Scientific measurement of human performance in relation to age has been of three main types: (a) Surveys, using tests either of performance or of mental abilities, such as so-called intelligence tests. (b) More detailed studies of performance, using laboratory experiments in which people are given carefully designed tasks to do under controlled conditions. (c) Studies of present practice, population trends, age distributions, and labour turnover in industry.

None of these approaches is sufficient on its own. Mental tests show us some of the main outlines of ability, and,

although their results provide only a sketchy picture of human performance, they permit studies to be carried out on a large scale and so give data about norms of performance at different ages which are not readily obtainable in any other way. Such tests have shown that functions such as intelligence, speed of action, strength, and ability to learn by rote all decline with age, usually from a peak performance in the twenties. The decline is slow until the sixties, more rapid thereafter. The shortcomings of tests as commonly used are that the scores lump together many different aspects of capacity, and that we often have little idea of what they measure and whether one unit of score is equivalent to another. They are also not well adapted to the study of what we may call the process of a man's performance—the sequence of events whereby he attains a given end-result.

These disadvantages may be avoided in laboratory experiments which enable us to study performance in greater detail, and give a clearer lead to the understanding of why changes come about. With large groups of people laboratory experiments are too laborious, and this means some uncertainty whether samples of different ages are representative, but with care this drawback can be minimized. I will not enlarge upon the findings of such experiments, because they are the burden of most of what I have to say later. One other limitation upon them must, however, be mentioned. It is seldom possible to use this technique to study performances over a long period of time—usually about half an hour is the limit. We must therefore be cautious when drawing inferences from the results for work done day in and day out. This caution is necessary for two reasons: first, that performance can often be maintained for short periods at a level which is impossible over a longer working spell; and, secondly, it is probable that some of the difficulties experienced by older people in an experiment would disappear with long-continued practice.

Because of these shortcomings, problems of employment must at some stage be studied among people doing their daily work. The value of experiments lies in their helping to sort out genuine age trends in industry which are likely to lead to continuing problems from the multitudinous forces of social and economic pressures and accidents of history which tend to confuse the picture. The task of studying ageing in industry is difficult and demands much more care and clear thought than appears at first sight. It is all too easy on the one hand to leap to conclusions on inadequate evidence, or on the other to become bogged down in a despair of caution over the number of complicating factors which might conceivably be involved.

What we need to do is to take the results of laboratory experiments and to use them to tell us what to look for in industry, then, if the expected age trends are found and they are bad, we need to use our experiments again to suggest ways in which the trends might be minimized or removed.

When we look at industry in this way, it is necessary to look in detail, not at whole industries or factories or classes of work, such as skilled, semi-skilled, or unskilled, but at particular operations. Performance at any task will depend upon the match which can be made between the demands of the task and the capacities of the man doing it. The demands made and the capacities involved can vary greatly according to what at first sight appear to be trivial details of the task. Changes of performance with age will occur when changes of capacity become such that they can no longer be matched to the demands of the task. When this happens there appear to be three logically possible ways whereby a match may be restored: (1) the change in the man might be arrested or reversed; (2) the demands of the job could be modified; and (3) the man could be moved to another job making less severe demands.

Present policy usually concentrates on the third of these possibilities: certain relatively low-grade jobs, such as door-keeping and sweeping, are reserved for old people. This

policy would seem inadequate, however, not only because it wastes the skill and experience of men who were formerly doing higher-grade jobs, but because the amount of low-grade work available is not sufficient for the numbers of old people who will have to be employed.

1. Arrest or Reversal of Age Changes

In so far as changes of ability are underlain by definite organic changes, this line of action involves medical questions with which I am not qualified to deal. There is, however, another type of age trend we can legitimately consider—namely, attitudes and opinions changing with age, which sometimes seem to place older people at a disadvantage. To take one example: older people often lack confidence in their ability to an extent which is not justifiable and is revealed only when circumstances force them to do what they believed to be impossible. This lack of confidence is doubtless fostered by popular sayings and opinions, such as, "You can't teach an old dog new tricks," which are apt to cause exaggerated ideas of disability and lead to unwillingness to try. It may be due also to other attitudes—for instance, the desire to deserve the respect due to age and not to fail in the eyes of younger people; or the belief that hard work brings premature ageing; or, sometimes, bitterness at failure to achieve an ambition or lack of some worth-while goal for which to work.

How to assess these attitudes we do not know clearly at present. We can find out what people say about them, but such statements are often inaccurate, not only because of deliberate falsification but because people often do not realize their true motives. The understanding of these forces is still the province of the shrewd and wise observer, although, when the bogies from which they derive their strength have been discovered, scientists and educators can help in dispelling them.

2. Changing the Demands of the Job

The field which undoubtedly offers the greatest opportunity to improve employment prospects for older people lies in changing the demands made by certain classes of job. Some jobs seem to be such that the skills involved are well maintained into old age, but there are a few important exceptions. Difficulties are not always easy to detect. They may not show in such statistics as production figures, because as a man gets older he seems often to compensate for any growing difficulties by increased care and effort until the strain becomes too great to be borne; then, instead of carrying on at a reduced efficiency, he changes to another job. The reason given for his change may not be a true one. Sometimes, for instance, a change is made ostensibly on medical grounds, but if these are examined they are, as Richardson (1953) has shown, found to be insufficient to account for the magnitude of the change involved. It may sound a surprising suggestion, but I think it is scarcely an exaggeration to say that when a job is found where there is a substantial loss, for almost any reason whatever, of people in the forties and fifties, an age difficulty should be suspected.

We may consider difficulties arising in industrial work under three heads:

(a) Speed

Fall in speed of performance with age is common but by no means universal. It is very much greater in some tasks than in others; and in some tasks at least there is clear evidence that where older people are slower is in perceiving and giving meaning to incoming signals for action rather than in the actual speed of making responding movements. The time required to deal accurately with an incoming signal and to take the necessary action varies with the signal and action involved, but is seldom, for a man in the twenties, less than about half a second (for a review of the literature see Welford, 1952). This is the maximum speed at which we should expect a young man to pick up

items individually from a pile and place them in a machine—with one signal from the pile and one from the machine making one article handled per second. For people in their late fifties and sixties the time seems to have risen on an average to about two-thirds of a second. The implications of this are clear and obvious—we need to reduce the rate at which distinct signals have to be dealt with to the point at which the effective limit of speed at a job is transferred from the reaction time of the man to the operation time of the machine. This can be done in several ways: (a) By grouping signals so that, given the first of a sequence, the ones following can be "assumed" and require only a minimum of attention. (b) By sequencing actions automatically by machine. To carry this to its logical limit would convert the machine operator into a machine minder, but comparatively minor alterations coming far short of this could often make the required difference. (c) By reducing the accuracy required—for example, by making it possible for finished articles to be tipped into a chute instead of having to be placed accurately on a pile. (d) By giving older people larger products to deal with, which take longer to process. This is already done with good effect in some factories.

The amount of perceptual "effort" can be reduced by logical natural relations in laying out a task, as in the commonly used arrangement for an assembly job when one part is taken from each of a number of boxes in turn along a row. This arrangement may not, however, be enough to reduce the difficulty of the task for older people. Probably some indication should also be given which makes it unnecessary for the operative to remember from second to second where he has got to along the row.

It is important to realize that the perception of signals and the shaping of action in response to them can often take place while a previous action is being carried out, so that, if signals for actions are available a little ahead of the time at which the action is required, slowness in dealing with them will not be as apparent as if they appear suddenly and action has to be taken at once.

More subtly, it appears that every time an action starts or stops attention is apt to be deflected, probably by the kinaesthetic stimuli which result from the rapid acceleration or deceleration. This means that if actions can be rounded and continuous they are likely to be substantially faster, especially for older people, than if they are jerky and intermittent. This is an additional point in favour of giving signals for action ahead of time, because when this is done actions can be made to flow into each other smoothly.

Very often speed and accuracy of performance appear to be compensatory. Excessive speed will lower accuracy, and vice versa. In tasks where this relation occurs it is commonly found that older people choose accuracy rather than speed and that the accuracy they achieve often offsets their loss of speed, because they waste less time making errors. The logical conclusion to be drawn from this, which is followed with success in many cases, is deliberately to place older people upon tasks for which care and accuracy are more important than speed.

The most serious effect of speed for older people appears when this compensatory relation cannot be exploited. This is particularly the case with operations which we may call *paced*, where actions have to be taken at a speed which is not determined by the operator, and any slowness will lead to an error or omission which cannot be redeemed subsequently. The best examples of this occur on certain rapid conveyor lines. The numbers employed on these appear to fall away sharply between 45 and 55, so that after 55 hardly any are left. There seems to be little difficulty in recruiting people for these jobs even as late as 40 or 45, and often they seem able to carry on after 55 at the same work if they can do it at their own speed. A possible way of mitigating this difficulty is to introduce buffer-stocks along the conveyor line, which would afford a slight latitude

in the timing of individual items and enable the operator, if he is slow at one moment, to make up time in the next. It should be pointed out that not all conveyor lines have this characteristic of rigid pacing of performance. Some work at a speed which is comfortably below the maximum the operator can stand, and others are such that it does not matter if an item is occasionally allowed to go by (Belbin, 1953).

Mere pressure for speed such as that imposed by piece rates appears to cause less difficulty to older people than does rigid pacing. The reason presumably is that they are able to adjust the speed to suit themselves and to give full play to the advantages they gain from care and accuracy.

A very interesting study by Weston (1949a) of performance at a visual task has shown that poor lighting, small size of detail to be seen, and lack of contrast between objects viewed and their background can lower speed of work between the twenties and the fifties, even when subjects are matched for visual acuity by Snellen charts and Jaeger test types. It seems clear, as Weston (1949a, 1949b) points out, that improvement in one or other of these respects could often raise the speed of work by older people, and that any given degree of improvement would benefit them relatively more than it would younger people. It is also possible, although I know of no evidence on this point, that analogous improvements could be secured in tasks involving listening, as, for instance, when inspection work has to be carried out in terms of the sound made by the moving parts of a machine. Amplifying the sound or keeping down background noise might raise the speed with which faults could be detected under these conditions, especially by older people.

(b) Complexity

Loss of speed or accuracy, or both, appears to be much greater with some more complex tasks than with simple ones. This is not to say that the more complex tasks cannot be done at all, although the maximum possible complexity is probably diminished. Nor is it to say that the longer time taken by older people over a highly complex task may not be accompanied by the application of knowledge which has required a long experience to gather, and which results in decisions and actions having a degree of skill not attainable by a younger man. At the executive level, the implication is that a load of routine work on which occasional important decisions are superimposed is likely to tell on an older man more than on a younger, unless the routine is so simple as to require hardly any attention. Delegation and comparative leisure would seem to be especially important in later middle age if the highest quality of decision is to be maintained.

At the operative level there is evidence to suggest that four types of complication are likely to cause difficulty for older people. First, where actions have to be performed without adequate sensory data to guide them, as, for instance, where a man cannot see what he is doing (Szafran, 1951). Second, where a large quantity of data is presented for digestion all at once, especially if it is in an ill-assorted order—logical sequencing in the presentation of information would seem likely to be helpful to older people. Third, where a quantity of evidence has to be pieced together without using aids to memory such as notes. The fourth, and perhaps the most interesting, type of complication is concerned with what essentially amounts to a kind of abstraction. When we handle an object directly, as, for instance, when we move an object from one position to another by hand, the relation between the perception and the action involved is direct and simple. So it is with hand tools, such as chisels and hammers. It is, however, not so with machine tools, where the direction, force, and form of actions may bear only indirect or symbolic relations to the effects they produce. A very simple example of this is that the turning of a vertical wheel may bring about a horizontal movement of a tool carriage. Research on what are called display-control relationships of this kind has

shown that some are better than others even for younger men. The difference appears to be much greater for older men.

It is possible to get used to any display-control relationship, although unnatural ones may cause temporary difficulty in time of stress and lead to accidents. Persistent difficulty is likely, however, when the relationships keep on changing, as when a man works in turn on several different machines which have different systems of control. I think it is fair to say there is a great need for standardization in machine design, taking already well-verified research into account.

(c) Physical Demands

We are often told that heavy work is unsuitable for older people, and yet at the same time it is clear that a very large number of older people are engaged upon work which is classed as at least moderately heavy (Industrial Welfare Society, 1951). Several reasons have been suggested why they are able to do this work. It may be that physical development acquired when young enables them to continue when old. It may be that the knacks they develop in the course of experience make the work in fact lighter for them than it would be for a younger man. It may be simply that moderately heavy work does not make demands for muscular effort which are beyond the capacity of most normal older people. Discussion of heavy work in relation to age is hampered by a lack of knowledge of what "heaviness" means. We do not know whether it should be assessed in terms of physical effort and, if so, whether the maximum physical effort at any time or the average over a period, or whether it should be in terms of activity which might involve a perceptual factor in the sense that as a man turns to and fro he has to keep on looking first at one thing and then at another. Alternatively, some heavy work seems to be so classed mainly because it is dangerous, demanding either physical fitness and maintenance of balance, as when working at heights, or vigilance, as when handling dangerous materials. It is possible that heavy work as usually conceived means work which "takes it out of you" in any of several different ways, and that it is not really correct to think of all types of heavy work as belonging to a single class.

All forms of heavy work may be contraindicated for some people, and some forms of heavy work for all older people on medical grounds. Where these are absent it appears that while older people show a strong tendency to move away from really strenuous work (Richardson, 1953), they continue on jobs in which considerable physical effort is interspersed with periods of lower demand. It is probably true to say that moderate demands for physical effort cause less trouble to older people who are fit than does pressure for speed.

3. Training

However successful a policy of adapting jobs to the needs of older workers may be, there will be some men and women, as now, who must, or will wish to, leave their jobs and learn new ones in middle life. Such changes are not to be undertaken lightly, because, unfortunately, studies of learning indicate with striking uniformity a fall in learning ability from the twenties or thirties onwards. Beyond this age, learning to a fully adequate level can be achieved by some people and at some jobs, but it usually takes longer, and may therefore be prohibitively expensive. Good performances by a few middle-aged people who do train for new skilled jobs is not a reliable guide to the capacity of the majority, because almost certainly there are many who feel it is hopeless to take up a new skill in middle life, and only those unusually confident apply.

"Learning" is used as a blanket term to cover several distinct processes. The material to be learnt has to be perceived and comprehended. It has to be memorized, retained over a period of time, and then produced for use on a subsequent occasion. Now, there is evidence that

older people can usually remember well what they already know. The difficulty in extreme old age is mainly in the memory of the immediate past. Some people complain of loss of short-term memory much earlier, and we may well wonder whether it begins in a mild way in the thirties, or even the late twenties. These are the ages at which difficulties in training are usually first reported. Once a skill has been learnt it usually survives well into old age. It would seem, therefore, that the problem is really in the actual act of learning, so that the difficulty for older people occurs during the training session itself, and that difficulties in later performance are not due so much to failure of retention as of not taking enough away from the training session.

Difficulties in training seem to be of two main kinds. First, the perception and understanding involved take longer, and training is usually a "paced" task. Measures to avoid this difficulty should aim either at slowing down the pace of instruction, especially in the early stages, or at giving the trainee control over the speed. Thus, for example, we should expect an older person to do better on his own than in a group. Again, there is a little evidence which suggests that, if the trainee's educational level is suitable, written instructions may be better than demonstration. With written instructions the trainee can go back if he misses a point and can ponder anything which is not clear. Another possible means of reducing the time stress of instruction is to prepare for a change of job well ahead and give a trainee some opportunity of getting acquainted with his new job at intervals while he is still working at his old one. It may also be worth while to give rests and pauses during the training sessions. William James said that we learn to skate in the summer and to swim in the winter. His principle seems also to apply on a very much shorter time scale. Learning is often more thorough when brief periods of practice are interspersed with brief periods of other unrelated activity. Just how far this is important for older people is not at present known, but it seems likely that a leisurely and apparently time-wasting instruction would often lead to quicker and more complete mastery than one carried out on more intensive lines.

The second learning difficulty is that the comprehension of a complex task may be very hard to attain. Means of avoiding this difficulty are not well known, but breaking a complex task down into readily comprehended units, and attention to clarity of instruction in terms which are in line with what the trainee already knows, seem obviously worth careful trial and study. There is some evidence that older people are less tolerant of theoretical than of practical instruction, and that they do better if they are allowed right from the start to manipulate the material or try for themselves the machine they are learning to use. The reason seems to be that manipulation helps short-term memory in the same way that writing notes on paper helps with arithmetic. Theoretical instruction is like demanding that the arithmetic shall be done mentally.

When a trainee has failed to learn but is nevertheless forced to do something about a task with which he is confronted, he will inevitably tend to fall back upon his previous experience. This is not only true when training is nominally complete, but occurs also during the actual training itself. During the first training period he will build up some kind of method of doing the task which he will carry over to subsequent periods. If he is fortunate his method may be correct, and although speed may be poor he will improve with practice. If, however, he leaves the first training period with gaps in his comprehension of the correct method, these will be filled from his past experience, which may not be appropriate and may thus lead to errors which will have to be corrected. There is good evidence (Kay, 1951) that corrections of errors of this kind which involve modifying a method already built up are very difficult, so that if a trainee starts wrong he will have disproportionately greater trouble later. The principle is well known in learning games, typewriting, etc. It would

seem to imply that the very first stages of training are all-important and that time spent over these is likely to be well repaid by savings later on.

Past experience can, of course, assist in the mastery of a new task when the task can be carried out by methods already familiar. Confusion seems to arise mainly when the methods required for the new and the former tasks bear some resemblance but are not entirely the same. This leads to the paradoxical situation that it may be easier to learn a new task which can be carried out by methods already familiar than to learn new methods for doing a task which has been done before. Also it may sometimes be easier to make a clean break from an old job than to transfer to a job which is superficially similar.

Other suggestions about training deserve consideration. For instance, older people may not like to take instruction from those younger than themselves or to perform in a manner they think inexpert in the presence of other younger trainees. The means of avoiding such difficulties are obvious. Again, it has been suggested that one of the reasons why older people find it difficult to learn is because they have got out of the way of learning, and that if a person makes a point of learning all through his life he will still be able to learn when he is old. Another possibility is that if a man has once learnt a skill while he is young he can take it up again when he is old, even though it has not been used during the intervening years; so that learning a variety of jobs while young provides a range of alternatives ready to hand if a change of work has to be made in later life.

To conclude, it would seem that, apart from social, economic, and strictly medical questions, we have two important leads towards improvement in the prospect of successful employment of older people. The first is a close scrutiny of methods of work and the design of machinery, especially machine tools. This means that the tackling of the problems of ageing has to be carried back from the shop floor to the drawing-office, and becomes in a large measure the responsibility of engineers. Parallel to this, we need a close scrutiny of training methods and perhaps the establishment and very careful administration of special methods for older people. Both would, I believe, have an important bearing upon the problems of the industrial medical officer, and I venture to suggest that both need the co-operation of the experimental psychologist.

These developments would benefit not only older people but middle-aged and younger people as well, although the proportionate benefit would increase with age. They would not, of course, overcome the problem of age in industry completely, but they could go a long way towards reducing it. The benefits would not all be immediate. There might be some immediate rise in production, but the main advantages would appear only gradually in the stability and flexibility of industry. Stability would increase owing to men being able to stay on a job to a later age, with the consequent avoidance of labour turnover and the difficulties it causes both to industry and to the men involved. Flexibility would be extended in the sense that when necessity dictated a change of work in middle life it could be made with less of the suffering it often entails at the present time.

I would like to express my sincere thanks to past and present members of the Nuffield Research Unit into Problems of Ageing. Most of what has been said here has been based on their work, much of it as yet unpublished.

COSTO-CLAVICULAR COMPRESSION OF
THE SUBCLAVIAN VEIN

BY

R. WYBURN-MASON, M.D.

Clinical Research Fellow, Royal Cancer Hospital

In recent years the conception of costo-clavicular compression of the brachial plexus has been recognized as often giving rise to symptoms formerly always attributed to the pressure of a cervical rib or to compression of parts of the plexus by the scalenus anterior muscle. Moreover, Eden (1939), Walshe, Jackson, and Wyburn-Mason (1944), and others pointed out that costo-clavicular compression may also involve the subclavian artery. Falconer and Weddell (1943) and Le Vay (1945), furthermore, described cases of costo-clavicular compression involving not only the nerves and artery but also to a slight extent the subclavian vein. I have not been able to find records of cases in which costo-clavicular compression or pressure by the first rib has produced its chief effect on the subclavian vein rather than on other structures. In the following two cases traumatic wrenching of the shoulder appears to have led to such a condition.

Case 1

A machine attendant aged 29 caught his right hand in a conveyor belt, which caused a violent abduction and pulling down of the limb. Something seemed to tear in the right side of the neck and axilla. He felt a severe aching in the axilla, neck, and shoulders, just above the cubital fossa and in front of the right wrist and back of the hand, and the limb felt heavy. Within an hour the arm and hand began to swell. The whole hand felt numb, tingled, and became cold. He was unable to bend fingers or wrist properly. Some four hours after the injury he was referred to hospital with intense oedema of the limb, which failed to subside. Two weeks later he suddenly developed a temperature of 100.8° F. (38.2° C.), rigors, pain in the chest, severe sweating, rapid respiration, and tenderness in the right axilla. He was admitted to hospital and treated with sulphathiazole and penicillin. He recovered from these symptoms in two weeks.

The condition of the arm remained unchanged for the next four months, at the end of which time he was referred to me. Examination then showed gross pitting oedema over the whole right upper limb. The veins were not visible

FIG. 1.—Radiograph of Case 1, showing the drooping of the right shoulder girdle. Note the different angles of the clavicles.

in the arm owing to the oedema. Some slight distension was observable in the right mammary veins. There was marked drooping of the tip of the right shoulder (about 3 in.—7.6 cm.). The right radial pulse was less easily felt than the left. B.P.: right, 142/90 mm.; left, 132/80 mm. With shoulders drawn back to the right B.P. was 110/40 mm., and the left 130/80

mm. Owing to the gross oedema it was impossible to tell if any muscle-wasting was present. All joint movements were limited by the oedema. Pin-prick was not appreciated over the inner side of the arm, forearm, and hand. It was found that if for a while the right arm was kept raised above the head the oedema diminished considerably. Radiographs confirmed the drooping of the right clavicle and scapula as compared with the left, but otherwise showed no abnormality (Fig. 1). A diagnosis of costo-clavicular compression of the subclavian vein was therefore made.

The patient was admitted to hospital and operation was carried out by Mr. A. D. Le Vay a year after the injury. The first rib was exposed through a supraclavicular incision and a large plexus of veins was found over the brachial plexus. The subclavian vein was compressed by the first rib, but contained no thrombus. The subclavian artery was normal. The omohyoid and scalenus anterior muscles were divided and 1½ in. (3.8 cm.) of the first rib underlying the brachial plexus and subclavian vein was removed. Some traction on the brachial plexus was necessary, and after the operation the patient developed slight ptosis, dropped wrist, and tingling and weakness of the four outer digits of the limb.

All oedema disappeared by the day after operation. He made an uninterrupted recovery, and returned to work five weeks after the operation.

Case 2

A cook aged 27 caught his right wrist in a food lift, which caused the whole arm to be wrenched downwards at the shoulder. This produced a sudden sensation of an electric shock passing up the arm. He was trapped for some time before he could be released. The arm began to ache, especially at night, the palm to tingle, and the limb swelled considerably throughout its extent during the next few days. The swelling was more noticeable when the weather was warm and was less marked on waking. The pain persisted for six months and was then replaced by numbness. The patient was referred to me 10 months after the injury.

On examination the hand and forearm showed severe pitting oedema. There was a marked drooping of the tip of the right shoulder. Partial fibrous ankylosis was present in the right finger and wrist-joints. No engorged veins could be made out in the oedematous limb, but the right mammary veins were dilated. The radial pulses were equal on the two sides. He seemed unable or disinclined to use the limb in any way, and it hung limply by his side. He could not be persuaded to exert any voluntary movement with it. All the tendon reflexes in the limb were unobtainable and all forms of sensation were apparently absent in a glove distribution reaching half-way up the upper arm. Radiographs confirmed the marked depression of the right as compared with the left clavicle, but showed no other abnormality. The arm was placed in a sling, so adjusted that it elevated the tip of the elbow and thus the tip of the shoulder. This resulted in a rapid disappearance of the oedema.

Two months later the patient was operated on by Mr. A. D. Le Vay through a supraclavicular incision, and partial removal of 1½ in. (3.8 cm.) of the first right rib was undertaken. Immediately after operation all the swelling rapidly disappeared, but complete paralysis and apparently complete loss of sensation of a hysterical type reaching as far as the axilla, in a glove distribution, remained. All the muscles responded normally to electrical stimulation. With massage, electrical stimulation of the muscles, and encouragement, symptoms gradually disappeared and he made a complete recovery within the next two months.

COMMENT.—It appears, therefore, that when the tip of the shoulder drops because of damage to or tearing of structures normally supporting it the subclavian vein may be compressed as it passes over the first rib, giving rise to venous oedema of the arm.

Significance of the Above Observations in Relation to
Oedema of the Arm Following Radical Mastectomy

After radical mastectomy swelling of the arm may occur whatever type of incision is used (see Veal, 1938). (In cases of malignant disease of the breast it occasionally occurs before operation.) The swelling may be brawny with thickening of the skin, or soft, with a thinned shiny skin. It is rare in the immediate post-operative period. It usually develops three to six months post-operatively, or it may not occur for a year or more. It may be accompanied by signs of recurrence of growth, such as a mass in the axilla, enlargement of the cervical lymph nodes, or nodules of growth in the scar. In other cases recurrent lymphangitis or cellulitis in the limb may precede the onset of oedema. In still others swelling occurs on return to normal activity with the arm. There may be no premonitory signs or symptoms. When swelling develops it may be persistent and progressive until the arm is enormous, or it may progress to a certain stage and then remain stationary, being unaffected by activity, dependency, rest, or elevation. Alternatively, the swelling may be intermittent, occurring during the period of activity and dependency of the arm and subsiding during rest and elevation. Usually the whole extremity is enlarged, but in some subjects the posterior portion of the upper arm is involved disproportionately. Disability of the limb is common and may reach complete incapacitation. Pain is frequent, and is either due to swelling or follows direct involvement of the brachial plexus.

Halsted (1921) demonstrated to his satisfaction the importance of lymphatic obstruction in production of the oedema, and this is the usually accepted explanation. He concluded that infection of the operation field leads to lymphatic obstruction, which results in swelling of the arm, and he applied to the condition the term elephantiasis chirurgica. All types of swelling are certainly not explicable on a single pathological basis, however, as it seems that the swelling may be caused by either lymphatic or venous obstruction; but it is difficult, especially in chronic cases, to differentiate clinically between the two types. The role of venous obstruction in this condition has received little attention. Veal (1937) studied 46 cases of swelling and 22 without swelling of the arm post-operatively and measured the venous pressure in the arm. He described venographic findings in 20 cases of post-operative swelling of the arm and classified the causes of the oedema into (1) lymphatic obstruction; (2) venous obstruction; (3) lymphatic and venous obstruction.

Lymphatic oedema is of a brawny type, persistent and only partially reduced by rest and elevation. The skin is firm and pits slightly, but does not wrinkle in the pit. This is the least common type after operation and constitutes about 10% of cases. Both superficial and deep lymphatics must be blocked. It may arise from recurrent or persistent infection of the soft tissues of the upper arm, axilla, and shoulder as a result of operative injury, in healed scars or recurrent carcinoma with ulceration of the skin surface. Patients often give a history of recurrent lymphangitis or cellulitis of arm and shoulder accompanied by chills, fever, and pain in the arm, neck, and shoulder. The cervical lymph nodes are often enlarged and tender. Swelling of the arm is usual with the first attack, but may subside with the infection. After recurrent attacks it persists. Occasionally direct extension of carcinoma is responsible for the lymphatic obstruction. Venograms show no block. There is no evidence of engorged collateral venous circulation or elevation of venous pressure in the arm.

Venous obstruction leads to a soft pitting type of oedema. The skin is thinned and tense, and wrinkles in the pit. Veal states that 70% of cases of post-operative oedema fall into this class. Swelling may temporarily disappear with rest and elevation. This type is commonly due to spread of malignancy to axillary and subclavian vessels. It may involve the wall of the vessels, leading to thrombosis. The veins may be occluded by benign operative scar tissues

within either a few weeks or months. X-irradiation may also cause scarring, with the same result. The vein is obstructed high in the axilla, as shown by phlebograms, and the external jugular vein may also be distended if the venous obstruction is above the entrance of this vein into the subclavian. The venous pressure in Veal's cases ranged from 19.5 to 140 cm. of water, with an average of 53 cm. (the normal at heart level is up to 12 cm. of water). Oedema of the arm may not occur until the pressure is above 25 cm.

According to Veal, ligation of the axillary vein does not cause oedema of the arm, provided sufficient tributaries are intact. Sudden occlusion of the axillary veins by thrombi, as in primary thrombosis and effort thrombosis, may lead to massive oedema of the limb, disappearing in a few days to weeks owing to the development of a collateral venous circulation, especially in the chest (Veal and McFetridge, 1935). These collaterals are, however, removed during mastectomy. Nevertheless, it has been shown above that obstruction of the subclavian vein into which the mammary veins drain, even if the latter are intact, will cause pitting oedema of the arm.

If the venous oedema is not soon relieved there is increasing evidence of lymphatic obstruction, and so cases merge into the lymphatic-venous type. This is the late result of venous obstruction, which leads to dilatation of lymphatics and incompetence of their valves. This is characterized by thickening of the skin with pitting oedema, and is only slightly affected by rest and elevation. Dependency of the arm helps to prevent emptying of the lymphatics. Infection may follow. Venographic and venous-pressure findings are as in the venous group.

I have investigated 32 cases of post-operative oedema of the arm after radical mastectomy usually followed by x-irradiation. They were seen at various stages from 6 months to 15 years after the operation. Of these, four showed a marked drooping of the tip of the shoulder on the affected side. In all four the arm swelling appeared early and was noted when the patient began to get about after the operation and before receiving x-irradiation, which thus could not have played any part in its causation. No distended veins were visible in the oedematous limb. The venous pressure in the two arms was measured in these four cases, and were found to be as follows:

	Affected Limb	Normal Limb
First case	105 cm. water	7.3 cm. water
Second „	73 „ „	10.4 „ „
Third „	47 „ „	10.3 „ „
Fourth „	88 „ „	9.6 „ „

Oedema could be relieved by elevation of the tip of the shoulder by a sling passing under and raising the tip of the elbow. This indicates that the oedema in these cases was not due to dependency, but to venous obstruction associated with the drooping of the shoulder girdle. An example of such a case is the following:

Case 3

Ten years before attending for examination a woman aged 58 had a left radical mastectomy for carcinoma of the breast. Within a few days of the operation she noticed swelling and heaviness of the left arm. X-irradiation over the clavicle and in the axilla was begun later, hence the swelling of the arm could not be the result of irradiation. She had little pain in the arm and no sensory disturbance. She had not noticed that posture had affected the swelling.

On examination the whole upper limb as far as the clavicle was enormously enlarged with both pitting and solid oedema (see Fig. 2). The left clavicle was obviously considerably lower than the right and pointed downwards and outwards. The left arm veins were partially buried and were grossly dilated in the region of the elbow. There was great tenderness on pressure over the neurovascular bundle below the clavicle. The blood pressure in both arms was 175/100 mm. The left pulse, but not the right, was slightly diminished on depressing the shoulder. X-ray scarring and telangiectases could be observed above the left clavicle. Venous pressure in the right antecubital vein was 7.3 cm.

of water, in the left 105 cm. Radiographs of the chest confirmed the lower position of the left clavicle (Fig. 3). A phlebogram carried out by injection into the antecubital veins showed a hold-up of the radio-opaque material at the outer edge of the first rib on the left, but not on the right. The arm was rested in a sling so adjusted as to elevate the

Fig. 3.—Radiograph of Case 3, showing the different position of the shoulder girdle on the two sides.

Summary

Two cases are described in which there occurred obstruction of the subclavian vein by the first rib as a result of tearing of structures supporting the clavicle. The injury resulted in gross pitting oedema of the arm, which was relieved by removal of a portion of the first rib. The significance of the observation in relation to some cases of post-operative oedema of the arm after radical mastectomy is discussed.

I wish to express my gratitude to Mr. A. D. Le Vay, who operated on Cases 1 and 2, and to the consultant staff of the Royal Cancer Hospital, for kind permission to publish this paper.

PYLORIC STENOSIS AND FIBROUS STRICTURE OF THE STOMACH DUE TO FERROUS SULPHATE POISONING

BY

F. G. M. ROSS, M.B., B.Ch., D.M.R.D.

Formerly Senior Registrar, Hammersmith Hospital, W.12

During recent years several accounts of the effects of poisoning from compound ferrous sulphate tablets have been published, notably by Forbes (1947), Thomson (1947, 1950), and Spencer (1951). There has been an increasing awareness of the danger if these tablets are accidentally swallowed by children. The following case is thought worthy of record, as it exhibits certain features not noted in the cases so far reported.

Case Report

A previously healthy boy, aged 17 months, swallowed between six and twelve tablets of a proprietary preparation of compound ferrous sulphate at about 2 p.m. on July 21, 1951. He vomited shortly afterwards, and this was followed by haematemesis. On admission to hospital an hour later he was found to be restless and collapsed. Gastric lavage was performed and anti-shock treatment instituted. He continued to vomit small quantities of bright-red blood all that day. Next day he was quieter and vomited some dark-brown fluid only once, at 11 a.m. No further haematemesis occurred. He was discharged on August 3, by which time he was vomiting only occasionally and his stools were normal in colour. His weight at this time was 19 lb. 4 oz. (8,730 g.).

After discharge from hospital he failed to improve. The vomiting gradually increased in severity, and he was readmitted to the same hospital on August 14. On examination he was found to be dehydrated and very restless. He weighed 17 lb. 12 oz. (8,050 g.). On August 17 and 20 he vomited large quantities of curds. On August 25 his weight was 16 lb. 12 oz. (7,600 g.). A barium meal examination done on August 28 was reported to show a stricture of the body of the stomach, through which the barium passed slowly, and some oesophageal dilatation (Fig. 1).

On August 31 he was transferred to Hammersmith Hospital. He was found to be a grossly wasted and dehydrated child, with depressed fontanelle; otherwise physical examination was negative. Intravenous saline and dextrose were given, and feeds by mouth of 1 oz. (28 ml.) of milk with casydol. He vomited five times on September 1, and seemed to have abdominal pain on taking feeds. Next day he was better and less dehydrated. It was thought that there was probably an obstruction at the lower end of the oesophagus. A gastrostomy was therefore performed on September 4, and from then on he was fed by this route. During the next week vomiting still occurred, but consisted mostly of mucus. A chest radiograph on September 1 showed the lungs to be clear. Next day stomach aspiration yielded 13 oz. (368 ml.) undigested milk and mucus.

Fig. 1.—Barium meal August 28, 1951. Stricture of body of stomach.

On September 13 x-ray examination showed the tip of the gastrostomy tube in the oesophagus and some air in the large bowel. A barium meal was given by mouth. The oesophagus showed some dilatation, but no obstruction was noted at the lower end. The stomach contained excess resting fluid. A sharply demarcated constricting band was seen passing horizontally round the lower part of the body of the stomach. Distal to this the pyloric antrum was seen to be narrowed and its outline was slightly irregular. The

Fig. 2. Barium meal September 13, 1951. Stricture of body of stomach, narrowing of pyloric antrum, and pyloric stenosis.

Fig. 3.—Barium meal 20 hours after Fig. 2. Air content of stomach demonstrates stricture and narrowing of pyloric antrum. Small amount of barium in transverse colon.

tally. There also appeared to be fibrosis and narrowing of the stomach distal to this stricture, with almost complete stenosis in the region of the pylorus.

On September 15 jejunostomy was performed, and three hours later hourly feeds were started through the tube. In the next three days he gained 11 oz. (312 g.) in weight, and his general condition was somewhat improved. However, subsequent to this the child's condition gradually deteriorated, and he died on September 20.

Necropsy (Dr. Keith Simpson).—Forty hours after death. Body in a poor physical state, with considerable loss of flesh and marked dehydration. Recent operations for both gastrostomy and jejunostomy completed successfully and without operative mishap—but with suppurative peritonitis ensuing after the second of these procedures. No residual corrosive change at the lips or in the glottis and no mechanical obstruction to the cardiac orifice. Liver showed

mild toxic change only. Some excess mucus and oedema fluid was found in the bronchial tree, but no pneumonia nor pulmonary collapse was seen. There was early extension of infection into the right pleural sac from the peritoneum. In the stomach there was remarkable thickening of the wall by scar tissue extending distally from the lower third of the body. A broad band of scar tissue contracted the pyloric antrum transversely, and thickening of the wall extended into the pyloric sphincter. In the scarred area there was distortion and narrowing of the gastric lumen.

The cause of death was acute suppurative peritonitis following jejunostomy for obstruction to the stomach by scarring due to poisoning with compound ferrous sulphate tablets.

Discussion

Very few cases of pyloric stenosis and fibrous stricture of the stomach due to the ingestion of poisons, without producing concomitant fibrous stricture of the oesophagus, can be found in the English literature, but apparently such cases are more common in foreign countries. Cases have been reported due to the following causative agents: sulphuric acid (Halstead, 1919); hydrochloric acid (Schulenburg, 1941; Joll, 1941); formaldehyde (Vinson and Harrington, 1929); tincture of iodine (Wilensky and Kaufman, 1939); and lysol (Grey Turner, quoted by Schulenburg, 1941). Very recently a case has been reported of pyloric stenosis arising in a 3-year-old boy about one month after swallowing 67 compound ferrous sulphate tablets (Crosskey, 1952).

Compound ferrous sulphate tablets consist of ferrous sulphate 3 gr. (0.2 g.), copper sulphate 1/25 gr. (2.6 mg.), and manganese sulphate 1/25 gr. (2.6 mg.), usually coated with sugar and coloured bright green. Somers (1947) and Forbes (1947) have shown that the ferrous sulphate is the lethal agent, the small amounts of copper and manganese making no difference to the toxicity of the tablets. Forbes (1947) and Spencer (1951) have independently suggested that the ferrous sulphate is converted in the stomach into ferric chloride, the latter producing the main local lesions.

Twenty cases of poisoning with compound ferrous sulphate tablets in children have been reported in the literature so far. Of these, 10 (50%) have recovered, all apparently remaining symptom-free after discharge from hospital, and 9 (45%) have died within two and a half days. One case (5%) recovered, but subsequently developed pyloric stenosis. Nearly all these patients vomited after taking the tablets, but 66.7% of those that died had haematemesis or blood in the stomach washings, compared with only 30% of those that recovered without sequelae.

Experimental work by Somers (1947) and Forbes (1947) in animals has demonstrated that the gastric changes are roughly proportional to the size of the dose for each species. In children the gastric appearances at necropsy have been consistent and similar to those found in the experimental animal. In children there is an area of haemorrhagic gastritis with oedema (Prain, 1949) situated in the middle third of the stomach near the greater-curve side and involving both walls. A less degree of similar reaction extends over the rest of the stomach. Microscopy shows oedema of the submucosa, necrosis of the mucous membrane, vascular thrombosis, and impregnation of the mucosa and vessel walls with iron. Forbes (1947) and Spencer (1951) emphasize the haemorrhages that occur into the stomach wall.

It is unfortunate that the stomach in the present case was not examined histologically. It is evident, however, from the accounts given of similar cases and experimental work in animals that the process of repair following the intense haemorrhagic gastritis, if given time, would lead to fibrous contracture of the pyloric antrum and pyloric stenosis. This fibrosis may also be increased by superficial peptic ulceration and subsequent scarring following the shedding of the gastric mucosa. In fact, the development of the fibrous reaction in the submucosa and muscular coat of the pylorus was noted in the biopsy specimen in Crosskey's case (1952).

In the present case the rapid development of the fibrous stricture of the pyloric antrum and the pyloric stenosis can be seen by comparison of the two barium-meal examinations done 16 days apart. This clearly excludes a congenital abnormality.

Summary

A case of pyloric stenosis and fibrous stricture of the pyloric antrum developing in under two months in a child after swallowing compound ferrous sulphate tablets is described. Death was due to acute suppurative peritonitis following jejunostomy.

The literature on ferrous sulphate poisoning and fibrous stricture of the stomach due to the ingestion of corrosive poisons is briefly reviewed.

My thanks are due to the physicians and surgeons under whose care the patient was at Hammersmith and Margate Hospitals for permission to publish the case, to Dr. J. Duncan White and Dr. J. P. Thierens for permission to use the radiographs, to Dr. Keith Simpson for his necropsy report, and to Mr. Basden for the reproductions of the radiographs.

METHOD OF PREVENTING INSULIN ATROPHY

BY

J. G. FOX, M.B., Ch.B.

R. B. McCONNELL, M.B., M.R.C.P.

H. S. PEMBERTON, M.B., F.R.C.P.

AND

D. C. WATSON, M.C., M.D., M.R.C.P.

(From the Diabetic Clinic, David Lewis Northern Hospital, Liverpool)

Many theories have been put forward to explain the development of fat atrophy occurring at the site of injection of insulin in some diabetic patients, and in our opinion no better summary of these views has been given than that of Marble and Smith (1942).

During an extensive survey of 57 cases of insulin atrophy occurring in this clinic it occurred to us that, whatever the exact mechanism of its production, the high local concentration of insulin at the site of injection is probably a significant factor. Dispersal of this concentration seemed to be a logical step towards lessening or preventing such atrophy.

The use of hyaluronidase as a spreading agent suggested itself. The obvious danger was too rapid absorption of insulin into the blood stream, with consequent hypoglycaemia. Several stabilized diabetics in hospital, not showing insulin atrophy, were therefore given their usual doses of insulin with added hyaluronidase. No appreciable change was found to occur in their diabetic control. No hypoglycaemia was observed, whilst, on the other hand, there was no evidence that the insulin was rendered ineffective. In studying the control of

diabetics by the inunction of an insulin hyaluronidase mixture, Bresgen and Heinlein (1951) also found that the insulin was not inactivated.

Accordingly, in 1951 three children who showed marked atrophy at whatever site insulin had been given were chosen for a trial. They lived in a home for diabetic children attached to the National Children's Home at Frodsham, Cheshire, and their diabetic condition was under constant supervision by trained nursing staff. Areas in which insulin had not been previously given were chosen in each child for regular injections of an insulin-hyaluronidase mixture, and injections have since been confined to these new sites.

The insulin-hyaluronidase mixture was made daily by dissolving 3 mg. of hyaluronidase in 400 units of soluble insulin (80 units per ml.). From this mixture the individual doses were drawn up. This addition of hyaluronidase to insulin did not produce any alteration in their diabetic control, and injections of the mixture caused no more discomfort than had injections of insulin alone.

Case Reports

Case 1.—A girl born on December 3, 1938, had been a diabetic since 1944. She was first seen by us in September, 1950, when she showed insulin atrophy in both arms and both thighs. Her parents stated that the atrophy developed in the arms in about six months and in the thighs in about four and a half months after beginning insulin injections. Her diet contained 250 g. of carbohydrate daily up to May, 1952, since when she has had a "free diet." Injections of soluble insulin twice daily from September, 1950, to February, 1951, in the arms and thighs greatly increased the atrophy already present. Though she has had no more injections in the arms and thighs since February, 1951, the atrophy remains unchanged. From March 1, 1951, to January 27, 1953, the insulin-hyaluronidase mixture was given into the buttocks only. The total daily dose varied during this period from 72 to 88 units. No subcutaneous atrophy of the buttocks has developed from the use of this mixture.

Case 2.—A girl (born September 15, 1943) had been a diabetic since 1948, and was first seen by us in August, 1950, when she showed marked insulin atrophy of both arms and both buttocks. We were informed by her parents that insulin atrophy was "very bad" in the arms within about nine months of starting insulin injections. Her diet contained 160 g. of carbohydrate daily at first; it being increased to 235 g. at present. From March 1, 1951, to October 28, 1952, the insulin-hyaluronidase mixture was given into the anterior abdominal wall only. The total daily dose varied during this period from 64 to 68 units. No subcutaneous atrophy of the anterior abdominal wall has developed.

Case 3.—A boy (born September 4, 1941) developed diabetes mellitus in 1949, and was first seen by us in May, 1951, when insulin atrophy was present in both arms. At that time his diet contained 190 g. of carbohydrate daily, and this has gradually been increased to 250 g. daily. Injections of soluble insulin were given twice daily, into the left thigh only, from May 26 to November 20, 1951, the total daily dose varying between 84 and 45 units. Atrophy was then observed to have developed at this site. Since November 21, the insulin-hyaluronidase mixture has been given into the right thigh only. The total daily dose has varied between 48 and 56 units. The mixture has been used for 16 months up to March 20, 1953, and has produced no atrophy in the right thigh.

Discussion

It would seem from our observations in these three cases that the addition of hyaluronidase to insulin has prevented atrophy developing, whereas, with insulin alone, atrophy

had appeared in a few months in each case. The chief benefit from the use of this method, if its value is confirmed, would appear to lie in the alleviation of this unfirmed, slightly effect of insulin therapy, which so commonly occurs in children and young women. Among 20 diabetic children at this home, insulin atrophy has occurred in 10 (50%).

There are, however, some practical points for consideration before the method can be applied to the routine outpatient treatment of diabetics. At present we believe that the insulin-hyaluronidase mixture must be freshly prepared each day, as its spreading action begins to diminish after eight hours. A more stable preparation would have obvious advantages. Further, it is probable that we have been using an excessive amount of hyaluronidase.

Summary

Three cases are described in which an insulin-hyaluronidase mixture has prevented the onset of insulin atrophy.

The practical difficulties in the giving and preparation of this mixture are discussed.

Medical Memorandum

A Case of Friedländer's Pneumonia Treated with Aureomycin

The incidence of Friedländer's pneumonia has been estimated as 0.8 to 4% of all pneumonias. Rosenthal (1949) points out that these figures are probably too high, as it is only the severe pneumonias which are admitted to hospital.

Before the introduction of the sulphonamides the mortality was approximately 80%. With their advent it fell to 60%, only to rise again when they were gradually replaced by penicillin—which is almost completely ineffective against this organism—as the treatment for all types of pneumonia. Gill (1951) believes that penicillin may actually be harmful, stating that all his patients treated with penicillin alone died. In the days before any specific treatment was given, 20% recovered. He suggests that this may have been due to the penicillin killing susceptible organisms, thereby giving the Friedländer's bacillus a free field.

Streptomycin has proved more valuable than the sulphonamides, and some encouraging reports have been published (Barber and Grant, 1952). However, as this condition can become chronic, and as the dosage of streptomycin needed may be high, complications of treatment may arise. Furthermore, strains exist which are resistant to streptomycin, so that some other antibiotic may be necessary. This is a report of such a case, in which aureomycin proved effective.

CASE REPORT

On January 17, 1951, a married woman aged 40, who had previously enjoyed good health and who was seven months pregnant (para 8) developed a "severe chill." She was attended by her doctor, who diagnosed influenza, which was at that time epidemic in Dublin. On January 19 she had a spontaneous precipitate delivery in the toilet. The next day she was admitted to the Mater Nursing Home under my care, her doctor having found evidence of consolidation in the upper lobe of the left lung. On admission this finding was confirmed, and she was noted to be extremely dyspnoeic. She was given oxygen, and started on penicillin and streptomycin in heavy dosage. Twelve hours after admission the cyanosis was less, but she complained of intense chest pain, which was not completely relieved by morphine. She was now coughing sputum which resembled tomato sauce in consistency and colour.

On examination the whole left lung was found to be consolidated. Toxaemia was marked and restlessness was extreme. The nature of the sputum, the degree of toxaemia, and the complaint of intense pain suggested a diagnosis of Friedländer's pneumonia. Aureomycin, 500 mg. every six hours, was begun. Bacteriological examination of the sputum was not possible until January 22, when a culture gave the following results: "Organisms were present in scanty numbers only. A growth of Gram-negative bacilli of the Friedländer group was obtained. The sugar reactions were characteristic." These organisms were subsequently demonstrated to be resistant to penicillin and streptomycin, but sensitive to aureomycin. On the same date the white cell count was 14,000 (74% polymorphs).

During January 22 and 23 there was a slight improvement in the clinical condition. Toxaemia was less but the cyanosis was still pronounced. X-ray examination showed involvement of the whole left lung.

On the night of January 24 the patient, after a bout of coughing, complained of an empty feeling in the left chest. When seen a few hours later she was found to have a left pneumothorax.

On the morning of January 25 fluid was present in the left chest. Culture of this fluid showed a heavy growth of Gram-negative organisms of the Friedländer group. This organism displayed the same sensitivity characteristics as that isolated from the sputum. X-ray examination showed almost complete collapse of the left lung with a fluid level in the fifth space.

Oral aureomycin was continued. In addition, the pleural cavity was aspirated daily and 100 mg. of aureomycin (intravenous preparation) was injected intrapleurally. In spite of these measures the pus remained thin. An intercostal drain was then inserted and permanent underwater drainage was established (Mr. E. O'Malley).

Regular intrapleural aureomycin was continued for many weeks, without rendering the pleural fluid sterile. The lung displayed little inclination to expand, although the quantity of fluid in the chest was gradually diminishing. It was considered that gross pleural thickening had occurred, and that spontaneous expansion was unlikely. On March 14 Mr. M. D. Hickey was consulted and the patient transferred to Rialto Chest Hospital on March 19. Daily aspiration of the pleural cavity was continued until April 17, when decortication was performed by Mr. Hickey. The operation was followed by almost complete expansion of the lung, with the exception of a small pocket in the lower anterior chest. This pocket was aspirated repeatedly.

By the end of May the sputum had decreased in amount and it had become increasingly difficult to aspirate any fluid from the pocket. During this time physiotherapy was carried out in an effort to promote complete expansion. On May 30 4 oz. (110 ml.) of very offensive sputum was coughed up; in this way her empyema pocket was emptied through a bronchial fistula. The amount of sputum immediately fell to a trace, and further attempts at aspiration of the pleural cavity were negative.

She seemed now to have achieved good expansion, although there was radiological obliteration of her left base, due to pleural thickening. Her general condition was excellent, and she was discharged from hospital on June 20.

When last seen (April, 1952), aeration of the left lower lobe seemed complete. She felt very well and had resumed her household duties.

I wish to record my thanks to Mr. M. D. Hickey and the other members of the staff of Rialto Chest Hospital, Dublin, for their assistance in the management of this case.

M. I. DRURY, M.D., F.R.C.P.I.,
Mater Misericordiae Hospital, Dublin.

Reviews

AVIATION MEDICINE

Human Factors in Air Transportation: Occupational Health and Safety. By Ross A. McFarland, Ph.D. Foreword by Brigadier General James S. Simmons, Dean of Harvard School of Public Health. (Pp. 830; 155 illustrations. \$13.00 or £5 6s. 6d.) London and New York: McGraw-Hill Book Company, 1953.

The author of this book is associate professor of industrial hygiene at Harvard and during the past 20 years has had extensive experience, not only of industrial hygiene, but also of aviation, particularly as applied to commercial flying on a global basis. He has been fortunate in his contacts with various international authorities in aviation medicine, both in civil and Service circles, and many of the statistics and views expressed in this book have been compiled from their publications and reports, as well as from proceedings of conferences, congresses, and meetings which he has attended. This help of associates he generously acknowledges in the preface. There is, understandably, a natural tendency throughout to accentuate the American viewpoint, which at times is not in accordance with the concept on this side of the Atlantic. But this may do good by helping to stimulate fresh thoughts and researches and so help on progress.

This voluminous book is profusely illustrated and adorned with a plethora of statistical tables. It contains a wealth of information on most aspects of medicine in its broadest sense as applied to aviation, especially in the realm of commercial flying. Reading is heavy going, but fortunately each chapter has a good summary and an extensive bibliography. The subjects discussed include the physical and psychological selection and the maintenance of efficiency of aircrew and ground staff; the training of aircrew; operational fatigue; ageing and efficiency; survival and rescue; the sanitary and quarantine control of airports and aircraft; the care and comfort of passengers and the transport of invalids; and the organization of an airline medical service.

Some of the statistics are not convincing. For example, those on the sickness and accident incidences of aircrew are based on the records of one airline only for a solitary year, and those concerned with the relative personnel strengths and cost of the medical services of various airlines are not comparable since the commitments differ so widely. Certain airlines provide medical services only for contract staff, some provide for both contract and local staffs, while others go further and give cover to wives and families. Moreover, the costs vary greatly, depending on the countries concerned along the routes.

Several subjects are considered in two or more places, and sometimes opinions expressed are contradictory. Thus, in considering whether aircrew who suffer from diabetes mellitus should be permitted to fly operationally, the author states on page 243, "An airman with diabetes mellitus is considered a hazard and should be disqualified from operating aircraft," whereas on page 265 he says, "Pilots suffering from diabetes should not be allowed to fly if they require insulin to control the disease." The latter view is contrary to the medical requirements as laid down by the International Civil Aviation Organization, which clearly state, "Proven cases of diabetes mellitus should be assessed as permanently unfit." This requirement applies to all licensed aircrew—pilots, navigators, engineers, and radio officers. Again, in discussing the important subject of antimalarial drugs for prophylaxis, there is a vague statement in Chapter 13 that "Chloroquine and Paludrine, developed during the war, may have several advantages over Atabrine," despite the opinion, expressed in Chapter 5, which reads as follows: "Paludrine is a widely used antimalarial drug. It has been used with good results and does not produce disturbing side effects or a discoloration of the skin. It is effective

both as a prophylactic and as a means of attenuating the disease. For these various reasons, aircrews are more inclined to follow out the instructions for using it prophylactically on entering malarial areas." Incidentally, although there are 103 bibliographical references to Chapter 5, there is no reference to the classic wartime researches of Hamilton Fairley, which clearly showed the value of paludrine (proguanil) as an antimalarial.

Anyone reading the sections on tropical medicine would not be made aware of the part played by European workers in this field, especially in Africa and Asia, to which so much reference is made. The Belgian, British, Dutch, French, German, and Italian schools of tropical medicine have contributed so much to the elucidation of problems of aetiology, prevention, and treatment of tropical diseases that due credit should have been given to their work. This failure to refer to important findings of pioneers in aviation medicine occurs in other sections. For instance, in discussing the pre-war researches into psychological selection tests for aircrew, no reference is made to the work of Bartlett and his colleagues or to the valuable sensori-motor apparatus to test co-ordination of limbs and eyes which was developed and assessed by Schuster and Williams. Further, there is no reference to Treadgold's findings on body-build and fitness for aircrew duty, or to the pioneer and outstanding work of Clements and Livingston on the subjects of heterophoria, binocular vision, and depth perception, or to Livingston's wartime researches on, and tests for, night vision. This is the most comprehensive book available on aviation medicine as applied to commercial flying and should prove valuable as a work of reference by those engaged in airline operations. As a textbook, it is likely to be heavy going for the student.

H. E. WHITTINGHAM.

SURGERY OF THE PANCREAS

Surgery of the Pancreas. By Richard B. Cattell, M.D., and Kenneth W. Warren, M.D. (Pp. 374; 100 figures. £2 10s.) Philadelphia and London: W. B. Saunders Company, 1953.

This is one of the most important surgical works that have appeared for some time. During the past 20 years, in which the surgery of the pancreas has been developed from an occasional adventure to a reasonably safe procedure, Richard Cattell has been entrusted with the greater part of the pancreatic surgery reaching the Lahey Clinic. He has probably done more pancreatic resections, and with more success, than anybody in the world, and he writes with authority and with a commendably balanced outlook.

One hundred and two pancreatic resections have been done at the clinic, with thirteen post-operative deaths. Eighty-eight of these operations were for cancer, with twelve deaths, a mortality of 13.6%. Cattell's analysis of this experience is instructive. He finds, for instance, that painless jaundice, which is usually considered the hallmark of cancer of the head of the pancreas, is the exception rather than the rule. Jaundice was present in all but three of the resectable cases, but it was painless in 22 only; indeed, pain was the commonest symptom and usually preceded the jaundice. The marked difference in symptomatology and in ultimate prognosis between cancer arising in the parenchyma of the head and cancer arising in the ampulla is well brought out. Forty-six patients with cancer of the head underwent resection, with a mortality of 17.3%; of these, two survived five years. Thirty patients undergoing resection for cancer of the ampulla had an operative mortality of 6.6%, and, of these, fifteen are now alive, three having survived over eight years. Pancreatico-duodenectomy for cancer of the head is now only proceeded with if it is clear that the growth nowhere involves the vena cava, the portal vein, or the superior mesenteric vessels.

The book is by no means limited to a discussion on cancer. The anatomy and physiology of the pancreas, congenital malformations, acute and chronic pancreatitis, pancreatic cysts, operative and traumatic injuries, and islet-cell tumours are all discussed fully. Chapter IV, on chronic relapsing pancreatitis, has more than 50 pages and 20 illustra-

tions on this highly important topic. Relapsing pancreatitis, like hiatus hernia, is a disease that has probably been with us undiscovered for many years. With a better knowledge of its symptomatology and augmented diagnostic facilities it is being recognized with increasing frequency as responsible for pains that have hitherto defied explanation. The writing is clear. The illustrations are excellent, for they are all well reproduced, and not one is superfluous. Altogether this is an admirable book.

HENEAGE OGILVIE.

THE ENDOCRINE ANGLE

Endocrine Treatment in General Practice. Edited by Max A. Goldzieher, M.D., and Joseph W. Goldzieher, M.D. (Pp. 474. £3 3s.) New York: Springer Publishing Company, Inc. London: Lange, Maxwell and Springer, 1953.

The title of this book is well chosen, since it is indeed about general practice and is not confined to the so-called endocrine diseases. The introduction of cortisone and A.C.T.H. has led to the treatment, with varying success, of many diseases with these drugs, and most are considered in the present volume. The introduction states that the book is intended to give the reader information of the type he might wish to obtain from a consultant at the bedside. Throughout, the consultant is an endocrinologist and continually the question is answered, "What is the endocrine angle on this patient?"

There are good sections on treatment of diabetes mellitus, on male and on female hypogonadism, and on male and on female sterility. Most diseases are grouped under systems such as gastro-intestinal, central nervous, musculo-skeletal, and so on. But the continual stressing of hormone therapy leads not infrequently to a distortion of emphasis, since the endocrine aspect is sometimes slight. The advised treatment of paroxysmal tachycardias wisely avoids endocrines and follows orthodox lines. But the first sentence in the section on constipation tells us that sluggish bowels are a symptom of many endocrinopathies, of which hypothyroidism is the most common. The section on diarrhoea starts with the statement that this is one of the classical symptoms of Graves's disease. Even abdominal pain is considered from the endocrine viewpoint, although we are warned that all possible organic causes should first be eliminated. Abdominal pain is common in the hypogonadal woman, in whom it is often of neurotic origin. But it may apparently also be due to hypocalcaemic hyperphosphataemia. The general clinician is not told how to deal with this abnormality.

The book yet contains a large amount of information. The authors are very enthusiastic about hormones and give much sound advice on prescribing them. Perhaps it is a pity there are no references. One would like to know, for instance, the evidence for advising cortisone in cases of high altitude sickness. The book will be welcomed by makers of endocrine products, but we hope that general practitioners do not often ask themselves the question, "How can I treat all my patients with endocrine drugs?" But that is the question the book tries hard to answer.

C. L. COPE.

PSYCHOLOGY OF CHILDREN

Childhood and Society. By Erik H. Erikson. (Pp. 398. £1 5s.) London: Imago Publishing Co. 1951.

Here is that rare thing, an American non-medical psychoanalyst. The author comes to psychology from art, and so (as he says) he bases his work "on representative description rather than on theoretic argument." This leads him to some reformulations of theory (infantile sexuality, the "eight stages of man") in a way that is interesting yet not compelling. One does not feel like learning or teaching his way of thinking, but nevertheless feels stimulated by a fresh presentation. The rest of the book makes the reader get to like the man and his clinical approach. The main theme is the interrelationship of individual emotional

development and the patterns of society in which the child grows up. The argument is developed without loss of respect for the individual's own developmental process.

The author has been sensitively in touch with various social groups. Two are contrasted: the Oglala sub-tribe of the Sioux, who live in the Pine Ridge Indian Reservation, South Dakota, and the Yurok, a tribe of fishermen and acorn gatherers on the Pacific coast. Here is good clinical material which adds on well to the descriptions of ordinary neurotic and psychotic children with which the study starts.

Erikson has much that is important to say about ego development. He discusses at length toys and the playing of children. About the causation of psychosis he remarks (p. 181): "The truism that the original problem is to be found in the mother-child relationship holds only in so far as one considers this relationship an emotional pooling . . . the primary deficiency in 'sending power' was in the child." This is a good way of putting the matter, but the reviewer has held the view that the original deficiency was usually in the total mothering-system, if not in the mother herself, and in the initiation of the presentation to the new individual of external reality. Both extremes must be allowed for, as well as an admixture of the two.

The book ends with studies of the childhood of Hitler and of Maxim Gorky. Surely this book justifies the training of some psychoanalysts from non-medical fields of study and experience, as is the practice in this country.

D. W. WINNICOTT.

ISOTOPES IN BIOCHEMISTRY

Isotopic Tracers in Biochemistry and Physiology. By Jacob Sacks, Ph.D., M.D. (Pp. 383. £3 8s.) New York and London: McGraw-Hill Book Company, 1953.

As a survey of the investigation of metabolic processes by means of isotopes, Dr. Sacks's book is of very considerable value and would be important if only for its bibliography, which contains about 700 references, mainly covering the period until 1950 but with some 120 of subsequent dates. Throughout this major biochemical section of his book Dr. Sacks is concerned to discuss how far the isotope techniques are valid or crucial, or are alternative or inferior to other procedures. His analysis of these points and of general principles is consistently critical and penetrating; and his writing is lucid, compact, and comprehensive in his surveys of carbohydrate, lipid, protein, and steroid metabolism. The introductory sections on physical measurement are useful, although that on the safe handling of radio-isotopes is somewhat unreal. Good descriptions are also given of problems of diffusion, calcification, and blood formation.

As the title indicates, this book is not primarily concerned with clinical applications, and it is perhaps unfortunate that authors still attempt to cover so many aspects of isotope work in books on any one field of application. Certain clinical uses are discussed here, but the opinions that the author expresses on their application are often slight and potentially misleading. I have the impression that the author is taking too great care to avoid any overstatement of the value of isotopes; and it is understandable that he should sometimes seem too disparaging. These defects, however, are incidental to the declared purpose of the book, to "discuss the principles involved in the use of isotopic tracers and . . . some of the limitations inherent in their use," and this has been thoroughly well and carefully done, and amply illustrated.

E. E. POCHIN.

A second edition has recently been issued of the *Textbook of Physiology and Biochemistry* by Professors G. H. Bell, J. N. Davidson, and H. Scarborough (E. & S. Livingstone, 50s.). Dr. Bruce Williamson's *Handbook on Diseases of Children* has been thoroughly revised for the seventh edition (E. & S. Livingstone, 21s.). Much new material has been added to Professor Boyd's *Textbook of Pathology* for the sixth edition (Henry Kimpton, 88s.), and several sections have been wholly rewritten.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY NOVEMBER 28 1953

THE PREVENTION OF INFLUENZA

Since the first isolation of influenza virus in 1933 many attempts have been made in this country and in the United States to make vaccines giving satisfactory protection against the disease. The results of the early trials of these vaccines were contradictory: a vaccine might afford good protection in one epidemic and yet prove almost valueless in the next. It is now believed that the inconsistent results were mainly due to two factors—lack of knowledge about variations in virus strains and lack of adequate control of the field trials. Until recently the available laboratory methods for the study of the antigenic nature of influenza viruses seemed to show that the virus produced a succession of mutants with new antigenic characters which enabled them to overcome immunity remaining in the population from previous epidemics. With the development of new techniques for the preparation of strain-specific sera an alternative concept of the nature of antigenic variation in the influenza virus has been gaining ground. When the Section of Epidemiology and Preventive Medicine discussed this subject last week at the Royal Society of Medicine, Professor T. Francis, jun., of Ann Arbor, described some of the results of work in his laboratory with absorbed sera. He believes his findings support the theory that the influenza virus antigens are finite in number and that strain differences may be due to variations such as in arrangement or quantity of these antigens rather than to the sudden appearance of completely new antigens. This work is still in an early stage, but if the concept remains acceptable it offers great promise for the future of influenza vaccines.

The second defect of some early vaccine trials was lack of adequate control, and in the opening pages of this issue the first report of the Medical Research Council's Committee on Clinical Trials of Influenza Vaccine is published. During the winter of 1951–2 the committee set up a preliminary trial to obtain serological evidence about the effect of a number of vaccines, and to provide experience in the methods for recording illness. This was followed by a carefully controlled trial of a suitable vaccine during last winter. Some 12,000 volunteers in centres scattered throughout the British Isles and representing several

different groups in the population were inoculated with either an influenza vaccine or a control bacterial vaccine. Care was taken to ensure random distribution of the vaccines, and the observers recording illness did not know which vaccine was received by individual subjects. Any difference between the vaccine and control groups could therefore be assumed to be the result of the vaccine. There was a significant reduction of influenzal illness in the group receiving the influenza vaccine, but no great difference between the groups in the incidence of other respiratory illness—a finding which confirms the belief that the groups were alike in every respect except for the vaccine. There seems little room for doubt that the reduction in influenzal illness among the volunteers who had been inoculated with the influenza vaccine was the direct result of the vaccine.

Many general practitioners will be surprised at the low incidence of influenza among the volunteers in the control groups, and it is possible that the criteria for diagnosis were too strict. Influenzal illness during the past winter was remarkably mild compared with that in many previous influenza A epidemics, and it may have been that a large proportion of sufferers continued at work and thus escaped the suspicion of infection. The report from the Public Health Laboratory Service published elsewhere in this issue shows that the epidemic of influenza A may not have reached many trial centres till almost three months after the vaccines had been administered, and experience suggests that the protective effect of the vaccine may have fallen considerably during the interval. The low incidence of illness and the generally long interval before volunteers were exposed to risk of infection were unfortunate from the point of view of those who designed the trial, but could hardly have been allowed for. In these difficult circumstances a 40% reduction in illness in the group receiving influenza vaccine must be considered a reasonably satisfactory result.

At the Royal Society of Medicine discussion last week one speaker expressed doubts about the application of serological methods to the assessment of a vaccine, and it is probably wise to make the assessment clinically at present. But full use of the laboratory can be made both for the control of variations in clinical diagnosis between different observers and different centres, the non-vaccinated group being used for this purpose, and as a means for excluding other known diseases which might in both the control and vaccine groups give rise to clinical signs and symptoms resembling those of influenza A. Epidemics of influenza A are generally fairly sharply defined in time, and exclusion of cases outside the epidemic period would probably prevent a certain

amount of dilution of the figures due to erroneous diagnoses occurring during the non-epidemic period.

Information about the presence of influenza virus A infections during the trial period was largely provided by the laboratories of the Public Health Laboratory Service, whose staff, as can be seen from the reported printed at page 1178, worked closely with clinicians and medical officers of health. Particular credit must be given to the general practitioner "spotters," who must have found it difficult to observe the exacting precautions necessary in obtaining specimens for virus tests. In previous years detailed epidemiological conclusions on the origin and course of epidemics in this country have necessarily been somewhat speculative, because of the lack of laboratory information. This lack of information was particularly unfortunate in 1951, when viruses of two different groups were present and probably caused illnesses with different degrees of severity. The figures of the Ministry of National Insurance and Pensions provide an accurate measure of the spread and extent of influenzal infections, but without support from the laboratory these figures lose much of their value from the epidemiological point of view.

Many of the problems of influenza epidemiology will probably remain unsolved until much more detailed information of the type collected by the Public Health Laboratory Service has been accumulated and correlated with information from other sources. An alternative approach to the epidemiology of influenza was described by Professor C. H. Stuart-Harris at the meeting of the Royal Society of Medicine already mentioned. He tested sera which had been collected for other purposes for their content of antibody to influenza virus soluble antigens, and showed the value of this method in tracing the appearance and progress of the virus in a community. This method might avoid some of the inevitable defects of an investigation such as that conducted by the Public Health Laboratory Service, but to provide useful information many specimens of sera would need to be tested. None of the methods used at present for the study of influenza epidemiology can give the whole picture, which is likely to emerge only when every source of information is used to the best advantage.

ACCIDENTAL POISONING OF CHILDREN

The accidental poisoning of children seems to be increasing in frequency, and, since most of the poisons are medicines of various kinds, these accidents are of particular interest to doctors. In England and Wales the age at which accidental poisoning is commonest is 1–2 years. In 1950 and 1951 combined there were

53 deaths from that cause among these young children. The number is not large, but it is not far short of the 58 deaths due to influenza (including influenzal pneumonia), and 1951 was an epidemic year for that disease. J. O. Craig and M. S. Fraser have recently investigated¹ the accidental poisoning of children in Scotland, and they found that among children attending two Scottish hospitals accidental poisoning has become much more frequent in the last twenty years. The evidence was not conclusive that this corresponds with a true increase of cases in the child population, but there seems to be no doubt of a sharp increase in the frequency of cases there since 1948. Evidence from Manchester affords some confirmation of the trend.² Discussing the registered deaths from this cause in England and Wales of children aged 1–4, D. Swinscow³ found no increase in frequency between 1931 and 1949, but he pointed out at the Annual Meeting of the B.M.A. this year, by which time later figures had become available, that the death rate showed a steady and notable inclination upwards from 1949 to 1951. The rise was particularly sharp when the death rate from medicaments was separated from that for all poisons, for the death rate from non-medical poisons had declined somewhat.

The proportion of these deaths in England and Wales that are caused by medicaments as opposed to household and miscellaneous poisons has always been considerable and seems to be rising. In 1931–9 it was 52%; in 1940–9 it was 62%; and in 1950–1, the last years for which figures have been published, it was 80%. In the Scottish cases Craig and Fraser found that those due to medicines had recently increased much more than those due to household poisons. After allowance is made for the different ways in which these figures were obtained and categorized, it remains fairly certain that they signify an increase in the last few years—and one that seems likely to be continuing—of the frequency of cases and deaths due to accidental poisoning by medicaments in Britain.

When the drugs and other medicaments causing these deaths are looked at, they are at first sight rather surprising in that most of them are usually considered to be fairly harmless. This is because it is their effect on the adult, not on the child, that is usually thought of. The dangers of ferrous sulphate have now achieved some publicity, and Dr. F. G. M. Ross adds to it by reporting at p. 1200 of this week's *Journal* the death of a 17-months-old boy as the result of pyloric stenosis and gastric stricture. The child

¹ *Arch. Dis. Childh.*, 1953, 28, 259.² Holzel, A., and James, T., *Med. Offr.*, 1951, 86, 169.³ *Arch. Dis. Childh.*, 1953, 28, 26.

swallowed only 6-12 tablets of ferrous sulphate, and vomited soon afterwards, but the tablets did serious and ultimately fatal damage to the stomach. Yet, even though deaths from this poison have been fairly well known for some years, ferrous sulphate caused the deaths of 17 children aged 1-4 in England and Wales in 1950-1. The antihistamines are now rapidly coming to the fore; they caused in this age group one death in 1948 (the first), four in 1949, six in 1950, and eight in 1951. Preparations of strychnine are also frequent causes of death, though it is not thought of as a dangerous poison because it is usually prescribed in small doses in tonics or, more rarely, laxative pills, neither of which types of preparation is handled in the home with much restraint. Aspirin has always been quite a common cause of poisoning in children, and methyl salicylate in liniments has been a serious danger in the past, though less so now.

In the prevention of these deaths the family doctor has an important part to play in warning parents about the dangers to their children of even apparently harmless preparations. Chemists, too, and other vendors of common poisons have a duty to their customers. There is also a strong case for legislation to compel the labelling of all these preparations as poisons, for that is what they are. These are preventive measures that could be taken in the light of what is now known about these deaths, but more needs to be discovered yet. In particular, the increasing frequency since 1948 is no doubt more difficult to explain than merely by pointing out that the Health Service began then. One effect of the Health Service seems to have been to bring medicaments into more homes than ever before, thus increasing the risk to children, and possibly larger quantities are prescribed than formerly, so that more is left over to lie around in the house. It is notable, for instance, that in all these years only one child in this age group died in England and Wales from a sulphonamide. One reason for this may well be that sulphonamide tablets are usually prescribed in fairly small numbers with the intention that they shall be taken in a specified course. Craig and Fraser show that tablets are a commoner cause of poisoning than liquids, and they are certainly more often prescribed than formerly, though not enough to account for the sharp rise in cases and deaths. We are still ignorant of some of the causes of these deaths, but this work does indicate the need for at least advice from doctors and sellers of poisons, and perhaps in addition the compulsory labelling as poisons of many common household remedies.

AGE AND WORK

While most people of working age still feel an obligation to care for their own children, many of them no longer feel obliged to support their blood relations at the other end of life's span. Aged parents and grandparents are left to fend for themselves in a manner that would have been thought shockingly callous 50 years ago, and probably few of its readers saw anything to question in a newspaper headline¹ that appeared last week—"Neglect of the Aged Sick: Welfare State Fails." The effects of this social trend, which seems to be increasing rather than diminishing, are exacerbated by that now well-known demographic change—the increase year by year of the proportion of old people in the population. In a paper appearing at p. 1190 of this week's *Journal* Dr. W. P. D. Logan discusses some of the population changes to be expected and in particular the occupational distribution of old people. At the outset he dispels a rather widespread misconception; it is that people are living to a much greater age than formerly, and it is even sometimes tendentiously expressed as a criticism of medical science for prolonging into a miserable senility the lives of people who would prefer to shuffle off this mortal coil. In fact, however, the expectation of life of a person aged 60 has hardly changed in the last 100 years. It is the expectation of life of young people that has so greatly increased, with the result that many more than formerly now reach the age of 60; but, having reached it, they will on average live only a year or two longer than their great-grandfathers.

It seems to be generally believed that men can work to a greater age in skilled occupations than in unskilled, and in light occupations than in heavy. Though this may be true in some respects, Dr. I. M. Richardson shows in an important contribution² that there is a considerable drift from skilled to unskilled work among older people, which sharply accelerates when the 40s are left behind. Though skill may sometimes diminish with age, its reduction does not seem to be a main cause of this drift. Rather do ageing people find their chief difficulty in responding quickly, and what often causes them more trouble than the physical exertion or the skill required to perform the job is the pressure of keeping up with the conveyor belt. Allowed to complete the task in their own time, they can carry it out with unimpaired skill. Again, there is nothing to be said for the common practice of looking on old people merely as retaining some of their faculties while others are gradually being dimmed. As Mr. A. T. Welford says in an article published at p. 1193 this week, while most of our scientific knowledge about ageing is of ways in which capacity and performance get worse with age, there are clearly ways in which age brings improvement, "such as steadiness of character, conscientiousness, and patience." These qualities have not yet proved

¹ *Manchester Guardian*, November 20.

² *Brit. J. Industr. Med.*, 1953, 10, 269.

³ *National Advisory Committee on the Employment of Older Men and Women: First Report*. H.M.S.O. 1953.

to be amenable to scientific investigation, even though they are often apparent to good employers, but the inability to enumerate and measure them is no excuse for ignoring them.

At the opening of his study of the health of middle-aged and elderly people at work, Richardson refers in passing to the adage that occupation is the best medicine. This is most dramatically seen to be true when the age incidence and causes of suicide are examined. The average age at which suicide is committed has been rising in Britain since 1900, so that it has been becoming increasingly a disorder of elderly people; and Dr. I. R. C. Batchelor and Miss Margaret B. Napier conclude in an article appearing at p. 1186 that of outstanding importance among the causes of these suicides is a community attitude making the old person feel useless and unwanted. The people they studied commonly complained of feeling lonely, and these writers emphasize the need for people to continue an occupation for as long as possible, and to develop other interests too, so that they may continue to be a part of the community. But it seems to be rather important here to distinguish the economic from the therapeutic reasons for staying at work, for many ageing people look forward with a lively pleasure to retirement so that they can at last occupy themselves with something worth while. The right approach was taken in the recent report³ of a committee appointed by the Minister of Labour when it recommended that people who can give effective service should have the opportunity to continue in work. The widespread desire to find ways and means of keeping old people employed is understandable in view of the rapidly mounting bill for old-age pensions—£238m. in 1948 to £501m. in 1978 at present rates—and the report points out that, if the skill of older people can be more fully used, the standard of living will be higher. But, when all is said and done, to anyone not wholly lapped in the Welfare State there must seem something incongruous in a generation which, ever demanding shorter hours of work, asks for its fathers' working days to be extended.

RESEARCH IN GENERAL PRACTICE

Research work under the conditions which obtain in most general practices can never be easy. It requires not only the impulse to continue routine work when the armchair beckons and the glass of sherry is waiting but also the capacity to pursue an objective which is unrelated to the demands of the daily round. It implies therefore not only unremitting industry but also the organization of the working day to give time for constructive thinking; more work on the one hand and more leisure on the other, and the family doctor may be pardoned for concluding that there never was a prescription more compounded of incompatibles. And yet this stimulus to the general practitioner to engage in research has come from his fellows and from others who sincerely wish him well. The inspiration for this movement towards research springs from two sources.

The first is the recognition that there is an army of potential field-workers, as yet unengaged, who should be studying disease not only in the individual but also in the community. The second is the appreciation that such work would encourage some good doctors who have experienced frustration, resentment, and inferiority in general practice, especially those who work in the large towns and cities. The opportunity is undeniable, but the difficulties are great.

The College of General Practitioners has accepted the organization of general-practitioner research as one of its most important functions, and it has issued a first report in the form of a "Research Newsletter."¹ A research committee has been formed and a research register has been opened. A number of distinguished experts have agreed to serve on a panel which is prepared to advise individual general practitioners on the practicability of their research projects and the best method of conducting their investigations. At the first annual general meeting of the College on November 14 Dr. G. F. Abercrombie described the research committee's programme and mentioned² some of the investigations which were already under way. Members who are essaying a common task will be introduced to each other so that the available clinical opportunities will be multiplied and the individual will have the stimulus of working in a team.

The intention of the College is not to direct and control such research but to support and assist it by all possible means. The most fruitful research is done by men who are pursuing their own ideas—and also the most sterile. The rare men of genius, like Mackenzie and Pickles, will pursue their pioneering path alone, but the rest of us must be grateful for friendly counsel. Research is one of the few great words in science, and we must be careful not to debase our limited coinage. The family doctor is more likely to err on the side of humility than of arrogance, and yet his work, even if humilitarian and inconclusive, can bring him personal satisfactions akin to those experienced by Harvey, by Bernard, and by Pasteur.

The research methods employed by family doctors must be historical, observational, and statistical; experimental procedures will usually not be accessible to them. Investigations must necessarily be concerned with the common disorders such as cancer, cardiovascular diseases, and even in these common illnesses a combined study by a group of practitioners will be required if results of value are to be obtained. A small group of doctors working happily together and looking after a compact community of 20,000 people could, in the space of a few years, write anew the natural history of some virus diseases. How fascinating it would be to learn the course of herpes zoster in such a township—the incidence, the age groups, the nerves involved, the relationship to varicella, and the precipitating factors. General practitioners are likely to be the first to observe the ill effects of a new drug, and it is hoped

¹ *Practitioner*, 1953, 171, 307.

² *British Medical Journal*, 1953, 2, 1154.

thetic plastics, including methyl methacrylate polymers, have been considered¹² as alternatives to cartilage. The physical properties of these materials can be readily controlled, and, once their biological "inertness" has been established, they would appear to offer many advantages.

MONKEY BUSINESS

The recent commotion in the daily press about the famous Piltdown remains was the sequel to an article¹ in the latest *Bulletin* of the British Museum (Natural History), the authors of which show beyond reasonable doubt that the Piltdown mandible and canine tooth are not genuinely fossil, but must be forgeries perpetrated about 1912-13 by some person unknown. The original cranial fragments are at the same time proved to be genuine, and possibly of Upper Pleistocene date.

The truth about the hoax, which seems likely to have been originally aimed solely at Charles Dawson, the finder of the Piltdown man, may never be known. Possibly its perpetrator intended at first to reveal the fraud after a short interval, but later, when even the experts accepted the specimens as genuine, took fright and dared not face what would have been the justifiable wrath of so many great men. However that may be, students of human pre-history feel a sense of relief that at long last an acceptable explanation has been found for the manifold problems raised by the Piltdown finds. No anatomist or palaeontologist to-day could regard without qualms a fossil man with a *Homo sapiens* cranium and the mandible of an ape. The usual refuge of the doubters—and they were many—has been to dissociate the jaw from the skull and thereby to evoke a fossil ape as well as the undoubted fossil man. This device did not recommend itself to palaeontologists and geologists in general, for fossil apes are unknown in Western Europe since the Lower Pliocene, perhaps 10 million years ago. The most recent opinion dates the Piltdown gravels to the last Interglacial, between 190,000 and 115,000 years ago. Unfortunately nobody followed up a clue that Waterston almost stumbled on a year after the discovery of the remains. He superimposed tracings taken from radiographs of the Piltdown mandible and of a modern chimpanzee's, showing that they were an almost perfect fit; and he concluded that it was as inconsequent "to refer the mandible and cranium to the same individual as it would be to articulate a chimpanzee foot with the bones of an essentially human thigh and leg."²

That acquired immunity of the host is responsible for the increasingly rapid breakdown of successive foreign transplants was noted by Gibson and Medawar⁹ in a clinical study of skin grafts. It was further demonstrated by Medawar's experimental work¹⁰ on skin transplantation in the rabbit, and more recently by Dempster's experimental studies¹¹ on skin and kidney transplantation. Gibson and Davis¹ report a similar increase in the speed of absorption of successive bovine cartilage implants, and they ascribe this, too, to immune factors.

Having at last disposed of the need to find a fitting evolutionary niche for an apparently important, but now the less incongruous, *Eoanthropus dawsoni*, we may now come into her again. The young lady of Swanscombe comes into her own as the undoubted earliest known human inhabitant of these islands, about 250,000 years old. Many have felt since her discovery in 1933 that the title was hers by right, but for others the Piltdown man has hitherto presented a bar to her succession.

Chemical Pathologist, St. Bartholomew's Hospital, London

This paper is intended to describe as fully as possible, but without unnecessary elaboration, the procedure to be adopted in the examination of urine under the conditions normally present in the surgery. The tests chosen are those considered to be the most informative and selective. Practically all the tests are qualitative and they are often described as simple, but it is important to realize that this is no reason for doing it in a careless or haphazard manner. Experience will soon show that a test done with care gives a result which so far as the test goes is satisfactory; whereas a test made without such care often gives a result which leaves the practitioner in doubt, and he then embarks on a series of repeat or confirmatory tests, wasting time and destroying his confidence in the original test. This means that without necessarily employing precise measurements it is essential to keep as closely as possible to the prescribed quantities and conditions.

Necessary Apparatus and Reagents

Necessary Apparatus and Reagents.
Apparatus.—Tapered urine glass to hold about 6 fl. oz. (170 ml.); a microscope having $\frac{3}{4}$ -in. and $\frac{1}{2}$ -in. (1.7-cm. and 0.4-cm.) objectives; a supply of glass slides and cover slips; dropping pipettes with rubber teats; a small electric or hand centrifuge carrying 10-ml. tapered glass centrifuge tubes is a great asset but not absolutely necessary; urinometer reading from S.G. 1000 to 1060; a plentiful supply of clean test-tubes 6 by $\frac{3}{4}$ in. (15 by 1.5 cm.) and a test-tube rack to hold 12 tubes; Bunsen burner or spirit lamp; simple water-bath or saucepan; tripod and wire gauze; several small glass funnels 3 in. (7.5 cm.) diameter; filter paper No. 1 Whatman 12.5 cm. diameter; litmus paper; two 25-ml. graduated glass cylinders; two beakers of 50-ml. capacity.

Reagents.—Strong hydrochloric acid; strong nitric acid; strong ammonia (0.880); acetic acid (33%); strong solution of iodine (liq. iod. fort., *B.P.*); saturated solution of ammonium oxalate; 25% solution of salicylsulphonic acid; 10% solution of barium chloride; hydrogen peroxide (20 vol.); 10% solution of ferric chloride; 3% solution of silver nitrate; absolute alcohol or industrial methylated spirit; Benedict's qualitative reagent; Fouchet's reagent (this is made by dissolving 25 g. of trichloroacetic acid in 100 ml. of water and adding 10 ml. of 10% ferric chloride solution); 5% alcoholic pyrimidone; chloroform; zinc acetate in powder; sodium nitroprusside crystals; ammonium sulphate crystals.

