the patients in their immediate locality. To allocate direct control of general hospital beds to each local chest physician, both for tuberculosis and non-tuberculous illness, should facilitate the immediate full and proper assessment of each newly diagnosed case. In this way recommendations for admission to major sanatoria would become more selective, and active therapeutics in the home (which must be supported by hospital facilities) would soon become more widely practised. The disrepute of the old "dispensary system" was largely attributable to its lack, in practice, of such proper facilities, though in theory these were often alleged to be available.

The solution of the appalling problem of waiting-lists for sanatoria is not to be found through ponderous central administration but by providing chest physicians with the necessary facilities to do their job properly.—I am, etc.,

Reading. W. H. TATTERSALL.

SIR,—The memorandum of the Ministry of Health on the treatment of tuberculosis, published in the *Journal* (July 15, p. 162), practically endorses most of the timely recommendations of the Scottish Committee in their crisis expansion programme. We all look forward to the provision of the urgently needed beds (plus nurses) in general and in fever hospitals. How many beds there are readily available for the admission of our patients we just don't know, but I feel that these facilities will not be so plentiful, nor will they be placed at our disposal as quickly as they are required. It has been acknowledged by the Scottish Committee as well as by the Minister that something else, and something almost immediately available, has got to be done without further delay. Long before the authorities concerned with, and responsible for, the control of tuberculosis deemed fit to take up the challenge, several enterprising chest physicians followed the lead given by Dr. Toussaint and organized some scheme of active domiciliary treatment.[1-6]

However, a crisis expansion of such an emergency scheme, which at once would make a large number of sanatorium beds quickly available for early and urgent cases, clearly depends on whether the chest physician can carry on collapse treatment at the chest clinic. A considerable proportion of the old dispensaries—though they are now called "chest clinics"—are lacking the equipment and often also the accommodation for *x*-ray examination and collapse treatment. In order to meet the requirements of a modern chest clinic, and to give the chest physician and the young trainee specialist the widest possible chance of diagnostic and therapeutic clinical work outside the chest hospital, I have suggested the introduction of mobile clinics.[7,8] Such a mobile unit, installed in a caravan, could—in a rota service—be operated by one travelling team in conjunction with the existing dispensaries of a suitable area. It is time now, as you put it in your leading article (July 8, p. 92), "that something is done as an emergency operation." The rapid transformation of our obsolete dispensaries—or rather "visiting stations"[9]—into workable chest clinics is one of the most urgent operations if the crisis expansion of the tuberculosis service is to become a reality.—I am, etc.,

Wolsingham, Co. Durham. E. G. W. HOFFSTAEDT.

Poliomyelitis and Inoculations

SIR,—In view of the recent discussions concerning the relationship between injection and the onset of paralysis in the injected limbs, I should like to give details of a case which was under my care in 1947, during the peak of the poliomyelitis epidemic. At that time I was resident medical officer in charge of medical wards in a general hospital. The patient concerned was a girl of 21 who was sent to me by an outside practitioner with a diagnosis of boils which would not respond to treatment.