Nature of the Specimen

Nature of the Specimen

It is important, particularly when testing for reducing substances, to know the time of the passing of the specimen in relation to the previous meal. The specific gravity of a urine will be influenced by marked variation in the fluid intake prior to the passing of the specimen. Traces of protein and increased cell content have a quite different significance in a fresh specimen passed in the surgery by a male patient from that of a specimen passed by a female patient, because the latter may have been contaminated by vaginal secretion. For most chemical examinations a fresh specimen is all that is necessary, but in the case of suspected haematuria, proteinuria, or infection it may be necessary to get a catheter specimen from a female patient.

Appearance and Colour.—Normal urine is of a straw colour which may be pale or dark merely because of variation in concentration. It is quite clear apart from an occasional cloud of mucus. Any turbidity is due to bacteria or suspended deposit which may be crystalline, amorphous, or cellular.

Reaction.—Normal urine is usually acid to litmus paper, but soon after a meal the alkaline tide may result in the production of an alkaline specimen which on standing will deposit a heavy cloud of earthy phosphates.

Specific Gravity.—In an average specimen this ranges from 1015 to 1020 and is influenced by the amount of fluid taken and by the loss of fluid by other channels than the urinary tract. The urine of a patient with chronic nephritis shows a more or less fixed low specific gravity, and limitation of fluid does not raise it appreciably. A specific gravity in the region of 1030 or over is usually due to the presence of sugar.

Deposit.—To the naked eye normal urine shows no appreciable deposit. Concentrated urines may show a deposit of urates, usually coloured pink, or a "Cayenne pepper" deposit of uric acid. The urates will dissolve immediately on warming the urine to about 60° C. Excess oxalates in a specimen of urine are usually recognized by microscopy; they appear in both acid and alkaline urine. Alkaline urines will usually have a phosphatic deposit readily soluble in a little acetic acid. Urates may also be deposited in a concentrated alkaline specimen.

Microscopical Examination of the Deposit

About 10 ml. of urine (which should be as fresh as possible) is centrifuged for 10 minutes at about 2,000 rev. per minute, and after removal of the supernatant fluid by decantation a drop of the fluid from the bottom of the tube, taken by a dropping pipette and teat, is transferred to a glass slide and covered with a coverslip. If a centrifuge is not available the urine should be allowed to stand for two to three hours in a tapered urine glass and a little of the deposit removed by a pipette and teat. Description of the cellular elements, casts, and crystals is usually of little help and it is best to learn to recognize them by practice on known specimens and comparison with the diagrams in textbooks of pathology. Apart from a marked excess of oxalates or uric acid the only crystals of importance are those of cystine; they are colourless, regular hexagonal plates, readily soluble in ammonia and hydrochloric acid but insoluble in acetic acid. Calcium oxalate crystals are envelope-shaped and are insoluble in acetic acid but soluble in hydrochloric acid. Uric acid crystals have always a red or brown colour and are insoluble in hydrochloric acid but soluble in solution of lithium or sodium carbonate. The commonest artifacts resembling cystine are maize-starch grains from dusting powders; these are readily recognized by their blue or black colour on the addition of solution of iodine.

Protein

Normal urine contains no proteins except a trace of mucin. Pathological proteinuria may be due to the presence of albumin, globulin, haemoglobin, methaemoglobin, or Bence Jones protein. As the tests depend on the appearance of a turbidity or precipitate, it is essential that the specimen should be filtered if it is not already clear. If the urine cannot be rendered completely clear, then some of the filtered specimen should always be used as a control to compare with the turbidity of the tested fraction.

¹ Weiner, J. S., Oakley, K. P., and Le Gros Clark, W. E., *Bull. Brit. Mus. (Nat. Hist.)*, 1953, **2**, 141.
² Waterston, D., *Nature*, 1913, **92**, 319.
³ Oakley, K. P., *Proc. geol. Ass.*, 1952, **63**, 271.

Boiling Test.—For this test the urine should be acid to litmus; if not, it should be made so by the addition of just sufficient acetic acid. Boiling an alkaline urine containing protein may convert the latter into alkaline metaprotein; this does not coagulate and on the subsequent addition of acetic acid it becomes acid metaprotein, also in solution, and a false-negative result is obtained. Take about 10 ml. of urine in a test-tube and, holding the bottom with the first finger and thumb, boil the upper third. A cloud or precipitate may be due to protein or the appearance of earthy phosphates owing to the loss of carbon dioxide rendering the urine alkaline. Add two or three drops of 33% acetic acid. Phosphates will disappear, but the protein turbidity will remain and may become more intense. If on heating a cloud appears well below the boiling point and disappears partially or wholly on further heating and then reappears on cooling, Bence Jones protein is present. The boiling test is sensitive and reliable if the urine is clear and acid before the test is made.

Salicylsulphonic Acid Test.—To about 5 ml. of urine in a test-tube add 10 drops of 25% salicylsulphonic acid. The presence of protein is shown by a turbidity or precipitate. This is a useful test, as the original reaction of the urine does not matter. It has the disadvantage that it will not discriminate between Bence Jones protein and other proteins, and it is possible to get a false-positive reaction with urines containing iodoxy after pyelography.

Blood

A chemical test for blood will indicate haemoglobin and its iron-containing derivatives such as methaemoglobin. To about 5 ml. of urine add three or four drops of 33% acetic acid and about one-fifth of its volume of solution of pyrimidone in alcohol, pouring the latter down the slanted test-tube so that it forms a layer above the urine. Add four or five drops of hydrogen peroxide (20 vol.) so that it causes a disturbance at the junction of the liquids. A positive result is shown by the immediate development of a mauve colour at the junction of the liquids spreading up into the alcoholic layer. The colour soon fades unless the amount of blood present is excessive. If the colour appears very slowly and increases steadily for from five to ten minutes, it is probably a false reaction due to the presence of iodides. This can be confirmed by adding about 1 ml. of strong nitric acid to about 5 ml. of urine and then adding about 1 ml. of chloroform. Any liberated iodine will dissolve in the chloroform, giving it a mauve colour. The pyrimidone test is quite sensitive but will not, of course, detect a few red blood cells such as can be seen in a microscopical examination of the deposit. It is a test for haemoglobin and will not distinguish haemoglobinuria from haematuria. Urines containing methaemoglobin will have a port wine or dark brown colour; its presence needs confirming by finding the characteristic absorption bands with a hand spectro-scope. The use of this instrument for detection of pigments in urine is well described in *Harrison's Chemical Methods in Clinical Medicine*.

Reducing Substances

In the surgery the important points are, first, is a reducing substance present? and, secondly, is it glucose? If the latter, then further tests may be necessary to establish the diagnosis of diabetes. Take 5 ml. of Benedict's reagent, measured if possible in the graduated cylinder. Place it in a test-tube and add 0.5 ml. or eight drops of urine by dropping pipette (held vertically). Mix by shaking and boil thoroughly for at least one minute, or place in a boiling-water-bath for five minutes, and allow it to stand for a few minutes. A positive result is shown by the presence of a yellow or reddish yellow precipitate. A green colour or a greenish precipitate should be ignored, as it is probably due to a concentration of normal urinary constituents. It is of the greatest importance that the quantity of urine to that of Benedict solution should not exceed 1 to 10 or many false positives will result.

As glycosuria, whatever its cause, depends upon the blood level, when the urine is collecting in the bladder it is important to know that enough carbohydrate has been taken to cause such a blood level. The actual concentration in the urine will also be influenced by the amount of fluid taken. The best time to test for glycosuria is in the first specimen passed one and a half to two hours after a fairly liberal carbohydrate meal. If a negative result is obtained it is unlikely that the patient ever passes glucose. Other reducing substances are not dependent upon the previous carbohydrate intake, and reduction may be obtained in the presence of lactose, pentoses, laevulose, and derivatives of salicylates taken in the form of aspirin, sodium salicylate, or para-aminosalicylic acid. Pentoses are of no pathological significance, but their presence inevitably gives rise to a suspicion of diabetes. They may appear after their ingestion in fruits, but occasionally persistent pentosuria, unaffected by diet, occurs as an inborn error of metabolism.

A very rare cause of reduction is due to homogentisic acid in alcaptonuria. The reduction due to pentoses is not very pronounced and will be much the same in any specimens, fasting or otherwise. Glycuronates are very rarely a real cause of difficulty and will be related to the ingestion of large amounts of some drug such as morphine, chloral, etc. In adults, lactose, except in very small amounts, is found only in the urine of nursing mothers and is specially apt to occur at the time of stopping breast-feeding. Lactose may occur in the urines of infants with gastro-intestinal disturbance; very rarely galactose is found in the urines of infants made ill by the taking of milk in any form. Laevulose is uncommon but will sometimes be found in the urine of those consuming large amounts of honey.

The commonest false positive is that due to salicylates. Its incidence bears no relation to meals. If suspected it can be recognized by adding about 10 drops of solution of ferric chloride to about 5 ml. of urine and noting the intense purple colour.

Confirmation of the presence of glucose can be made by osazone and fermentation tests, and minute traces may be detected by chromatography; but the relation of the reducing substance to meals is usually sufficient evidence on which to base the diagnosis of glycosuria.

Acetone Bodies

The acetone bodies present in urine may be acetone, diacetic acid (aceto-acetic acid), and β -hydroxy butyric acid. Qualitative tests are available only for the acetone and diacetic acid. Ketonuria is usually associated with diabetes, but it can occur in any condition in which there is deprivation of or failure to use carbohydrate. Children rapidly develop acetone bodies in the urine when carbohydrate is cut off by vomiting or fasting.

Rothera's Test.—In a test-tube place ammonium sulphate to about the 1-in. (2.5-cm.) level and add about 10 ml. of urine. Shake well until most of the ammonium sulphate has dissolved. To this add three or four drops of a fresh solution of sodium nitroprusside, made by dissolving a few crystals in about 1 in. of water in a test-tube so that a fairly deep red solution results. Then add one drop of strong ammonia and mix well. A positive result is shown by the appearance of a deep purple colour. The test is given by both acetone and diacetic acid and is extremely sensitive. Because of this sensitiveness slight colour production should be ignored, and negative results indicate that there is no degree of ketosis. If the positive reaction is marked it is as well to perform a further test with ferric chloride, which, being relatively insensitive, has a greater significance if positive.

Ferric Chloride Test.—To about 10 ml. of urine add solution of ferric chloride drop by drop, mixing well after each addition, until the precipitated ferric phosphate appears to be maximum. Filter, and if the filtrate is free from any marked reddish colour add another drop of ferric chloride. If the phosphates have not been fully precipitated a further precipitate will result and the fluid must again be run

through the filter paper. To the clear filtrate add the ferric chloride solution drop by drop and notice if a red or reddish brown colour develops. It is very important to add the ferric chloride with care as excess destroys the colour of the iron salt formed with diacetic acid: false negatives are always due to excess of reagent. Of the acetone bodies only diacetic acid gives a colour. As the test is not very sensitive a genuine positive result indicates a fairly marked degree of ketosis. Drugs such as salicylate can give an intense purple or reddish purple colour but a negative nitroprusside test. If there is any doubt about the genuine nature of a ferric chloride test, take 10 ml. of urine in a cylinder and add 10 ml. of water, transfer to a small beaker, and boil until the volume is reduced to about 10 ml. Repeat the ferric chloride test. Any diacetic acid will have been converted to acetone and driven off by the boiling and no colour will now be obtained. Drugs will not be volatile and the result will be practically the same as in unboiled urine.

Bile Pigments

Bile pigments are present in urine only in jaundice, so a patient who shows no sign of pigmentation of the sclerotics is unlikely to have bile pigment (bilirubin) in his urine. Bile pigment may cause the urine to vary in colour from orange to deep brown; occasionally on standing there is a greenish tint due to oxidation to biliverdin. A characteristic of urine containing an appreciable amount of bile pigment is that, on shaking, the froth acquires a yellow tinge. Dark urines due to concentration, urobilin, blood pigment derivatives, and drugs do not show this. The yellow colour of the froth is not easily recognized in artificial light.

Iodine Test.—To about 10 ml. of urine add about one-tenth of its volume of dilute iodine solution—that is, 1 part of liq. iod. fort. diluted with 20 parts of water. Pour the iodine slowly down the side of the slanted tube so that it forms a layer on the surface of the urine. A green ring developing at the junction of the two liquids is proof of the presence of bile pigment. This is a good but not very sensitive test.

Fouchet's Test.—For the detection of small quantities of bile pigment this test is the most reliable. To about 10 ml. of urine add about 2 ml. of 10% barium chloride solution. Mix well and filter. The precipitated barium sulphate and phosphate will absorb the bile pigments and after the filter paper has been allowed to drain it should be opened out flat on a white tile or another filter paper. Two drops of Fouchet's reagent are dropped in the centre. The presence of bile pigment is shown by the production of a green or greenish blue colour due to the oxidation of the bilirubin.

Bile Salts

The Sulphur Test.—Place about 50 ml. of clear urine in a beaker or urine glass and from a sprinkler or pepperpot sprinkle dry flowers of sulphur on to the surface. A positive result is shown by the sulphur particles streaming towards the bottom of the vessel. The beaker is best viewed by transmitted light; shaking must be avoided. This test cannot be done properly in a narrow vessel such as a test-tube. It is a sensitive test but can be given by other substances capable of lowering surface tension. Urine from a case of jaundice of some duration with much bile pigment will not necessarily show any bile salts as these are excreted only in the early days of the onset of obstructive jaundice and sometimes when a case of infective hepatitis is clearing up.

Urobilin

The presence of urobilin in the urine indicates either excessive haemolysis with excess production of the pigment or of some degree of liver damage. It is excreted partly as the colourless chromogen urobilinogen and partly as the yellow or orange pigment. On standing, urobilinogen is slowly converted to urobilin and the colour of the urine will deepen. Marked urobilinuria closely resembles the

colour of bile pigment, but the froth is not coloured on shaking and gives no reaction with iodine or Fouchet's reagent. There is no point in trying to distinguish between urobilin and urobilinogen, and the best test is Schlesinger's, which gives a reaction with either.

Schlesinger's Test.—To about 10 ml. of urine in a test-tube add two drops of liq. iod. fort. or any comparable solution of iodine; mix well. In another tube place about 1 g. of powdered zinc acetate and add about 10 ml. of absolute alcohol or industrial methylated spirit. Shake well and mix the two fluids, pouring from one tube to another several times, and then filter. A positive result is shown by a filtrate that while yellow or pinkish yellow to transmitted light will show a definite green fluorescence by reflected light. The test is best carried out in daylight. This test is sensitive, and unless the fluorescence is readily perceptible an excess of urobilin can be excluded.

Chlorides

It is sometimes important to know if a patient is excreting a reasonable amount of chloride, and this can best be ascertained by adding to about 10 ml. of urine about 1 ml. of strong nitric acid and 2 ml. of solution of silver nitrate. Normal urine should give a heavy white curdy precipitate. No precipitate or only a slight turbidity or opalescence indicates a marked chloride deficiency in that specimen.

Refresher Course Book.—The first collection of articles in the Refresher Course for General Practitioners (fully revised) are available as a book containing 55 chapters, price 25s. Copies can be obtained either direct from the Publishing Manager, B.M.A. House, Tavistock Square, London, W.C.1, or from booksellers.

BUTAZOLIDIN SYMPOSIUM

CLINICAL AND EXPERIMENTAL OBSERVATIONS

A symposium on "butazolidin" (phenylbutazone) was held under the auspices of the Empire Rheumatism Council at the Royal Society of Medicine on November 13. The clinical section was under the chairmanship of Dr. W. S. C. Copeman, and Professor E. C. Dodds presided over the experimental section.

Dr. O. STEINBROCKER (New York) presented the results he and his colleagues had obtained with both short- and long-term butazolidin treatment. They found that it was a powerful analgesic, but that its antirheumatic effect, if any, was slight. They had compared the effects of intra-articular injections of butazolidin and hydrocortisone, and, although they had not observed any significant differences in the results, he was not prepared to attribute an antirheumatic action to phenylbutazone on this basis. The incidence of side-effects was 22% in the short-term therapy, and it was found that toxicity occurred in one-third of the cases on long-term treatment. At all periods administration of the drug was fraught with hazards. Dr. Steinbrocker emphasized that no serious toxic effects were encountered in the first 500 cases treated by his group, but that following this two major episodes occurred within one week. He warned against undue optimism and advised weekly analysis of urine and blood counts during the whole course of treatment.

Analgesic Action

Dr. J. P. CURRIE (Glasgow) compared the analgesic action of butazolidin with that of other analgesic antipyretics and newer analgesics. In conditions other than "rheumatism"

butazolidin was a poor analgesic, and he thought that there was some specificity for "rheumatic" pain. In a series of some 1,200 cases not only was the incidence of toxicity extremely low, but even mild side-effects were rarely seen.

It was known that toxicity was increased by the simultaneous administration of amidopyrine and barbiturates, and in Glasgow they were very careful to stop all other drugs during the administration of butazolidin. He suggested that the high incidence of toxic effects encountered by other observers might be due to the fact that phenobarbitone was so extensively used. The potency of pyrazol derivatives in relieving the symptoms of rheumatoid arthritis appeared to be proportionate to their experimental trauma-protective effect, and it was suggested that further screening of pyrazol compounds should make use of this association.

Dr. G. R. NEWNS (Sheffield) discussed the results obtained in 197 cases treated with phenylbutazone. There was sustained relief of pain in 65% of patients, but the drug did not affect the course of the rheumatoid process. Toxic effects occurred in 25% of cases, and included gastrointestinal disorders, skin rashes, agranulocytosis (with one death), and oedema. In spite of the high incidence of toxicity he considered the use of butazolidin in rheumatoid disease was justifiable and that it was particularly useful in the rehabilitation of the more long-standing cases.

Blood Concentrations and Toxicity

DRS. ENA BRUCK, M. E. FEARLEY, and R. I. MEANOCK (London) reported that the incidence of toxic effects increased considerably with increasing blood concentrations of phenylbutazone. When the blood concentration rose above 10 mg./100 ml., 85% of patients developed toxic effects, as against 37% with blood concentrations between 5 and 9 mg. and 12% between 0 and 4 mg. Maximum relief of symptoms occurred with blood concentrations between 5 and 10 mg./100 ml. Increasing the blood concentration to above 10 mg. did not produce further relief of symptoms. In view of the marked variations in absorption of the drug in different individuals they considered it was impossible to formulate a rigid dosage schedule which would prove satisfactory in the majority of patients.

The discussion was opened by Dr. F. DUDLEY-HART (London), who agreed that butazolidin was a powerful analgesic without specific antirheumatic effects. Its value, he thought, was greater in osteoarthritis than in rheumatoid arthritis and he had found it effective in Paget's disease and metastatic carcinomatosis.

Dr. JOHN GLYN said that they had treated 11 cases of rheumatic fever at the Bellevue Hospital, New York, and found that the results were comparable with those produced by salicylates. The constant and dramatic response of the joint inflammation as well as the immediate effect on pyrexia and tachycardia provided some evidence that in this condition butazolidin had more than a purely analgesic effect.

Professor R. DOMENOS (Saarbrücken) said that he and his colleagues had found that the effect of butazolidin in inhibiting formalin-induced inflammatory oedema in rats was significantly greater than that of A.C.T.H. or cortisone. They were unable to demonstrate any correlation between the adrenal ascorbic-acid-depleting effect of various drugs, including phenylbutazone, and their anti-inflammatory effect. He considered this lack of correlation indicated that butazolidin did not act via the pituitary-adrenal axis. Experiments in rats showed that the effects of phenylbutazone were not influenced by adrenalectomy and that renal excretion of various substances, including P.A.S. and penicillin, was appreciably delayed by butazolidin.

Dr. R. M. MASON (London) presented observations he had made on uric acid metabolism in four patients with gout and one patient with Paget's disease who was treated as a control. These patients took 600 mg. of butazolidin daily by mouth, and in all but one, who developed congestive heart failure, there was a persistent though slight in-

crease in uric acid excretion and a corresponding fall in blood levels. He believed that the explanation for the differing results reported by other observers lay in the variable preponderance of water-retaining and uricosuric effects in individual patients.

Effect on Clotting Time

Dr. J. G. HUMBLE (Westminster Hospital) reported that in 44 patients treated with butazolidin the clotting time was significantly increased in six cases and in 14 cases the prothrombin times were prolonged. Experiments showed that butazolidin plasma would correct the deficit in "tromexan" plasma and in "aged" normal plasma. It would not correct that in patients suffering from liver disease and obstructive jaundice. He considered, therefore, that the cause of the clotting effect was due to deficiency of prothrombin. This was confirmed by the two-stage prothrombin assay. The oral administration of vitamin K₁ resulted in a prompt return to normal of both prothrombin and clotting times.

DRS. A. HILL and M. S. GOOD (Aylesbury) had studied the effect of butazolidin on C-reactive protein, but the number of cases was too small to enable them to reach any definite conclusions. Their preliminary observations, however, led them to believe that further studies in this field would be amply justified.

Dr. P. O. WILLIAMS (London) reported that butazolidin caused retention of sodium and water during the first few days of treatment, but with continued administration of the drug both water and salt excretion returned to normal. In 13 patients who developed oedema while on treatment with butazolidin all except one had some demonstrable cardiac or renal lesion. He suggested, therefore, that oedema did not develop during therapy unless there was some other pre-existing defect in the control of salt-and-water balance. Since oedema occurred only under these circumstances he did not favour the routine prescription of the low sodium diet. When oedema does develop it should be regarded as more than a simple side-effect of the drug.

SIR RICKARD CHRISTOPHERS, 80

One of the leading malariologists of the century, Sir Rickard Christophers, celebrated his eightieth birthday this week (on November 27). Colleagues who have worked with him in recent years may find it hard to believe that he is anything like that age, though anyone familiar with the extent of his work—work still in progress, needless to say—will wonder how one man can have found time to accomplish so much. He graduated in medicine in 1896, and his first contact with the disease with which his name will always be associated was in 1898, when with J. W. W. Stephens and C. W. Daniels he was appointed a member of the Malaria Commission of the Royal Society. The investigations conducted in 1899–1900 by the Commission in Central and West Africa laid the foundation of the study of malarial epidemiology. For the first time the conceptions of endemicity in malaria as now understood were set out, and for the first time the principle of segregation of the susceptible immigrant from indigenous infection was laid down as a major antimalarial measure. The connexion between blackwater fever and malignant tertian malaria was also established.

A year or two later Christophers and Stephens carried out researches in India which had a profound effect on the future of malariology in that country, for they stimulated general interest in the study of malaria problems. One important discovery was that different species of anophelids are very selective in their choice of breeding-place and vary widely in their capacity for transmitting malaria—the foundation of the modern concept of species sanitation. Christophers entered the Indian Medical Service in 1902, and during the next few years he was busy studying the life cycle of

MEDICAL JOURNAL 1215

Correspondence

Because of the present high cost of producing the Journal, and the great pressure on our space, correspondents are asked to keep their letters short.

Seven Insulins in Britain

SIR,—Since Monday, November 16, seven insulin preparations are available on the British market, three old and four completely new, to the medical profession and the diabetics of this country. The whole question of these new insulins was discussed by interested doctors at the annual meeting of the Diabetic Association last July, and it was felt most strongly that the introduction of all these little-known new preparations at once would be most confusing to doctors and hence even dangerous to patients. It was unanimously agreed to advise the authorities that it should be introduced first. This opinion was immediately forwarded both to the Ministry of Health and to the British Insulin Manufacturers. Events have shown that this expert medical opinion has been completely ignored. And, after all, several diabetic centres have worked intensively at testing these new products for the British Insulin Manufacturers, and the neglect of our known opinion has been our reward.

I feel that the above should be made public in your columns in the hope of preventing a similar occurrence again, because I think there will be further modifications of insulin within the next few years. I should like to know what other steps, apart from raising the matter in Parliament, we might take to ensure that the considered opinion of those deeply concerned with the best treatment of diabetes in this country should not again be ignored.—I am, etc.,

R. D. LAWRENCE.

London, W.1.

Insulin Zinc Suspensions

SIR,—We feel that the series of papers on the new insulins (*Journal*, November 7) require comment. We have been using "lente" insulin for the treatment of diabetic outpatients, selecting only patients requiring high doses of insulin or those in whom satisfactory control had not been achieved with other insulins. So far lente insulin has been tried in 15 cases, all of whom have been at work. In general, we agree with the authors of the several papers that in such patients lente insulin will frequently achieve satisfactory control with a single daily dose. In some respects, however, our impressions differ from those conveyed by some of the papers and by your leading article.

Drs. J. D. N. Nabarro and J. M. Stowers (p. 1027) suggest that the present mixture of lente insulin is not suitable for the British dietary habit, and your leading article (p. 1037) supports their suggestion that the proportions of crystalline suspension and amorphous insulin should be altered. This would add yet another mixture to the many available, which seems quite unnecessary. The bulk and carbohydrate content of a meal can be varied independently by any dietitian, and in this way the dietary habits of the patient can be adjusted to the type of insulin. In our experience there is no characteristic dietary habit, for, while many patients are accustomed to take their main carbohydrate meal at midday in the form of sandwiches, others habitually have it at night. It seems to us unjustifiable on the experience of some 30 cases to suggest that a mixture of insulin which has been found suitable for some 500 patients in Denmark is unsuitable in this country. Like Drs. I. Murray and R. B. Wilson (p. 1023), we have found patients who have not been as well controlled on lente insulin as on globin or a mixture of soluble and zinc protamine. We do not agree, therefore, with the suggestion of Dr. Wilfrid Oakley

various blood parasites—notably *Hepatozoon canis*, *H. gerbilli*, and *Babesia canis* in both their mammalian and insect hosts—the anatomy and histology of the tick, and the newly discovered parasite of kala-azar. In 1909 he founded the Central Malaria Bureau at Kasauli and started the collections which formed the basis for systematic study of the mosquito fauna of India. He returned to this work after military duty during the first world war in Mesopotamia, where, as might be expected, he made important observations on the anopheline fauna of that country.

In 1924 he published his classic paper on the mechanism of immunity against malaria in communities living under hyperendemic conditions. In the same year he described a new technique for the accurate measurement of the spleen, which has been used as a standard method in India for malaria surveys ever since. Before retiring from the I.M.S. in 1932 Christophers was director of the Kala-azar Commission in Assam in 1924–5 and of the Central Research Institute in Kasauli from 1925 to 1932. His volume on Anophelini in the "Fauna of British India" series appeared in 1933.

(Walter Stoneman, London)

phelini in the "Fauna of British India" series appeared in 1933.

From 1932 to 1938 Christophers was professor of malarial studies at London University with his headquarters at the London School of Hygiene and Tropical Medicine. Strains of monkey malaria had recently become available for study, and he was quick to realize the importance of this new field of research. In collaboration with J. D. Fulton he conducted a series of comparative studies of the respiratory metabolism of *Plasmodium knowlesi* and *Trypanosoma rhodesiense*, the first observations of their kind in this field. After six years he left London and settled in Cambridge, where he now lives and works. During the second world war he was in charge of the mosquito repellent inquiry. During his investigation of the repellent properties of several hundred substances he devised new methods for breeding large numbers of mosquitoes in the laboratory and techniques for the testing of repellency. When hostilities ceased he found himself at last free to return to his first love, the mosquito. He is at present engaged on a study of the natural history and structure of *Aedes aegypti*, and this, we understand, is nearing completion. Recently he delivered the Manson Lecture on "Malaria in the Field" before a large and enthusiastic audience at the London School of Hygiene.

A list of all the honours Sir Rickard has received would be a lengthy one. He was appointed C.I.E. in 1915, made Honorary Physician to the King from 1927 to 1930, and knighted in 1931. He has received numerous medals, among them being the Queen Wilhelmina Jubilee Foundation Medal in 1928 and, this year, the Buchanan Medal of the Royal Society, to which he was elected in 1926. His presidency of the Royal Society of Tropical Medicine and Hygiene ran from 1939 to 1943.

His work continues, and he still maintains an interest in a side-line study, that of geology. His many friends, not least those in India, will join in extending their heartiest good wishes to him and to Lady Christophers on this occasion.

(p. 1021) that globin and P.Z.I. insulin should be withdrawn. No paper reports local reactions to the new insulins. Two of our patients who are sensitive to globin and P.Z.I. have also developed local reactions to lente insulin.

Drs. Nabarro and Stowers suggest that insulin should be injected one hour before breakfast. We have not found this necessary. Many of our diabetics leave for their work at 6 a.m. after taking their insulin and a light breakfast at 5.30 a.m. They have a second breakfast when they get to work. They would be reluctant (and unlikely) to get up before 5 a.m. in order to inject their insulin.

There is no doubt that the new insulins, particularly lente, are a valuable addition to the range available for treating diabetes. We do not think that any one preparation can cover the whole range of the diabetic population; the other insulin preparations which are available have still a place in out-patient treatment.—We are, etc.,

A. STUART MASON.
D. VEREL.

London, E.1.

SIR,—We should be grateful if you would allow us to comment on some of the points raised in the three articles on the insulin zinc suspensions ("lente" insulins) published in the *Journal* of November 7, and in your leading article on this topic in the same issue (p. 1037).

In his authoritative paper Dr. Wilfrid Oakley (p. 1021) suggests that, while the time is ripe for the introduction of "lente" insulin, the marketing of "semilente" and "ultralente" should be deferred. However, as Drs. Ian Murray and Robert B. Wilson make clear in their article (p. 1023), some diabetic patients cannot obtain with lente alone a control superior to that achieved with the previously available insulin preparations: they need a mixture of lente with semi- or ultralente. It would seem a pity to deny to these patients, few though they are, the advantages of the lente series when many of their fellow patients will certainly be gaining these advantages—from the lente preparation used by itself. Very careful trials have been and are being carried out with both semilente and ultralente in Denmark and in this country, and the results are certainly favourable.

Drs. Nabarro and Stowers suggest that an 80 u. per ml. ultralente preparation is desirable. It was not anticipated by Novo, or indeed by the other manufacturers, that there would be any great demand for the preparation in this strength; but, if there should prove to be such a demand, steps will be taken to meet it. As regards their desideratum of a lente preparation that can be mixed with soluble insulin to give a mixture of predictable effect, the Novo Laboratories have this under very active consideration. We would, however, point out that semilente can be so mixed, that in its action it resembles soluble insulin fairly closely, and that in future the only major sphere of usefulness of soluble insulin may well prove to be that of diabetic emergencies. In other words, for everyday use the lente series will be sufficient.

As regards their final suggestion that for the lente preparation a semilente-ultralente ratio of 2:8 (or 1:4) would be more suitable to the British dietary than the present lente ratio of 3:7, it can be stated that Novo also have this matter under consideration. While prepared to make any necessary adjustment in lente for this country, Novo are unwilling to do this unless the need for it is generally accepted. Other things being equal, it would obviously be undesirable to have a lente preparation that differed in its composition from country to country; though doubtless, in view of the multiple dietary variations that do exist, a case could be made for such variation.

Finally, in connexion with the implication in your leading article that supplies of the lente insulins are inadequate, we would point out that unless the size of the demand is known it is impossible to say whether or not supplies will be sufficient. While demand may outrun the supply, there are no grounds at present for advising doctors not to prescribe the lente insulins for those patients who will clearly be suited by them.—We are, etc.,

Appendix in Hernial Sac

SIR,—Recent correspondence in the *Journal* on the incidence of inflamed appendices in hernial sacs has revealed six cases—two inguinal (Dr. T. E. Winckworth, September 5, p. 567; Mr. H. B. Walker, October 17, p. 886) and four

femoral (Dr. T. D. S. Holliday and Mr. J. R. A. White, two cases, October 3, p. 779; Dr. D. G. Maurice, two cases, October 17, p. 887). In all except one the appendix was removed through the incision used for the exploration of the hernia. The surmise of the true incidence depends on recording details of such cases when the question is raised, and hence the following notes of a true strangulation of the appendix which I recently encountered are offered.

A moderately thin woman of 36 was suddenly seized with pain in the right groin followed by vomiting. Over the next few hours a small lump in this region, noticed by the doctor, gradually became tender, and the patient was referred to hospital. A small, fixed, tender, cherry-sized lump was found over the right femoral region. There was no discoloration and no source of infection in the leg. Exploration revealed a U-loop of a fairly long appendix tightly strangulated in the femoral canal, the tip and base being normal. The appendix was removed, none too easily, as the portion of caecum to which the base was attached could just be drawn into the canal and no more. Repair was then carried out, and this was followed by rapid recovery.

As regards the question of normal appendices in hernial sacs also raised, I recently removed an appendix the tip of which protruded through an inguinal sac on the left side in a small child—an unexpected manoeuvre.—I am, etc.,

Wolverhampton.

HENRY B. YOUNG.

SIR,—I have noted the various letters on this subject and am particularly interested in Mr. H. B. Walker's case in a 7-weeks-old infant (*Journal*, October 17, p. 886).

Some years ago I had a similar case in the Royal Hospital for Sick Children, Glasgow. The patient, a boy, was born two months prematurely and on admission he was 3 weeks old and weighed 3 lb. 12 oz. (1.7 kg.), so that he was operated on five weeks before he should have been born. A large right scrotal hernia had been present since birth but gave no trouble until the day before admission, when it increased in size and became irreducible, with continuous vomiting and constipation.

Under a general anaesthetic, the large mass of hernia was reduced by taxis except for a sausage-shaped swelling which still extended along the inguinal canal into the scrotum. It could be rolled under the fingers, and it was diagnosed as probably the appendix. In spite of the protests of the theatre sister I decided to operate. The large sac was dissected out and opened. It contained the appendix, which was gangrenous in the distal two-thirds, owing to strangulation in the neck of the sac. The appendix was removed and the hernia repaired. Recovery was uneventful.

It is well to remember that, while strangulation in inguinal hernia in infants is uncommon, it certainly does occur. The danger of a reduction *en masse* in such a case is well known, and it would appear from this case that the possibility of leaving a strangulated gangrenous appendix after apparent complete reduction by taxis must be borne in mind.—I am, etc.,

Glasgow.

WILLIAM BEATTIE.

Overseas Service

SIR,—Mr. Ian Fraser (*Journal*, October 31, p. 987) is right. It is lamentable that in a great imperial and maritime country thousands should be moaning for comfortable jobs in the N.H.S. at home when there is so much work to be done in places like the Gold Coast. Tough work, certainly, but so remarkably varied and highly coloured. He is right, too, in asserting that a doctor should be paid more than most other classes of expatriate, the mental and physical strain of a medical officer's work being so much heavier. Compare it, for example, with that of a person sitting in an office in secretariat or treasury.

A serious deterrent to service overseas now is the greater difficulty in re-settling, compared with pre-1948 times, after normal retirement, or earlier retirement for health, family, or other reasons. Here the Ministry of Health could help by a directive that whenever a post in the N.H.S. is being filled, whether hospital (other than teaching) or general practice, any applicant who has served six or more years in the armed Forces, Colonial Service, or mission field, and is otherwise adequately qualified, should have preference over all applicants who have not so served.

It is unfortunate that there is in medical circles in this country a certain bias against those of us who work overseas. If at a refined medical gathering one mentions that one is in the Colonial Service (as I used to be), or a ship surgeon (as I am now), there is a distinct drop in the temperature. A directive such as that outlined above would be simple and just, and its benefits would be felt in many quarters.—I am, etc.,

Bristol, 8.

G. L. ALEXANDER.

SIR,—I refer to the article by my friend Mr. Ian Fraser on the need for medical officers in the Gold Coast (*Journal*, October 31, p. 987) and your annotation (p. 984). A poet has written that "the thoughts of youth are long, long thoughts." The thoughts of young medical men and women are long enough to stretch ahead to the end of a normal period of service in the Tropics, and to cause them to ask about their prospects of employment on returning home, for I do not think that Mr. Fraser would suggest that service in the Tropics should be for the term of one's natural life.

If, like myself, the returning physician, surgeon, sanitarian, pathologist, ophthalmologist, etc., is a native of Northern Ireland, he will find, for example, that the public health service there is completely closed to him by the regulation which debar anyone from holding a public health appointment unless he has been continuously resident in the United Kingdom for five years immediately preceding. If he seeks a hospital appointment he comes up against the age limit, and if he seeks to enter general practice he finds that the panel has been virtually closed for some years. I am not well informed about the position in the rest of the United Kingdom, but within the circle of my own acquaintance I could name two surgical specialists, an ophthalmic specialist, a pathologist, and the chief health officer of a State, none of whom are employed in their specialties. The principal medical officer of a colony obtained a public health appointment of the grade open to persons qualified for two years.

If, as Mr. Fraser says, the specialist service in the Gold Coast is the first priority, I can think of no more potent attraction to bring good men and women into the service, and keep them there for the full term of service, than the assurance that the emeritus medical officer who is highly qualified academically and by experience and by achievement will be employed in a post worthy of his capacity on his return.—I am, etc.,

Belfast.

H. G. CALWELL.

Medical Needs in the Gold Coast

SIR,—As one who has been in the Gold Coast Medical Service, I read your annotation (*Journal*, October 31, p. 984) with considerable concern. You write of a country subject to rapid economic and political change. Rapid political change may well be, but the evidence of rapid economic change is difficult to see. We must remember that the Gold Coast is, in the sterling area, second only to Malaya in earning dollars, and her economic future is reasonably assured. The prospect of uncertainty of employment of non-Africans during the next forty years is so remote as to be out of sight. As Mr. Ian Fraser writes (*Journal*, October 31, p. 987), "Certainly this [Africanization] will happen in time, but at the moment the question does not arise."

It is indeed an exaggeration to imply that qualified Africans are reluctant to return home. Only one Government scholar has remained in the United Kingdom, and all privately qualified Africans have returned to the Gold Coast except one. This has occurred over the last twenty years, during which some twenty scholars have been sent to the United Kingdom. The Government scholar who stayed behind is now fully ready for appointment "to fill one of the many specialist posts available" mentioned by Mr. Fraser. It remains to be seen whether he will get appointed. It can be stated with every confidence that all who wish to go and help can do so with assured prospects of work

in an exhilarating field where, in the absence of the accustomed diagnostic aids, there is required greater clinical acumen.—I am, etc.,

K. A. TAYLOR.

Ecceles.

Symptoms of Temporal Arteritis

SIR,—Like Dr. K. V. Crowther (*Journal*, October 17, p. 888), I have been interested in the association of joint pains with arteritic symptoms in temporal arteritis. I met this association in the first case which I saw 17 years ago, and from my subsequent personal experience of the disease and from that of others it is evident that the association is not fortuitous. While Dr. Crowther's case may have had an arteritis near the hip-joints, an arthritis in those joints is a more probable explanation of the sudden pain around the hips. The late Dr. John Gray, who examined the temporal artery section in my first case, while not able to exclude polyarteritis nodosa, was more struck by a similarity of the condition to rheumatic arteritis. I have recently had a case² of a febrile illness with headaches, arthritis, and the general manifestations so like those of severe "temporal arteritis" that, though the temporal arteries appeared clear, I felt that it was almost certainly a case of that condition.

We should not regard the joint symptoms, the cerebral symptoms, or scalp ulceration as complications so much as different aspects of this complaint. No one denies that its most striking features are polyarteritic and, in particular, an arteritis of the temporal vessels. But the degenerative collagen changes are soon seen to be both periarterial—hence the very interesting and unusual scalp ulceration described by Dr. David Kendall (*Journal*, August 22, p. 418)—and widespread in other tissues. The fever, anaemia, loss of weight, and joint symptoms which are so often seen in temporal arteritis rank it as a generalized "collagen" or "pararheumatic" disease akin to rheumatism, acute diffuse lupus erythematosus, dermatomyositis, and the rest. Perhaps it is a manifestation of the hypersensitivity state largely peculiar to old people. Certainly prolonged cortisone and A.C.T.H. are its best treatment, with salicylates as a less effective reserve.—I am, etc.,

G. H. JENNINGS.

Edgware.

Sickle-cell Anaemia

SIR,—The paper on sickle-cell anaemia by Dr. G. M. Edington (*Journal*, October 31, p. 957) raises many important points, though perhaps none is more interesting than the observation that sickle-cell disease becomes less severe with age, and that, in fact, his oldest patient, aged 44 years, had no attacks or crises for nine years. It was already known that the onset of the disease is not at birth or even in very early infancy. Vandepitte and Louis¹ reported recently that they had discovered a test for sickle-cell anaemia which was positive even in babies with "pre-clinical" sickle-cell anaemia.

In Africa it has been difficult to accept the homozygous theory of sickle-cell anaemia of Neel² and Beet.³ With the great number of Africans showing the sickling phenomenon one would expect a disease occurring in all homozygotes to be more common. It was then reported by the Lambotte-Legrands⁴ and Foy and his colleagues⁵ that a search among the younger age groups showed sickle-cell anaemia to be more frequent, and it was suggested that the disease was rare in adults because those who suffered from it failed to grow up. This seemed to be impossible at least so far as those African tribes were concerned in whom very high incidences of the sickling trait had been discovered⁶—so high that they had to include homozygotes. The sickling gene seems to vary in the amount of abnormal haemoglobin it confers in different families,⁷ and it is possible therefore that in these tribes in many instances one gene produces rather less than 25% of the abnormal haemo-

globin, so that even homozygotes fail to accumulate the level of more than 50% which seems to be necessary to cause the anaemia. However, Dr. Edington's observation that sickle-cell anaemia becomes less severe with advancing age might go far in clarifying what up to now was a difficulty to those wanting to reconcile the homozygous theory with the sickle-cell anaemia incidence found in Africa. It is noteworthy that thalassaemia also becomes less severe with age, and, provided it is possible to keep those who suffer from it alive with transfusions, even severely ill children can become virtually symptom-free when they reach adolescence. Dr. Edington's observations tally with some of my own and in retrospect they fit in with what I noticed in some adults in Uganda.

It might be worth while in future investigations of sickle-cell anaemia incidence to differentiate between those homozygotes who actually suffer from the disease and the others who are at risk only. The first group would be found largely in childhood, and the second would include apparently healthy neonates and adults. In parallel with thalassaemia the purely clinical diagnosis of sickle-cell anaemia would then be divided into a major, minor, and minimal dyscrasia. On a recent visit to Greece I found that Professor Choremis already made such a subdivision for purely clinical reasons. The parallel between thalassaemia and sickle-cell anaemia can be carried further. Both the potentially lethal thalassaemia gene in Italy and Greece and the sickling gene in Africa should have died out rather than exist at the high frequency at which they are actually found. Neel¹ has recently summarized possible explanations for this apparent paradox. One is that a very high mutation rate reproduces the gene often enough to replace the loss caused by deaths from sickle-cell anaemia; another is that sickle-cell haemoglobin may confer a reproductive advantage balancing the genetic disadvantage—the theory of "balanced polymorphism." Thus Brain² recently drew attention to the possibility that sickle-cell haemoglobin might give relative protection against malaria parasites. This theory, if confirmed, would go far in helping to explain the geographical distribution of the trait (it is a fact that its incidence is high only in regions where there is much malaria) and would usefully supplement the purely anthropological approach to the phenomenon.

Thalassaemia and sickle-cell anaemia have in common a significant percentage of foetal haemoglobin in the red cells. It has recently been possible to differentiate between adult and young infants' red cells by means of a specific agglutinating serum,³ and, although the number of tests is not yet large, the only adults whose cells were also agglutinated by the anti-foetal red cell agglutinin were all sickle-cell anaemia and thalassaemia major patients and some—but not all—carriers of the thalassaemia and of the sickling trait. This suggests that all these individuals had, in common with young infants, a component of their red cell envelope not found in normal adults. It may not be a coincidence that the decline in the "natural resistance" of the newborn to malaria takes place when it loses its foetal haemoglobin.—I am, etc.,

Anal Fissure in Children

SIR,—In the descriptions of fissure in ano which appear in general medical journals there is often no reference at all to its occurrence in children (*Journal*, October 10, 1953). Yet this common condition is possibly even commoner in childhood than in adult life. It is true that the natural history of anal fissure is similar in adults and children, but a few differences are worth noting.

In the large majority of children in whom a fissure is found the onset can clearly be dated back to a time when large constipated stools were passed, often with an acute

febrile illness; occasionally, and especially in infants, the onset synchronizes with a bout of acute enteritis. The typical case presents as a child who, with dramatic suddenness, has developed an intense fear of defaecation. The abdomen is often distended, there may be bouts of abdominal pain, and sometimes defaecation is accompanied by vomiting. In the worst cases, in which chronic obstipation has been allowed to develop, a "rockery" of faecal masses can be felt in the abdomen, and in a few overflow incontinence of stools occurs. In childhood sentinel tags are uncommon, and complications such as mucosal polyp, abscess formation, and fistula formation extremely rare.

The results of simple medical treatment are almost uniformly good, and possibly children are more amenable than adults in this respect. In 30 consecutive patients a cure resulted in 27; 2 further patients did not return to report progress; and in 1 other the fissure had not healed completely after intermittent (and possibly inefficiently applied) treatment over a period of several months. In all but a few the treatment was carried out by the mother at home. In a small number in whom the mother's co-operation was doubtful, and the response unsatisfactory, medical treatment was repeated in hospital with good results. In a few severely constipated cases olive oil enemata were given as a preliminary measure. Fissures seen in the acute stage healed within two, or at most three, weeks. The chronic fissures sometimes took several weeks to heal, but eventually disappeared completely. In one child a fissure recurred after apparent cure, but this was probably due to obstipation in a patient with grossly defective toilet training.

The essential of treatment is to relieve pain and the consequent spasm which prevents healing of the fissure. For this purpose 1% amethocaine ointment was applied to the raw area: in this strength it proved effective, and there were no examples of induced skin sensitivity which has been described with higher concentrations in adults. The mother was shown how to insert the ointment on a pledget of wool firmly wrapped on an orange stick or on the tip of her small finger (with the nail cut short), a procedure which she was instructed to carry out three times daily and particularly before defaecation was expected. Her relief, and the child's, at the demonstration of complete painlessness induced by the surface analgesic were potent factors in ensuring co-operation in treatment. The children were encouraged to defaecate at a regular time each day. Small quantities of liquid paraffin were given several times daily and continued for several months after cure. It was not found necessary to make any changes in the diet.

Although chronic fissures in childhood respond satisfactorily to treatment, and undoubtedly some acute fissures resolve spontaneously, it appears advisable to treat all cases early. By so doing not only is unnecessary suffering obviated, but the formation of a habit of chronic constipation (which can persist indefinitely even after the fissure has healed) is forestalled.—I am, etc.,

Bristol.

JOHN APLEY.

Thyrotoxicosis and Purpura

SIR,—The publication in the *Journal* of October 31 (p. 976) of the medical memorandum by Drs. W. G. D. Caldwell and M. Meikle on one of those rare cases in which thyrotoxicosis and purpura are associated prompts me to record the following case, the only one of this type which I met with amongst about 2,000 cases of thyrotoxicosis during the years 1921–51. I will report those details only which are relevant to the subject of the letter.

A married woman aged 40 was sent to me on September 11, 1948, suffering from typical thyrotoxicosis. She had had no treatment. On being given the choice of medical or surgical treatment she at once chose operation. She was admitted on September 13 and prepared with Lugol's solution, min. 7 (0.42 ml.) three times a day, until September 20, when I performed a bilateral subtotal thyroidectomy. As the iodine was given for the first time, she reacted very well. No iodine was given after operation. She had no upset and was sent home on October 1

with a healed wound and doing well. On my return from holiday a fortnight later I found an urgent message to visit her at once. She was in bed suffering from sleeplessness due to three days' intolerable itching in both lower limbs. She had many purpuric bruises on both legs and thighs, and stiffness of her knees. She was readmitted and the pathologist reported on her blood as follows: October 18, 1948, haemoglobin 80%; red cells 4,270,000; colour index 0.94; red cell morphology normal; leucocytes 9,100 (polymorphs 6,051; lymphocytes 2,457; monocytes 455; eosinophils 46; basophils 91); Arnett count, shift to left; platelets 185,000. No further purpuric areas appeared and the condition subsided without incident in two to three weeks. The stiffness of the knees improved, but did not altogether disappear for some months. She made a very rapid recovery from the thyrotoxicosis, was in full charge of her business two months after operation, and has remained in very good health.

On careful investigation of her history it was found that her symptoms had begun about five days before operation. She had spasms of coldness down her spine and stiffness of the knees, and had reported this to the nurses. It had continued after operation, but had not become really troublesome until after she returned home. The only explanation I could think of was that she had a rare idiosyncrasy to the potassium iodide in the Lugol's solution. Is it possible, if this view is correct, that the condition of severe thrombocytopenic purpura recorded in association with thyrotoxicosis may be due to long-continued administration of Lugol's solution in patients with a similar idiosyncrasy to potassium iodide?—I am, etc.,

Bradford

PETER MCEWAN.

Niels Stensen

SIR,—Your paragraph on Niels Stensen (*Journal*, October 31, p. 992) contains the sentence: "He became a convert to Roman Catholicism and was nominated as Bishop of Titiopolis," which appears to give the impression that he was made a bishop merely as a result of, or as a reward for, his conversion.

Stensen's discoveries were not at first appreciated in his own country. He therefore went to Florence, where he was appointed anatomist to the Hospital of Santa Maria Nuova. It was while in this city that he became convinced of the truth of Catholicism, and he was received into the Church in 1667. Mainly through the influence of Griffenfeldt he was nominated to the post of Anatomicus Regius in the University of Copenhagen. He could not be made a professor to the university, as no Catholic was permitted to hold that position. Two years later he returned to Italy, where he began his studies for the priesthood. He received holy orders in 1675, and two years after was consecrated bishop. He worked in Münster, Osnabrück, Paderborn, and Cologne as a priest. He gave all his possessions to the poor and lived a life of mortification.—I am, etc.,

Llwynypia.

M. S. PATHY.

Succinylcholine Chloride for Casualty Anaesthesia

SIR,—I should like to make a few points on the subject of succinylcholine chloride for casualty anaesthesia. First, Dr. D. C. Adamson has stated (*Journal*, October 31, p. 993) that he observed relaxation of the cardiac sphincter when succinylcholine was given during oesophagoscopy. I find it hard to believe that this is a property of the drug in question, as there are reasons for believing that it only acts on the striated muscle of the upper half of the oesophagus. Furthermore, the sphincter may be seen opening with each inspiration when the oesophagoscopy is carried out under local analgesia alone.

Secondly, I would like to stress that the sequelae of a combination of succinylcholine chloride and short minimal anaesthesia can be very uncomfortable to the patient. Distressing muscular stiffness appears to be by no means a rare complaint if these anaesthetics are carefully followed up. I observed another sequela while doing a series of some 30 anaesthetics for in-patient E.C.T. which I have not seen referred to. A high proportion of patients given thiopentone succinylcholine chloride developed sore throats after a variable delay of up to two hours. None given thiopentone

gallamine triethiodide did so, and the further interesting fact emerged that it was those who had a completely or almost completely modified convulsion who developed the complaint. I am indebted to Dr. J. G. Bourne for the suggestion that this "sore throat" was the patients' interpretation of stiffness of the pharyngeal muscles. Had these been out-patients, or had an endotracheal tube been passed, I doubt whether this disadvantage of succinylcholine chloride would have been observed or properly interpreted.

Thirdly, I feel that casualty anaesthesia will always be administered in part by those who are not specialists in the field of anaesthesia, and the requirements of such a technique are safety, simplicity, effectiveness, and the use of drugs with which the administrator is likely to be familiar with apparatus which is likely to be already found in most casualty theatres. I think the following technique meets with these requirements: 5 to 10 ml. of ethyl chloride is sprayed into the empty chloroform bottle on a standard Boyle's machine and the cork is replaced. Two litres of oxygen and 6 litres of nitrous oxide a minute are run through the machine and the lever on the chloroform bottle is raised until the ethyl chloride can just be smelt emerging from the mask. Induction is then commenced.

This ensures adequate oxygenation and at the same time precludes access to the patient of a sudden strong concentration of ethyl chloride vapour.

Initially the mask need not be held against the face, and induction by this method appears to be much smoother and more pleasant to the patient than one would anticipate. The concentration of ethyl chloride is gradually increased, but it is rarely necessary to depress the plunger on the bottle. Emergence is rapid, overdosage is almost impossible, and neither salivation nor vomiting is a feature of this technique.—I am, etc.,

Thornton Heath.

V. P. WORDSWORTH.

Laryngeal Vertigo

SIR,—Dr. C. W. M. Whitty's "cough syncope" (*Journal*, November 7, p. 1047) is a better title than the present one. During the winter it is not an unusual occurrence for a patient in general practice to complain that a severe spasm of cough has produced a momentary blackout of vision or even loss of consciousness. But, when this complication under the misnomer of laryngeal vertigo was the plea in defence of a suspected drunk-in-charge, I, as the police medical witness, agreed with the opposing counsel that I had never before seen a case (and was therefore presumably unfit to recognize one). However, in his turn, the otorhinolaryngologist appearing for the defence had to admit that his only personal experience of such a case was a wartime one in which he had advised the grounding of an R.A.F. pilot—in fact, the present defendant.

May it not be that the few cases which have filtered into a specialist department have given both title and apparent rarity to this "general practice" symptom?—I am, etc.,

R. N. C. SMITH.

Ilford.

A Case of Anthrax

SIR,—I feel that the following case is sufficiently unusual to be worthy of record.

A woman of 27, a Civil Servant, was admitted to hospital on July 9. About seven days prior to admission she noticed a small spot on the skin over the right clavicle which she thought was due to an insect bite. Very soon swelling of the surrounding skin occurred, and this spread to involve the right side of the neck and the front of the chest. The swelling was painful and there was considerable itching of the skin. On admission she was severely ill with a subnormal temperature and peripheral circulatory collapse. The blood pressure was unrecordable, but she was able to give a fairly clear history. The whole of the front of the chest, including the breasts, and the right side of the neck were swollen by very firm oedema and the overlying skin was erythematous and patchily haemorrhagic. Just above the right clavicle there was a shallow ulcer with a dark red base about 1 in. by $\frac{1}{2}$ in. (2.5 cm. by 1.25 cm.) in size. There was some serous exudate but no pus. A few inconspicuous vesicles surrounded the ulcer.

Anthrax was considered, but at first not seriously, as there was nothing in the history to suggest a possible source of infection. Fortunately swabs were taken both from the base of the ulcer and from one of the vesicles, and from each Gram-positive bacilli were found on direct examination. These were later proved to be *Bacillus anthracis* and the diagnosis was confirmed by pathogenicity tests. She was at once treated with penicillin, 1 million units six-hourly, until July 18. Recovery from the toxæmia and peripheral circulatory failure was reasonably rapid, but the oedema decreased slowly and the local lesion took nearly a month to heal completely. She was given terramycin, 2 g. daily, from July 20 to July 27. On July 17 she became pyrexial for the first time, and on July 18 she began to complain of pain in the calves, and this pain rapidly increased in intensity. By July 19 there was severe hyperæsthesia of both legs, marked loss of power in all the muscle groups of the legs, and some weakness of the wrists and hands. All the tendon reflexes were brisk and equal and a full neurological examination showed no other abnormalities. An irregular fever, reaching 103° F. (39.4° C.) on one occasion, continued until July 31. The pain and weakness gradually decreased and she was discharged from hospital free from all signs and symptoms on August 8. It was assumed that she had had an acute "toxic" polyneuritis, but the rapid recovery and the absence of changes in the reflexes seem to make this diagnosis unlikely. A lumbar puncture was not performed.

Infection in this case is believed to have been due to an insect bite. The medical officer of health for Croydon has informed me that no cases of human anthrax have been reported in the past few years, but that a case of animal anthrax was notified in December, 1952, at premises within two miles of the place in which the patient thought she had been bitten by an insect.—I am, etc.,

Thornton Heath, Surrey.

G. P. BAKER.

Rupture of the Spleen after Glandular Fever

SIR.—The description by Mr. R. W. Tudor (*Journal*, October 10, p. 813) of rupture of the spleen in a case of infective mononucleosis recalls a similar example.

A schoolgirl, aged 6 years, who had had transient jaundice two months earlier, tripped on her nightgown when going upstairs and fell forwards. She was admitted to hospital with pallor, rapid pulse, and tenderness over the middle of the abdomen. Her condition was stationary over several hours. There was no evidence of blood in the stools and the urine was normal. The history of transient jaundice suggested the possibility of a previous hæmolytic crisis. The medical registrar, Dr. C. Cohen, however, postulated a glandular fever with jaundice, splenomegaly, and subsequent rupture. In view of persisting abdominal rigidity, laparotomy was considered advisable, and this diagnosis was confirmed. The peritoneal cavity contained much clotted blood. The spleen was enlarged to about four times the normal size, and showed a rupture round the upper third, linear on the outer and contused on the inner aspect. Splenectomy was performed and a pint (0.57 l.) of blood was transfused. She made good progress, and she was discharged twelve days later.

Blood counts after operation showed: white cells 23,800 (polymorphonuclears 56%; lymphocytes 38%; monocytes 6%). On the fourth post-operative day: red cells 4,050,000; Hb 66% (9.7 g.); white cells 19,700 (neutrophil polymorphonuclears 29%; lymphocytes 62%; monocytes 6%; eosinophils 2%; basophils 1%); reticulocytes 5%; platelets 527,000; Race-Coombs test negative; 4 nucleated red cells per 100 white cells; red cell fragility normal; moderate degree of microcytosis, but cells well filled with hæmoglobin. Six days after operation the Paul-Bunnell test was positive in dilution of 1 in 128; thymol turbidity 9.4 units; thymol flocculation 2+; alcohol turbidity 14.7 units; zinc sulphate turbidity 9.4 units; colloidal gold 2; alkaline phosphatase 9.6 units. The urine showed absence of bile salts and bilirubin, and slight increase of urobilin. Specimen.—The cut surface of the enlarged spleen presented numerous small opaque white spots, less than 1 mm. in diameter, which were not raised above the surface. Microscopic examination showed the sinuses packed with blood, no gross sinus proliferation, but the Malpighian bodies enlarged as a result of central oedema. There was diminution of the lymphoid element of the Malpighian body and an increase centrally in the reticulo-endothelial cells.

Jaundice is not a usual accompaniment of glandular fever. The further occurrence of splenomegaly and of rupture of the spleen spontaneously or after minor trauma has been described in the relatively few cases to which Mr. Tudor has referred.—I am, etc.,

Carlisle.

R. M. HILL.

POINTS FROM LETTERS

Appendix in the Hernial Sac

Mr. R. T. BURKITT (Nairobi) writes: I have just seen Dr. T. E. Winckworth's letter (*Journal*, September 5, p. 567). Some years ago I had a similar case, the gangrenous appendix this time lying in a small femoral sac. The interest in this case was accentuated by the fact that the patient was aged 92. If I remember rightly she made a satisfactory immediate recovery from the operation, but, as so often happens in old people, the enforced recumbency was too much for her and she died some weeks later.

Mr. N. N. IOVETZ-TERESHCHENKO (Georgetown, British Guiana) writes: Although Dr. T. E. Winckworth (*Journal*, September 5, p. 567) has not met anyone who has also found an appendix in a hernial sac, the condition is not particularly rare. In the first reported case of survival after removal of a perforated appendix the viscus was found in the sac of what was thought to be a strangulated right inguinal hernia (Hall, R. J., 1886, *N.Y. med. J.*, 43, 662). Since then many cases have been reported, mostly from Latin countries. Personally, I have on eight occasions found the appendix in a hernial sac and removed it—three times in a right femoral hernia and five times in a right inguinal hernia. So far in only one case was the appendix actually acutely inflamed at the time of removal.

Oily Stools and Antibiotic Therapy

Dr. RUSTOM JAL VAKIL (Bombay) writes: In view of the extensive and universal application of newer antibiotics, I would like to call attention to an apparently common, though innocuous, side-effect of such therapy. Routine inspection of stools after the therapeutic use of newer antibiotics, such as aureomycin, terramycin, and erythromycin, has disclosed the frequent appearance (in over 10% of cases) of oily or fatty stools. Examination reveals a layer of oil or oily droplets floating on top of an otherwise healthy stool. The incidence of this phenomenon appears almost twice as great with erythromycin as with terramycin and aureomycin. The condition, which is apparently quite harmless, may appear even within 48 hours of the inception of antibiotic therapy and may outlast it by several days or weeks (up to five weeks in one case).

Succinylcholine Chloride for Casualty Anaesthesia

Dr. D. J. ADDERLEY (Epsom) writes: There is one stage in the use of succinylcholine chloride in the casualty department described by Drs. T. Vaz and J. M. Bishop (*Journal*, October 17, p. 885) at which difficulties may be experienced—namely, that at which the needle is introduced into a vein before strapping the syringe to the hand. I have found when giving succinylcholine chloride alone, prior to thiopentone for electro-convulsive therapy, that very small quantities of the drug released into the circulation give rise to most unpleasant sensations in a conscious patient. This has occurred, for example, when a second attempt at venepuncture has been necessary owing to extraveneous leakage. The patient looks terrified, cries out, and raises his hand to his throat as if feeling choked. The quantity required to produce this effect could easily be injected in the early stages of this technique, but if care is taken to avoid this no trouble should arise.

Spectacles

Dr. M. ASTON KEY (Southsea) writes: Dr. C. F. Hadfield (*Journal*, October 17, p. 886) has quoted Dr. Samuel Gee as professing contempt for spectacles as a remedy for migraine. Let me recount the experience of another senior physician of one of our largest London medical schools, who told me himself that he had occasionally fallen unconscious in a ropewalk tube train in an attack of migraine, and had been carried out and laid on the platform until he recovered. He had consulted four leading London oculists without benefit. He then consulted the late Mr Ernest Clarke, who prescribed spectacles which immediately relieved him, and the trouble ceased.

Avalanche of Advertisements

Dr. B. SANDLER (Urmston, Lancs) writes: I should like to draw attention to one of the minor nuisances in life which medical practitioners must suffer from advertisers in this country. A though I changed my surgery four years ago and have several times notified pharmaceutical houses I have never had even a acknowledgment of my letters, and an avalanche of advertising material still follows me round on my holidays and elsewhere. Can anyone suggest a satisfactory method of informing the pharmaceutical houses that the net effect of their failure to address letters to the correct address is very effectively neutralize the value of all their advertising?

Obituary

Sir LANCELOT BARRINGTON-WARD, K.C.V.O.
Ch.M., F.R.C.S., F.R.C.S.Ed.

Sir Lancelot Barrington-Ward, formerly Surgeon to the Household of the late King George VI, died at his home at Bury St. Edmunds on November 17 at the age of 69. Earlier this year he underwent a serious operation in the General Infirmary at Leeds.

Lancelot Edward Barrington-Ward was born at Worcester on July 4, 1884, the second of the five sons of the late Canon M. J. Barrington-Ward, all of whom were King's (or Queen's) Scholars at Westminster School and all of whom attained eminence in later life.

(Press Portrait Bureau, London)

One of his younger brothers, Mr. R. M. Barrington-Ward, was Editor of *The Times* from 1941 up to the time of his death in 1948. Lancelot Barrington-Ward was educated at Westminster and Bromsgrove Schools, gaining classical scholarships to both, and at Worcester College, Oxford, where he was a classical exhibitor. For his medical training he went to Edinburgh and graduated M.B., Ch.B., with

honours, in 1908. He was elected F.R.C.S.Ed. in 1910, became a Fellow of the Royal College of Surgeons of England in 1912, and in the following year proceeded to the Ch.M., again with honours, being awarded the Chiene medal in surgery in the same year. After holding the appointment of house-surgeon at the Edinburgh Royal Infirmary, he came south to The Hospital for Sick Children, Great Ormond Street, where he served successively as casualty officer, house-surgeon, and medical superintendent. His experience and interest in children's surgery gained him a post on the surgical staff of the hospital in 1914. On the outbreak of war later in that year he went off immediately to the Balkans, serving as surgeon-in-chief of No. 2 Serbian Relief Fund Hospital with the rank of honorary colonel in the Serbian Army Medical Service, and for this work he received the award of the Order of St. Sava. Later he worked as a surgeon in military hospitals in this country. When still a young man Barrington-Ward's ability as a surgeon was widely recognized, and he was called in during the illness of Prince Albert (later King George VI), on whom he performed an appendicectomy in 1918. During his lifetime he operated on other members of the Royal Family, including the late Queen of Norway. In 1935 he was created K.C.V.O., and in the following year was appointed Surgeon-in-Ordinary to the Household of the Duke and Duchess of York, continuing from 1937 as Surgeon to His Majesty's Household. Last year he was appointed an Extra Surgeon to the Queen's Household.

In addition to his work at Great Ormond Street Barrington-Ward was on the staff of the Royal Northern Hospital, where he eventually became senior

surgeon, and he also had a large consultant practice. He was an examiner in surgery for the Universities of Edinburgh and St. Andrews. His experience in children's surgery is recorded in the many articles he published in various journals, and he wrote an excellent textbook entitled *Abdominal Surgery of Children*. He also edited and contributed to the *Royal Northern Text-book of Operative Surgery*. His work on idiopathic dilatation of the colon was of outstanding merit. He was appointed Hunterian Professor at the Royal College of Surgeons of England in 1952. His success as a surgeon was not due only to his technical skill and clinical judgment: he was a most gentle and sympathetic surgeon, and had the enviable knack of obtaining the confidence of the children who were his patients.

Barrington-Ward was a man of many parts, for, in addition to being a classical scholar—a rare accomplishment in a surgeon—and distinguished in his profession, he was a great sportsman, and knowledgeable enough about agriculture to have been made president of the Surrey Agricultural Association. On the Rugby field he was among the best players of his day, and was selected to play for England four times in 1910. He had the distinction of playing against Wales in the first international match played on the new Twickenham ground. Earlier he had played for Edinburgh University during six seasons, and was captain of the side in 1908. He also boxed for the University as a middle-weight. In later years he became a keen golfer.

Barrington-Ward was twice married. His first wife, formerly Miss Dorothy A. Miles, whom he married in 1917, died in 1935, leaving him with three daughters. In 1941 he married Miss Catherine Reuter, and she survives him. There was one son of the second marriage.

B. C. MAYBURY, M.B., F.R.C.S.

Mr. B. C. Maybury died suddenly at St. Thomas's Hospital, Hydestile, Godalming, on November 15 at the age of 65. He had been ill since his summer holiday.

Bernard Constable Maybury, the third son of the late Dr. A. V. Maybury, of Portsmouth, was born on February 9, 1888. From Epsom College he went on to study medicine at St. Thomas's Hospital, graduating M.B., B.S., with honours in surgery, in 1910. He won many distinctions as a student at St. Thomas's, including the Treasurer's gold medal and the Cheselden medal for anatomy and surgery. He became F.R.C.S. in 1913.

After qualification Maybury held a number of house appointments at St. Thomas's until 1915, when he entered the R.A.M.C. to serve as a surgeon specialist in the first world war, first at Netley and later in France and Italy with No. 9 Casualty Clearing Station. He was particularly interested in peripheral vascular injuries at this time, an interest that he had acquired from Sir George Makins. He made many friends among the surgeons working at casualty clearing station, and at the end of the war a group of these surgeons founded the Travelling Surgical Club, the members of which visited surgical centres in most European countries between the two wars. Maybury was a very popular member and he derived great pleasure from the club's journeys and meetings. The two great influences in his younger days and during his training were Makins and Wallace. His interest in military surgery was inspired by them, and he carried on their teachings and traditions at St. Thomas's. He was appointed to the staff after the

first world war and was junior surgeon to Sir Cuthbert Wallace until the latter's retirement: they worked together in the founding of a professorial surgical unit at the hospital.

Maybury was essentially shy and retiring, and it was difficult to get him to write or to speak in public. His rare contributions to discussions at the Royal Society of Medicine were a joy to all who heard them, and his two most important contributions to surgical literature—the articles on peritonitis and diseases of the appendix, jointly with B. W. Williams, in Choyce's *System of Surgery*, and the treatment of traumatic false aneurysm and arteriovenous fistula in the *Bulletin of War Medicine* (1945)—will live for ever. A profound and critical thinker, he was scrupulous in his attention to detail. He had a horror of error and was himself the acme of integrity. When faced with an unusual or difficult clinical problem he was at his best, and the number of his colleagues who sought his advice on professional and other matters was the greatest tribute to his wisdom. He could be brusque on occasion, but none of his patients doubted his sympathetic understanding of their troubles.

He was an excellent teacher for the more intelligent, though sometimes it was difficult to hear all that he said. His skill as an operator was quite remarkable—he never made an unnecessary movement and appeared unhurried and deliberate; in fact he was a very rapid operator.

He retired from the staff of St. Thomas's at the age of 60, five months before the National Health Service Act became operative, and went to live in Hampshire, where he was extremely happy with his family and his house and garden. His services to Salisbury General Hospital, given in a purely advisory capacity, were greatly appreciated by all who benefited from them. He was a skilled craftsman, not only as a surgeon but also as a plumber and carpenter, and derived great enjoyment from these hobbies.

He married Miss Isobel Lyall in 1930 and she survives him, together with their two young children. All those who knew him will feel the loss of a true friend and a wise counsellor.—R. W. N.

We are indebted to Sir MAX PAGE for the following appreciation: B. C. Maybury was one of those intelligent and efficient people who do their full share of work in life with a minimum of self-advertisement—and this despite the fact that as a student he gained almost every prize and medal open to him and then proceeded to mount the surgical ladder steadily, except during some years of work at a casualty clearing station in the first world war. He was naturally a self-effacing and reticent man, and I think his close professional association with Sir George Makins and Sir Cuthbert Wallace caused him to develop a conservative and critical attitude towards surgical problems. He was a neat and speedy operator, and his mastery of the technique of abdominal surgery was generally recognized from the time of his casualty work in France till his full maturity at St. Thomas's. His clinical judgment was excellent, although as a teacher of the average student he was not popular. The more advanced student and the postgraduate, however, appreciated the sterling worth of his counsel. It is worth noting that among his patients were to be found many doctors and their relatives. "B.C." disliked committees and their works, but would attend if a matter which interested him was under discussion: he could then be strong in opposition if his convictions were challenged. He wrote little and then usually only under pressure from without; in his rare contributions in debate he spoke with authority and with a full grasp of his material. By his passing we may well regret the loss of one of the few remaining fully equipped surgeons of the past era.

C. F. MARTIN, M.D., C.M., F.R.C.C.

Dr. Charles F. Martin, formerly dean of the faculty of medicine and professor of medicine at McGill University, died in Montreal on October 28 at the age of 85. He was one of the leading medical men in Canada.

Charles Ferdinand Martin was born in Montreal and educated at Montreal High School and at McGill University, where he graduated in medicine in 1892. After a period of postgraduate study in Europe he returned to Montreal and was appointed lecturer on pathology and on medicine at McGill. He was also elected to the staff of the Royal Victoria Hospital in 1895. In time he became physician-in-chief there, and he remained on the consultant staff after his retirement in 1934. His contributions to medical literature reflected his interest in internal medicine and in medical education.

The medical school at McGill University owes much to Martin, who was professor of medicine and dean of the faculty from 1923 to 1936, and also acting principal of the university for a time. Much reorganization was undertaken during his tenure of office, and he persuaded many famous and able men to join him in his labours. In 1934 he collaborated with Dr. Wilder Penfield in founding the Montreal Neurological Institute. He played a leading part in the foundation of the Royal College of Physicians and Surgeons of Canada, and he served as president of the American College of Physicians (1928-9), the Association of American Medical Colleges (1929), and the Canadian National Commission for Mental Hygiene. In 1948 he was awarded the first Alfred Stengel Memorial Medal by the American College of Physicians, and only last June he received the Starr Award of the Canadian Medical Association for his work in furthering medical education in Canada.

Dr. WILLIAM MCINTYRE BROWN died on October 27 at his home at West Kirby, Cheshire, on his 83rd birthday. Born at Dublin in 1870, he was educated at University College, Liverpool, and took the degrees of M.B., Ch.B. of the Victoria University of Manchester in 1894. Soon after the foundation of the University of Liverpool in 1903 he received the corresponding degrees of the new university, proceeding to the M.D. in 1908. After graduation, he first held the appointment of house-physician at Liverpool Royal Infirmary, and then settled at West Kirby, remaining there in active practice until failing health forced him to retire in 1946. During the whole of this 50 years the welfare of his patients was his sole preoccupation. His skill and devotion gained him a large circle of patients and friends. He was one of the old type of practitioner who regarded his work as a privilege, and he could always find time to listen, advise, and comfort. His great kindness and sympathy towards all those in need of help will long be remembered.—P. B. P.

With the death on October 15 of Mr. W. BRITAIN JONES, of Middlesbrough, at the age of 76, the people of Tees-side have lost a well-known and much-loved personality. The son of the Rev. T. T. Jones, William Britain Jones was born at Rhymney, South Wales, on October 5, 1877. He received his medical training at University College, London, taking the London degrees of M.B., B.S. in 1909. After graduation he held a house appointment at Ashton-under-Lyne Infirmary, and in 1911 moved to Middlesbrough to become house-surgeon to the North Ormesby Hospital. Later he became honorary surgeon to the hospital and medica

superintendent and surgeon to the Municipal (now General) Infirmary, Middlesbrough. Apart from his hospital operating sessions and his work in private practice as a consulting surgeon, he devoted his life to the development of the General Hospital: its present high status owes much to his foresight, energy, and administrative powers. He was a quick and brilliant surgeon, and in spite of a very busy life he always found time to help a younger man in difficulties, he always approached with patience and tact. He had the welfare and training of his nurses very much at heart, and many of them owed much to his interest and help. A great individualist with marked personality, he never took kindly to red tape and unnecessary form-filling, and was never at a loss for most expressive language in which to voice his opinion. He was chairman of the Clevedon Division of the B.M.A. for a short time in 1940. A keen student of many subjects besides surgery, he took an intelligent interest in psychic phenomena and gave popular lectures thereon, for he was a gifted and fluent speaker. He leaves a widow, one daughter, and two sons.—J. E. M. P.

Dr. F. H. ALEXANDER, of Angmering, died on October 29 at the age of 77. He was one to whom B.M.A. members in Sussex owed so much. His brief fatal illness started within two hours of his last attendance at a meeting of the Sussex Branch council, of which he had been a member since 1927; a few months ago he had a long and painful indisposition resulting from an injury sustained in his efforts to attend the annual general meeting of the Branch (of which he was president three years ago). He had been an active member of the West Sussex (formerly Chichester and Worthing) Division for as long as records exist, and he attended meetings of the executive committee with the greatest regularity for 30 years. He was chairman of the Division in 1929-30 and vice-chairman in 1930-1, and he had represented it on the Representative Body continuously since 1935. Frederick Hugh Alexander was born on April 17, 1876, and received his medical education at University College Hospital, obtaining the conjoint qualification in 1902 and the London M.B. two years later. He was in general practice at Littlehampton from 1905 to 1935, with the exception of his period of service as a captain in the R.A.M.C. in the first world war, service which included the Gallipoli campaign. Later he took a great interest in the British Legion and was a founder member of the Littlehampton branch and vice-president of the Sussex council. He was for many years divisional surgeon to the St. John Ambulance Brigade and was responsible for its reorganization and the invigoration of its activities in the Littlehampton area. Keen on sport of all kinds, he was for some time captain of the local hockey club and a vice-president of the cricket club, but in later years his own recreations were fishing and golf. He retired from practice in 1935 to Angmering, where he was a churchwarden and active in all village affairs. Throughout his life in Sussex he was universally admired for his gentleness and unassuming manner and for his unfailing kindness to all who approached him.—T. P. M.

The treasurer of the Medical Defence Union writes: Your admirable obituary notice (*Journal*, November 7, p. 1051) of "BILL" TUCKER (senior) prompts me to record an almost unknown incident connected with him. It happened in 1905 that I was medical officer on a steamer which called at Bermuda, so naturally I called on Tucker, for he and I had many times played football together. He gave me an excellent lunch, and that was the last time I saw him. Shortly after my return to England a man was apprehended who had been masquerading as Dr. W. E. Tucker and committing numerous frauds in connexion with purchases and sales of practices. One of the prosecution's needs was to prove that this man was not the man he pretended to be: somehow or other the late Dr. A. G. Bateman, then secretary of the

Medical Defence Union, heard that I had recently been in Bermuda and "tipped off" Scotland Yard to that effect. I was thereupon visited by a C.I.D. officer, who questioned me as to my movements. On hearing that I had actually been Tucker's guest only two or three months before, he said, "You are the man we need," and promptly arranged to subpoena me to appear as a witness at the forthcoming Warwick Assizes. The prisoner, who incidentally was a man of about 60 and a bigamist to boot, had the nerve to cross-examine me when I declared in court that he was not the William Eldon Tucker whose name appeared in the *Medical Register*; but, as has been demonstrated recently in other cases, to attempt to shake a witness who knows he is telling the exact and literal truth does not really help a defendant's case, and he was duly sentenced to three years' imprisonment. I at once joined the Medical Defence Union and have been a member ever since.

Dr. HUGO BOGER, who died on October 29 in the Hospital of St. John and St. Elizabeth at the age of 61, was the son of Dr. Hugo Boger, a medical practitioner who had a large general practice at Beni, in Bolivia. He was born at Reyes, Bolivia, on December 8, 1891, and was educated at St. Joseph's College, Norwood, becoming a medical student at University College Hospital during the first world war. In his final years there he worked single-handed as surgical dresser and unqualified house-surgeon to the late Mr. Wilfrid Trotter. He was captain of both the U.C.H. and the United Hospitals association football teams. After qualifying M.R.C.S., L.R.C.P. in 1922, he started a general practice among the South American and Spanish residents of London. In 1940, at the height of the air raids on London, he courageously took over a panel practice in Paddington because he wished to assist the country in which he had been resident for so many years. He liked panel practice so much that he continued it up to a few weeks before he was admitted to hospital as a patient. He was Vice-Consul for Bolivia in London for twenty-four years. Dr. Boger bore a striking resemblance to the late Henry Ainley, the actor, for whom he was frequently mistaken in the street. He leaves a widow, formerly Miss Dorothy Treadwell, a son, and a daughter.—A. M.

Dr. P. G. CARNEY, who died at his home at Clonskeagh, Dublin, on November 8 at the age of 63, had a distinguished career in the R.A.M.C. in both world wars. Born at Cootehill, County Cavan, in 1890, Philip Gerard Carney was educated at St. Mary's College, Dundalk, and at University College, Dublin, graduating M.B., B.Ch. of the National University of Ireland in 1914. After holding a resident appointment at the Mater Misericordiae Hospital, Dublin, he entered the R.A.M.C. in 1915 and served in France until 1918. He was awarded the Military Cross and the Croix de Guerre, with palm, in 1918 and for his war service he was admitted to the honorary degree of M.Sc. of the National University of Ireland in 1919. He then took a permanent commission in the R.A.M.C. and served in the Punjab and on the North-West Frontier of India until 1923, when he retired from the Army for family reasons. On return to civilian life he entered private practice at Cootehill, becoming district medical officer for the area in 1924. He re-entered the R.A.M.C. on the outbreak of the second world war in 1939 and saw service in France, the Middle East, and Greece until 1945, being mentioned in dispatches in 1944. Most of his time was spent in the Middle East, where he commanded a field ambulance in the second Libyan campaign against Rommel, and for two years he commanded the 53rd General Hospital at Haifa. He was released from the Army in 1945 with the rank of lieutenant-colonel and returned to his practice at Cootehill and to his duties as district medical officer until failing health forced his retirement in 1951. His outstanding personal qualities were simplicity and an unfailing kindness

and sympathy to everyone, especially the sick poor, by whom he was well loved. His intense interest in his work and his zeal for his patients never flagged, and if he had been less conscientious he might have been still alive. He died from arteriosclerotic hypertension. His chief hobbies were reading, archaeology, sailing on the broad lakes near Cootehill, and gardening.

Medico-Legal

DISTINGUISHING A PSYCHOPATH

During the trial at the Old Bailey on November 3 of Francis Wilkinson, 24, furnaceman, of Balham, who was sentenced to death for the murder of 5-year-old Miriam Susan Gray at the house where he was a lodger, Mr. Justice Hilbery queried the definition of the words "psychopathic personality."

Dr. Desmond Curran, psychiatrist, stated he had examined Wilkinson in Brixton Prison. "I have no doubt that Wilkinson should be regarded as the possessor of a psychopathic personality, or what is generally called an anomaly of character. I don't believe he is suffering from any mental disease."

The Judge asked what he meant by psychopathic personality. "I am collecting from various psychiatrists their definitions. Now, what is yours? *Psyche*, the soul, and *pathos*, illness: *sickness of the soul* I can appreciate; but what is your definition?"

Dr. Curran said he would read the definition as given by Dr. Denis Hill, who gave evidence before the Royal Commission on capital punishment. His definition was: "The diagnosis of psychopathic personality is made on persons of habitual abnormal behaviour, behaviour which has been abnormal from childhood; and the disorder of behaviour is seen in abnormal emotional reactivity, so that the individual who has it shows abnormal outbursts of temper, outbursts of emotional violence, and alcoholic excesses, often repeated, or suicidal attempts, and in some cases homicidal attempts."

The Judge: Does it mean the individual must exhibit all those things, those abnormalities, to be a psychopathic personality?

Dr. Curran replied he thought it was agreed that the individuals differed and there was no sharp dividing line.

The Judge: Every habitual criminal must be a psychopath if that is so.

Dr. Curran said he did not think every habitual criminal would show some of the features given in the definition.

The Judge: And what of abnormal behaviour? Do you agree normal behaviour is honest behaviour?—I don't know what is normal behaviour.

Mr. Christmas Humphreys (prosecuting): In the world of psychiatric medicine, is it right there is an elaborate classification of the disease of the mind?—Yes, there are many.

And in the study of psychiatric medicine there is at present a tendency to put into a new group those persons who do not suffer from a disease of the mind, but suffer from some form of character deficiency or emotional instability which makes it impossible for them to enter into normal contact with society?—Yes.

So when you say he is a psychopath, you are inferentially saying he is distinct from a person suffering from a distinct disease of the mind?—Yes.

Not within M'Naghten Rules

Dr. J. C. McL. Matheson, principal medical officer at Brixton Prison, who was called by the prosecution, said he agreed with Dr. Curran in that Wilkinson could be called a psychopath. He was not suffering from any mental disease which would bring him within the M'Naghten rules. But Wilkinson was abnormal.

The Judge: He is a misfit?—Yes.

The Judge ruled that there was no evidence that Wilkinson was suffering from a disease of the mind which would bring him within the M'Naghten rules.

According to the prosecution, Wilkinson, early on the morning of August 15, went into the kitchen where Miriam was sleeping, shone a torch on her, and hit her with the leg of a chair, fracturing her skull. He then made an attempt to assault her sexually.

Wilkinson's mother, Mrs. B. Wilkinson, said that her son had always been restless and could not sleep at night. No one would sit beside him in a cinema because he would disturb them by his restlessness. When he was 8 or 9 he had a great shock when he found a newborn baby torn in half in a dustbin. She found that one day he had broken a mirror because he could not bear to see himself; afterwards he told her he had not known he had done it. His father could not get on with him, and she broke the home up by leaving. She left because she could not stand it any longer.

Notice of appeal has been lodged.

Medical Notes in Parliament

LORDS' VIEWS ON SMOG

LORD AMULREE turned the attention of the House of Lords on November 18 to smog, describing its dangers to health and urging that action should be taken to prevent or minimize its occurrence, with particular reference to the extended use of smokeless fuel. In the severe fog of December, 1952, between 4,000 and 5,000 people died from the effects of the fog. There was also a big increase in the sickness rate.

The reason why the fog of 1952 was more dangerous than any suffered before was that there was a much greater concentration of sulphur dioxide in the air. It seemed that there was some kind of correlation between the sulphur dioxide content of the air and deaths from fog. More important was what could be done to stop the occurrence of fogs in future. Obviously it was going to take a long time, but one would like to know that the Government and local authorities were aware of the problem and doing something to meet it. What was being done, for example, to increase the use of smokeless fuels, which would go far to solving the fog question in general, and the formation of smokeless zones? A large range of industries was exempted from the powers given under the Public Health Act, 1936, but a firmer line should surely be possible in 1953. A new factor in London was the erection of power stations, of which there were nine on the banks of the Thames, in the valley where the worst conditions making for fog would occur. He was told that 97% efficiency could be obtained in washing the fumes. The solid part was efficiently extracted, but what was evil to health was the fumes. The N.H.S. fog masks, he thought, would not be of much value in dealing with the tiny particles, which could get round the corners of the mask and penetrate the gauze.

LORD HADEN-GUEST said it was calculated that 5,000,000 tons of domestic coal were consumed in Greater London during the six winter months. That sent into the atmosphere from 800 to 1,000 tons of smoke a day, 2,000 to 3,000 tons of sulphur dioxide a day, and up to 2,000 tons of carbon monoxide a day. One of the difficulties in the way of effective action was the simple administrative one that there was no single authority in London to control smoke pollution. The L.C.C. were taking preliminary steps to facilitate the formation of such an organization.

The EARL OF LISTOWEL mentioned some remedial measures which the L.C.C. would include in evidence to be submitted to the Beaver Committee. The first was to provide the public with information about the damage caused by fog. How many, for instance, knew that smokeless fuels gave off as much sulphur as coal or coke, or that fuel oil gave off half as much sulphur again as an equal weight of coal or coke? Even if there were smokeless zones the main evil of sulphur remained without a remedy. People contemplating the construction of new power stations must surely in the light of the second fact pause

for thought. Within an area of 20 square miles in London there were three large power stations—Battersea, Fulham, and Lotts Road—which burned 60% of all the coal used in the area. There was a lack of basic data from which firm conclusions could be drawn. A serious difficulty about washing the smoke was its expense.

No Authoritative Pronouncement

The EARL OF SELKIRK, Paymaster-General, said that the provision of smokeless fuel was only part of a big and intractable problem of long standing. Even were the atmosphere cleared of smoke there would still remain the problem of the colourless gases, sulphur dioxide and carbon monoxide. They were not yet in a position to make an authoritative pronouncement. Roughly half the smoke came from industrial plant, and the other half from the 16 million domestic grates. Only about a quarter of these grates could use coke, the only smokeless fuel available in any quantity. The high-grade smokeless fuels cost half as much again as coke, and unless their cost could be brought within the reach of the average householder there was no prospect of their making more than a small contribution to smoke abatement. He deprecated the banking up of coal fires at night, particularly in foggy weather, and said the Government would like that to be known. The cleansing of flue gases at power stations was a difficult subject. It was done at Battersea before the war, but there was no statutory obligation to carry it out. It was expensive, and not entirely satisfactory. The Beaver Committee would be making an interim report, which would be available in a few days' time.

Foreign Doctors and Dentists

MR. RAYMOND GOWER asked the Minister of Health what steps had been taken to employ the services of foreign doctors now domiciled in this country. MR. IAIN MACLEOD stated on November 19 that foreign doctors who had secured registration by the General Medical Council and who were domiciled in this country could, and did, take part in the National Health Service on equal terms with their British colleagues.

Doctors' Surgeries

MR. A. BLENKINSOP asked the Minister of Health on November 19 what action he had taken to help secure an improvement in the condition and equipment of general practitioners' surgeries and waiting-rooms. MR. IAIN MACLEOD said he understood that the chairman of the General Medical Services Committee of the B.M.A. wrote last month individually to all the 20,000 or so general practitioners taking part in the Health Service calling their attention to their responsibilities in providing a proper standard of surgery and waiting-room. He proposed to await the results of this approach.

Retiring Age

MR. WILLIAM BLYTON asked the Minister of Health on November 19 whether, in view of the Government policy of encouraging people to continue working instead of taking a pension, he approved the action of a regional hospital board in terminating the contract of a doctor medical superintendent at the age of 60 years without consulting the hospital management committee principally concerned, who were desirous of retaining their medical superintendent. MR. IAIN MACLEOD stated that under the terms and conditions of service of hospital medical staff a hospital doctor's regular contract came to an end when he was 65 (or 60 if he was a mental health officer), but his employing authority might retain him temporarily after that age. No approval on the Minister's part was needed.

Nerve Gas Experiments

MR. IAN WINTERBOTTOM asked the Parliamentary Secretary to the Ministry of Defence what special inducements were offered to Servicemen to take part in dangerous experimental

work, such as research into nerve gases. MR. NIGEL BIRCH, replying on November 17, said that volunteers for special types of experimental work, including chemical warfare research, were paid sums which varied between the different kinds of experiments. This extra pay was normally at the rate of between 10s. and 15s. a week. The men were volunteers, the nature of the experiment was clearly explained to them, and they were given a chance to withdraw. There had been only one fatal accident since 1922.

Private Members' Bills

Among 19 Bills presented by private members in the House of Commons on November 18 was one by Colonel M. Stoddart-Scott "to make it compulsory for the exchange of certificates of medical examination between persons before marriage." The second reading was fixed for March 26, 1954.

There were also a Coroners Bill, "to amend the law on the fees and allowances payable by coroners to witnesses, to persons summoned to attend as witnesses, and to medical practitioners making post-mortem examinations by the coroner's direction or at the coroner's request (for February 12); an Animals (Cruel Poisons) Bill, to prohibit the killing of animals by strychnine or other cruel poisons, and to amend the Pharmacy and Poisons Act, 1933 (for March 12); a Protection of Animals (Anaesthetics) Bill, to repeal the Act of 1919 and to extend the provisions of the Protection of Animals Acts in relation to the performance of operations on animals (for February 12); and a Safety in Employment (Inspection and Safety Organization) Bill, to ensure the representation of employees in the establishment and maintenance of conditions of safety and health in employment, which is supported by Dr. A. D. D. Broughton and Dr. Barnet Stross (for February 26).

Industrial Diseases Benefits

The House of Commons gave an unopposed second reading on November 23 to the Industrial Diseases (Benefit) Bill. MR. O. PEAKE, Minister of Pensions and National Insurance, explained that it extended the provisions of the Pneumoconiosis and Byssinosis Benefit Act, 1951, to cases of partial disablement. A large number of persons had failed to get compensation either under the Workmen's Compensation Acts or the industrial injuries scheme for two reasons; many had contracted pneumoconiosis before it was covered under the Workmen's Compensation Acts, and others leaving the prescribed industries had failed to prove their disablement within the time limit. It was believed that 15,000 cases were likely to succeed under the Bill. A flat rate of payment equal to one-half the rate payable for total disablement under the 1951 Act was proposed. It was estimated that in a full year the charge on the industrial injuries fund would be £750,000 for pneumoconiosis patients and about £50,000 to £60,000 for other diseases. The total cost would be about £1,500,000 a year, which would tend to diminish annually.

Dr. EDITH SUMMERSKILL welcomed the Bill on behalf of the Opposition. Dr. BARNET STROSS urged the need of a comprehensive cover to ensure that every human being was safeguarded if he was rendered ill or crippled by his occupation. Dr. H. MORGAN protested that this was a petty measure, and ran away from the responsibility of doing justice to men in the mining industry.

Certain dental charges have been repealed by regulations. They were imposed under the National Health Service Act, 1951. The charges concerned are those on dentures supplied as part of a course of clinical dental teaching at certain teaching hospitals. These are Guy's Hospital, King's College Hospital, the United Newcastle-upon-Tyne Hospitals, the United Leeds Hospitals, and the United Liverpool Hospitals. The regulations are the National Health Service (Remission of Dental Charges) (No. 2) Order, 1953.

Universities and Colleges

UNIVERSITY OF OXFORD

Sir Howard Florey, F.R.S., has been appointed the representative of the University on the governing body of the Lister Institute of Preventive Medicine.

Dr. A. G. McD. Weddell has been appointed delegate of St. Catherine's Society on the Hebdomadal Council.

In Congregation on August 1 the degree of B.M. was conferred on N. F. Brooks, J. W. Pearson (in absence), and Josephine Bradford (in absence).

UNIVERSITY OF CAMBRIDGE

The following appointments are announced: Dr. D. H. M. Woolham, University Lecturer in Anatomy; Dr. G. F. Roberts and Dr. B. M. Herbertson, University Lecturers in Pathology; Dr. A. P. Waterson, University Demonstrator in Pathology; and Dr. R. A. Parker, University Assistant Pathologist to Addenbrooke's Hospital, all with tenure from October 1, 1953, for three years.

In Congregation on August 1 the following medical degrees were conferred:

M.D.—*D. O'Brien, E. J. Holborow, B. H. Vawdrey, J. Gloster, E. G. Pyn, L. D. Osler, F. J. Y. Wood.

M.B., B.CHIR.—*P. M. O. Massey, W. B. Hepburn, E. D. Williams, Mrs. Esther S. Kerr.

*By proxy.

UNIVERSITY OF LONDON

Sir Archibald Gray has been reappointed a Crown Member of the Court of the University for a further period of five years from October 1, 1953.

The following have been nominated, appointed, or reappointed as representatives of the University on the governing bodies indicated in parentheses: Sir Archibald Gray, Dr. C. F. Harris, and Dr. Andrew Topping (British Postgraduate Medical Federation); Sir James Paterson Ross (Guy's Hospital Medical School); Professor Dorothy Russell (Institute of Ophthalmology); Dr. H. B. May and Professor H. R. Robinson, F.R.S. (Queen Mary College); Dr. M. I. A. Hunter and Professor J. Whillis (Royal Dental Hospital of London, School of Dental Surgery); Professor J. Z. Young, F.R.S., and Mr. E. G. Slesinger (St. George's Hospital Medical School); Professor W. C. W. Nixon (St. Mary's Hospital Medical School); Mr. J. P. Hedley (St. Thomas's Hospital Medical School); Sir Charles Harington, F.R.S., and Sir Archibald Gray (University College Hospital Medical School); Professor R. Hare (Wright-Fleming Institute of St. Mary's Hospital Medical School); Professor R. V. Christie (Inter-university Council for Higher Education in the Colonies).

The following have been recognized as teachers of the University in the subjects indicated in parentheses: St. Thomas's Hospital Medical School, Dr. J. G. Bourne (Anaesthetics); Dr. J. M. Tanner (Physiology). St. Bartholomew's Hospital Medical College, Mr. I. M. Hill (Surgery). Royal Free Hospital School of Medicine, Mr. J. C. R. Hindenach (Orthopaedics). London Hospital Medical College, Mr. J. E. Richardson (Surgery). St. Mary's Hospital Medical School, Dr. H. L. Thornton (Anaesthetics); Dr. W. F. Widdas (Physiology). University College Hospital Medical School, Mr. H. R. I. Wolfe (Surgery). University College, Dr. D. H. L. Evans (Anatomy). Dr. D. N. Baron has been granted probationary recognition for two years from July, 1953, as a teacher of pathology (chemical pathology) at Middlesex Hospital Medical School.

The title of Professor Emeritus of Physics in the University has been conferred on Professor H. R. Robinson, F.R.S.

The following candidates have been approved at the examinations indicated:

M.D.—Part I: Marion M. Ashforth, Marie J. Bouton, W. Brumfit, P. H. Connell, H. Foster, P. Glasman, J. F. Horley, P. J. Koblenzer, F. H. Lumb, T. G. Paxon, J. C. Pond, H. R. C. Riches, J. J. Segall, B. Strickland.

M.S.—Part I: C. I. Cooling, E. L. John.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW

At a meeting of the Faculty held on September 7, with Dr. Andrew Allison, President, in the chair, E. Armitage and S. Sachdev were admitted Fellows of Faculty *qua* physician and R. S. Cowie was admitted a Fellow of Faculty *qua* surgeon.

INFECTIOUS DISEASES AND VITAL STATISTICS

Summary for British Isles for week ending November 7 (No. 44) and corresponding week 1952.

Figures of cases are for the countries shown and London administrative county. Figures of deaths and births are for the 160 great towns in England and Wales (London included), London administrative county, the 17 principal towns in Scotland, the 10 principal towns in Northern Ireland, and the 14 principal towns in Eire.

A blank space denotes disease not notifiable or no return available. The table is based on information supplied by the Registrars-General of England and Wales, Scotland, N. Ireland, and Eire, the Ministry of Health and Local Government of N. Ireland, and the Department of Health of Eire.

* Measles not notifiable in Scotland, whence returns are approximate.
† Includes primary and influenzal pneumonia.
‡ Includes puerperal pyrexia.

Vital Statistics

Trichinosis in Liverpool

Professor Andrew B. Semple, Medical Officer of Health for Liverpool, reports that up to the week ending November 21 some 68 cases of trichinosis had occurred in the Liverpool area over the previous two weeks. Eighteen of these patients have been admitted to hospital. Most of the cases are mild, but three patients are seriously ill. The source of the infection has been traced to a sausage factory in the city, and investigations are still proceeding to trace back the infection further. Nearly all the persons affected give a history of eating raw sausage meat. Further cases are still being found, and there is no evidence that new infections are occurring.

Infectious Diseases

The largest variations in the notifications of infectious diseases in England and Wales during the week ending November 7 were increases of 188 for measles, from 842 to 1,030, and 108 for whooping-cough, from 2,067 to 2,175.

The largest rise in the incidence of measles was 73 in Cumberland, from 55 to 128, due to the outbreak in Workington M.B., where the cases rose from 51 to 121. The other large rises in measles were 42 in Lincolnshire, from 9 to 51 (mainly due to an outbreak with 32 cases in Horn-castle M.B.), 43 in Lancashire, from 205 to 248, and 36 in Yorkshire West Riding, from 64 to 100. The largest rises in the notifications of whooping-cough were 42 in Lancashire, from 216 to 258, 38 in Surrey, from 53 to 91, and 37 in London, from 98 to 135. 1,187 cases of scarlet fever were notified, being 39 fewer than in the preceding week; the largest decrease was 29 in London, from 87 to 58. The number of notifications of diphtheria was 18, the same as in the preceding week. The notifications involved nine counties, compared with only four in the previous week. The chief features of the returns were decreases in Staffordshire from 9 to 5 and in Lancashire from 7 to 2.

94 cases of acute poliomyelitis were notified; these were 28 fewer for paralytic and the same number for non-paralytic cases as in the preceding week. The largest returns were Lancashire 15 (scattered over 13 administrative areas); Wiltshire 9 (Calne and Chippenham R.D. 3, Highworth R.D. 3); Warwickshire 6; Yorkshire West Riding 6.

358 cases of dysentery were notified, 36 fewer than in the preceding week. The largest centres of infection were London 71 (Greenwich 12, Islington 10); Yorkshire West Riding 62 (Bradford C.B. 40); Lancashire 51 (Bolton C.B. 34); Yorkshire North Riding 28 (Middlesbrough C.B. 27); Essex 17; Middlesex 16.

Graphs of Infectious Diseases

The graphs below show the uncorrected numbers of cases of certain diseases notified weekly in England and Wales. Highest and lowest figures reported in each week during the nine years 1944-52 are shown thus -----, the figures for 1953 thus ———. Except for the curves showing notifications in 1953, the graphs were prepared at the Department of Medical Statistics and Epidemiology, London School of Hygiene and Tropical Medicine.

Week Ending November 14

The notifications of infectious diseases in England and Wales during the week included scarlet fever 1,400, whooping-cough 2,410, diphtheria 26, measles 816, dysentery 370, acute poliomyelitis 95, paratyphoid fever 1, and typhoid fever 1.

The Services

The name of Captain M. A. Lerner, R.A.M.C., appears in a list of those mentioned in dispatches in recognition of gallant and distinguished services in Malaya, during the period January 1 to June 30, 1953.

The President of the U.S.A. has bestowed the decoration of Legion of Merit, Degree of Legionnaire, upon Surgeon Captain T. B. Lynagh, R.N., for distinguished services in operations in Korean waters.

The *London Gazette* has announced the following awards by the President of the U.S.A. in recognition of gallant and distinguished services during the operations by the United Nations in Korea:

Legion of Merit, Degree of Legionnaire.—Colonel G. Anderton, O.B.E., late R.A.M.C., (now R.A.R.O.).

Bronze Star Medal.—Captain H. I. Jory, R.A.M.C.

The *London Gazette* has announced the award of (a) the Army Emergency Reserve Decoration and (b) First Clasp to the Army Emergency Reserve Decoration to Major R. F. Lawrence, R.A.M.C., retired.

Surgeon Commanders R. I. Bence, D.S.C., R.N.V.R., C. K. Churches, and S. A. Sewell, R.A.N.R., and S. L. Townsend, R.A.N.V.R., and Surgeon Lieutenant-Commander J. R. H. Peat, R.N.V.R., have been awarded the Royal Naval Volunteer Reserve decoration.

Medical News

Rabbit Myxomatosis.—The danger of this disease to laboratory rabbits kept for experimental purposes is pointed out in Newsletter No. 7 of the Laboratory Animals Bureau, M.R.C. Laboratories, Hollyhill, London, N.W.3. Vectors of the disease include mosquitoes and midges, and they should be prevented from entering rabbit houses by the proofing of windows and other openings. Airlock doors are needed, outer garments and footwear have to be changed by those entering the rabbit houses, and insecticides may be useful. Diseased rabbits should be killed immediately, the carcasses burnt, the cages disinfected, and contacts isolated for seven days. A strong immunity to myxomatosis, lasting for at least 12 months, can be conferred by vaccination with the Boerlarge strain of the Shope fibroma virus. The Bureau cannot say where the vaccine is to be obtained until the Carrington Committee investigating the Kent outbreak has reported.

Dr. Ludwig Guttmann, director of the spinal injuries centre at the Ministry of Pensions' Stoke Mandeville Hospital, has been awarded the rehabilitation prize of the World Veterans Federation. He is its first recipient. Dr. Guttmann was born in 1899 in Upper Silesia, and graduated at Freiburg University in 1924. By 1937 he had become medical director of the department of neurology and neurosurgery at the Jewish Hospital, Breslau, but in 1939 the policy of the Germans compelled him to leave. He then came to Oxford and worked on nerve regeneration. At the end of 1943 he was asked to start a spinal unit at the Ministry of Pensions Hospital, Stoke Mandeville. He was awarded the O.B.E. in 1950.

Help for Visitors.—A memorandum outlining social facilities for visitors from Canada and the U.S.A. is obtainable from Dr. G. Wolstenholme, Director, The Ciba Foundation, 41, Portland Place, London, W.1. The Horse Shoe Club exists to foster friendship and exchange of medical research and clinical workers between Canada, the U.S.A., and Britain. Details may be obtained from the hon. secretary, Dr. C. S. Nicol, St. Bartholomew's Hospital, London, E.C.1. The Society for Visiting Scientists aims to exchange ideas between scientists of Britain and those from overseas. It provides food and accommodation. Particulars may be obtained from Miss E. Simpson, assistant secretary of the Society, 5, Old Burlington Street, London, W.1. The Ciba Foundation, a trust independent of the pharmaceutical firm, arranges scientific conferences and also provides accommodation for visitors from overseas. Full information can be obtained from the Director, Dr. G. Wolstenholme, at the address above.

United Hospitals' Festival Choir.—The choir, conducted by Colin Ratcliffe, is to give two concerts next year at the Royal Albert Hall: the first is Mozart's "Requiem," with the Philharmonia Orchestra, on January 20, and the second (probably Verdi's "Requiem") with the London Symphony Orchestra on June 3. Rehearsals are held every Thursday between 8 and 10 p.m. at the Church of the Most Holy Trinity, Brompton. Membership is open to anyone who works in any capacity in any hospital, and applications will be considered from anyone who has done so in the past. There are vacancies for all voices. Requests for membership should be directed to the Choir Secretary, Flat 1, 93, Lexham Gardens, London, W.8.

Thunberg Memorial Volume.—Supplement 111 of *Acta Physiologica Scandinavica* (1953, vol. 30) is a memorial volume to Torsten Thunberg, the distinguished Swedish physiologist and biochemist, who died in 1952. He occupied the chair of physiology at Lund University from 1905 to 1938. The volume includes an account of his scientific work, a full bibliography of his writings, a description of the great new Institute of Physiology at Lund, and a number of papers from Thunberg's Swedish colleagues and friends.

Family Doctor.—A timely warning against the dangers of fire at Christmas time appears in the new issue of *Family Doctor*, with advice on fire-guards and first-aid. A new series of "How to Live with your Nerves," by Dr. Walter C. Alvarez, of the Mayo Clinic, begins this month. Sir Russell Brain, P.R.C.P., gives an account of the Royal College of Physicians, London, and Dr. W. Edwards writes about the patient's protest that doctors never tell you anything in hospital.

COMING EVENTS

Pyrogens.—A symposium on the assay and detection of pyrogens will be held at University College, London, W.C.1, on Friday, December 11. Particulars may be obtained from Dr. K. R. Capper, Pharmaceutical Society of Great Britain, 17, Bloomsbury Square, London, W.C.1.

Internal Medicine Congress.—The third International Congress of Internal Medicine will be held in Stockholm from September 15 to 18, 1954. The president will be Professor Nanna Svartz, and the secretary-general Professor Anders Kristenson. The two main subjects for discussion at the congress will be the pathogenesis and treatment of hypertension, and the common characteristics of mesenchymal diseases (collagenous diseases) and their nature. Further information may be obtained from Third International Congress of Internal Medicine, Karolinska Sjukhuset, Stockholm 60.

NEW ISSUES

Journal of Neurology, Neurosurgery, and Psychiatry.—The next issue (Vol. 16, No. 4) will be available in a week's time. The contents will include:

THE BRAIN-STEM LESIONS IN PARKINSONISM. J. G. Greenfield and F. Dawn Bosanquet.
ROENTGENOLOGICAL EXAMINATION OF THE ARNOLD-CHIARI MALFORMATION WITH THE ZIESSER DES PLANTES PROCEDURE. H. Verbiest.
TEMPORAL LOBE EPILEPSY WITH PERSONALITY AND BEHAVIOUR DISORDERS CAUSED BY AN UNUSUAL CALCIFYING LESION. Murray A. Falconer and Desmond A. Pond.
SPINAL PATHWAYS SUBSERVING DEFECATION AND SENSATION FROM THE LOWER BOWEL. P. W. Nathan and Marion C. Smith.
SUBSTANCES WHICH SUPPORT RESPIRATION AND METABOLIC RESPONSE TO ELECTRICAL IMPULSES IN HUMAN CEREBRAL TISSUES. H. McIlwain.
THE SEX-RATIO IN CONVULSIVE DISORDERS WITH A NOTE ON SINGLE-SEX SIBSHIPS. Christopher Ounsted.
PROGNOSTIC FACTORS IN ELECTRIC CONVULSIVE THERAPY. Robert F. Hobson.
BOOK REVIEWS.
INDEX TO VOL. 16.

Issued quarterly; annual subscription £2 2s., single copy 12s. 6d.; obtainable from the Publishing Manager, B.M.A. House, Tavistock Square, London, W.C.1.

SOCIETIES AND LECTURES

A fee is charged or a ticket is required for attending lectures marked *. Applications should be made first to the institution concerned.

Friday, November 27

INSTITUTE OF LARYNGOLOGY AND OTOTOLOGY.—3.30 p.m., clinical meeting for general practitioners. Mr. J. C. Hogg: Relationship Between Sinusitis and Chest Disease.

Saturday, November 28

WEST MIDLANDS PHYSICIANS ASSOCIATION.—At Queen Elizabeth Hospital, Birmingham, 11 a.m., autumn meeting.

Monday, November 30

INSTITUTE OF PSYCHIATRY.—5.30 p.m., Dr. E. Stengel: lecture demonstration. LONDON UNIVERSITY.—At London School of Hygiene and Tropical Medicine, 5.30 p.m., Special University Lecture in Pathology by Professor J. R. Squire: Nephrotic Syndrome.

POSTGRADUATE MEDICAL SCHOOL OF LONDON.—4 p.m., Dr. B. G. C. Ackner: Management of Some Common Sexual Difficulties.

Tuesday, December 1

BRITISH POSTGRADUATE MEDICAL FEDERATION.—At London School of Hygiene and Tropical Medicine, 5.30 p.m., Dr. W. D. M. Paton: Anticholinesterases.

INSTITUTE OF DERMATOLOGY.—5.30 p.m., Professor C. A. Keele: Hyperhidrosis.

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL.—4.45 p.m., Thomas Percy Legg Memorial Lecture by Mr. V. E. Negus: The Relationship Between Rhinology and Laryngology and the Thyroid Gland.

MIDDLESEX COUNTY MEDICAL SOCIETY.—At North Middlesex Hospital, 3 p.m., clinical meeting.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m., Arris and Gale Lecture by Mr. G. J. Hadfield: Effect of Hormones on Healing.

ST. MARY'S HOSPITAL MEDICAL SCHOOL.—At Wright-Fleming Theatre, 5 p.m., Dr. H. K. Waller and Dr. R. Lightwood: Breast Feeding.

WEST END HOSPITAL FOR NERVOUS DISEASES.—5.30 p.m., Dr. B. C. Parsons-Smith: neurological demonstration.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Causes of Failure of Contraceptive Diaphragms

Q.—What are the possible causes of failure of the diaphragm contraceptive cap? In the last year I have had 3 failures in 20 patients.

A.—The diaphragm contraceptive cap ("Dutch cap") is remarkably reliable in the experience of those who specialize in giving advice and instruction in contraception. It must, of course, be used in conjunction with an efficient spermicidal jelly, of which there are several preparations on the market.

Unaccountable failures are rare, and a failure rate of 3 in 20 cases strongly suggests some error in the fitting of the diaphragm, inadequate instruction of the patient in its use, or failure on the part of the patient to follow instructions implicitly on all occasions. It is not uncommon for a woman who conceives to deny any breakdown in technique, only to confess years later that she did in fact depart from instructions. The commonest causes for failure of an occlusive diaphragm are:

1. Incorrect placing of the cap by the patient. Many women require long and patient instruction and few can feel their cervix unless specially taught to do so. If the cervix cannot be felt by the patient a watch spring (instead of a coiled spring) diaphragm may be easier and safer to use. Even then there should be a periodic check by the doctor to make sure that she is inserting it correctly.
2. Removal of the cap too soon after coitus. There should be an interval of eight hours.
3. Use of the cap without a spermicidal preparation, or the practice of coitus several hours after its insertion without supplementing the spermicidal jelly.
4. Omission of the cap on isolated occasions; sometimes the patient even forgets she has not inserted it.
5. The cap may not fit as well as it appears to do when tested in the doctor's surgery. At that time the woman may be nervous and tense, whereas during coitus the pelvic muscles are relaxed.
6. Use of the cap in cases in which it is not suitable. The coiled-spring diaphragm, for example, is not reliable if the vaginal walls are lax and the anterior fornix is shallow; retroversion is a contraindication in certain cases.

Abortifacient Pastes

Q.—In "Pye's Surgical Handicraft" (1950, 16th edition, p. 386) *utus* (formerly *aretus*) paste is recommended as a simple and effective way of producing abortion up to about the sixteenth week. Is this a generally held opinion? If so, of what is the paste composed, and how is it applied?

A.—Abortifacient pastes of the type mentioned have been marketed on the continent of Europe, in the United States, and in Britain since about 1930. They consist essentially of alkaline soaps medicated with iodine and astringents. They have a strong haemolytic and cytolytic action, and act by chemical rather than mechanical irritation of and act by chemical rather than mechanical irritation of the uterine wall. The paste is injected (through the special cannula supplied with the tubes) into the lower part of the uterus, outside the membranes, the amount depending on the duration of pregnancy. Expulsion of the ovum generally takes place 24 to 36 hours after injection. Anaesthesia is not necessary, but the injection should be made slowly, without pressure, and with due regard to asepsis. If there is any pain or bleeding the injection should be stopped at once. The method should never be used during the first

Wednesday, December 2

EDINBURGH CLINICAL CLUB.—At Royal Hospital for Sick Children, Edinburgh, 4 p.m., clinical meeting. Dr. Margaret MacK. Methven: Case Conference in the Psychiatric Department.

INSTITUTE OF DERMATOLOGY.—5.30 p.m., Dr. H. Haber: Bullous Eruptions of the Skin.

INSTITUTE OF UROLOGY.—4.30 for 5 p.m., Mr. F. R. Kilpatrick: Tuberculosis of the Renal Tract.

MIDLAND MEDICAL SOCIETY.—At Birmingham Medical Institute, 8.15 p.m., Mr. A. Lawrence Abel: Present Position of the Cancer Problem.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.—7.30 p.m., Professor A. D. Macdonald: Applied Pharmacology.

ROYAL INSTITUTE OF PUBLIC HEALTH AND HYGIENE.—3.30 p.m., Sir Harold E. Whittingham: Hygiene and Sanitation in Aviation (illustrated).

SOCIETY OF PUBLIC ANALYSTS.—At Chemical Society, 7 p.m., Professor C. H. Gray: Recent Advances in Medical Chemistry.

Thursday, December 3

BRITISH POSTGRADUATE MEDICAL FEDERATION.—At London School of Hygiene and Tropical Medicine, 5.30 p.m., Dr. R. M. B. MacKenna: Scientific Approach to Dermatology.

CHADWICK TRUST.—At Wright-Fleming Institute of Microbiology, St. Mary's Hospital, 5 p.m., Malcolm Morris Memorial Lecture by Professor P. W. Windeyer: Radiotherapy in its Relation to Dermatology.

FACULTY OF HOMOEOPATHY.—At Royal London Homoeopathic Hospital, 5 p.m., clinical evening.

GLASGOW UNIVERSITY MEDICO-CHIRURGICAL SOCIETY.—At Glasgow University Union, 7.30 p.m., Professor J. N. Davidson: A Biochemist Looks at the Cell.

HONYMAN GILLESPIE LECTURE.—At University New Buildings, Edinburgh, 5 p.m., Dr. E. B. French: Pigmentation.

INSTITUTE OF CHILD HEALTH AND INSTITUTE OF NEUROLOGY.—At National Hospital, Queen Square, W.C.1, 5.30 p.m., Dr. L. T. Hilliard: Mental Deficiency and Paralytic Syndromes.

INSTITUTE OF LARYNGOLOGY AND OTOTOLOGY.—At Royal College of Surgeons of England, 5.30 p.m., Dr. Michael P. Ward: Ascent of Mount Everest: Medical Problems.

LIVERPOOL MEDICAL INSTITUTION.—8 p.m., Symposium: Pathology of Tuberculosis.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5.30 p.m., otolaryngology lecture by Dr. Michael P. Ward: Ascent of Mount Everest: Medical Problems.

ST. ANDREWS UNIVERSITY.—At Physiology Department, Dundee, 5 p.m., Mr. V. E. Negus: Ciliary Action.

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL.—5 p.m., Dr. Denis Williams: neurology demonstration.

SOCIETY OF CHEMICAL INDUSTRY: MICROBIOLOGY GROUP.—At Medical Society of London, 6.15 p.m., papers by Professor M. Stacey, D.Sc., F.R.I.C., F.R.S., Mr. A. E. James, B.Sc., A.R.I.C., Dr. F. Fletcher, Mr. A. R. Lockwood, B.Sc., A.R.I.C., and Mr. A. W. Wilkinson on Dextran.

Friday, December 4

HEBERDEN SOCIETY.—At Royal College of Surgeons of England, 3.30 p.m., Heberden Oration for 1953 by Sir W. Russell Brain: Spondylosis: The Known and the Unknown.

INSTITUTE OF DERMATOLOGY.—5.30 p.m., clinical demonstration by Dr. R. T. Brain: Diseases of Children.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—Professor Charles Wells: The Suprarenal Gland, its Surgical Significance in Health and Disease.

POSTGRADUATE MEDICAL SCHOOL OF LONDON.—4 p.m., film and commentary by Dr. R. G. Macfarlane: Marrow Puncture.

ROYAL MEDICAL SOCIETY, Edinburgh.—8 p.m., Dissertation by Mr. J. C. Guinard: Astronautical Medicine.

WHIPPS CROSS HOSPITAL MEDICAL SOCIETY.—8.30 p.m., debate. Motion: Corporal Punishment has no place in the Penal System of an Enlightened Society. Proposer, Mr. G. Benson, M.P.; Opposer, Dr. W. J. O'Donovan.

Saturday, December 5

MIDLAND TUBERCULOSIS SOCIETY.—At Birmingham Chest Clinic, Professor R. S. Pilcher: Bronchiectasis in Children.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Roads.—On November 13, 1953, at Shrewsbury, Salop, to Eve (formerly Daniel), wife of Peter Roads, M.D., a daughter—Gillian Mary.

Rugg-Gunn.—On November 20, 1953, to Patricia, wife of Surgeon Commander M. A. Rugg-Gunn, M.D., M.R.C.P., R.N., a son.

DEATHS

Barlet.—On November 4, 1953, at the French Hospital, London, W.C.1, Jehan Meredith Barlet, M.D., of Putney, London, S.W.

Blunt.—On November 10, 1953, at his home, Tyrrel Road, Chandler's Ford, Hants, Thomas Edward Blunt, M.R.C.S., L.R.C.P., Surgeon Captain, R.N., retired.

Cook.—On November 10, 1953, at Malvern Mill, Blockley, Glos, Robert Haldane Cook, M.D., aged 87.

Graham.—On November 6, 1953, Charles Lester Graham, M.B., Ch.B., J.P., of Netherby House, Wigan, Lancs, aged 67.

Henry.—On September 11, 1953, in Barbados, British West Indies, Arthur Martin Henry, M.R.C.S., L.R.C.P., L.D.S., Surgeon Lieutenant-Commander, R.N., retired, late of Chelmsford and Burnham-on-Crouch, Essex.

Luce.—On October 26, 1953, at her home, Milford, Surrey, Ina Marion Luce (formerly Clarke), F.R.C.S.I.

Shepherd.—On October 19, 1953, at his home, 27, Sea Lane, Goring-by-Sea, Sussex, Douglas Robert Chaplin Shepherd, M.B., B.S., M.R.C.P.

Stansfeld.—On October 24, 1953, at Brocklesbury, East Preston, Sussex, Dorothy Gales Stansfeld (formerly Parsons), L.M.S.S.A.

Sykes.—On October 30, 1953, at Glenbank, Kinross, Inverness-shire, Stanley Parkinson Sykes, M.B., Ch.B., Lieutenant-Colonel, R.A.M.C., retired, aged 67.

Watson.—On November 6, 1953, at his home, The Elms, Church Street, Wellingborough, Northants, Andrew Watson, M.B., F.R.C.S.Ed.

six weeks of pregnancy, otherwise the paste may escape past the small ovum and enter the Fallopian tubes and peritoneal cavity. The above instructions are based on those issued by manufacturers of these pastes.

The advantages of this method of inducing abortion are simplicity in technique and avoidance of anaesthesia. Although the method is often successful, reports indicate that the process of expulsion of the ovum is sometimes protracted for as long as five or six days, and operative interference to complete the abortion is required in 10 to 20% of cases. It is claimed that this method avoids such risks as rupture of the uterus and laceration of the cervix which attend other procedures. Nevertheless, such risks are not excluded, and cases of perforation of the uterus by the cannula are recorded. In early pregnancy at least, the paste may pass through the tubes and give rise to pain and collapse, and even peritonitis. At any time during pregnancy there is a real risk of endometritis and salpingitis, as well as extensive necrosis of the uterine wall. The paste can penetrate the myometrium, and can enter the chorio-decidual space and the blood stream to produce severe and sometimes fatal haemolysis. Fatal embolism, septicaemia, and kidney and liver lesions are all recorded, while non-fatal sequelae include chronic pelvic infection and sterility. Even when major complications are avoided, the bleeding following the abortion tends to be unusually heavy and prolonged.

Cases illustrating all these types of ill effects are described by R. W. Weilerstein,¹ who also gives many references in the Continental medical literature, all of which indicate the dangers of abortifacient pastes. By 1932 there were already reports of at least 25 fatalities in the German literature alone. In 1932 the American Medical Association published a report² calling the attention of the medical profession to the dangers of this method of inducing abortion, and the same journal has since given repeated warnings in its editorials.

It is only in recent years that the use of abortifacient pastes has received much attention in Britain, but they now appear to be obtaining adherents who are naturally attracted by the simplicity of the method and do not always appreciate the risks. These pastes are neither as safe nor as efficient as is often stated, but it has to be remembered that the same can be said of nearly all methods for inducing abortion. It is a matter of choosing the method which is least dangerous for any particular patient.

Sewage on the Garden

Q.—At a large military establishment near here the raw sewage is passed through "digesting" tanks, where it remains for 12 days. It is then dried for periods of one to six months, depending on the weather. After this treatment it is used for garden manure. What is the risk of amoebiasis or other intestinal disease as a result of contamination of fruit or vegetables?

A.—There is little risk of infection from this source. Amoebic cysts survive for only three to four weeks in water, and the higher the bacterial content of the water the shorter the life of the cyst. The practice outlined in the question is fairly uniform throughout the country, and no ill results are reported.

Cleft Palate

Q.—Does a cleft palate ever close spontaneously, or is an operation always indicated?

A.—A cleft palate never closes spontaneously; an operation is always indicated.

Curare and Peptic Ulcer

Q.—Is curare of any use in the treatment of peptic ulcer?

A.—I doubt if there is any scope for this drug in the management of peptic ulcer.

Suppositories for Hypnotics

Q.—In Switzerland it is not unusual to give hypnotics as suppositories. The idea is to prevent the cases of over-dosage which sometimes occur when hypnotics are taken by mouth. May I know your expert's opinion of this practice, and also a suitable prescription for giving a hypnotic in this way?

A.—The rectal administration of drugs is more popular on the Continent than in Britain. Except in certain special cases there is no particular advantage in administering drugs in this way. Anyone intent on taking an over-dose of barbiturates could swallow the suppositories and so produce the lethal effect. Thus the safeguard of rectal administration in this respect is slight, though perhaps there is less likelihood of suppositories being swallowed inadvertently than pills. Further, barbiturates can on occasion produce a very irritant effect on the rectum, and their rate of absorption is much more variable when administered in this unaesthetic way. Quinalbarbitone sodium ("seconal") is made up in suppositories containing 0.13 g., while the slightly longer-acting sodium amylobarbitone ("sodium amytal") is available in suppositories of 0.2 g.

Ergot Preparations and Migraine

Q.—Are any ill effects likely to follow the prolonged and frequent use of dihydroergotamine for migraine? A woman in her early forties is getting increasingly frequent attacks of migraine, and this drug affords the most certain relief of any remedies tried. Can dihydroergotamine be used prophylactically?

A.—Toxic effects from the use of ergotamine tartrate in the treatment of migraine are very uncommon, but occasional cases of ischaemic neuritis, gangrene of a finger, and exacerbation of anginal symptoms have been reported.¹ Dihydroergotamine is generally considered to be less toxic than ergotamine tartrate, and toxic effects from its repeated administration in migraine must be extremely rare. Dihydroergotamine may be used prophylactically, but the results are capricious, and its major value is when given at the first warning of an attack.

Pendulous Breasts

Q.—What is the best way of dealing with breasts that have become unduly pendulous after breast-feeding?

A.—The most useful treatment is to ensure that the breasts are always kept well supported by a suitable brassière. Time alone will then probably improve matters. Exercise of the pectoral muscles—by breast-stroke swimming, for example—is sometimes advised, but is of doubtful value.

"Any Questions?" Book.—The second book of selected "Any Questions?" is available, price 7s. 6d. (postage 6d.). Copies may be obtained either direct from the Publishing Manager, B.M.A. House, Tavistock Square, London, W.C.1, or from booksellers.

AN EPIDEMIOLOGICAL STUDY OF RHEUMATOID ARTHRITIS ASSOCIATED WITH CHARACTERISTIC CHEST X-RAY APPEARANCES IN COAL-WORKERS

BY

W. E. MIAL, M.B., B.S.

Member of the Scientific Staff, Medical Research Council, Pneumoconiosis Research Unit, Llandough Hospital, Cardiff

IN CO-OPERATION WITH

ANTHONY CAPLAN, M.D., M.R.C.P.

Member of the Pneumoconiosis Medical Panel, Cardiff

A. L. COCHRANE, M.B., B.Ch., D.P.H.,

G. S. KILPATRICK, M.B., M.R.C.P.Ed.

AND

P. D. OLDHAM, M.A.

Members of the Scientific Staff, Medical Research Council, Pneumoconiosis Research Unit

[WITH SPECIAL PLATE]

A new syndrome has been described in coal-workers (Caplan, 1953) in which rheumatoid arthritis is associated with nodular fibrosis of the lung which is radiologically similar to, but distinguishable from, the massive fibrosis appearing in complicated pneumoconiosis. A syndrome which describes an association between two pathological conditions affecting different parts of the body is usually founded on a clinical impression but is rarely studied by epidemiological methods. Such methods may determine whether the association is more than a chance occurrence of the two conditions in the same subject. This paper describes an epidemiological study of rheumatoid arthritis in a community of coal-miners in South Wales to investigate this new syndrome.

Characteristic Chest X-ray Appearances

The radiological features of progressive massive fibrosis (P.M.F.) in coal-workers' pneumoconiosis have been fully described (Fletcher *et al.*, 1949). At the beginning, ill-defined opacities develop upon a background of category 2 or 3 simple pneumoconiosis; these gradually enlarge over a period of several years to produce irregular shadows which usually become more clearly defined; ultimately the masses may occupy most of a lobe and may be associated with distortion of surrounding structures and accompanied by emphysema. An example of the early stages of the development of such a shadow is shown in Fig. 1 (see Special Plate), and a typical example of advanced massive fibrosis is shown in Fig. 2.

The type of chest lesions associated with rheumatoid arthritis in miners is strikingly different in some respects. There is a much more rapid development of numerous discrete rounded opacities scattered diffusely throughout

both lung fields. These lesions seem to appear in crops, the lesions in each crop being similar in size and rate of development. Over a period of a few months they attain a diameter of 1-2 cm., occasionally as large as 5 cm., and thereafter as a general rule they change relatively little over a period of years; they may gradually enlarge, and cavitation may occur in them; occasionally they contract to form stellate scars or they may calcify. Characteristically these lesions develop upon a background of less simple pneumoconiosis than does typical P.M.F.: whereas P.M.F. rarely, if ever, starts when there is less than category 2 simple pneumoconiosis, these "rheumatoid" lesions are often seen with a background of only category 1. Fig. 3 illustrates a typical example of the "rheumatoid" type of chest x-ray picture in a coal-miner aged 40 with a history of rheumatoid arthritis for the past eleven years. The x-ray appearances described above have been noted only in men exposed to a dust hazard and have no similarity to the interstitial pneumonitis occurring in cases of rheumatoid arthritis described by Ellman and Ball (1948).

Planning of the Investigation

The chest x-ray films used in this study were all of miners or ex-miners examined in the Rhondda Fach, a South Wales mining valley where over 95% of the mining and ex-mining population had been x-rayed (Cochrane *et al.*, 1952). In 896 cases these films had previously been classified as showing either P.M.F. (788) or clinically significant tuberculosis (108); from this group Caplan, as the first observer of the syndrome, selected all films showing the radiological appearances which he thought would be associated with rheumatoid arthritis. Twenty such films were selected. These 20 cases and a randomly selected group of 60 controls,

stratified by age and chosen from the miners whose films had been read and discarded as showing none of the characteristic appearances, were visited at their homes by a physician who was not aware of the x-ray findings. When visiting these men, a standard questionnaire was used and all joints of the arms and legs were examined in cases in which the history suggested arthritis.

To check the reproducibility of reading the chest films, all 896 films were re-read by the same observer, and to determine the inter-observer error of diagnosis of rheumatoid arthritis in field-survey work another physician visited all selected cases and any controls who had shown some evidence of rheumatoid arthritis. This small study of intra- and inter-observer error is described in the Appendix.

All men considered by either physician to have rheumatoid arthritis, and the 20 cases selected because of their characteristic chest x-ray films, were more fully investigated later. A positive diagnosis of rheumatoid arthritis was made only when at least two of the following criteria were satisfied: (1) A typical history of symmetrical polyarthritis with or without residual deformity; (2) characteristic changes of rheumatoid arthritis in the x-ray films of hands or feet; and (3) a positive differential agglutination test for rheumatoid arthritis (Rose *et al.*, 1948).

In this investigation we were particularly keen to miss no cases of rheumatoid arthritis, and as a consequence several of the men considered to be doubtfully positive when seen at their homes when investigated further either failed to fulfil the criteria or were proved to be suffering from some other arthritic condition.

Results

Prevalence of Rheumatoid Arthritis

The proportion of cases of rheumatoid arthritis found among the control group of cases of P.M.F. or tuberculosis (3%) was greater than that reported in the normal population. In the Sickness Survey (Stocks, 1949) a prevalence of 0.419% among all males and females over the age of 16 was found, and in a recent investigation of rheumatism in coal-miners in Lancashire, Lawrence and Aitken-Swan (1952) reported less than 1% of cases in the same age groups, suggesting that the prevalence of this disease among miners is no higher than in the general population, but it should be noted that massive fibrosis itself is probably less common in Lancashire than in South Wales (unpublished data, Pneumoconiosis Research Unit).

As a higher prevalence of rheumatoid arthritis was found among cases of massive fibrosis than had been expected, it was clearly necessary to determine its prevalence in miners with and without simple pneumoconiosis, and two further groups were selected in the same way as the group with P.M.F. Several doubtfully positive cases in these other x-ray groups were also fully investigated, but with negative results. Table I shows the prevalence of rheumatoid arthritis in the four x-ray groups visited.

The prevalence is very much higher in the group with characteristic chest x-ray films than in any of the other three groups. Indeed, in these cases the diagnosis of rheumatoid arthritis could have been made from the chest x-ray films alone with more than a 50% chance of being correct. The prevalence of this type of arthritis also seems to be greater in cases of P.M.F. than in miners with simple pneumoconiosis or with chest x-ray films which show no signs of pneumoconiosis.

Table II is a summary of the clinical and x-ray findings of the 20 cases with characteristic x-ray appearances and of the two cases in the P.M.F. group, and shows those who were proved to be suffering from rheumatoid arthritis. It was found that there was no close correlation between the more

typical "rheumatoid" chest x-ray film and the activity, severity, and time of onset of arthritis, or between the chest x-ray films and the radiological evidence of rheumatoid arthritis in the hands and feet. The analysis by age, dust exposure, and somatotype does, however, reveal some points of interest.

TABLE I.—Prevalence of Rheumatoid Arthritis Among Miners and Ex-miners, Analysed by Chest X-ray Appearances

Clinical Findings	Chest X-ray Groups			
	Characteristic "Rheumatoid" Lesions	Progressive Massive Fibrosis or Clinically Significant Tuberculosis	Simple Pneumoconiosis	Normal
	No. (%)	No. (%)	No. (%)	No. (%)
Proved rheumatoid arthritis	11 (55%)	2 (3%)	—	—
No rheumatoid arthritis	9 (45%)	57 (97%)	92	112
Total	20 (100%)	59* (100%)	92	112

The difference between those with characteristic rheumatoid chest x-ray films and the control group of P.M.F. is highly significant. The difference in incidence between the P.M.F. group and the simple pneumoconiosis and normal group is exactly at the 5% level of significance. * One patient in this group had died in the interval between the x-ray survey and this investigation.

(a) Age.—The mean age of men with typical "rheumatoid" chest x-ray films and with arthritis was 48.9 years, compared with 41.5 years for those with similar chest films but without arthritis. This difference is not statistically significant ($0.10 < P < 0.20$). The "rheumatoid" lung lesions may precede the onset of arthritis by several years, as is discussed later, and it is possible that a number of men with typical x-ray films and without arthritis may develop it at a later date. The average age of onset of arthritic symptoms among the proved cases was 41.7 years.

(b) Total Dust Exposure.—The total duration of dust exposure has a mean of 22.6 years in the proved cases, as opposed to 16.3 years in those without arthritis. This difference is statistically significant ($0.01 < P < 0.02$). Age and total length of exposure to dust are of course correlated, and by making allowance for this fact it should be possible to throw some light on which is more closely related to the arthritis. The mean age of the proved rheumatoid arthritis cases can be compared with that of those without arthritis when the length of dust exposure has been allowed for, and, similarly, the duration of dust exposure standardized for age can be compared in the two groups. When this is done there is no significant difference between the two groups either in age ($0.60 < P < 0.70$) or in dust exposure ($0.10 < P < 0.20$), but whereas length of dust exposure, which previously was significant, now becomes just less than significant, all suggestion of a difference in age has vanished. Thus the dust exposure might be a factor differentiating the two groups, and age probably only so far as it is related to dust exposure. This difference, however, is not established with any degree of confidence.

(c) Stone Dust Exposure.—When analysed according to years of exposure to stone dust some interesting results are forthcoming. Taking the group with characteristic "rheumatoid" x-ray films and the control group of P.M.F. cases, we find there is no statistically significant difference between their exposure to stone dust, though it is possible that such a difference is present but not revealed in these relatively small groups. In the group with typical "rheumatoid" x-ray films, however, there are nine men who have had exposure to stone dust, and seven of these occur in the group of eleven who have proved rheumatoid arthritis. Two occur in the group without arthritis. The probability of this occurring fortuitously is 8%. Of these nine men, five have had a stone dust exposure of three years or more, and all these have rheumatoid arthritis. The probability of this occurring fortuitously is only 3%. The significance, if any, of this curious finding will be determined only when further cases of this syndrome are investigated. It is of interest to note that Collis and Yule (1933),

The readings of the x-ray films of the hands and feet are scored as follows: 0 = normal or doubtful changes of rheumatoid arthritis; 1 = minimal changes of rheumatoid arthritis; 2 = moderate changes of rheumatoid arthritis; 3 = marked changes of rheumatoid arthritis. N.R. = no record. * Observers A and B, see Appendix.

who analysed the Registrar-General's Decennial Supplement for 1921-3, found a remarkably increased mortality from a wide range of diseases in men exposed to a silica risk. This included a fourfold increase in the mortality rate from chronic rheumatic conditions.

(d) Somatotype.—It is often said that rheumatoid arthritis affects people of asthenic build. In this series anthropometric measurements were made, using the body index suggested by Rees and Eysenck (1945), which is

$$100 \times \text{stature in cm.}$$

$$6 \times \text{mean chest diameter in cm.}$$

Analysis shows that the group with typical "rheumatoid" chest x-ray films but without arthritis are similar in body build to the control cases with P.M.F., but those with arthritis have a higher mean "body index"—that is, they are of a more asthenic type. This difference may be a sampling effect, but if it is justifiable to assume that all the cases with typical "rheumatoid" chest films have some factor predisposing to the development of arthritis (see under Discussion) then this predisposing factor is not related to somatotype, and the difference in body build is probably secondary to the rheumatoid arthritis.

Clinical Investigations

Clinical examination, the x-ray appearances of peripheral joints, the erythrocyte sedimentation rate, and the differential agglutination test all indicated that the type of arthritis seen in these miners differs in no way from rheumatoid arthritis in other people. Of the 12 men who gave histories suggestive of rheumatoid arthritis, positive differential agglutination tests were obtained in eight. No positive result was obtained in any case without a history of polyarthritis. These findings agree with those found in other series of rheumatoid arthritis in males, and would not be expected in other arthritic conditions, with the possible exception of disseminated lupus erythematosus (Ball, 1952).

The Middlebrook-Dubos agglutination test was also carried out. This test, which is based on the agglutination by tuberculous patients' serum of sheep's red cells sensitized to tuberculin, seems to be of limited value except in research into the pathogenesis of tuberculosis, the false positives and false negatives being so numerous that the significance of the result in any individual case cannot be determined. In this series we found 8 positive results (agglutination to a titre of 1:8) in 18 sera tested (44%). In a series of 133 cases of early progressive massive fibrosis, agglutination to a titre of 1:8 occurred in only four cases (3%). This suggests that the lesions in the lungs are a form of tuberculosis, and there is other evidence which supports this, but both the Middlebrook-Dubos and the Rose agglutination test are based on the agglutination of sensitized sheep's cells by human serum, and may be interrelated.

Sputa or laryngeal swabs were cultured for tubercle bacilli in all cases, but there was only one positive (No. 8), and in his case morphologically atypical tubercle bacilli were isolated, which, however, produced tuberculosis on guinea-pig inoculation.

One man of 72 years (Case 1) has died since this investigation was made. His arthritis dated from 1926 and caused him to leave coal-mining in 1928 after having worked 25 years underground, chiefly as a collier. The significant clinical findings are shown in Table II, and x-ray films of his chest and hands are shown in Figs. 4 and 5. A summary of the post-mortem examination conducted by Dr. D. Rivers is given below.

Post-mortem Findings in Case 1

External Appearances.—The body was that of a well-nourished elderly male with numerous coal-pigmented scars present on the hands and forearms and pitting oedema of the lower limbs. Characteristic periarticular swellings and gross deformities of rheumatoid arthritis were present in the elbows, wrists, knees, and ankles. There was subluxation and severe ulnar deviation at all metacarpo-phalangeal joints

of the left hand, with spindling of the proximal interphalangeal joints; the right hand showed much less deformity, but changes typical of severe rheumatoid arthritis. The small toes of both feet had been amputated and there was pronounced lateral deviation of both large toes. No rheumatoid nodules were present.

Internal Appearances.—Pleural adhesions were present in both sides of the chest. Both lungs were enlarged and there was some bullous emphysema at the apices and along the free margins. The cut surface of the right lung showed a group of circumscribed fibrous nodules in the apex of the upper lobe, some of which were joined by narrow bands of black fibrous tissue. These fibrous lesions were 1-2 cm. in diameter, were almost entirely black in colour, but had a whorled appearance formed by thin concentric laminae of yellowish-white fibrous tissue. A number of similar lesions were scattered throughout the rest of the lung, and in addition there were numerous small dust-pigmented fibrous nodules varying from 1 to 2 mm. in diameter. Most of both the larger and the smaller lesions showed central softening and necrosis, but there was no definite caseation or other evidence of tuberculosis. The left lung showed essentially similar appearances, and in the lower part of the upper lobe there was also a large mass of black dust-pigmented fibrosis measuring 5 cm. across its greatest diameter. Central softening and necrosis were present in this mass, but again there was no definite evidence of tuberculosis. Both lungs showed a moderate number of soft-coal-dust foci uniformly distributed throughout their parenchyma, and both were congested and oedematous. The mediastinal lymph nodes were enlarged, black, and firm. There was some cardiac enlargement with right ventricular hypertrophy and atheroma in the main pulmonary arteries and their smaller branches. The liver, spleen, and kidneys were very congested. All other organs appeared normal.

Microscopical Appearances.—The histological features of the predominant type of lung nodule were essentially similar. Each had a large amorphous eosinophilic centre with numerous cholesterol clefts, and in some of them patchy calcification was present. This zone was surrounded by dense collagenous fibrosis, the inner layers of which were hyalinized, and the ghost structure of collagen could be identified towards the periphery of the central zone. In some lesions this central zone consisted of completely hyalinized collagen. A large amount of coal dust was distributed between the fibres of collagen and throughout the centres of the lesions.

Sections of the large mass in the left lung showed it to consist of largely hyalinized dense collagen containing areas of eosinophilic necrosis and cholesterol clefts and heavily impregnated with coal dust. No definite histological evidence of tuberculosis was identified in sections of the nodules or the mass, and no acid-fast bacilli could be found in Ziehl-Neelsen preparations.

Comment.—The cause of death was considered to be congestive cardiac failure due to coal-workers' pneumoconiosis. Though the macroscopical and microscopical appearances of the individual lung lesions are often seen in cases of P.M.F., and the rounded nodules are similar to those described by Gough (1947) as infective nodules, it is unusual to find them so large, so sharply circumscribed, or so numerous and widely distributed as in this case. The pathological evidence supports the contention that the lesions are unlikely to differ in aetiology from that of P.M.F., but material from a case in the active phase is essential to establish this more firmly. It is probable that the lesions described here were active about the time of onset of this man's arthritis 27 years ago, and the appearances are now those of a completely healed infection.

Discussion

This investigation has confirmed the observation that a particular type of radiological appearance in the chest x-ray films of coal-miners is closely associated with the presence of rheumatoid arthritis.

P.M.F. in coal-workers is generally regarded as tuberculosis modified by the presence of coal dust (Gough, 1947; Fletcher, 1948). How do these typical "rheumatoid" lung lesions differ from ordinary P.M.F.? The pathology of this syndrome has been studied at necropsy in only one radiologically characteristic case, but necropsies have recently been performed on seven cases of rheumatoid arthritis in coal-workers with chest films similar to, but less typical than, those described in this series, and evidence of active tuberculosis was found in five of them. The only two men with "rheumatoid" lung lesions who have had a positive sputum culture in life were noted to have morphologically atypical bacilli which, however, produced tuberculosis in guinea-pigs on inoculation.

In spite of the two types of lung lesions tending to merge into one another, we can say in general of the "rheumatoid" lesions that from the radiological point of view there is comparatively little simple pneumoconiosis relative to the time of appearance of the lesions; from the industrial point of view exposure to stone-dust inhalation seems important; from the bacteriological point of view the tubercle bacilli may be abnormal; and from the pathological point of view the lesions are individually similar to the infective nodules commonly found in the neighbourhood of the fibrotic masses of P.M.F. but are larger, more numerous, more discrete, and more widespread than are usually seen in complicated pneumoconiosis.

We have reported here only the results of an investigation in one mining valley, but a number of other cases of this syndrome have been studied. One most interesting finding concerns the time relationship between the development of rheumatoid arthritis and the development of the characteristic "rheumatoid" chest x-ray appearances. It seems likely that in most cases the onset of arthritic symptoms coincides with the development of the lung lesions. In some cases, however, the characteristic x-ray appearances may precede the arthritis by several years, and one case has been found of a miner who developed rheumatoid arthritis six years before his first chest x-ray film was taken; this showed simple pneumoconiosis. The next film, taken five years later, showed the typical "rheumatoid" appearances.

It has been shown that there is probably an increased prevalence of rheumatoid arthritis among cases of P.M.F. On the evidence available it is not possible to state whether the P.M.F. predisposes to rheumatoid arthritis, or whether rheumatoid arthritis predisposes to P.M.F., or whether the factors predisposing to rheumatoid arthritis also predispose to P.M.F. This problem can only be investigated epidemiologically by determining the attack rates of rheumatoid arthritis in men with and without massive fibrosis. It is nevertheless of interest to seek an explanation of the association of rheumatoid arthritis with these characteristic "rheumatoid" lung lesions, and there are at least three possible explanations of this association.

The simplest hypothesis is that the changes in the lung are merely one manifestation of the rheumatoid syndrome and are unrelated to typical P.M.F. Kellgren (1952) has suggested that the inflammatory lesion in the connective tissues in rheumatoid arthritis may be due to collagen breakdown, and it is possible that such changes in the lungs would be made more radio-opaque by the migration of dust-laden phagocytes to these areas of inflammation. This hypothesis is possible, but it is improbable for the following reasons: (a) Such lesions, even if less obvious, would have been seen at necropsy in non-miners. (b) There is some clinical and post-mortem evidence that the lesions are tuberculous. (c) Similar radiological findings have never been reported in association with rheumatoid arthritis. No similar cases were found among non-miners in the Rhondda Fach scheme, where almost 90% of the adult population of 20,000 people were x-rayed (Cochrane *et al.*, 1952).

Discarding the first hypothesis, then, the second explanation of the association is that the pathological changes reflected in the x-ray film may play the part of a chronic septic focus, one of the many other postulated factors in the

aetiology of rheumatoid arthritis. Against this hypothesis we have the fact that in one case the arthritis preceded the development of typical "rheumatoid" lung lesions by more than six years, and in other cases there may be a latent period of as much as 11 years between the development of the typical lung lesions and the onset of arthritis.

It is possible, therefore, that neither of these hypotheses is correct and that there is some other factor which is causally related to both the arthritis and this type of "rheumatoid" lung lesion—for example, a more fundamental generalized abnormality of tissue reaction to dust and infection.

As these "rheumatoid" lung lesions in miners can develop several years before, concurrently with, or several years after the onset of arthritis, the suggestion is that there may be a particular type of tissue reaction to dust and tuberculosis in the lungs of miners who are predisposed to the development of rheumatoid arthritis. Recent work on adrenal cortical hormones and their relationship to rheumatoid arthritis and to tissue reaction suggests that this may be part of the explanation.

A.C.T.H. and cortisone are known to diminish the inflammatory response to trauma and chemical irritants (Shapiro *et al.*, 1951), to diminish the tuberculin reaction (Long and Miles, 1950; Long *et al.*, 1951; Pickering, 1952), and to inhibit the migration of dust cells in animals receiving intratracheal injection of powdered quartz (Harrison *et al.*, 1952). The formation of silicotic granulomata after intraperitoneal injection of powdered quartz is inhibited or diminished by cortisone in some experimental animals (Magarey and Gough, 1952; Schiller, 1953). These are the effects of excess A.C.T.H. and cortisone. Methods of assaying the levels of circulating A.C.T.H. and cortisone are not yet sufficiently developed to indicate whether these hormones are diminished in cases of rheumatoid arthritis; but Venning, Johnson, and Rose (1951) demonstrated a lowered excretion of certain groups of adrenal steroids in cases of rheumatoid arthritis, and Pearce (1950) found pituitary changes in patients dying with active rheumatoid arthritis, which he considered secondary to adrenal dysfunction. It is possible that rheumatoid arthritis may be related to adrenal or pituitary function, but, as Pickering (1952) points out, there is apparently no increased prevalence of this condition in cases of Addison's disease and Simmonds's disease, and it is therefore unlikely that it is simply due to a pituitary or adrenal defect; but such a defect may contribute to its aetiology, and, similarly, may contribute to the type of tissue reaction causing these "rheumatoid" lung lesions.

Summary

An epidemiological investigation of a syndrome in which rheumatoid arthritis is associated with characteristic chest x-ray appearances in coal-workers is described.

The widespread nodular fibrosis shown in these x-ray films is radiologically distinguishable from typical progressive massive fibrosis, but the available evidence suggests that the aetiology of both types of lesion is similar.

The prevalence of rheumatoid arthritis among cases with these characteristic chest x-ray films is over 50%; among cases of P.M.F. it was found to be 3%; whereas no cases were found in two similar groups of miners with and without simple pneumoconiosis.

The significant epidemiological, clinical, and pathological findings are given, and some possible explanations of the relationship between the "rheumatoid" lung lesions and the arthritis are discussed.

We wish to acknowledge our indebtedness to our colleagues in the Pneumoconiosis Research Unit for much helpful criticism and advice, and particularly to Dr. J. C. Gilson, the director; to Dr. C. M. Fletcher and R. F. Mahler, until recently members of the Unit; and to Dr. D. Rivers, who supplied the report on the pathology of this syndrome. The x-ray films of the peripheral

joints were kindly read for us by Dr. J. H. Kellgren and Dr. J. Sharp, of the Manchester Rheumatism Research Centre; the differential agglutination tests were performed by Dr. J. Ball, of the same unit; and the Middlebrook-Dubos tests were carried out by Dr. Geraint James and Dr. F. O'Grady at the Middlesex Hospital. It is a pleasure to record our thanks to them, and to the miners who so willingly co-operated in this survey.

APPENDIX

(a) *Intra-observer Error in Reading Characteristic Chest X-ray Appearances.*—All 896 films were read twice by the same observer. On the first occasion 20 films were selected as showing these typical appearances and divided into four groups—A, B, C, and D—group A being the most typical, group D the least typical. On the second occasion 27 films were selected, and divided in three groups only—A+B, C, and D. On the second reading, 16 of the 20 original films were reselected; only one of the four cases not reselected on this occasion was a proved case of rheumatoid arthritis, but 11 new cases not previously selected were added in this group; clinically none of these was a case of rheumatoid arthritis, but none was fully investigated in hospital. Of the 16 selected on each occasion, 13 were allotted to the same subgroups as previously. These results are shown in Table III.

TABLE III.—*Intra-observer Error in Reading "Rheumatoid" Chest X-ray Films in Miners*

First Reading	"Rheumatoid" Chest X-ray Appearances	Second Reading			
		A and B	C	D	Total
A and B	6	6	1	—	6
C	1	1	1	—	2
D	—	—	—	2	2
Not selected on first reading	—	—	4†	7†	11
Total	7	7	6	9	22

Cases selected on first reading were all fully investigated.
* One of these cases had proved rheumatoid arthritis, the other three not.
† These 11 cases selected on second reading but not selected on first reading all had no clinical evidence of rheumatoid arthritis, but were not fully investigated in hospital.

(b) *Intra-observer Error in Clinical Diagnosis of Rheumatoid Arthritis under Field-survey Conditions.*—Two observers visited cases at an interval of about three months. In this study 20 men with characteristic x-ray films but thought by Observer A to be possible cases of rheumatoid arthritis were visited by both doctors. Table IV shows the result of this investigation. It will be seen that both observers agreed on the clinical grading of 20 of the 25 men, but both thought two were cases of

TABLE IV.—*Inter-observer Error in the Clinical Diagnosis of Rheumatoid Arthritis in the Field*

Observer A	Clinical Grade	Observer B			
		Certain	Probable	Possible	Total
Certain	7 (7)	7 (7)	—	—	7 (7)
Probable	1 (1)	—	3 (1)	—	4 (2)

Negative	—	—	—	—	—
Total	8 (8)	7 (7)	3 (1)	1 (1)	11 (9)

The numbers in parentheses indicate proved cases of rheumatoid arthritis.
Certain = Typical history + marked residual signs.
Probable = Typical history + minimal residual signs.
Possible = Typical history + no residual signs.

rheumatoid arthritis when this diagnosis was not substantiated, and both thought one case normal when in fact he was suffering from rheumatoid arthritis. Observer A saw 16 cases he thought positive, of which 12 were later proved cases, and 9 he thought negative, of which 1 was later a proved case. Observer B saw 12 cases he thought positive, of which 10 proved to be so, and 13 cases he thought negative, of which 3 were later proved cases. Such disagreement as occurred

is partly explicable by the desire to find very early cases of a disease in which the earliest symptoms and signs are not usually clearly defined.

(c) *Inter-observer Error in Reading Characteristic X-ray Changes of Rheumatoid Arthritis in the Hands and Feet.*—Two observers from the Manchester Rheumatism Research Centre kindly read the films of the hands and feet of the 20 cases with typical "rheumatoid" chest x-ray films. Their readings are plotted against each other in Table V. In read-

ing the films of the hands there was agreement in 13 of the 19 cases, but in 5 cases one observer noted changes (3 of which were osteoporotic changes only) which were not noted by the other observer; in the remaining case the difference was only one of degree. In reading the films of the feet, however, there was agreement in 18 of the 19 cases. Table V also indicates that the x-ray changes in the feet seemed less likely to be present than in the hands, but when present they were more severe. In this series, four cases of proved rheumatoid arthritis had no changes in the x-ray films of the feet, whereas only one case had no changes in the x-ray films of the hands; nevertheless, among these 11 cases of rheumatoid arthritis six had moderate or marked changes in the feet, whereas only two had moderate or marked changes in the hands. Typical x-ray changes of rheumatoid arthritis were never read by either observer in this series for any case which had no other clinical evidence of arthritis; there was one case of proved arthritis which both observers agreed had no x-ray changes in the hands or feet. This study would have been improved if a normal control bone had been used when each film was taken. Many films were read as "doubtful" because osteoporosis cannot be accurately assessed without such a control.

BLOOD SUPPLY OF THE FEMORAL HEAD

BY

MICHAEL HARTY, M.Ch., F.R.C.S.

University Lecturer in Anatomy, University of Cambridge

[WITH SPECIAL PLATE]

Towards the close of the eighteenth century William Hunter had raised London to the position of one of the best anatomy schools in Europe. He visited Albinus, the celebrated Dutch anatomist, in 1748, and admired his injected anatomical specimens. On returning to London, Hunter developed and elaborated this technique, and many of his original examples are preserved in the Hunterian Museum at the University of Glasgow. This collection contains a number of illustrations of the circulus articuli vasculosus, which Hunter had described originally in 1743.

Materials and Methods

The injected specimens used in this investigation were removed from recent post-mortem bodies or from the anatomical dissecting-rooms. They were dehydrated and cleared in oil of wintergreen (methyl salicylate). Red lead and starch were employed for the intra-arterial injections in Figs. 1 and 2 and indian ink was used for Figs. 6 and 7.

Circulus Articuli Vasculosus.—Since Hunter's original description, this vascular articular anastomosis has been given various anatomical situations. In his account Hunter states, "All round the neck of the bone there is a great number of Arteries and Veins, which ramify into smaller Branches and communicate with one another by frequent Anastomoses like those of the mesentery." These vessels he placed by the margins of the articular cartilages in the subsynovial tissues (Figs. 1 and 2). Some more recent accounts put the circulus articuli vasculosus at the attachment of the joint capsule to the bone. This attachment may coincide approximately with the margin of the articular cartilage in those diarthrodial joints which permit little movements, such as the joints between the intervertebral articular facets. In the adult femoral neck, however, the regions are separated by from 2 to 5 cm. The head of the femur derives its main blood supply from the subcapital anastomosis, as the contribution via the ligamentum teres is, at any age, limited to a small medial segment of the head of the femur. Davies (1946), when discussing the dynamics of haemarthrosis, emphasized the richness and superficial position of the capillary fringe in the synovial membrane.

Retinacula.—The arterial circle at the base of the femoral head is supplied by arteries situated on the neck of the femur between the synovial membrane and periosteum. The vessels are concentrated postero-inferiorly, superiorly, and occasionally anteriorly. The synovial membrane covering these vascular bundles is thrown into longitudinal ridges, to which the term "retinacula" was first applied by Weitbrecht, of St. Petersburg, in 1742. The postero-inferior retinaculum is a very definite structure in the human femur, and shows as a duplication of synovial membrane measuring 1 cm. or more in 76% of specimens examined (Figs. 2, 3, and 4). This pleat of synovial membrane always contains medium-sized arteries, situated at the attachment to the periosteum of the neck or anywhere along the pedunculated area (Figs. 2, 4, and 5).

The Pericapsular Anastomosis.—The afferent arteries to the retinacular vessels are derived from another anastomosis on the capsular attachment towards the base of the neck. This pericapsular corona, which is part of the trochanteric anastomosis, gets its blood supply from the ascending branches of the medial femoral circumflex, the superior gluteal, the obturator, and profunda femoris arteries, as well as from small communications from the acetabular margin

BIBLIOGRAPHY

vessels. Arteries leaving this pericapsular anastomosis enter numerous bony foramina at the base of the femoral neck and pierce small openings in the attachment of the joint capsule. All these arteries are accompanied by a rich plexus of veins, which play an important part in the intravascular thrombosis associated with avascular necrosis of the femoral head.

Ontogeny

During the growth period the circulus articuli vasculosus is situated on the periphery of the epiphysal plate of cartilage and sends branches deeply to the bony epiphysis as well as recurrent vessels to the actively growing metaphysal region (Fig. 6). The marked vascularity of this juxta-epiphysal area, compared with the adjacent diaphysal bone, is obvious in injected specimens (Fig. 7). Harris (1933) pointed out that these metaphysal vessels terminate in large tortuous loops as end-arteries—in contrast to the epiphysal vessels, which anastomose freely. The retinacula in the growing child are well developed, but they are shorter and more firmly attached to the periosteum of the neck than in the adult hip-joint.

Freshly injected specimens demonstrate that the greatest concentration of intra-osseous blood vessels is in the region of Babcock's triangle. This triangle appears in antero-posterior skiagrams as an area sparse in trabecular bone situated inferiorly to the femoral head. An equally obvious triangle, often obscured by the acetabular rim, is seen superiorly at the junction of head and neck (Fig. 8). In fact, the whole base of the head is surrounded by this triangular tunnel, which is utilized by blood vessels to supply and drain the head of the femur. The afferent arteries to this vascular circle can be seen entering the subcapital bony foramina (Fig. 2).

Conclusions

The head and neck of the femur derive their significant blood supply from the pericapsular anastomosis at the base of the neck. The vessels which pierce the capsular attachment are subject to severe trauma and compression in dislocations of the hip-joint and in basal fractures of the femoral neck. These factors, together with pressure from local haemorrhage, jeopardize the vascular channels of the head of the bone.

Basal fractures of the neck of the femur in childhood are frequently complicated by avascular necrosis of the head. The more firm attachment of the synovial membrane to the periosteum of the neck is suggested as an aetiological component for this complication. While the epiphysal plate of cartilage is present the head of the femur depends on the retinacular vessels for its nutrition, as the consensus of reliable opinion is that the vessels in the ligamentum teres are immaterial for the vitality of the head.

Babcock's triangle is a common site for the early manifestations of bony tuberculosis of the hip-joint in children. This very vascular growing region, which is subject to repeated minor traumata and has a slow rate of blood flow, offers a well-protected culture bed for any circulating tubercle bacilli.

In transvesical adduction fractures of the femoral neck the superior and anterior retinacular vessels are always torn, whereas the vessels in the pedunculated postero-inferior retinaculum often escape actual rupture in their continuity but are badly distorted. This alteration of alignment and lumen, which slows or obstructs the local circulation and may lead to eventual thrombosis and avascular necrosis, is a strong argument in favour of early and gentle reduction of this fracture as advocated by recent writers.

I am grateful to Professor J. D. Boyd for departmental facilities, to Dr. A. M. Barrett for the post-mortem material, to Mr. J. A. Fairfax Fozzard for the photography, and to Mr. R. Smith for technical assistance.

HYPOTHERMIA WITH AUTONOMIC BLOCK IN MAN

BY

JOHN W. DUNDEE, M.D., F.F.A.R.C.S.

T. CECIL GRAY, M.D., F.F.A.R.C.S.

(From the Department of Anaesthesia, University of Liverpool)

P. R. MESHAM, M.B., Ch.B., D.A.

AND

W. E. B. SCOTT, M.B., B.Ch., D.A.

(From the Royal Southern Hospital, United Liverpool Hospitals)

The reduction of oxygen consumption that accompanies a fall in body temperature and the possibilities that induced hypothermia opens up in the field of cardiac surgery and for the poor-risk patient have been the topics of numerous recent publications (Bigelow, Callaghan, and Hopps, 1950; Bigelow, Lindsay, Harrison, Gordon, and Greenwood, 1950; Churchill-Davidson *et al.*, 1953; Annotation, *Brit. J. Anaesth.*, 1953; *Lancet*, 1953). So obvious are the advantages of a state of affairs wherein the cellular oxygen requirements are markedly reduced that they need not be further discussed.

In the past local hypothermia had been produced for a variety of purposes—for example, the relief of pain (Bell, 1812) and the treatment of carcinoma (Arnott, 1851)—but it was not until 1936 that Smith and Fay first induced generalized hypothermia as a treatment for neoplasms (Smith and Fay, 1939). These workers appreciated the necessity of abolishing the body's normal reactions to cold—namely, shivering and vasoconstriction—to facilitate the cooling, and for this purpose they used deep narcosis. The increase in oxygen consumption produced by shivering had already been noted by Voit in 1878, and it was not until 1916, when Krogh eliminated this reaction by curarization, that a fall in oxygen consumption could be demonstrated at lowered body temperatures (Martin, 1930).

In 1948 McQuiston pointed out the possibility of applying the principle to cardiac surgery in hypoxaemic children, and published details of 25 cases (McQuiston, 1949).

The term "artificial hibernation" was originally used by Simpson (Simpson and Herring, 1905) and later by Smith and Fay (1939) to describe the state of induced generalized hypothermia. The recent reintroduction of the term is due in the main to the French workers Laborit and Huguenard (1951). They first studied the potentiation of anaesthesia by promethazine ("phenegan") and diethazine ("diparcol") (Laborit, 1950), and postulated that these drugs produced a partial block of the autonomic nervous system, thus diminishing the body's unfavourable reactions

to surgical trauma (Goldblat, 1951). These workers believe that in certain circumstances death may result from overaction of the autonomic nervous system in an attempt to maintain constant the body's internal environment (Laborit and Huguenard, 1951). Following this reasoning, they attempt to produce a block as complete as possible of the neurovegetative system at all levels, and it is this state which they refer to as "artificial hibernation." To achieve this result the "lytic cocktail" was devised, consisting of the above-mentioned drugs, together with pethidine and chlorpromazine ("largactil"). This latter is known to be a profound depressor of autonomic activity (Courvoisier *et al.*, 1953). A mild degree of hypothermia (34–35° C.) is used to reinforce the autonomic block (Huguenard, 1953).

The technique which we describe is a combination of induced hypothermia and "artificial hibernation," wherein the lowered body temperature is obtained by surface cooling, the lytic cocktail being employed to eliminate the body's normal responses to cold. Our object differs from that of the French workers in that we are primarily concerned with obtaining a reduction in body metabolism, the autonomic block being used only to facilitate the production of hypothermia.

The studies of Kayser and Hiebel (1952) have shown how inaccurate is the term artificial hibernation as applied to man. For this reason we prefer to call the technique "induced hypothermia with autonomic block." This paper is a report of 26 cases in which this technique has been used for major surgery.

Techniques

Production of Autonomic Block and Cooling

With a few minor exceptions the technique followed was the same in all cases. Premedication consisting of pethidine, 100 mg., and promethazine was given intramuscularly three to four hours pre-operatively. An intravenous infusion of normal saline or 5% dextrose was set up about one hour later as a vehicle for administration of the lytic cocktail. The constituents of this were the same for all cases—namely, chlorpromazine 50 mg. (2 ml.), pethidine 100 mg. (2 ml.), and promethazine 50 mg. (2 ml.). Because of the irritant effect of chlorpromazine the injection was made into the drip tubing as far away from the needle as possible. The initial injection was generally 2 ml., followed by supplements of 0.5 to 1 ml. at intervals of 15 to 20 minutes. Modifications in this dosage are discussed later.

Those patients who were not asleep before the beginning of the infusion became unconscious after the first or second dose of the cocktail. With one exception this had occurred within 30 minutes of administration of the first dose. The rapidity of onset of unconsciousness and its depth were a guide to the time to begin surface cooling. On an average this was one and a half hours before operation (range one to three hours). Ice-bags were first placed on the groin, and, in the absence of a response to this, the body was completely covered with ice. Shivering was looked for closely, and its occurrence taken as an indication for a further dose of the cocktail. In all cases cooling was continued until the patient was taken to the theatre. The amount of ice used in the early cases was much less than in later ones; this was partly due to attempts to follow the French methods and partly to caution with a new technique.

During the period of preparation, observations were made of B.P., pulse, and respiration every 15 minutes. Rectal temperatures were taken with a thermocouple which had been previously checked against a mercury clinical thermometer. These were recorded together with frequent observations on the condition of the patient, as assessed by colour, degree of consciousness, presence or absence of shivering, and the drugs administered.

Anaesthesia

The principles of this did not vary from those we would have used for similar cases under normal circumstances. Abdominal and thoracic cases received a sleep dose of barbiturate (if necessary), a relaxant, and nitrous oxide and oxygen (usually 2 litres of each), respiration being controlled or aided throughout. Endotracheal intubation by the oral route was carried out in every case. Induction in non-abdominal cases was with thiopentone and suxamethonium, intubation following topical application of 2% amethocaine or lignocaine to the larynx. Maintenance was with nitrous oxide and oxygen, with or without trichlorethylene or pethidine. There was an enormous variation in dosage from that which would be expected in normal cases, and this is discussed later. Replacement of blood loss was carried out as for normal cases. During the operation observations were made as for the period of cooling.

Rewarming

No attempts were made to hasten this process. On return to bed the patients were covered with a single sheet, and the appearance of shivering was an indication for the application of further covering. It was explained to the nursing staff that for the first 12 hours or so after operation they were to consider their patients to be poikilothermic and to treat them as such, removing blankets should a hyperpyrexia occur. In addition to the routine observations of temperature, B.P., etc., details were noted of post-operative analgesics and sedatives as regards both dosage and time of administration. Note was made of when the patients responded to their name, and this was later compared with the time when they themselves thought they awakened.

Special Investigations

Oxygen uptake was determined at various times during the cooling, the operation, or the rewarming in 12 cases, all of which maintained their spontaneous respiration comparatively undepressed. This was determined by using a Benedict-Roth spirometer. Pre-operative readings were carried out before the pethidine and promethazine were given. Observations during operation were limited to those cases in which, because of the depth of unconsciousness produced by the lytic cocktail and hypothermia, it was possible to avoid the use of an inhalational anaesthetic agent. It was felt that the presence of a gas such as nitrous oxide would unduly complicate the interpretation of results. Towards the end of the series routine analysis of the urine was carried out before and for several days after operation.

Observations

Table I gives a list of operations performed and details of patients.

TABLE I.—Details of Patients and Operations

Case No.	Sex	Age	Operation	Duration Hr. Min.
1	M	24	Portocaval anastomosis	4 40

26	F	47	Total cystectomy	3 30

Respiratory System

Despite the fact that neither atropine nor hyoscine was given as premedication, no increase in secretions was noted during either cooling or operation in any case. The lytic cocktail invariably slowed the respiratory rate, but this was accompanied by a slight increase in tidal volume. At the temperatures which we reached before operation (36° to 27.4° C.) there were no instances of alarming decreases in respiratory rate, 8 to 10 a minute being the average when the patients were taken to the theatre. These changes were reversed during rewarming. Diminished sensitivity of the larynx, as might be expected from the doses of pethidine used, was very marked. Intubation was carried out in six cases at the end of the cooling, without any barbiturate, and in no instance was there a very pronounced reaction from the patient. This laryngeal insensibility was a disadvantage in one case.

Case 20.—The operation was laparotomy for intestinal obstruction. During cooling, moist sounds in the chest were heard and pulmonary oedema was diagnosed. On closer examination silent regurgitation of gastric contents was detected. Tracheal suction was carried out and the passage of an oesophageal tube revealed a full stomach.

Cardiovascular System

Average blood-pressure changes during the cooling and the operation are shown in Table II, and the suggested prin-

TABLE II.—Blood-pressure Changes During Cooling and Operation

" fall	60/30
" minimal B.P. during operation	50/30
" maximal fall	60/30

cipal factors causing the pressure falls during operation in Table III. Hypotension of varying degrees occurred during establishment of the autonomic block in every case and during most of the operations. Pressure falls following the first 2 ml. of the cocktail varied enormously from patient to patient and were unpredictable. This led us to introduce a test dose of 1 ml. in poor-risk cases, subsequent doses depending on the B.P. response to the first injection. The fall in B.P. which followed administration of the lytic cocktail had a large postural element in each case, and

FIG. 1.—B.P., pulse, and temperature changes occurring before, during, and after operation in Case 24. Postural falls in pressure occurred as follows: A=after first dose of cocktail with patient sitting up; B=removal from bed to theatre; C=when head of table was raised. A and B were treated by the head-down position and C recovered spontaneously. D=patient back in bed.

could be reduced, but not abolished, by raising the foot of the bed (Fig. 1). The rise in pressure that was noted in one case during operation was attributed to the Trendelenburg position, which was used during the whole procedure.

From Table II it can be seen that pulse pressure is affected little during the operation, even at the lowest pressures. This might be expected because of vasodilatation due to chlorpromazine. A prominent feature throughout the series

TABLE III.—Suggested Principal Factors Causing Fall of B.P. During Operation

Posture		11	Hypothermia		2
Blood loss		5	Barbiturates		1

was the extreme sensitivity of the B.P. to haemorrhage. Quite significant falls occurred after even slight loss, the pulse remaining almost unchanged. This is due to loss of compensatory mechanisms.

In the absence of shivering the pulse rate fell by 10 to 20 beats a minute during the establishment of the autonomic block and cooling. Shivering invariably raised the rate by 20 to 40 a minute. The changes were very variable during operation, but on the whole there was little variation from that produced by the cooling. The average rate during operation was 80 a minute, values ranging from 55 to 104.

Cardiac irregularities were detected in three cases during cooling. In two instances auricular extrasystoles appeared at the lower temperatures, but disappeared spontaneously during the rewarming. These irregularities were of less importance than the auricular and ventricular fibrillation occurring in the following two cases.

Case 21.—A marked fall in B.P. followed the test dose of cocktail. Cooling was easily achieved, the temperature dropping rapidly to 32° C. At this stage cardiac irregularities were detected. Following thoracotomy the temperature fell to 28° C. and the pulse was grossly irregular, remaining so throughout the operation. A post-operative E.C.G. confirmed the presence of auricular fibrillation. Recovery was slow, and 34 hours post-operatively, when the temperature had reached 32.5° C., normal sinus rhythm reappeared.

Case 17.—A woman aged 48 was admitted for mitral valvotomy. She had a grade 3+ condition of her valve and was frequently in failure. She was orthopnoeic, cyanosed, and had a greatly enlarged right ventricle with signs of basal congestion. She was considered an extremely grave risk by the physicians, but, in view of her complete invalidism and hopeless prognosis, exploration was thought to be justified. After 4 ml. of cocktail the temperature dropped to 32.5° C. Her condition was described as much improved and she had become pink in colour. Her B.P. had dropped from 110/60 to 80/50 and her pulse rate from 80 to 48. When her temperature had reached 31.8° C. ice-bags were applied, and an hour later the temperature was 30.7° C. but her B.P. suddenly became unrecordable. Her pulse rate was 60. Elevation of the foot of the bed restored the B.P. to 85 systolic. Unfortunately, there was a delay in beginning the operation owing to the previous case taking much longer than had been estimated, and her temperature was allowed to fall to 28.4° C. before she was taken to theatre. This was 4 hours 20 minutes after the initial dose of cocktail and three hours after the first application of ice. Her systolic B.P. was 95 and she had had 9 ml. of cocktail. Her pulse was satisfactory, and she was pink. On opening the chest her temperature fell nearly 3°, to 25.7° C., and her heart rate slowed to 50. The surgeon estimated her systolic pressure at 100 and her pulmonary arterial pressure at 60 mm. Hg. The heart seemed to have shrunk to less than its normal size and did not fill the pericardial sac. The ventricular beat seemed weak and rather ineffective. On dilatation of the valve ventricular fibrillation began and was arrested after five and a half minutes by application of an electrical defibrillator (110 V. in 0.1-second impulses). Normal beat was resumed, but fibrillation recurred during suture of the auricular appendage. All efforts to restore this heart failed.

In the majority of cases the B.P. and pulse returned to normal as the temperature rose. In a few patients, however, a secondary fall in B.P. occurred about one to two hours post-operatively. This always responded to posture and small transfusions.

Temperature Changes

On the average a drop of 0.5° C. was obtained during the administration of the cocktail before the application of ice. During the period of cooling before operation a further average drop of 3.4° C. (1 to 10° C.) occurred. Fig. 2 shows temperatures existing during operation in

FIG. 2.—Temperatures recorded during operation. Continuous lines=thoracic and abdomino-thoracic cases. Dotted lines=abdominal cases. Broken lines=non-abdominal cases.

24 cases. Perhaps the most significant observation was the fall in temperature of about 2° C. occurring in all cases in which the chest was opened. This did not take place after abdominal section.

The majority of patients had regained their normal temperatures in about 10 hours after operation, though one case already reported (Case 21) remained subnormal for 48 hours.

Bleeding

This varied considerably from case to case, and apparently bore little relation to the existing B.P. In 14 cases there was a marked postural ischaemia; in four cases, despite suitable posturing, bleeding was much increased, while in the remaining eight the amount of bleeding appeared normal. One case of reactionary haemorrhage occurred. This took place 16 hours post-operatively and was of moderate severity.

Excessive bleeding in the absence of any rise in arterial B.P. may be attributable to a rise in venous pressure. This may be a factor at lowered temperatures, when, as has been shown by Bigelow, Lindsay, and Greenwood (1950), venous pressure is likely to rise.

Case 7.—This patient showed excessive bleeding during radical mastectomy; the degree of hypothermia was only moderate (34° C.), but may have been sufficient to exacerbate an already raised venous pressure due to a failing myocardium.

Apart from any consideration of the B.P., bleeding at low temperatures may be due to some interference either with the ability of vessels to retract or with the formation and contraction of blood clot. This may have applied to Case 22.

Case 22.—This man, undergoing splenectomy and transection of the stomach for portal hypertension, bled excessively throughout the operation, which, largely for this reason, lasted six and a half hours. During most of the time his B.P. ranged from 50 to 90 systolic and 40 to 65 diastolic. All efforts to arrest the oozing in the portal bed were unsuccessful, and when

the patient was returned to bed his rectal temperature was 31.5° C. and blood was pouring out of his under-water drain almost as fast as it was transfused. Owing to the large replacement of blood, adequate amounts of calcium gluconate and vitamins C and K were added to the transfusions, but only when the temperature reached 32° C. did the haemorrhage stop. At this time he had received 19 pints (10.8 litres) of blood; the measured loss corresponded. Altogether during and following his operation this man received a total of 21 pints (11.9 litres) to compensate for his loss, and he died 48 hours later, apparently from a transfusion reaction. Necropsy was not performed. At operation the liver was about half the normal size and an advanced degree of cirrhosis was present. The pathologist expressed the opinion that it was remarkable how he had managed to carry on with so little liver tissue. There seemed little doubt that this man's prothrombin level was so low that the clotting of his blood even with slight degrees of hypothermia was seriously affected.

Anaesthesia

The total dosage of all drugs given in thoracic and abdominal cases is shown in Table IV. From this it is immediately apparent that there is a striking reduction in the amount of thiopentone used. If those cases with liver damage are excluded a similar, though less marked, reduction in the amount of D-tubocurarine chloride used is evident. In cases with liver damage comparatively large doses of D-tubocurarine chloride were required (Table V), showing that the observation of Dundee and Gray (1953) in this respect holds true in hypothermic patients. Reversal of the effects of the D-tubocurarine chloride by neostigmine at the end of operation was as in normal cases (Fig. 3). Where suxamethonium was used for intubation its duration of action was normal.

TABLE IV.—Total Dosage of Anaesthetic Agents in 22 Abdominal and Thoracic Cases

Thiopentone	No. of Cases	D-tubocurarine Chloride	No. of Cases
Nil	7	Up to 20 mg.	6
Up to 100 mg.	7	20–30 mg.	5
100–200 mg.	4	30–40 mg.	1
250 mg. +	4	40 mg. +	1
Pethidine	No. of Cases	Others	No. of Cases
Nil	18	Nil	13
Up to 50 mg.	3	Lytic cocktail	2
50 mg. +	1	Chlorpromazine	1

* Excluding five cases with known liver damage. One case received gallamine triethiodide as relaxant.

TABLE V.—Comparison of Amount of D-tubocurarine Chloride Required by Patients with Abnormal Liver Function, and Those in Whom There Was No Reason to Suspect Liver Damage

Liver Function	No. of Cases	Average Duration of Operation (Minutes)	Average Dose of D-tubocurarine Chloride (mg.)
Normal	16	160 (35–320)	26 (5–48)
Abnormal	5	244 (145–385)	58 (50–75)

Post-operative Period

One formed the impression that the general condition of these cases was better than normal after operation. There was a reduction in the amounts of analgesics needed in the first two post-operative days, compared with normal requirements (Table VI). Seven subjects received no sedative or analgesic drug from the end of operation to their discharge from hospital. Although, on the average, patients responded to their names about three and a half hours after opera-

FIG. 3.—Spirometry tracing showing satisfactory reversal of gallamine triethiodide by neostigmine. The last dose of relaxant (40 mg.) had been given 30 minutes before the neostigmine.

tion, yet they themselves think that they did not waken for a further seven hours. This time is significant, as it coincides with the time of administration of the first dose of analgesic.

The complications occurring during this period are listed in Table VII. The three cases with respiratory trouble cleared up with orthodox treatment. The haematemesis which occurred in Case 24 was attributed to trauma during removal of the thermocouple from the oesophagus. It is worth mentioning that this was the only occasion on which rectal temperatures were not recorded, the reason being that excision of the rectum was contemplated in addition

TABLE VI.—Post-operative Analgesics (22 Cases). All Analgesics Recorded as Equivalent Doses of Pethidine (10 mg. Morphine or 8 mg. Methadone Considered Equal to 100 mg. Pethidine)

	First Dose		Total Dosage (mg.)	
	Time from End of Operation	mg.	First 24 Hrs.	Second 24 Hrs.

Sudden B.P. fall	1
Paralytic ileus	1
Haematemesis	1
Hyperpyrexia	1
Later:	
Paralytic ileus	1
Pulmonary embolism	1

to removal of the bladder. Paralytic ileus, which eventually proved fatal in Case 4, was attributable to the surgical procedure, although one cannot dismiss the possibility that autonomic block played some part.

The only hyperpyrexia that was noted occurred in our first case, which is worthy of mention.

Case 1.—The patient was returned from the theatre with a temperature of 34° C. and instructions were given that readings should be taken every 15 minutes. Two hours later a nurse, who was not conversant with the thermocouple, took the oral temperature and found that it was not recordable by a clinical thermometer. She immediately covered the patient with a heat cradle, and by the time the next reading was due the temperature was 39° C. Once the source of heat was removed the temperature gradually returned to normal.

Nursing staff who have been trained to conserve body heat on all occasions find it difficult to get used to patients lying in bed after operation covered only by a sheet. When the lessons from this case were pointed out to them we had no more trouble.

Deaths

Five deaths occurred in this series of cases (Table VIII). We feel that in two cases (Cases 17 and 22) hypothermia may have contributed to the outcome. One cannot dismiss

TABLE VIII.—Cause of Death

Case No.	Time Post-operatively	Cause
4	16 days	Paralytic ileus and peritonitis
16	24 hours	Peritonitis and cardiac failure
17	On table	Ventricular fibrillation followed by asystole
22	48 hours	? Transfusion reaction
24	13 days	Pulmonary embolism

the possibility that the technique played some part in Cases 4 and 24, although this seems unlikely, since the deaths occurred on the 16th and 13th post-operative days respectively. It is difficult to say what parts surgery and hypothermia played in the following case.

Case 16.—This patient suffered from senile dementia with incipient cardiac failure. The instability of this cardiovascular system was shown by a marked B.P. fall following the first dose of cocktail. Hypotension persisted throughout the cooling and for most of the operation, during which the temperature fell to 31.6° C., at which the pulse became irregular. There was a moderate reactionary haemorrhage 16 hours after operation. Rewarming was slow, but the patient's condition gradually improved.

Death occurred suddenly 24 hours post-operatively, when the temperature had reached 34° C. Necropsy revealed peritonitis and appearances suggestive of left ventricular failure.

Difficulties Encountered During Production of Autonomic Block and Hypothermia

In 17 cases there was no shivering or difficulties of any kind. Since this is a new technique the difficulties we encountered in the remaining nine cases are discussed in detail. These are listed in Table IX. Inability to control shivering

TABLE IX.—Difficulties During Cooling

	No. of Cases
Shivering difficult to control	4
Difficulty in producing hypothermia	3
Cardiac irregularities	3
Regurgitation	1
Restlessness	1
Uncontrollable B.P. fall	1

was generally accompanied by a slow fall in temperature. Resistance to the production of autonomic block occurred in the following four cases.

Cases 9 and 18.—Whereas the average dose of cocktail was 7 ml., in the presence of thyrotoxicosis we administered 12 and 13 ml. respectively to these patients, supplemented by intramuscular pethidine and diethazine in No. 18, and with thiopentone in both. Once the initial difficulties were surmounted, satisfactory cooling occurred in both.

Case 13.—This patient was a morphine addict, and even after 10 ml. of the cocktail the autonomic block was incomplete, and the rectal temperature never fell below 35.5° C.

Case 23.—Although this patient weighed only 9 st. 7 lb. (60 kg.) and had a Hb of 41% he proved the most difficult case encountered to date. The administration of 12 ml. of the cocktail over 100 minutes produced no effect on the B.P., and intense shivering was occurring. During the next hour 50 mg. of pethidine and 150 mg. of diethazine were given intramuscularly, the same doses together with 50 mg. of chlorpromazine and 50 mg. of thiopentone being given intravenously. This did not abolish shivering and the temperature fell to only 35° C. Shivering was then controlled by curarization, but in spite of the intensive application of ice the temperature fell by only 1° C. in 50 minutes.

This subject had been receiving nightly doses of butobarbitone (400–600 mg.) and promethazine twice daily for a month. These may have led to a tolerance to the drugs administered, but cannot explain the resistance to cooling when shivering had been completely abolished.

Further difficulties are illustrated in the following cases.

Case 11.—In this instance there was considerable doubt about the activity of the chlorpromazine. Despite the elimination of obvious shivering, presumably accomplished by the pethidine (Dundee *et al.*, 1953), the fall in temperature was negligible. This view is substantiated by the appearance of vasoconstriction following the application of ice.

Case 2.—A peculiar feature here was the almost complete absence of the usual narcotic effects of the cocktail despite a satisfactory response in all other respects. This deficiency was remedied by the use of 25-mg. doses of thiopentone.

Special Investigations

Oxygen Intake.—Fig. 4 includes all the observations that were made on 12 subjects, values being expressed as a reduction from the normal and temperatures as falls from 37° C. As can be seen, it was possible to follow only half the patients throughout the whole procedure, but isolated observations on the remainder were in agreement with these. The overall picture of falls in oxygen intake with hypothermia agrees with the findings of Bigelow, Lindsay, Harrison, Gordon, and Greenwood (1950) and Dundee, Scott, and Mesham (1953) in dogs. A constant observation not shown in Fig. 4 was a drop of 8–10% in oxygen intake that occurred after the cocktail, before the application of ice and drop in body temperature.

Urine Analysis.—This was done in eight cases only. A slight reddish coloration was present for three to four days in three cases. There was no haematuria on spectroscopic examination, and the colour is probably due to the breakdown products of the phenothiazine derivatives, as two of

these cases received promethazine as a sedative in the post-operative period.

The presence of ketone bodies could be detected in three cases after cooling and post-operatively, although clinically and biochemically there was no evidence of acidosis. In one case this persisted until the fifth post-operative day, but

FIG. 4.—Relationship of oxygen intake (expressed as a percentage of normal) to fall in rectal temperature (expressed as a percentage of normal). o—o=observations made in the absence of shivering. Those joined together are serial readings during cooling and operation. O indicates isolated observations at any period of the procedure. X=readings taken when the patient was shivering.

cleared up after 48 hours in the others. Glycosuria was detected in two cases; in both instances the patient had received dextrose intravenously when the temperature was 30–32° C. This cleared up when the temperature was raised. Depression of the glycolytic activity of the liver at low temperatures is a possible explanation of this phenomenon.

Discussion

This paper has been written with the purpose of drawing attention to some dangers of hypothermic techniques. All the patients in this series stood to benefit from the production of hypothermia. Some who were rejected for anaesthesia by orthodox techniques made a highly successful recovery. The high mortality occurred in the group of patients who were seriously ill and who were grave operative risks by any standards. It is considered that in this group the method gave the best chance of survival. Our purpose in observing this series has been to obtain a preliminary assessment of the method of producing hypothermia by external cooling combined with autonomic block. It is useful to know that reduction of temperature can be satisfactorily and easily produced in patients, without the necessity for an extracorporeal arteriovenous shunt (Delorme, 1952), a procedure which it seems to us carries its own risks. It is apparent from our experience that an degree of hypothermia can be obtained by this technique. It is a method, moreover, which avoids an undesirable depth of anaesthesia or prolonged periods of respiratory arrest due to curarization, which would otherwise be necessary to avoid shivering.

Our experience both in this series and in animal experiments has led us to two conclusions. First, that the danger

of serious cardiac irregularity at temperatures lower than 28° C. is real, and is particularly imminent if cardiac manipulation is required. Secondly, the difference in oxygen consumption between a patient at 28° C. and one at 25° C. is insufficient, in the present state of our knowledge, to warrant the extra risks involved by proceeding to lower temperatures.

The reduction in bleeding during hypothermia has not always been as marked as was expected. At low temperatures the prolongation of the clotting time and/or bleeding time has on occasion been a source of embarrassment. We are proceeding to investigate the effect of different prothrombin levels on the clotting time of blood at different temperatures. We feel that, before hypothermia is employed for cases of portal hypertension with liver cirrhosis, the clotting-time of the patient's plasma should be estimated at various temperatures so that the critical level may be ascertained.

It seems to us reasonable also that hypothermia might be an added risk in patients whose myocardium is damaged (see Cases 7, 17, and 21). Initial heart-lung experiments which we have performed in the dog have confirmed the findings of Knowlton and Starling (1912) that the myocardium is affected at lower temperatures, and suggest that the Starling response to stretching the myocardial fibres is less efficient. It is therefore questionable whether any degree of hypothermia—say below 30° C.—is justifiable in cases with a damaged myocardium until further work has been carried out to elucidate this problem.

A weakness in this technique has been the comparative lack of control of the patient's temperature. If the hypothermia becomes too intense, as when allowance has not been made for the 2–3° C. fall which always occurs on opening the chest, there is no adequate means of correcting the situation. This is no fault of the autonomic blockade, but is a technical problem, to which we are giving consideration.

The indications for hypothermia would seem to be:

1. When a degree of hypotension is required to control haemorrhage either for patients in whom large blood loss is expected, or in whom even a small blood loss will embarrass the work of the surgeon. We have never been convinced of the safety of hypotensive techniques in which the supply of blood carrying oxygen to the tissues is reduced without any effort being made to reduce to some extent the oxygen demands.

2. In patients with a severe degree of anaemia which cannot be corrected before operation. This series has included four cases of oesophageal varices in which there was a marked degree of anaemia and which responded to transfusion only by further haematemeses. The combination of anaemia with the hypotension which is so helpful to the surgeon in these cases is justifiable only if the oxygen demands of the patient are reduced by hypothermia. This

is well illustrated by Case 3 (Fig. 5), when a patient whose Hb was only 50% was maintained for 44 hours at a B.P. averaging 60/30 (minimum 35/25). His recovery was complete and uneventful.

3. In operations on the heart and great vessels in which it may be necessary to cut off the cerebral circulation for a period of time. In this regard a startling observation was made in Case 17. For 17 minutes, at 25° C., after all possibility of cerebral circulation had ceased, this patient's respiratory centre continued to function, as evidenced by quite normal respiratory movements.

4. In thyrotoxicosis which cannot be controlled by medical treatment. One case in this series had been presented for operation on two previous occasions and returned to the ward because of an uncontrollable pulse rate of 160 a minute. Induction of hypothermia reduced this to 80 a minute, considerably improved the general condition of the patient, and enabled an operation to be performed, which was followed by an uneventful recovery.

5. Presumably in neurosurgery there will be indications for this technique, but up to the present we have had no experience with this application.

6. In certain therapeutic indications such as hyperpyrexia occurring in pituitary disorders or post-operatively in children, and in thyroid crises.

Summary

The history of the production of hypothermia in man is reviewed, and a method described for its production in man with the help of block of the autonomic nervous system.

The use of this technique in 26 cases undergoing operation is described.

Observations are recorded of the changes that occurred in the respiratory system, the cardiovascular system, and the body temperature, with the amount of bleeding.

Dosages of anaesthetic agents and post-operative analgesics are discussed, as are post-operative complications and deaths that occurred.

The troubles that we encountered during the production of the autonomic block and cooling have received special mention.

Our findings concerning the relationship of oxygen intake to temperature, and the presence of abnormal constituents in the urine following this technique are reported.

We are indebted, among others, to Professor C. A. Wells and Mr. R. W. Doyle, with whose co-operation this study was made possible. We are also grateful to Dr. J. Harper, of Pharmaceutical Specialities (May & Baker) Ltd., for supplying the chlorpromazine (largactil), promethazine (phenegan), and diethazine (diparcol) for this investigation; and also for his courtesy and assistance.

THE PRODUCTION OF HYPOTHERMIA

BY

JOHN W. DUNDEE, M.D., F.F.A.R.C.S.

W. E. B. SCOTT, M.B., B.Ch., D.A.

AND

P. R. MESHAM, M.B., Ch.B., D.A.

(From the Department of Anaesthesia, University of Liverpool)

The effect of hypothermia in diminishing the body's oxygen consumption has led to a recent interest in this as an aid to anaesthesia in the poor-risk case and in major surgery. Man is equipped with a highly effective mechanism for combating the effects of cold, and the first step in the production of hypothermia must be to overcome this response. This can be achieved by deep anaesthesia (Bigelow *et al.*, 1950), the use of muscle relaxants (Krogh, 1916), or by the "lytic cocktail" or "liberation cocktail" introduced by the French workers Laborit and Huguenard (Huguenard, 1953).

We have compared the efficacy of these three methods in facilitating the production of hypothermia in the anaesthetized dog by means strictly comparable to those applied in man, and the individual constituents of the "lytic cocktail" have been studied. Their effect on the rate of fall of the rectal temperature after the application of ice, and on the amount of shivering produced, has been studied. We have also investigated the effect of hypothermia, induced with the aid of the constituents of the "lytic cocktail," on oxygen intake, heart rate, and respiration.

Methods

Unselected mongrel dogs were used, varying in weight (8-16 kg.) and age. Basal narcosis was induced by the intraperitoneal injection of 30 mg./kg. pentobarbitone in a 3% solution at approximately blood heat (Adams, 1944). Once the dogs were asleep endotracheal intubation with a cuffed tube was carried out by the aid of a topical application of 2% amethocaine or 2% lignocaine. Forty-five minutes after induction of anaesthesia adjuvant drugs were administered in doses as follows: pentobarbitone, 15 mg./kg.; D-tubocurarine chloride, 3 mg./kg.; chlorpromazine, 2 mg./kg.; pethidine, 4 mg./kg.; promethazine, 2 mg./kg. The "lytic cocktail" comprised all of the last three in the doses mentioned. With the exception of pentobarbitone (which was given intraperitoneally), all drugs were given by deep intramuscular injection mixed with 1,000 Benger units of hyaluronidase. Immediately the muscle relaxant was given the cuff of the endotracheal tube was inflated and the animals' respiration mechanically controlled with oxygen for periods of three to four hours. A similar procedure was adopted when respiration failed because of hypothermia. Fifteen minutes after injection of the adjuvants the animals were covered with ice-bags. Cooling continued for 90 minutes, when the animals were gradually heated up by the help of hot-water bottles and a hair-drier.

These doses of the constituents of the "lytic cocktail" are similar to those which are given to man. The total amount of pentobarbitone (45 mg./kg.) administered to those animals who received it as an adjuvant will result in deep anaesthesia (Adams, 1944). In the case of D-tubocurarine chloride, 3 mg./kg. was given, as we found that this will invariably produce apnoea over the period of our investigations, and it can be safely reversed some three to four hours later by neostigmine 5 mg. and atropine 2 mg.

In order to reduce the factor of individual susceptibility of the dogs to the drugs and to cooling, the experiment was planned so that during its course each animal received each of the adjuvants. As will be reported later, three dogs died during this study. In the case of two of these the death occurred when the last adjuvant drug was being investigated, so that the series with these is complete. In the third instance the fatality was with the first drug, and no readings obtained from this dog are included in the results.

Rectal temperatures were noted by a thermocouple every five minutes, and the presence or absence of shivering was noted at similar intervals. The heart rate was recorded every 15 minutes. Oxygen intake was measured by means of a direct recording of respiration on a spirometer containing oxygen. To reduce resistance to respiration all valves were removed from the instrument and a small soda-lime canister was inserted close to the endotracheal tube. Care was taken to see that the circuit was leak-proof, and at temperatures below 30° C. respiration was aided during the period of observation. This ensures full oxygenation of the blood and eliminates respiratory depression as a cause of decreased oxygen intake (Bigelow *et al.*, 1950). Another factor which may well interfere with the readings is the excretion of nitrogen by the dog when breathing from a spirometer containing oxygen. To overcome this a large flow of pure oxygen was administered by a T-piece once the endotracheal tube was in position, and between readings the animal was maintained on pure oxygen.

Results

On all occasions the normal temperature of the animal was taken as that immediately before the administration of the adjuvant drug—that is, three-quarters of an hour after the intraperitoneal administration of the basal narcotic. For

FIG. 1.—Relationship of oxygen intake to temperature. Minus values indicate continuous readings in the absence of shivering. X, Isolated readings taken when the animal was shivering.

the sake of simplicity all temperatures are recorded as variations from this normal. In order to compare the amount of shivering under various conditions a point system was adopted. The presence or absence of palpable shivering was noted at five-minute intervals, one point being recorded for every positive observation. The average of six observations with each of the drugs studied can be seen in Table I. This shows the fall in temperature which took place every 15 minutes and the total amount of shivering every 30 minutes. In each of these dogs preliminary studies of oxygen intake under the effects of 30 mg./kg. pentobarbitone revealed that there were negligible changes over the period from 40 to 180 minutes after the injection of the barbiturate. Thus any changes which we have recorded are due to the hypothermia or adjuvant drug. As in the case of temperature, the normal readings for oxygen intake, pulse rate, and respiratory rate were taken to be those recorded immediately before the administration of the adjuvant. Changes in oxygen intake are expressed as percentages of the normal, whilst alterations in pulse rate are recorded as absolute changes from normal.

FIG. 2.—Relationship of heart rate to temperature. Minus values recorded when no shivering was occurring. X, Readings taken during bouts of shivering.

TABLE I.—Effects of Various Drugs and Combinations of Drugs on Average Fall in Rectal Temperature in the Dog and Amount of Shivering After Covering with Ice. (See Text for Explanation of Method of Recording Amount of Shivering.)

Drugs	Dose, mg./kg.	Average Fall in Rectal Temperature °C.						Average Amount of Shivering		
		Time in Minutes after Covering with Ice						Time in Minutes After Covering with Ice		
		15	30	45	60	75	90	0-30	35-60	65-90
Pentobarbitone	30	0.8	1.5	2.7	3.7	4.5	5.2	2	4	5.4
Pentobarbitone 30 mg./kg. plus the following, given 45 minutes later:										
Pentobarbitone	15	1.5	3.4	5.1	6.7	7.6	9.1	0	0	0.5
D-tubocurarine chloride	3	1.2	3.2	5.0	6.6	8.1	9.5	0	0.6	0.8
"Lytic cocktail," comprising:										
Chlorpromazine	2									
Pethidine	4	1.7	3.3	5.1	6.9	8.5	10.4	0	0	0.5
Promethazine	2									
Chlorpromazine	2	2.2	3.3	5.6	7.5	9.0	10.6	0	0	0
Pethidine	2	1.0	2.3	3.5	4.9	5.7	6.5	0	2.3	3.2
Promethazine	2	1.1	2.6	4.0	4.7	5.2	6.0	1.2	3.5	5.7

Fig. 1, showing the relationship between oxygen intake and temperature (10 observations), demonstrates a fall in the former as the latter decreases. However, when shivering occurs there is a consistent rise in oxygen demands. The lowered temperature may be seen to have a similar relationship to heart rate and respiratory rate in Figs. 2 (25 observations) and 3 (10 observations) respectively; but here again rises are constantly provoked by the onset of shivering. Apnoea is apt to occur at a rectal temperature of 25° C., but severe respiratory depression has been noted at temperatures of 29° C. and under.

Cardiac arrest occurred in three dogs at temperatures of 23° C., 23.5° C., and 26.5° C., respiration being unaided in all cases. It is significant that lower temperatures (21° C.-22° C.) have been obtained without untoward effects in those animals in which respiration was fully controlled with oxygen.

FIG. 3.—Relationship of respiratory rate to temperature.

Discussion

From Table I a comparison of those recognized methods of facilitating the production of hypothermia can now be made. An analysis of the results obtained with deep anaesthesia, curarization, and the "lytic cocktail" is given in Table II. This expresses the average temperature fall obtained using these methods after 90 minutes' cooling as a percentage of that occurring with basal narcosis alone. The amount of shivering which occurred during the last hour of cooling is similarly expressed. It is apparent from Tables I and II that there is little to choose between these three methods as regards rate and amount of temperature fall, and abolition of shivering.

A similar analysis of the effects of the constituent drugs of the "lytic cocktail" is also shown in Table II. From this it may be seen that by far the most active constituent

TABLE II.—The Fall in Rectal Temperature that Occurred After Covering with Ice for 90 Minutes and the Amount of Shivering that Occurred During the Last Hour of the Cooling Expressed as a Percentage of the Observations Made Under Similar Conditions with Basal Narcosis Alone

	Percentage of Similar Readings with Basal Narcosis Alone	
	Fall in Rectal Temperature at 90 min.	Amount of Shivering, 35-90 min.
Recognized methods of facilitating the production of hypothermia:		
(a) Deep narcosis	+75	-95
(b) Curarization	+83	-85
(c) "Lytic cocktail"	+100	-95
Individual constituents of the "lytic cocktail":		
(a) Chlorpromazine	+104	-100
(b) Pethidine	+25	-42
(c) Promethazine	+15	-2

in facilitating the production of hypothermia is chlorpromazine. Pethidine, while moderately effective in eliminating shivering, has comparatively little effect in aiding the fall in temperature. The effects of promethazine appear to be negligible. A graphic representation of the rate of temperature fall obtained with chlorpromazine, pethidine, and promethazine (Fig. 4) demonstrates a steady fall in temperature with chlorpromazine. In the case of pethidine and promethazine the onset of shivering causes a marked

FIG. 4.—Rate of fall of rectal temperature when animal was immersed in ice with (a) chlorpromazine, (b) promethazine, (c) pethidine. * Average time after beginning of cooling to onset of shivering. --- Hypothetic continuation of the steady fall in temperature that occurred with pethidine and promethazine before the onset of shivering.

reduction in the rate of temperature fall. A hypothetical continuation of the steady fall occurring before the onset of shivering shows that neither of these drugs would have been as effective in facilitating the fall in temperature as chlorpromazine. A possible explanation of this may be the occurrence of clinically undetectable shivering. That this can occur has been shown by previous electromyographic studies (Göpfert and Stuffer, 1952).

It is not the purpose of this paper to consider the mode of action of these drugs in facilitating hypothermia, but one point, however, seems worthy of mention. A dog in which hypothermia has been induced with the aid of pethidine will

show a very marked increase in the degree of shivering following the intramuscular administration of n-allyl-normorphine (3 mg./kg.). It is interesting to conjecture whether this is due to a reversal of the analgesic effect of pethidine in regard to thermal sensation (Evans, 1952) or whether it is due to a reversal of its central effects.

The fall in oxygen intake which we have observed during hypothermia closely resembles that reported by Bigelow *et al.* (1950). He induced hypothermia by cooling dogs sufficiently anaesthetized to eliminate shivering, and made no use of the "lytic cocktail." It is difficult to make a comparison with the findings of Churchill-Davidson *et al.* (1953), as these workers do not give sufficient details of their method of measuring oxygen consumption.

This could suggest that, provided shivering be eliminated, a fall in oxygen intake occurs with hypothermia irrespective of how this is produced.

Summary and Conclusions

A study has been made of the production of hypothermia facilitated by (1) deep anaesthesia, (2) curarization, (3) the "lytic cocktail." All three appear to be equally effective.

The active constituent of the "lytic cocktail" appears to be chlorpromazine. Pethidine decreases shivering somewhat while producing but little fall in temperature. Promethazine seems to have little effect.

Observations have been made on the effect of hypothermia on oxygen intake, pulse rate, and respiratory rate. All three are depressed at lowered temperatures, irrespective of how these are obtained.

We are indebted to Pharmaceutical Specialities (May & Baker) Ltd. for liberal supplies of chlorpromazine and promethazine used in this investigation.

The Scientific Film Association has issued a catalogue of films on psychology intended primarily to help in the selection of films for research workers and senior students, teachers of psychology, and lay audiences. The films, of which there are 107, were made between the years 1930 and 1953, and all are believed to be available in the United Kingdom. About 70 of them have been appraised by methods evolved by the S.F.A. during the last 10 years, and the appraisals are included in the catalogue to help in selecting films. The catalogue is divided into seven sections: (1) Developmental Psychology, (2) Educational Psychology, (3) Testing Techniques, (4) Industrial and Applied Psychology, (5) Animal and Experimental Psychology, (6) Abnormal Psychology and Psychiatry, and (7) Juvenile Delinquency. Information is included on the running times of films, whether they are talkies or silent, and whether in black-and-white or in colour. Some are available free and others must be hired, and some are available only for special types of audience—that is, from which laymen are excluded. The catalogue lists many films made in Canada and the U.S.A. as well as Great Britain, and includes some made in Denmark, the U.S.S.R., Belgium, and Germany. While the Scientific Film Association itself does not distribute the films, the catalogue gives a list of owners and distributors from whom they may be borrowed. It is obtainable from the association at 164, Shaftesbury Avenue, London, W.C.2 price 7s. 6d. (8s. 1d. post free). It may be of particular interest to teachers of psychiatry.

HIBERNATION ANAESTHESIA IN MAJOR SURGERY

A REPORT OF 36 CASES

BY

ANGUS SMITH, F.F.A.R.C.S., D.A.

Consultant Anaesthetist, Charing Cross Hospital

AND

J. G. FAIRER, M.R.C.S., D.A.

Registrar in Anaesthesia, Charing Cross Hospital

In major surgery, particularly in the case of malignant disease, where the patients are often cachectic and very ill, it is often not possible to contemplate surgical intervention. If an operation is started, after an hour or two of traumatic surgery the patient's condition deteriorates, and, however carefully the cardiovascular system is supported by intravenous transfusions, a state of shock develops. The completion of the operation may become an urgent matter, and the extent of the operation may have to be modified. Under effective "hibernation" anaesthesia the patient does not react in any way to the surgical stimulus, however severe or long-continued. Furthermore, intravenous transfusion is confined to replacing only the volume of blood lost. This is surprisingly small when measured, amounting to 300-400 ml. in extensive pelvic clearances. The body temperature drops to between 95 and 96° F. (35 and 35.6° C.), but this is only an indication that the autonomic blockade has succeeded, and it returns to a degree or two above the pre-operation level in six hours. The state of the patient approaches in many ways that found in the mammiferous hibernating animal, but it is not a truly comparable condition.

The defence mechanisms of the body for the preservation of the *milieu intérieur* of Claude Bernard against stress, aggression, or change in the external environment are largely the function of the autonomic nervous system. The hypothalamus, with its connexions with both the cerebrum and the autonomic system, has thus a large part in the control of the internal environment.

Conventional methods of anaesthesia attempt to modify these autonomic defences. This is done by depressing the cerebral functions, and in this way modifying the thalamic and hypothalamic control of the autonomic system; or, working from the periphery, by obtunding the stimuli that call the defence mechanisms into action. In the vasomotor system the defence mechanism, working through the mediation of the autonomic nervous system, causes the shutting of the pre-capillary sphincters and the opening of the arteriovenous shunts (Chambers *et al.*, 1943). This increases the circulating blood volume and also increases the venous oxygen tension, in order to combat the aggression. In the central nervous system, experimental work would indicate that the shunt mechanisms are not present; consequently, following aggression the oxygen supply to the vital centres is not diminished and may even be increased. In the peripheral circulation, if the stress is at all long-continued, these same defence mechanisms result in capillary dilatation, and the increased pressure at the venous end of the capillary loops is followed by fluid loss into the tissues, with diminution of the circulating blood volume. This leads to anoxia, building up of acid metabolites, and, finally, atony of

the peripheral vessels—the fatal peripheral failure which no amount of intravenous or intra-arterial infusion will reverse. In this way the patient dies as a direct result of his attempt to preserve his *milieu intérieur*.

Physical Cooling

For many years attempts have been made to modify the reaction of the body to surgical aggression by means of physical cooling. It has been found by Prec *et al.* (1949), Bigelow *et al.* (1950), and Bigler and McQuiston (1951), and others that when the body temperature has been finally reduced by physical means the oxygen consumption of the tissues is markedly lowered. It is then possible to undertake surgical operations requiring the exclusion of the heart, or lungs, from the circulation for several minutes, without anoxic damage to the tissues.

However, the application of ice-packs, refrigerated blankets, and other external cooling in itself constitutes a stimulus which calls the defence mechanism into action. This is shown by increased oxygen consumption and heart rate, and by shivering in order to maintain body temperature. Only when the defence mechanism is overcome do the body temperature and the oxygen consumption drop (Prec *et al.*, 1949; Jaulmes, 1953). It is at this stage, on the way to final dissolution of the subject, that these operations can be performed.

The artificial hibernation technique evolved by the French workers, Jaulmes, Laborit, Huguenard, and others owes little to physical cooling of the subject from without, but depends on the specific neuroplegic effect of drugs, mainly those of the phenothiazine group on the autonomic nervous system. The phenothiazine derivatives include the antihistamine drugs promethazine hydrochloride ("phenergan") and promethazine-8-chlorotheophyllinate ("avomine"), which has a central action, particularly upon the vomiting centre, and chlorpromazine ("largactil"), which has no antihistaminic action. This drug seems to act centrally on the autonomic system as a neuroplegic, and it has a pronounced anti-adrenaline effect and a direct depressant action on the temperature-regulating mechanism.

Laborit *et al.* (1952) have described a detailed plan for producing a state of artificial hibernation which has guided us in our efforts to ameliorate the condition of patients subjected to major surgical procedures. He relies on the use of a "lytic mixture" consisting of 50 mg. of promethazine, 50 mg. of chlorpromazine, and 100 mg. of pethidine, which is administered intravenously in divided doses in the hour before operation. The hibernant state is maintained by giving, intravenously, one of three "cocktails" containing, among other drugs, aneurine, pethidine, promethazine, chlorpromazine, diethazine hydrochloride, sparteine sulphate, ascorbic acid, ethyl alcohol, and procaine. In addition acetosterandryl, neostigmine, and heparin are given intramuscularly.

Present Investigation

We have attempted, so far as is practicable, to avoid the polypharmacy of our French colleagues. The technique which we now adopt and which has given excellent results in our hands in a variety of major surgical procedures is as follows. The patient is given 50 mg. of promethazine-8-chlorotheophyllinate by mouth two hours pre-operatively. One hour later this is followed by a subcutaneous injection of 100 mg. of pethidine with 1/150 gr. (0.43 mg.) of hyoscine hydrobromide. The patient is brought to the anaesthetic room and the mixture of promethazine, pethidine, and chlorpromazine, in the proportions advocated by Laborit, is given in divided doses in the half-hour preceding operation. During the injection the pulse rate rises at first but later settles to a level a little above the resting rate, and remains unaltered despite the duration or severity of the surgical procedure. The respirations become shallow and may increase in rate, while the systolic blood pressure tends to fall and is maintained in the region of 100 mm. Hg. At the conclusion of the injection the patient is somnolent and apathetic but can still be roused. A small dose of 5% thio-

pentone, 2-3 ml., is given to produce unconsciousness, and tracheal intubations may then be performed with ease.

The patient is transferred to the theatre, where small doses of relaxants are given when required. Oxygen is administered if the respiratory excursion is inadequate, particularly in those cases requiring the steep Trendelenburg position. In prolonged operations, if the pulse rate begins to rise we have been able to re-establish control by a small supplementary dose of the original mixture. Great care is taken to replace any blood lost, as the patient is not able to compensate for gross diminution or increase of circulation blood volume. Our experience so far has been of patients aged from 28 to 76 years, and has included the following operations: gastrectomies, Wertheim's hysterectomies, hysterectomies, total colectomies, anterior pelvic exenterations, adherent malignant ovarian cysts, laminectomies, bilateral mastectomy and a second operation of prostatectomy on the same patient, together with less extensive operations in patients who would normally be considered poor risks.

Case Reports

Case 6.—A married woman aged 76, weighing 8 st. 4 lb. (52.6 kg.), had had two operations for carcinoma of the body of the uterus. She was admitted for symptoms of large-bowel obstruction with a large tumour arising from the pelvis with ascites. B.P. was 180/120. Six hours after admission she developed gross cardiac irregularity and electrocardiography indicated a coronary infarction. She was thought to be unfit for operative intervention. Two days later her condition became grave and fibrillation was occurring at a rate of 140, with a pulse deficit of 10-20 beats at the wrist. She was treated by the technique described above. Operation entailed the removal of a large adherent malignant ovarian mass involving the sigmoid colon, which was resected, and an anastomosis was performed, with a colostomy above. During the operation, which took three hours, she received 400 ml. of blood to replace the estimated loss. Her pulse rate remained irregular throughout at 90-100 a minute. Her rectal temperature was 96° F. (35.6° C.) at the conclusion of the operation. She was rousable within three hours of the end of the operation and regained consciousness after six hours. Her rectal temperature rose to 100.2° F. (37.9° C.) during this period and her pulse rate remained irregular at the same rate. She has made an uneventful recovery.

Case 23.—A man aged 46, weighing 8 st. 6 lb. (53.5 kg.), had generalized Paget's disease with involvement of the spine. He had had spastic paraplegia and loss of sphincter control for eight months. A myelogram showed a spinal block at the level of the fourth dorsal vertebra. We obtained an autonomic blockade by the method described, and an extensive decompression of the spinal cord was undertaken by performing a bilateral laminectomy from the fourth to the eleventh dorsal vertebra. Blood loss was very rapid and was replaced by a transfusion of 4 pints (2.3 litres). His pulse remained steady at 90-100 a minute and his systolic pressure was sustained at just over 100 mm. Hg. Recovery was uneventful and his neurological condition was improving.

Conclusions

It is impossible to assess statistically the advantages of any anaesthetic technique. From the small series of 36 cases involving really major surgery we have been impressed by the excellent condition of the patients, however extensive or long-continued the operation. We have had no deaths due either to the use of the method or to the operations performed. At no time during any of the procedures or during the post-operative period has the condition of the patient caused any anxiety. Furthermore, there has been no post-operative vomiting, nausea, or headache. The patients require less nursing care than normal, heavy post-operative sedation is not required, and there have been none of the post-operative complications which might have been expected to follow such major surgery. The patients are contented with this technique, for, although they can be roused,

most of them have complete amnesia from the time they leave the ward until six to eight hours after the operation. The freedom from post-operative pain and restlessness during this period seems to aid their recovery, for when the autonomic blockade has worn off they are cheerful, rested, and relatively free from pain.

The great advantage of this modification of Laborit's technique has been that we are now able confidently to undertake the anaesthetic care of patients who previously would have caused great anxiety, or would have been considered unfit to withstand major surgical intervention.

Summary

A brief account is given of a simplified method of producing autonomic blockade, as a method of preventing surgical shock during and immediately after major operations. The patient's condition has been better, both during and after the operation, than when conventional anaesthetic techniques have been used.

We would like to thank our colleagues and the nursing staff of the hospitals at which this work has been done for their sustained interest, and also Messrs. May & Baker Ltd. for supplying the drugs used.

THE BACTERIAL CONTENT OF HUMAN SMALL INTESTINE IN DISEASE OF THE STOMACH

BY

JUDITH CREGAN, B.Sc.

E. E. DUNLOP, M.S., F.R.C.S., F.R.A.C.S.

AND

NANCY J. HAYWARD, M.Sc., Ph.D.

(School of Bacteriology, University of Melbourne, and the Royal Melbourne Hospital)

It has already been shown (Cregan and Hayward, 1953) that when the human intestinal tract is healthy the small intestine is not colonized by a resident flora. Such organisms as are found there are so few in number that they must be regarded as transient contaminants passing through with the ingesta. The present work was undertaken to determine the effect of disease of the stomach on the flora of the small intestine. The results showed that neither a low gastric acidity nor the presence of a profuse flora in the stomach necessarily lead to the development of a resident flora in the small intestine. The antibacterial mechanism operating in the small intestine is therefore independent of the gastric germicidal barrier.

Experimental

The patients chosen for the experiment were undergoing operation for gastric or duodenal ulcers or gastric carcinoma. In addition, there was one patient with a subtotal gastrectomy of two years' standing and a small oesophageal hiatal hernia. He was operated on for recurring haematemesis and melaena. All had been given light nourishment and had then fasted for at least four hours before the operation.

The methods of collection and bacteriological examination of specimens and evaluation of results were exactly as previously described (Cregan and Hayward, 1953), and are stated only briefly here. The contents of the intestine were removed directly through the bowel wall with syringes. Thus the possibility of contamination was reduced to a minimum, the levels of the intestine sampled could be anatomically defined, and parts of the intestine remote from the diseased stomach but exposed during the operation could be sampled. A standard bacteriological procedure was followed with all specimens so that results could be assessed quantitatively as well as qualitatively, the degree of growth being graded from $\pm$ to ++++. It was shown (Cregan and Hayward, 1953) that + or $\pm$ growth indicated a transient flora and that ++ or +++ growth indicated a resident flora at the site sampled.

Results

Twenty-two cases were included in the investigation, and in each case the sites sampled were the upper jejunum, the mid-gut, and the lower ileum within 8 to 12 in. (20 to 30 cm.) of the ileo-caecal sphincter. In addition the stomach was sampled in all but four cases. The quantitative results are shown in Table I and the qualitative results in Table II.

Effect of Gastric Acidity and of Profuse Contamination of the Stomach

Of the 14 cases in which gastric acidity was determined, seven showed normal acidity or hyperacidity. The stomach, the upper jejunum, and the mid-gut were either sterile or contained only a transient flora in all of these seven cases. The lower ileum was colonized by a resident flora in three of them. These findings do not differ significantly from those in normal subjects. The remaining seven cases in which gastric acidity was determined showed hypoacidity or achlorhydria. In four of these (Cases 8, 9, 10, and 11) the

flora of the small intestine did not differ from normal, and in the other three both the stomach and the upper jejunum contained a resident flora, but by the time the intestinal contents had reached the mid-gut their bacterial content had been reduced to a transient flora. It is apparent that the subnormal gastric acidity of this group of cases did not affect the normal ability of the small intestine to prevent multiplication of bacteria in its lumen and to destroy large numbers of bacteria entering it from a heavily contaminated stomach.

Of the eight cases in which gastric acidity was not tested, six were of advanced gastric carcinoma and almost certainly had a low gastric acidity. The results from this group confirm the finding that when large numbers of bacteria enter a normal small intestine from a diseased stomach they are destroyed by the time the mid-gut is reached, if not earlier. In only two of the seven cases in which the stomach contained a resident flora (Nos. 17 and 21) did the profuse contamination persist even as far as the upper jejunum.

Cases 9 and 10, with only a transient flora in the stomach, indicate that lowered gastric acidity, even achlorhydria, is not necessarily accompanied by an increase of bacteria in the stomach.

Qualitative Results

The qualitative results are shown in Table II. As in the study of cases in which the intestinal tract was normal, the organisms found in the upper intestine in the present investigation were predominantly Gram-positive species of the general type more commonly associated with the mouth than with the lower intestinal tract. However, Gram-negative species of faecal type were found more often in this study, and in Table I a resident flora is designated oral or faecal in type. It must be noted that this designation is not intended to suggest the origin of the organisms.

In any one patient there was a correlation between the species found at each level of the tract. There was no apparent association between particular species and the disease or the general condition of the patient. In particular, *Candida albicans*, which has been said to be commonly associated with carcinoma of the stomach, and the toxin-

Discussion

In all these 22 patients undergoing gastric operations the mid-gut (lower jejunum or upper ileum) yielded at most a transient flora, although in 10 of the cases the gastric germicidal barrier was defective and the stomach was heavily contaminated. Even in the case of subtotal gastrectomy of two years' standing in which there had been prolonged reduction of stomach secretions the mid-gut yielded only a transient flora (actually $\pm$ growth). The other cases show that advanced disease of the stomach, with associated physiological and anatomical changes, does not encourage the development of a resident bacterial flora in the small

intestine. Therefore an antibacterial mechanism, distinct from that of the stomach, must operate in the small intestine. Failure to recognize that there are two independent mechanisms and that the stomach mechanism may be defective and the small intestine mechanisms be intact has led to the widely held misconception that if the gastric secretions are reduced or absent organisms from the large bowel will invade the small intestine. For example, Wells and Welbourn (1951) state that achlorhydria following gastrectomy causes "bacteria which normally inhabit the colon to grow freely all the way up the small intestine and in the gastric stump." This view has arisen from studies of samples, generally only from the duodenum and the stomach, removed by passing a tube via the mouth (Knott, 1927; Rices, Sears, and Downing, 1928; Torrey, Kahn, and Salinger, 1930; Dick, 1941, quoted by Bethell *et al.*, 1942; French and Thompson, quoted by Frazer, 1949).

The results reported here show that a consideration of a single specimen from the upper small intestine could be misleading. The upper jejunum was heavily contaminated in 5 out of 10 cases in which the stomach contained a resident flora (Table I), but the scarcity of organisms further on in the mid-gut in all cases showed that this was not due to an invasion from the large intestine but to an abnormally heavy intake of organisms from the diseased stomach. In all cases reported here the antibacterial mechanism of the small intestine was functioning, whether gastric acidity was increased, decreased, or normal.

Further, this misconception has led to the suggestion that vitamin-B deficiencies in the post-gastrectomy syndrome (Welbourn, Hughes, and Wells, 1951; Wells and Welbourn, 1951), in the sprue syndrome, and possibly also in pernicious anaemia, pellagra, and nutritional megalocytic anaemia (Frazer, 1949) arise because bacteria invading the small intestine deprive the host of vitamins. This suggestion cannot rest on the fact that the stomach secretions are deficient. Until it has been shown that the small intestine's antibacterial mechanism is defective in these cases the theory has no sound foundation.

The work of Sinek and Reimann (1931) supports the findings reported here. They found that low gastric acidity was not necessarily associated with an increase in the incidence of *Bact. coli* in the duodenum.

More recently Barber and Franklin (1946), who examined swabs taken from the stomach and duodenum during stomach operations, found that, although the stomach was infected in 25 out of the 50 cases they examined, the duodenum was infected in only seven. They do not draw special attention to this fact, and the misconception has persisted in spite of their work.

No indication of the factors that determine whether a resident flora is established in the lower ileum can be seen from this work. Whereas 12 out of 21 cases yielded a profuse ileal flora in these cases of disease of the stomach, only 2 out of 14 did so when the intestinal tract was normal (Cregan and Hayward, 1953).

Summary

In cases of disease of the stomach presenting for operation the small intestine was found to contain only a sparse transient population, irrespective both of gastric acidity and of the degree of contamination of the stomach.

It is deduced that the small intestine has an antibacterial mechanism which is independent of the gastric germicidal barrier.

We would like to thank Professor S. D. Rubbo, professor of bacteriology, University of Melbourne, for his constant helpful advice; Mr. E. S. R. Hughes, acting out-patient surgeon, Royal Melbourne Hospital, for providing the specimens of two of the cases; Dr. Jacqueline Walker for assistance with the identification of species of *Candida*; the staff of the Royal Melbourne Hospital; and Miss Marjorie Krohn for technical assistance. One of us (J. C.) was in receipt of a personal grant from the National Health and Medical Research Council.

TREATMENT OF ACUTE PANCREATITIS WITH HEXAMETHONIUM BROMIDE

BY

RUSSELL M. DAVIES, F.F.A.R.C.S.

F. T. MOORE, O.B.E., F.R.C.S., F.R.C.S.Ed.

AND

D. WYNN-WILLIAMS, M.S., F.R.C.S.

Queen Victoria Hospital, East Grinstead, Sussex

In 1889 Fitz described three types of acute pancreatitis—haemorrhagic, gangrenous, and suppurative—based on the gross pathology of the gland. McWhorter (1932) collected 64 cases and classified them as follows: (1) acute or subacute pancreatitis in which there was no haemorrhage but in which the gland was enlarged, oedematous, and very hard; (2) the haemorrhagic, in which haemorrhages were present but there was no evidence of gangrene or suppuration; (3) cases with gross necrosis or gangrene but no suppuration; and (4) cases with suppuration or definite abscess formation.

A classification on an aetiological basis suggested by McWhorter (1932) and Jones (1943) adds little to our knowledge.

A. Infectious Origin.—(1) By extension along the lymphatics; (2) by extension from the blood stream; (3) by extension along the pancreatic ducts, from the duodenum or from the bile ducts; (4) by direct extension from infected foci; (5) following activation of bacteria in the normal gland; (6) by bacterial permeability from adjacent diseased viscera.

B. Non-infectious Origin.—(1) Mechanical, including stasis in the ducts. (2) Chemical, and originating in activated ferments resulting from (a) bile; (b) duodenal contents; (c) degenerated duct contents; (d) autolysis. (3) Degenerative changes in the pancreas: (a) secondary to benign or malignant tumours; (b) resulting from vascular degeneration or haemorrhage; (c) toxic changes following systemic disease. (4) Trauma.

C. A Combination of Two or More of the Above Factors.

The disease most commonly occurs in the fifth and sixth decades in obese males. Bisgard and Baker (1940) pointed out the frequent association of cholelithiasis. The disease may affect the whole gland or may be limited to the head, the body, or the tail. The extent of necrosis depends upon the violence of the biochemical explosion. If small areas alone are involved they may be absorbed or converted into fibrous tissue; but, if large, the necrotic areas soon slough or suppurate.

Ian Aird (1949) states that "a complicated network of theory has been woven around pancreatitis in order to relate it to gall-bladder disease but without any conclusive or all-embracing theory." We believe that pancreatitis is due to a vascular accident and that the findings of biliary pathology are coincidental.

One of us was impressed with the similarity in pathology of thrombosis and embolism in other organs, and treated with systemic heparin two cases of acute pancreatitis confirmed by exploratory laparotomy. The results were satisfactory, but led to a continuous ooze of blood from the suture line in each case. Although pain was relieved the loss of blood from the suture lines was sufficient to require intravenous blood transfusion. We concluded that the systemic heparin may have been responsible for the recovery of these two cases, which we classified, according to McWhorter's criteria, as gangrenous lesions of part of the head.

The following two cases were treated with hexamethonium drugs, and had a very smooth convalescence.

Case 1

An obese male aged 64 had been in good health until the morning of May 5, 1952, when he was seized with a sudden agonizing abdominal pain. It was located around the umbilicus and the left flank.

On examination he was found to be very shocked, and was frequently vomiting small amounts of bile-stained fluid. His face was livid and beaded with sweat, and the extremities were cold and damp. The abdomen was uniformly rigid, with maximum tenderness around the umbilicus. No other abnormal physical signs were discovered. A provisional diagnosis of pancreatitis was made. This was confirmed by exploratory laparotomy. The relevant findings were an injected peritoneum and a hard oedematous dusky-red pancreas with darker patches in the head. The proximal 3-4 in. (7.5-10 cm.) of the small gut was distended and scattered and traced with lymphatic vessels. The omentum revealed fat necrosis. The biliary tract was normal on palpation. The abdomen was closed without drainage.

The day following exploratory laparotomy the patient remained in great pain, and for this reason a bilateral posterior splanchnic block was performed with 1/2,000 amethocaine. The relief from pain was dramatic and the improvement in the clinical condition most marked. Pain began to return after complete control for approximately six hours. It seemed reasonable to believe that ganglion-blocking agents, such as hexamethonium, would similarly relieve pain, and that administration of this drug would have none of the difficulties or dangers of repeated splanchnic blocks. Oral hexamethonium bromide, 250 mg., was given via the indwelling Ryle's tube twice a day, and the activity of the drug was observed by blood-pressure readings, carried out by the nursing staff. Pain disappeared after six hours, and the next day it was possible to assess the patient as convalescent. Treatment with hexamethonium was continued for five days, the patient being discharged, cured, on the tenth day. He remained well up to the time of submitting this report.

Case 2

This patient was a man aged 52. His history was complicated by a previous perforation of a peptic ulcer six years previously. Three years before his present illness he was subjected to gastrectomy, this being followed by a complete remission of his indigestion.

On the day of admission (August 9, 1952) he was seized with violent upper abdominal pain, mainly localized to the right hypochondrium. He frequently vomited small amounts with each severe attack of pain, which appeared to be colicky in type. The abdomen was explored and a considerable quantity of free sero-sanguineous fluid was found. The great omentum was studded with islets of fat necrosis and several feet of the small intestine was injected, distended, and traced with lymphatic vessels. The pancreas was hard, oedematous, and of a deep-red colour over the whole visible surface of the gland. The biliary tract felt normal on palpation. The abdomen was closed without drainage.

Hexamethonium, 250 mg., was given as soon as the patient was conscious, and this was continued twice a day for the next seven days, four-hourly blood-pressure readings

again being carried out by the nursing staff. The following day he was pain-free, and convalescence was smooth and uneventful. He was discharged fit and well 12 days after operation.

Discussion

The treatment of acute pancreatitis has previously been based on its frequent association with cholelithiasis. It is our opinion that the findings of biliary calculi are coincidental, and that the pathological changes in the gland can be explained wholly in terms of a vascular catastrophe. The more serious or fulminating lesion can be explained by thrombosis or embolism of a main pancreatic vessel. Certainly the appearance of the gland at operation is supportive evidence, but the picture is clouded by the biochemical action, which releases a sanguineous or sero-sanguineous fluid rich in pancreatic ferments. If small areas only are involved they may be absorbed, converted into fibrous tissue, or calcified. It is impossible to reverse a pathological process which has involved sloughing or abscess formation, and this parallel may be seen in the upper or lower limb when embolism or thrombosis occurs in a main vessel. Survival of an organ depends on the location of the thrombosis or embolism, the state of the collateral vessels, and the presence or absence of vasospasm.

It is reasonable to suppose the same vascular phenomena take place in the pancreas, but the exact nature of the process must remain a matter of conjecture.

Andrew Dale (1952) reported optimistic results from the treatment of acute pancreatitis with splanchnic blocks. Our own experience of a single case before this publication supports his findings, but the mode of action is not understood. Ganglion-blocking drugs seem to produce an excellent result. The disease is robbed of its terrorizing pain. It, of course, cannot affect the established gangrenous or suppurative process in a gland which must be subjected to drainage.

In our experience exploratory laparotomy is indicated even if there appears to be no doubt about the diagnosis, as an assessment of the degree of destruction of the gland is then possible, and in the case of gangrenous, sloughing, or suppurative lesions drainage of the gland is indicated. Associated cholelithiasis should be ignored unless the pathology can be directly related to "inflammatory changes" in the pancreas. The inflammatory changes bear a striking resemblance to thrombosis or emboli of the main vessels to other intra-abdominal organs and the upper and lower limbs. Gangrene, sloughing, and suppuration follow gross disturbances of the blood supply, and the severity of the symptoms may be related to the extent of the infarction.

We feel, however, that types 1 and 2 of Fitz's classification might well be treated with drugs of the methonium group. In the cases reported hexamethonium was chosen arbitrarily. Each member of the methonium group varies in effect from ganglion to ganglion, and it may well be that some other member of the group would have a more pronounced action on the splanchnic ganglion. Paton (1951) suggests that tetramethonium may have this action.

In our two cases the relief of pain and the improvement in the general clinical condition were contrary to previous experience. We feel that a vascular catastrophe is the causative factor in acute pancreatitis, and further investigation along these lines may lead to a better understanding of the disease and simplify the treatment.

ADDENDUM.—Since submitting this paper for publication two further cases have been treated with equally successful results. Case 3, a man aged 62, admitted with severe abdominal pain, general collapse, and urinary diastase of 75. Diagnosis was confirmed by exploratory laparotomy, and he was treated with hexamethonium bromide. He was discharged on the tenth post-operative day and has remained free of symptoms for five months. Case 4 was that of a man of 72 with typical acute abdominal pain. The urinary diastase was 68. Exploratory laparotomy confirmed the diagnosis, and treatment with hexamethonium relieved him of his pain. He was discharged from hospital on the twelfth day and has remained free from symptoms for four months.

We are grateful to Mr. Edward Muir for his interest and co-operation.

Institute of Dental Surgery

It is a common experience for dental surgeons to be confronted by small children, aged from 2 years upwards, suffering from gross caries of their deciduous dentition. This condition may arise from a variety of causes, and it is often difficult to decide what is the principal factor in a particular case. If, however, a child known to have normal dental structures suddenly develops rapid decay affecting particularly the labial and buccal surfaces of his teeth, the possibility of chemical damage must be considered. It has been observed that such damage often occurs after the protracted use of some of the commonly used iron tonics.

Certain of these iron tonics are very acid. Representative samples, tested with a Cambridge pH meter, gave the following hydrogen-ion concentrations:

	Undiluted pH	Diluted to 50% with water pH
Syr. ferr. phosph. co.	1.5	1.9
Mist. ferr. sulph. pro infant., N.F.	1.67	2.28
Elix. ferr. glucon., R.F.H.	3.52	3.8
Mist. ferr. et ammon. cit., N.F.	6.66	7.7
"Colliron"	8.56	8.87

The deleterious effect of acids on the teeth is well known. McClelland (1926) showed that teeth left in a solution of pH 4.5 for twelve hours suffered some degree of decalcification, and Stafne and Lovstedt (1947) reported many cases of dental damage following the prolonged and regular sipping of pure lemon juice (pH about 2.5). Hardwick (1950) has demonstrated that the amount of enamel decalcification that occurs when a tooth is immersed in an acid solution does not depend entirely on the pH of the solution but also on the nature of the acid. For example, N/100 lactic acid, with a pH of 2.9, in some circumstances produced etching of the enamel, whereas N/100 hydrochloric acid (pH 2.0) did not.

A laboratory test to ascertain the effect on the teeth of certain stock iron tonics was carried out. Sound teeth were suspended for a week in the various liquids at blood temperature with part of the crown immersed beneath the surface. In this case the resultant degree of damage to the teeth was proportional to the acidity of the solution. Syr. ferr. phosph. co. caused the most damage, the exposed enamel flaking freely away from the cusps of the tooth. Mist. ferr. sulph. produced severe etching and decalcification of the enamel, which could be scraped off the surface with a finger-nail. Elix. ferr. glucon. produced very slight etching, with milky-white decalcified areas. No macroscopical effect was observed on the teeth immersed in mist. ferr. et ammon. cit. or colliron.

It is the custom to advise that some iron tonics, notably Parrish's food, should be taken through a straw or a glass tube, but this presents practical difficulties, and in small children the parent usually gives it undiluted from a teaspoon. If this practice is continued for long the teeth often present a typical clinical picture—decalcification of the labial surfaces of the upper incisor teeth, usually accompanied by dental caries. If, as is often the case, the tonic is sweetened with syrup, the risk of caries will be considerably increased. In severe cases the teeth eventually disintegrate, break off level with the gum, and leave roots that quickly become diseased.

Syrup *per se* has been observed to cause damage to the teeth. The original sugar dummy, where the parent wrapped a lump of sugar in a handkerchief and thrust it in the child's mouth, has been popularly superseded by the immersion of a rubber dummy in rose-hip or blackcurrant syrup before use, with frequent replenishments throughout the day and night. This, if continued for any length of time, results in a startling destruction of nearly all the teeth. The pH of a popular brand of blackcurrant syrup is 3.

It is not suggested that dental damage invariably follows the use of iron tonics. The amount of harm depends on the acidity of the tonic; on the frequency, length, and method of administration; and on individual susceptibility. But the regular introduction into the mouth of highly acid and syrupy fluids is obviously a potential risk to the dental structures.

Medical Memorandum

Spontaneous Rupture of the Oesophagus Treated by Operation

Although, following Barrett's comprehensive review in 1946, the symptomatology of spontaneous rupture of the oesophagus is firmly established, failure of recognition remains the greatest impediment to successful treatment. If the diagnosis is made early, and immediate operative repair effected, the patient has an excellent chance of complete recovery. It is clear from recent reports, both British and American, that, in spite of the occasional survival of a patient after repeated thoracentesis, plus delayed drainage of the pleural cavity or of a localized abscess, the treatment of choice is immediate operation, and the transpleural approach seems preferable to the mediastinal one. To the growing list of successful cases the following is added.

CASE REPORT

On January 4, 1950, a manual labourer aged 53, without previous history of digestive upset, was admitted to hospital with the complaint of severe left-sided pain of six hours' duration. He had been celebrating the New Year holiday by an indulgence in alcohol much beyond his wont, and he felt rather seedy when he returned to work on the 4th. At the mid-day break he ate, without appetite, his lunch, and thinking that some beer might act as a stimulant he drank a pint, and felt, if anything, rather worse. He thereupon, in continued hope, had a second pint, and he had not long finished it when he felt sick, and brought up a large vomit of food and beer. He continued to feel uncomfortable and he retched violently, and as he did so was seized with a sudden excruciating pain in the left side about the lower part of the chest. He distinctly remembers that he had expected to vomit on this occasion, but did not in fact do so. The pain was so agonizing that he was almost struck to the ground. He was helped to his home, and six hours later, about 6.30 p.m., was admitted to hospital. The original pain over the left chest was still present, and it had spread across the epigastrium and through to his back between his shoulder-blades.

On admission he was pale, distressed, and sweating; his temperature was 96.8° F. (36° C.), pulse 112, respiration 22, and blood pressure 110/85. There were dullness and diminished air entry over the left lung base, and some tenderness but no rigidity in the epigastrium. He was originally thought to be suffering from pneumonia. At 10.30 p.m. his blood pressure had fallen to 98/70 and his pulse had risen to 150, while the left lung base was completely dull on percussion and breath sounds were absent. The left chest was needled and brown turbid fluid, smelling of beer, aspirated. No subcutaneous emphysema was observed. At this stage a diagnosis was made of spontaneous rupture of the oesophagus with perforation into the left pleural cavity, and arrangements were put in hand for operation, an intravenous plasma drip being set up. In spite of this and the administration of morphine, the patient continued in great pain and severe shock.

Operation was carried out at 1.30 a.m., the left thoracic cavity being opened through the bed of the eighth rib. About 2 pints (1.1 litres) of opaque brown fluid, smelling of beer, welled out of the pleural cavity and there was considerable contamination of the cavity with food particles. A ragged tear about 2 in. (5 cm.) long was found in the pleura over the lower end of the oesophagus, and a longitudinal tear about 1 in. (2.5 cm.) in length in the left postero-lateral wall of the oesophagus an inch or so above the diaphragm. The rent in the oesophageal wall was clean-cut and healthy-looking, the tissue around it greyish black and necrotic. It was notable that whenever the pleural cavity had been cleared of stomach contents the condition of the patient greatly improved. The rent in the oesophagus was easily repaired with interrupted catgut sutures, and the wound in the chest wall closed, the pleural cavity being drained through a stab wound.

The next day the patient's condition was satisfactory and it remained so. Fluids were allowed by mouth on the second post-operative day. Convalescence was somewhat retarded by a haematoma at the posterior end of the thoracotomy wound, and a slight purulent discharge from the stab wound, so that he did not leave hospital until February 1. On his discharge he felt reasonably fit but was troubled with a slight cough. He was referred back to hospital on February 17 because of increasing breathlessness and cough. X-ray examination then showed an abscess cavity in the lower lobe of the left lung. While the patient was awaiting admission to the thoracic unit he coughed up the contents of the abscess, and thereafter the pulmonary infection rapidly resolved. He returned to work in April and has been in full work since and in excellent health.

COMMENT

The history of the abortive vomit with sudden agonizing pain and collapse in a previously healthy man, the profound shock, only partially alleviated by plasma transfusion, the resistance of the pain to morphine, and the rapidly increasing dullness at a lung base suggested the diagnosis: the aspiration from the left pleural cavity of stomach contents confirmed it. The absence of clinical evidence of surgical emphysema may be accounted for by supposing that the gastric contents, having ruptured the oesophagus, very rapidly tore a large gap in the left pleural membrane, and that gastric contents and air found a readier egress into the pleural cavity than into the tissues of the mediastinum. This case supports the view that the best hope for patients with spontaneous rupture of the oesophagus is early operation, and that much time should not be lost in pre-operative attempts to overcome shock completely, for this end is unlikely to be achieved except by operation.

I wish to thank Dr. James Brown and Mr. David Proctor for making the diagnosis, and Dr. James Stewart for the excellent anaesthetic management of a very ill patient.

Reviews

RESEARCH IN WARTIME

History of the Second World War: Medical Research. Edited by F. H. K. Green, C.B.E., M.D., F.R.C.P., and Major-General Sir Gordon Covell, C.I.E., M.D., D.T.M.&H., D.P.H. (Pp. 387. 40s.) London: H.M. Stationery Office. 1953.

This volume of the official history of the second world war describes the achievements of medical research undertaken for purposes connected with the war and sponsored by the Medical Research Council, the fighting Services, and other Government departments. Although some purely clinical subjects are excluded, the field covered is wide, especially since some of the matters brought in have a tenuous connexion with the war effort, or belong largely to the periods before or after the war: examples are the Prophit survey, the vole bacillus vaccine, a survey of mycoses, partition chromatography, and the use of radioactive isotopes. There is an excellent account of work done by scientists in conjunction with Service personnel to improve the safety and efficiency of the combatant. The variety of this work and its influence even on the design of weapons and other equipment will surprise anyone not familiar with it. The prevention of infection in wounds and burns, the nature of shock, blast injury, the transfusion of blood and blood products, and "chemical defence research" (with emphasis on B.A.L.) also naturally find their place. Descriptions are given of the development of penicillin, of new methods for preventing or treating typhus and malaria, of studies of epidemic hepatitis and serum jaundice, hospital cross-infection, and air disinfection. A chapter is given to the nutritional studies on which our rationing system was so successfully based and to treatment of starvation as seen at such places as Belsen.

The book is full of interesting and unfamiliar information. How many people know, for instance, that whole serum was issued as tetanus antitoxin early in the war to save the time needed for purification, that portions of the International Standards for antisera were sent to Canada in 1940 for safety, that a passenger lost both hands from frostbite after being ferried across the Atlantic in a bomber, that conscientious objectors were used for experiments on the transmission of scabies, that anaesthetized volunteers were used to determine whether life-saving jackets would safely support an unconscious man, or that the discovery of *Br. melitensis* infection in cattle once led to a suspicion of bacterial sabotage? Although many contributors were responsible, the editors have clearly played a large part in producing this volume, since its style is singularly uniform and lucid. It worthily places on record the achievements of perhaps the most fruitful period of research in our history, a period when every task was urgent and every first-class brain was ready to help in furthering it. Each chapter has an ample bibliography, and readers for years to come will find this a valuable work of reference.

L. P. GARROD.

INTRODUCTIONS TO GENERAL PRACTICE

An Approach to General Practice. By R. J. F. H. Pinsent, M.A., M.D.(Cantab.). With foreword by Sir Lionel Whitby, C.V.O., M.C. (Pp. 166. 12s.) Edinburgh and London: E. and S. Livingstone. 1953.

An Introduction to General Practice. By D. Craddock, M.B., Ch.B., D.Obst.R.C.O.G. With foreword by Sir Heneage Ogilvie, K.B.E., D.M., M.Ch., F.R.C.S. (Pp. 552. £2 2s.) London: H. K. Lewis. 1953.

These two books by obviously able and conscientious general practitioners are well worth reading.

Dr. Pinsent takes the young doctor through his first surgery and then introduces him to the office work of general practice, to his colleagues, and to his patients. The chapter on the mind of a doctor is full of wisdom and understand-

ing. He puts in a plea for research and welcomes the College of General Practitioners. He demands the highest clinical standards and urges the young practitioner to get some professional work outside general practice so as to avoid letting his mind become hidebound. Dr. Pinsent has an observant eye and an inquiring mind. He knows precisely when to consult, when to send to hospital, and when to treat on his own. Perhaps for this reason he is slightly condescending towards consultants, though he correctly describes the etiquette of a domiciliary consultation. He is full of self-assurance and pride in his work. These are admirable qualities, but they may be the cause of stumbling. Even with open x-ray departments and pathological laboratories many practitioners admit that they consult not only to have a diagnosis confirmed but also to find out what is wrong or how to treat. It is no doubt useful to have guidance about the sort of condition which requires hospital treatment and the sort which should be treated at home, but it is unwise to make set rules. It is also unwise to give the impression that sending a patient to hospital relieves the general practitioner of all responsibility. Sending a patient to hospital should be like calling in a consultant. To consult, as Dr. Pinsent shows, is to share but not to shed responsibility.

Dr. Craddock has written almost a textbook. He discusses briefly and "tidily" the conditions commonly met with in practice, dealing more fully with mother and child and family planning. His wide knowledge will be the envy of his colleagues. His detailed account of the techniques and prescriptions used in practice will be invaluable to old and young. His style is didactic and his opinion sometimes open to criticism. Not everyone believes in the virtue of adrenaline cream. He, too, demands a high clinical standard and holds a firm belief in the value of the general practitioner not only as a physician but as a philosopher.

Such a textbook accentuates the difference between hospital practice and general practice. The difference exists, but, if there is a fundamental difference of method in, for example, history taking and clinical examination, there is a danger that general practice may come to have a mystique as well as a technique of its own. This will widen the gulf. Men such as registrars having been trained in hospital will not accept nor be accepted by the mysteries of general practice. Only the young men with little hospital experience will find an entrance. If that occurs there is something wrong either with medical education or with general practice.

These books will be helpful if they are used to crown but not to supplant the training and ideals learnt in a good medical school. General practice must advance in step with the advances of medicine, and these are made in hospitals. Only a close association with hospital work will enable a general practitioner to keep abreast. Only close association with general practitioners will enable the hospital to keep a sense of proportion and humanity.

C. W. WALKER.

MORE SOCIAL MEDICINE

Social Medicine. By S. Leff, M.D., D.P.H., Barrister-at-Law. (Pp. 297. 28s.) London: Routledge and Kegan Paul. 1953.

This volume is the first of a series integrated to form a survey of human biology, and to be written by a number of authors. It is intended to provide a guide for doctors and other health workers in the exploration of social medicine. The author defines social medicine, but, like so many others before him, fails to provide a definition which is both concise and clear. The preface envisages possible criticism of the book on the grounds of undue emphasis on environmental and social factors. Any criticism on that score would be quite unjustified: environmental conditions have been too much neglected in recent years by the medical profession, and any trend in the opposite direction is to be welcomed rather than deplored. The vast industry of the

author is obvious from the text, and from the long list of his sources, which are fully catalogued and carefully referenced. The index is comprehensive and accurate. The paper, printing, and binding are excellent.

Dr. Leff looks far beyond the frontiers of this country: his outlook on social medicine is international in character, and that is good. There is a tendency here and in America to be too engrossed in the work near at hand and to forget that it is the duty of the advanced and fortunate countries to provide the greatest possible help to the backward peoples of the world. This book gives many striking examples of appalling conditions in some countries abroad, and will help to make conscience less easy and effort in aid more intense.

The language at times lacks precision. Some of the statements are too sweeping: for example, "diabetes . . . is cured by an injection of insulin," and "asthma is caused by a spasm of the bronchioles, and is cured by drugs which relieve the spasm." It all depends on what is meant by "cured"—the chronic asthmatic might well argue wheezily about that. Then there is a statement that diphtheria immunization was not introduced into Great Britain until 1941; it was, in fact, commonly practised in this country so long ago as 1927, and in one English city alone 16,000 persons were immunized against diphtheria in 1935.

This book is well worth reading, but I am unable to commend it as unreservedly as I did the author's previous book on the health of the people.

C. METCALFE BROWN.

A HOMOSEXUAL'S VIEW

The Homosexual Outlook: A Subjective Approach. By Donald Webster Cory. With an introduction by Dr. Albert Ellis. (Pp. 326. 18s.) London: Peter Nevill. 1953.

The publication in an English edition of this book must be considered timely (perhaps almost too timely!) in view of the excited interest in the problem of homosexuality existing at present. The book is unique in the history of serious homosexual literature in the sense that it is a comprehensive sociological study written by a self-avowed homosexual, who is neither a physician nor a lawyer. The problem is, therefore reviewed from the inside, as it were, as well as objectively. This approach is in a way advantageous, for no one can be held to be altogether detached and objective in dealing with an emotionally overcharged problem of this kind.

The appearance of *Sexual Behaviour in the Human Male* (the first volume of the Kinsey Report) came as a startling revelation to the public, lay and medical alike, of the vastness of the homosexual problem. This book provides information on the nature (rather than the extent) of the problem which will surprise the reader, even if he regarded himself as already knowledgeable. Mr. Cory maintains that, from the sociological point of view at any rate, homosexuality should be regarded and treated as an important minority problem in the same way as colour prejudice, anti-semitism, and anti-Catholicism in Protestant countries (and anti-Protestantism in Catholic countries), and similar problems that have to be dealt with. It is for that very reason that objective judgments are so seldom forthcoming, for the hostile emotions aroused in the majority groups at the worst vitiate sound evaluation, and at the best give rise to biased rationalizations.

As to the efficacy of analytical psychotherapy in any of its forms in the treatment of psychosexual inversion, the author maintains that well-established homosexuality can never be eliminated. All that it can serve to do is, in certain cases, to release whatever heterosexual potentialities there may be in the patient's make-up by freeing him from his irrational fears and guilt-feelings. While this may help in bringing about a more satisfactory social adjustment, it cannot be regarded as a "cure."

As to the moral-theological aspect of the question, many will find themselves in disagreement with the author; but this side of the problem should not be allowed to bedevil

the reader's outlook, provided he consistently distinguishes between the concept of sin and that of crime, as all sound moral theologians should do.

Without comment I conclude this short review with a quotation from Dr. Albert Ellis's introduction: "All told, *The Homosexual Outlook* is by far the best non-fictional picture of the American homosexual and his problems that has yet been published. It is *must* reading for all inverts and for everyone who wishes clearly and fully to understand the question of homosexuality. It is a decidedly serious, honest, discerning, moving and creditable piece of work. Even those who most violently disagree with its views will find this volume to be stimulating and worthwhile reading."

E. B. STRAUSS.

VOMITING IN INFANCY

Les Vomissements du Nourrisson. By Emilio Roviralta. (Pp. 240; 80 figures. 1,800 francs.) Paris: Editions Médicales Flammarion. 1953.

Vomiting in infancy has been described by a medical student as a headache to parents and doctors; and when this assessment is apt—as in some of the recurrent, cyclical, and chronic cases—the chief reason is uncertainty about the cause. Professor Emilio Roviralta, who has had a long experience of paediatric surgery in the Polyclinic of Barcelona, has done a notable service to clinical medicine, as well as to paediatric surgery, by preparing this study. He exposes and attacks some of the false teaching about vomiting in infancy, and pleads for accurate case-taking, careful clinical examination, and the more general use of radiography. This is the road leading to correct diagnosis, and therefore to appropriate treatment.

At many centres in Britain the advice tendered so skilfully and authoritatively by Professor Roviralta is already followed, and abnormal conditions such as partial hernia of the stomach, diaphragmatic hernia, chronic duodenal stenosis, broncho-oesophageal hernia, and oesophageal atresia, with their puzzling clinical symptoms, are well known and are considered in differential diagnosis. But even in these centres much could be learnt from reading and pondering over this book, which has the great merit of being based on the personal experience of a worker who thinks clearly and honestly. His conclusions are especially valuable because they have had to find their way through a finely critical sieve. There is emphasis on many points of practical importance: for instance, the radiologist should be specially experienced in paediatric radiology; the vomiting baby may choke himself by inhaling food; and to give barium to a baby whose oesophagus is stenosed is likely to be dangerous. These facts, and many others to which the author refers, should be more widely known, and the volume is likely to be of interest not only to the experienced paediatrician and paediatric surgeon but also to the younger clinician, who will be stimulated by the scientific integrity of the work and its presentation. Radiographs are published to illustrate the reports, and there is a long bibliography.

NORMAN B. CAPON.

Though thriving on decay and often the cause of it, the fungi have yet given man many priceless benefits; high among them are penicillin, ergot, and Château Margaux '29. A few species out of this great host of parasites and saprophytes cause diseases with which we are familiar; many more destroy crops and have on occasion brought starvation by causing potato famines; others, again, reduce dwellings to dust—dry rot having been at least the physical cause of the fall of the House of Usher. An excellent account of these ubiquitous and influential plants has now come from the pen of Dr. John Ramsbottom under the title *Mushrooms and Toadstools* (Collins, 30s.). He writes for the layman, though he does not stoop to popularize a serious study, giving a discursive and often amusing account of his subject, on which he is an international authority. Doctors with a bent for natural history will enjoy this book, and it may be particularly commended as a Christmas present. It is well produced and contains many beautiful illustrations in colour and monochrome.

SATURDAY DECEMBER 5 1953

HYPOTHERMIA

In the past little attention has been paid to the fluctuation of body temperature in a patient undergoing a major surgical operation, but in recent months the increasing interest in induced hypothermia has raised the question whether the maintenance of a normal body temperature is desirable at all times. The fact that a fall in body temperature is accompanied by a corresponding reduction in the oxygen consumption of the tissues led to the suggestion that hypothermia might be helpful when, in cardiac and cerebral surgery, the interruption of blood flow to the vital organs is contemplated. Various methods have been proposed for reducing the body temperature in man. First, the temperature of the patient's environment can be lowered after routine induction of anaesthesia, controlled at such a depth as to prevent shivering. This reduction of temperature is achieved either by immersion in cold water,¹ by a draught of cold air,² or by a cooling blanket.³ A second method is to create an artificial arterio-venous fistula and cool the blood during its passage through the fistula.⁴ And, thirdly, French authors⁵ have recently claimed that a combination of drugs—the "lytic cocktail," containing pethidine, promethazine ("phenegan") and chlorpromazine ("largactil"), which is thought to be the most active constituent—has a specific action on the thermo-regulating mechanism and autonomic system and thereby lowers the patient's body temperature.

Chlorpromazine has been developed from the alkylamine derivatives of the aromatic base phenothiazine. It is said to be almost completely devoid of anti-histaminic activity, but it has several incompletely defined actions on the central nervous system, including central depression extending particularly to the vomiting centre and possibly to the sensory, motor, and autonomic activities of the thalamus and hypothalamus. In addition to exerting these central effects, chlorpromazine is reported also to be an anti-adrenaline compound.

Elsewhere in this issue Dr. J. W. Dundee and his colleagues and Drs. A. Smith and J. G. Fairer report the first two series in this country of the use of the "lytic cocktail" as a new method of anaesthesia for

poor-risk patients undergoing surgical operations. In both these series the majority of the operations performed were for either gynaecological or abdominal conditions. As the theoretical advantage of the use of hypothermia in such cases is based on the reduction of metabolism it is interesting to note that in Dr. Dundee's series the average fall in body temperature of 3.4° C. was accompanied by a fall of oxygen consumption of approximately 20%. In one patient the body temperature was reduced nearly 10° C., yet the oxygen consumption fell by only 10%. This case emphasizes the danger of shivering, even at such low temperatures, for if it is not properly controlled it must necessarily throw an extra load on the circulation and increase the risk of ventricular fibrillation. The fact that these drugs produce an autonomic blockade in man is confidently expressed by Dr. Dundee and his colleagues in the title of their paper, but they do not present any evidence to corroborate such a view. It is possible that their findings might be accounted for on the basis of depression of the central nervous system. The mortality of 20% (hypothermia being a contributory cause of two deaths) in this series of 25 cases is a salutary warning to other anaesthetists eager to use this technique, and note should also be taken of the incidence of post-operative complications, including vomiting, haemorrhage, prolonged hypotension, and a sudden fall in blood pressure. These findings by experienced observers make it easier to place some of the previous extravagant claims for this technique in their correct perspective. It is perhaps a pity that the Liverpool team did not study the use of chlorpromazine alone, for more knowledge of the actions of this much discussed drug is still needed.

In their studies on the use of hypothermia in animals Dr. Dundee and his colleagues made a number of interesting observations. First, whether they used deep pentobarbitone anaesthesia, light pentobarbitone anaesthesia and muscle relaxants, or the "lytic cocktail," they found that all three methods brought about approximately the same rate of fall in body temperature. Further, they concluded that the value of pethidine and promethazine ("phenegan") in reducing metabolism and preventing shivering was dubious. These findings might suggest that, provided sufficient depression of the shivering reflex was obtained, the "lytic cocktail" possessed no great advantage over more familiar methods of anaesthesia.

Another recent paper on the use of hypothermia comes from Swan and his colleagues⁶ in Denver. Their series comprised fifteen patients, mostly children, who had undergone cardiac operations while they were in a state of hypothermia, with body temperatures ranging from 21.5° C. to 26° C. Hypothermia was induced during anaesthesia (thiopentone—cyclopropane—ether) by immersing the patient in iced water. At operation the chest was opened and in thirteen cases the circulation was stopped for periods varying from 2 to 8½ minutes by clamping the venae cavae, the aorta, and the pulmonary artery. The heart or pulmonary artery was then opened and the operation performed under direct vision. By this method four cases of atrioseptal defect and nine cases of pulmonary valvular stenosis were repaired, with only one fatality. The authors claim to have made great progress in the prevention of two serious complications of operations on the open heart under hypothermia—namely, ventricular fibrillation, which is combated by the use of an injection of a solution of 0.5 mEq potassium in 2 ml., and coronary air embolism, which is prevented by complete immersion of the heart in saline at the time of the closure of the cardiectomy.

Such results from the use of hypothermia in cardiac surgery are the most encouraging that have yet been published. But knowledge of this subject is still not sufficiently advanced to justify the use of deep hypothermia in general surgery. Great caution must be used in the selection of cases, and one hazardous procedure, induced hypotension, should not automatically justify a further hazardous procedure, hypothermia. The method of lowering the body temperature may not be of great importance: further comparative studies between the usual anaesthetic techniques and the "lytic cocktail" in conjunction with physical methods of inducing hypothermia will be needed before the matter can finally be settled.

B.C.G. IN SCHOOLS

To many it must seem strange that official sanction has now been given¹ for the B.C.G. vaccination of older schoolchildren before the completion of an official trial designed to determine how useful such a scheme would be. But to appreciate the reasons for this development it is necessary to probe a little more deeply. In 1949 the Ministry of Health and the Department of Health for Scotland authorized chest physicians and others to use B.C.G. in tuberculin-negative persons in contact with tuberculosis, especially home contacts, hospital nurses, and medical students.² This

limitation was placed because out of the vast schemes of vaccination abroad the only cogent scientific evidence that seemed applicable to the British scene was of its value in those peculiarly exposed to the disease, in whom it reduced the incidence at least of primary and early post-primary tuberculosis.^{3,4} This first scheme has been working well, though in some areas, even now, the numbers vaccinated fall short of those that qualify. However, important questions on the true value of mass vaccination remained unanswered. Although there was no indication for vaccinating all tuberculin-negative persons, did any section of the population, not individually known to be in contact with cases of the disease, merit consideration? What degree of protection would be expected under ordinary conditions of life in an industrial community with a comparatively low and falling mortality, moderate morbidity, and fairly high living standards? How much emphasis relative to other antituberculosis measures should the authorities place on mass vaccination in the general campaign? Of all sections, children about to leave school and enter the industrial world seemed to call for attention. No adequate statistically controlled trial of B.C.G. (including random and not voluntary selection of persons to be vaccinated or left unvaccinated, and specific planning in advance rather than analysis in retrospect) had been made anywhere on such a group, and the desirability of remedying this deficiency had been repeatedly urged.⁵ Only two countries—Britain and the U.S.A.—had the resources for a trial and were in the advantageous (or shameful, according to the point of view) position of not already having established widespread B.C.G. vaccination; if not seized, the opportunity would be lost.

Accordingly the Medical Research Council set up a Tuberculosis Vaccines Clinical Trials Committee under the chairmanship of Dr. P. D'Arcy Hart and with Ministry of Health representation. The committee planned a large-scale controlled trial both of B.C.G. and of vole bacillus vaccine (Wells) in secondary modern school leavers in the Home Counties and in and around Birmingham and Manchester, and the work was put in the hands of the Council's Tuberculosis Research Unit. Apart from discreet

and welcome information⁶ that this research scheme started towards the end of 1950, that over 50,000 young people enrolled between then and the end of 1952, and that its machinery is running smoothly, we are unlikely to hear anything definite from this committee for several years. This is as it should be, since premature assessment of results of any statistical investigation of a protective in tuberculosis might be misleading. A controlled study of B.C.G. vaccination in schoolchildren and others on rather different lines had been initiated by the U.S. Public Health Service in 1947.⁷

Pressure to introduce B.C.G. vaccination in this country as a routine measure for all school leavers has not been lacking in the meantime. Some tuberculosis specialists and paediatricians argued that, even though the M.R.C. investigation was expected to give a quantitative assessment of the true value of the vaccine in present-day circumstances in Britain, the evidence from abroad justified this further action being taken forthwith. The reasoning of these advocates followed two lines: first, since contacts were already offered the vaccine here on the basis of acceptable evidence of efficacy, school leavers who were about to be exposed, in the mass, to an increased risk of contact with the disease might, by extrapolation, be expected to derive at least some benefit; secondly, a few of the recent mass vaccination studies abroad, comprising follow-up of unvaccinated along with vaccinated groups, are regarded as highly suggestive or more,^{8,9} shortcomings¹⁰ and differences in milieu notwithstanding. Admittedly a scheme in which every tuberculin-negative child in the appropriate age group was offered the vaccine could give no information on the latter's efficacy in the succeeding years unless the attack rate of tuberculosis proved to be nil—which could not be expected.^{11,12}

Impressed by these lines of argument as representing a reasonable viewpoint—though not the only one—the Ministry of Health has now¹ offered all local health authorities in England and Wales additional supplies of B.C.G. should they wish to extend its use to children approaching their 14th birthday, while continuing the scheme of vaccination of contacts. At the same time a memorandum¹³ giving a balanced review of the status of B.C.G. has been provided to assist the local authorities, but, wisely, no attempt is made to influence their individual decisions whether to take action or not. Those authorities who adhere closely to the favourable views already mentioned will undoubtedly go ahead, strengthened in their decision by the knowledge that the vaccine is harmless and that local and glandular complications are not troublesome in adolescents. If they do so, the Ministry urges that there should be no interference with

the current M.R.C. investigation proceeding in certain areas (this should not happen, since the intake of children has been completed and the volunteers have left school). Other authorities will be more cautious, believing that there is no need for urgency in an improving tuberculosis situation; that it is better to wait two or three years for the results of the M.R.C. investigation concerned with this very problem; and that the exposure to which these young people will be subjected in their various occupations will, on the average, be so much more dilute than those of individual contacts covered by the first national scheme that the consequent protective benefit may be quite small. These authorities will in turn be strengthened in their decision by the preliminary report of the U.S. Public Health Service's controlled trial,⁷ which states that a large proportion of the tuberculosis appearing in the first few years of their scheme was in the group initially tuberculin-positive and therefore not candidates for B.C.G.; so far the amount of tuberculosis occurring in the initial tuberculin-negative persons, whether vaccinated or not, is still too small to show if B.C.G. has been effective. This report concludes that at present the American studies "do not indicate that tuberculosis in this country would be more effectively controlled by adding mass vaccination programs." The decision facing each local health authority is thus far from easy, since the issue is unclear. It is known that some have already decided to take part in the new scheme, and others to postpone extension. Either course is probably in accord with the discharge of their responsibilities to the community.

INFECTION AND POLIOMYELITIS

At the World Health Organization conference on poliomyelitis held at Rome in September there was much discussion about the spread of infection and its prevention. The general public is naturally much concerned about this, and it is doubtful whether the medical profession, concentrating on treatment, has in Britain given enough attention to what is known of the infectivity of the disease and to preventing its spread. The belief is commonly held that, in an epidemic of poliomyelitis, virus is widely and indiscriminately spread throughout the population, and that a clinical case is a rare incident in an outbreak of mass infection. This view has been contradicted again and again by careful studies of infected communities, and there is no virological or epidemiological evidence to support it. On the contrary, these studies invariably show that the virus is spread by close contact and that the path of its spread, when it can be traced, is quite narrow. Adamson,¹

describing a winter epidemic among Eskimos in Hudson's Bay territory, showed how the spread of infection from one settlement to another followed the movement of man across hundreds of miles of frozen snow. The nature of the country and the habits of the people sharpened the lines of this epidemic, but the same pattern can be traced in all types of communities. Silverthorne² described the investigation of outbreaks in Dufferin County, Ontario, a rural area of over 500 square miles with 14,000 inhabitants, most of them living in large farms and villages. When poliomyelitis broke out, a team of experts moved in and studied the problem by carefully inquiring into the habits and movements of all contacts. Out of 28 cases, close contact with a previous case was proved in 17; moreover, of the 28 cases, only 12 were frank clinical cases; the other 16 suffered from the "minor illness" and would probably not normally have been recognized as cases of poliomyelitis. Of 37 cases described by Casey,³ 29 were paralytic, and all of them followed short visits to the vicinity of a previous case. Examples quoted so far refer to rural areas, but Casey and others⁴ have described similar investigations in the centre of Chicago. When a case was reported, a block of dwellings round the patient was defined and all residents aged under 25 came under survey; their habits at work and play, especially for the three days before and after the onset of illness in the case, were scrutinized. For control, another block, at least half a mile away, was chosen for a similar survey. This method was called "intensive neighbourhood study." Among 66 persons regarded as contacts, 37 fell ill, 24 diagnosable as poliomyelitis; among 109 non-contacts in the block, 4 fell ill; and among 115 non-contacts in the control block, 5 fell ill. The contact was always a close one, usually in the family or among playmates. Pearson and others⁵ studied household infection: in 127 households where there was no known contact with poliomyelitis, virus was isolated from 2 (1.6%); in 45 households with non-familial contact, virus was present in 8 (18%); and in 8 households where there was a paralytic case it was found in 6 (75%).

We must regard the family as an infected unit. The clinical case, although quite possibly a more efficient spreader of infection, is not a solitary victim of the virus: it can usually be shown by virus studies that all or most of the other members of the family are infected almost simultaneously.⁶ How the family is first infected and how the virus spreads

from one person to another are problems still not solved. The type of contact necessary is evidently the type of association that occurs in families, among playmates, at children's parties, and in neighbourly visits. Faecal and respiratory spread are both possible, and hands may be infected by both faecal and respiratory organisms.

Though the exact mechanism of transfer is still uncertain, it is clear that people inside the family infect people outside. Most of these people remain well though infectious, but some become ill with headache, sore throat, nausea, muscular pains, irritability, and malaise. These are the symptoms of the minor illness of poliomyelitis; they are not clear-cut, but, in a known contact, clear enough to suggest infection. How often these illnesses occur can be determined only by close inquiry, and we have mentioned above that Silverthorne reported 16 minor illnesses out of 28 cases. A problem worth looking into is how many cases admitted to hospitals during epidemics of poliomyelitis and finally diagnosed as "constipation and headache," "myalgia," and so on are in fact suffering from this poliomyelitis minor illness.

With all this knowledge, can anything be done to block the line of infection? Quarantine of contacts is the obvious attack, and Agerholm has vigorously pleaded for it.⁷ But, if it is to be effective in this disease, all intimate contact with other people must cease. If children are excluded from school, they must also be excluded from playgrounds, sandpits, parks, alleys, and courtyards. If adults must not go to work, neither must they visit cafés, pubs, or cinemas. Can such restrictions really be enforced? In city life it is most unlikely; in the country similar restrictions are already accepted in outbreaks of foot-and-mouth disease. If compulsion is impracticable, persuasion and public opinion might be more effective. When a case occurs in a family, the parents should be told the facts and asked to co-operate. A simple illustrated pamphlet might help to secure this. During epidemics the public should be informed by press and poster of the dangers of contact infection. It is unlikely that intelligent parents would run risks. As Agerholm points out,⁷ in 1950 people cancelled visits to the Isle of Wight of their own free will. If anything is to be achieved, public health policy must be based on facts: the parents of a paralysed child should no more be heard to say that "the health people have been round and disinfected everything." A good deal of what passes for contact supervision in the common infectious diseases has become a matter of dull routine, delegated to health visitors and sanitary inspectors. In poliomyelitis there is need for expert and inspired inquiry.

A NEW SYNDROME

The work of a pneumoconiosis medical panel might be thought at first to be restricted to routine duties in a narrow specialty and unlikely to afford opportunities for original observation, but it was in the course of his routine duties in assessing cases of pneumoconiosis for industrial injury benefit that Dr. A. Caplan¹ noticed a high incidence of rheumatoid arthritis associated with massive fibrosis in cases of pneumoconiosis. Of 51 cases with rheumatoid arthritis 90% showed massive fibrosis, whereas in 14,000 other cases of pneumoconiosis only 30% had massive fibrosis. On assembling the radiographs of the 51 cases Caplan further noticed that in a quarter of them the pulmonary shadows were of a peculiar and uncommon form. Instead of the usual gradual enlargement of irregular fluffy opacities to form large massive shadows, in these cases multiple, well-defined, round opacities 0.5-5 cm. in diameter appear relatively quickly, usually in the periphery of the lung fields on both sides. The background of simple pneumoconiosis is also less well marked than is usual in progressive massive fibrosis (P.M.F.). After they have appeared, these round shadows usually remain stationary, but sometimes enlarge slightly, may cavitate, and in long-standing cases show some signs of shrinkage. In three fatal cases tubercle bacilli were recovered from areas of massive fibrosis, and Caplan suggested that the joint changes might be a form of "tuberculous rheumatism."

Further epidemiological study was required to establish the validity of this special syndrome and to discover the real association between P.M.F. and rheumatoid arthritis, for the apparent association noted in compensation cases might have been due to a greater likelihood of men with both arthritis and P.M.F. to apply for disablement benefit than men with either alone. Fortunately an appropriate epidemiological instrument was immediately available for such a study, the results of which we publish this week at page 1231. In 1951 Dr. A. L. Cochrane, of the Medical Research Council Pneumoconiosis Research Unit, had x-rayed 95% of all the miners and ex-miners living in the Rhondda Fach.² In 896 of these men a radiographic diagnosis of P.M.F. or clinically significant tuberculosis had been made. From the films of these men Caplan selected 20 as showing the particular appearance which he thought would be associated with rheumatoid arthritis. A random sample (stratified for age) was taken from the films he had rejected, and similar control groups of cases with simple pneumoconiosis or normal films were also chosen. A physician unaware of the radiological diagnosis visited all these men at home to inquire about symptoms of arthritis. The men with a suggestive history were examined, and if necessary fully investigated to confirm the diagnosis. Of the cases selected by Caplan 11 (55%) were found to have rheumatoid arthritis, a proportion differing significantly from the 3% in the controls with P.M.F. or tuberculosis and

none in the other controls. While this epidemiological work has not fully confirmed the association between rheumatoid arthritis and ordinary P.M.F.—for the prevalence in P.M.F. was only just significantly greater than in the normal controls—it demonstrated the reality of the special syndrome described by Caplan. It seems that, given a chest radiograph of a miner which shows the characteristic "rheumatoid" appearance, a diagnosis of rheumatoid arthritis may be made with rather more than a 50% chance of being right.

Among the 20 cases with the "rheumatoid" type of opacity there was a suggestion that arthritis was associated with slightly longer dust exposure, especially to stone dust. The Middlebrook-Dubos agglutination test was positive in 8 of 18 sera tested (44%), contrasting with only 3% of 133 cases of early P.M.F. Only one patient had a positive sputum, and in one elderly man who died there was no evidence of active tuberculosis, the round lesions being histologically similar to ordinary massive fibrosis. There is thus only a suggestion that the pulmonary lesions are tuberculous: the true pathological condition can be shown only by necropsy or biopsy study of recent lesions.

There seems to be no satisfactory explanation for the association between the lung and joint changes. The latter are quite typical of rheumatoid arthritis, unlike those found in hypertrophic pulmonary osteoarthropathy and fibroma of the lung. It seems unlikely that the lung shadows represent a modification by dust of rheumatoid changes occurring in the lung, for no such changes are found in the lungs of ordinary cases of rheumatoid arthritis.³ However, rheumatologists do occasionally observe extensive pulmonary fibrosis in cases of rheumatoid arthritis, more chronic than that described by Ellman and Ball,⁴ and similar lesions have been described in other collagen diseases.⁵⁻⁸ Miall and his colleagues dismiss the possibility that the arthritis is a response to the pulmonary lesions acting as a "septic focus" because of the long interval that may elapse between the onset of each, and they favour a hypothesis that a deficiency of adrenocortical hormones may underlie both the arthritis and a modified response of the lung tissues to dust and infection. Now that this syndrome has been described it will no doubt come to be noted with increasing frequency. Unpublished cases have already been observed in men exposed to other dusts than coal. Miall and his colleagues have provided us with a striking example of the value of epidemiological study, on a defined and unbiased population, in revealing the existence of a syndrome first suspected from clinical observation. Their account, in an appendix, of the observer error encountered in subjective methods of assessment, both of radiographs and joints, should encourage other clinicians to follow their example and test their own abilities with the same critical courage.

SYNTHETIC OXYTOCIN

The first synthesis of a new group of biologically important substances calls for recognition by doctors as well as chemists. That of oxytocin, the principal uterine contracting and milk-ejecting hormone, has lately been

reported by du Vigneaud and others¹ of the Department of Biochemistry, Cornell University Medical College. This is the first polypeptide hormone to be synthesized. But from a footnote to an accompanying publication² it appears that a similar success has probably been achieved also in the case of lysine vasopressin. The latter is a closely related hormone, and a synthetic polypeptide synthesized by similar methods to those used in the synthesis of oxytocin has been found to possess pressor and antidiuretic activity. Oxytocin can be thought of as a cyclic polypeptide and side-chain, with a cystine residue as its key component. Four other amino-acid residues are joined in a closed ring through cystine; they are, in order, tyrosine, isoleucine, and glutamic and aspartic acids (as amides). In a side-chain, attached to one arm of the cystine residue, are proline, leucine, and glycine (as amide). The deduction of this structure by chemical reasoning was perhaps the most important step in du Vigneaud's achievement. Its synthesis, with a first yield of 360 mg., is no mean accomplishment in organic chemistry.

The biological activity of the synthetic preparation has been confirmed, in respect of uterine contraction on an isolated rat uterus, and in respect of milk ejection on a human subject. The total activity, assayed by the chicken-depressor method, is 29,000 units, and the activity per unit weight has been compared with purified preparations of the natural hormone. Although chemical identity is not specifically claimed by du Vigneaud and his colleagues, the evidence for it is thus strong. The case of vasopressin is of further interest from the apparent existence of an inter-species difference in composition. From earlier work on purified natural preparations of hog (leucine) and beef (arginine) vasopressin it had been concluded these hormones differ from oxytocin only in the replacement of the leucine and isoleucine residues of the latter, in lysine vasopressin by phenylalanine and lysine, and in arginine vasopressin by phenylalanine and arginine. The difference between hog vasopressin and beef vasopressin is thus confined to a single residue—lysine in the one, and arginine in the other. Lysine vasopressin has been synthetically prepared, and shown to possess biological activity. A fuller report on this work will be awaited with interest, as also will the confirmation by synthesis of the inter-species difference. While there is usually a considerable gap between laboratory synthesis and practical production—and du Vigneaud's synthesis of oxytocin is laborious—the relatively good yield which he has obtained encourages the hope that supplies of synthetic hormone will eventually become available.

A FORGOTTEN CHAPTER

The new College of General Practitioners in its first annual report refers to a piece of forgotten history—the abortive attempt to found such a college just over 100 years ago. One statement is made, however, which, though literally accurate, may be misunderstood. In

¹ du Vigneaud, V., Ressler, Charlotte, Swan, J. M., Roberts, C. W., Katsoyannis, P. G., and Gordon, S., *J. Amer. chem. Soc.*, 1953, 75, 4879.
² du Vigneaud, V., Lawler, H. Claire, and Popenoe, E. A., *ibid.*, 1953, 75, 4880.

describing the movement to set up the college in the 'forties of the last century the writer says: "The British Medical Association showed itself in favour. A meeting held on November 26, 1844 (Dr. Webster, President, in the chair), resolved," etc. Actually Dr. Webster was never President of the British Medical Association as we now know it, but of an earlier, short-lived, and Ishmaelite body which had assumed that title in 1836, claiming to represent the medical practitioners of the United Kingdom. In 1844 the *Medical Times* reported the British Medical Association as having "met in the person of Dr. Webster on September 28. The secretary was absent, and the resolutions appear to have been moved by the president, seconded by the president, put to the vote by the president, and carried by the president. He was the whole meeting." It was not until 1856, ten years after the first British Medical Association had disappeared without trace, that the body which had hitherto been known as the Provincial Medical and Surgical Association became the British Medical Association.

Nevertheless, Dr. George Webster, a zealous medical reformer of his time, took a principal role in formulating the demand for a charter of incorporation for general practitioners. He was the principal figure at a meeting at Hanover Square on March 14, 1845, when "there were about 1,200 gentlemen present, including the most respectable general practitioners in all parts of London." From a letter by a "village surgeon" who attended the meeting we learn that there was also "a fair sprinkling of country practitioners, as many as, considering the sickly season of the year, and the constantly existing difficulty of locomotion inherent in our calling, could reasonably be expected." An attendance of 1,200 would be considered a bumper one in these days, even in times of medico-political crisis, notwithstanding a less sickly season and better means of locomotion. But, like many other events of this kind, it was only a firework display. Blunders were made in the election of the permanent committee, the draft charter of incorporation was sent to the Home Secretary without being submitted to another general meeting, the confidence of the profession was largely forfeited, and the enthusiasm petered out. The Royal Colleges, too, were not pleased at the use of the words "medicine" and "surgery" in the proposed title of the college. The Home Secretary at that time was the rather ineffective Sir James Graham, who had drafted no fewer than four Bills for the regulation of medical practice. In the last of these he introduced a proposal for a college of general practitioners, but it was a meaningless affair which would have been dependent upon the Royal Colleges.

The present movement has proved much more successful than that of 100 years ago, and the new College, which gained a membership of more than 2,000 before it had been in existence for six months, has been established with good will on all sides of the profession. It is now consolidating itself, building up regional faculties, and preparing to play a major part in the academic field both for general practice and for general practitioners.

CLINICAL PATHOLOGY IN GENERAL PRACTICE

INFECTED URINE

BY

CUTHBERT E. DUKES, M.D., M.Sc., F.R.C.S.

Pathologist and Director of Research Laboratories, St. Mark's Hospital, London;
Pathologist, St. Peter's Hospital for Stone, London

One of the commonest reasons for suspecting a urinary infection is because the urine appears turbid, but this may, of course, be due to other factors than bacterial infection.

It is generally possible to decide fairly quickly whether or not turbidity is due to infection or to other causes. A turbidity which disappears on warming is due to urates only, but if the turbidity remains after the test-tube has been warmed then another sample should be taken and a few drops of acetic acid added, because a cloudiness which clears up with acetic acid only is due simply to phosphates. If the turbidity persists both after warming and after acidifying with acetic acid then it is probably due to pus, to blood, or to bacteria. Urine that is "bell clear" in appearance is very seldom infected.

Microscopical Evidence of Infection

The presence of infection is confirmed by the detection of pus or bacteria in the urine. An infected urine generally contains pus cells, and microscopical examination is the only way of identifying these. Chemical tests for pus are so insensitive and open to so many fallacies that they are hardly worth performing.

The simplest and quickest way of carrying out the microscope test is to take a drop of the urine and run it into the chamber of a Fuchs-Rosenthal slide, such as is used for the examination of cerebrospinal fluid. This differs from the ordinary blood-count slide in that it is ruled to enclose 16 mm.² and has a depth of 0.2 mm., whereas the haemocytometer slide is only 0.1 mm. in depth.

If a drop of urine is pipetted into such a C.S.F.-counting chamber and allowed to settle it can be examined in a few moments, and microscopical examination will show at once whether or not the urine contains pus or blood. One great advantage of this method is that no centrifuging is necessary. Another is that one can decide at once whether the turbidity of the urine is due to pus, blood, bacteria, or crystals, and, if pus is present, roughly how much there is.

The more usual method of carrying out a microscopical examination is first to centrifuge the urine, then to place a drop of the deposit on an ordinary microscope slide, cover this with a cover-glass, and examine with the sixth objective. This is certainly the best method, but if no centrifuge is available the urine may be allowed to stand in a conical vessel for a few hours until a deposit has formed. After decantation of the supernatant urine a drop of the deposit is collected in a pipette and examined on a slide beneath a cover-glass.

Before passing on to bacteriological tests it is worth recalling that sometimes tests for pyuria may give an indication of the location of the infection in the urinary tract. The two-glass test is often sufficient for deciding whether pus comes from the urethra or the bladder. To perform this test the patient is asked to pass urine into two glasses. Pus present in the first glass is assumed to be derived from the urethra, and that in the second from the bladder or kidneys.

In suspected pyelitis or pyelonephritis and in some cases of renal tuberculosis it may be necessary to examine specimens of urine collected separately from the bladder and each kidney. A unilateral tuberculous lesion of the kidney gives rise to pyuria from the affected kidney, whilst the

urine from the opposite kidney and the bladder is clear. Uncomplicated cystitis shows the presence of pus in the bladder urine, but the urine from each kidney is free from pus and sterile. When large quantities of pus are found in urine this is almost always due to cystitis. Pyelitis, pyelonephritis, prostatitis, and urethritis usually give rise only to a relatively slight degree of pyuria.

Collection of Specimens for Bacteriological Tests

Specimens of urine for bacteriological examination need to be collected with special care and to be examined as soon as possible. Catheterization is not always necessary. For male patients a mid-stream specimen collected after cleansing the urethral orifice is generally quite satisfactory for bacteriological tests. Catheterization is more often required with female patients; in fact, if urine from women is found to contain a few pus cells and bacteria a catheter specimen is generally necessary in order to decide whether or not infection is present. Naturally catheterization should be avoided if possible, and it is worth pointing out that with reasonable care a clean specimen can often be obtained from a woman patient. A preliminary examination of this may be enough to decide whether or not catheterization will ultimately be necessary. The collection of a "clean" specimen of urine from infants or young children is a task which may tax the ingenuity and resources of all concerned.

Microscopical Examination of Stained Films

The next step is the examination of stained films from the centrifuged deposit, and for the preparation of these a drop of the deposit is spread evenly over a microscope slide and allowed to dry. The film is then fixed with heat by passing it three times through a flame. All urinary deposits should be stained with Gram's method as a routine. The great advantage of this stain is that it distinguishes between the staphylococci, which are Gram-positive and appear purple in the stained film, and gonococci, which are Gram-negative and stain red. It is useful also in distinguishing the common Gram-positive diphtheroids and Döderlein's bacilli from Gram-negative bacilli such as *Bact. coli*, etc.

Whether or not any other stains should be used depends on the nature of the case. If there is no reason to suspect tuberculosis or other unusual infection, it is not necessary as a rule to stain more films. On the other hand, if the Gram stain shows the presence of pus cells but no bacteria, or if tuberculosis is suspected, the films should be stained by one of the methods used for acid-fast bacteria. Tubercle bacilli are rarely found in large numbers in the urine, and it may take several minutes' search to find them in a stained film, but bacteria like staphylococci, *Bact. coli*, and other coliform organisms are present in such large numbers that they can be recognized by one glance at the stained film.

Bact. Coli Infections

Infection with *Bact. coli* is a common finding. It may give rise to infections of the kidney, bladder, prostate, or epididymis, each of which has its own distinctive symptomatology. When the urine is found to be infected with *Bact. coli* the next step is to discover which part of the urinary tract is affected. This may generally be decided from the clinical history and the results of physical examination, but in exceptional cases it can be determined only after the collection of urine from the bladder and each kidney separately.

Meanwhile the problem remains, why has the infection occurred? *Bact. coli* is a relatively harmless microbial species and rarely causes trouble in organs which are functioning normally, so it becomes the object of clinical examination not only to decide where the infection is located but also why this region is affected. Many *Bact. coli* infections of the urinary tract are unlikely to be permanently cured until some underlying structural or functional defect has first been removed. Special predisposing causes are peculiar to different periods of life, such as infancy, pregnancy, or the years when prostatic obstruction is apt to set in.

Urine infected with *Bact. coli* is hazy when passed and has an opalescent appearance. If the urine glass or bottle is held up to the light and rotated to circulate the urine, the haziness appears like a drifting mist, a very characteristic feature. This is caused by the innumerable bacteria suspended in the urine. The haziness of the urine varies in intensity in different samples, being most evident in the early-morning urine. Later in the day the urine may be almost clear. The hazy opalescent appearance is only found in samples of urine almost free from pus. If much pus or blood is also present it will cause a turbidity which conceals the characteristic appearance of a simple bacilluria. In some cases of *Bact. coli* infection the urine has a peculiar fishy odour, but this is not invariably characteristic. The faculty of smell is rarely used as an aid to diagnosis in any branch of medicine nowadays, and without being fastidious most of us would agree with the views of the seventeenth-century physician who wrote: "It is too base and sometimes dangerous for the physician to put his nose to the urine to discern the stench thereof."

Proteus and Pyocyanus Infections

Urine infected with proteus has the same general appearance as in *Bact. coli* infections but may also contain a small quantity of viscid ropy mucus in which the pus cells are suspended. The reaction is usually alkaline, and triple phosphate crystals and amorphous phosphates are commonly found in the deposit.

Infections with proteus may occur either in the bladder or in the kidney and are generally of a more severe character than *Bact. coli* infections, and more difficult to cure. *Ps. pyocyanus* is found in the urine under similar circumstances to *B. proteus*. If pus is present in large quantity this may develop a bluish green colour on standing.

Staphylococcal and Streptococcal Infections

The presence of staphylococci in urine may be the result of chance contamination in collection, and it is common to find these and other bacteria in any stale specimen which has begun to undergo ammoniacal fermentation. In these circumstances, of course, the presence of staphylococci is of no pathological significance; but if they are recovered from urine which has been carefully collected and examined without delay the finding of these organisms is an important observation. Staphylococcal infections may occur in the kidney, bladder, prostate, urethra, and epididymis. They may be associated with calculous disease and provide evidence of both the existence and the nature of a stone. The examination of stained films from the centrifuged deposit of the urine is a test which should never be omitted in calculous disease. In stones associated with staphylococcal infections the films may show enormous numbers of Gram-positive cocci, though the bacteriological culture plates may yield only a few colonies. When the urine is infected with staphylococci or proteus, and is strongly alkaline in reaction, further tests should be carried out to see whether or not the infecting bacteria ferment urea. Most strains of staphylococci and proteus ferment urea and thus render the urine alkaline, leading to the precipitation of phosphates and calcium carbonate.

Streptococcal urinary infections are rare, but it is fairly common to find streptococci in the urine in mixed infections, especially in severe urinary sepsis associated with carcinoma of the bladder or vesico-colic fistula. Pure streptococcal

infections of the urine may be found in cases of pyaemic abscess of the kidney and chronic urethritis and prostatitis.

Gonococcal Infections

Three laboratory tests may be used in the diagnosis of gonorrhoea—namely, microscopical examination of films, bacteriological examination of cultures for gonococci, and the gonococcal complement-fixation test. The film method is usually sufficient for the recognition of acute gonorrhoea, but in chronic infections it is best to make use of both films and cultures. This is especially important when the finding of Gram-negative diplococci in films is an unexpected observation, and also in tests for cure in chronic gonorrhoea. In all medico-legal cases all three methods of examination should be employed. These tests will be discussed in more detail in a later article in this series.

Urinary Tuberculosis

Three methods are available for the detection of tubercle bacilli in urine: stained films, cultures, and animal inoculation.

The film method is the easiest and requires least apparatus. It has the advantage that it takes only a few minutes to carry out, and so a report can be given without delay. The tubercle bacillus is the only pathogenic acid-fast bacillus likely to be present in the urine, and with proper precautions it is unlikely that a trained observer will report a false positive by mistaking one of the non-pathogenic acid-fast bacilli for the tubercle bacillus. The stained film is therefore the regular routine method of examination. If acid-fast bacilli having the typical morphological characters and staining reactions of tubercle bacilli are found in stained films in association with red blood cells and pus, then, as a general rule, no further tests are necessary, and the diagnosis of tuberculosis may be considered to be established. If acid-fast bacilli are found which are not quite typical in microscopical appearances, then it is best to reserve a final opinion until the results of the cultures are available, or until virulence tests have been undertaken. On the other hand, when acid-fast bacilli are found in a urinary deposit unaccompanied by blood cells or pus then it is always necessary to proceed to confirmatory tests before accepting these acid-fast bacteria as genuine tubercle bacilli.

Culture tests for tubercle bacilli are not difficult to carry out and are a routine procedure in hospital laboratories. They are useful for the further study of acid-fast bacilli of uncertain character found in films. They should also be undertaken in cases in which there is a possibility of a tuberculous infection although acid-fast bacilli have not been found in the stained films. In a small percentage of cases of urinary tuberculosis tubercle bacilli may be obtained from cultures when they could not be found by examination of films. This is because the pathologist can plant out on the culture media a much larger volume of urine than could be searched in a film; therefore, when tubercle bacilli are relatively scarce it is only to be expected that some cultures may be positive when the films have been negative.

Guinea-pig inoculation is the final court of appeal in tuberculosis; but it should not be resorted to unless other methods of diagnosis have failed. It is an expensive test, it takes at least three to six weeks to complete, and it involves an experiment on a living animal which, naturally, should only be undertaken with reluctance. Experience has shown that the guinea-pig inoculation test very rarely reveals the presence of tubercle bacilli which could not have been discovered by films or by cultures. In fact the culture method is probably a more delicate test than guinea-pig inoculation, especially when large quantities of the centrifuged deposit of urine are spread over several culture tubes. By this distribution of the centrifuged deposit it is possible to submit for examination a larger volume of urine than can be injected into one guinea-pig. However, there are certainly some occasions when animal-inoculation tests are indispensable—for example, in identifying suspicious acid-

fast bacilli recovered by culture, and in the examination of material which is limited in quantity and obtained with special difficulty, such as urine collected by catheterization of the ureters.

Sensitivity Tests

The range of antibiotics is steadily extending, consequently there is an increasing demand on the services of the laboratory for carrying out sensitivity tests in cases of urinary infection. It is well established that most staphylococci and streptococci recovered from urinary infections are sensitive to penicillin whereas *Bact. coli* and other coliform organisms are generally insensitive to penicillin, though often sensitive to chloramphenicol, aureomycin, or oxytetracycline. If the urine is infected with *B. proteus* or *Ps. pyocyanea* response to oxytetracycline or streptomycin may be expected in some cases. The laboratory control of chemotherapy will be discussed more fully later in this series.

Next article on Clinical Pathology.—"Tests of Renal Function," by Dr. R. I. S. Bayliss.

Refresher Course Book.—The first collection of articles in the Refresher Course for General Practitioners (fully revised) are available as a book containing 55 chapters, price 25s. Copies can be obtained either direct from the Publishing Manager, B.M.A. House, Tavistock Square, London, W.C.1, or from booksellers.

THE LIBRARY OF THE ROYAL SOCIETY OF MEDICINE

An extension to the library of the Royal Society of Medicine is being opened this week, on Friday, December 4, by the Marquess of Salisbury. The new library, which is to be called the Wellcome Research Library, has been provided through the generosity of the Wellcome Trustees. To celebrate this occasion we have pleasure in printing below an authoritative account by a special correspondent of the origin and growth of the library of the Royal Society of Medicine.

The Royal Society of Medicine was founded in 1907 following the amalgamation of a number of specialist medical societies and the Royal Medical and Chirurgical Society of London. Some of the special societies had built up collections of books, but the chief foundation of the library of the Royal Society of Medicine was the library of the Royal Medical and Chirurgical Society of London. It is impossible to neglect the history of the library of the R.M.C.S. in any account of the library of the R.S.M., and even to-day some of the library regulations of the parent society remain unchanged.

Foundation of the R.M.C.S. Library

According to the first minute of the meeting which led to the foundation, in 1805, of the Medical and Chirurgical Society of London it was "Resolved unanimously that a society comprehending the several branches of the medical profession be established in London, for the purpose of conversations on professional subjects, for the reception of communications and for the formation of a library." When the first secretary, John Yelloly, reported on "the dignified and important objects for which this society has been established" he placed high among them "the collection of an extensive and select professional library." A library committee was set up in 1806, when £100 was provided to buy books. Presentations were received, and by 1808 the library had about 500 volumes.

The First Honorary Librarian

In 1810 the Society moved from its first house at 2, Verulam Buildings, to 3, Lincoln's Inn Fields, which was

shared with the Geological Society. The growth of the library was not forgotten at this time, for the Medical and Chirurgical Society obtained the right to erect bookcases in the meeting-room. Some members had already shown an interest in "arranging the library," and in 1812 Bateman was appointed honorary librarian; he thought highly enough of his office to mention it on the title-page of his *Delineations of Cutaneous Diseases* (London, 1817). James Atkinson in his *Medical Bibliography* has left this description of the first honorary librarian: "He was then [i.e., a year before Bateman's death] a spare, oblique, marasmoid figure, labouring much under disease, and a cornucopia of whims and self-possessions or conceits; but of a very irritable kind. He then gave me the idea that he never could have been the quiet discreet registrar of disease, which bears so much semblance in his works, and I confess that from the state of exuvium in which I saw him, I should have set him down for anything but a clever man—I mean, in science, as an *homo saturatim inbutus*. We must recollect, however, that when any man is unwell, it is not the time to take his portrait." Soon after his appointment, Bateman, in company with Yelloly, made a book-buying journey to Paris, and the library benefited greatly from this.

The first printed catalogue was issued in 1816. Two years later a supplement appeared and a library copy formed from these and kept up to date by the insertion of new entries remained in use for many years. This same period saw the establishment of practices which are still followed to-day. In 1817 the number of volumes which a member might borrow was raised to eight, though new books and journals less than a month old could not be borrowed. In 1818, with the appointment of Samuel Cooper to assist Bateman, the custom was established of entrusting the supervision of the library to two honorary librarians. A third point of present-day practice also dates from this time. It was ordered in 1816 that a written request from the member concerned must be presented by anyone claiming to be borrowing books on his behalf; this was after "a person unknown had taken out books in Dr. Goode's name."

In 1819 the Society moved to 30, Lincoln's Inn Fields, and in 1820 to number 57, where it remained for the next 14 years. There is no known record of the effect on the library of these repeated removals, but the occurrence of unusually high binding costs at this time suggests that the books suffered physical damage.

In 1822 the Council ordered that "all new English publications be sent in as soon as published, subject to their being returned to the booksellers, if presented by the authors to the Society." This practice was modified in 1826, when the Council ordered that books laid before it for approval should have been seen by one of the librarians and "sent forward with his sanction."

For some years it seemed to have been one of the duties of the resident clerk "to deliver out the books," but in 1832 an "assistant to the librarians" was first employed, apparently solely for library duties under the supervision of the librarians.

In 1835, when the Society moved to 53, Berners Street, a reviewer in the *Lancet* of April 23 made some harsh criticism of London medical libraries in his notice of Forbes's *Medical Bibliography*. He said of the R.M.C.S. library: "It is only lately that any French journals have been added: no German or Italian, or any other continental medical journal beside the French is now received. Only a minority of modern works, and those slowly, are procured. . . . The utmost ignorance of foreign medical literature evidently prevails among the managers." A new catalogue was started in 1837, and a copy was distributed to every Fellow in 1844. By 1847 storage space was giving concern, but the deficiencies in the collections were an even greater anxiety. A committee of 21 Fellows was created to inquire into these deficiencies and to prepare lists of books for purchase. As a result, 432 books (57 English, 153 French, 175 German, 5 Italian, and 42 Latin) were bought in 1848 at a cost of £253 10s. 9d.

A Great Bibliographer

In 1855 Benjamin Robert Wheatley, one of the great bibliographers, became sub-librarian. The library held about 17,000 volumes and was growing by annual increases of 500. One of Wheatley's first tasks was to provide an index of the library's possessions. This work, containing more than 35,000 references, was ready in manuscript in 1860. It had a double value: not only did it show what the library held; it also showed obvious gaps, and efforts were made to fill them by the immediate purchase of 150 works on botany and chemistry. The average daily number of readers in the library was 12. It seems that even at this time the library recognized the need for supplementing its own resources in order to satisfy Fellows, for in 1863 comes the first mention of a subscription being placed with Kimpton's circulating library. The growing awareness of the importance of the public health and epidemiological aspects of medicine was reflected in the policy of collecting sanitary and public health reports "for their value in illustrating results of sanitary measures on death rates and for the presentation of figures not available in the reports of the Registrar-General."

In the annual address in 1868 the President commented on the addition of 519 books, and continued, "with reference to what has been said of the library, I must add that every Fellow who requires a book which is not there, ought to enter it in the recommendation book, and, in all probability, the librarians will order it at once." The collections of periodicals, too, had been greatly enriched, and in the annual report for 1870 there is a note that at the general meeting "Dr. Webster made a few remarks as to the superiority of the Society's library to any foreign library he had ever seen in relation to the completeness of its journal collection."

Increase in Accommodation

In 1871-2 a new reading-room was built, giving space for 27,000 volumes, and for the first time the Society had library accommodation which was distinct from the meeting-rooms. With the new reading-room came a rearrangement of the books which it was hoped "would render the library as noted for convenience and ease of reference as it has long been for its value and extent." In the following session (1872-3) 3,171 books were lent, and 3,156 readers used the library. A contemporary comment on the increase in the Society's expenditure said that this "was partly due to a greater number of books of importance than usual having been brought before the Library Committee, but is greatly owing to the increasing growth in the number of important new foreign journals, which are much in request by the Fellows and constantly being added to the Library tables." With the new reading-room arranged, Wheatley turned to the preparation of his great three-volume catalogue and subject index of the library. Work began in 1874 and the catalogue was published in 1879. From the 17,000 volumes of 1860 the library had now grown to 31,000.

It is possible here to make only brief mention of the growth of the periodical collection as it appears from the

catalogues of 1844, 1856, and 1879. A catalogue of 1844 has this manuscript note on a fly-leaf:

Library contains:

Journals entered as such	49
Journals entered under other heads	190
Transactions entered as such	34
Transactions entered under various heads	133

It was the practice, followed in all three catalogues, to make a distinction between "Transactions," which indicated a periodical published under the auspices of some medical or scientific society, and "Journals," which covered periodicals issued without official support from any particular society. This 1844 catalogue is prefaced by a "list of the periodical publications which are to be found on the library tables, alphabetically arranged." The list is under two headings, British and Foreign. The British periodicals numbered 13, the foreign 10. By 1879 the total number of journals and transactions thus catalogued had risen to 177.

Although nine supplements to the 1879 catalogue, covering the years 1880 to 1901, were published, no new catalogue was printed thereafter. Such works are increasingly difficult to prepare and long delays in publication made the production of an up-to-date printed catalogue virtually impossible. In common with most other medical libraries, the Society's library has come to rely on the card catalogue of its own collections and to use such international biblio-

graphical works as the Surgeon-General's *Catalogue* and the *Index Medicus* as guides to the literature. Nevertheless, in its day, Wheatley's catalogue of 1879 was a very valuable publication.

In 1881 he was given the title of resident librarian; in the next year an assistant was also employed in the library. Wheatley died in 1884. There were 93 applicants for the vacant post; the Council appointed James Bailey, of the Radcliffe, who remained for three years before moving to the Royal College of Surgeons, where he carried out a complete reorganization of the College library.

Sir John MacAlister

Bailey was followed by Mr. (later Sir) John MacAlister. His contribution to the progress of the R.M.C.S. and to the formation of the R.S.M. extended far beyond the library; yet to him, as a librarian alone, the Society owes a vast debt, whilst outside the Society he made a great name for himself in the little world of professional librarians and in the history of the Library Association. Although he was unable to accept the invitation, it is worth recalling that in 1905 MacAlister was invited to attend the International Library Congress in St. Louis as one of the representatives of European librarianship. At the time of his appointment about 3,900 books were borrowed annually and about 4,500 readers used the library. Storage space was becoming an acute problem. In the words of the president at that time, "every year there was increasing difficulty in placing the books of the constantly growing library. The room used for the Society's meetings, the council-room, and the committee-room all contained books." The Society moved to larger premises in 1889, at 20, Hanover Square, but three

Interior of the Wellcome Research Library.

years later further work had to be done there to give additional library space. In 1905 a new store to house 10,000 books was built behind the meeting-room. Even so, books were again invading the corridors.

It was not until MacAlister's day that the library "services" as well as the library collections received serious attention. Quite early in his term of office he made the library more accessible by an increase in the hours of opening. (By 1898 the library was open daily from 11 a.m. to 6.30 p.m.) In the *Lancet* of June 16, 1910, a letter appeared over his signature offering a service to provide abstracts and to undertake searches of the literature for Fellows living abroad. He wanted to make it as easy for "the man in the Andes" to benefit from the library as for the man in Wimpole Street. It was primarily to benefit the man who was unable to come and use the library himself that MacAlister planned library "services."

Amalgamation

In the first years of this century MacAlister was deeply concerned in the negotiations which, in 1907, resulted in the formation of the Royal Society of Medicine. The amalgamation brought several special collections of books to enrich the Society's library, of which the most extensive were the libraries of the Obstetrical Society of London (15,000) and of the Odontological Society (5,000). The Laryngological Society had placed its books in the care of the R.M.C.S. in 1902; the Ophthalmological Society of the United Kingdom, whilst maintaining its separate existence, deposited its library, under special conditions, in the new R.S.M. These additions not only filled gaps in the collection of the R.M.C.S. but also provided duplicate copies of many important early works. The benefit of this duplication has become increasingly apparent with the growth of the library's lending service.

Following the amalgamation, MacAlister carried through the building of the Society's house on its present site. This new building was opened in 1912.

In 1924 the room formerly known as the Marcus Beck Laboratory was handed over to the library, and, as the present Marcus Beck Library, houses a collection of historical works. The Society's historical collections had been greatly enriched in MacAlister's time by gifts from many Fellows, noteworthy among whom were Sir William Osler—he gave the library its only copy of the first edition of Harvey's *De Motu Cordis*—and Albert Chalmers, from whom came a valuable bequest of pamphlets and books which included amongst other rare items a fine copy of the *editio princeps* of Celsus's *De Medicina*. At this time, too, the modern books were arranged in a broad classification which brought collections of books together under a number of headings corresponding fairly closely with the interests of the various Sections of the Society.

Extension of Service

In 1925 the hours of opening were again extended. On Thursdays and Fridays the library remained open until 10 p.m. and was no longer closed during August, although late opening was suspended during that month. In the same year the service providing abstracts and bibliographies was officially extended to all Fellows. This year also marked the end of MacAlister's long term of service to the Society. He had been appointed secretary and consulting librarian in 1901, and throughout the period his influence on the development of the library, under its successive librarians, Archibald Clarke, C. R. Hewitt, and H. E. Powell, was of inestimable value. The library which he first directed in 1887 served 745 Fellows. At his retirement this number had grown to 4,000.

By the middle 'thirties the library had further grown under Mr. G. F. Home. He introduced a formal classification on the Brussels system; to its ever-growing collections of journals he added the most complete collection in the country of the great French and German encyclopaedic works. The scope of the journal collection was also increased. Most of the American State journals of medicine were included

as well as a number of smaller hospital journals. Their value was derived mainly from the growing custom of reporting original work in them at an earlier date than would have been possible in the large national journals. The collection of sanitary reports was also increased as a result of efforts to collect the annual reports of all medical officers of health. A *List of Periodicals in the Library* complete to December, 1937, was published in 1938. The bibliographical services were maintained and arrangements made to file and preserve copies of all lists prepared and all translations made so that they remained as a source of information for all Fellows. Indeed, this service was almost too successful. Its usefulness produced increasing demands, with the result that the time-lag between the receipt of a request and its satisfaction became a pressing problem. In an effort to lessen inconvenience to Fellows a quick reference service was introduced, aiming at the speedy tracing of a limited number of articles to provide either an adequate review of a subject or a starting-point from which a Fellow can follow a subject in greater detail. This was indeed a period of rapid expansion, and at the time of his retirement Mr. Home left a greatly enlarged and enriched heritage to his successor, Mr. P. Wade.

By 1939 the library stock was approaching the 200,000 mark and space was again becoming scarce. Extra stacks had been erected in the basement and structural alterations made on the first floor to give more space.

The outbreak of war arrested the immediate demands on space, but inevitably brought its own problems. Some 40,000 of the rarer books and journals were moved out of London. They were stored so as to be available, and eventually provision was made for a small reading-room in this store. The main library also remained open. In addition to the photostat machine, microfilm apparatus was provided in order to copy material needed by Fellows in the Services; and microfilm readers were distributed, through the Army authorities, to establishments abroad. As in the first world war, the library was again opened to members of the Allied Forces.

After the war strenuous efforts were made to close the gaps in runs of important Continental journals. Once again an honorary librarian, Dr. T. C. Hunt, followed in the steps of the first honorary librarian, and made a Continental tour in search of material to complete the collections. Thanks to a generous grant from the Rockefeller Foundation, the Central Medical Library Bureau was set up and carried out extensive copying (from the Society's and other libraries' stocks) of out-of-print journals urgently needed by war-damaged libraries at home and abroad.

A Contribution of Outstanding Value

With the renewed flow of books and periodicals, the return of volumes from their store, and the increase in the number of Fellows, space was once again the main pre-occupation of the Council and librarians. The library began to spill over into corridors and committee-rooms as it had done previously, and the need for enlargement became increasingly urgent. Sir Henry Dale had been president of the Society during the years 1948-50 and was fully aware of these problems. On relinquishing office to Lord Webb-Johnson, he announced an offer from the trustees of Sir Henry Wellcome to provide a large sum of money for the extension of the library. This could be achieved by adding a fourth floor to the Society's house and altering the existing second floor so as almost to double the library space. At a Council meeting on October 17, 1950, the president reported the offer and expressed his deep appreciation of it. He called it "the most important matter which had been considered by the Council of the Society since 1907." The moment indeed was propitious, as Lord Webb-Johnson's experience in similar constructional enterprises was unrivalled. The result has been the addition of the fine Wellcome Research Library—a contribution of outstanding value to the progress of British medicine. For some years the librarians are, as a result of the most generous act in the history of the Society, again free from the recurrent anxiety about space.

TOBACCO A BLESSING?

"NO," SAY THE HUNTERIANS

"That tobacco is a blessing" was the proposition moved at a discussion meeting of the Hunterian Society at Apothecaries' Hall on November 16. After a number of speeches, serious and quizzical, the proposition "That tobacco is a blessing" was defeated, in an assembly of about 200 people, by a very large majority. The opener of the debate in favour of the motion was to have been Sir Alan Herbert, who was prevented by illness from attending. He sent a note in which he qualified his advocacy of tobacco by admitting that smoking was a barbarous practice and that a pipe was not really enjoyable until it was absolutely filthy.

Sir HENEAGE OGILVIE, President of the Society, who proposed the motion, said that he was ready to admit that cigarette smoking was a dirty, expensive, and psychopathic habit, likely to lead to cancer of the lung, duodenal ulcer, smoker's heart, and ash on the waistcoat. But the motion referred not to cigarettes but to tobacco, and who would say that tobacco was not a blessing? Wherever strong men went out into the wide open spaces of the earth they were accompanied by their pipes; statesmen smoking cigars presided over the councils of nations. It was smokers who had given us dominion over palm and pine, who had ensured that Britons never should be slaves. What was England before Raleigh? A downtrodden outpost of Europe. But after Raleigh how great she had become. The Dutch, the French, had failed to beat her. Napoleon and Hitler (a non-smoker, by the way) had gone down before her. "I do not feel that we can risk the great decadence that would be bound to come to a country which has no minor vices."

The Cost to the Community

Mr. DICKSON WRIGHT was the leading advocate on the other side. To him smoking in any form was anathema. A blessing? Perhaps so, to the man who indulged in it, but what of the community? The amount of tobacco consumed in a year would fill every cubic inch of space in St. Paul's Cathedral. The annual tobacco bill was £800 millions. A good smoker might consume half a hundredweight a year. He believed that many smokers secretly deplored their bondage to it. The habit was unattractive. He preferred the dignified figures of the past—the younger Pitt, Melbourne, Disraeli—to the pictures of their descendants, Baldwin with his pipe and Churchill with his cigar. On the stage how incongruous it would be to have Hamlet uttering his soliloquy pipe in mouth. What would Shakespeare have thought of a Noel Coward piece with smart sayings interrupted by cigarette puffs? He had counted the number of times cigarettes were lighted on the stage in modern plays—the record was 53 in a single play. In the auditorium the waning and waxing of interest in a play could be estimated by the manner in which the cigarettes glowed and smouldered out. He also complained of smoking by dignitaries of the Church. It was incongruous for a minister of the Gospel to allow himself to smoke whilst condemning lots of things of a more physiological nature. In private life he thought that ladies lost some of their charm by smoking. At no period of her life was a woman improved in appearance by a cigarette. It was a great triumph for the tobacco manufacturers when they overcame the delicacy of the female sex. It only remained for them to get the habit firmly established in the schools and then the home market would be fully saturated.

Smoking in the medical profession, Mr. Dickson Wright continued, was also a bad thing. The doctor whose clothes, breath, and fingers were malodorous from tobacco was a less good doctor. Nurses too—the question of smoking in uniform was exercising that matriarchal body, the General Nursing Council. At hospital the administrative staff, the porters, the cooks, the maids all smoked at their work. There seemed to be little restraint anywhere in the use of tobacco. It was not a blessing to the country; we should be much happier without it.

A Word in Defence

Dr. R. R. BOMFORD appeared as the chief supporter of the motion. He claimed only that this innocent herb had been a pleasure, a solace, and sometimes a delight to peaceful, well-adapted personalities for at least 400 years. He reminded the audience of the vast numbers of people employed in the tobacco industry, of the £600 millions or more that it produced in revenue, of the fact that it prevented thousands of people from getting fat, of the contribution it made to the serenity of the home, of the fact that a by-product was an excellent sheep dip. Much of the propaganda against it was irrational and prejudiced. In a recent controversy both cancer and smoking were subjects charged with emotion, so that it was not surprising that the combination led to outpourings of biased wrath. He had no quarrel with the work of Professor Bradford Hill and his associates, but it would be interesting to learn a little about the fate of male non-smokers. Did they retire to dark corners and die slowly from myocardial degeneration?

He complained of the term "addiction" as used in the case of tobacco. Smoking was a habit but not an addiction; there were no withdrawal symptoms. If people were to give up smoking because of the fear of dying from cancer of the lung they might as well give up bacon and eggs for breakfast, because this increased the coagulability of the blood and so made the partaker more liable to coronary thrombosis.

Smoking and Lung Carcinoma

Dr. HORACE JOULES, speaking with great earnestness, asked why, if tobacco was such a blessing, it was necessary to spend so many millions on persuading people to take up the habit. Of the dire results of smoking he pointed to the smokers' cough, which in the man who had been long addicted to a heavy daily consumption of cigarettes was not to be distinguished from the cough of lung cancer or advanced tuberculosis. Bronchitis was a curse of the community, and largely accounted for the fact that expectation of life of persons over 50 was little above the figure in the early part of this century. In 1950 16½ million working days were lost by the insured population on account of chronic bronchitis. Tobacco was said to be a germicide, but in fact it prepared the bronchi for infection. Professor Bradford Hill's dispassionate study had not been refuted by any tobacco concern. Far more people were now dying of lung cancer than of pulmonary tuberculosis. There were three times as many deaths as from road accidents. Excessive smoking was hindering the surge forward in preventive medicine, particularly in respect of chest diseases. The difficulty was that the Treasury had a vested interest in this "blessing" to the tune of some £630 millions a year. He pointed to the vast amounts of tobacco imported which had to be paid for in dollars, while the allocation of cortisone was negligible by comparison. He begged his audience to experience the improvement in physical and mental well-being which would follow three months' abstinence.

As stated, the show of hands resulted in so large a majority against the proposition "That tobacco is a blessing" that the numbers were not counted.

Last year, according to the statutory Home Office return, over two million experiments on living animals were performed. The great majority of these (86%) involved no operative procedure, but simply inoculation, modification of the diet or environment, or administration of a drug or toxin. About 250,000 experiments were surgical operations under anaesthesia, many being of a minor character. Over half of all the experiments were made during the preparation, testing, and standardization of therapeutic substances; another 400,000 on behalf of Government departments and bodies such as the Medical and Agricultural Research Councils; 200,000 for public health purposes or directly for the diagnosis of disease, and 96,000 in the course of cancer investigations. Throughout the year 4,491 persons held Home Office licences, although apparently 1,335 licensees performed no experiments.

Reports of Societies

ACUTE LUNG INFECTIONS IN GENERAL PRACTICE

The subject of common acute lung infections in general practice was discussed by the General Practice Section of the Royal Society of Medicine on November 28.

Dr. JOHN FRY opened the discussion by defining the magnitude of the problem; 25% of all the patients he saw in his general practice were suffering from respiratory infections, and chest diseases accounted for 10% of all deaths. Acute pneumococcal pneumonia was a rarity in general practice, and textbook descriptions and classifications of the pneumonias were confusing and inadequate. Non-specific pneumonia without clinical signs of consolidation was common and received little mention in the books, and there was little agreement about the precise meaning of acute bronchitis; to some it meant merely productive cough with fever, to others the diagnosis required the presence of definite physical signs of abnormality.

Pneumonia was first classified on the basis of clinical description, then the morbid anatomists distinguished lobar and broncho-pneumonia, and most recently Dr. Scadding had emphasized the distinction between specific bacterial or viral pneumonias and the non-specific pneumonias, in which there was some abnormality in the respiratory tract predisposing to invasion by commensals. In general practice this classification was not altogether practical, since elaborate procedures were often required for precise bacteriological diagnosis.

A Clinical Classification

Dr. Fry said that in his own practice in South-east London he saw 60 to 80 patients with acute respiratory disease each year, mainly in the autumn and winter. He had found the highest incidence (135 per 1,000 at risk) in the over-70 and 5-to-9 age groups. He placed little reliance on pathological or radiological investigation and subdivided his cases into diffuse, with scattered and bilateral signs (53% of his cases), and local, with signs in one or more localized areas only. The second group were subdivided into those with (5%) and without (42%) clinical signs of consolidation. The diffuse infections had a sudden onset with cough and variable dyspnoea, and the physical signs included bilateral rales or rhonchi or both; these infections were either primary (no previous chest history) or secondary (previous chronic bronchitis, measles, or whooping-cough). The diffuse primary type occurred mainly in the under 10's and the diffuse secondary type in the over 40's. The cases with local signs of consolidation formed a small group (12 patients only); they usually responded to antibiotics.

Cases with local signs without clinical evidence of consolidation were very common in Dr. Fry's practice, but were scarcely mentioned in standard books. They were mild infections occurring at all ages, but especially in children, and rapidly resolved. The onset was insidious, though there was often a preceding nasal discharge; the systemic disturbance was variable, and the patients often remained ambulant with little or no fever or tachycardia. There might be an irritating cough, or chest pain, and at one or other base there was an area of diminished air entry, maybe impaired percussion note, and a shower of inspiratory rales. There was disappointing correlation of the radiological appearances with the clinical signs. The erythrocyte sedimentation rate and white-cell count were usually normal, specific pathogens in the sputum were not found, and in only a very few patients were virus complement fixation tests positive. The condition might be caused by a primary low-grade infection, or by mechanical aspiration bronchial embolism producing segmental or lobular collapse, with secondary infection. Treatment consisted in control of the infection, when necessary, and postural drainage with breathing exercises to overcome the mechanical factors.

Dr. Fry concluded by asking a number of questions, for which answers had still to be found. What, he asked, was the relative importance of mechanical embolism, allergy, and degeneration; what was the influence of season and climate; what was the relation of chronic bronchitis and influenza to the acute chest; and what part did fog play?

Aetiological Factors

Dr. J. G. SCADDING said that a classification, to be logical, must be on the same basis—for example, aetiological—throughout. With the pneumonias this was impossible, because there were still unidentified aetiological agents, and present knowledge was often difficult to apply in actual practice. Furthermore, not every infection had only one aetiological agent, and often mechanical factors played a part. He referred, in this connexion, to the series of cases described by Ramsay and himself in 1939; these patients were suffering from acute upper respiratory infections or chronic bronchitis with an acute flare-up, and were found to have localized opacities in the radiograph. This was attributed to aspiration of mucus infected with upper-respiratory-tract commensals with resulting obstruction of a bronchus, notably in the posterior segments when the patient was recumbent. This was followed by absorption of the alveolar air and a mild pneumonic reaction.

Dr. Scadding then outlined his own classification of the pneumonias. There were two main groups: *Specific infections*: (a) bacterial (pneumococcal pneumonia was still common in hospital practice); (b) viral (of which the psittacosis-ornithosis group was the only named one, though there certainly were other unidentified pneumotropic viruses causing what was still sometimes known as primary atypical pneumonia); (c) associated with viruses (notably with measles and influenza) and due to the combined action of virus and bacteria; and (d) rickettsial (Q-fever) and other rarer infections. *Aspiration pneumonias*: (a) diffuse—that is, bronchopneumonia—including post-operative, deglutition, terminal, hypostatic, and inhalation pneumonias; (b) localized; and (c) suppurative pneumonia. He related two typical case histories to illustrate the differences between virus pneumonia and aspiration pneumonia. The patient with virus pneumonia, in contrast to the one with aspiration pneumonia, had severe constitutional disturbance, with only minimal respiratory symptoms.

Aetiological diagnosis, in Dr. Scadding's opinion, was difficult. Bacteriological examination of the sputum was hampered by irregular distribution of pathogens in the sample. Serological diagnosis was dependent on the demonstration in a rising titre of specific antibodies or cold agglutinins, and could often be made only retrospectively. Treatment must be started without a precise diagnosis, and Dr. Scadding referred to a previously published study undertaken in 1950 in which the results of treatment of clinical pneumonia by standard methods—penicillin or sulphonamides—were compared with treatment by aureomycin and by chloramphenicol. In this trial the standard treatment was at least as effective as the newer antibacterial agents, was accompanied by fewer side-effects, and was much cheaper.

Radiological Diagnosis

Dr. PETER KERLEY showed an interesting series of radiographs illustrating the radiological features of different types of pneumonia. In pneumococcal pneumonia the opacity spread out from the hilum, and when the whole lobe was consolidated its bulk was usually increased. Increase in the bulk of a lobe or a segment was a feature of all bacterial pneumonias, while interstitial changes predominated in the virus diseases unless there was secondary infection. Pseudo-cavities due to acute vesicular emphysema were common during resolution in children. Delayed resolution and atelectasis were rare, but might be followed by bronchiectasis. Tuberculous pneumonia, measles pneumonia, and virus pneumonias (sometimes involving multiple segments) associated with upper respiratory infections were also illustrated.

Correspondence

Because of the present high cost of producing the Journal, and the great pressure on our space, correspondents are asked to keep their letters short.

Sterilizing Ampoules

SIR,—Your issue of November 21 (p. 1165) reports an action for damages brought by two patients in whom spinal anaesthesia was followed by paraplegia. This was said to have resulted from contamination of the anaesthetic by phenol, in a solution of which the ampoules had been stored.

I wish to suggest that the antiquated practice of storing ampoules, whether of such solutions, of catgut, or any other material, in disinfectant solutions, or even of "dishing them up" in such solutions, should be altogether abandoned. The surface of these ampoules, if the surgeon is to open them, must of course be sterile, but this can be ensured in more convenient and less dangerous ways, apart from the use of heat, which is applicable to some of them. There are two obvious possibilities: (1) that they be sterilized by the manufacturer, and protected against contamination before use by covering with "cellophane" or enclosure in an outer glass tube; and (2) that they be sterilized chemically by the user, but after immersion for a sufficient time in a suitable solution they should be transferred to sterile distilled water to free them of the disinfectant, and then stored in an air-tight container until required. It does not seem to be generally understood that once an object has been sterilized it can be kept so indefinitely, or as near sterile as does not matter, merely by protection from atmospheric dust. An easy way of ensuring this is to place the ampoule in a plugged sterile test-tube. If something more elaborate and commodious is wanted, it should not be beyond modern engineering skill to construct a cabinet, of itself sterilizable, which would accommodate numbers of such ampoules under conditions affording complete safety.

If it is a fact that solutions can traverse the apparently intact walls of these ampoules, it would be a wise precaution to colour the disinfectant solution strongly so that the results of this process can be seen. A suitable disinfectant would be liq. formaldehydi chirurgicis acting for six hours: this will kill anything, including spores, which phenol will not.—I am, etc.,

London, E.C.1.

LAWRENCE P. GARROD.

Amoeboma of the Caecum

SIR,—In his memorandum (*Journal*, November 14, p. 1087) Mr. E. N. Callum tells a sad story which might well have had an even sadder ending. While Mr. Callum gives us details of his surgical interference, there are many other things that he does not tell us. For example, he says that the patient was a clerk of 34 years, but he does not tell us where he spent those 34 years. Since an amoeboma does not grow in three days, it would have been interesting to know what earlier symptoms the patient had had, or, in the complete absence of any symptom, an assurance of this fact. He states that, on the original diagnosis of appendix abscess being made, antibiotics were given, but he does not tell us which antibiotics and especially whether they included aureomycin, for example, for which amoebicidal properties are claimed. One would like to know what the pathologist thought about the supposed neoplasm during the three weeks between the operation and the sloughing of the abdominal wall; in fact, we are never told what the pathologist did eventually conclude about the tumour, and we have only the title of the paper to suggest that it was an amoeboma. Had it been a neoplasm combined with an *Entamoeba histolytica* bowel infection, the immediate result might well have been the same.

Mr. Callum's comment is both wise, in that he gives the excellent advice that when doubtful masses are found in the bowel amoebiasis should be excluded, and laudable, in that he risks personal criticism to ensure that others do not fall into the same error—but he does not go far enough. In his last sentence he writes: "... while the presence of unusual masses in the rectum or elsewhere in the bowel may call for a search for *Entamoeba histolytica* in the stools before proceeding to surgery." Does he mean one or two hurried stool examinations by the hospital technician, who will rarely be experienced in identifying *Entamoeba histolytica*? If so, surely the procedure would be valueless to exclude amoeboma. Even a dozen such examinations by an experienced parasitologist would be inadequate and would take time that could be much better spent in the carrying out of an adequate therapeutic test with emetine.

This case report exemplifies the timeliness of the memorandum presented by the council of the Royal Society of Tropical Medicine and Hygiene at the recent World Conference on Medical Education; two of its main points were that all students should be taught to include in their case histories the past geographical movements of patients, and that their courses of instruction should at least include a few lectures on tropical medical and surgical emergencies that are likely to be encountered in non-tropical countries.—I am, etc.,

London, W.1.

L. EVERARD NAPIER.

Malaria in Ex-Servicemen

SIR,—Sir Neil Hamilton Fairley, in his letter about "Malaria in Ex-Servicemen" (*Journal*, November 21, p. 1157), states: "Outside the armed Forces and the various hospitals for tropical diseases, many patients with vivax malaria only receive treatment with schizonticidal drugs..." (my italics). He goes on to recommend, apparently in all cases, a course of one of the 8-aminoquinoline drugs.

In the Refresher Course article on malaria (*Journal*, October 27, 1951, p. 1021), Sir Gordon Covell writes: "The routine administration of (the 8-aminoquinolines) in all cases of vivax malaria is not recommended. They should be reserved for the treatment of stubbornly relapsing cases, more especially in circumstances where there is no risk of reinfection."

As the vast majority of the cases of vivax malaria in ex-Servicemen, at least in those returning from Korea, do not fall into the category of "stubbornly relapsing" it would be of interest to know why these eminent authorities differ.—I am, etc.,

Glasgow.

I. B. MUNRO.

SIR,—The attention recently given to relapsing malaria in the medical press is most timely. I venture to suggest that the huge majority of medical men are nevertheless left without the faintest idea of the optimum treatment for this condition. I have found that a number of practitioners in this neighbourhood have been grateful for some forthright guidance in this matter, with consequent benefit to their ex-Service patients. I therefore feel that practitioners would warmly welcome a simple directive from the Ministry giving clear-cut advice on the therapy of malaria. One has only to question patients admitted for malaria to discover the urgent need for such authoritative guidance.

The corollary to this is the great research opportunity that is being lost through lack of any standardizing of treatment. The arguments in favour of self-determination in prescribing are irrelevant when applied to the treatment of tropical diseases in temperate climates.

There is one other point I should like to stress. Far too little prominence is given to one of the great cardinal signs of malaria—namely, vomiting. In any ex-Servicemen from Korea suffering from pyrexia and vomiting without physical signs, malaria should be thought of first.—I am, etc.,

Worcester.

C. F. J. CROPPER.

Histoplasmosis in Great Britain

SIR,—The lack of clarity in our paper must have been due to its brevity. We meant to infer that the cases described, including that of Duncan,¹ did not conform to the criteria accepted for *Histoplasma capsulatum*. This in fact has been accepted by Duncan himself in his letter (*Journal*, November 14, p. 1103).

To correct and amplify the statement made in the latter part of his letter I should point out that we now have information to the effect that, including the case described by us, five cases of disseminated histoplasmosis have occurred in Great Britain, and two cases showing the local manifestations without apparent dissemination (including the case described by Duncan in 1947) have also been reported, making seven cases in all. Of these five cases of disseminated histoplasmosis, one was diagnosed during the patient's lifetime (the case we described), another was suspected during the patient's lifetime but confirmed on necropsy. The three other cases were only diagnosed at necropsy. Of this group of five cases, four gave positive cultures of *Histoplasma capsulatum*, whereas the fifth did not, the organism in this case only being identified in stained sections of the tissues. Of the two cases presenting with local lesions, the case described by Duncan gave a positive culture which was not typical of *Histoplasma capsulatum*, but probably due to related species now given the name of *Histoplasma duboisii*. Positive culture was not obtained from the other case.

It is extremely difficult to know whether it is justifiable to distinguish the clinical manifestations of the condition due to *Histoplasma capsulatum* from that due to related species, but there would appear to be some evidence at least to suggest that the disseminated histoplasmosis as classically described is invariably due to the typical *Histoplasma capsulatum*.—I am, etc.,

Romford, Essex.

Control of Tachycardia by Quinine

SIR,—With reference to Dr. C. W. F. Winckel's letter (*Journal*, November 14, p. 1103), Wenckebach was not the first to discover the beneficial effect of quinine in some heart disorders. Pride of place goes to Senac, who published an account of quinine being used in such circumstances in the year 1749.¹ Wenckebach merely followed up a chance observation of one of his patients who was taking quinine, and discovered that it was exerting an effect on the heart rate.—I am, etc.,

Collingborne Ducis.

Cough Syncope

SIR,—Professor E. P. Sharpey-Schafer (*Journal*, October 17, p. 860) describes the physiological mechanism of syncope after coughing. The syncope from coughing was shown to be due to vasodilatation following stimulation of baroreceptors by large arterial cough transients. It is interesting to note how this syncope can be induced by stimulating the carotid sinus reflexes,¹ and one feels that in syncope after coughing this particular reflex plays a large part. Watching these patients, who are usually short-necked people, coughing, one observes the tendency to raise the shoulders and tighten the neck muscles.

I am of the opinion that these patients who lose consciousness, and all who cough violently and thus induce different degrees of dizziness, should be taught to cough differently. As soon as the patient feels "the upper respiratory tickle" he should bend slightly forward, pushing his chin forward and stretching the neck muscles. I do not know if this manoeuvre protects the

carotid sinus, reducing the stimuli to the receptors there, or if the varying of the stance adopted reduces the violence of the cough. Professor Sharpey-Schafer points out that when coughing is associated with expectoration there is no syncope, and the usual posture adopted when bringing up phlegm is one with the neck extended.

During the last two years I have had three cases of syncope after coughing. One was a doctor, aged 48, who had not smoked for four years because it made him cough so much. He had a fit of coughing when sitting playing bridge, and this was followed by an attack of syncope with slight convulsions. Another was an accountant aged 38—a heavy smoker. He fell in the street following a coughing bout. I had previously warned this man of the possibility of syncope, because I had seen him coughing. A third case was that of a man aged 80, a heavy smoker, who had a coughing bout in a train and fell on the carriage floor. Each of these three men could be described as being short-necked. Only the second patient wore tight neckwear.

The first and second patients had had no previous attacks, but the third had had them on a number of occasions and was afraid to consult a doctor, believing he was suffering from some strange malady. It is possible that in the case of this elderly man he was prone to frequent attacks because of atheromatous changes in the blood vessels causing increased hyperactivity of the vagal reflex arc.² None of these three patients have had any attacks of syncope since they have adopted the posture that I have described.

It would be interesting if one could ascertain the difference in the intrathoracic pressure in a patient coughing with his shoulders shrugged, and coughing with his neck extended.—I am, etc.,

Hove.

Treatment of Plantar Warts

SIR,—Every day I am confronted with warts plantar, warts palmar, warts digitate, warts acuminata, warts plane, and warts vulgar, and they never cease to rouse my spleen because they are there, because their possessors demand their instant removal, and because this puts me to so much unnecessary trouble and expense of time. For I know that I do not know very much about warts; and yet I know enough about their ways to know that they have the laugh of me—they, and the owners of the gift of charming. Whereas I have to bring a whole armoury to bear, curettes, cylinders of carbon dioxide, containers of liquid nitrogen, red-hot wires, x-ray tubes, and the like, the charmers blithely pronounce the warts cured and behold they vanish—sometimes, but sufficiently often to impress. Those people who believe that such things only happen to the simple-minded in the depths of the country should read of what befell Sir Francis Bacon in Paris in the year 1576, as recorded by Walter de la Mare (on p. 690) in his delightful anthology *Come Hither*. To those who feel that there is more virtue in numbers and a planned experiment I recommend an article by Bruno Bloch.¹ There is no doubt about it, the charmers and we are armed like David and Goliath. And their mystification at their success is not the least galling part of the matter. And so, Sir, beset as I am by these verrucosities which I detest and which are a daily reproach to me, I have been goaded into writing to you by the telling shafts of your annotator on plantar warts (*Journal*, November 14, p. 1093), who has no doubts about our ignorance of this subject. My observations do not go very far, but they might form a stepping-stone for others.

There are at least two kinds of plantar wart. One is painful and penetrates the skin deeply. It can be curetted out most satisfactorily, and when this is done leaves a deep, round hole with an overhanging rim of stratum corneum. The other kind is a dry, crumbling affair, causes little pain, and is superficially placed in the skin. Curettage of this kind discloses the wart as a plaque of tissue compounded of hundreds of small warts. The hole left by this second kind is a shallow thing, polycyclic in outline. The natural history of each kind after curettage varies, for whereas the former is usually cured the latter usually reforms. The resistance of the latter kind to curettage is typical of its behaviour with every kind of treatment, and so is the

willingness of the former to disappear. These two kinds of wart are well known as "the plantar wart" and "the mosaic wart."

Thus far there is nothing new, but Dr. J. A. R. Miles and I discovered² that the clinical distinction was also histological. The bulky plantar wart contained eosinophilic inclusion bodies, both intracytoplasmic and intranuclear. The mosaic wart did not. This plantar wart which contained inclusion bodies we proposed to call a myrmecia for historical reasons. The myrmecia, we found, occurred on the hands occasionally, where it preserved its clinical characteristics, except for a greater projection above the surface on account of the absence of pressure. The common wart of the hands was devoid of inclusion bodies, and where a patient had warty hands and feet myrmecia would pair with myrmecia, and common wart with mosaic wart. In a transmission experiment the myrmecia extract gave rise to a myrmecia and the common wart extract to common warts. Finally, Strauss and others in America,^{3,4} working independently, claimed to have photographed wart virus under the electron microscope. They found the virus in some warts but not others, and it seemed to me from their description that the warts which produced virus were identical with our myrmecia.

Nothing which I have seen since we wrote our article has made me want to alter our conclusions.—I am, etc.,

Edinburgh, 12.

SIR,—Your annotation (*Journal*, November 14, p. 1093) prompts me to suggest a simpler method of treating plantar warts than those described. This method was described by Dr. W. Gillies Annan¹ and consists in injecting a 5% aqueous solution of phenol through normal skin at the edge of the wart into its base. The prick is painless, but the actual injection is very painful for a few seconds. The patient, however, walks away painlessly and cured, for the wart disappears in a few weeks.

I have dealt with dozens in this way without a failure. I always warn the patient—usually a school-child—that the injection will be painful for a moment, but with explanation this prospect is usually accepted when weighed against the continual pain of walking on a wart: and most children are quite ready to be brave.

My only modification of Dr. Annan's method is to use less fluid than he suggested. I find that 1–3 min. (0.06–0.18 ml.) is usually sufficient. He recommended 5–10 min. (0.3–0.6 ml.). The method is speedy, apparently safe, and sure.—I am, etc.,

Reading.

Routine Lumbar Puncture in Primary Tuberculosis

SIR,—This problem, mentioned in "Any Questions" (*Journal*, November 7, p. 1058), was well illustrated by a boy aged 2 who was admitted under my care last March with an acute tonsillitis and meningism. Lumbar puncture produced a normal C.S.F. He became afebrile on the third day, but the temperature began to rise on the fifth day and meningism developed again, so that a further lumbar puncture was carried out, and this showed all the changes of tuberculous meningitis.

The boy was in contact with his grandfather and had been under regular observation for tuberculosis for some time. One year previous to admission the Mantoux 1/100 was positive, so that he had evidently been infected at least a year prior to admission. It is possible that the acute infection precipitated the tuberculous meningitis, but it seemed to me more likely that the lumbar puncture had done so.

The boy's further history is of interest, as he developed poliomyelitis whilst still under treatment, but the paralysis was limited to the left upper arm which has never been injected, though he was receiving daily intramuscular streptomycin injections into each thigh before, during, and after the superadded virus infection occurred.—I am, etc.,

London, N.18.

IAN G. WICKES.

Lumbar Puncture

SIR,—Dr. William Goody, in his article on lumbar puncture (*Journal*, November 7, p. 1040), made no mention of the lateral approach. If the needle is inserted an inch (2.5 cm.) from the midline the tough intraspinal ligament is avoided and the progress of the point of the needle through the dura is more readily detected by the fingers. Very little practice is required to estimate correctly the angle that the needle must make to the median sagittal plane.—I am, etc.,

REX BINNING.

Hove.

SIR,—I was interested in the article by Dr. W. Goody on lumbar puncture (*Journal*, November 7, p. 1040), which, I gather, was only a preliminary article in a series. There are, however, two questions I would like answered: (1) should a lumbar puncture ever be performed in the home, and (2) if so, when?—I am, etc.,

W. A. BALL.

Petworth, Sussex.

Milk and Protozoal Infections

SIR,—The publication of Professor B. G. Maegraith's letter (*Journal*, November 7, p. 1047) stimulates me to record the following facts that have recently come to hand through the kindness of Miss L. M. Fagg, nursing sister at the Baptist Mission Hospital, Yakusu, Belgian Congo. We were interested in the suggestion made in the article by Professor Maegraith, Mr. T. Deegan, and Dr. E. Sherwood Jones (*Journal*, December 27, 1952, p. 1382) that a positive suppressive effect of milk might explain the low incidence of malaria in infants wholly breast-fed, and the further suggestion of Dr. F. Hawking (*Journal*, May 30, p. 1201) that the suppression of malaria in the experimental animal raised on a milk diet might be due to the negligible amounts of p-aminobenzoic acid in milk.

During a short period, ten of eleven children under the age of 6 months admitted as in-patients to the Yakusu Hospital had ring-forms of *P. falciparum* present in the thick drop. None of these infants had received any food whatsoever but their mother's milk. Investigations are being continued to discover if other factors are involved.—I am, etc.,

S. G. BROWNE.

London, S.E.9.

Treatment of Tetanus

SIR,—The recent correspondence (*Journal*, November 14, p. 1099) on the prognosis and treatment of tetanus gives the impression that modern treatment rests entirely on the use of the newer relaxants, antitoxin, intubation or tracheotomy, and controlled respiration. No reference is made to surgical excision of the site of infection, but surely the question of whether or not this has been, or can be, carried out is of primary importance in prognosis; other forms of treatment cannot be fully effective if toxin is still being produced at the site of infection.

In 1944, while working with a medical team of the Friends' Ambulance Unit in a very remote part of South-west China, a case of fairly severe tetanus under my care recovered without any adjuvant treatment beyond morphine, chloral, and bromide. No antitetanic serum was available at that time. The site of origin was a septic pulp wound of the right thumb sustained three weeks previously, and symptoms had been present for 10 days at least. The terminal phalanx was amputated immediately, and over two weeks elapsed before the spasms started to abate. I feel sure that recovery was only possible because of the complete extirpation of the site of origin of toxin.

It is to be hoped that recent medical advances in the treatment of tetanus will not obscure the essentially surgical pathology and treatment of the disease.—I am, etc.,

PATRICK D. RAWLENCE.

Diss.

Cancer and the Public

SIR.—Dr. James Brailsford (*Journal*, November 14, p. 1104) is still attempting to spread alarm and despondency among the surgeons who deal with cancer. He has in other letters said, "We have no cure." Certainly no surgeon confronted by a patient with a small, hard, non-fluctuating lump in her breast would promise her relations that she could be cured. But the results of skilful and bold surgery are well worth while. There are different grades of malignancy, and some cases of cancer are hopeless from the start; even at the time of diagnosis the growth has already caused metastases by spread through arteries or lymphatics. Professor McKinnon, of Toronto University, who displays some large and depressing statistics, thinks that the breast cases who live for very many years after the operation are not properly malignant.¹ But this is the opinion only of a distinguished man; he cannot prove it and we need not believe it. Certainly I know women who are well 25 years after removal of breasts that were proved by pathologists to be cancerous. The word "cure" is applicable there.

A large proportion of those in whom the trouble "recurs" after six or seven years have had excellent health in the meantime. It is absolutely wrong to say that untreated women with cancer who live for some time are free from pain, mental misery, or ulceration. Simple mastectomy was much practised by country surgeons 60 years ago; the results were appalling and gave surgery a bad name—operations must be thorough.

Human adult life is not a very long affair, and if surgeons can in a certain proportion of their cases, give a middle-aged woman 5, 10 or even 15 years of cheerful life before the onset of old age (in which she is certain to be afflicted in many ways) they have done very well for her. Claudio said (in *Measure for Measure*): "The miserable have no other medicine but only hope. Let not Dr. Brailsford try to take this away.—I am, etc.,

Hastings.

Public Health Laboratory Service

SIR.—While I would agree entirely with Dr. M. T. Parker's opinion (*Journal*, November 7, p. 1048) that close co-operation between the hospital and public health services is essential, and that the form that it takes should depend upon local circumstances, I regard his original description of the function of the Public Health Laboratory Service (*Journal*, October 10, p. 823) as wholly misleading.

Unless there is to be an absurd degree of duplication of resources, I would suggest that the work of the Public Health Laboratory Service should properly be confined to the investigation of established outbreaks of infectious disease, and the routine bacteriological control of water, milk, food, and other environmental factors. General practitioners are now making an increasing use of the facilities offered by the local hospital laboratory, where the haematological, bacteriological, biochemical, and histological aspects of any case can be considered side by side, to the great advantage of the patient. Moreover, the local hospital bacteriologist can offer a diagnostic service at least as efficient as that at the area public health laboratory. Any tests which may be of a particularly specialized nature can be, and often are, referred direct to the appropriate central reference laboratory.

Most of Dr. Parker's article would serve very well as a description of the services already available to general practitioners at the local hospital laboratory. The investigation of some of the illnesses listed would seem to be quite outside the province of the Public Health Laboratory Service, which is fundamentally a bacteriological service. For example, it appears that blood is going to be examined for evidence of glandular fever. Most haematologists would agree that neither a negative nor a positive Paul-Bunnell test should be accepted without a total and a differential white cell count. Such contact as I have had with junior bacterio-

logists under training for the Public Health Laboratory Service has made it clear that the study of haematology plays no significant part in their curriculum. Dr. Parker's article has important implications, and it should be made clear whether the opinions he expressed are to be regarded as the considered policy of the Public Health Laboratory Service.—I am, etc.,

Chertsey, Surrey.

ROBERT J. EVANS.

Site for Vaccination

SIR.—I read with interest Dr. J. Cantor's letter about the vaccination on the sole of the foot (*Journal*, November 7, p. 1050). I had myself only seen and performed vaccination on the arm or thigh, and was surprised when the local general practitioner here vaccinated my daughter just lateral to the second lumbar vertebra. He said he invariably used this site, and claimed almost 100% "takes." This site still allows the baby to be bathed in shallow water, is usually free from faecal and urinary contamination, and it will be concealed by bathing costume or evening dress in later life.

The only disadvantage I can see with the sole of the foot is that if the child is vaccinated or re-vaccinated when she is several months old it will be painful when crawling or walking, and she can easily pull the dressing off—neither factor applying to vaccination at the lumbar site.—I am, etc.,

Ghent, Belgium.

DOROTHY M. ROELS.

SIR.—I was interested to read Dr. J. Cantor's reference to the sole of the foot as a vaccination site (*Journal*, November 7, p. 1050). Six years ago it occurred to me that this would have the advantages that Dr. Cantor has pointed out, and I started using this site then, and always do so now in the case of female infants, except when the mother does not wish it. The only way in which my experience seems to differ from that of Dr. Cantor is that I do not find the percentage of "takes" quite so high on the sole of the foot, as, for instance, on the arm.—I am, etc.,

Canterbury.

PATRICK OSBORNE.

Orthopaedic Care in Poliomyelitis

SIR.—Dr. Hugh Garland and Mr. J. M. P. Clark (*Journal*, November 14, p. 1105) appear to apportion blame equally to "senior members of our profession" for "bickering in public," but Sir Reginald Watson-Jones, President of the British Orthopaedic Association, was doing no more than his duty in pointing out to the Welsh Regional Board the omission of an orthopaedic surgeon in their panel for research in acute anterior poliomyelitis. The Leeds region is to be congratulated for following for the past six years the usually accepted pattern of treatment for this disease.—I am, etc.,

Norwich.

H. A. BRITAIN.

Piperazine in the Treatment of Threadworms

SIR.—Following the publication of our report on a clinical trial (*Journal*, October 3, p. 755) the subsequent wide use of piperazine hydrate in the treatment of threadworms has elicited reports of side-effects not in accordance with our experience. In relation to the very considerable number of cases treated in general practice these reports are few, side effects having been recorded in 14 adults and 6 children. Nevertheless, we consider them worthy of attention. The manifestations are similar in all cases, notably giddiness and lack of co-ordination resulting in dropping things. Sick ness, inability to focus vision, and a sense of detachment have also been noted. These effects have, for the most part, been mild and recovery has been rapid.

Predominantly, these side-effects have occurred in adults as may be associated with wide variations in weight of the patient and with variation in capacity of the domestic tablespoon as unit of measure. Also, the piperazine hydrate is embodied in heavy syrup vehicle which forms a high meniscus when the spoon is completely filled. It is thought that these three factors have occasionally resulted in dosage considerably in excess of

recommended 50–75 mg./kg. The variation in the domestic tablespoon was investigated by measuring the capacity of nine spoons drawn from different households. Each spoon was filled level with water and also to its maximum with the heavy piperazine syrup. While the variation in capacity of tablespoons is notorious, the findings listed below are of interest:

Spoon No.	Filling Level with Water	Overfilling to Maximum with Piperazine Hydrate Syrup
1	5 drachms	8 drachms
2	6 " "	8 " 40 min.
3	6 " 20 min.	6 " 10 "
4	6 " "	9 " 20 "
5	6 " "	9 " 50 "
6	5 " 40 "	9 " 20 "
7	6 " 40 "	9 " 25 "
8	6 " 10 "	8 " 40 "
9	5 " 20 "	8 " 10 "

Note: 1 drachm = 3.5 ml. 60 minims = 1 drachm.

These can be summarized as follows: Of the nine tablespoons filled level with water one held $\frac{1}{2}$ fl. oz. (14.2 ml.), two held 25% excess, and six held 50% excess. Of the nine tablespoons filled to the maximum with piperazine hydrate syrup, eight held 100% excess or more, and one held 50% excess. To take the worst example, it will be observed that in spoon No. 5 the dose of syrup may reach nearly two and a half times the intended 4 drachms.

It is recommended that, in the use of this drug, account must be taken of variation in weight of the patient, and that for the treatment of adults the prescribed quantity should be measured in a graduated medicine glass.—We are, etc.,

R. H. R. WHITE.
O. D. STANDEN.

London, N.W.1.

Sweating in Shock

SIR.—In the *Journal* of October 10 (p. 832) Dr. Ronald Woolmer suggested that some other explanation than sympathetic overactivity was needed for sweating during shock or surgical operations. Experiments carried out by Dr. T. S. Lee and myself¹ have suggested that sweating accompanies extensive central nervous activity of various kinds and that the sweat glands of the axillae, palms, and soles sweat most readily in response to such central nervous causes. Mild sympathetic excitation *per se* does not give rise to sweating.

Although it is undesirable to seek teleological explanations for all phenomena, Dr. Woolmer's request for such an explanation can be met in this case. Extensive central nervous activity in primitive man is most likely to have resulted from fear, anger, hunger, love, or injury, and in all these circumstances recognition of friend or foe is important. Since sweating in the axillae has the strongest smell and since sweating of the soles, and to some extent also of the hands, will leave the most scent in the tracks, it seems teleologically sound that those regions should sweat the most readily in response to central nervous stimuli. Sweating of the hands may also help grasping.—I am, etc.,

Singapore.

Single-sample Test in Differential Diagnosis of Jaundice

SIR.—The evidence presented by Dr. Ian Wang (*Journal*, October 31, p. 971) for the inclusion of cholesterol determination in single-sample liver-function tests is undoubtedly convincing, but is liable to be received unfavourably by our already overburdened laboratories. However, there is a simple substitute in the form of the lipid turbidity test described by Kunkel *et al.*¹ which, although indicating changes in the total lipids (which is very often influenced by the phospholipid fraction), appears to parallel very closely the cholesterol content of serum.

The reagent and technique are extremely simple and require a minimum of working time: 1% liquid phenol in 12% NaCl in distilled water is kept in the refrigerator and 0.2 ml. of serum is mixed with 6 ml. of this phenol/saline solution. After standing for 30 minutes, the mixture is shaken and read as in the case of thymol turbidity. The units are calculated by assigning an

arbitrary value of 15 units to a suspension of BaSO₄ (3 ml. of 1.15 g. BaCl₂·2H₂O in 100 ml. water made up to 100 ml. with 0.2N H₂SO₄), which is read as a standard. My own range of normal variation is about 2 to 10 units, but it is a wise procedure for each laboratory to determine its own normal limits. I have used this test for a number of years, and, in addition to Dr. Wang's interpretations, have found it of value in distinguishing between acute and chronic hepatitis, since the former gives high normal or even elevated values, while the onset of cirrhosis is usually accompanied by low values. Indeed, a value below 2 units is of grave prognostic import. High values are found in fatty liver due to alcoholism when often the only abnormality is a raised lipid, while in biliary cirrhosis associated with xanthomatosis very high figures are encountered.

A valuable feature of this lipid test is that it enables one to eliminate false positive thymol turbidities which sometimes (though not always) occur in the presence of a raised lipid. In a recent paper dealing with liver function tests in myeloma, Dr. L. L. Griffiths² found difficulty in correlating some of his positive thymol turbidities with results obtained by other workers in this field. I feel these anomalous positive results are false reactions due to excessive lipid, particularly as Dr. Griffiths's excellent electrophoresis figures show an increase in β globulin in the sera in question and it is now fairly well established that lipid forms a complex with β globulin.

Before using the lipid test, I used to check the thymol turbidity by putting up 0.3 ml. of serum in 7.5 ml. 15% alcohol, which Mawson and I³ found to give almost identical turbidities to those obtained in the thymol test. However, I still carry out this alcohol turbidity test in order to have, together with the lipid reaction, a double check on the thymol reading.—I am, etc.,

Preston.

Turner's Syndrome in the Male

SIR.—The accompanying photograph was taken within three weeks of my reading the article by Drs. R. Sougin-Mibashan and W. P. U. Jackson on Turner's syndrome in the male (*Journal*, August 15, p. 371). The subject is a Zulu youth who had but recently arrived in Durban to seek work. By statutory regulation all such persons have to undergo a medical examination before they can be employed, and as a medical officer to the Native Administration Department about 120,000 go through my hands each year. This is the first case remotely resembling the Turner syndrome that I have seen during the past seven years.

Age 19 years, height 5 ft. 1 in., well built and muscular with a masculine voice, masculine distribution of body hair, a larger than average penis, but testicles small and firm. In addition to the webbing of the neck, the photograph distinctly shows congenital malformation in both ears. Mentally he was bright and gave a good account of himself. He disavowed interest in sex, and never had an erection.

He promised to return for further investigation, but this now seems unlikely. I gather from my staff that he looked upon my activities toward himself as a form of witchcraft, and it was obvious that he was anxious to be off.—I am, etc.,

Durban.

D. F. MACKENZIE.

Nocturnal Myoclonus

SIR,—In regard to your annotation (*Journal*, November 21, p. 1148) on nocturnal myoclonus, I should like to ask whether all the discussion on what has been termed "Ekbom's syndrome" since 1944¹ does not refer to the same subject as that of your annotation. If so, the general opinion seems to have been that the syndrome, sometimes familial in nature, is not definitely related to epilepsy.

Surely the tendency for the myoclonic jerks to appear on going to sleep may be compared to the occasional so-called "hypnagogic apparitions," the myoclonic jerks being due to the lowering of cortical control on going to sleep, and the hypnagogic apparitions being due to the commencing of dreams before brain unconsciousness has been fully established. I think this was an old view entertained before discussion on the subject was resuscitated by the writings of Ekbom and others. I should like also, if possible, to hear whether during the nocturnal myoclonus periods the knee-jerk responses are of the trepidation type.—I am, etc.,

F. PARKES WEBER.

London, N.W.1.

REFERENCES

- 1 Ekbom, K. A. (1944). *Acta med. scand.*, 118, 197.
- 2 Ibid., 1945, Suppl. 158.

SIR,—Last May the *Journal* contained a description of proctalga fugax wherein a hint was given that the condition was an epileptic variant (*Journal*, May 16, p. 1083), and a subsequent correspondent (*Journal*, July 25, p. 224) effectively dealt with this concept by describing his ability to abort this manifestation, including the vaso-vagal sequel precipitated by a heavy operating session, by the intake of amphetamine, but despite the effectiveness of this reply we continue to receive suggestions embracing varied psychosomatic conditions under this generic term and which certainly simplifies the treatment thereof.

I now note the inclusion of nocturnal myoclonus (*Journal*, November 21, p. 1148), which I would have considered in varied effect to be common to all, increased by fatigue, and much more manifest in the lower species. Our little puppy is a past exponent of the art; he includes a manifest tremor of the masseter muscles with same and would not dream of going to sleep without such accompanying enjoyment. Like the knee-jerk, it would be the absence of them that would portray the abnormality, not their presence, and unless we regain our sense of perspective we shall soon be including all forms of sleep-association states, dreams, somnolence, somnambulism, and narcolepsy as epileptic aberration.—I am, etc.,

Tipton, Staffs.

L. H. EUNSON.

SIR,—Arising from your annotation on this subject (*Journal*, November 21, p. 1148), I would like to draw attention to the involuntary jerking which occurs in some people when taking antihistamine drugs. This usually occurs at night and is commoner in the legs. The symptom was first noticed with promethazine hydrochloride, but has since occurred with chlorcyclizine hydrochloride, diphenhydramine hydrochloride, and mepyramine maleate. My experience with the other antihistamines has been limited, and it is quite possible that the jerking may occur with any one of this series of drugs. The exact incidence of this symptom is difficult to estimate. It may not be spontaneously complained of, but if specific inquiries are made it is found to be quite common. In some cases the jerking may be associated with restlessness and general excitement.

That nocturnal myoclonus may be linked with epilepsy is also interesting in connexion with the antihistamines, as it is known that these drugs may precipitate fits in known or potential epileptics. They have also been shown to increase the E.E.G. abnormally in epileptics.¹ In my own experience fits have been precipitated on four occasions by antihistamines and a history of fits is, in my opinion, a clear contraindication to antihistamine therapy.—I am, etc.,

POINTS FROM LETTERS

The General Practitioner and the Psychiatrist

Dr. JOAN W. KIPLING (Hull) writes: I should like to endorse Dr. G. L. Russell's doubt (*Journal*, October 24, p. 939) that "the majority of marital problems can be dealt with satisfactorily by the general practitioner." While some marriages are marred by comparatively simple and well-defined factors—for example, sex difficulties, sterility, lack of economic co-operation—many more are affected by a combination of several factors. If the G.P. lacks wisdom, interest, and, above all, time to deal with marital disharmony he can in most areas call on the help of the Marriage Guidance Council, whose workers are trained to consider social, ethical, and legal, as well as medical and psychological, aspects of marriage and to refer to consultants in each of these fields any case of exceptional difficulty. Many G.P.s welcome help given in such time-consuming work, although many would no doubt undertake more of it themselves if time allowed. Some undergo the training offered by the National Marriage Guidance Council.

Paroxysmal Paralytic Myoglobinuria

Dr. J. D. ROSANELLI (Tortola, British Virgin Islands) writes: In connexion with the discussion of the aetiology of this disease in the paper by Dr. Stephen D. Elek and Mr. Hugh F. Anderson (*Journal*, September 5, p. 533), it is noteworthy that myoglobinuria is invariably associated with creatinuria. Creatinuria regularly disappears on the administration of riboflavin (Hoff, F., 1948, *Medizinische Klinik*, Thieme, Stuttgart, and *Klinische Physiologie und Pathologie*, 1952, Thieme, Stuttgart). It is tempting to speculate that the experimental diet used by Agren (*Svenska Läkart.*, 1944, 41, 665) was not only deficient in aneurine but also in riboflavin. It is regrettable that the phenomenon of the "idiomuscular bulge" and the usually concomitant creatinuria have not been observed in this case.

Eponyms

Dr. W. E. MEDD (Farnham Common, Bucks) writes: There is a dark movement gaining ground which teaches that the names of diseases should be descriptive and not eponymous: thyrotoxicosis not Graves's disease; not Von Recklinghausen's disease but hyperparathyroidism. May I expound an apologia for the eponym? I like names that have a ring of history, names that recall those who were mighty physicians in palmier days. Surely a patient with Addison's disease can feel that he is merely making a small sacrifice for the perpetuation of the memory of the greatest of the Guy's triumvirate; whereas if he had adrenal hypoadrenalism even that crumb of comfort would be denied him. How delightful to have Albright's syndrome; but if one contracted polyostotic fibrous dysplasia one would feel that one was falling to bits. The full glory of the eponym is reached in the multiple-barrelled form: Hand-Schüller-Christian, Rendu-Osler-Weber—those give the tongue something to roll round, and you can almost smell the mothballs in their morning coats and dear old top-hats. Let us condemn dull impersonal names, utility names in a utility age. Can we do no better than X disease or Q fever?

Cancer and the Psyche

Dr. E. JOYCE PARTRIDGE (Exeter) writes: I wish to put forward a plea that some of the money spent on research into the causes of cancer be directed into psychosomatic channels on the grounds that there may well be something in the attitude of mind (either conscious or unconscious) of the cancer victim which predetermines the development of the malignant cells. It has been suggested that it is changes in the body fluids which precede and invite the wanton multiplication of a given cell—i.e., initiate its cancerous growth. If this be so it is worth while to recall that the body fluids are those representatives of the soma which most readily respond to the activities of the psyche: tears, the dry mouth and the polyuria of fear, the changes in the gastric juice accompanying anxiety and mucous colitis, to mention but a few obvious examples.

Breast-feeding in Oxford

Dr. STELLA RING (Bexley) writes: Dr. Grace H. Walker (*Journal*, October 31, p. 995) is surely putting the cart before the horse. Breast-feeding is an expression of maternal love, not a cause, and as such is of incalculable value to the mother and the child. Artificial feeding can be an eminently satisfying experience, and some mothers even feel thirst and breast fullness when giving a bottle; but many more have to be comforted because they themselves are frustrated, however well the baby grows, by the failure of such a link.

Obituary

BASIL HUGHES, D.S.O., M.B., F.R.C.S.

Mr. Basil Hughes, for many years honorary surgeon to the Bradford Royal Infirmary, died in the Hospital of St. John and St. Elizabeth in London on November 21 at the age of 75.

Basil Hughes was the son of Captain J. E. Hughes, R.N., and was born in the village of Hales, Staffordshire, on March 30, 1878. He was educated at Eastman's Royal Naval Academy and at Selwyn College, Cambridge, where he took the mathematical tripos in 1900. He was some time making up his mind about what career to take up, hesitating between music, veterinary science, and school teaching. In 1904 he graduated B.Sc. at London University. He then decided to study medicine, and he entered King's College Hospital Medical School with a Sambrooke scholarship. His student career continued as brilliantly as it had begun, for he was awarded the second-year medical student scholarship and the Jelf medal in 1906 and the Tanner prize and a senior scholarship two years later. He qualified in 1909, graduated M.B. at Cambridge in the following year, and took the F.R.C.S. in 1911. After holding the appointments of house-physician and house-surgeon at King's College Hospital, he became casualty officer at the Royal Free Hospital, house-surgeon at Paddington Green Children's Hospital, and clinical assistant at The Hospital for Sick Children, Great Ormond Street. He then moved to Yorkshire to become pathologist and resident surgical officer at the Bradford Royal Infirmary, an appointment he held from 1911 to 1913.

On the outbreak of war in 1914 Hughes left his newly established practice as a consulting surgeon to enter the R.A.M.C. as a lieutenant, becoming regimental medical officer, first, of the 6th battalion and then of the 5th battalion of the West Yorkshire Regiment. Later he served as a surgical specialist and finally as officer in charge of the surgical division of general hospitals in France and Salonika, attaining the rank of major. It was when he was in Salonika that he was called upon to operate on the Serbian Minister of War, who had a depressed fracture of the skull. Hughes was twice mentioned in dispatches, and in 1918 he was awarded the D.S.O. and the Serbian Order of St. Sava for his services. He made a great reputation as a military surgeon, for he was a rapid and gentle operator. Quick to point out the danger of underrating shock, he also took exceptional pains to maintain asepsis during the treatment and dressing of wounds.

After the war Hughes returned to Bradford, and in 1919 he was appointed honorary surgeon to the Children's Hospital and a surgical specialist under the Ministry of Pensions. Three years later, after his appointment as senior surgeon to the Bradford Municipal General Hospital, he was elected to the staff of the Bradford Royal Infirmary as assistant honorary surgeon. Later he became honorary consulting surgeon to both institutions. In the last war Hughes's experience in the treatment of wounds was invaluable, and from the time of the Dunkirk evacuation until the end of the war he operated on a large number of wounded men, many of whom were admitted to St. Luke's Hospital. In 1943 he was elected a founder fellow of the International College of Surgeons in recognition of

his standing as a surgeon and of his contribution on the classification of war wounds in the book *Surgery of Modern Warfare* (1941), edited by Mr. Hamilton Bailey. He was also a founder fellow of the Association of Surgeons of Great Britain and Ireland. His experiences in the war of 1914–18 provided him with the material for *War Surgery, from Firing Line to Base*, a book written in collaboration with Dr. H. Stanley Banks, who contributed the chapters on the bacteriological aspect of war surgery. Hughes was also a frequent contributor to the medical journals during the height of his career.

Relinquishing his hospital appointments in 1945, he retired to Cornwall, where, until he had a serious illness a year ago, he greatly enjoyed the management of his 56-acre farm at Par. He married Miss Norah Blayney, formerly well known as an actress, in 1932, and she survives him.

We are indebted to Mr. H. HAMILTON STEWART for the following appreciation: I had the good fortune, in my early days, to be assistant surgeon at the Bradford Royal Infirmary under Mr. Basil Hughes, and I shall always consider it a great privilege to have worked with him. He possessed a most colourful personality, due in part, no doubt, to his Welsh ancestry. He was a musician and a mathematician, and agriculture also interested him. After retiring from a very active life as a surgeon he took an agricultural course at Cambridge before he settled down to run his own farm in Cornwall. It must be rare for such diverse qualities to be present in any one man.

Hughes was cheerful and good-tempered, and he could often be heard coming along the corridors whistling a tune. He had at one time a great phase for "keeping himself alkaline," as he believed that this was necessary for good health. His lunch on a long operating day would consist of a plate of raw vegetables, which he would eat with apparent relish. He was very fond of driving in an open car even in the depths of winter, when most men after operating would have feared pneumonia. As a surgeon, he was indefatigable, and he was always alive to any advances. He did a great deal to enhance the prestige of Bradford as a surgical centre. Patients came from all parts of the country to be treated by him.

He was a most dexterous surgeon, with fine hands, and there were few in this country who were his equal in surgical technique. As a result of his experience as a children's surgeon he was an advocate of small incisions. I should say that one of the main reasons for his great success as a surgeon was his gentleness in handling human tissues. He will long be remembered by his friends and by his numerous patients.

Sir LANCELOT BARRINGTON-WARD

K.C.V.O., Ch.M., F.R.C.S., F.R.C.S.Ed.

A. J. M. B. writes: Sir Lancelot Barrington-Ward (whose obituary notice was published in last week's *Journal*) was senior surgeon of the Wood Green and Southgate Hospital for 18 years, and had been on the surgical staff for over 20 years before that. Those of us general practitioners who knew him there will always remember with affection his Wednesday visits. Exactly at 2.30 p.m. he would walk in briskly, his trim athletic figure reminding us of the days when he was a Rugby international and a redoubtable amateur boxer at Edinburgh University. Glancing at us with an expression that seemed to be an amusing blend of courtesy and raillery that seemed to bow deeply and ask, "What problems have you for me to-day?" He set himself a high standard of work and expected it from others. As a member of the staff once said, "When the chief arrives, this hospital springs to attention." It was certain that he commanded deep respect as well as affection. The hospital, though very small compared with the others which he attended, was in a sense one of his hobbies. He had watched its growth and develop-

ment with loving care, had acted as chairman of the hospital council for 13 years, and was ever ready to devote time to promoting the welfare of the patients and staff. Countless numbers of our patients in the district have good cause to be grateful for his wise advice and surgical skill; and we, his colleagues, mourn him as a friend and cherish his memory.

Dr. WILLIAM KERR RUSSELL, who died on November 5 after a prolonged period of ill-health, was born at Stewarton, Ayrshire, on April 12, 1874. Educated at Kilmarnock Academy and Glasgow High School, he graduated M.B., C.M. at Glasgow University in 1897. He settled in practice at Sunderland in 1899 and retired in 1948 on account of ill-health. He was a very active member of the B.M.A. and an ex-chairman of the Sunderland Division. He was also a founder member of the West End Medical Society and ex-chairman and member of the council of the Glasgow and Aberdeen North-eastern University Club. "Willie," as he was affectionately known to his colleagues, was a first-class example of the good family doctor of a previous generation. He was guide, philosopher, and friend to his patients and nothing was allowed to come between him and their welfare. A memorial service was held at Trinity and St. James's Presbyterian Church, where he had been an elder for 43 years.—J. S. M.

Medical Notes in Parliament

CLEAN FOOD BILL

The Food and Drugs (Amendment) Bill was given a second reading in the House of Lords on November 24.

Viscount WOOLTON, who moved it, said that its first main purpose was to ensure a higher standard of cleanliness in places where food was prepared or handled. Under Clause 6 the Ministers of Food and Health were given powers to make *ad hoc* regulations suited to the conditions of many different kinds of businesses and foods. A start would be made with new hygiene regulations, and after that would come registration of all premises where food was stored or handled, beginning with premises where food infection was most likely to occur, such as catering establishments. The second main purpose was to bring up to date the protection of the public against the use of substances and processes liable to render food injurious to health. It was sought to do this by preventing the addition of any substance to food, or the abstraction of any constituent, or the use of any treatment in preparing food, which made it injurious to health. The present law had proved inadequate, particularly in dealing with what was described as chronic toxicity. This was dealt with in Clause 5, which laid it down that the cumulative effect of additions or abstractions, or ingredients or processes, must be taken into account when the possibility of injury to health was being thought of.

The machinery by which the Bill's provisions would be put into effect would be, broadly speaking, by administrative control of standards of food hygiene and composition from the centre, by way of regulations, and it would then be for local authorities to execute and enforce these regulations. It was intended in due course to introduce a consolidating measure. Answering a point made by Lord Silkin, he stated that it was certainly intended that the Bill should cover restaurants.

Cleanliness in Restaurants

Lord WEBB-JOHNSON said it was fitting that a member of the medical profession should welcome the Bill, and it was gratifying that definite action was being proposed. The parts of the Bill that appealed to him were those that dealt with misleading advertisements and labels, those which imposed requirements, and those that were to regulate the addition of chemicals. He welcomed the assurance that

the Bill was to apply to restaurants. Clause 6 referred to the provision, maintenance, and cleanliness of sanitary and washing facilities, apparatus, furnishings, and utensils, but there was no reference to the personnel. It was extremely difficult to ensure that the workers would be clean, not only in themselves but in their clothing and so on, but it was a matter of first importance, and had been so treated in the Factory Acts. It had been suggested that the public could be a big controlling factor in imposing the adoption of cleanly methods in the serving of food. That was true, but the public were not particularly well informed on the statutory requirements, nor necessarily well educated in the correct way of handling food.

Lord HADEN-GUEST said that the Bill, with some amendments, would be a valuable safeguard of the national health. Not everything could be done directly by the drafting of the Bill, and it would be necessary to have more regulations, not fewer, to carry out its purpose, and they should be written in plain English so that they could be clearly understood. There was one point which he was not sure could be dealt with by regulations, although they could be made. In food shops and all places concerned with the distribution of food it was necessary to have a higher standard of personal cleanliness, and he believed that could come only from health education and training.

Lord SALTOUN gave some figures showing the extent of the habit of eating out, and the number of cases of food-poisoning. He quoted the Caterers' Association as stating that they sold some 10,000 million meals a year to the public, and the Ministry of Health Chief Medical Officer's analysis of the 255 outbreaks of food-poisoning that were traceable in the 21 months from April 1, 1950, to December 31, 1951—41 of them occurred in hotels, restaurants, and cafés, and 31 in works canteens. More recent figures for the first nine and a half months of this year showed that, out of 700 traceable outbreaks, 27 occurred in hotels, etc., and 17 in works canteens. Lord SEMPILL repeated Sir Edward Mellanby's criticisms about food manipulation and the use of agents in flour, and Viscount BLEDISLOE protested about the amount of advertising "booming" various foods and synthetic preparations as likely to enhance health or improve the general wellbeing.

Old-age Pensioners

Mr. R. H. TURTON, Parliamentary Secretary to the Ministry of Pensions and National Insurance, replying to a short debate on November 23 about the hardships of old-age pensioners, quoted the results of the national food surveys, which were instituted in 1951 and dealt with the calorie intake of the pensioners. Although the figures did not show a very bright picture, he said, they showed a considerable improvement. In January and February, 1951, the calorie intake was 7% below the requirements based on the B.M.A. scales. When the increase in retirement pensions was introduced last year the level rose to just over 100% of the B.M.A. requirements, and the most recent figures showed that for the first quarter of 1953 it was 4% over those requirements.

Fluoride Treatment of Teeth

Mr. WILLIAM ROSS on November 24 asked the Secretary of State for Scotland if he would state the areas in which an effort was being made to reduce dental decay by the application of solutions of sodium fluoride, and what knowledge had been gained from these efforts. Mr. J. STUART informed him that work of this kind had been carried out among schoolchildren in Dundee, Edinburgh, and Fife. While it promised to afford a measure of protection against dental decay, it would be some years before final conclusions could be drawn about its place in preventive dentistry.

Scottish Lunacy Laws

Mr. A. WOODBURN asked the Secretary of State for Scotland on November 26 whether he would make a further statement on the intentions of the Government to set up a

Royal Commission to consider and report on mental illness and deficiency in Scotland. Mr. J. STUART replied that the whole field was covered by the Committee on the Scottish Lunacy and Mental Deficiency Laws under the chairmanship of Lord Russell that reported in 1946. A further inquiry at this date was unnecessary, but he was considering the report and proposed in due course to lay a White Paper before Parliament as a basis for further discussion.

Fog Masks for Old People

Mr. B. TANNER asked the Minister of Health on November 26 whether, in view of the fact that most of the patients who would require masks as a protection from fog would be old people in the low income group, he would allow such masks to be issued free of any prescription charge. Miss PAT HORNSBY-SMITH, the Parliamentary Secretary, said that there were no grounds which would justify drawing a distinction between masks and other necessary drugs and appliances prescribed by general practitioners. Where the charge could not be met without hardship the usual simple arrangements for securing a refund applied.

Tuberculosis Waiting-lists

Mr. IAIN MACLEOD, Minister of Health, stated in reply to Brigadier F. MEDLICOTT on November 26 that the numbers of patients suffering from tuberculosis who were on the waiting-lists for admission to hospitals were 9,378 at the end of 1950, 7,096 in 1951, and 6,126 in 1952.

Vaccination Among Immigrants

Mr. S. P. VANT asked the Minister of Health on November 27 whether entrants into Great Britain were asked to produce a certificate of vaccination against smallpox. Mr. IAIN MACLEOD said they were not normally, but if it was necessary to consider placing passengers from an infected area or craft under surveillance they might be asked whether they could produce evidence of recent vaccination.

Medico-Legal

ALLEGED FATAL BLOOD TRANSFUSION

Judgment was entered for the Southend Group Hospital Management Committee in the Queen's Bench Division on November 27 in an action in which it was alleged that the negligent administration of a blood transfusion at Southend General Hospital caused the death of a patient. On the third day of the trial, after hearing all the evidence, Mr. Justice Hilbery ruled that there was no case for the jury to consider.

The plaintiffs in the action were Mr. and Mrs. E. F. Webb, of Hadleigh, Essex. They claimed damages from the Management Committee in respect of the death at the hospital on November 21, 1951, of their son, Raymond L. Webb, aged 26. They alleged negligence by the house-surgeon, Dr. Joseph A. Ryan. It was stated that Dr. Ryan was not a defendant in the action, because he could not be traced. He was said to have returned to Canada, where he qualified. The Management Committee denied negligence, and pleaded further that Dr. Ryan was not their servant, although he was under contract to them at the time.

The plaintiffs contended that Dr. Ryan's only medical qualification was a degree obtained at Dalhousie, Nova Scotia, in May, 1951, and that he was not temporarily registered at the material time by the General Medical Council, and that he was not entitled to practise when he was appointed to his post at Southend General Hospital on August 18.

Raymond Webb entered hospital on October 28, 1951, and was successfully operated on for haemorrhoids on October 29. Between November 8 and 12 he had haemorrhages and was given blood transfusions. On November 18 the fourth blood transfusion was given, but was unsuccessful.

Rigor set in, accompanied by nausea and high temperature, and the transfusion was discontinued. On November 21, after the patient's reluctance had been overcome, he was given another transfusion. He reacted in the same way as on the 18th. By 5 p.m. his temperature rose to over 103° F. (39.4° C.) and his pulse became imperceptible. In spite of treatment he died at 8 p.m. A post-mortem examination showed death to have been caused by toxæmia, due to infected blood, and it was plaintiffs' case that the infection was introduced into their son's system during the transfusion.

Mr. F. R. Overend, assistant secretary of the General Medical Council, said in evidence that at the time Dr. Ryan was not registered, but agreed that temporary registration would have been granted if Dr. Ryan had asked for it. The fact that Dr. Ryan was not registered had nothing to do with his qualifications or ability.

Dr. J. W. Lacey, pathologist at St. John's Hospital, Chelmsford, giving evidence of a post-mortem examination of Raymond Webb, said that death was due to the presence in the blood stream of *Bacterium coli-aerogenes*. There was no question of the blood groups being incompatible. Given the circumstances of the patient's death, everything unquestionably pointed to the fact that the blood given in the transfusion of November 21 contained an enormous number of these organisms. He agreed that fatal reactions could be caused by the presence in the transfused blood of dead bacilli, which would be extremely difficult to detect. That could happen without negligence on anybody's part.

An Unhappy Chance

The case for the Management Committee was that the death of Raymond Webb was an unhappy chance—one of those rare cases where fatal reactions followed the transfusion of blood which was both sterile and compatible.

Mr. J. J. Shipman, who was senior surgical registrar at Southend General Hospital in 1951, said Dr. Ryan was a competent young surgeon and his ability in administering a blood transfusion was above the average. The witness said he ordered the transfusion on November 21, and he considered it a reasonable decision. The patient's haemoglobin content was only 44%.

Dr. W. D. Nicoll, senior registrar in the department of pathology at the hospital, said that the blood used on November 21 and on November 21 was compatible and sterile. The blood used on November 21 was checked again on November 22. It was compatible, but a culture taken from it developed a heavy growth of *Bacterium coli*. This he thought was due to the fact that the bottle had been left uncapped in the ward for several hours.

Dr. D. C. Caldwell, consultant pathologist at the hospital, said he was not surprised that Dr. Lacey had found infection in an examination carried out five days after death. He thought it likely that the infection stemmed from the site of the operation. Cross-examined, he agreed that something in the transfused blood caused the patient's death, but he did not agree that there was infection in the blood. He did not know what caused death.

Dr. G. Discombe, pathologist at the Central Middlesex Hospital, gave evidence that he agreed with the conclusions arrived at by Dr. Caldwell.

At the conclusion of evidence Mr. Justice Hilbery said there was "not a shadow of evidence" to support the allegations of negligence against the hospital. One allegation which he said should never have been made was that concerning Dr. Ryan's non-registration. Dr. Ryan was a young man with full and proper qualifications obtained in Canada. An allegation that the hospital was negligent in entrusting the blood transfusion to a young man recently qualified was absurd; particularly as he was said in evidence to have been exceptionally competent. People were not entitled to make charges of negligence and put them on the record of the court, without some evidence to support them, in the hope that they might be able to discover something to justify them. There was no evidence that the bottle in question had become infected because of the way it had been handled by Dr. Ryan or anyone else.

Saying there was no evidence on which the jury could find a verdict for the plaintiffs, he entered judgment for the defendants.

INFECTIOUS DISEASES AND VITAL STATISTICS

Summary for British Isles for week ending November 14 (No. 45) and corresponding week 1952.

Figures of cases are for the countries shown and London administrative county. Figures of deaths and births are for the 160 great towns in England and Wales (London included), London administrative county, the 17 principal towns in Scotland, the 10 principal towns in Northern Ireland, and the 14 principal towns in Eire.

A blank space denotes disease not notifiable or no return available. The table is based on information supplied by the Registrars-General of England and Wales, Scotland, N. Ireland, and Eire, the Ministry of Health and Local Government of N. Ireland, and the Department of Health of Eire.

Vital Statistics

Industrial Accidents and Diseases

The number of workpeople (other than seamen) in the United Kingdom whose deaths from accidents in the course of their employment were reported in October was 124, compared with 117 in the previous month and 116 (revised figure) in October, 1952.

The number of cases of industrial diseases in the United Kingdom reported during October was as follows: lead poisoning, 1; other poisoning, 13; anthrax, 3; epitheliomatous ulceration, 8; chrome ulceration, 13; total, 38. There were no deaths.—*Ministry of Labour Gazette*, November, 1953.

Graphs of Infectious Diseases

The graphs below show the uncorrected numbers of cases of certain diseases notified weekly in England and Wales. Highest and lowest figures reported in each week during the nine years 1944-52 are shown thus -----, the figures for 1953 thus ———. Except for the curves showing notifications in 1953, the graphs were prepared at the Department of Medical Statistics and Epidemiology, London School of Hygiene and Tropical Medicine.

Medical News

Royal Society.—Last Monday Dr. E. D. Adrian, O.M., delivered his presidential address to the Royal Society. The great volume of scientific publication nowadays made it difficult for him, he said, to pick out any one discovery for particular mention. "There has been great activity in many lines, but for the time being we seem to have passed the stage of really startling discoveries." In the most promising fields the general line of advance could be foreseen for a few years at least. It would be safe to expect, for instance, valuable developments in the fields of synthetic chemistry and in our understanding of the structure of proteins, the nature of viruses, and the action of enzymes. "But we are well prepared for them: they will not startle us unless they show some fault in the accepted theories." Dr. Adrian then spoke of some of the difficulties created by the rapid expansion of science. On the one hand, boundaries between different scientific disciplines were becoming blurred; on the other, new specialist groups were arising. Long ago it had passed the competence of one mind to keep the enormous territory of science in focus. At the close of his address Dr. Adrian alluded to the physical basis of memory. "We must start each morning with our brain structure modified by what happened to it the day before," he said. It was now possible to examine the reactions of a single nerve cell by thrusting a microelectrode into it, and the changes produced by repeated activity were being studied. However, the storage process might well involve a chemical as well as a physical reorganization. Evidence was accumulating that the transmission of signals from one cell to another depended on the release from the cell terminals of stimulating molecules and their rapid destruction by enzymes.

Scientific Exhibition.—At the B.M.A. Annual Meeting next year in Glasgow there will again be a scientific exhibition, open from July 5 to 9. This event proved very popular at the meetings at Dublin and Cardiff. To the exhibitor it offers unique opportunities of discussing his work with colleagues from at home and abroad. Medical research and current medical practice and techniques are suitable subjects for exhibition. Space is limited, so potential exhibitors are advised to apply for stands as soon as possible, and certainly not later than December 31. Full information and application forms can be obtained from the Secretary, British Medical Association, B.M.A. House, Tavistock Square, London, W.C.1.

Air Attendants.—The St. John Ambulance Brigade can provide air attendants for patients travelling by air both in Britain and abroad. The attendants are qualified in air duties and emergency midwifery in addition to first aid and nursing. The service is voluntary, and the only payment is the attendant's fare and reasonable out-of-pocket expenses. All attendants are fully insured. At present this service is limited to British European Airways, but it is hoped to extend it soon to other air corporations. Applications for attendants should be made to the Officer in Charge of Register, St. John Ambulance Brigade Headquarters, 8, Grosvenor Crescent, London, S.W.1 (telephone, Sloane 9861). If special equipment is likely to be required the doctor should give warning of this beforehand.

Anglo-French Exchange Bursaries.—Applications are now invited for the bursaries which will be awarded in 1954 to young British doctors under the exchange scheme arranged by the French Embassy in London between the Institut National d'Hygiène in Paris and the Ciba Foundation in London. The value of the French grants is 60,000 francs a month, tax free, and they will be awarded for periods of two to four months to doctors who wish to obtain clinical experience or carry out medical research in France. Since the aim of the exchange is to spread in each country knowledge of achievements, outlook, and methods on the other side of the Channel, preference will normally go to candi-

SCARLET FEVER

Infectious Diseases

The largest variations in the notifications of infectious diseases in England and Wales during the week ending November 14 were increases of 235 for whooping-cough, from 2,175 to 2,410, and 213 for scarlet fever, from 1,187 to 1,400, and a decrease of 214 for measles, from 1,030 to 816.

The largest rises in the incidence of scarlet fever were 46 in Lancashire, from 165 to 211, and 38 in London, from 58 to 96. The largest fluctuations in the local returns of whooping-cough were rises of 76 in Yorkshire West Riding, from 195 to 271, 55 in Kent, from 43 to 98, and 55 in Norfolk, from 43 to 98, and falls of 49 in Staffordshire, from 125 to 76, and 33 in Surrey, from 91 to 58. The largest decreases in the number of notifications of measles were 79 in Cumberland, from 128 to 49, and 79 in Lancashire, from 248 to 169, while the largest increase was 34 in Staffordshire, from 88 to 122. 26 cases of diphtheria were notified during the week, being 8 more than in the previous week. The chief feature of the returns was a rise in Staffordshire from 5 to 13. 7 of the 13 cases were notified in Coseley U.D., where 7 cases were notified a fortnight earlier.

95 cases of acute poliomyelitis were notified. These were 6 more for paralytic and 5 fewer for non-paralytic cases than in the preceding week. The largest returns were Yorkshire West Riding 12, Lancashire 11, Dorsetshire 7 (Wimborne and Cranborne R.D. 5), London 5, and Lincolnshire 5.

Notifications of dysentery numbered 370, and were 12 more than in the preceding week. The chief centres of infection were Yorkshire West Riding 98 (Bradford C.B. 60, Halifax C.B. 17), Yorkshire North Riding 18 (Middlesbrough C.B. 18), Lancashire 54 (Manchester C.B. 11, Bolton C.B. 9), London 47 (Islington 8), Middlesex 25 (Willesden M.B. 9), Warwickshire 17 (Birmingham C.B. 17), and Leicestershire 11 (Leicester C.B. 11).

In Scotland 105 cases of dysentery were notified in Glasgow and 37 in Edinburgh.

Week Ending November 21

The notifications of infectious diseases in England and Wales during the week included scarlet fever 1,613, whooping-cough 2,510, diphtheria 28, measles 793, dysentery 362, acute poliomyelitis 88, paratyphoid fever 9, and typhoid fever 2.

The Services

Surgeon Commander Robert M. Coplans, R.A.N., Officer in Charge of the Royal Australian Naval School of Air Medicine and Naval Specialist in Hygiene, has been appointed Honorary Physician to the Governor-General of Australia. Colonel P. R. Hawe, T.D., R.A.M.C., T.A., has been appointed Honorary Colonel of a Territorial Army Unit, in succession to Colonel J. P. Clarke, T.D., R.A.M.C., T.A., whose tenure has expired.

dates who are in teaching, or in posts where they can pass on the experience they have acquired. Application forms may be obtained from Dr. G. E. W. Wolstenholme, Ciba Foundation, 41, Portland Place, London, W.1. The closing date for applications is February 22, 1954.

Medical Artists.—The Medical Artists Association of Great Britain will shortly hold an examination of work submitted by those seeking membership. The last date for entries is January 30, 1954. Entry forms may be obtained from the honorary secretary, the Rotunda, the Radcliffe Infirmary, Oxford.

First-aid Resuscitation.—On the advice of the Medical Research Council, the mixture of oxygen and carbon dioxide formerly carried in local authority ambulances for first-aid resuscitation is now being replaced by pure oxygen.

Professor B. W. Windeyer has been appointed Dean of the Middlesex Hospital Medical School. Professor Windeyer graduated in Sydney, Australia, in 1927. Since 1942 he has occupied the London University Chair of Radiology (Therapeutic) at the Middlesex Hospital. He succeeds Sir Harold Boldero.

Miss Grace Hoare, personal assistant to the Editor of the *British Medical Journal*, has retired after 45 years' devoted service to three of the *Journal's* editors.

COMING EVENTS

The 10th International Congress of Medicine in Sport will take place in Belgrade from May 19 to 22, 1954. Further information may be obtained from Dr. Vojin Smolaka, Belgrade, Deligradska 27, Yugoslavia.

International Society of Orthopaedic Surgery and Traumatology.—The sixth congress of the International Society of Orthopaedic Surgery and Traumatology will be held in Berne, Switzerland, from August 30 to September 3, 1954. All correspondence should be addressed to the secretary-general of the Society, Mr. J. Delchef, M.D., 34, rue Montoyer, Brussels, Belgium.

NEW ISSUES

British Journal of Ophthalmology.—The next issue (Vol. 37, No. 12) will be available in a week's time. The contents include: OCULAR COMPLICATIONS OF DIABETES MELLITUS. G. I. Scott. OCULAR COMPLICATIONS OF DIABETES MELLITUS. Leonard H. Howells. LENS EXTRACTION IN DIABETIC PATIENTS. A. B. Nutt. OCULAR MANIFESTATIONS IN LÖFFLER'S SYNDROME. D. M. J. Velzeboer. AMYOTROPHIC TEST IN PRIMARY GLAUCOMA. G. Cristini and N. Pagliarini. SMALL VOLUNTARY MOVEMENTS OF THE EYE. B. L. Ginsborg. SYMPATHETIC OPHTHALMIA FOLLOWING AN OPERATION FOR RETINAL DETACHMENT. Walter Kornbluth and Richard Stein. UNUSUAL CASE OF DOUBLE PRIMARY TUMOUR. Ida Mann, P. C. Yates, and J. P. Ainslie. THE LEGEND AND SHRINE OF SAINT TRIDUANA. John Foster.

Issued monthly; annual subscription £4 4s., single copy 8s. 6d.; obtainable from the Publishing Manager, B.M.A. House, Tavistock Square, London, W.C.1.

SOCIETIES AND LECTURES

A fee is charged or a ticket is required for attending lectures marked ●. Applications should be made first to the institution concerned.

Monday, December 7

● HUNTERIAN SOCIETY.—At Talbot Restaurant, London Wall, E.C., 7 for 7.30 p.m., dinner meeting. Discussion: A Pain in the Neck, to be opened by Dr. J. W. Aldren Turner and Mr. H. Osmond-Clarke. ● POSTGRADUATE MEDICAL SCHOOL OF LONDON.—4 p.m., Professor A. Haddow: Recent Trends in the Experimental Pathology of Cancer. ROYAL EYE HOSPITAL.—5.15 p.m., Dr. T. H. Whittington: The "Refraction Case." Six Factors Producing Good Sight. ROYAL INSTITUTE OF PUBLIC HEALTH AND HYGIENE.—5 p.m., First Harben Lecture by Sir Henry Dale, O.M., F.R.S.: Changes and Prospects in Medicinal Treatment (illustrated). UNIVERSITY COLLEGE, LONDON: DEPARTMENT OF BIOCHEMISTRY.—At Physiology Theatre, 4.45 p.m., public lecture by Dr. H. Gutfreund: Molecular Forces in Protein Solutions—(1) Molecular Interaction in Protein Solutions.

Tuesday, December 8

CHelsea CLINICAL SOCIETY.—At South Kensington Hotel, 7.30 p.m., dinner, followed by a discussion: Dictators and Their Doctors, to be opened by Mr. A. Dickson Wright. INSTITUTE OF DERMATOLOGY.—5.30 p.m., Dr. P. D. Samman: Reticulosis. LONDON UNIVERSITY.—At Anatomy Lecture Theatre, University College, 5.30 p.m., Special University Lecture in Psychology by Professor Otto Koehler (Freiburg): Thinking Without Words. Illustrated with lantern slides and films.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—5 p.m., FitzPatrick Lecture by Dr. Maurice Davidson: Medicine in Oxford, A Historical Romance: From the Laudian Code (A.D. 1636) to the Early XIXth Century. ROYAL EYE HOSPITAL.—5 p.m., Professor Arnold Sorsby: Nature of Congenital Anomalies. ROYAL INSTITUTE OF PUBLIC HEALTH AND HYGIENE.—5 p.m., Second Harben Lecture by Sir Henry Dale, O.M., F.R.S.: Changes and Prospects in Medicinal Treatment (illustrated). ST. MARY'S HOSPITAL MEDICAL SCHOOL.—At Wright-Fleming Theatre, 5 p.m., Mr. Aleck W. Bourne: Non-malignant Conditions of the Cervix. WEST END HOSPITAL FOR NERVOUS DISEASES.—5.30 p.m., Mr. I. R. McCaul: Investigation of Cerebral Tumour.

Wednesday, December 9

INSTITUTE OF DERMATOLOGY.—5.30 p.m., Dr. H. Haber: Reticulosis. INSTITUTE OF NEUROLOGY.—5 p.m., Dr. H. Hecan (Paris): The Ballet's Syndrome and its Minor Forms. INSTITUTE OF PSYCHIATRY.—At Maudsley Hospital, 5.30 p.m., public lecture by Dr. Eliot Slater: The M'Naghten Rules and Modern Concepts of Responsibility. INSTITUTE OF UROLOGY.—4.30 for 5 p.m., Mr. J. G. Sandrey: Urological Emergencies in General Practice. LIVERPOOL MEDICAL INSTITUTION.—At Liverpool Royal Infirmary, 3 p.m., clinical meeting. POSTGRADUATE MEDICAL SCHOOL OF LONDON.—2 p.m., Professor G. MacG. Bull: Tests of Renal Function. ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 p.m., Bradshaw Lecture by Sir Reginald Watson-Jones: Fracture Treatment in the Next Half Century. ROYAL INSTITUTE OF PUBLIC HEALTH AND HYGIENE.—5 p.m., Third Harben Lecture by Sir Henry Dale, O.M., F.R.S.: Changes and Prospects in Medicinal Treatment (illustrated). ST. MARY'S HOSPITAL MEDICAL SCHOOL.—At Wright-Fleming Theatre, 5 p.m., lecture-demonstration by Dr. J. D. W. Pearce: Psychological Medicine. SOCIETY OF CHEMICAL INDUSTRY: FOOD GROUP: NUTRITION PANEL.—At Medical Society of London, 6.30 p.m., Dr. R. Passmore: Some Recent Investigations of Human Calorie Requirements.

Thursday, December 10

ALFRED ADLER MEDICAL SOCIETY.—At 11, Chandos Street, London, W., 8 p.m., Dr. L. P. E. Laurent: Psychosomatic Effects of Obesity. ● INSTITUTE OF CARDIOLOGY National Heart Hospital.—9.30 a.m., Dr. Maurice Sokolow (California): Quinidine. ● INSTITUTE OF CHILD HEALTH AND INSTITUTE OF NEUROLOGY.—At National Hospital, Queen Square, W.C.1, 5.30 p.m., Dr. B. H. Kirman: Epilepsy and Paralytic Syndromes. INSTITUTE OF DERMATOLOGY.—5.30 p.m., Dr. R. W. Riddell: Superficial Fungus Infections of the Skin. PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.—7.30 p.m., Professor A. A. Miles: Biological Standards. POSTGRADUATE MEDICAL SCHOOL OF LONDON.—3.30 p.m., Professor G. MacG. Bull: Tests of Renal Function. ROYAL ARMY MEDICAL COLLEGE.—5 p.m., Dr. J. S. Wilson: Work of the Public Health Laboratory Service. ROYAL COLLEGE OF PHYSICIANS OF LONDON.—5 p.m., FitzPatrick Lecture by Dr. Maurice Davidson: Medicine in Oxford, A Historical Romance: From the Early XIXth Century to A.D. 1914. Epilogue. ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m., Robert Jones Lecture by Mr. St. J. D. Buxton: Arthroplasty. ROYAL SOCIETY.—4.30 p.m., Sir Francis Walshe, F.R.S.: The Contribution of Clinical Observation to Cerebral Physiology. ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE.—7.30 p.m., Dr. Henry Foy: Influence of the Intestinal Flora on the Synthesis of Haemopoietic Factors in the Megaloblastic Anaemia of Africans. ST. ANDREWS UNIVERSITY.—At Physiology Department, Dundee, 5 p.m., Dr. C. M. Fletcher: Observer Error in Clinical Medicine. ST. GEORGE'S HOSPITAL MEDICAL SCHOOL.—5 p.m., Sir Paul Maltinson: psychiatry demonstration.

Friday, December 11

INSTITUTE OF DERMATOLOGY.—5.30 p.m., clinical demonstration by Dr. P. D. Samman: Reticulosis. OSLER CLUB OF LONDON.—At 11, Chandos Street, W., 7.45 p.m., Dr. Leonard Colebrook, F.R.S.: Emile Roux (December 17, 1853-1933). POSTGRADUATE MEDICAL SCHOOL OF LONDON.—4.30 p.m., Professor G. MacG. Bull: Tests of Renal Function. ROYAL MEDICAL SOCIETY, Edinburgh.—8 p.m., Symposium: Nephritis. SOCIETY OF PUBLIC ANALYSTS: BIOLOGICAL METHODS GROUP.—At Anatomy Lecture Theatre, University College, 2.30 p.m., joint meeting with Pharmaceutical Society. Symposium on The Assay and Detection of Pyrogens. Papers by Mr. T. D. Whittet, B.Sc., Ph.C., Mr. K. L. Smith, M.P.S., and Mr. M. Dawson, Ph.C., and Professor J. P. Todd, Ph.D., Ph.C., F.R.I.C.

Saturday, December 12

BIOCHEMICAL SOCIETY.—At Department of Biochemistry, London Hospital Medical College, 11 a.m., 324th meeting. Scientific papers. SOUTH-EAST METROPOLITAN REGIONAL TUBERCULOSIS SOCIETY.—At King's College Hospital Medical School, 10.30 for 11 a.m., annual meeting. Demonstration by Dr. Clifford Hoyle: Sarcoidosis—assisted by Dr. John Dawson and Dr. Gordon Mather.

APPOINTMENTS

ABSE, DAVID WILFRED, M.D., D.P.M., Full-time Associate Professor of Psychiatry, the School of Medicine, University of North Carolina, Chapel Hill, North Carolina, U.S.A. EAST ANGLIAN REGIONAL HOSPITAL BOARD.—Pamela M. Hellings, M.B., Ch.B., D.A., Anaesthetic Registrar at United Norwich Hospitals; J. G. Weir, M.B., Ch.B., Registrar in Psychiatry, Addenbrooke's Hospital and Fulbourn Hospital. EVANS, RICHARD GERWYN, M.B., B.Ch., C.P.H., Assistant Medical Officer of Health, Breconshire County Council. HIRD, GORDON, M.B., Ch.B., D.P.H., Assistant County Medical Officer of Health, Warwickshire. HOSPITAL FOR SICK CHILDREN, Great Ormond Street, London, W.C.—H. E. Lockhart-Mummery, M.Chir., F.R.C.S., Part-time Senior Surgical Registrar; Doreen P. Pallot, M.B., B.S., D.A., Resident Anaesthetic Registrar; Josephine J. Candy, M.B., B.Ch., and Marion R. MacKay, M.B., B.Ch., Junior Resident Anaesthetists; N. J. Rotfield, M.B., B.S., D.C.H.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Frequent Defaecation

Q.—A 40-year-old married man complains of symptoms which point to an unusually sensitive colon. Certain foods and drinks cause distressing frequent defaecation. Among these are oatmeal, yeast extracts, malt, treacle, beer, and stout. These articles of diet do not in ordinary quantities produce loose stools, but they cause him to have anything from eight to twelve apparently normal motions a day. The complaint has troubled him since about the age of 18 years. What is the explanation of these symptoms?

A.—The symptomatology described might have either a psychological or an organic basis. In either case, the simplest and best treatment would seem to be the avoidance of the offending articles of diet, provided that this does not lead to nutritional inadequacy. If it should be found impracticable, or deleterious to health, to restrict the diet in the way required, fuller investigation of the case is essential. If an organic basis can be clearly demonstrated—such as protein allergy, or inadequate digestion or absorption of some food material—appropriate corrective treatment should be instituted. If, however, no organic basis can be found, the advisability of psychotherapy must be considered.

When dietary restriction is practised, it is a good thing to examine the actual food intake quantitatively and in some detail; any likely deficiencies can then be corrected by appropriate supplementation.

Von Recklinghausen's Disease

Q.—Have there been any recent advances in the treatment of von Recklinghausen's disease? Is it possible to form any estimate of the likely rate of progression in an individual case?

A.—There have been no recent advances in the treatment of generalized neurofibromatosis (von Recklinghausen's disease). There are no special features which enable an estimate of the progression of the disease to be made.

Sedimentation Rate in Subacute Rheumatism

Q.—How reliable is the erythrocyte sedimentation rate as an index of activity in subacute rheumatism?

A.—The erythrocyte sedimentation rate is a valuable index of activity in subacute rheumatic fever, but, like all laboratory tests, it is not as reliable as clinical signs. It is seldom normal in the presence of physical signs. It may, however, be abnormally raised in the absence of clinical signs of rheumatic activity. In those circumstances it should be regarded as indicating a subclinical inflammatory process. Since in rheumatic fever the heart should be rested until all activity has subsided, it would be unwise to allow such patients to get up until the sedimentation rate has been within normal limits for at least 2-4 weeks, depending on whether the heart has previously been damaged. If there has been carditis in the acute attack, 4 weeks of bed rest, or sometimes even longer, is indicated after the erythrocyte sedimentation rate has become normal. The only exception to this generalization is in older girls, aged 14-20. In this age group sedimentation rates may remain high (say, 20-30 mm. per hour) for prolonged periods, often increasing at the menses, without any physical signs of activity or any adverse effects after letting the patient get up. It should be remembered that the erythrocyte sedimentation rate is a non-specific response and depends upon the presence in the body somewhere of an inflammatory process or tissue destruction, both of which lead to increased fibrinogen in

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Clements.—On November 21, 1953, at Poole, Dorset, to Sheila Mayer, wife of Dr. P. W. Clements, a daughter—Gillian Jane. Gribble.—On November 28, 1953, at The London Hospital, London, E., to Mary (formerly Watkins), wife of Michael Gribble, B.M., B.Ch., a son—Julian de Gruchy. Marley.—On November 30, 1953, at Cobden Hill House, Radlett, Herts, to Daphne (formerly Garrod), wife of Reginald S. Marley, M.S., F.R.C.S., a sister for Susan, Jennifer, David, and Gavin—Hilary.

MARRIAGES

Bird.—Batemans.—On November 21, 1953, at Christ Church, Fulwood, Sheffield, Julian Davis Bird, M.B., Ch.B., D.A., to Nora Bateman, S.R.N., S.C.M. Bowie.—Whitfield.—On November 20, 1953, in London, William Wilson Bowie, M.B., Ch.B., D.Obst.R.C.O.G., to Enid Mary Whitfield, M.B., Ch.B., D.C.H.

DEATHS

Arthur.—On November 17, 1953, at Llandrindod Wells, Radnorshire, William Daniel Arthur, M.B.E., M.R.C.S., L.R.C.P., Colonel, late R.A.M.C., retired, of Llandaff, Cardiff. Beetham.—On November 20, 1953, in hospital, Herbert William Beetham, L.R.C.P.&S.Ed., L.R.F.P.S., of 6, Lidgett Park Road, Leeds, Yorks, aged 46. Ealand.—On November 11, 1953, Ralph Martin Ealand, M.R.C.S., L.R.C.P., late of Bathaston, Somerset. Edmon.—On November 6, 1953, at the Grove Hospital, Tooting, London, S.W., Joseph Bramhall Edmon, M.D., D.P.H. Hareley.—On November 6, 1953, at his home, 71, Lichfield Road, Sutton Coldfield, War, George Cleverdon Hareley, M.C., M.B., Ch.B., husband of Alice Muriel Hareley, M.B., Ch.B., formerly of Erdington, Birmingham, aged 66. Hatch.—On November 16, 1953, Herbert Lincoln Hatch, M.B., B.S., D.P.H., of Pinner, Middlesex. Henderson.—On November 14, 1953, at Bexhill-on-Sea, Sussex, Henry John Henderson, M.C., M.B., B.S., formerly of Amersham, Bucks. Johnson.—On November 17, 1953, at Nearfield House, Bawtry, Yorks, Frederick Johnson, O.B.E., M.B., Ch.B., aged 77. Latham.—On November 3, 1953, at 8, Ravenslea Road, Wandsworth Common, London, S.W., Donald Victor Latham, M.D., M.A.O., D.Obst.R.C.O.G., late of Grahamstown, South Africa, and Dar-es-Salaam, Tanganyika Territory, aged 56. Lee.—On November 17, 1953, at 8, Glebe Road, Worthing, Sussex, Clifford Harry Lee, M.R.C.S., L.R.C.P., aged 57. Macpherson.—On November 14, 1953, Charles Wattie Macpherson, M.B., Ch.B., of 277, Bramhall Lane South, Bramhall, Cheshire. Nicholson.—On November 10, 1953, at Fairings, Fitchampstead, Berks, Frederick Dering Nicholson, M.D. Poole.—On November 11, 1953, at his home, 29, Balcombe Road, Horley, Surrey, Arthur Henry Poole, M.D., aged 86. Price.—On October 30, 1953, at his home, 315, Sheen Road, Richmond, Surrey, Lorenz Arthur Price, I.S.O., L.R.C.P.&S.Ed., formerly of Colombo, Ceylon. Robson.—On November 10, 1953, at Dar-es-Salaam, Tanganyika Territory, Thomas William Robson, M.R.C.S., L.R.C.P., formerly of Hazel Grove, Cheshire, aged 37. Stone.—On November 9, 1953, at 30, Foxley Hill Road, Purley, Surrey, Ernest Richard Stone, M.B., B.Ch., D.T.M. Woodwright.—On November 13, 1953, at his home, The Grove, Branksome Park, Bournemouth, Hants, William Henry Edward Woodwright, F.R.C.S.I., Lieutenant Colonel I.M.S., retired.

the plasma. The Wintrobe method sometimes gives anomalous results (readings which appear normal even with marked clinical signs of activity) and it is better to use the Westergren method, which gives readings more generally in accord with the clinical state.

Chapped Hands

Q.—What is the most satisfactory treatment of the chapped hands so frequently seen in diabetics? As this condition is associated with cold weather, would the dry, cold climate of Alberta (Canada) aggravate the condition further?

A.—The use of glycerin and rose water or some hand lotion containing glycerin is the most satisfactory treatment for chapping.

The condition appears to be dependent essentially upon the humidity of the atmosphere, which in cold weather is usually low. It is aggravated by winds, especially drying winds, usually from north and east, and by irritants such as soap and alkalis. If the humidity is low (indicated by a low dew-point) in Alberta, especially in cold weather, as seems probable, it would tend to provoke chapping.

Spasmodic Torticollis

Q.—What treatment is advised for the spasms in a case of chronic spasmodic torticollis?

A.—Spasmodic torticollis is most resistant to treatment. Medicinal treatment is of little value. Relaxation exercises and extension of the neck may be of temporary help. Immobilization of the cervical spine in plaster or in a plastic collar is often the most useful measure, though obviously in no way dealing with the unknown cause of the condition. Operative measures, in particular division of the upper cervical anterior roots, have been resorted to in some cases, but the results are by no means uniformly successful.

Switzerland for the Asthmatic

Q.—What special advantages can Switzerland offer to asthmatic patients that are not available in Britain? Are any special types of asthmatic patient particularly likely to benefit from going there?

A.—Switzerland has many obvious attractions for the British, but the particular advantage which it has to offer Britain's asthmatic patients is a climate far less conducive to infective changes in the respiratory tract. The death rate from bronchitis in England and Wales is 63.5 per 100,000 of the living population, while for Switzerland the figure is 6.8. The death rate from asthma in England and Wales is 7.0 per 100,000 and for Switzerland it is 4.2.

Changes of environment are known to benefit asthma when unsuspected allergens are thereby removed, when the psychological factors, also often unsuspected, are eliminated, or when the climate benefits the infective factor in asthma. All three types of asthma might indeed benefit by removal to Switzerland, but it is only for the infective type that one might claim that Switzerland, owing to its dry and warm climate, was particularly likely to result in improvement.

There is no reliable information whether asthmatic children do, in fact, do better in Switzerland than in Britain, and so far as the writer knows there are no means of getting asthmatic children to Switzerland on medical grounds to any form of institution. There is certainly no official scheme.

Tuberculosis in Paediatric Wards

Q.—Should cases of tuberculous meningitis and military tuberculosis be treated in a children's ward? Is it safe to admit suspected cases of pulmonary tuberculosis to the ward, provided any found to be open are isolated at once?

A.—If separate accommodation is available it is probably best not to treat cases of tuberculous meningitis and military tuberculosis in children's wards. Cases of tuberculous meningitis in particular are often exceedingly ill, and

the meningitic cry may be very distressing to other patients. However, there is probably little risk of infection of other children as long as the patient does not have an adult type of pulmonary tuberculosis. Primary tuberculosis in children can be regarded for practical purposes as non-infective, although if such cases are treated in a ward with other children simple precautions should be observed, such as having separate crockery and linen.

Children with the adult type of pulmonary tuberculosis, with cavitation, should, of course, be excluded if possible, and isolated at once if they are diagnosed in the ward.

Lysozyme

Q.—Is the antibacterial action of lysozyme in tears in any way comparable to that of the antibiotics? Has lysozyme any therapeutic possibilities?

A.—Lysozyme was first isolated by Sir Alexander Fleming in 1922 in the secretion of the nasal mucosa. Subsequently it was found to be particularly plentiful in tears, but it is present also in many other tissues. Its antibacterial effect constitutes one of the defensive mechanisms of the body. The action of lysozyme is comparable to the antibiotics only because it is one of the many naturally occurring agents against bacteria. Its therapeutic efficacy is, however, low.

B.C.G. During Diphtheria-pertussis Immunization

Q.—Would it be inadvisable to Mantoux test and give B.C.G. vaccination to a healthy child aged 16 months while he is undergoing immunization with a combined diphtheria-pertussis vaccine? The B.C.G. vaccination team will be in this district shortly, and I would like to know what to do.

A.—This is a case where recommended procedure will depend to some extent on the child's environment. If it is known that the parents and other intimate contacts of the child are not suffering from open tuberculosis, and that the home and environmental conditions are such that the child is unlikely to be exposed to the risk of tuberculous infection, tuberculin testing and B.C.G. vaccination would not be regarded as an urgent measure. If, on the other hand, the chances of the child being exposed to tuberculosis are uncertain, it would be wise to test and vaccinate now when the opportunity presents, since the child is still at an age when tuberculous infection could be serious. Inoculation with the combined diphtheria-pertussis mixture, if it does not contain alum, is unlikely to cause much local or systemic reaction, and ordinarily there would be no contraindication to B.C.G. vaccination during the course of the other immunizations. If need be, the last injection of the combined prophylactic could be deferred for another month or more; and even if the B.C.G. vaccination is not done now it would be useful, and perfectly safe, to have the child tuberculin tested for future reference.

"Any Questions?" Book.—The second book of selected "Any Questions?" is available, price 7s. 6d. (postage 6d.). Copies may be obtained either direct from the Publishing Manager, B.M.A. House, Tavistock Square, London, W.C.1, or from booksellers.

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 4499. TELEGRAMS: Aitology, Western, London. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the British Medical Journal alone unless the contrary be stated. Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors overseas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. House, Tavistock Square, London, W.C.1 (hours 9 a.m. to 5 p.m.). TELEPHONE: EUSTON 4499. TELEGRAMS: Britmedad, Western, London. STUDIES ON PANCREATITIS*

BY
ERIC G. SAINT, M.D., M.R.A.C.P.

AND
SARA WEIDEN, M.Sc.

(From the Clinical Research Unit of the Walter and Eliza Hall Institute of Medical Research and the Royal Melbourne Hospital)

In the same year as von Mering and Minkowski (1889) produced experimental diabetes in dogs by ligating the pancreatic duct, Fitz (1889), of Boston, described a case of "acute catastrophic inflammation of the pancreas." It is a regrettable fact that, 63 years later, the knowledge of exocrine and endocrine physiology of the gland, based on the brilliant work of Pavlov (1902), Bayliss and Starling (1902), and Banting and Best (1921-2), far outstrips the understanding of the clinical entities of pancreatitis. There are several reasons why this should be so: in the first place, pancreatitis is often difficult to diagnose, for the most suggestive symptom—pain—is variable both in site and in intensity, and is closely mimicked by other intra-abdominal conditions; secondly, diagnostic laboratory tests are by no means infallible; and, finally, little is known of the pathology of pancreatitis.

Acute and chronic pancreatitis have long been regarded as separate clinical and pathological entities, the one presenting as an acute abdominal emergency, and the other as a rare cause of abdominal pain, obstructive jaundice, wasting, steatorrhoea, or diabetes mellitus. Comfort *et al.* (1946) have established a link between acute and chronic pancreatitis in their now classical description of "chronic relapsing pancreatitis." Not the least important part of their work was to draw attention to the aetiological significance of alcoholism.

The publication of several reviews on acute pancreatitis (Paxton and Payne, 1948; Warren, 1948; Lipp and Aaron, 1950; Roberts *et al.*, 1950), on subacute pancreatitis (Gray *et al.*, 1938; Macnab, 1949), and on chronic relapsing pancreatitis (Maimon *et al.*, 1948; King, 1949; Gambill, 1949) indicates the amount of contemporary interest in the subject. In Australia, Rose (1951) and Heinz (1952) have reviewed experience in Sydney and Melbourne. While these statistical surveys provide an important overall picture of the incidence and complications of pancreatitis, they are less helpful with regard to information on pathogenesis and individual clinical patterns.

The present work was undertaken, (1) to investigate the clinical features of acute and chronic pancreatitis;

*An abbreviation of this paper was presented to the Australasian Medical Congress (British Medical Association) in August, 1952. The work was aided by a grant from the National Health and Medical Research Council, Australia.

(2) to elucidate some of the aetiological factors involved; (3) to study possible associated disturbances in gastric and hepatic function; (4) to evaluate laboratory tests as aids to diagnosis; and (5) to clarify the position with respect to treatment.

Between October, 1951, and July, 1952, 24 cases of acute and chronic pancreatitis were studied.

Methods of Study

In addition to full clinical examination, diet histories were taken by Miss C. N. Turner (dietitian at the Clinical Research Unit of the Walter and Eliza Hall Institute of Medical Research and Royal Melbourne Hospital). The following investigations were also made:

(1) *Estimation of urinary diastase*, using Dodds's modification of Wohlgemuth's method (Dodds and Dickens, 1925), was carried out during attacks of pain.

(2) *Intravenous Secretin Test*.—The method of Dornberger *et al.* (1948), based on the original studies of Agren *et al.* (1936), was closely followed. A double lumen tube was swallowed by the patient in the fasting state. The progress of the tip of the tube into the duodenum was followed fluoroscopically. Gastric contents were aspirated by Wangenstein suction and the duodenal contents were collected in 30-ml. test-tubes under slight negative pressure (estimated at 20 mm. Hg). After two ten-minute samples of fasting duodenal content had been aspirated, Wyeth's secretin was given intravenously, in a dosage of 1 unit per kg. body weight. The total volume and the bicarbonate content of each sample, estimated by the titrimetric method of Van Slyke, were recorded.

(3) *Gastric Function*.—A histamine test meal was done on most patients, many of whom also had gastric biopsy performed.

(4) *Liver Function*.—Estimation of serum bilirubin, alkaline phosphatase, serum proteins, and the cephalin-flocculation test was performed on most patients. A few also had a liver biopsy done.

(5) *Oral Sugar Tolerance Test*.

(6) *Gelatin Absorption Test*.—This test of protein digestion, based on a technique described by Krauel (1944), was performed on four patients. Gelatin, 50 g., was given orally, and the level of the serum amino-nitrogen was followed at hourly intervals for five hours.

(7) *Radiological Studies*.—Plain x-ray films of the pancreatic area and barium meal x-ray films were taken in most patients, and where cholecystectomy had not previously been performed a cholecystogram was done.

Acute Pancreatitis

Eleven cases of acute pancreatitis were studied. The age and sex incidence of patients is shown in Fig. 1. In 10 of these cases the diagnosis was made either on clinical grounds or at laparotomy, but in one case severe pancreatitis was an unsuspected and surprising finding at necropsy. Two of these patients died.

Pain and persistent vomiting were the most frequently presenting symptoms. The pain was felt in the epigastrium and radiated to the right and left hypochondrium, and through to the back at the level of the twelfth dorsal to the second lumbar vertebrae. The quality and intensity of the pain were rarely, however, of great diagnostic value: in two patients right-sided localization closely simulated

Fig. 1.—Age and sex distribution of 11 cases of acute pancreatitis. White squares, males; black squares, females.

Fig. 2.—Serial urinary diastase levels in six cases of acute pancreatitis.

pain. Biochemical tests showed this to be of obstructive type. Transient glycosuria was noted in two cases within 48 hours of onset, and in one fatal case acute diabetic coma developed five days after the onset of symptoms.

Estimation of the urinary diastase was of great help in the differential diagnosis of pancreatitis from other acute abdominal conditions. A level of over 100 units is diagnostic of pancreatitis. Although moderate elevation of the urinary diastase has been observed in some cases of perforated peptic ulcer, the significantly high levels, 400–1,000 units, which at times are found in patients with acute pancreatic necrosis should guide the surgeon in this often difficult clinical problem. Serial diastase levels in six cases are shown in Fig. 2. It will be seen that there is a tendency for the diastase to fall to normal levels within two to five days after the onset of pain. Estimation of the urinary diastase test is therefore of real value only if it is done soon after the onset of pain.

Aetiology

Cases fell into three aetiological groups: (1) associated with gall-stones; (2) associated with alcoholism; and (3) apparently due to primary infection.

(1) *Cholelithiasis* (three cases).—Halsted (1901) and Opie (1901) were the first to point out the association of pancreatitis with a calculus obstructing the ampulla of Vater. In

most reviews on acute pancreatitis, gall-stones have been present in 50–80% of patients. In the present limited series of cases the relatively few patients with proved gall-stones is quite a striking feature.

In one patient it was possible to obtain useful correlation between the clinical features and the histological findings in both the liver and the pancreas.

A 73-year-old man with hypertensive vascular disease developed acute abdominal pain and vomiting, and became slightly jaundiced. Laparotomy was performed. The head of the pancreas was swollen and indurated. Material was obtained from this site with a liver biopsy needle; and liver tissue was also taken for section. Cholecystenterostomy was performed. The pancreas showed acute inflammatory changes (Fig. 3), and in the liver severe cholangitis was present.

Fig. 3.—Section of pancreatic tissue obtained by means of an aspiration liver biopsy needle at laparotomy in a man with pancreatitis complicating cholelithiasis, showing acute interstitial inflammatory changes. (Haematoxylin and eosin. $\times 150$.)

Fig. 4.—Section of pancreas showing acute necrosis in a woman dying of acute infectious hepatitis.

(2) *Alcoholism* (five cases).—Many early writers—for example, Egda (1907)—noted that acute pancreatitis often followed a bout of heavy drinking. Five of the patients under review were exceptionally heavy beer or spirit drinkers, but in none of them was there any evidence of biliary disease. It is of possible significance that all of them had arterial hypertension. In three patients pain followed a bout of heavy drinking.

In February, 1952, a 32-year-old man had severe abdominal pain after a drinking bout. His urinary diastase was 400 units. Five days after admission he lapsed into diabetic coma. He improved with insulin but died two days later from bilateral bronchopneumonia. At necropsy severe pancreatic necrosis was found. The common bile duct and gall-bladder were normal. It is of great interest that an identical twin brother of this patient also had severe pancreatic necrosis, from which he recovered, in 1949.

Two patients had recurring attacks of abdominal pain related to alcoholic episodes. That pancreatitis of this nature is primarily a medical rather than a surgical problem is indicated by the fact that recurrence of pain in these two patients ceased in a period of nine months' observation when they stopped drinking and were able to eat good diets.

(3) *Infection* (two cases).—Certain viruses are known to cause acute pancreatic inflammation. Mumps is the classical example, of which there was one instance in this series. Poppel and Berrow (1949) noted symptoms referable to pancreatitis in no fewer than 17 of a series of 95 cases of mumps. Since both mumps orchitis and meningo-encephalitis without parotitis are known to occur, it is conceivable that occasional obscure cases of pancreatitis may be due to infection with the mumps virus, without demonstrable enlargement of the parotid glands.

Pancreatitis is occasionally an associated condition in severe cases of infectious hepatitis (Lucké, 1944).

A middle-aged woman developed classical signs and symptoms of infectious hepatitis and died in hepatic coma. At necropsy widespread necrosis of the liver cells was found, and the pancreas showed necrotic changes (Fig. 4).

Transient elevation of the urinary diastase has been noted in several cases of acute infectious hepatitis of moderate severity; it is possible that mild pancreatitis may be a common complication of infectious hepatitis.

A strain of Coxsackie virus pathogenic to man is known to cause acute pancreatitis in suckling mice (Pappenheimer *et al.*, 1951), but so far pancreatitis attributable to this virus has not been recognized clinically.

Treatment

The diagnosis of acute pancreatitis may present considerable difficulty, and if an occasional laparotomy is needlessly performed little harm to the patient is likely to follow. Nevertheless, if the diagnosis of acute pancreatitis can be assured conservative treatment is urged.

Pain was satisfactorily controlled with pethidine. Morphine may actually aggravate pancreatic pain.

Continuous gastric aspiration was applied until pain and vomiting ceased. Aspiration of gastric juice prevents vomiting and inhibits the hormonal stimulation of the flow of pancreatic juice.

Loss of electrolytes necessitated accurate replacement with intravenous glucose-saline and potassium chloride. Edmondson *et al.* (1952) and Roberts *et al.* (1950) have drawn attention to the dangerous degree of hypochloreaemia and hypokalaemia which may occur in pancreatic necrosis; and a factor which the former authors show to have been hitherto neglected is the binding of calcium when fat necrosis is extensive, indicating that intravenous injections of calcium gluconate should be given in severe cases.

Although acute diabetes is a rare complication, the urine and blood sugar should be repeatedly estimated and insulin given when necessary.

Secondary infection is a threat to life in acute pancreatic necrosis. Therefore penicillin (500,000 units six-hourly) and streptomycin (0.5 g. twice daily) were given to all cases.

In cases in which clinical or radiological evidence pointed to cholelithiasis elective cholecystectomy was performed after the attack of pancreatitis had subsided.

Chronic Pancreatitis
Chronic pancreatitis is in some respects a misnomer, for the

natural history of the majority of the 15 patients studied (see Fig. 5) pointed to a relapsing, recrudescing form of disease. The pathology which was observed in patients on whom operation was performed during attacks of pain was that of oedema or haemorrhagic necrosis of the gland. In several patients these repeated attacks had ultimately caused destruction of the acinar and islet tissue, with fibrosis and even calcification, leading to deficiency of both internal and external secretion.

The clinical history of four male patients closely resembled the description of chronic relapsing pancreatitis given by Comfort *et al.* (1946). Another syndrome was that observed in eight female patients who had attacks of pancreatitis following cholecystectomy. The remaining three patients formed a miscellaneous group.

Chronic Relapsing Pancreatitis

All four patients were males. Three of them had essential hypertension; three had been heavy consumers of alcohol. Three patients had a laparotomy performed at one time or another, and, although pancreatitis was noted, there was no evidence of associated biliary disease.

The initial manifestation of the disease was that of recurring attacks of abdominal pain, during which the urinary diastase was raised. In one patient only a few weeks intervened between attacks of pain, but in the remainder several months of freedom from pain were enjoyed. Sometimes a distressing feature was that pain persisted despite a variety of operations undertaken on the biliary tract.

A 51-year-old man, once a heavy beer-drinker, had been admitted to hospital on 16 occasions between 1944 and 1951 with attacks of pancreatic pain. In 1944 his gall-bladder had been removed, but when examined it did not appear to be diseased. Twice the common bile duct was drained during attacks of pain. Ultimately he became a pethidine addict. In one attack of pain relief was obtained by bilateral splanchnic block; a right-sided sympathectomy, removing ganglia from D8 to L2, seemed to give more prolonged relief until his death two months later from spontaneous intraperitoneal haemorrhage. Investigations showed impaired fat absorption, a mild diabetic type of sugar-tolerance curve, achlorhydria, and atrophic gastritis. At necropsy the pancreas was shrunken, and histologically showed replacement of much of the pancreatic acinar tissue by fat (Fig. 6). Severe atheroma of the aorta was present.

The disease tends to be progressive, and in less fortunate patients the replacement of acini by fibrotic tissue and deposits of calcium may have profound metabolic effects.

A 49-year-old man had frequent attacks of pancreatic pain and ultimately developed diabetes mellitus. Pain made life

Fig. 6.—Section of pancreas from a case of chronic relapsing pancreatitis. The gland was considerably shrunken. Much of the acinar tissue has been replaced by fat. (Haematoxylin and eosin. $\times 150$.)

Fig. 7.—X-ray film of the pancreatic area in a middle-aged man with relapsing pancreatitis and diabetes mellitus, showing diffuse calcification throughout the gland.

Fig. 5.—Age and sex distribution of 15 cases of chronic pancreatitis. White squares, males; black squares, females.

intolerable, and he lost 3 st. (19 kg.) in weight. Investigations showed impaired fat absorption and poor gelatin digestion. An x-ray film of the pancreatic area (Fig. 7) showed diffuse calcification.

The diagnosis of chronic relapsing pancreatitis is based on the history of recurring episodes of upper abdominal pain without other obvious cause, and evidence of deficiency of either internal or external pancreatic secretion, such as glycosuria and hyperglycaemic sugar tolerance (see Fig. 8), frank steatorrhoea, wasting, or a low flat type of gelatin absorption (see Fig. 9). The finding of a raised urinary diastase is of the utmost importance in diagnosis in obscure cases. In advanced cases a search should be made radiologically for pancreatic calcification.

FIG. 8.—Oral sugar tolerance curves in seven cases of chronic pancreatitis.

In three cases liver biopsy was performed. In one case mild fatty change, presumably of nutritional origin, was found. Gross degrees of fatty change and actual cirrhosis have been noted by other observers (for example, Fiesinger and Olivier, 1933; Snell and Comfort, 1937; Sharp *et al.*, 1952). Whether these cirrhotic changes in the liver develop *pari passu* with pancreatic fibrosis as a result of suboptimal nutrition, or whether they are the result of impaired digestion of fat and protein due to pancreatic insufficiency, is open to debate. In one case gastric biopsy showed severe atrophic gastritis.

The treatment of chronic relapsing pancreatitis is a problem beset with extraordinary difficulties. In the early stages recurrent attacks of pain may be prevented by improving the diet and enforcing strict abstinence from alcohol; but with regard to the more advanced cases there is at present no uniformity of opinion regarding the correct course of action which should be taken. Many American surgeons advise interruption of the afferent nervous pathways, either by limited splanchnic nerve section (de Takats, Walter, and Lasner, 1950) or unilateral sympathectomy

FIG. 9.—Gelatin absorption curve in four cases of chronic pancreatitis. The level of amino-nitrogen is followed at intervals for five hours after the administration of gelatin (50 g.).

(Hurwitz and Gurwitz, 1950), or by the more radical bilateral lumbo-dorsal sympathectomy combined with splanchnicectomy (Connolly and Richards, 1950). However, Cattell and Warren (1952) maintain that these measures offer only temporary relief from pain and advise pancreatoduodenectomy.

Our own experience is too limited to be of value. In three patients the pain was temporarily abolished by bilateral splanchnic block. In only one patient was a limited sympathectomy performed, and his early death two months after operation prevented adequate assessment of the result.

Relapsing Pancreatitis Following Cholecystectomy

All eight female patients in this group had what might be called the "gall-stone diathesis"—most were obese, most had hypertension, and three were known to have had diabetes mellitus for some time. In all patients calculi were present when the gall-bladder had been removed. Often within a few months of cholecystectomy these patients experienced attacks of upper abdominal pain. Often this was felt below the right costal margin, and led them to believe that their pre-operative biliary colic had returned. Abnormally high levels of urinary diastase were noted during these attacks.

An obese 45-year-old woman with mild diabetes mellitus had her gall-bladder removed for cholelithiasis. Six months later she had a severe attack of abdominal pain lasting two days. The urinary diastase was 1,000 units. Two further attacks occurred and on each occasion the diastase was raised.

In some cases it was noted that pain followed an unusually large fatty meal. Alcoholism and frank dietary deficiency did not seem to be causative factors; in fact, improvement in many cases occurred when measures were taken to reduce weight by advising smaller non-fatty meals.

It seems likely that many patients suffering from the so-called "post-cholecystectomy syndrome" have, in fact, a mild recrudescence of pancreatitis. Doubilet and Mulholland (1949) maintain that spasm of the sphincter of Oddi may cause a rise in pressure in the common bile duct sufficient to lead to regurgitation of bile into the pancreatic duct in patients with a common channel. It is known that bile injected experimentally into the pancreatic duct causes chemical inflammation. They advise section of the sphincter; but we regard the factual basis of their hypothesis as unproved, and none of our patients have been subjected to this operation.

Other Causes of Chronic Pancreatitis

A 23-year-old woman with a long history of ulcerative colitis and a grossly deficient diet had an attack of severe abdominal pain. At laparotomy acute pancreatitis was found, but the organ was also fibrous, indicating chronic pathological change.

Ball *et al.* (1950) described interstitial chronic inflammatory changes in a high proportion of cases of ulcerative colitis examined at necropsy. Since nutritional hepatitis is also common in ulcerative colitis it is reasonable to assume that malnutrition plays an important part in the causation of pancreatitis in this condition.

A 34-year-old woman had infectious hepatitis in 1949. This was followed by frequent attacks of abdominal pain. All investigations were negative except for the finding of high diastase levels up to 152 units during the attacks.

The clinical evidence was in favour of a direct causative relationship between this patient's pancreatitis and the original infection with the virus of infectious hepatitis.

A 26-year-old man had attacks of upper abdominal pain and intermittent jaundice of obstructive type. He also had symptoms of diabetes mellitus. At laparotomy the pancreas was fibrotic and indurated, but the gall-bladder and common duct were normal. The gall-bladder and common duct were drained and the jaundice subsided.

No obvious cause of chronic pancreatitis was found in this case. Obstructive jaundice is not an uncommon manifestation of chronic pancreatitis (Selesnick, 1952), and this case illustrates an important point in the surgical management.

When the gall-bladder is not diseased, under no circumstances should it be removed, for later it may be used with advantage in a short-circuiting operation for the relief of jaundice.

Intravenous Secretin Test

The results of this test in eight normal subjects, five patients recovering from acute pancreatitis, and eleven patients with chronic pancreatitis are shown in Fig. 10. In each group a very wide range of values of both volume and bicarbonate content of the duodenal contents was found.

Although there is an obvious statistical tendency towards lower volumes and bicarbonate content in patients recovering from acute pancreatitis and in patients with chronic pancreatitis, the degree of overlap in values as compared with normal healthy subjects is enough to render the test unsuitable for ordinary diagnostic purposes. Dornberger and his colleagues arrived at a similar conclusion.

FIG. 10.—Scatter diagram showing volume and bicarbonate content of duodenal aspirate after the administration of secretin intravenously in eight normal subjects, five patients recovering from acute pancreatitis, and eleven patients with chronic pancreatitis. + = mean value.

Discussion

With respect to pancreatitis it is clear that there are many unsolved problems. Even clinical recognition is not always an easy matter: acute pancreatitis is not always correctly diagnosed, and chronic pancreatitis may manifest itself under a number of guises which may tax the diagnostic skill of the clinician. Once an increased awareness of this condition becomes prevalent among physicians and surgeons, however, and once the habit of calling for urinary diastase estimations in cases of obscure abdominal pain is acquired, it is likely that more cases will come to light, with opportunities for further study.

One of the difficulties encountered in the diagnosis of milder cases of acute and relapsing pancreatitis is the lack of reliable laboratory tests. The finding of high levels of pancreatic enzymes, either in the serum or in the urine, should suggest pancreatitis, but there is evidence that such elevation is often transient. In our hands the secretin test has been of little practical value. Innerfield *et al.* (1952a, 1952b) have demonstrated a high level of plasma anti-thrombin activity in both acute and relapsing pancreatitis, and it is possible that this may prove to be a subtle laboratory test of considerable value. In suspected chronic pancreatitis, steatorrhoea (faecal fat content more than 30%), a hyperglycaemic sugar-tolerance curve, and calcification of the pancreas should be looked for.

If these investigations prove negative despite a strong clinical suspicion of pancreatitis, diagnostic laparotomy is justifiable. The pancreas should be carefully inspected and palpated. However, it is believed that closer correlation between naked-eye appearances and actual histology is demanded, and to this end a technique of obtaining biopsy

material is being developed, using a Franseen aspiration liver biopsy needle (the material shown in Fig. 3 was obtained by this means).

In the attempt to elucidate the aetiology of pancreatitis it was apparent that a heterogeneous group of conditions was being grouped under one heading only by virtue of the fact that one organ, the pancreas, was predominantly affected. Now the only things shared in common by infectious hepatitis, Laennec's cirrhosis, infectious cholangitis, and xanthomatous biliary cirrhosis are pathological changes in the liver resulting in jaundice, yet we do not refer to these diseases collectively as "hepatitis." The same reasoning may with justification apply to the pancreas. Chronic pancreatitis complicating ulcerative colitis is a totally different entity from pancreatitis following cholecystectomy; likewise, pancreatitis complicating biliary calculi has an entirely different pathogenesis from that occurring in alcoholic subjects.

What are the factors known and believed to be the cause of pancreatitis? Trauma to the pancreatic ducts, during gastrectomy for example (Millbourn, 1949), causes pancreatic inflammation. Any condition which causes reflux of bile into the pancreatic ducts may also produce pancreatitis. This is presumably the mechanism in those cases of pancreatitis following cholecystectomy in which pressure gradients in the common bile duct are believed to be disturbed. When calculi obstruct the ampulla, in addition to reflux along the "common path," infection is probably an added factor.

There is accumulating clinical and experimental evidence that, as with the liver, certain foodstuffs have a protective action on the pancreas. Fatty changes and fibrosis in the pancreas have been shown to be present (Waterlow, 1948; Davies, 1948) in undernourished native races at necropsy. Necrotic pancreatic lesions have been demonstrated in rats fed on a low-protein diet (Lindsay *et al.*, 1948). It is probable that methionine is an essential protective metabolite, for when the ethyl analogue of methionine, ethionine, which blocks the utilization of methionine, is fed to experimental animals pancreatic necrosis invariably occurs (de Almeida and Grossman, 1952). The clinical counterpart of these experimental findings is the type of pancreatitis which occurs in malnourished alcoholic patients and as a complication in patients suffering from ulcerative colitis. In alcoholic patients there is also the possible additional aetiological factor of the stimulation of excessive quantities of pancreatic juice during a drinking bout. In our studies with the double lumen tube it was noted in control subjects that the rate of flow of duodenal aspirate was trebled when 2 oz. (57 ml.) of brandy was introduced into the stomach.

The presence of arterial hypertension in a high proportion of patients with pancreatitis has been commented upon by Heinz (1952). Care must be taken in interpreting these statistics, for many patients of middle age with cholelithiasis, who comprised a large number of his cases, tend to have the obese hypertensive diathesis. There are a few hints, however, that this correlation may not be entirely coincidental, for there are on record in the literature a number of cases of pancreatitis complicating familial hypercholesterolaemia (Holt *et al.*, 1939; Collett and Kennedy, 1948; Klatskin and Gordon, 1952). There is evidence also that genetic factors may be involved in the causation of chronic relapsing pancreatitis. Comfort and Steinberg (1952) reported on a family in which the condition occurred in four generations; our own observation of acute pancreatic necrosis occurring in identical twins is also of interest. The relationship between hypercholesterolaemia and the development of atherosclerosis is well known, and it is an intriguing possibility that vascular disease may be at least a condition which predisposes to the development of pancreatitis.

Finally, the possibility of a virus infection, either of mumps or of infectious hepatitis, must not be disregarded in obscure cases.

Thus a variety of aetiological factors, acting either alone or in combination, may lead to pathological change in the

pancreas sufficient to cause clinical manifestations. The following entities can be quite sharply differentiated: (1) *Traumatic pancreatitis*, following surgery of the stomach and duodenum; (2) *virus pancreatitis*, complicating mumps and possibly infectious hepatitis; (3) *reflux pancreatitis*, complicating biliary calculi and following cholecystectomy; (4) *chronic nutritional pancreatitis*, or "chronic relapsing pancreatitis," occurring in malnourished alcoholic patients; (5) *metabolic pancreatitis*, complicating hyperlipaemia and hypercholesterolaemia.

The difficult problem of treatment must be approached with this aetiological perspective in view. Surgery plays no part in the immediate management of acute pancreatitis, when electrolyte replacement and the prevention of secondary infection are considerations of life-saving importance. When acute symptoms have subsided an attempt must be made to assess the predominant aetiological factor involved; if radiological studies reveal the presence of biliary calculi cholecystectomy should be performed, but if there is no evidence of gall-bladder disease cholecystectomy is absolutely contraindicated, for it may be necessary to use the gall-bladder later in a short-circuiting operation if further attacks of pancreatitis lead to obstructive jaundice. If the patient is an alcoholic, abstinence must be enforced and a high-protein diet advised. All that can be said at the present time about reflux pancreatitis following cholecystectomy is that control of weight and limitation of fat intake have yielded good results: one waits for further reports from those surgeons who courageously perform ampullary sphincterotomy.

The position with regard to surgery in chronic relapsing (nutritional or metabolic) pancreatitis is still by no means settled. If it is proved that splanchicectomy and lumbo-dorsal sympathectomy offer only temporary relief from pain it will be necessary to resort to pancreaticoduodenectomy. This might seem an unwarranted surgical risk, but such is the severity of the pain and the misery of the patient that heroic measures are called for in some cases. Moreover, in competent surgical hands these risks have been greatly reduced, as has been shown by Smith and Brown (1952), in their experience of surgery of carcinoma of the pancreas.

Summary

The clinical features and laboratory investigations in 24 proved cases of acute and chronic pancreatitis have been studied at the Royal Melbourne Hospital, Melbourne, Australia.

It is felt that the confusion of thought which exists on this subject might in part be dispelled if attention was paid to aetiological aspects of the problem. Reasons are presented for considering traumatic pancreatitis, virus pancreatitis (mumps and infectious hepatitis), "reflux" pancreatitis, chronic nutritional pancreatitis, and metabolic pancreatitis as distinct clinical entities.

In acute pancreatic necrosis good results were obtained with conservative treatment—continuous aspiration of the gastric contents, electrolyte replacement, and the administration of antibiotics.

Chronic relapsing (nutritional) pancreatitis is a condition characterized by recurrent attacks of pancreatic oedema and necrosis causing pain; ultimately destruction of the gland and replacement fibrosis lead to wasting, steatorrhoea, and diabetes. Pancreatic calcification is occasionally visible radiologically and induration of the head of the pancreas may cause obstructive jaundice.

In the absence of biliary calculi, cholecystectomy is contraindicated in chronic pancreatitis. When severe and unremitting pain becomes a feature in advanced cases a choice must be made between sympathectomy and pancreaticoduodenectomy.

Relapsing "reflux" pancreatitis was found to occur in female patients following cholecystectomy. Further data on the mechanics of the sphincter of Oddi and the common bile duct are required before agreement on the surgical relief of these patients can be reached.

The diagnosis of mild cases of acute and chronic pancreatitis may be difficult. Although elevation of the urinary diastase level is helpful this may be only transient. Collateral evidence of steatorrhoea, glycosuria, pancreatic calcification, and impaired protein digestion should be sought for in diagnosing chronic pancreatitis of all types.

We wish to thank those members of the honorary medical staff of the Royal Melbourne Hospital who kindly referred patients for investigation. We also wish to acknowledge the help we have received from our colleagues in the Clinical Research Unit.

In an appeal for funds, signed by Dr. Elliott P. Joslin, the president, the Diabetes Foundation announces that it was incorporated in 1953 with wide powers to include not only activities concerning the support of research and camps for diabetic children, formerly dealt with by separate funds, but also the administration of a new hospital teaching clinic which it is hoped to build as soon as the necessary money is available.

L-NORADRENALINE IN TREATMENT OF SHOCK IN CARDIAC INFARCTION

BY

K. SHIRLEY SMITH, M.D., B.Sc., F.R.C.P.
 Physician and Cardiologist, Charing Cross and London
 Chest Hospitals

AND

A. GUZ, M.B., B.S.

Former House-Physician, Charing Cross Hospital

Cardiac infarction is more often than not accompanied by shock. Usually it is transient and passes off as the pain abates under the influence of morphine. In some patients it persists and appears to contribute to an early fatal issue, while, in a few, shock gravely complicates the clinical state during a period of several days or even a week in an illness which in four cases out of five ends in death. It is in this last group that physicians have felt the lack of therapy to combat peripheral circulatory collapse, in which pressure may fall to levels that can hardly, if at all, be recorded, with disappearance of pulse and loss or clouding of consciousness. Intravenous infusions of hypertonic glucose, plasma, blood, and dextran have been used, and slight success has been claimed. In spite of its obvious possibilities, adrenaline has been discarded in this condition; it may raise the pressure but the risk of ventricular fibrillation is too great. On the other hand, other pressor drugs of the sympathomimetic amine series have been shown to raise the blood pressure without increasing the rate or the work of the heart. It was the claim of anaesthetists that the laevo-rotatory form of noradrenaline secured their patients against serious falls of pressure during major operations which led us to the use of this substance in cardiogenic shock. In this paper we report the results of the use of L-noradrenaline bitartrate ("levophed") in the six instances in which we have employed it for this purpose.

Material and Methods

We have, so far, treated only six patients suffering from shock in myocardial infarction with infusions of L-noradrenaline bitartrate, restricting this treatment to those patients whose lives we judged to be immediately threatened by shock. As L-noradrenaline is a sufficiently powerful overall vasoconstrictor to be effective in doses ranging from 5 to 40 µg. a minute when used in the treatment of any peripheral vasomotor collapse (Swan, 1952), we ensured a sufficient dilution by adding 4 ml. of 1/1,000 L-noradrenaline bitartrate solution to a litre of isotonic solution, either of 5% dextrose or of 4.3% dextrose in 0.18% saline, thus giving a drug strength of 4 µg. per ml. Normal saline as a vehicle was avoided in view of the danger of introducing excess of sodium ions into the circulation when heart failure existed or might supervene. Intravenous drip infusions were set up with one or other of these solutions, and preparations were made to continue the infusions for periods of a few hours to a few days. The concentration of drug necessary to keep the blood pressure at a chosen level varied greatly with each patient, but it was sometimes found that drip rates of more than 36 drops a minute were required. As this would entail giving a total infusion of more than three litres in 24 hours, the concentration of the L-noradrenaline bitartrate was increased as much as necessary—on one occasion to 64 ml. per litre—so as to be able to reduce the drip rate by the same factor. By this means the risk of circulatory overloading was abolished,

although the control of the blood pressure by adjustment of drip rate became less sensitive.

In accordance with the main indication already mentioned, the use of L-noradrenaline infusion was considered whenever the systolic blood pressure was progressively falling in cardiogenic shock or when it was found to be 80 mm. or less for more than 24 hours, especially in the presence of a very small pulse pressure and oliguria. That we have been reluctant rather than anxious to employ this treatment is shown by the fact that two of our six patients were pulseless when the infusion was begun.

The presence of a nurse capable of measuring the blood pressure reliably was found to be essential. Throughout the whole period of the treatment vigilant attention had to be given to the drip rate, which might spontaneously vary with corresponding and perhaps dangerous fluctuations in blood pressure, which was generally kept between 100 and 110 mm. systolic. It was found that there was a direct and immediate relationship between drip rate and the blood pressure; with a turn of the regulating screw the pressure could be raised or lowered at will. On one or two occasions when the infusion was brought to an end the blood pressure fell abruptly; it therefore became our rule to discontinue the infusion by degrees while a close watch was kept on the blood pressure.

Case 1

A man aged 49 was admitted to hospital at 2 p.m. on June 16, 1952, on account of sudden very severe pain in the centre of the chest and vomiting. For three years he had had angina of effort; there had been cardiographic evidence of old antero-septal cardiac infarction, and the blood pressure was usually 140/90. He was extremely ill and shocked, and was drenched in sweat. The temperature was 97° F. (36.1° C.), and the heart sounds were distant. The systolic blood pressure was 60. Injections of morphine totalling 4 gr. (50 mg.) were needed for relief of pain, and an intramuscular injection of 12,500 units of heparin was given. Although the condition improved during the day, the pressure during the following morning varied between 70 and 65 mm. systolic. In spite of intravenous injections of nikethamide, the pulse at the wrist disappeared, the extremities being cold and clammy.

An intravenous infusion of 20 oz. (570 ml.) of plasma failed to bring improvement. To a second similar quantity 4 ml. of 1/1,000 L-noradrenaline was added. Immediately this had started, the pressure rose to 100 and was maintained at 90 by an infusion rate of 60 drops a minute. Thereafter, the infusion was continued with 4.3% dextrose in 0.18% saline containing 16 ml. of 1/1,000 L-noradrenaline per litre; a drip rate of 36 drops a minute sufficed to keep the systolic pressure in the neighbourhood of 90 (Fig. 1). The condition of the patient remained critical, in spite of oxygen administration and maintenance of the drip throughout the day; on one occasion when it accidentally stopped the patient at once became pulseless. A pint (570 ml.) of plasma brought no improvement, but renewal of the L-noradrenaline infusion at once restored the pulse, while the pressure rose to 95 and later 115. The drip had to be maintained continuously for 48 hours, but when it was then discontinued the pressure fell slowly from 120 to 85, at which level it remained. An electrocardiogram showed antero-posterior infarction of the heart.

The patient made a gradual recovery in spite of temporary congestive heart failure, and he was discharged from hospital on July 27. Two months later he was readmitted in severe left ventricular failure, which in spite of every effort worsened and ended fatally on October 19, about four months after the onset.

Necropsy showed fibrotic scars of cardiac infarctions involving the posterior and lateral walls of the left ventricle and the anterior wall in the neighbourhood of the septum. The right coronary artery and the circumflex branch of the left coronary were occluded 2 cm. from the origin in each case.

FIG. 1.—Graph showing rise of systolic pressure during intravenous infusion of dextrose-saline containing L-noradrenaline, 4 ml. 1/1,000 solution to the litre, in a patient with severe cardiac infarction and shock (Case 1).

Case 2

A woman aged 67 was admitted for an operation on her left hip. Clinical examination showed no cardiovascular abnormality save a blood pressure of 170/90. The operation was performed at noon on September 22, 1952. There had been little trauma or blood loss, but near the end of the operation she suddenly collapsed and became pulseless. Surgical shock was diagnosed, and an intravenous plasma infusion containing 4 ml. of 1/1,000 L-noradrenaline to the pint (570 ml.) was given, whereat the blood pressure became measurable at 80. On surgical grounds the infusion was changed to whole blood, and later to normal saline, but always with the same addition of L-noradrenaline, and at the rate of 40 to 60 drops a minute. Eleven hours after the start of the operation the patient regained consciousness. She had pain at the site of the operation, but nowhere else.

On the next day the condition had further improved. There was still no cardiac pain and the heart sounds were faint. Continuance of the L-noradrenaline-saline drip, now changed to 0.18% saline, enabled the blood pressure to be kept at about 100 mm. systolic, and the level could be raised or lowered at once by quickening or slowing the drip.

On September 24 an electrocardiogram revealed that the unsuspected cause of the collapse had been a large through-and-through antero-lateral infarction of the heart. The patient remained dependent on the L-noradrenaline infusion; although she was not breathless and the urinary output remained good, the sacrum and legs became oedematous. Fluid-balance charts revealed that 6 pints (3.4 litres) more fluid had been taken in than had been excreted in the previous 36 hours. This was remedied by quadrupling the concentration of L-noradrenaline and reducing the rate of the drip to 15 to 20 a minute. Heparin and bismouacetate were then started. The L-noradrenaline administration had to be continued for five days, when a very gradual cessation was begun; any sudden reduction in drip rate was followed by an abrupt and dangerous fall of systolic pressure, so that the pro-

FIG. 2.—Graph showing rise of systolic pressure during intravenous infusion of dextrose-saline containing L-noradrenaline in varying concentration. Case 3, suffering from acute posterior cardiac infarction with initial complete A-V block and auricular fibrillation.

cess of cessation took 72 hours to complete. The systolic blood pressure then remained at 85 mm., with a pulse of 100 a minute. During the next two months in hospital, the pressure fluctuated between 90/50 and 105/70, which was the reading on discharge. Seven months later there was no dyspnoea or angina, and the blood pressure was 105/70.

Case 3

A man of 53 was admitted at 6.30 p.m. on May 8, 1953, with a history of a sudden onset of severe retrosternal pain. He had vomited twice and sweated profusely. The extremities were cold, the temperature being 96.2° F. (35.7° C.), and the pulse regular at 36 a minute. The blood pressure was 80 systolic. The heart sounds were faint and the cervical veins engorged.

Electrocardiography confirmed the clinical presumption of complete A-V block and showed auricular fibrillation as well as patterns of an extensive posterior cardiac infarction. The blood pressure fell steadily in spite of general measures to combat shock, and one hour after admission it was 55 systolic, the patient looking as if about to die. The pulse rate was 40 a minute.

As soon as an infusion of dextrose-saline containing 4 ml. of 1/1,000 L-noradrenaline per litre was started he looked better and uttered some words. At an infusion rate of 20 drops a minute the blood pressure rose swiftly to 80–115 systolic. Within 15 minutes of the infusion being started there was a sudden reversal to normal rhythm at 80 a minute (Fig. 2).

After one and a half hours of this treatment the drip rate was gradually slowed without fall of the blood pressure, and during the next two hours the L-noradrenaline concentration in the infusion was halved. It was discontinued after a total duration of just over three hours. During the next two months there was uninterrupted convalescence with improving effort tolerance. At a later examination the heart was found to be not enlarged and the pressure remained around 130/80.

Case 4

A woman aged 73, a patient of Dr. D. I. L. Gleed, of Finchley, was seen in consultation on March 15, 1953. She had for nine years suffered from angina of effort, and had latterly been taking 50 trinitrin tablets weekly. At noon she was seized with an attack which caused collapse with loss of consciousness. She was grey and sweating with a weak pulse at 60 a minute. She vomited twice.

Examination six hours after the onset showed the patient still shocked, with a pulse of 72 and blood pressure 105/75. An electrocardiogram showed extensive postero-lateral infarction of the heart. Admission to hospital took place the same evening, when the pulse had quickened to 100 and the pressure had fallen to 90 systolic. Signs of congestive heart failure were developing, and there was pericardial friction to the left of the sternum.

At 1.30 a.m. that night renewed collapse occurred with sweating and unconsciousness; the systolic pressure fell to 50 and the pulse was hardly perceptible. At 2.5 a.m. an intravenous infusion of dextrose-saline containing 2 ml. of 1/1,000 L-noradrenaline per litre was started. Instantly the condition improved, the systolic pressure rising to 80 and later to 100. Throughout the day of March 17 the condition remained fairly satisfactory in that, despite sweating and chilliness of the extremities, the pressure was maintained at the same level by adjustment of the drip rate. Electrocardiography that evening showed that right bundle-branch block had now developed. The white cells numbered 31,200 per c.mm. During the following night the condition again became very grave, the pulse becoming weaker, with increasing signs of collapse. The drip rate was increased, but in spite of this and of an intravenous injection of theophylline with ethylenediamine the heart rate increased to 100 while the pulse became imperceptible. Death took place 66 hours after the onset of the illness.

Necropsy showed a recent infarction in the interventricular septum extending to the adjacent parts of the anterior and posterior walls of the left ventricle. The anterior part of the septum had become thinner, with the beginning of dilatation in this part of the ventricle. The remainder of the myocardium showed diffuse patches of fibrosis. Patches of calcified atheroma were found in both coronary arteries and their main branches. While the vascular lumen was in places much reduced, no occluding thrombus could be found.

Case 5

A woman of 75 was seen in consultation with Dr. Alan Strachan, of Sutton, on April 18, 1952, when she was in a state of cardiogenic shock. This had set in at 10 a.m. that day, about half an hour after an injection of morphine and atropine preparatory to dental extractions. It later transpired that three years previously a similar injection for gallstone colic had been followed within a few minutes by collapse, with pallor and a thready pulse. On that occasion there had been swift recovery after an injection of nikethamide, but in the present attack pain had developed around the trunk at the level of the diaphragm. The foot of the bed was raised and oxygen was given. The condition improved, but the pain persisted, later centring over the right upper quadrant of the abdomen.

At the consultation that evening there was pain across the lower part of the back with a bruised feeling in the upper part of the abdomen. The patient was shocked though not in distress; the pulse was regular at 64 a minute, and the blood pressure was 85 systolic. The clinical state did not permit thorough examination, but the heart sounds were heard softly at all areas, and there was no pericardial

friction or gallop. There was no tenderness in the abdomen; arterial pulsation was felt readily in the feet. An electrocardiogram showed low voltage in standard leads, intraventricular conduction defect, and lateral subendo-cardial ischaemia. It was concluded that acute coronary insufficiency had followed a sudden severe fall of blood pressure as a result of abnormal sensitivity to an injection of morphine and atropine.

During the following day or two the condition fluctuated; the symptoms lessened but the blood pressure remained at 80 systolic. On April 22, four days after the onset, an intravenous drip infusion of dextrose-saline containing 4 ml. per litre of 1/1,000 L-noradrenaline was set up at 6 p.m. The blood pressure began to rise within a minute or two, and reached 90 after ten minutes. It then increased steadily to 120 at the end of 30 minutes. Slowing the drip was followed at once by a drop to 110, and this level was maintained without difficulty for four hours (Fig. 3). At the end of this time the systolic pressure was 105, and one litre of the infusion had been given. It was then discontinued.

FIG. 3.—Graph showing rise of systolic pressure resulting from intravenous infusion of dextrose-saline containing L-noradrenaline started on the fourth day of cardiogenic shock due to acute coronary insufficiency (Case 5).

On the following morning the general condition had much improved and the pressure was 100. Three months after the onset the patient was up and about quietly, with a blood pressure of 110/75. The cardiogram showed regression of the patterns representing myocardial ischaemia. Radioscopy showed mild left ventricular hypertrophy, normal hilar shadows, and clear lung fields.

Case 6

A man of 61 who had been treated for cardiac infarctions in 1948 and December, 1952, was under periodic observation until, in the summer of 1953, he began to complain of dyspeptic symptoms, and a barium meal examination led to a diagnosis of carcinoma of the pylorus. Partial gastrectomy was performed by Mr. Norman Lake on August 20, with complete removal of a pyloric carcinoma. During the operation the patient never received less than 30% oxygen. Soon after the operation was started he became shocked and the pulse was faint and irregular. He was transfused with 2 pints (1,140 ml.) of blood, and after return to the ward the blood pressure was 130/90. During the next 36 hours the blood pressure fell gradually to 80/65, and he appeared to be moribund. It was judged that this illness was due to infarction of the heart, but cardiography could not be carried out at once. It was decided to give L-noradrenaline.

The infusion of dextrose-saline containing 8 ml. of 1/1,000 L-noradrenaline per litre was begun at a rate of 26 drops a minute. The blood pressure quickly rose to 110/85. In order to maintain this pressure it was necessary to raise

the drip rate to 40 drops a minute, and after 18 hours to double the concentration of L-noradrenaline and reduce the infusion rate from 40 to 30 drops a minute. At this stage a cardiogram showed antero-septal and postero-lateral infarctions. After a further six hours it was necessary to double the concentration again, and yet again seven hours later. The L-noradrenaline concentration was then 64 ml. per litre and the infusion rate 36 drops a minute. Over the next 12 hours the blood pressure was maintained at 110/85 with no further increase in concentration of the drug, and with a decrease in the rate of infusion to 24 drops a minute. The patient then suddenly developed a pulmonary embolism and died at 1.30 a.m. on August 25, one and a half hours after the onset of this complication.

The necropsy confirmed that there was a massive pulmonary embolism involving the whole right lower lobe. The anastomosis of the stomach remnant to the jejunum was intact and no evidence of secondary neoplastic deposits was found. There was severe widespread atheroma of the coronary arteries. A large antero-septal infarction and a small postero-lateral infarction of the heart were present. There were also three old infarctions involving the posterior and lateral walls of the heart. In the left ventricle a great part of the muscle had been replaced by fibrotic tissue.

Discussion

The shock in myocardial infarction needs no special treatment if it is slight. It is upon the treatment of severe and continuing cardiogenic shock that controversy has centred. While some clinicians have employed oxygen, infusions of hypertonic glucose solutions, and stimulants such as nikethamide, these methods have not given constant or convincing results. There has naturally been a temptation to use pressor substances such as adrenaline and ephedrine, and, although they have been advocated in the past by Fishberg (1937), they have been generally condemned on account of the risk of inducing ventricular fibrillation (Eggleston, 1947; Wood, 1952).

The introduction of noradrenaline, and particularly of L-noradrenaline, the optical isomer which acts mainly upon blood vessels, has revived interest in the use of pressor substances in shock. This compound is the most powerful overall vasoconstrictor known and it lacks many of the pharmacological actions that have rendered adrenaline and ephedrine dangerous in cardiac infarction. Thus, in contrast to adrenaline, it does not increase the rate of the heart or the cardiac output; this is the result of reflex vagal cardio-inhibition, for L-noradrenaline stimulates mildly, but definitely, the isolated mammalian heart and the heart of the human under the influence of atropine. Also, whereas adrenaline raises the systolic pressure by its profound cardiac effects and hardly influences or actually lowers the diastolic pressure because of muscle vasodilatation, L-noradrenaline increases both systolic and diastolic pressure as a result of the marked generalized vasoconstriction (Goldenberg *et al.*, 1948). Moreover, Reale *et al.* (1950) have shown that, in the healthy subject, intravenous L-noradrenaline does not increase the oxygen consumption, as does adrenaline. Additional support for the use of this substance in shock due to heart disease comes from Burn and Hutcheon (1949), who have shown that L-noradrenaline is a coronary vasodilator in dogs and cats, but species differences exist and no work has been found on the action of the drug on the adult human coronary artery.

In experimental myocardial ischaemia in dogs produced by tying a coronary artery, Corday *et al.* (1949) demonstrated the harmful effects of hypotension on the infarcted zone and showed that such effects could be reversed by correcting the hypotension. In addition, Sayen *et al.* (1952) have shown that an L-noradrenaline infusion causes a rise in oxygen tension in the ischaemic zone, an effect greater than that produced by pure oxygen inhalation, while no ectopic beats or other arrhythmias were observed during the course of the infusion. On the other hand, Wiggers (1952) has pointed out that such experiments have been performed

on dogs in which intercoronary anastomoses are better developed than in man, and he groups noradrenaline with adrenaline and ephedrine as potentially dangerous in myocardial infarction owing to the increase in the work of the heart and the risk of ventricular arrhythmias.

After weighing all such clinical and experimental evidence, it remains clear that even serious risks might be accepted when the blood pressure in cardiogenic shock is progressively dropping, when the pulse is disappearing, and death wellnigh at hand.

Some work on the use of L-noradrenaline in the shock attending myocardial infarction in man has already been published. Miller and Baker (1952) employed this treatment in seven such patients. A rise of blood pressure was produced in four and in no instance was there any arrhythmia. Six of the patients died. The criterion for use in these cases was a systolic blood pressure of 80 or less continuing for four hours, and they concluded that the results might have been better had infusion been started earlier. Maintenance of infusion until the improvement in the circulatory state was established, and gradual rather than abrupt cessation was advised. More favourable results have been reported by Kurland and Malach (1952), who treated with L-noradrenaline 14 patients suffering from shock due to cardiac infarction. In 12 cases there was a significant pressor response, but the ultimate results were disappointing, as five died from 1 to 41 days after recovery from the state of shock and only four ultimately survived. No arrhythmias that could be attributed to the infusion were observed, although these workers recorded intense venous spasm, phlebitis, and ulceration of the skin at the site of the infusion as occasional complications.

Although our series of six cases is a small one the results are encouraging, since four of these patients survived for four months or more. Three of them were still alive at intervals of six to thirteen months after infarctions which caused grades of shock so severe and prolonged that death appeared to be imminent. In no case did L-noradrenaline cause harm. In spite of the increase in systemic and pulmonary resistances heart failure was never induced by the treatment.

In this grave state of cardiogenic shock there are two elements; the shock and the underlying myocardial injury. Study of our cases endorses what must have been the clinical impression of many—that the degree of shock is not necessarily proportional to the extent of the infarction. If shock is severe and the lesion is gross, then a fatal issue may be determined by the extreme disorganization of the heart. But when, as is sometimes the case, a lesser injury is attended by grave shock, then there is the possibility of recovery and subsequent reasonably good myocardial function, if the critical phase of shock can be surmounted, as exemplified in three of our cases. In the three patients who have died, necropsies have revealed multiple infarctions, old and new, representing a high degree of myocardial damage.

Summary

Six patients in severe shock due to cardiac infarction have been treated by intravenous infusions of dextrose-saline containing L-noradrenaline (levophed). In all of them a fatal issue appeared imminent or probable, the systolic blood pressure falling to levels between 45 and 80, and in two instances the wrist pulse disappearing.

In each case the start of the infusion was followed at once by clinical improvement, the systolic pressure rising to levels between 90 and 100, while the pulse again became palpable; where consciousness had been lost it was regained.

Two patients who had had previous infarctions responded in this way to the infusion, but died within three and four days, recent as well as old infarctions being proved at necropsy.

The remaining four patients made good recoveries after discontinuance of the infusions. Although one died of congestive heart failure four months after the cardiac infarction, the other three were alive and active at intervals ranging from six to thirteen months afterwards, their lives apparently having been saved by the treatment.

The criteria for infusion of L-noradrenaline are discussed and the methods and precautions necessary for its use described.

We are indebted to Dr. N. S. Plummer and Mr. David Trevor for allowing us to study their patients (Cases 3 and 2); to Dr. Alan Strachan, of Sutton, for his help in the clinical observations and treatment of Case 5; to Dr. D. I. L. Gleed, of Finchley, for her initial records of Case 4; to Dr. W. Evans for the pathological reports on Cases 1 and 4; and to Dr. H. Neville Stafford for the necropsy report on Case 6.

ACUTE DISSEMINATED ENCEPHALOMYELITIS AND ACUTE DISSEMINATED SCLEROSIS RESULTS OF TREATMENT WITH A.C.T.H.

BY

HENRY G. MILLER, M.D., F.R.C.P.

Assistant Physician and Lecturer in Neurology

AND

JAMES L. GIBBONS, M.B., B.S., D.P.M.

Research Assistant in Neurology

Royal Victoria Infirmary and the Medical School, King's
College, Newcastle-upon-Tyne

The treatment of seven cases of acute disseminated encephalomyelitis with A.C.T.H. was reported in a previous paper, in which the theoretical basis for trial of the drug was discussed (Miller, 1953). The results of treatment were held to be suggestive enough to warrant further trial. Three further cases have now been treated, and they are briefly reported below.

We have also used A.C.T.H. in the treatment of seven patients with acute exacerbations of disseminated sclerosis. Glaser and Merritt (1952) have already reported on the use of the drug in disseminated sclerosis. They treated 33 cases of the disease, giving 80 to 100 mg. daily during a course of 14 days' duration. These were chronic cases, and none had experienced significant remission during the three years preceding treatment, or since the onset of the disease in cases of less than three years' duration. Twelve patients showed significant improvement. The syndromes benefited were spastic-paretic, cerebellar-ataxic,

bladder dysfunction, and visual impairment of recent origin. Oculomotor disorders, sensory impairment, and reflex changes remained unaffected. The effects observed appeared during the course of drug administration and rarely persisted for more than seven to fourteen days after the end of treatment. In most cases the disease later resumed its usual course, though these authors believed that subsequent maintenance treatment with 75 to 150 mg. of cortisone daily might possibly retard its progression. They considered that the beneficial effects of the drug represented "secondary physiological phenomena due to the hyperadrenal state," whether produced by interference with abnormal immunological reactions in the central nervous system, suppression of inflammatory and connective-tissue responses, or the effect on nervous excitability of chemical changes related to the profound metabolic disturbance which A.C.T.H. is known to produce. A somewhat similar transitory improvement in cases of established disseminated sclerosis has been reported by Fog (1951).

We have, however, restricted the experimental use of A.C.T.H. to patients with a recent acute exacerbation of unequivocal established disseminated sclerosis. All cases had recently developed an acute neurological episode with some objectively assessable focal disability, either a fresh manifestation of the disease or the sudden aggravation or reappearance of a previous symptom. No patient was showing any sign of spontaneous improvement when treatment was begun, and progressive deterioration was evident in several. It seems reasonable to believe that the onset of an acute neurological episode of this nature signals the development of fresh plaques in the central nervous system. Although there is no general agreement on the pathogenesis of disseminated sclerosis, nor indeed on the histopathological changes present in recent lesions, it seemed justifiable to make a trial of A.C.T.H. in such cases.

We had found apparent improvement in acute disseminated encephalomyelitis, which shows several clinical and pathological similarities to disseminated sclerosis. Moreover, if an abnormal immunological reaction were responsible for such exacerbations (Pette, 1942) there are theoretical grounds for believing it might be aborted by A.C.T.H. There are similar grounds for believing that A.C.T.H. might also lead to the resolution of the acute inflammatory reaction which was considered by earlier authors—for example, Marburg (1906, 1942)—to be the basis of acute episodes of disseminated sclerosis. If, however, the initial change of the disease is demyelination, possibly as a result of enzymatic disorder (Lumsden, 1951), A.C.T.H. would be unlikely to have any effect once the process had begun, although such a view of the disease does not preclude the possibility that long-term administration of the drug might possibly prevent the development of fresh lesions.

It was felt that by selecting our cases on the above lines it would be possible to make an initial assessment of the effects of the drug on a relatively small number of cases, with a view to a more extended trial if the results were suggestive enough to justify this. It may be remarked that the collection of cases satisfying these criteria proved quite unexpectedly difficult.

In all cases of acute disseminated encephalomyelitis and disseminated sclerosis treated, 25 mg. of A.C.T.H. was given intramuscularly every six hours, usually for a period of five days. Repeated eosinophil counts were made, but in all the cases reported adequate adrenal response was obtained with this dosage.

Acute Disseminated Encephalomyelitis

The three additional cases of acute disseminated encephalomyelitis treated with A.C.T.H. comprise one case of special interest—an example of encephalomyelitis occurring during the course of acute rheumatic fever—and two patients suffering from encephalomyelitis following measles.

Case 1

Encephalomyelitic illness arising during the course of acute rheumatic fever in an 11-year-old boy of low average intelligence. Rapid recovery, beginning within 12 hours of administration of A.C.T.H.

Six weeks before his acute neurological illness this boy developed a febrile sore throat with muscle pains. This cleared up within a week but left him off colour, eating badly, and losing weight. Three weeks after the onset of the initial infection he developed a transient coalescent multi-form erythematous rash, and a week later an acute poly-arthritis with which he was admitted to hospital. At this time he was toxic, but only occasionally febrile, with a pulse rate of 122, a systolic apical murmur, triple rhythm, and partial auriculo-ventricular block with occasional dropped beats. During two weeks in hospital the joint pains were greatly relieved by salicylates, there was only an occasional spike of fever, and the E.S.R. fell from 125 to 41 mm. in the hour (Westergren). However, the child remained ill, and a continuing carditis revealed itself by persisting cardiographic signs, an increasingly loud murmur, and an episode of probable pleuropericardial friction.

Seventeen days after admission to hospital he was observed to be drowsy, and within thirty hours passed through stages of deepening stupor, lighter during the day and deeper nocturnally, to become almost unrousable.

Examination revealed slight neck stiffness, unequal sluggish pupils, spontaneous nystagmus, and a generalized increase of deep reflexes with extensor plantar responses. Within the next six hours he became profoundly hypotonic, with absent deep reflexes, and entirely unresponsive even to painful stimuli. The pressure and composition of the spinal fluid were entirely normal. An E.E.G. showed diffuse slow activity, chiefly in the delta range.

At this stage, 36 hours after the onset of neurological symptoms, he was given 50 mg. of A.C.T.H. followed by four injections of 25 mg. at six-hourly intervals. Improvement was evident within twelve hours. The patient was easily rousable, answered questions, and took food. Neck stiffness was less, the pupils were equal but sluggish, muscle tone was normal, and plantar responses remained extensor. Neurological improvement from this time was progressive. For three days the child was unduly drowsy at night, but at the end of this time symptoms and signs had entirely disappeared and the plantar responses were flexor.

Following this the child developed several syncopal attacks accompanied by extreme bradycardia, with a pulse rate as low as 38, which were improved by ephedrine. The E.E.G., however, showed progressive improvement, though the rheumatic process continued in a subacute form, and within seven days an apical diastolic murmur and involuntary movements typical of Sydenham's chorea made their appearance.

Case 2

Measles encephalitis in a boy of 10. A.C.T.H. given from the seventh day of the neurological illness. Improvement slow but progressive to complete recovery.

Four days after the appearance of a typical measles rash, when this previously healthy child appeared to have recovered, he suddenly became quiet and apathetic. He lay almost motionless thereafter, refusing food. On the third day he became mute and his legs stiff. On the fourth he developed retention of urine, and examination on admission to hospital showed him to be flushed and restless, with meningism, general hyperreflexia, extensor plantar responses,

and a normal spinal fluid. Twelve hours later he was barely rousable, and was febrile—99.6° F. (37.6° C.). The signs were unchanged, except that his stupor was deeper and the legs had become flaccid and the arms spastic.

A.C.T.H. was given at once. Twelve hours later he was more easily rousable but remained mute. Twenty-four hours after the first dose he was making semi-purpose movements with his arms and meningism had decreased. Twenty-four hours later the tendon reflexes became normal, and during the next few days tone in the limbs varied from hour to hour. Improvement from this time was progressive but very slow, and it was not until the fifteenth day of the illness (three days after completion of his five-day course of A.C.T.H.) that facial expression became normally mobile. Two days later the plantar responses had become flexor, and 48 hours after this he began to talk. He remained emotionally labile and inattentive for at least three weeks, and convalescence was prolonged.

Case 3

Severe measles encephalitis in a girl of 3½, with myoclonus, coma, hyperpyrexia, and death within four days of onset, after 36 hours' treatment with A.C.T.H.

Five days after the appearance of measles this child was noticed to be unusually quiet and to have apparent brief lapses of consciousness. During the next two days her condition deteriorated, with increasing drowsiness and occasional muscle-twitching. On examination at this time she was deeply stuporous, but resisted violent stimuli. She was febrile—100.2° F. (37.9° C.)—and generally hypertonic, with hyperreflexia, absent abdominal reflexes, and extensor plantar responses. Repeated myoclonic twitching was present in the left hand and foot. There was no meningism and the spinal fluid was entirely normal. A.C.T.H. and suitable sedatives were administered at once. Twelve hours later stupor had deepened to an unresponsive coma. Convulsive twitching was bilateral and continuous, shifting from one group of muscles to another. During the subsequent 24 hours these movements ceased except in both eyelids, all four limbs became flaccid, and death occurred in hyperpyrexia after an illness of four days' duration. Permission for necropsy was refused.

Comment

Cases of acute disseminated encephalomyelitis in association with rheumatic fever similar to Case 1 have been described by van Bogaert *et al.* (1932). Although these illnesses are clinically similar to para-infective encephalomyelitis of more familiar types, a rather different pathological basis has been described by Costero (1949), who found a diffuse cerebral angiitis of "hyperergic" type in fatal cases of rheumatic fever both with and without cerebral symptoms.

By comparison with Case 1 the two cases of measles encephalitis (Cases 2 and 3) were disappointing, especially as success has already been claimed for the use of A.C.T.H. in this condition (Ligterink, 1951). In Case 2 treatment was not begun until the fifth day of the disease, and, although admittedly the patient gradually recovered from this time onwards, there was no dramatic response to A.C.T.H.: the disease ran a course with which we are familiar in untreated cases, convalescence being protracted. Case 3 deteriorated rapidly in spite of treatment. This may well be considered to fall into the second group of cases which we have considered on theoretical grounds unlikely to respond to treatment—"the rapidly fatal encephalomyelitic illness of which the pathological basis is a diffuse cerebral purpura."

Disseminated Sclerosis

Eight acute episodes of disseminated sclerosis in seven patients have been treated with five-day courses of A.C.T.H., as shown in the Table. Each case satisfied the criteria already described. We had hoped that A.C.T.H. might cause rapid resolution of the acute lesions of the

Details of Cases of Disseminated Sclerosis

Case	Age and Sex	Duration of History	Apparent Provoking Factors	Clinical Features of Acute Episode	Background Disability	Results of Treatment
A1	27 M	2 years	0	Spastic weakness and paraesthesiae in right hand for one week	Spastic paraplegia. Difficulty in micturition. Ataxia	Disappearance of acute symptoms. Relief of spasticity and bladder disorder. No change in reflexes
A2	38 M	2½ "	0	Exacerbation of weakness of legs	As above	Relief of bladder symptoms only. Euphoria
B	38 M	10 "	0	Acute exacerbation of spastic paraplegia 6 weeks before. Later widespread painful paraesthesiae	Spastic paraplegia. Dysuria. Ataxia	Decrease of long-standing spasticity in right leg. No change in reflexes. Euphoria
C	49 M	6 months	0	Ataxia of gait, with flexor spasms in legs	Bilateral pyramidal signs. Paraesthesiae. Little weakness	No change. Euphoria
D	42 F	17 years	Febrile sore throat one week before	"Useless" left arm for 4 days	Spastic paraplegia. Dysuria. Ataxia	No change
E	33 M	9 "	0	Increasing spastic paraplegia and paraesthesiae for two days	Nil (complete previous remission)	" "
F	31 F	16 "	Common cold 23 days before	Spastic tetraplegia developing during a few hours	Spastic weakness of right leg	Aggravation of symptoms during treatment
G	20 F	4 weeks	0	Increasing weakness of legs for three days. Optic neuritis	Nil	Aggravation of symptoms during treatment. Euphoria (subsequent course of illness confirmed diagnosis)

disease, with concomitant improvement in symptoms. It seemed possible that the control of acute episodes might lessen permanent damage to the nervous system and so improve both immediate and long-term prognosis.

The results were, however, profoundly disappointing. The first patient treated appeared to respond (Case A1). His most recent symptoms—spasm and paraesthesiae in the right hand—resolved during the course of treatment, while bladder control was improved and spasticity reduced without change in the reflex signs. Several weeks later, however (Case A2), a second acute episode in the same patient was characterized by a rapidly developing exacerbation of paraplegia, ataxia, and recurrent bladder symptoms. This exacerbation proved entirely unresponsive to a similar course of A.C.T.H., with the sole exception that dysuria was again apparently improved. In no other case was improvement in acute symptoms observed. One other patient (Case B) showed a definite decrease in long-standing spasticity, while his more recent symptoms remained unchanged. Case G had acute visual impairment, but became dramatically worse during the five days of treatment. The one really striking effect of A.C.T.H., observed in four patients, was the rapid development of marked euphoria, sometimes with extravagant claims of subjective improvement in function for which no objective basis could be found. This euphoriant action is well known, and makes clinical assessment difficult, for a cheerful patient may make much more effort than a depressed one in such tests as those for muscular power.

It will be seen that the only definite benefits derived by these patients are among those enumerated by Glaser and Merritt—decrease in spasticity and improved bladder function. We must conclude from this small group of patients that A.C.T.H., given in physiologically adequate dosage over the course of five days, has no specific effect on the acute manifestations of disseminated sclerosis. There seems no reason to believe that cortisone would be any more effective. The place of A.C.T.H. or cortisone in maintenance treatment, with the aim of preventing fresh lesions, remains to be established.

Discussion

In all we have now treated 10 cases clinically diagnosed as acute disseminated encephalomyelitis with A.C.T.H., and the results are on the whole distinctly encouraging. Two cases followed measles, two varicella, and three respiratory infections; one occurred in association with acute rheumatic fever, and one after body-chilling, while the remaining illness developed apparently spontaneously (subacute necrotic myelitis). In seven patients marked improvement occurred during five-day courses of the drug, and in five instances quite unequivocal clinical improvement appeared within 12

hours of the initial injection of A.C.T.H. The two complete failures were in subacute necrotic myelitis and in the very acute measles encephalitis described above (Case 3)—cases which on theoretical grounds would seem very unlikely to respond. These illnesses tend, of course, to spontaneous and often dramatically rapid recovery, and we cannot yet be certain that the course of the illnesses was in fact altered by the administration of A.C.T.H. Nevertheless the evidence in favour of this view is very suggestive, and may perhaps be regarded as more so when it is observed that improvement occurred within twelve hours of instituting therapy in four of the six patients in whom treatment was instituted within forty-eight hours of the onset of neurological symptoms, but in only one of the four cases in which the symptoms were of longer duration. Such rapid improvement in early cases is entirely in keeping with the hypothesis on which this therapy is based (that acute disseminated encephalomyelitis represents a neurological analogue of urticaria or "anaphylactoid purpura"), and is surely the reverse of what might be expected did our case records represent the natural history of encephalomyelitic illnesses unaffected by therapy.

Consideration of these results suggests two further approaches. Clinically it would be of interest to observe the effects of the more rapidly acting intravenous cortisone or compound F on the severe acute encephalitic illnesses in this group. Secondly, observations on the possible therapeutic action of cortisone or A.C.T.H., as opposed to their verified prophylactic effect, in experimental "allergic" encephalitis might yield further information on what might be hoped for in dealing with the disease in man.

It appears, however, that while most cases of acute disseminated encephalomyelitis show definite clinical improvement during a five-day course of A.C.T.H., a similar course of treatment produces no effect on acute episodes of disseminated sclerosis. This finding permits of two possible interpretations. Either acute disseminated encephalomyelitis responds to A.C.T.H. and acute disseminated sclerosis does not, or neither disease is influenced by the treatment and the differences observed are inherent in the natural history of the two syndromes. Although we believe the second interpretation to be the less likely, it cannot be doubted that the two conditions are distinct. It has never been suggested that post-exanthematous or post-vaccinal encephalomyelitis develops into disseminated sclerosis. Nor have we ever encountered in disseminated sclerosis that dramatically rapid spontaneous resolution of gross neurological signs within hours or days which is a common occurrence in the patient with acute disseminated encephalomyelitis. Furthermore, follow-up studies of apparently spontaneous acute disseminated encephalomyelitis have shown that recurrence is unusual and that the prognosis

after survival of the acute illness is good (Thygesen, 1949; van Bogaert, 1950; Miller and Evans, 1953). That the ultimate prognosis of recovered neuromyelitis optica, which we regard as a variant of acute disseminated encephalomyelitis, is similarly favourable has been clearly shown by Scott (1952).

The differentiation of acute disseminated encephalomyelitis from acute disseminated sclerosis is therefore of much more than academic importance, but it may be very difficult in the acute stage. Both illnesses show signs of disseminated lesions in the neuraxis, both tend to occur in young adults, and both often follow non-specific infections, especially of the respiratory tract. In our experience the diagnostic criteria offered by McAlpine (1931) are invaluable, but the need for further study is demonstrated by the following recent case.

Seven weeks before admission to hospital a young man of 19 developed an acute influenzal illness, epidemic at the time in the Army camp in which he was serving, and associated in his case with quite severe pain in the left eye which lasted for three days. He recovered completely from his symptoms within a week, but seven days later vision in the left eye suddenly became blurred. Examination at this time revealed a unilateral retrobulbar neuritis with papillitis; there were no abnormal signs elsewhere. Sight in the left eye became normal within a week and the patient remained well until one month later, when he developed acute backache, followed by weakness and stiffness of the legs, constipation, and retention of urine. Examination at this time revealed some pallor of the left optic disk, nystagmus at the extremes of lateral gaze, and signs of a partial transverse lesion of the spinal cord in the mid-dorsal area, with loss of proprioceptive sensation in the feet and of impairment of superficial sensibility to the seventh thoracic dermatome. The spinal fluid contained 73 lymphocytes per c.mm., but was otherwise normal. Improvement from this lesion was rapid, and a mild spastic paraparesis with some left optic atrophy was at the time of writing the only evidence of his illness.

Was this a case of rapidly healing biphasic encephalomyelitis, showing some similarity to the syndrome of neuromyelitis optica, and with only slight danger of recurrence? Or must it be labelled as disseminated sclerosis, with all the sinister implications of that diagnosis? The answer to such problems seems less likely to depend on further refinements of clinical diagnosis than on the development of such ancillary aids as are suggested by the immunochemical studies of Kabat *et al.* (1948) or the refined colloidal gold reaction described by Lange and Harris (1949), which may ultimately furnish diagnostic instruments of critical importance.

Summary

Three further cases of acute disseminated encephalomyelitis personally treated with A.C.T.H. are reported, bringing the total of cases treated to 10. In seven patients marked improvement occurred during five-day courses of the drug, and in five of these unequivocal clinical improvement was observed within 12 hours of the initial injection of A.C.T.H. The two complete failures were in cases of subacute necrotic myelitis and catastrophic measles encephalitis. Improvement occurred within 12 hours in four of the six cases in which treatment was instituted within 48 hours of the onset of neurological symptoms, but in only one of four cases treated later in the course of the illness. This finding is regarded as a further indication that the course of the illness was favourably influenced by treatment.

Similar courses of A.C.T.H. were given during eight acute exacerbations of disseminated sclerosis in seven patients. Although euphoria was often present and improvement in chronic spasticity and bladder dysfunction occasionally observed (in keeping with results previously reported), acute symptoms showed no improvement comparable to that seen under similar conditions in acute disseminated encephalomyelitis.

The importance and the occasional difficulty of distinguishing between these two clinically similar but biologically distinct acute neurological syndromes are discussed and illustrated.

We wish to thank practitioner and consultant colleagues in Region No. 1 for their kind co-operation in referring cases for treatment, and the Medical Research Council for a supply of A.C.T.H.

CONSERVATIVE SURGERY IN THE TREATMENT OF ULCERATIVE COLITIS

BY

STANLEY O. AYLETT, F.R.C.S.

Surgeon to the Metropolitan Hospital; Assistant Surgeon
to the Westminster Hospital Teaching Group

There is no doubt that the modern improvements in ileostomy bag design have relieved an ileostomy of some of its terrors, but, in spite of this and the reports of many patients who have returned to most of their former activities, it would be idle and false to pretend that the prospect of an ileostomy for the rest of life is one that does not bring dismay and gloom to those of finer sensibility. Many patients for whom an ileostomy is contemplated or performed are in their youth and in their early married and home life, and few can believe that such distortion of the normal channels of evacuation is likely to prosper that alliance and that household. It is surely right that surgical opinion should not accept the inevitability of permanent ileostomy combined with total colectomy and excision of the rectum as the routine surgical treatment of the disease without the fullest exploration of more conservative methods. Devine and Devine (1948), in a series of cases, have put forward a technique whereby the rectum is preserved and continuity of the intestinal track re-established; and Corbett (1952), working along similar lines, has reported successful cases. Both of these methods entail the full discharge of ileal content through an ileostomy that is retained for varying periods of time, but the method of continuity suggested in this paper, dependent as it is upon immediate ileo-pelvi-rectal anastomosis, carries no such disadvantage.

Those antagonists of any attempt to preserve rectal function contend that the inflammatory changes precept in the rectal mucosa continue in spite of removal of the rest of the colon and that the mucosa is unable to withstand the proteolytic effect of the ileal contents which are poured into it. Moreover, they regard the possibility of cancerous change in the remaining portion of the bowel as a very real one, and in the event of existing

complications of the disease being present, such as arthritis or pyoderma, they believe that these are not cured so long as a portion of the large bowel remains.

In certain cases, at least, it is doubtful whether these fears are real, and it is still more dubious whether they should prevent the surgeon from an attempt at restoration of continuity of the bowel. Devine and Devine have described the regression of the acute inflammatory change in the rectum, once its connexion with the colon has been severed, so that the mucosa returns practically to its original state, and my own experience supports this view. That the rectum and anal canal can withstand the proteolytic action of small-intestinal content has been proved to my satisfaction by my experience with anastomosis of the small intestine to the rectum for other conditions (Aylett, 1951, 1952), so that this consideration, too, cannot be held as a bar to attempts at functional restoration.

Suitable Cases

In the type of case upon which a conservative operation is proposed, the possibility of cancerous change in the remaining rectum is not a real one. Counsell and Dukes (1952) have shown that in ulcerative colitis cancerous changes occur either in association with a dense fibrous-looking stricture or as a result of malignant changes supervening in true adenomata. The common inflammatory pseudo-polyps and oedematous mucosal tags are not pre-malignant and may disappear completely with the amelioration of the disease. Where the rectum is studded with true adenomata the nature of which will be revealed by pre-operative biopsy examination, or where, in the course of sigmoidoscopic examination, stricture formation is identified in the portion of the bowel it is proposed to retain, any consideration of conservative surgery must naturally be abandoned in favour of an ileostomy with complete removal of the colon and rectum. In the absence of such changes, even though the typical acute inflammatory appearances with pseudo-polyps are obvious, I consider that the operation should be planned with a view to retention of the rectum.

Of the five cases reported below, one had a severe pyoderma. In this case at least, the condition resolved completely, and the return of the rectal mucosa to a normal appearance encourages us to believe that other extra-bowel lesions may resolve in a like manner, with a conservative operation retaining rectal function.

It is not within the scope of this paper to consider the numerous indications for surgical intervention in this disease, but if conservative surgery is to be contemplated it is essential that stricture formation in the rectum and the lowermost part of the colon shall be absent. In dealing with the case that is under prolonged medical treatment the closest co-operation between physician and surgeon is therefore essential, so that operation shall not be delayed until this complication has developed. It is only by sigmoidoscopic examination that the early stage of bowel changes likely to go on to stricture formation can be recognized, and this investigation must therefore be carried out at frequent intervals throughout the patient's illness. Distensibility of the rectum and colon is at all times diminished in cases of ulcerative colitis, as the normal elasticity of the bowel is reduced by the oedema and inflammatory changes that affect all its layers, but the start of actual stricture formation is suggested when the sigmoidoscope feels held or gripped at any level of the bowel within the scope of the examination, or if the wall feels thickened and unduly taut. In all such cases medical treatment should be abandoned in favour of surgery, as, if the former is prolonged, stricture formation will develop and retention of a functioning rectum will be impossible.

A conservative operation will also be out of the question if perirectal abscess and fistula formation is present,

but if the disease is regarded as one in which both physician and surgeon have an equal interest, and one in which operation does not carry the inevitability of permanent ileostomy, then the disease is unlikely to be allowed to reach the advanced stage before surgery is undertaken. Finally, the prospect of the retention of rectal function, by overcoming both the patient's disinclination to submit himself to an operation which is to result in a permanent ileostomy and the physician's natural reluctance to advise such a procedure until the very last, may help to avoid the "Belsen" type of case in which any operation must carry an appreciative mortality.

Operative Technique

The abdomen is opened through a left paramedian incision and the ileum divided close to the caecal valve. Both free ends are closed, and the proximal end is anastomosed to the pelvi-rectal region of the colon by side-to-side anastomosis.

The colon is then divided about 2 in. (5 cm.) above this site and the free ends are brought out on to the skin surface in the left iliac fossa (Fig. 1).

The patient is thus left with an end of the colon, a little above the anastomosis, opening on to the surface of the abdomen. This provides a safety-valve effect, so that any pressure, the result of the accumulation of intestinal content or flatus in the rectum, which might be sufficient to break down the anastomosis between the ileum and the colon is prevented from developing, as the contents will discharge through the colostomy before enough tension to produce damage has been built up. In actual practice, although considerable quantities of flatus are passed, the amount of ileal content that escapes on to the abdominal surface is not great and has not been sufficient to produce excoriation of the skin. Nevertheless, I feel sure that the absence of any suggestion of a leakage in my cases at the anastomotic site has been due to the safety-valve effect of this colostomy, and that an intraperitoneal anastomosis carried out through grossly diseased bowel wall without this device would be fraught with great danger of leakage. The idea of decompression of the bowel by this method was first introduced by Muir (1947), who employed the technique when carrying out a right hemicolectomy.

In two of the five cases recorded below the condition of the patient at the completion of the ileo-pelvi-rectal anastomosis was good enough to enable the colectomy to be carried out at the same operation, so that only the distal free end of the colon was drawn out on to the surface of the abdomen. The general condition of most patients, however, would not permit of this, and the colectomy must be delayed until sufficient improvement has been achieved as a result of the ileocolostomy.

Closure of the safety valve some three to four weeks after the initial operation is the next step in the planned treatment of the condition. By this time the anastomosis will have united soundly, and there is then no need of the safety-valve effect. Moreover, it is best that this should be closed before the abdomen is reopened to remove the colon, as the risk of faecal contamination of the abdominal wound is thereby reduced. In Case 5 of the series reported, however, it was necessary to carry out the colectomy before the closure of the colostomy, as, after a period of great

FIG. 1.—The final altered anatomy, with the distal ends of the colon exteriorized.

improvement in the child's general condition following the first operation, deterioration began as a result of constant haemorrhage from the isolated colon. Colectomy was the final stage of operation in the remaining two patients. (Fig. 2.)

The progress of all patients after the ileocolostomy has been absolutely smooth and there has been no anxiety with regard to saline or fluid unbalance. Until a return of peristalsis, intravenous therapy has been continued, but, apart from an immediate post-operative blood transfusion, no continuance of this form of therapy has been necessary, even in those who, prior to the operation, needed weekly blood transfusions to maintain a normal blood picture.

FIG. 2.—The colectomy has been completed and the safety-valve colostomy closed. The photograph is that of a child aged 10 years.

The safety-valve colostomy discharges about the third day and ileus has never been severe enough to necessitate gastric suction. Once the bowels start to function, a day or two after the colostomy has acted, the discharge from this becomes steadily less.

The improvement in the general condition of the patient is rapid. Appetite and well-being return; fever and toxæmia disappear as quickly as after an ileostomy, and the emaciated patient puts on weight.

Case Reports

Case 1.—A woman aged 30, was admitted in November, 1951, with acute ulcerative colitis supervening upon a chronic condition of 19 years' standing. Bleeding and toxæmia were severe. In spite of all forms of treatment the condition deteriorated. Sigmoidoscopy showed appearances typical of an acute stage of the condition, with changes extending right down to the anal canal. The mucinase activity of the faeces was 400 units and the pre-operative weight was 6 st. 5 lb. (40.4 kg.). Ileo-pelvi-rectal anastomosis was carried out in February, 1952. The relief of symptoms and improvement in general condition were rapid. Colectomy was postponed until September, 1952. Before it was undertaken proctoscopy revealed a rectal mucosa that appeared normal. The ulcerative condition had completely disappeared. At the final operation the outward appearances of the distal segment of the colon and the upper rectum were seen to have changed dramatically. The sodden and inflamed bowel found at the initial operation had resolved and, with the exception of a slight thickening, appeared normal. The mucinase activity in the stool at the time of the final discharge was nil and her weight was 7 st. 11 lb. (49.4 kg.). The bowels were opened eight times in the 24 hours, and she was completely continent.

Case 2.—A man aged 46 was admitted in March, 1952, with a two-years history of ulcerative colitis. He had been in hospital elsewhere for the previous six months. Recently diffuse pyoderma of his face and neck had developed. Mucinase activity of the stool was 416 units. The bowels

were opened every two hours and there was a loss of weight of about 2 st. (13.2 kg.). His pre-operative weight was 8 st. 6 lb. (53.5 kg.). In view of failure to respond to medical treatment, operation was undertaken in April. Colectomy was carried out at the time of the pelvic anastomosis. Before discharge six weeks later the mucinase activity had fallen to 83 units. By September his bowels were being opened twice in the 24 hours, the pyoderma had subsided, and there was a weight gain of 17 lb. (7.7 kg.). The patient remains well. The ulceration of the rectal mucosa has healed entirely and with the exception of some oedema the mucosa appears normal.

Case 3.—A man aged 44 was admitted in March, 1952, with a seven-years history typical of ulcerative colitis. He had been in and out of hospital on numerous occasions, and in the acute attacks the rectal discharge necessitated visits to the toilet every 20 minutes. Sigmoidoscopy revealed changes of acute ulcerative colitis involving the rectum. The present attack failed to respond to medical treatment and anastomosis was carried out in May. The colectomy was completed in June. The patient's improvement was rapid. In September his bowels were opened eight to ten times a day and he was completely continent. He had gained 7 lb. (3.2 kg.) in weight, was fit and well, and was back at work. Rectal examination revealed a mucosa that was more oedematous than normal and which tended to bleed on pressure with the end of the proctoscope. The acute inflammation, with pseudo-polyposis formation present pre-operatively, had entirely disappeared. No blood was present in the stool.

Case 4.—A girl aged 10 was admitted in March, 1952, with a two-years history of periodic diarrhoea and blood in the stools. The haemoglobin on admission was 78%. Sigmoidoscopy and barium-enzyme examinations showed appearances of acute ulcerative colitis. The mucinase activity of the stool was 125 units. In spite of medical treatment the child's condition deteriorated steadily and multiple transfusions were required. At one time the haemoglobin fell rapidly to 46%. Blood-stained purulent discharge from the anus was almost constant, and operation was delayed only on account of the child's age. In September it seemed apparent that without operation she would die, and the anastomosis was therefore carried out. The improvement in her condition was dramatic. Three weeks later there was severe haemorrhage from the colostomy communicating with the isolated colon, and this continued. Colectomy was therefore carried out, and since that date her improvement to normal health has been uninterrupted. The mucinase activity of the stool is nil, and the rectal mucosa appears normal. The safety-valve colostomy has since been closed. There were six bowel actions in the 24 hours.

Case 5.—A woman aged 42 was admitted in July, 1952, with a 13-years history of chronic ulcerative colitis with acute exacerbations. She had been in hospital on numerous occasions. Recently there had been a steady decline in general health, constant blood-stained stools and discharge, and loss of weight. Sigmoidoscopy revealed typical changes of the condition down to the lower rectum, and barium-enzyme x-ray examination showed the terminal ileum to be involved. Ileo-pelvi-rectal anastomosis with colectomy and removal of the terminal 2 ft. (60 cm.) of small intestine was therefore undertaken. Since operation the general improvement has been great. The patient has put on 13 lb. (5.9 kg.) in weight and is in normal good health. She is completely continent, although the bowels are opened 10 times in the 24 hours. Blood is absent from the stool, and the pseudo-polyposis visualized and demonstrated by biopsy before operation has subsided.

Comment.—In the fulminating case of ulcerative colitis associated with perforation the same sphincter-preservation should be aimed at. Such cases should be especially suitable for this type of operation, as the pathological changes occurring in the lower colon and rectum are acute and likely to be completely reversible. The general technique,

however, requires modification in view of the desperate condition of the patient. It is useless to attempt suture of the perforation, as the stitches will fail to hold in the diseased bowel wall, and, in any case, further perforations are usually impending at other sites in the colon. The caecum and colon as far down as the lower third of the pelvic colon must be excised, the distal end of the latter being brought out as a colostomy. Anastomosis of the ileum to the pelvi-rectal region would add a further quarter of an hour to the operation, and as the patient is unlikely to withstand this prolongation of operative time the severed end of the ileum is brought out as an ileostomy. Restoration of continuity of the bowel is delayed until the patient has fully recovered from the initial operation.

Discussion

I cannot agree with Counsell and Goligher (1952) in accepting the possibility of malignant change in ulcerative colitis as the dominating consideration in its surgical management. When true adenomata or stricture formation are present, then there is no question of the nature of the surgery that must be undertaken, but to advocate the removal of the rectum to prevent the formation of cancer when there is no certainty of its development is, I consider, too radical advice. The five specimens concerned in this article have been searched for cancer change and none has been found. It is unlikely to exist in the residua of the large bowels which have been retained, in view of the great improvement in the patients' general condition and the subsidence of the inflammatory changes, confirmed by proctoscopy. That the disease may recur in the rectum is a possibility, but the short follow-up of the present series has shown, so far, no indication of such a relapse. Even should a proportion have a return of symptoms, the establishment of an ileostomy and the excision of the rectum and terminal colon is no great surgical feat, and it can surely be reserved for those for whom it is a necessity rather than condemn all and sundry to a permanent ileostomy.

I have remarked on the noticeably smooth post-operative recovery of these patients, and from my own experience with ileostomies I have no doubt whatsoever about which is the easier. On this ground alone the operative mortality is likely to be very much less than the considerable mortality that accompanies ileostomy, and is an added argument in its favour.

Frequency of bowel action is unavoidable, but it is a small price to pay to escape an ileostomy life. In the second patient reported in the series the caecum appeared only mildly affected with the disease, and it, instead of the small intestine, was anastomosed to the pelvi-rectal junction. This patient has only two actions a day, and that this modification can be applied in other cases with advantage is a possibility.

Summary

The preservation of the rectum and of the normal channel of evacuation is advocated in those cases of ulcerative colitis in which fibrosis, pelvi-rectal suppuration, or true adenoma formation is absent from this part of the large intestine.

A method whereby this can be carried out without a preliminary ileostomy is described. The ileum is divided and its proximal end is anastomosed to the pelvi-rectal region. The colon above the site of the anastomosis is cut across and both free ends are exteriorized. The distal colostomy opening is subsequently closed and colectomy performed.

Immediate subtotal colectomy is advocated as the operative method of choice in the fulminating case.

Cases are reported in which a return to good health has followed treatment by the methods described.

I would like to thank Dr. E. R. Cullinan, in whose charge these patients have been, for his collaboration and advice in this work; Dr. C. B. Lewis, who has been responsible for the anaesthesia in these cases; and the nursing and resident staff of the Gordon Hospital for their unfailing care and attention to the patients.

Since this paper was prepared the initial stages of the operation have been successfully carried out in four other patients. One of these now has her bowels open three times a day only.

PHLEGMASIA CAERULEA DOLENS

BY

PETER MARTIN, V.R.D., M.Chir., F.R.C.S.Ed.

Surgeon and Lecturer in Surgery, Postgraduate Medical School of London; Surgeon, Chelmsford Hospital

Phlegmasia caerulea dolens occurs in the limbs as a result of what would appear to be complete or almost complete obstruction to the venous outflow. It is of sudden onset, and is often associated with extreme cyanosis, swelling, pain, and shock, resulting in circulatory stasis of such a degree that gangrene follows in approximately a half of all cases.

The condition is rare, but has attracted much attention, particularly in France, and has been called variously pseudo-embolic phlebitis, blue phlebitis (Grégoire, 1938), and gangrenous thrombophlebitis (de Vega and Andrés García, 1946). DeBakey and Ochsner (1949) suggested the name phlegmasia caerulea dolens, and this seems an adequately descriptive term. Since then further cases have been reported (Clain and Nussbaum, 1950; Haimovici, 1950; Veal *et al.*, 1951; Miles, 1951; Turner, 1952).

Causation

The condition may occur when the main vein of a limb is suddenly obstructed. Veal *et al.* described cases that resulted from prophylactic ligation of the inferior vena cava in ilio-femoral thrombophlebitis with or without embolism, and I have seen the most alarming cyanosis and swelling after ligation of the common iliac vein for repeated embolism.

On account of repeated pulmonary embolism a man aged 63 had the common iliac vein ligated, thrombosis being present in the femoral vein. The following day he was moderately shocked and complained of severe pain in the thigh and leg. The affected leg was grossly swollen, intensely cyanosed, and much colder than its fellow, the distal pulses being hardly felt. The leg was elevated to 45 degrees and reflex heating and tolazoline hydrochloride were given; within three hours the swelling had practically disappeared and a full bounding pulsation was felt in the dorsalis pedis and posterior tibial vessels.

More usually it would seem to follow thrombophlebitis, occurring spontaneously or after operation, or in the puerperium, or as a result of pressure or invasion of a vein by neoplasm, or in association with blood disease.

A woman aged 54 was admitted to hospital with a thrombophlebitis of the right leg. She had suffered from attacks of phlebitis in the right leg during the thirty months prior to admission, and two and a half years previously had had a splenectomy, at another hospital, for a supposed Banti's syndrome. She was treated in hospital with penicillin, heparin, and dicoumarol, but, as a result of haemarthrosis and epistaxis, anticoagulants had to be stopped. Five weeks later there was a sudden onset of severe pain, swelling, and cyanosis of the right leg.

On examination the patient was seen to be severely shocked, the right leg was intensely swollen and cyanotic up to the knee, and the distal half of the leg was cold and pulseless. The femoral pulse was palpable, but more distal pulses were not felt. A diagnosis of embolus was considered, but no origin was apparent, and it was thought that the ischaemia was the result of a massive venous obstruction.

Conservative treatment by elevation, reflex heating, and tolazoline hydrochloride was instituted, but after three days it was obvious that a patch of tissue in the sole of the foot was gangrenous. The swelling gradually subsided and the cyanosis diminished slightly. Investigation of the blood showed a polycythaemia vera, which was treated by radioactive phosphorus. After five weeks the gangrenous area, fortunately small and superficial in extent, sloughed and distal pulses became palpable. However, cyanosis and moderate swelling persisted and it became evident that all the superficial veins of the limb were thrombosed, and that there was a thrombosis of the inferior vena cava.

Six months later the patient was getting about, with the legs bandaged to control the swelling, and the pulses were all normal, a foot plethysmograph at this time showing a greatly diminished but adequate flow in the right foot with no response to reflex heating, thus indicating venous obstruction of such a degree that no reserve blood flow was available.

Massive venous thrombosis as a result of polycythaemia vera in this case caused such a degree of venous obstruction as to jeopardize the life of the limb. Swartley *et al.* (1942) reported a case occurring in an upper extremity, resulting in gangrene of the forearm.

Why only a minute proportion of cases of thrombophlebitis are followed by this train of alarming symptoms is not at present understood, and there are certainly other factors concerned apart from venous obstruction from thrombophlebitis.

Clinical Features

Clinically, the onset is one of dramatic suddenness and is associated with severe pain, sometimes of the greatest intensity. At the same time there is marked swelling of the limb, associated with shock which may even be fatal, and cyanosis occurs which varies greatly in degree, but which may be almost black. The arterial pulse may not be detectable in the distal parts, and the swelling of the limb will render its detection even more difficult. The limb rapidly cools off, and the appearances are similar to those of arterial embolism; this has led to exploration of the femoral artery on a number of occasions (Audier, 1935; Wertheimer and Frieh, 1935; Lindgren, 1937; and Sackenreiter, 1940). Gangrene may ensue, and may be of any degree from a superficial necrosis to a massive death of tissue demanding major amputation which is fatal in 25% of cases. On the other hand, the condition may settle down slowly, the swelling and cyanosis gradually disappearing, and the limb circulation returning almost to normal with or without a post-phlebotic syndrome of varying degree persisting. Sometimes recovery is as sudden as the onset, and it may be partial or complete. Death may occur at the onset from shock associated with loss of fluid into the affected limb and excessive pain, or it may occur later on as a result of gangrene. Pulmonary embolism is a common complication. There seem to be two main varieties, either swelling and cyanosis or arterial symptoms predominating, the latter simulating embolism. More often the types are mixed and there are signs of both venous and arterial occlusion.

It has been shown experimentally (Audier and Haimovici, 1938) that gangrene due to venous obstruction in an organ can be produced only if every vein draining that organ is ligated—in other words, if there is complete venous obstruction—and it may be that in some cases which proceed to massive gangrene this is in fact the mechanism. If this were so, recovery would seem impossible and recanalization could not occur in time to prevent massive death of tissue.

Illustrative Cases

As in fact most cases recover to a greater or less degree—sometimes with no loss of tissue, sometimes with minor gangrene—it seems to me that factors other than total venous obstruction must be significant in this syndrome.

A man aged 67 developed, on the fourth day after a partial gastrectomy, a sudden intense swelling of the left lower extremity up to the level of the groin, and the swollen limb became deeply cyanotic. He was severely shocked, and examination showed a palpable femoral pulse but no distal pulses, and the whole limb was much cooler than the unaffected limb. The next day, after a sudden pain in the chest, the patient died. Post-mortem examination revealed a pulmonary embolus as the immediate cause of death, and the affected limb showed a recent acute thrombophlebitis of the internal saphenous vein, the result of an infusion into this vessel, with no evidence of thrombosis of any other vein, and with no obstruction to the arterial tree.

In this case it seems that an acute superficial thrombophlebitis may have induced a spasm in either the veins or the arteries, or in both the veins and the arteries, of the limb, resulting in cessation of the circulation.

De Sousa Pereira (1946) found that where an isolated segment of vein is the site of thrombophlebitis there is accompanying venospasm extending far beyond the vein affected, and that this spasm can be relieved by anaesthesia of the vein wall or by interruption of the efferent pathways of the sympathetic chain. That veins can go into very effective spasm will be agreed by anyone who has had the experience of intravenous therapy or of operations on veins. Even varicose veins, where muscular walls are atrophied and often largely replaced by fibrous tissue, may be seen to contract.

Diminished oscillations of an artery in close proximity to a vein which is the site of thrombophlebitis has been demonstrated by DeBakey *et al.* (1939), and the association of arterial spasm with deep thrombophlebitis has been emphasized by Boyd (1947). Sutton (1952) reported a case of spasm of the brachial artery of such a degree as to render the hand and fingers bloodless after an intravenous infusion into the superficial median basilic vein at the elbow.

A woman aged 25, thirty weeks pregnant, was admitted to hospital complaining of a cramp-like pain in the left leg on movement. On lying in bed there was a dull ache in the limb together with a feeling of numbness. The limb was pulseless from the femoral artery downwards, there was a patchy cyanosis, and both leg and foot were cold. Sensation was normal and the toes could be moved voluntarily. The picture suggested an embolus, but there was no apparent origin for this, and the case was treated conservatively. Among other procedures, heparin was given via intravenous saline drip. On the third day, while I was examining the patient, she had a rigor, and the most remarkable change came over the affected limb, the cyanosis being replaced quite rapidly by an intense hyperaemia, the pulses throughout the limb becoming full and bounding, and the temperature of the limb gradually becoming higher than its contralateral fellow. Two weeks later the only abnormality was a mild post-phlebotic syndrome.

It seems that in this case an idiopathic deep thrombophlebitis initiated a severe degree of arterial spasm. No doubt sudden rigor was the result of impurities in the heparin and saline drip, and gave rise to a functional sympathectomy which itself "released" the spasm. Dissection of amputated limbs and post-mortem specimens has shown an apparently healthy arterial tree without any evidence of obstruction, though limbs removed by delayed amputation may show the distal arteries close to the gangrenous area filled with thrombus.

Discussion

In phlegmasia caerulea dolens the disappearance of the arterial pulse may be due to a reflex arterial spasm initiated by an irritative thrombophlebitis. On the other hand, when there is oedema and swelling of an extremity resulting from venous obstruction the digital pulse may become impalpable. In fact, in such a limb oscillations recorded by a sensitive galvanometer may be completely masked in spite of a normal blood flow. Clinically, therefore, disappearance of the distal pulses may not necessarily indicate any active spasm of the arteries, especially in those cases in which the swollen cyanotic type of affection predominates. There is no doubt that massive thrombosis of all, or the vast majority, of the veins of the limb results in gangrene, but in those cases in which recovery takes place partial venous obstruction by

thrombus is rendered temporarily complete by an associated spasm of the remaining veins in the limb. At the same time there may be some degree of arterial spasm as well, and it is these several factors, varying in degree, which give rise to the different clinical varieties.

The condition may well be of medico-legal importance, for the development of gangrene in a limb following operation for varicose veins does not necessarily mean that the main artery or even the main vein has been tied.

Much of the treatment is indicated by the pathology. Heparin should be given to achieve and maintain a clotting-time of 15 to 20 minutes, and associated shock is treated by transfusion and other methods. The affected limb should be elevated to an angle of at least 45 degrees to take the best advantage of gravity, and, if the patient's general condition allows, supervised active exercises should be vigorously pursued.

Veal *et al.* recommended this treatment in all cases, and considered that any sympathetic release should be avoided, as it increases the embarrassment of an obstructed venous system. They also stated that if the condition follows ligation of a main vein the ligature should be removed immediately.

If, however, the argument is accepted that the obstruction to the venous drainage is to some degree functional, then it would appear advisable to try to break this reflex by a method of sympathetic release, and, as I have indicated above, it seems to me that there must be a large measure of spasm, at least in those cases which have a chance of recovery.

In a heparinized patient any sympathectomy by resection or by paravertebral injection is dangerous and very likely to produce a retroperitoneal haematoma, and should therefore be avoided. A quite adequate sympathectomy can readily be achieved by means of heat applied to the trunk and unaffected limbs, liberal doses of alcohol, one of the best available vasodilators, and the induction of deep sleep with soluble amylbarbitone in doses of 3 gr. (0.2 g.) hourly until the patient is difficult to rouse, or liberal doses of morphine if pain is severe. This is a regimen appreciated by patients, and it has the advantage of allaying anxiety, besides achieving its effect on the sympathetic. The affected limb should be kept at room temperature, as should any limb threatened with gangrene, and intra-arterial tolazoline may be tried, although I have not been very greatly impressed with this procedure, and my own preference is for the intravenous route in urgent cases. As soon as the patient is fit enough, the elevated limb should be exercised actively several times a day under the supervision of a physiotherapist. In many cases the swelling resolves, the pain is relieved, and the circulation returns, often rather suddenly, in whole or in part. If return of circulation is incomplete, massive or superficial gangrene may result. Pulmonary embolism is a common danger, but heparinization will tend to prevent this complication. In the event of minor or major gangrene developing, removal of tissue (or amputation) should be restricted to the dead part, since the circulation in the surviving proximal segment has always completely recovered before the need for ablation of dead tissue arises.

Summary

The association of acute ischaemia or even gangrene with thrombophlebitis of the extremities is discussed, and the name phlegmasia caerulea dolens is considered to be adequately descriptive.

The different clinical manifestations are described.

The mechanism of the ischaemia is considered, and a theory advanced to account for the varieties.

Treatment is described in outline.

SURVIVAL OF TRANSFUSED RED CELLS IN SCURVY

BY

C. MERSKEY, M.D., M.R.C.P.

Department of Medicine, University of Capetown

The pathogenesis of the anaemia of scurvy is obscure. One view is that the mechanism may be inadequate haemopoiesis due to deficiency of vitamin C. Vilter *et al.* (1946) and others have suggested that there may be a haemolytic process.

The theory of haemolysis has been based on the occurrence of reticulocytosis and abnormally high serum bilirubin and faecal and urinary urobilinogen values in patients with scurvy and anaemia. These findings are not necessarily due to haemolysis. A more reliable indication may be obtained by studying the fate of transfused red cells. As search of the literature has not revealed any report of such an investigation in scorbutic patients, studies of the survival of transfused cells have been made in eight patients with scurvy and anaemia and in one with scurvy but without anaemia.

In six of these patients the transfused red-cell survival time was greatly reduced, and this was interpreted as evidence of a haemolytic process.

Material and Methods

Eight adult male patients (seven Bantu and one Indian) who manifested severe scurvy and anaemia with normoblastic bone marrow have been investigated. The ninth patient, an adult male Bantu, was scorbutic but not anaemic. For some time before admission to the Groote Schuur Hospital these patients had been on a diet severely deficient in vitamin-C content, consisting almost solely of mealie meal (maize) and white bread. All presented the classical picture of scurvy, with spongy haemorrhagic gums, follicular hyperkeratoses, and intramuscular haematomata. There were no signs of any other disease.

The investigation of the eight anaemic cases was divided into four stages as follows:

(1) Initially the patient was kept at complete rest in bed, without any medication and on a diet entirely lacking vitamin C (mealie meal porridge without milk or sugar, stamped mealies, white bread without butter or jam, and black tea and coffee).

(2) After the short control period of rest in bed, the patient was given one transfusion of citrated bank blood which had been stored for at least 36 hours. Between 2 and 4 pints (1.1 and 2.3 litres) of blood were given in each case according to the degree of anaemia. The vitamin-C content of the blood used in each transfusion was not determined, but the average vitamin-C content of 8 pints (4.5 litres) of blood, taken and stored for 36 hours under the same conditions

as the transfused blood, was found to be 1.45 mg. per 100 ml. The vitamin-C-free diet was maintained during this stage.

(3) Between 8 and 18 days after transfusion the patient was given by intramuscular injection 500-1,000 mg. of ascorbic acid daily for a period of 6-10 days while still receiving the vitamin-C-free diet.

(4) Finally, the patient was given a full diet.

In Case 5 the investigation had to be curtailed because he developed chest pain, possibly due to pulmonary embolism. He was therefore given vitamin C on the third post-transfusion day.

In the non-anaemic patient a blood transfusion was given on the day of admission to hospital without a preliminary period of observation. He was investigated for six days thereafter whilst kept in bed on the vitamin-C-free diet without any other medication. On the seventh day he demanded his discharge. He was given 1,000 mg. of ascorbic acid intramuscularly and a full diet; he was subsequently seen as an out-patient.

The red-cell survival times were determined by the Ashby technique, using potent anti-A and anti-B sera (Mollison, 1951). In Case 6, with blood group O, powdered anti-M serum in the form of powdered globulin was used. The estimations of survival times were made either daily or on alternate days. In Cases 2 and 3 the estimations were made on capillary blood. In the other seven cases venous blood was used. In each estimation at least 2,000 cells were counted.

Whilst the patients were on the control diet every possible precaution was taken to prevent them from receiving extraneous sources of vitamin C, apart from the ascorbic acid given by injection and the small quantity in the transfused blood. In error Case 6 was given a glass of sour milk on the sixth day after transfusion, but no other breach of the strict dietary control is known to have occurred.

No other medication was given at any stage except that Case 4 received one injection of 25 mg. of A.C.T.H. on the 18th day after transfusion for the purpose of testing adrenocortical function. This patient bled severely on that day and was immediately given a second blood transfusion; in all other cases only one transfusion was given. As part of another investigation four cases (Nos. 2, 5, 7, and 9) received an intravenous injection of the sodium salt of para-aminohippurate; in addition Cases 2 and 5 received an injection of sodium thiosulphate, whereas Cases 7 and 9 were given inulin.

Results

The Table shows blood findings in each patient before and after transfusion, before vitamin-C therapy, and on discharge. Figs. 1 and 2 show the red-cell survival times for the nine cases.

In Cases 2, 5, and 8 the red-cell survival could not be regarded as being abnormal. In Case 2 the survival-time curve was normal except that the red cells seemed to disappear rapidly at a stage one week after the beginning of vitamin-C therapy. Cases 5 and 8 were followed for only three and six days respectively before being given vitamin C.

In the remaining six cases (Nos. 1, 3, 4, 6, 7, and 9) the transfused red-cell survival times were much shortened. The effect of administering vitamin C in these six cases was as follows. In Cases 3, 6, and 7 the abnormal degree of red-cell destruction diminished coincidentally with the administration of ascorbic acid as indicated by the flattening of the red-cell survival curves. In Cases 1 and 9 the increased rate of destruction persisted for two to three days after ascorbic acid therapy was started. Case 4 was investigated for 18 days before ascorbic acid was given. On the 18th day he bled severely from nose, mouth, and gums, and required a second blood transfusion. An injection of 25 mg. of A.C.T.H. had been given on that day to assess adrenocortical function. The increased rate of disappear-

FIG. 1.—Red-cell survival curves for Cases 2, 4, 5, 8, and 9. Case 4 received two transfusions. The arrow indicates the beginning of treatment with ascorbic acid.

ance of the donor cells continued after haemorrhage ceased, and the red-cell survival curve did not flatten until 9-10 days after the beginning of ascorbic acid therapy.

Haemoglobin values were determined in each case *pari passu* with the estimation of volume of packed red cells.

Of the six cases in which there was rapid disappearance of donor cells, four (Cases 4, 6, 7, and 9) showed a fall of haemoglobin simultaneously with the decrease in volume of packed red cells, whilst in Cases 1 and 3 the haemoglobin did not drop below the immediate post-transfusion level. It is noteworthy that in Cases 4 and 9 the fall of haemoglobin and packed cell volume occurred despite a great increase of reticulocytes.

FIG. 2.—As for Fig. 1. Cases 1, 3, 6, and 7.

Of the three cases (Nos. 2, 5, and 8) in which the red-cell survival times were found to be normal, the one which could be followed adequately (Case 2) had haemoglobin above the post-transfusion level. In this patient there was a marked reticulocytosis on the day of transfusion and for several days thereafter. This could be attributed perhaps to rest in bed or possibly to some intake of vitamin C a few days previously of which no history could be obtained. The degree of anaemia in Cases 2 and 5 before transfusion was as severe as that of patients in whom the red-cell survival was very much reduced.

All the patients were Rh-positive. The direct and indirect Coombs tests were negative in every case. All recovered completely and were discharged from hospital feeling well.

Comment

It appears that at least in some cases of scurvy with anaemia there is an abnormally rapid rate of disappearance of transfused red cells.

The phenomenon of excessive rate of disappearance of donor cells may be due to either haemorrhage or haemolysis. In the six cases described above in which transfused red cells disappeared rapidly there was no haemorrhage to account for this. The gums were haemorrhagic, but the loss of blood from this source is negligible, as the tests for occult blood in the stools were almost invariably negative. In Case 4 there was considerable haemorrhage, but the disappearance of donor cells had been excessive prior

to this, and continued to be excessive even after haemorrhage ceased. The patients had intramuscular haematoma, but these did not seem to increase in size after transfusion. This is not a matter on which one can dogmatize, since the haematoma were not measured. The shortened survival time of red cells seemed to be due to haemolysis.

Pigment studies, such as the measurement of stool and urine urobilinogen excretion, were not made in these patients. Bronte Stewart (1950, 1953) studied a similar group of patients with scurvy and anaemia in this hospital who were not transfused. He found that their urobilinogen excretion was greatly increased above normal values. This was related in large degree to the presence of intramuscular haematoma. He was unable to interpret his findings as providing positive evidence of an intravascular haemolytic process, although the occurrence of such haemolysis could not be excluded with certainty.

The course of the anaemia of scurvy patients who are merely put to rest in bed, without any other therapy and while still receiving a vitamin-C-deficient or vitamin-C-free diet, is important in this discussion. Other workers have reported observations on this point. In a few cases there has been spontaneous remission of the anaemia (Ungley, 1938; McMillan and Inglis, 1944; Vilter *et al.*, 1946). In the majority the anaemia has remained stationary (Mettier *et al.*, 1930; Ralli and Sherry, 1941; McMillan and Inglis, 1944; Vilter *et al.*, 1946).

In occasional cases there has been a rapid increase in the degree of anaemia despite increased reticulocytosis (Mettier *et al.*, 1930; Jennings and Glazebrook, 1938; Vilter *et al.*, 1946; Bronte Stewart, 1950; Brown, 1951).

It is not clear why there is this variability of course of the anaemia on rest in bed alone. Pirani (1952) has shown that small but significant amounts of ascorbic acid are present in the adrenal glands and other tissues even in the most advanced states of scurvy. It is possible that rest in bed might promote remission of the anaemia by diminishing the general metabolic demand for vitamin C and thereby making the tissue vitamin-C reserves available for erythropoiesis. Whether or not this will occur might depend on the ratio of the amount of vitamin C available to the amount required.

Such a balance mechanism might account for the extremely rapid disappearance of donor red cells in so many cases in this investigation, because the large transfusion of blood increases the general metabolic demand for the inadequate amount of available tissue vitamin C.

The speed with which donor cells were eliminated and the rapid fall in the patients' haemoglobin appeared to be in excess of the fall in haemoglobin observed by other authors in patients who had not been transfused and who had been kept in bed on a vitamin-C-free diet.

Thus, whilst the results of this investigation support the view that there is a haemolytic factor causing diminished survival time of red cells transfused to scurvy patients, they do not necessarily indicate that a haemolytic process is the cause of the anaemia in untreated cases. Further investigation to elucidate this point is planned.

It is curious that the abnormally rapid rate of red-cell destruction appeared to persist in three cases for some days after vitamin-C therapy was begun. It is possible that the cells were "prepared for destruction" and could not be saved by the treatment. Alternatively, it is possible that the haemolytic mechanism persisted for some days owing to some tissues having a prior claim to the added vitamin C.

Summary and Conclusions

Eight cases of scurvy with anaemia and one without anaemia have been observed whilst at rest in bed on a vitamin-C-free diet. Transfused red-cell survival times were determined in each case and found to be abnormally short in six of the nine patients. In three of these six patients the increased rate of red-cell destruction

persisted for some days after the beginning of vitamin-C administration. In the remaining three of the nine patients the donor red-cell survival times appeared to be normal, but two of these cases could not be studied adequately, and even the one who was adequately followed showed a rapid fall in the number of transfused red cells one week after vitamin-C therapy was started. It is possible that the blood transfusion materially increased metabolic demands for vitamin C, and this factor may have contributed to the rapid destruction of donor cells. With this reservation, the results of this investigation support the view that a haemolytic process is an important factor in the pathogenesis of the anaemia of scurvy.

ADDENDUM.—Since this paper was prepared an additional nine Bantu male patients with scurvy and normoblastic bone marrow have been studied by the same methods. Three of these, who were severely anaemic, were transfused with sedimented red cells from 1 pint of blood. All three patients eliminated the transfused red cells very rapidly. In the remaining six patients 1 pint of blood was first removed; subsequently they were transfused with 1 pint of blood. Red-cell survival was greatly decreased in five of these patients, the sixth patient having a normal red-cell survival time. The sixth patient (and one of the five with diminished red-cell survival) was not anaemic. The other four were anaemic. It appears that the proviso inserted in the main body of the paper that overtransfusion might be playing some part in the abnormal red-cell survival in untreated scurvy is unnecessary. Red-cell survival was abnormal even when a replacement transfusion was substituted for simple transfusion. An increase in the protein content of the diet by the addition of thoroughly stewed meat also did not alter the diminished red-cell survival in the last four patients studied. In the combined series there were thus 14 anaemic patients and 2 non-anaemic patients who were maintained on the vitamin-C-free diet for more than seven days. Of the anaemic cases 13 had greatly diminished red-cell survival. Of the non-anaemic cases, red-cell survival was normal in one and diminished in the other.

My thanks are due to Professors F. Forman and J. F. Brock, in whose departments this work was carried out; to the C.S.I.R. Research Unit directed by Professor J. F. Brock for technical assistance; to numerous house-physicians for help; to the University of Capetown Staff Research Fund for a grant to cover expenses; and to Lederle Laboratories Division of the American Cyanamid Company, New York, for supplies of anti-M serum. This work was done with support from the Lady Tata Memorial Trust.

The Association of Universities of the British Commonwealth has published a useful list of postgraduate fellowships, scholarships, grants, etc., for advanced study and research, tenable at universities in the United Kingdom, together with details of some of the more important awards tenable overseas by British graduates. The list is published by the Association at 5, Gordon Square, London, W.C.1. Academic interchange between the universities of Britain and those of other European countries has been sponsored by the British Council for several years. The Council has now published a pamphlet (*University Interchange between the United Kingdom and other European Countries, 1948-1953*) listing all such interchanges.

CEREBELLAR NECROSIS IN A CASE OF SUBARACHNOID HAEMORRHAGE

BY

A. L. WELLS, M.D., M.R.C.P.I., D.C.P.

From the Institute of Pathology, Queen's University, Belfast

The possible dangers from lumbar puncture to patients with increased intracranial tension are well known. The main one is forcible impaction—"coning"—of the brain-stem and cerebellum into the foramen magnum, following excessive and rapid drainage of cerebrospinal fluid from the lumbar theca. This may or may not be accompanied by uncus herniation through the tentorium cerebelli. These risks are mentioned only briefly in the standard neurological textbooks, but their mechanisms have received some close attention in the literature (Jefferson, 1938; Cairns, 1939).

A less frequently cited complication is the precipitation of cerebral haemorrhage, and Schube and Raskin (1936) mention 14 examples occurring in the literature. Two of these were cases of cerebral aneurysm. Androp (1939) reports a case in which death occurred, following lumbar puncture, from haemorrhage into the spinal cord and brain-stem.

Necrosis of the cerebellar tonsils was present in the following case of subarachnoid haemorrhage due to rupture of a cerebral aneurysm. Lumbar puncture was performed three times in the course of the illness. This necrotic lesion is considered to have resulted from an extreme and possibly prolonged degree of coning of the cerebellum. So far as I am aware, such a lesion has not been described before.

Case History

A 41-year-old housewife was admitted in an unconscious state to a country hospital in Northern Ireland on November 14, 1951. She had complained of headache since November 9, and had collapsed on the 13th. On examination there was pronounced neck stiffness, and a subhyaloid haemorrhage was present below the right optic disk. At lumbar puncture the fluid was blood-stained and under obviously greatly increased pressure. The supernatant fluid was xanthochromic.

The patient's condition improved somewhat until November 17; she was more conscious, but now complained of diplopia, although an external ocular paresis could not be demonstrated. On the 19th lumbar puncture was repeated, and yellow fluid not under increased pressure was obtained. Following this, she complained of headache, and became drowsy. A right lower facial weakness was noticed at this time.

Again there was some improvement, and on November 24 lumbar puncture was performed for the third time. A few drops of clear fluid, not under pressure, were obtained. In a matter of minutes she became shocked and lapsed into semicomatose.

The patient was transferred to the neurosurgical unit at the Royal Victoria Hospital, Belfast, where she arrived at midnight of the same day. She was deeply comatose on admission, with marked neck stiffness, extensor plantar reflexes, and B.P. 150/80 mm. Hg. The pupils were unequal, and fixed in dilatation. Papilloedema was not thought to be present. X-ray examination of the skull failed to reveal any fracture, and the pineal gland was not visible.

Operation was undertaken immediately. In view of the previous right-sided signs, a left temporal burr-hole was made under local analgesia. The dura was found to be

tense, but needling did not produce any fluid, bloody or otherwise. Three burr-holes were then made on the right side, and dark blood clot and old blood were evacuated from both the subdural and the subarachnoid spaces on that side. A pronounced but only transient improvement took place in the patient's condition, and death occurred at 5 p.m. on November 25.

Post-mortem Findings.—Necropsy was performed 17½ hours after death. On opening the skull an extensive subarachnoid haemorrhage became apparent, and it was found to be present chiefly over the base of the brain, more particularly on the right side. Its source was a ruptured aneurysm 1 cm. in diameter on a branch of the right middle cerebral artery, fairly high in the Sylvian fissure. The brain was generally swollen, the right temporal lobe more than the left. On sectioning the brain the subarachnoid haemorrhage was seen to extend for about 3 cm. into the substance of the right temporal lobe from the region of the aneurysm. No other intracerebral haemorrhages were revealed. Gross hernias of the uncus and cerebellum were observed, the latter very marked indeed, so that it was only with difficulty that the cerebellar tonsils and the brain-stem could be delivered from the foramen magnum. The lower 1.5 cm. of the tonsils was swollen, discoloured, and haemorrhagic. Histological sections from these affected areas showed recent haemorrhagic necrosis, in which there was an acute inflammatory cell reaction, together with fibrinoid necrosis of the walls of several small vessels.

Discussion

The clinical diagnosis of subarachnoid haemorrhage, including episodes of unconsciousness, could be satisfactorily, if superficially, confirmed at necropsy on the basis of the findings described above. It is in trying to reconstruct the precise chronological details of these changes that problems arise.

It is probable that a potentially reversible degree of uncomplicated cerebellar coning developed early in the clinical course. However, the age of the necrotic process in the tonsils was only about 24-48 hours. This particular lesion, if precipitated by lumbar puncture, was more likely to be related to the last occasion than to the first two. The intracerebral haemorrhage, too, was of recent occurrence, but its histological details do not permit of such an accurate estimate of its age. It may have been precipitated also by the third lumbar puncture, but equally well may have arisen earlier, either spontaneously or in relation to the previous lumbar punctures. Irrespective of when and how this latter haemorrhagic lesion took place, it seems indisputable that it materially aggravated the degree of cerebellar coning already present. Schaller (1933) and Masserman (1934) pointed out that foraminal herniation is due not so much to a direct "plugging" effect following the withdrawal of cerebrospinal fluid as to oedema of the brain which develops subsequently. An intracerebral haemorrhage could be visualized easily as contributing to this. Clearly, in the present case, at least three distinct factors—subarachnoid haemorrhage, cerebral haemorrhage, and lumbar puncture—interacted in a complex manner to produce the pathological end-result described.

These speculations, academic and inconclusive though they may be, do not invalidate the general warning of the dangers of injudicious lumbar puncture in cases of subarachnoid haemorrhage. It is impossible to escape the conclusion that lumbar puncture in this case contributed at least to the cerebellar coning and necrosis, and possibly further subarachnoid bleeding. It would seem that, once the diagnosis is established by the withdrawal of evenly blood-stained fluid which leaves a xanthochromic supernatant fluid after centrifuging, there are no further indications for lumbar puncture in cases of subarachnoid haemorrhage.

Summary

A case of subarachnoid haemorrhage due to rupture of a cerebral aneurysm is described. Death occurred

after the third lumbar puncture. At necropsy, cerebral haemorrhage, cerebellar coning, and tonsillar necrosis were found. No reports of the last-named lesion can be found.

I am grateful to Professor J. H. Biggart and Dr. J. E. Morison for assistance and criticism. Mr. C. A. Calvert, F.R.C.S., kindly gave me permission to publish this case.

ACUTE DERMATOMYOSITIS

BY

LEWIS CLEIN, M.B., M.R.C.P.

Senior House-Physician, Ashford Hospital, Middlesex;
Late House-Physician, Central Middlesex Hospital

Recent articles (Oppel *et al.*, 1950; Thorn *et al.*, 1950; Suzzman and Rudolph, 1951) have shown the value of cortisone and A.C.T.H. in acute dermatomyositis. A further case of this rare disease responding dramatically to cortisone therapy is described.

Case History

A domestic servant aged 24 was admitted to the Central Middlesex Hospital on May 14, 1952. She had been in good health till three months previously, when her fingers became stiff and swollen at times. A week before admission her left hand felt weak, and the following night a sensation of tightness developed in her throat. She could not swallow properly. When she awoke the following morning (May 10), both hands felt weak. They were not painful. The weakness and stiffness of the finger- and wrist-joints soon involved the elbows and shoulders, and later both her knees and hips-joints and her back. Her legs felt useless and her muscles became increasingly painful and tender to pressure. On the same day a bright red rash started on the dorsal surface of her hands, soon spreading up both arms, and a similar rash involved both legs. On May 12 her eyelids felt swollen and stiff and they were red-rimmed. This condition lasted only a few hours. Throughout this time she felt ill and had lost her appetite completely. She vomited on three occasions. Each movement was an effort, and she ached all over when she attempted to shift herself in bed.

Physical examination showed her to be well nourished but very ill. Her temperature was 104.6° F. (40.3° C.). Her tongue was heavily furred, and her skin was hot and clammy. There was a diffuse confluent erythematous rash on the dorsal aspects of both feet and on the upper arms. In other areas irregular red macules were present. The rash was mainly confined to the limbs, but had a few extensions on the skin of the abdomen and back. She was profoundly weak, being unable to sit up, and only with difficulty could she straighten her arms or bend her knees. All her muscles were tender on palpation and felt firm and full. The superficial reflexes were normal.

On May 15 her temperature was 103° F. (39.4° C.). The rash appeared to be clearing from the forearms and from the dorsal surfaces of her feet. However, she seemed weaker and to have become worse. She was totally unable to move herself and could swallow fluids only, as she had marked dysphagia. She had a troublesome watery diarrhoea and retention of urine developed, which required catheterization. Her general condition was deteriorating so rapidly that it was decided to give cortisone immediately, and 100 mg. was injected intramuscularly at 5.30 p.m. An hour later she could move herself in bed more freely and could bend her

knees. Next morning there was definite improvement. The temperature had fallen to 101.8° F. (38.8° C.). She could raise her arms above her head, sit up without help, and swallow without difficulty. Her muscles felt flabby and hypotonic. The knee-jerks had returned. The rash was fainter. Cortisone, 100 mg. twice daily, was given.

Improvement continued, and within four days the temperature had fallen to 98.6° F. (37° C.), the rash had almost completely faded, and her general condition had improved so greatly that cortisone was discontinued. The following day she had a partial relapse. The muscles became more tender and tense and she had two rigors, the temperature reaching 102° F. (38.9° C.). Cortisone, 25 mg. six-hourly, was recommenced.

On May 21 the rash reappeared on the back of both hands and the front of both arms. It was bright red and confluent. Her limb movements, however, were now quite free and her muscles were not tender. The rash became more extensive for the next two days. On the elbows and knees it was confluent, the flexures were pinky red and the eyes were red-rimmed. It then began to fade once more, and was last seen on May 6, when only small erythematous areas on the left forearm were noted.

On June 3 cortisone was discontinued. A.C.T.H. gel, 40 I.U. twice daily intramuscularly, was begun. For two days after the change there was a recurrence of slight muscle stiffness, and on June 5 the temperature rose to 102.4° F. (39.1° C.). However, the patient became rapidly stabilized on the dosage, and on June 10 she was allowed up.

On June 17 the A.C.T.H. dosage was reduced to 40 mg. once daily, and ten days later it was discontinued altogether, the patient having then had 1,500 mg. of A.C.T.H. and 2,200 mg. of cortisone in 43 days. Her history was now one of gradual but continued improvement. Muscle power increased steadily. At first inclined to shuffle along and to tire easily on walking, she walked normally on discharge. She could write distinctly and effortlessly. On July 8 she was discharged. There were then no abnormalities on physical examination.

The patient returned to her home in Ireland two days after discharge from hospital and has written to me on several occasions since. She has remained well, but complained of some weakness and stiffness of her wrist and finger-joints about six months after her return. As this continued she was admitted in April, 1953, at my request, to St. Laurence's Hospital, Dublin, under care of Dr. H. J. Counihan, who wrote to me that the changes present were like those of rheumatoid arthritis and that, apart from these changes in her fingers, her general condition was satisfactory. She was discharged from hospital again in May, 1953, and has been receiving injections of cortisone. According to the patient, her fingers and wrists have become fully mobile again—so much so that she is returning to London to recommence work shortly.

Most of the significant investigations are summarized in Table I.

TABLE I.—Blood and Urine Investigations in Case of Dermatomyositis

A muscle biopsy was carried out, and Dr. Walter Pagel reported as follows: "Fragments examined are fat tissue with some haemorrhages and peripheral muscle, with some occasional hyalinization, but without any regenerative or inflammatory cellular changes. The nuclei are well stained throughout." It is possible, however, to obtain an indefinite or negative biopsy report on material obtained from one muscle while material from another shows typical changes (W. Pagel, 1952, personal communication). Suzzman and Rudolph's case also lacked a positive biopsy report, but was in every way a typical acute example of the disease.

Not much emphasis has been laid on the quite frequent occurrence of a polymorphonuclear leucocytosis in acute dermatomyositis, but cases besides the present one showing this feature have been described (Table II).

TABLE II.—High Leucocyte Counts Found During Course of Acute Dermatomyositis

	White-cell Count	Polymorphonuclears	Primitive Polymorphs
Keil (1940)	70,000	With polymorphonuclear leucocytosis	
Holmes (1948)	63,600	89%	34%
Oppel et al. (1950)	64,600	60%	
Suzzman and Rudolph (1951)	31,000	81%	5%
Clein (1953)	59,800	55%	40-5%

Summary

A case of acute dermatomyositis in a young woman is described, the diagnosis being made on the classical clinical picture presented, despite the absence of definite histological proof. Prompt remission following the use of cortisone was noted, with partial relapse when it was discontinued too soon.

Emphasis is laid on a high polymorphonuclear leucocyte count during the course of the disease.

Treatment with A.C.T.H. or cortisone is believed to be the method of choice in acute cases.

I should like to thank Dr. R. A. J. Asher for his encouragement and permission to report this case, which was treated under his care; Dr. W. Pagel for carrying out the pathological examination and for advice; Dr. D. A. Brewerton for many helpful suggestions; and Dr. H. J. Counihan for reinvestigating the patient and forwarding his helpful report to me.

The Wellcome Film Unit has produced two new 16 mm films entitled "The Dissection of a Mosquito for Malaria Parasites" and "Pinning Mosquitoes," both in colour with sound. The first is a demonstration by Mr. P. G. Shute of the Medical Research Council's Malaria Reference Laboratory. After showing the phases of the life cycle of the malaria parasite within the mosquito, the film demonstrates how the salivary glands of the insect are pressed out and prepared for examination so that the sporozoites can be identified. The removal of the stomach and the detection of oocysts are then demonstrated. (Running time, ten minutes.) The second film shows how mosquitoes should be pinned, how to stage and label the pinned insects for permanent display and how to pack them for dispatch through the post. It was produced in collaboration with the Department of Entomology at the London School of Hygiene and Tropical Medicine. (Running time, five and a half minutes.)

Medical Memorandum

Familial Incidence of Sialectasis

Cases of recurrent swelling of a salivary gland associated with characteristic x-ray appearances, and due to causes other than calculus, are seen from time to time. Such cases are described in detail in the literature, but there is sparse reference to any familial tendency, so that the occurrence of the condition in three generations of a family, all treated at Southend General Hospital, is of some interest.

REPORT OF CASES

Case 1.—In 1938 Mrs. X, then aged 50, was seen with a left-sided facial swelling which had been present on and off for 24 years. Until recently she had been able to make the swelling disappear by digital pressure, and stated that the disappearance coincided with the escape of fluid into her mouth. However, in the month prior to admission she had not been able to do this.

Sialogram of Case 1, showing a severe degree of sialectasis with gross dilatation of ducts.

Examination revealed a swelling in the region of the left parotid gland. It was lobulated and variable in consistency, the upper portion being firm, the lower portion fluctuant. (From a drawing in the case notes, the swelling appears to have been about the size of the patient's ear.) Radiotherapy brought about complete resolution of the swelling, and there has been

no further recurrence in the succeeding 15 years. A recent sialogram, however, showed a dilatation of the main duct and some of the smaller ducts, as well as terminal cystic dilatations (see illustration).

Case 2.—In 1942 Miss X, then aged 26, a daughter of Mrs. X, was seen with a swelling of the right side of the face, present on this occasion for three weeks. She gave a history of having had swellings of both sides of the face at different times since childhood, and had had treatment elsewhere. The parotid gland on the right side was found to be irregular, and was considered to be cystic. There was a discharge of flocculated material from Stensen's duct on that side, and a swab of this material subsequently grew a non-haemolytic streptococcus. A probe was passed up the duct, and no stone felt. The left parotid was slightly lumpy. A course of deep x-ray therapy was given with very good effect, and there was no recurrence for six years. An ear infection at that time, associated with some lymphadenitis, caused a temporary flare-up. The patient reappeared in April, 1952, with a recurrence of symptoms—intermittent swelling of one or other parotid gland, which at times was painful. A sialogram done at this time showed dilatation of all the ducts, but to a less degree than her mother's.

Case 3.—A son aged 7 of Miss X, who had married and had three children, was seen in October, 1951, with a history of swellings on both sides of the face, starting several months previously. That on the left side had subsided completely, but on the right side only partially, and tended to recur from time to time. The swelling would sometimes occur during a meal, accompanied by pain, and would subside after an hour or two. A sialogram showed the "snow-storm" appearance characteristic of an early stage of sialectasis, where the finest terminal ductules only are involved.

DISCUSSION

The underlying pathology in this condition, known variously as sialectasis, sialangiectasis, or chronic recurrent parotitis, is obscure, but the essential feature is obstruction of the parotid ducts. Diagnosis is dependent in the final instance on sialography, and the reader is referred to the writings of Payne (1931, 1933) and to the well-illustrated article by Rose (1950) for the technique and description of the sialographic types.

Pearson (1935), discussing the possible mechanism of the swelling, considers that obstruction of the ducts plays a prominent part, either by spasm, oedema, mucus plugs, or epithelial debris, or by the presence of an abnormally viscid saliva. He quotes Steinitz (1929) as a believer in the abnormally viscid saliva theory, and indeed most authors are agreed that the character of the saliva differs from the normal in these cases. Normal parotid secretion is watery, with very little mucus, but the saliva in this condition becomes more mucoid in type and may contain flakes and casts, plugs of mucus and cells, and has been compared with frog's spawn.

Meyer (1934) believed the condition to be due to an acid saliva, and found some improvement with alkali treatment. He also thought that allergy might play a part, and described a case of a boy aged 6 years with parotid swellings associated with the passage of rosy saliva, in whom he obtained positive skin reactions to certain foodstuffs. With the removal of these foodstuffs from the diet the swellings subsided. Sialography in this case showed dilatation of the minor ducts; and it is of interest to note that the boy's mother and his grandmother had a similar condition. No other examples suggesting a familial tendency can be traced in the literature, although two of Pearson's cases were brother and sister. These appeared in a whole series which he described, and, beyond mentioning that they were brother and sister, he made no further comment.

Monro (1951) is another who regards allergy as a main aetiological factor. His case showed a high eosinophil count in the blood and also in the parotid secretion, while the actual blockage of the orifices of Stensen's ducts was brought about by plugs of viscid purulent saliva, observed to be rich in eosinophil leucocytes.

It would seem reasonable to correlate the possible allergic nature of the condition, with its occurrence in different generations of a family as reported here and as described by Meyer, on the grounds of an inherited allergic diathesis, though the occurrence of primary congenital structural changes in cases of sialectasis has not been disproved.

I am grateful to Mr. Rodney Maingot, Mr. Donald Barlow, and Mr. Andrew Monro for permission to publish the above cases, and to Mr. Robert Monro for much constructive criticism in preparing this report.

MERVYN SMITH, M.B., F.R.C.S.

Formerly Senior Surgical Registrar, Southend General Hospital.

The Southend-on-Sea Hospital Management Committee has recently accepted a Trust from Mr. Sydney F. Body, for many years associated with hospitals in the town, expressed in favour of the medical staff of the group of hospitals. The Trust, *inter alia*, provides: (a) For an annual lecture to be known as the Sydney Body Lecture to be given by an eminent speaker; (b) the award of a medal, not necessarily annually, for merit or research in any approved medical subject in its widest sense. The first Sydney Body medal is to be awarded to Dr. William Evans for his meritorious work in cardiology. Dr. Evans was, until 1946, a consulting physician at the General Hospital, Southend.

Reviews

TEXTBOOK OF OBSTETRICS

A Textbook of Obstetrics. By Professor Bruce T. Mayes, M.V.O., M.B., B.S., F.R.C.S.Ed., F.R.A.C.S., F.R.C.O.G. (Pp. 1,040; 19 coloured plates, 537 illustrations. Price 100s.) Sydney: Australasian Publishing Co. London: George G. Harrap. 1953.

This is a beautiful book which, once the reader has got used to its price, gives pleasure merely to flick over the pages, to glance here and there at the excellent and numerous drawings and photographs, to pause and read a careful description of a nursing brassière or of some day-to-day procedure such as rectal examination, or to become absorbed in the author's asides of personal experience and observation. Even the areas on the abdomen over which the foetal heart is to be heard with greatest intensity are indicated by dots which are heart shaped. How many authors or teachers point out which particular parts of the hands and arms are likely to escape attention during routine scrubbing up, and which become contaminated during drying with a towel? Similar examples of care and devotion to detail, and of art for art's sake, shown by this outstanding teacher could be quoted from almost every page.

The book not only reflects the ability and character of the author, but also the Australian practice of obstetrics, which Professor Mayes does much to encourage by making special reference to any original work carried out in that country. It provides rather more than students in Britain would be expected to know, but its size is accounted for by its wealth of illustrations and spacious type-setting, rather than by digressions into the realms of the specialist.

The author errs on the side of conservatism and hesitates to abandon completely some of the older methods of treatment, such as vaginal packing for placenta praevia and the tape-and-catheter method for replacing prolapsed cord. It is surprising too not to find any reference to the use of penicillin in the treatment of syphilis, to the giving of ergometrine before the delivery of the placenta, even for third-stage bleeding, or to gas-and-air analgesia. But what do these or similar points matter? There is usually more than one way of doing a thing well, and any omission and faults are more than counterbalanced by a host of highly commendable features. Those who learn and practise under the rather different conditions which obtain in Britain, and who have many cheaper textbooks from which to choose, may regard this one as having a spiritual rather than utilitarian appeal. None, however, could deny that it has appeal. It is fascinating: there is even an account of a case of retained placenta successfully treated by injecting the cord with coconut milk obtained from a near-by palm.

PULMONARY TUBERCULOSIS

Pulmonary Tuberculosis: Pathology, Diagnosis, Management, and Prevention. By Walter Pagel, M.D., F. A. H. Simmonds, M.D., D.P.H., and Norman Macdonald, M.B., M.R.C.P.Ed. Third edition. (Pp. 728; illustrated. £4 4s.) London: Geoffrey Cumberlege (Oxford University Press). 1953.

The third edition of this well-known monograph on pulmonary tuberculosis will be welcomed by everyone interested in the subject. The book is divided into five parts—pathology, diagnosis, prognosis, management, and lastly epidemiology and prevention. The clinician may find the introductory section on pathology tedious and top-heavy, occupying, as it does, more than a quarter of the text. In it the consideration of bronchogenic tuberculosis has been extensively revised, and special attention is directed to the significance of the primary cavity in the young adult.

Physical signs in pulmonary tuberculosis receive scant notice. Indeed, the art of physical examination of the chest,

which takes so long to acquire, is now rapidly dying out as more and more attention is given to the x-ray findings. I was glad to read in the treatment of haemoptysis that the authors "are not impressed with the argument which favours the withholding of morphine during the bleeding phase, on account of the supposed danger arising out of depression of the cough reflex." Having witnessed the disastrous result which may follow the more modern method of sitting the patient up so that he may cough up the blood, I am inclined to agree. The surgical text has been largely rewritten, although there is now no surgeon included in the team of authors. In some ways I feel this is regrettable, for the surgeon should be able to give a better account of his operations, his reasons for selection of cases, and the factors which may lead to failure, than can the physician.

I have frequently tested the previous edition by using it as a book of reference in clinical work, and have seldom failed to find the information required. The book contains over 300 figures and illustrations, which are extremely well reproduced. I have no hesitation in recommending this edition to the profession. It is an admirable work, a credit both to the authors and to the publishers.

G. E. BEAUMONT.

GENERAL PHYSIOLOGY

General Physiology. By Bradley T. Scheer. (Pp. 613; 110 figures. £2 16s.) New York: John Wiley and Sons, Inc. London: Chapman and Hall. 1953.

Professor Scheer has endeavoured to write a book for the "prospective specialist in biology, including medicine." He has borne in mind the limited time available in the curriculum and has attempted the broadest treatment possible in the circumstances. In so doing he has excluded old or outmoded theories with little relation to present-day concepts. The assumption is made that the work of the student is based on practical experimental work and that he is going to collaborate with Professor Scheer in his experimental rather than a merely textbook approach to physiology.

The book is in five parts—physico-chemical foundations, chemical dynamics, energy transformations, development of organisms, and the integration of the organism. The author sets out well and clearly the basic physical chemistry and the electron theory of atomic structure. Throughout the book he interprets phenomena in terms of atomic structure and valency changes. Avoiding the human, or rather treating the human being as a biological type, the author ranges widely over all the manifestations of life. The book is clear, well written, and can be recommended to anyone anxious to interpret and understand biological phenomena in terms of modern scientific concepts.

A. ST.G. HUGGETT.

SYMPOSIUM ON EVOLUTION

Symposia of the Society for Experimental Biology. Number VII: Evolution. (Pp. 448. £2 5s.) London: Cambridge University Press. 1953.

In this symposium there are twenty-three contributions to the general subject of evolution from many different points of view. The organisms discussed range from bacteria to man and from ferns to butterflies, and the light which their studies throw on evolution serves to emphasize the fundamental unity of the organic world.

There is a masterly introduction by J. B. S. Haldane. He first of all defends mathematical genetics against the criticism of Waddington that "very few qualitatively new ideas have emerged from it." He points out that many ideas "have emerged so completely that their origin is forgotten." Others, such as the findings by Penrose and Haldane that some genes which are deleterious to human beings are kept in being only by mutation, have not yet penetrated far, since the view is still widely held that the human race could be permanently freed from such genes by negative eugenics.

Pringle opens with a discussion of the origin of life; Haldane stresses the fact that recent work on bacteria and viruses indicates that a simple organism "can incorporate and reproduce indefinitely constituents of another by processes which cannot be called sexual." It is possible that two or more kinds of life began independently and then in some way came together. Medawar discusses the remarkable diversity of the antigens found in different members of one mammalian species and the ways in which the dangerous effects on pregnancy have been partly overcome. He makes the important generalization that "endocrine evolution is not an evolution of the hormones but an evolution of the uses to which they are put."

Hinshelwood makes a valuable survey of his recent work on bacterial adaptation, and Demerec contributes a paper on the reaction of genes of *Escherichia coli* to certain mutagenic agents, such as manganous chloride and ultra-violet rays. Other notable papers are on the genetical structure of populations (Mather), stochastic processes and the growth of bacterial colonies (Kendall), and epigenetics and evolution (Waddington).

The juxtaposition of factual information from so many points of view in a rapidly growing field renders the volume invaluable to the general biologist interested in evolutionary mechanisms. The British Council and the Rockefeller Foundation are to be thanked for financial aid towards the cost of publication.

S. C. HARLAND.

BIOASSAY OF HORMONES

Ciba Foundation Colloquia on Endocrinology. Volume V: Bioassay of Anterior Pituitary and Adrenocortical Hormones. Edited by G. E. W. Wolstenholme, O.B.E., M.A., M.B., Ch.B., assisted by Margaret P. Cameron, M.A., A.B.L.S. (Pp. 228; 53 illustrations. 25s.) London: J. and A. Churchill. 1953.

This is one of twelve informal colloquia that have been arranged by the Ciba Foundation and subsequently published under the editorship of Dr. G. E. W. Wolstenholme, with the assistance of Miss Margaret Cameron; recordings of the discussions were made by Miss N. Bland. The usual high standard to be expected from Ciba Foundation publications is here conspicuous throughout, and this has been found to be by no means incompatible with the "house party" atmosphere which the preface says has been attempted at all such conferences. The contributors come from widely separated groups, but they are studying common problems of assay of the pituitary and adrenal hormones. The results are of interest to all research workers and to research-minded clinicians.

There is an initial discussion on the requirements for clinically useful endocrine bioassays by Albert Segaloff, of New Orleans. The section on thyrotrophic hormone considers bioassay in the hypophysectomized rat using P^{32} ; assay by iodine¹³¹ (by Gilliland and Russell Fraser of the British Postgraduate Medical School); and chick assays using P^{32} by A. C. Crooke and Joyce Matthews, of Birmingham University. The section on gonadotrophins is illuminated by an excellent record of original work by W. R. Butt and A. C. Crooke on chromatography of urinary gonadotrophins. The clinician will be interested to find a chapter on their clinical use and clinical applications. E. B. Astwood, of Boston, discusses biological tests for luteotrophin as a basis for assay. Discussions on prolactin, including conventional methods of assay, and the assay of urinary prolactin are included in this section.

In section four, on the bioassay of growth hormone, C. H. Li considers the well-established procedures such as weight in normal plateaued rats, hypophysectomized rats, and dwarf mice, increase in tail length of hypophysectomized rats, and increase in width of epiphyseal cartilage of the tibia of such rats. Also discussed is the use of radioactive tracers to investigate increase in liver weight, change in nitrogen constituents of the blood, change in serum phosphorus and phos-

phatase, change in nitrogen and phosphorus balance, and increase in protein synthesis. E. Reid, of Cambridge, considers the assay of growth hormone for diabetogenic activity, a field in which the Cambridge Biochemical School have been pioneers.

Perhaps the most interesting sections are five and six, on adrenocorticotrophic hormone and adrenocortical hormones. In particular I should like to mention the important contribution by C. H. Gray and D. M. V. Parrott on the measurement of A.C.T.H. activity in plasma by the depletion of ascorbic acid in the adrenal cortex of the hypophysectomized rat. Ingle reviews the recent work done in his laboratory on the effect of adrenalectomy and adrenal steroids on muscle work. Marthe Vogt discusses observations on comparative biological assays of adrenal cortical steroids. J. A. Nissim, of Guy's, considers the assay of glucocorticoids, with liver glycogen estimations in mice and rats. Bush writes a most important section on paper chromatography of steroids, in which he has played such a leading part, and the application of this method to assay problems. J. H. Gaddum, of Edinburgh, brings his wisdom to some invaluable closing remarks.

S. L. SIMPSON.

DERMATOLOGY IN GENERAL PRACTICE

Dermatology in General Practice. By Jacob Hyams Swartz, M.D. Foreword by Professor C. Guy Lane, M.D. (Pp. 581; 253 figures. £4 4s.) London: Baillière, Tindall and Cox. 1953.

It is not possible in the compass of five or six hundred pages to give anything like a complete account of all the diseases of the skin, and the problem of pruning is one to which an author of a textbook for non-dermatologists must find his own solution. Dr. Swartz, in this book, has aimed at making some mention, however brief, of all the dermatoses; he has left very few disorders unnamed, though his descriptions of some of the rare ones are perforce often little more than can be found in a medical dictionary.

After a very short introductory section on the anatomy and physiology of the skin and a longer section on the care of the skin, the main part of the book consists in the description of individual disease pictures classified according to regions. This part of the book follows the orthodox lines which have been familiar in textbooks for several decades, and there is little that is new on diagnosis and aetiology. It is perhaps desirable to be dogmatic in a work of this kind, but many of Dr. Swartz's statements are so highly controversial that the dermatologist can hardly leave them unchallenged. For example, acne varioliformis "is probably a tuberculide" requiring, one may observe, the treatment of "hygiene, large dosages of vitamin A, and a high protein diet" (p. 97).

The author's account of treatment is, on the whole, well done and it records plentifully his personal preferences, but there is no mention of isonicotinic acid hydrazide for tuberculosis, nor of mepacrine for lupus erythematosus. This is not because the book is out of date, for cortisone, A.C.T.H., and the antibiotics are given very adequate consideration. The book includes a long section on mycotic infections, of which the author has made a special study, and a chapter on syphilis. Treatment by irradiation is briefly mentioned, the antibiotics are reviewed, and A.C.T.H. briefly considered. Finally, there is a practical formulary of over 30 local applications written in a confusing combination of English and doubtful Latin. It is noticeable that the author has but little use for the modern emulsifying bases.

Notwithstanding these criticisms, this should be a useful book. It includes a good deal of information not usually presented to the general practitioner, it is clearly written and profusely illustrated with photographs which are on the whole good. It is doubtful, however, whether there is anything about this book which presents a serious challenge to others of its kind already well known in Britain.

MOUSE CARCINOGEN IN TOBACCO TAR

The experimental production of skin carcinoma in mice by painting them with cigarette tar has been performed in the U.S.A. by Drs. E. L. Wynder, E. A. Graham, and A. B. Croninger. The results are to be published soon.¹ Some indication of the size of the lung cancer problem in England and Wales now may be seen briefly by comparing some death rates. In 1900 the crude annual death rate attributed to lung cancer was 8 per million persons. Fifty years later it had increased to 278 per million. In 1950 the disease caused 12,241 deaths, a total which comprised 24% of all cancer deaths in men at all ages and 40% in men of ages 45-54. The increase, which has continued since and seems likely to do so in the future, is only in very small part due to the increasing proportion of the population who live to the ages of higher cancer susceptibility. If part is due to better diagnosis, not the whole increase is spurious, and in Doll's moderate opinion² the real increase may well be more than half. As Doll points out further, the importance of this conclusion is that it holds out hope for prevention, for an increase of such extent and rapidity is almost certainly due to a potent environmental factor. The earlier conclusions of Doll and Hill in Britain,³ and of Wynder and Graham in the United States,⁴ did not at first obtain universal endorsement, partly because of a proper scientific caution, and partly for human reasons of a different kind, but the intervening three years have seen a growing acceptance, first, that the reported increase in incidence is real, and secondly that its major cause is smoking. Doll was the first to acknowledge that no proof is ever absolute, and that only by further experiment can confidence be increased until finally the truth is unquestioned.

The study by Wynder and his colleagues of the production of carcinoma with cigarette tar is an important contribution. They conclude from a survey of the literature that all previous attempts to induce cancer in mice with tobacco products were successful in the production of only seven epidermoid cancers

of the skin—a poor result, perhaps due in part to inadequate methods and too short a period of observation. In their own investigation a tar condensate, obtained by smoking a popular brand of cigarette in an apparatus designed to simulate human smoking methods, was applied in relatively large quantities, and over a long period, to the skin of mice (of the CAF₁ line). Of 81 mice so treated, 36 developed epidermoid cancer of the skin after a mean time of 71 weeks. This is a long latent period amounting to about half the life span of the animals used, and the rather moderate activity of the tar is shown by a parallel experiment in which 25 mice treated in the same manner with a solution of methylcholanthrene all developed carcinomata within 18 weeks. No tumours were observed in a control series treated with the solvent (acetone) alone.

What is the significance to be attached to these experiments? The fact that carcinogenicity had not hitherto been very clearly demonstrated as a property of cigarette tar did not invalidate the evidence already existing to incriminate tobacco. Equally, on the other hand, it cannot be claimed that the new results—suggestive as they are—afford any formal proof that the agent in cigarette tar which is capable of inducing cancer in the skin of mice is necessarily responsible for the increased incidence of bronchogenic cancer in man. Their true significance would seem to be rather that they represent an effort, made in accordance with the general acceptance of the nature of the risk and its almost certain cause, to identify the latter with precision. If the actual carcinogenic or possibly co-carcinogenic agents in tobacco remain to be identified it may be noted that no spectroscopical evidence of the presence of 3:4-benzpyrene was found by Wynder's associates, in agreement with a similar observation by Waller.⁵ Subject to the provisions made above, the new results might also be thought to increase the unlikelyhood that arsenic is the carcinogenic agent, since this is incapable of inducing cancer on application to the skin of animals.

The present developments must not be allowed to obscure the wisdom of Doll's view, that it may be unnecessary to await the isolation and identification of a specific carcinogenic agent before doing something to halt the rapid increase in mortality and to turn it into an even more dramatic decline. Few now doubt that abolition of the cigarette, or abstinence from its use, would be the most beneficent single step in cancer prevention available to us to-day. Short of this ideal, research will assuredly continue, and indeed should be promoted with much increased vigour, to identify the cause and allow prevention by its removal. Finally, the question arises whether the

combined weight of evidence is now so compelling as to convince the tobacco industry itself that there may be some connexion between tobacco and cancer of the lung.

RADIOLOGY AND LUMBAR DISKS

It is now about twenty years since it became recognized¹ that sciatica is nearly always caused by a protrusion of either the fourth or fifth lumbar intervertebral disk pressing on the fifth lumbar or first sacral nerve root. Though this observation may seem simple to-day, an enormous "disk" literature has grown up. This alone suggests that all the problems are not yet solved, and indeed opinions still differ widely on diagnosis, treatment, and prognosis.

While it is generally conceded that radiology is important in diagnosis, many authorities disagree sharply on how important, and particularly do they disagree about contrast radiography. The necessity for taking plain radiographs of the lumbo-sacral spine is universally agreed. But it must be emphasized that this investigation is chiefly of use in narrowing down the differential diagnosis, and in particular excluding a more serious lesion such as a metastasis or tuberculous infection. Even so, such gross pathological lesions as these, though usually easily recognized at operation or necropsy, may not appear on the best radiographs—including tomographs.² Radiology is a rather insensitive test, and often bony destruction is considerable before it is visible. Serial radiography is therefore necessary in a case of sciatica that does not respond to conservative therapy.

While plain radiographs convey limited yet indispensable information, too much must not be read into them. Some doctors who see scores of disk lesions every year become very astute in their clinical diagnosis and probably achieve an accuracy of over 90%. Having made a confident and usually correct clinical diagnosis, they are tempted to demonstrate the site of the offending disk on the radiograph. The only occasion on which a protruded disk can be seen on a radiograph is when it is calcified. Unfortunately this type of degeneration is almost unknown in low lumbar disks, though curiously common in the relatively very rare protruded thoracic disks.³

There are certainly some radiological signs suggestive of disk protrusion, but they may be dangerous if they lull the physician or surgeon into even greater

confidence in his already firm clinical diagnosis. Here two points are relevant. The first is that the volume of a lumbar disk is 10 ml. or more. If less than one-tenth of it protrudes, it is sufficient to press hard on a nerve root and cause intense sciatica. Such a small diminution in total disk volume will be quite undetectable on a radiograph. The second point is that disks desiccate. This is common in old age. When desiccation occurs, backward protrusion by no means necessarily follows, but radiographically the disk space becomes much narrowed and secondary osteoarthritic changes usually appear. Thus a normal disk space does not exclude the diagnosis of a protruded disk, and a grossly narrowed space is not proof of protrusion.

Four out of five cases get better when treated conservatively, and an even higher proportion of cases of lumbago are restored to health,⁴ but for the residue of cases surgery is usually the treatment of choice. The fact that it is not always—even though very often—as dramatically successful as drawing a tooth has been largely responsible for the mass of literature on the disorder. And, just as occasionally the cause of the pain is not a tooth at all, so with disks. Myelography helps in diagnosis, but it has the more important function of revealing a tumour—usually benign—which may lie several inches higher up the spinal canal and be quite invisible at low lumbar laminectomy.

In many centres in Britain there is a prejudice against myelography, especially among orthopaedic surgeons. Their distaste for all contrast media, gas or liquid, is great. The opinion is sometimes expressed that the method is not without danger and that serious sequelae, especially arachnoiditis, are common. Again, no contrast substance, even with the best technique and interpretation, reveals all protruded disks. And critics also contend that the procedure is not only harmful but redundant, since clinical diagnosis is so accurate. On the other hand, at most neurological centres in this country myelography is held to be an essential investigation. At the Lahey Clinic 4.3% of 1,104 cases operated upon for supposed disk lesions were tumours of the cauda equina.⁵ Love⁶ reported that eight spinal tumours, whose signs simulated those of disk lesions, were removed at the Mayo Clinic during the same period as 100 disk lesions were operated upon. And Barr, co-author of the paper drawing the attention of the world to the true cause of most cases of sciatica, whose opinion cannot lightly be dismissed, has said that there is only one way by which catastrophes can be avoided—routine myelography.⁷

SELF-HELP AND PUBLIC HEALTH

We get used to hearing year by year that the health of the nation improves, so it is timely of Sir John Charles to remind us in his latest report¹ that "it is not sufficient that the man in the street should rest in a quiet acceptance of all the benefits of a steadily improving environment as if they were part of nature's boundless provision." Nature's provision is far from boundless, as is apparent to the man in the fields if not to the man in the street, and even the State's provision is the more effectual for co-operation from the people using it. But in spite of disastrous flood and fog in 1952 the citizens of England and Wales remained remarkably healthy—if the inference may be drawn from figures for notified diseases and registered deaths. Outstanding among the diminishing causes of death is tuberculosis: the death rate from all forms was 240 per million, a conspicuous fall from the average figure of 535 per million for 1945-9. By contrast 1952 was notable for deaths from cancer of the lung (14,218) much exceeding those from all forms of tuberculosis (10,585). This reversal owed more to the fall in tuberculosis deaths than to the rise in lung-cancer deaths, but the latter seem to be increasing uninterruptedly even so. We discuss elsewhere (p. 1362) some new American work on the production of experimental cancers in mice by tobacco-smoke extract, and it seems that those who are yet unconvinced of any connexion between smoking and cancer of the lung are being left increasingly little space to manoeuvre in. Another severe disease on the increase is leukaemia, with 2,043 deaths. The death rate from it has been rising for many years, and it is hardly likely that improving diagnosis can be responsible, at least for all the increase. Mortality was 74% higher than in 1938, and the comparative mortality index in the five years 1948-52 (with 1938 mortality taken as 1.00) rose as follows: 1.32, 1.50, 1.58, 1.66, and 1.74.

The figures for admissions to mental hospitals continued to increase, there being 62,258 in 1952 as compared with 59,288 in 1951 and 27,979 in 1939. But this does not necessarily imply that there are more mentally disordered people; the likelier explanation is that people nowadays more readily seek or agree to admission than formerly. Again, the number of mental defectives under guardianship and on the books of hospitals continued to rise, being 62,704 in 1952, about 1,000 more than in the previous year. But the increase is probably due to the growing recognition of mental defect as a clinical condition and social problem, and also to increasing difficulty in assimilating these people into society as industrialization spreads.

Referring to tasks that parents should be undertaking on behalf of their children, Sir John Charles finds that they are failing in their duties in some respects. "Infant vaccinations against smallpox are 70% less than they should be, and for both diphtheria and smallpox the proportion who have their immunity maintained by reinoculation or revaccination is deplorably low." Further, "the same sorry tale of parental carelessness is to be recounted in relation to dental care,"

¹ Report of the Ministry of Health for the Year Ended December 31, 1952, Part II. 1953. H.M.S.O. 6s. 6d.

and "there is something very far wrong when more children under 15 years of age die from accidents in their homes than are killed on our congested thoroughfares." The uptake of Government-provided orange juice and cod-liver oil for infants is "less than half of what it should be." There are these and other signs in this admirable report that a great many people would be better employed making some slight efforts on behalf of themselves and their children instead of crowding consulting-rooms and hospitals to repair the health they have allowed to decay from neglect.

THE MANAGEMENT OF ULCERATIVE COLITIS

None of the theories put forward to explain the aetiology of ulcerative colitis has yet led to a logical and generally effective regime of treatment. The management must therefore be based on a sound application of general principles; and in assessing the effect of the various measures adopted there is no disease in which it is more important to bear in mind the background and natural course of the malady. Wittkower¹ found that in most of these patients psychological abnormalities were present before the colitis began, and it is now widely recognized that they are people characterized by emotional immaturity, often having a pathological parental attachment and perhaps being extremely meticulous and fussy. Successful results from psychotherapy have been claimed by Daniels.² And, although the more generally held view is that only transient benefit, if any, can be expected from such treatment, it is nevertheless true that the medical care cannot be planned to best advantage without an understanding of the psychological situation and of the various emotional crises which often initiate relapses. No one is as well placed as the family doctor to evaluate these environmental factors; and it is on a correct appraisal of them, and by taking into account the possibilities of satisfactory adjustment of emotional problems, that the best estimate of the prognosis of an early case may perhaps be based.

In planning the details of treatment it is well to remember certain general considerations. At the best the illness is likely to last for many months, and acceptance of this fact by patient and doctor is the first step towards successful management. On the other hand, although remission followed by relapse is the usual sequence, apparently complete and lasting recovery is not unknown, and for this reason alone the patient should not be subjected too early to mutilating surgery. This is not to say that operation should be reserved for the moribund; selection at the right time of the right patient for ileostomy and perhaps colectomy requires the co-operation of physician and surgeon and taxes the judgment of both. Elsewhere in this issue Mr. S. O. Aylett recommends, for suitable cases, an operation which preserves rectal function. It is now fashionable to advise rather earlier surgery, which in our present ignorance is probably correct; but many will echo the words of Marino,³ who said that the more ileostomies he per-

¹ British Medical Journal, 1938, 2, 1356.

² Med. clin. N. Amer., 1944, 28, 593.

³ J. Amer. med. Ass., 1947, 133, 1001.

⁴ Hoffbauer, F. W., et al. Ann. Intern. Med., 1953, 39, 267.

⁵ Bargen, J. A., ibid., 1953, 39, 285.

formed the more he wished there were some other method of caring for these patients. In the medical treatment there is general agreement only about the necessity for complete rest, which should be continued as long as there is fever or more than two or three stools in 24 hours. Almost equally important, in view of the drain of protein from the bowel and the common occurrence in the liver of fatty change or even cirrhosis,⁴ is a high-protein diet. An adequate intake can nearly always be assured by the addition of concentrated supplements such as soluble casein. At least in the active phases fruit and vegetables must be largely excluded from the diet, and for this reason vitamin C and the B complex must be given in full doses. Anaemia is always present, and, though it may respond to the administration of iron by mouth, transfusion often seems to be of general benefit in addition to raising the haemoglobin level and should not be reserved only for the severely anaemic. During acute exacerbations courses of penicillin by injection, should be tried, though they rarely cause dramatic improvement. Again A.C.T.H. or cortisone have occasionally appeared to initiate remission in a fulminating case, but usually have little or no effect. For relief of painful colon spasm associated with wind there is probably nothing better than a tablespoonful of charcoal and 5 minims (0.3 ml.) of a tincture of belladonna three times a day, the dose of the latter being gradually increased to the limit of tolerance. The present tendency is to regard colon wash-outs as of very limited value. In conclusion it may be reaffirmed that most success in the management of this distressing disease attends those who are best able to bring continued hope, encouragement, and support to the rather inadequate and dependent sufferer.

NIGHT WORK AND SHIFT CHANGES

The effects that night work and shift changes have on output and absence from work were the subject of a recent investigation carried out by the Medical Research Council Group for Research in Industrial Psychology.¹ For the most part the results confirm the work already done in this field, but they may come as something of a surprise to readers not already acquainted with it. The most striking fact is that there is very little difference in the rates of output on day and night shifts. In two of the ten factories with which the inquiry was concerned, the output from the night shifts was in fact very slightly the higher. This may be explained away, but the fact remains that the comparative ratio in output between day and night shifts was shown to be only of the order of 101:99.

The evidence shows, however, that there are features of night work which need to be more carefully borne in mind than they are at present. The article contains an impressive table showing that the percentage of absence uniformly falls week by week while day work is continued, and uniformly rises week by week when a shift changes over to night work. Moreover, the opinions expressed by the members of a sample of workers who were interviewed showed, as might have been

expected, that night work was highly unpopular. Digestive troubles and sleeplessness were much complained of, and it is noteworthy that, out of the 150 men in the sample, no fewer than 65 took patent medicines every day or several times a week. The types taken suggest, it is said, that they were relied on "to counteract disorders of the stomach."

The authors sum up by saying that "there is not the least doubt that night work is unpopular and in the long run is detrimental to health, efficiency, and the enjoyment of life. In every group of workers, some break down in health after a few weeks, months, or years of night work. . . . Almost all workers are adversely affected in some degree." This may be thought to be a somewhat strong conclusion in view of the evidence on which it is based in this paper. Adverse comparisons between day and night work in regard to output and lost time have been difficult to make since the Health of Munition Workers Committee presented its report in 1918. Moreover, so far as shift working in general goes, the Ministry of Labour has just reminded us that Departmental Committees reported in 1934 and 1945 that they were unable "to discover any grounds for supposing that [it] increases sickness rates or the incidence of digestive or nervous disorders," though the familiar effects on family and social life were again reported on, especially in 1945. But it seems to be obvious that the serious disturbance in the pattern of daily life which shift work brings with it must have its physical effects, provided it is done over a long enough period. It is therefore to be hoped that this research will be continued by following up a sample of cases over a decade or so.

CHELATION

Chelating agents, like exchange resins, are yet another of the tools which the industrial chemist has passed on to the physician. The word chelation ($\chi\eta\eta$, a claw) indicates the ability of certain chemicals to donate atoms—usually oxygen, nitrogen, or sulphur—which will form co-ordinate bonds with polyvalent metallic ions: the result is a stable, water-soluble, non-ionic metallic "ring" in which the metal is firmly held.¹ It is important to note that the resulting compound is not precipitated. The avidity of a chelating agent for a particular metal varies. For example, lead is more strongly bound than calcium and will displace the latter from a chelated complex. The best known of these agents in practical use is ethylenediamine tetracetic acid (E.D.T.A.) (marketed commercially as "versene," "sequestrene," "trilon," "nullapon," etc.), though citric, malic, lactic, and tartaric acids are all natural chelating agents, and both chlorophyll and haemoglobin are examples of chelated complexes.

The possible uses of chelation are very numerous. It is already used in industrial processes as varied as the softening of water (by removing calcium), the removal of trace metals from dyes to improve colour, the

preservation of food, the improvement of soils (humus contains chelating agents which bind iron and calcium), and the removal of traces of radioactive substances. As for the uses of chelation in medicine, lead poisoning is an obvious indication; and a recent conference² was called at the Massachusetts General Hospital to discuss the possibility of using E.D.T.A. in this condition. Animal studies have confirmed its ability to remove such ions as calcium, lead, yttrium, and plutonium, and if given in the acid form it rapidly causes fatal hypocalcaemic tetany. In therapy, therefore, the calcium salt should be used; this appears to be non-toxic and is not broken down, 95% being recoverable from the urine. The suggested daily dose is 1 g. per 30 lb. (14 kg.) body weight in a 3% solution intravenously for five days, followed by a rest period. Preliminary reports by Foreman³ and Rubin⁴ and their collaborators suggest that calcium E.D.T.A. may be effective during acute exacerbations of lead poisoning in man. Moreover, this form of treatment has an added advantage in that no free ions are liberated in the mobilization of lead. How much of the metal can be removed from the bones has yet to be determined, but animal experiments are encouraging.²

Chelation may have a use in arsenic and mercury poisoning. Foreman and his colleagues gave calcium E.D.T.A. to a patient with berylliosis, though with little obvious effect. E.D.T.A. has also been instilled into the bladder and renal tract to dissolve stones with some success,⁵ but it tends to cause severe mucosal irritation unless used in a very dilute solution. Proeschner⁷ has shown that very small amounts of E.D.T.A. will preserve blood for long periods without danger, and it has obvious uses as an anticoagulant. There are many other possible applications, both therapeutic and experimental, for these versatile substances.

LOUSE INFESTATION

The extent of infestation in the towns of England and Wales had scarcely been realized until the wartime evacuation scheme brought many householders in the reception areas into unaccustomed contact with the problem. Mellanby carried out an investigation into the prevalence of the head louse in England on behalf of the Board of Education,¹ and later published results of a four-year survey ending in September, 1943.² He found, generally speaking, that there was a considerable variation in the incidence of head lice in different age groups, in the two sexes, and in different areas. As the result of intense activity by various officers of the health services during the next few years, infestation by lice and nits seems to have been reduced. "Nevertheless," wrote Mellanby, "in our industrial cities nearly 50% of pre-school age children of both sexes and of school girls are verminous. Older girls and women are the only section of the population which has become lousier during the war."² The Chief Medical Officer of the Ministry of Education, discussing³ this problem, mentioned that Lieutenant-Colonel Madock carried out an investigation in 1947 similar to Mellanby's of 1942-3. It is a grave reflection on the cleanliness of our urban

population that 18.2% of patients admitted to a group of hospitals (the same as reviewed by Mellanby earlier) were in 1947 reported by competent nursing staff to be infested. At the end of this account the infestation of problem families is specially described and the use of a family service unit commended. But surely this is carrying the Welfare State too far; while some encouragement is desirable, at least the parents might be expected to keep the family reasonably clean. Ewan⁴ has stated that 11.1% of 51,349 children examined at routine medical inspections had unclean heads, and he also quoted similar figures from the statistics of other Scottish education authorities. The rates of infestation in the different wards of the city or in the different categories of schools in Glasgow are not given, but in other areas there is evidence to show from the results of routine examinations for cleanliness, particularly those carried out on the reopening of schools after the Christmas holiday, that in certain schools up to 45% of the girls in attendance may be shown to be lousy or to have nits.

Recent reports have emphasized the family as the unit of infestation. Ewan, for example, has asked that the medical officer of health for the city should be directed to apply for the reintroduction of legislation similar to the Scabies (Scotland) Order, 1941. This wartime regulation had its counterpart in England, and gave the medical officer of health power to inspect premises, to examine persons accommodated in these premises, and to compel verminous persons irrespective of age to submit themselves for cleansing. These orders resulted in the virtual disappearance of scabies; simultaneously the number of persons found to be verminous was reduced considerably.

Infestation is particularly noticeable in the second-generation immigrants in various urban areas, and the real administrative difficulty in controlling it now lies not in the cleansing of schoolchildren, which is easily carried out under the provisions of the Education Act, 1944, but in the fact that the mothers and sisters of the affected children form reservoirs of infestation. Attempts to eliminate it are frustrated by lack of powers to treat relatives in the homes. There is no power under which medical officers of health either in England and Wales or in Scotland can force persons suspected of being lousy to submit to examination, though the Public Health Act of 1936 (Section 85) authorizes him to enter premises and to deal with articles as well as the fabric of the premises if these inanimate objects are affected by vermin. There is a strong case for giving the medical officer of health powers similar to those in the Scabies Order, which ceased to be operative in 1947.

Persuasion has been tried and found wanting; home visits, either by school nurses or by the sanitary staff of the local authorities, have not been adequate to eliminate the hard core of infestation. It is surely time that the freedom of the louse to breed in a small but troublesome number of dwellings in this country was finally curtailed.

CLINICAL PATHOLOGY IN GENERAL PRACTICE

GLYCOSURIA AND HYPERGLYCAEMIA

BY

CHARLES H. GRAY, M.D., D.Sc., M.R.C.P., F.R.I.C.

Professor of Chemical Pathology, University of London; Chemical Pathologist, King's College Hospital, London, S.E.5

Glycosuria and hyperglycaemia are closely related because, except in those patients with a lowered renal threshold, glycosuria is always an indication that the blood sugar is higher than normal. While recent advances in our knowledge of renal physiology have invalidated the concept of a renal threshold as an unvarying and characteristic concentration of glucose in the blood—above which glycosuria occurs, and below which it does not—there is no doubt that from the clinical point of view this concept is justified and of real value. In most people the renal threshold is about 180 mg. per 100 ml., a value which the blood sugar normally never exceeds; glycosuria does not therefore occur. Hyperglycaemia with a blood-sugar concentration exceeding the normal threshold, as occurs in diabetes and in a few other pathological conditions (see below) leads to the appearance of sugar in the urine. In patients with a normal renal threshold glycosuria is absent when the blood sugar is below 180 mg. per 100 ml., a trace is detectable when the sugar concentration is around 200 mg. per 100 ml., while a complete reduction of the usual clinical testing reagents is given when the blood sugar is 300 mg. or more per 100 ml.

Glycosuria can, however, also occur without a raised blood sugar in renal glycosuria, in which condition the renal threshold is lower than normal, being sometimes as low as 80 mg. per 100 ml. The threshold is sometimes raised, especially in diabetes; hyperglycaemia with blood-sugar concentrations above the normal threshold can then occur without glycosuria.

Tests for Reducing Substances in Urine

The presence of a reducing substance in the urine may be investigated by Benedict's test* or by the recently developed "clintest" tablet test. Fehling's test is less sensitive and less specific and has little to recommend it. Benedict's test is less easy to perform properly than the clintest, which has many advantages in general practice because no external source of heat is required. The very rapid and convenient screening test using clintest with undiluted urine is especially valuable, but a positive result should always be confirmed by the standard technique recommended by the manufacturers.

Significance of Reducing Substances in the Urine

The urgency with which the general practitioner must act upon finding that the urine of his patient reduces Benedict's solution or the clintest tablet must depend entirely upon the clinical condition. Most patients with diabetes mellitus give a clearly defined history of the disease, and if a positive test for reducing substances in the urine is found in a patient with loss of weight, pruritus, thirst, and polyuria there is no point in arranging elaborate investigations to decide whether or not the reducing substance is glucose. The problem of the moment is whether the patient has diabetes, and, if so, whether the condition is an urgent one requiring immediate treatment with insulin. This will depend on the presence or absence of severe ketosis.

Reducing Substances and Ketone Bodies in the Urine.—As soon as a urine is found to contain a reducing substance,

Rothera's test* for acetone and aceto-acetic acid should be performed. If it is strongly positive it should be followed by Gerhard's ferric chloride test* for aceto-acetic acid. The Rothera reaction is much more sensitive than the ferric chloride reaction, and when the latter is positive the ketosis is more severe. Much care, however, must be taken in the interpretation of the ferric chloride test; patients who have been unwell have often taken salicylates or aspirin previously, and the distinction between the colour reaction given by salicylates in the urine and that given by aceto-acetic acid is by no means as clear-cut as many books suggest. The classical means of distinguishing the ferric chloride reaction due to salicylates from that due to aceto-acetic acid is that the latter reaction becomes negative after boiling the urine, but this is hardly ever necessary, because the patient himself will be able to say whether he has had aspirin or salicylates. A positive ferric chloride reaction due to aceto-acetic acid will be accompanied by an extremely intense Rothera reaction which will be negative if the reaction is due to salicylates.

Some difficulty might be expected if there is severe ketosis and the patient has had either of these drugs, but the presence of heavy glycosuria and ketone bodies in the urine, together with such evidence of pre-coma as recent vomiting, shortness of breath, abdominal pain, giddiness, and acetone in the breath, must be taken as an indication for immediate treatment with glucose and insulin. It may indeed be dangerous to wait for a blood-sugar determination unless facilities for this investigation are readily available. It is the opinion of those with special experience that patients in diabetic coma or pre-coma are best treated in centres with facilities for the control of this condition. All that is required, therefore, is that the patient should be given a dose of 40 units of insulin, together, if possible, with 50 g. of glucose by mouth, and then sent to hospital. In the absence of clinical signs of pre-coma a blood-sugar determination may also be dispensed with in reaching a diagnosis of diabetes if the history is typical and reducing substances and ketone bodies are present in the urine.

Reducing Substances Without Ketone Bodies in the Urine.—Matters may be very different when there are no ketone bodies in the urine. Even then the case with a classical clinical history of diabetes requires little in the way of further investigation, although it is wise never to treat a patient as a diabetic without at least one definitely abnormal blood sugar. For this reason it is unwise to institute treatment in those cases without ketosis before confirming the diagnosis. A blood sugar should be done one and a half to two hours after a full carbohydrate meal, when a figure greater than 180 mg. per 100 ml. is certainly indicative of true diabetes. However, as is shown below, the value of the single blood-sugar determination, although excellent when the blood sugar is definitely raised, is of less value when the concentration is only slightly above the upper limit of normal or when the relationship between the collection of the blood and the time and nature of the previous meal is uncertain.

On the other hand, if on clinical grounds the practitioner thinks that the diagnosis of diabetes mellitus is unlikely, a single determination of the blood sugar may help, but it is usually essential to carry out a glucose-tolerance test. It is always worth while looking for glycosuria in two samples—the early morning sample passed before breakfast and the

*See also the article in this series by Dr. H. E. Archer on "Urine Testing in the Surgery" (November 28, p. 1211).

sample taken one and a half hours after a full carbohydrate meal; glycosuria is most likely to be present and heaviest in this second sample. If in a patient not receiving insulin the amount of reducing substance in the urine is not greatly increased about one and a half hours after a carbohydrate meal, the reducing substance is unlikely to be glucose.

The identification of a reducing substance in urine is very seldom required. The value of the osazone test and of the yeast fermentation tests in distinguishing glycosuria has been over-emphasized. The osazone test is difficult to carry out, and even in the hands of the experts is not always as reliable as has hitherto been believed. Fermentation tests, too, are not always satisfactory, for many of the common varieties of yeast ferment sugars other than glucose. The recently developed paper chromatographic method of detecting and identifying reducing substances in the urine is by far the most satisfactory yet devised. With this technique it has recently been shown that in pregnancy lactosuria is twice as common as glycosuria, the former being found in as many as 50% of the antenatal patient attendances. All things considered, the identification of a reducing substance in urine should be undertaken by laboratories specializing in this kind of investigation.

A Single Determination of the Blood Sugar

In many cases of diabetes, even in those in which the clinical history is not entirely typical, the diagnosis may be definitely established by the determination of the blood sugar. The interpretation of the result obtained depends upon the knowledge of the effect of the previous meal upon the blood-sugar concentration. It is shown below that after 50 g. of glucose in the fasting condition the blood sugar normally rises from a fasting level of 80-100 mg. per 100 ml. to not more than 180 mg. per 100 ml. and returns to normal within two to two and a half hours of the beginning of the test. When instead of having 50 g. of pure glucose the food consists of an ordinary mixed meal the blood glucose will not rise quite so high but will take a longer time to return to normal. After a breakfast consisting of eggs and bacon and two or three slices of bread with butter and marmalade, the blood sugar may rise to 140 or 150 mg. per 100 ml. and yet take up to three hours to return to the fasting concentration, whereas after a typical tea of bread, butter, jam, and cake, conditions will approximate more closely to the events occurring in the glucose-tolerance test. It is clear, therefore, that with a typical clinical history a single blood-sugar determination, taken one and a half to two hours after a meal, giving a result above 150 mg. per 100 ml. will almost certainly establish the diagnosis. On the other hand, a blood sugar well below 150 mg. per 100 ml. is not diagnostic of diabetes, and further investigation is necessary by the glucose-tolerance test.

Glucose-Tolerance Test

This test is more often used to exclude the diagnosis of diabetes mellitus than to establish its presence, for it is necessary only in those mild cases free from all symptoms of diabetes in which a single determination of the blood sugar gives an equivocal result.

It is essential to give the patient a full carbohydrate diet for seven days before carrying out this test. If not, a mildly diabetic type of curve may be found in a normal person.

After a full carbohydrate regime the patient is fasted overnight, blood and urine specimens are collected and analysed quantitatively and qualitatively for sugar before and half, one, one and a half, two, and two and a half hours after 50 g. of glucose dissolved in 200 ml. of water. The urine specimens should also be examined qualitatively for ketone bodies. In the normal curve the fasting blood sugar is below 110 mg. per 100 ml.; there is a rise to less than 180 mg. per 100 ml., and a return to the fasting level within two to two and a half hours. A second type of curve which is found in normal persons is the so-called lag storage curve in which the half-hour blood analysis shows an abnormally high concentration of sugar (up to 250 mg. per 100 ml.), but

the specimens at one and a half and two hours have returned to the fasting level. Such a curve found in patients free from symptoms of diabetes is of no pathological significance and may account for the presence of sugar in the urine between half and one hour after a high carbohydrate meal, because of rapid absorption.

A normal curve is found in renal glycosuria, when sugar appears in the urine at times when the blood concentration is not abnormally high. Although renal glycosuria is usually of no pathological significance it should be borne in mind that the condition may be accompanied by other forms of renal tubular dysfunction causing amino-aciduria and, or alternatively, abnormal phosphorus excretion leading to persistent rickets. Such cases are rare, but the condition should be borne in mind when glycosuria without symptoms of diabetes is found in childhood. Indeed, all cases of glycosuria in childhood should be referred for diagnosis to a diabetic clinic.

The glucose-tolerance curve is abnormal and usually due to diabetes when the fasting blood sugar is above 110 mg. per 100 ml., the blood sugar rises to a level above 180 mg. per 100 ml. and fails to return to normal values within two to two and a half hours. However, abnormal curves may also be found in sepsis, carbohydrate starvation, hyperthyroidism, severe liver disease, Cushing's syndrome, and some cases of acromegaly, in all of which glycosuria may occur. Usually the non-diabetic causes of an abnormal glucose tolerance are obvious from the clinical findings and the abnormality is not very great.

Glycosuria and Hyperglycaemia in Known Diabetics

Glycosuria and hyperglycaemia must also be considered in relation to the known diabetic, possibly on insulin treatment, who is being controlled by the practitioner. The insulin requirements may be readily assessed by means of routine urine tests for glucose and ketone bodies, but occasional blood-sugar determinations are of value. The time at which the blood or urine should be collected depends upon the type and number of doses of insulin the patient is receiving. Sometimes an early morning specimen may be the best, sometimes the midday specimen, and in other circumstances both. It is not the purpose of this article to supplant the excellent manuals on the treatment of diabetes, but a few general principles may be useful.

While usually the presence of heavy glycosuria may be regarded as an indication for increasing insulin dosage, this is not always the case. The early morning specimen may contain sugar secreted into the bladder in the early part of the night after the evening meal. Clearly a urine test carried out on such a specimen will give no indication of the dangers of early morning hypoglycaemia. For this reason the bladder should be emptied immediately on waking and a further specimen of urine passed as soon as possible before breakfast. In this way the second specimen will be an indication of the fasting blood sugar; this specimen is the one most useful in controlling the dose of protamine-zinc insulin. Similarly it is better to test the second of two specimens passed before lunch or tea in cases on a morning dose of soluble insulin.

In cases on two doses of soluble insulin the morning specimen may be useless as a guide to dosage because the evening insulin may not act long enough to prevent morning glycosuria, but at the same time any increase in insulin dosage may produce hypoglycaemic attacks during the night.

Blood-sugar estimations make treatment easier but are not always essential. In diabetics with a normal threshold periods of hyperglycaemia will usually be accompanied by a heavy glycosuria. Determination of the blood sugar in a diabetic patient receiving insulin treatment and not responding with clinical improvement may show that the patient still has a high blood sugar. On the whole, however, determinations of blood sugar in patients with known diabetes are of particular value in indicating hypoglycaemia and provide an indication for the reduction of the insulin dosage.

In any diabetic it is useful to know the renal threshold, because in patients with a low threshold insulin dosage cannot be adjusted by urine tests alone. Some reasonable control is possible if the insulin dosage is decreased when glycosuria disappears and increased when ketones appear in the urine. The threshold may be estimated by a series of analyses of sugar in the blood and urine. A convenient technique is as follows. Four hours after the morning injection of insulin the patient should empty his bladder. Ten minutes later the blood-sugar level should be determined, and as soon as possible after this, preferably within fifteen minutes, the bladder should be emptied again. No food must be taken from an hour before the first emptying of the bladder to completion of the test. The patient has a low renal threshold if more than slight traces of sugar appear in the second urine specimen and the blood-sugar level is below 160 mg. per 100 ml.

Collection and Preservation of Blood for Sugar Determination

Blood collected for analysis of its sugar content must be preserved with one drop of formalin or by the addition of potassium fluoride. It is best, however, to obtain prepared tubes from a local laboratory.

Most of the methods for determination of blood sugar are not entirely specific and the values are usually 15-25 mg. per 100 ml. higher than the true amounts. The figures for sugar concentration given in this article refer to capillary blood; it is important to remember that the content in venous blood is less than that in capillary blood. The difference is not great during fasting, but after a carbohydrate meal it may amount to as much as 20-70 mg. per 100 ml.

CHANGES AND PROSPECTS IN MEDICINAL TREATMENT

SIR HENRY DALE'S HARBEN LECTURES.

Sir Henry Dale, O.M., delivered the three Harben lectures, 1953, at the Royal Institute of Public Health and Hygiene on December 7, 8, and 9, taking as his subject, "Changes and Prospects in Medicinal Treatment." The chair was taken on the successive evenings by Sir Henry Tidy, Dr. J. Browning Alexander, and Sir Arthur MacNalty.

TREATMENT OF PRIMARY CAUSES, INFECTIONS, IMMUNOLOGY, AND CHEMOTHERAPY

In his first lecture Sir Henry Dale began a review of the remarkable changes which, during the past half-century, and largely in the recent quarter, have so transformed the whole aspect of medicinal treatment of disease that what was earlier recognized, by doctors and patients alike, as one of the more backward and ineffective aspects of medical activity had become one of the most successful and scientifically progressive. Medical men of his own generation hardly needed to be reminded of the days when "doctors' medicine" formed the target for a grim kind of humour. There was then a great disparity of aim and interest between the pharmacology of the laboratories and the therapeutic practice of the wards. What pharmacology had to say even about the action of the few unquestionably valuable drugs at that time had little reference to their therapeutic use. Paul Ehrlich complained of the pharmacologists of his time that if he asked them how quinine produced its effect they

would tell him how it acted on the frog's muscle or on the mouse's brain, when what he wanted to know was how it specifically attacked the malaria parasites, causing them to disappear from the blood of a sufferer from malaria. What he wanted to know was how certain doses would cure the patient, not how large doses would poison him.

The lecturer illustrated some of the conditions which prevented the development of therapeutics as a science at a period well within living memory. He said that he mentioned these bygone anomalies and frustrations only to serve as a background for a discussion of the predominant factors which had brought about an astonishing change, a veritable transformation of the whole therapeutic outlook, in recent years.

The stimulus came largely from what at the time appeared to be an essentially new idea in therapeutics, the idea that a medicine should be used to remove or prevent the cause of a disease or a failure of health, whereas the most that had been previously expected of any medication was the relief or mitigation of symptoms, except perhaps in obvious cases, such as the removal of intestinal worms, where the cause of a disease had been readily visible to the naked eye. Of course, the relief of symptoms might still be the most immediate need for the patient and the most urgent duty of the physician. Nobody would depreciate the value of digitalis because it was essentially a remedy for symptoms, not an agent for the eradication of the cause of them, or because pharmacology might not yet have completed its account of the way in which the active constituents of digitalis produced their effects.

The Fertile Nineties

It was, however, to the conception of radical treatment of the primary causes of disease as the initiating stimulus in this new development that he would, in the first instance, ask special attention. The decade beginning with 1890 had a special significance in this respect. During that decade there were also profound discoveries in physics—the discoveries of Röntgen, Becquerel, J. J. Thomson, and Rutherford. The first two years of that decade saw the advent of three new lines of medicinal treatment, all concerned with the eradication, removal, or prevention of the primary causes of disease. These were the discovery by Emil von Behring of the diphtheria and tetanus antitoxins, Paul Ehrlich's first (though not practically successful) trial of chemotherapy, and George Murray's first successful treatment of a deficiency disease, myxoedema, by administering thyroid gland in myxoedema. From these separate seeds, in due course, were to develop the luxuriant growths of a progressive therapeutics based on immunology, chemotherapy, and endocrinology, respectively.

It would be possible, of course, to trace the ultimate origin of all immunological treatment to the inoculation against smallpox, practised originally in the middle of the eighteenth century, and more particularly to Jenner's vaccination introduced as that century was drawing to its close. But the last decade of the nineteenth century was surely the great fertile period. Sir Henry Dale devoted the remainder of the first lecture to a discussion of the different types of remedial agent which deal directly with diseases due to infections by actions which stop the growth of the infecting organisms and lead to their elimination. These were the natural immunological remedies and the artificial chemotherapeutic agents, including the antibiotics.

Immunological Remedies

From 1892 onwards inoculation with killed cultures of bacilli was undertaken for protection against cholera and later against plague. Afterwards came Almroth Wright's similar immunization against typhoid, effective in the first world war; and then the active inoculations against diphtheria and tetanus. Many years were likely to pass, however, before the antitoxins could be spared from the list of essential remedies; perhaps they never would be spared.

Further advances in the effectiveness of both methods of conferring immunity, active and passive, against bacterial infection seemed most likely to come from a deeper know-

ledge of the chemistry of the antigenic constituents of bacteria and their toxins. Again the first impulse to inquire into this field came from Ehrlich's well-known side-chain theory, which gave a quasi-diagrammatic but essentially a chemical conception of the relation between antigen and antibody. Most recent conceptions did little more than restate the essential idea of Ehrlich in more modern terms, with the aid of such new chemical knowledge and conceptions as Ehrlich himself would have been eager to incorporate in his theory. Such a theory, in any case, had its chief value as a scaffold for ideas, making it possible to build a new exploratory extension of the fabric of experimental research.

Chemotherapy

Already in 1891 Ehrlich was intent on the possibility of discovering new artificial compounds which would have a maximum affinity for the toxic agent or parasite with a minimal affinity for the organs of the infected animal or human being. He was trying methylene blue because it visibly stained the malaria parasite under the microscope; and, tried on the human being, it had a certain therapeutic action, though not as good as that of quinine. The first early promise of successful chemotherapy appeared in 1903, at a time, said Sir Henry Dale, when he himself happened to be working in Ehrlich's laboratory. Ehrlich and Shiga had then already discovered trypan red, which would cure a trypanosome infection in mice. From this starting-point came progress, eventually, to suramin (germanin). From another (atoxyl), development led to salvarsan, as the earliest major practical triumph of chemotherapy. In recent years other effective agents, including several antimalarials, had appeared.

In 1935 came the introduction of prontosil, and then its active moiety sulphanilamide and the various derivatives; and while this development was still proceeding Florey and his co-workers, in 1939, re-examined the possibility of producing and purifying, on a scale adequate for systematic clinical trials, Fleming's penicillin; and the curative action of penicillin had been found to extend far beyond the contemplated range of bacterial infections. It had, for example, provided an additional remedy for syphilis, so safe and effective that even the importance of salvarsan had receded. After this came the first claims of the new range of other antibiotics—streptomycin, and chloramphenicol, with a chemical structure of unexpected simplicity, and many others. There seemed to be a prospect now of an indefinite series of antibiotic agents, many of the more recent of which showed a similarity in what might be called the "spectra" of their antibiotic actions; so that it might be supposed that such a series of equivalents was embarrassing rather than useful, but that would be a hasty judgment. The development of resistant strains might give special value to a range of alternatives.

In summing up, Sir Henry Dale said that all the evidence appeared to favour the conception of successful chemotherapy as normally due to a relatively long-persistent action, involving a corresponding maintenance of effective concentration of the remedial agent in the blood—a war of attrition rather than a *Blitzkrieg*. The general type of action, at the levels of concentration normally obtainable in actual treatment, was to suppress the further multiplication of the infecting organisms rather than to kill them outright. The whole tendency of some recent evidence favoured the view that this chemotherapeutic effect was produced by rendering unavailable to the parasitic organism some essential nutrients, which its nuclear apparatus specifically required for the purpose of its normal multiplication.

He thought the rapid advance in recent years of such an intimate cellular biochemistry was likely to provide a basis for interpretation which Ehrlich would have rejoiced to adopt in place of his more diagrammatic conception. But the initiative was due to the brilliant imagination and determined scientific enterprise of Ehrlich, the centenary of whose birth was to be celebrated a few months hence, on March 14, 1954; and, by a coincidence, the following day, March 15, was the centenary of the birth of Emil von Behring, the discoverer of the diphtheria and tetanus antitoxins.

HORMONES

In his second lecture Sir Henry Dale spoke first of deficiency diseases, including conditions due to endocrine and vitamin deficiencies, in which the treatment, once the nature of the condition had been recognized, was the obvious one of replacement by administration of what was missing. Murray's treatment of myxoedema was the first example of the success of a replacement therapy. After this there was a long interval, during which, though there were discoveries in endocrinology, most of these had no direct applications to treatment by replacement. One exception concerned the rather rare condition of *diabetes insipidus*, due to a deficiency of the pituitary posterior lobe, in some cases following, perhaps, injury in the neighbouring hypothalamus—a condition which could be made good by injection of post-pituitary extract. He did not know even yet whether the new synthetic pressor principle would also have an anti-diuretic action.

He had a vivid memory of the days of disillusionment and doubt among research workers, with regard to the practical possibility of any further successes on these lines. There was at that time no warrant for assuming, from the experience thus far available, that other hormones, even if they existed, would be accumulated in other endocrine glands in such quantities as to be obtainable from them by extraction. They might, on the other hand, be so unstable in their chemical properties, that they would inevitably be lost in any method applied for their extraction. Uncertainties of this kind, and the knowledge of the failure of so many attempts, had a strong deterrent effect until there came the discovery in 1921, by Banting and Best, two young and inexperienced Canadians, who found that the diabetic hormone of the pancreatic islets could actually be extracted, and produce its remedial effects when artificially injected. This provided a new starting-point for active and progressive research in a much wider field of endocrinology.

It would be superfluous on his part to elaborate the importance of insulin in the treatment of diabetes, and its revolutionary effect so far as the sufferers from that disease were concerned. It seemed, however, that the discovery of insulin had had an effect of much greater importance in making possible other discoveries. It led to a new spirit of optimism and enterprise. The sealed book was opening at last, and the subsequent years saw further chapters disclosed. The concurrent advance in the methods of organic chemistry had been important factors in accelerating this progress. But there had been a two-way traffic, and the rapid widening of this new prospect in endocrinology had served as a powerful stimulus to the necessary advances in biological and organic chemistry. Diseases due to other hormone deficiencies came in succession under treatment by direct replacement, and a long series of steroid hormones from the gonads and the suprarenal cortex had been isolated, and later made by artificial synthesis. This series afforded a striking example of the manner in which endocrine functions, differentiated and described in physiological terms, had been clearly associated with steroid chemical structures differing in detail, but still bearing a very close relationship in their general plan.

The qualified expert could easily take a whole course of lectures for the presentation in detail of this subject alone. Another such course might be devoted to the story of the astonishing series of functionally different hormones which had been successfully recognized as existing within the small compass of the anterior pituitary lobe. Each of these hormones had some separate function. Up to 1934 claims had been put forward by different investigators for the recognition of some nine different hormones in this one very small anterior pituitary lobe, though he did not think it could be regarded as quite certain that all of those so described were different. And the question was not made easier by some recent observations by Best and his present co-workers showing that, when the pituitary body had been removed from rats, insulin itself would act as a growth-promoting hormone in the sense that regular injection evoked a renewal of the normal growth.

He thought it should be noted, before leaving this aspect of the general subject, that the instances of a completely successful treatment of a hormonal defect, by direct replacement of what was missing, were still not numerous. The thyroid gland and its constituents in myxoedema, posterior lobe extract in *diabetes insipidus*, and insulin in *diabetes mellitus* were still the outstanding examples, though many successes of a lesser kind could of course be claimed.

Another point to which he wished to draw attention, concerning the therapeutic use of hormones, was that physicians, in more than one important instance, were employing these or their artificial analogues, not to replace defects in the ordinary sense, but to produce their physiological actions at intensities above the normal, physiological range. This was true of the use of oestrogenic hormones, or the analogous stilboestrol, to restrain the growth of prostatic cancer in the male, and testosterone to restrain the growth of mammary cancer in the female. A more conspicuous example was the use of cortisone and A.C.T.H. to allay pain and swelling in the joints in rheumatoid arthritis; and he asked his audience to note that these uses of hormones, for purposes other than the repair of hormonal deficiencies, provided a bridge between the treatment of causes and the treatment of symptoms.

Vitamins

Sir Henry Dale turned next to the accessory nutritional factors or vitamins. This was far more ancient history. The antiscorbutic value of fresh fruits and vegetables had been discovered, forgotten, and rediscovered almost in each century from the sixteenth onwards. Even during the first world war support was still being given on high authority to the idea that scurvy was due to acidity or reduced alkalinity of the blood. The value of cod-liver oil in rickets was discovered in 1840, but even after the first world war rickets remained a pathetically frequent malady amongst children in industrial areas. Then came the work of Mellanby on rickets, which, with the earlier researches of Hopkins and others on the more general significance of such dietary deficiencies, initiated an amazingly rapid advance of knowledge in this field.

Looking back, one found it difficult to believe that even for some years after the first world war the belief was still current that vitamins were substances present in such minute proportions in such complex mixtures, and probably so unstable, that it was quite doubtful whether any of them would ever be isolated or made otherwise accessible to detailed chemical examination. But between 1926 and 1939 at least 10 vitamins had been isolated, identified, and made artificially. Here again, as in the case of the hormones, this progress, when it once began, was astonishingly rapid.

Antihistamines

After glancing at the claims and uses of the various vitamins as practical remedies, Sir Henry Dale devoted the remaining section of this lecture to the introduction in recent years of the antihistaminic series of remedies. This illustrated what appeared to him to be, possibly, a new phase in therapeutic enterprise—the discovery of remedies preventing the action of a substance—histamine in this case—which had been recognized as the common, proximate cause of the symptoms of a group of diseases and pathological syndromes.

SUBSTANCES MODIFYING THE TRANSMISSION OF NERVOUS EFFECTS

In his closing lecture, before proceeding to some general conclusions, Sir Henry Dale discussed another example of recent advance based upon new and still progressive knowledge of the chemical changes concerned in the natural reactions of the body. This dealt with the activities and therapeutic possibilities of substances, both natural and artificial, which modified the actions of chemical transmitters of nervous effects at synaptic junctions. It had been known for nearly 40 years that acetylcholine had stimulating actions, not only on the plain muscle and gland cells responding to

autonomic nerve impulses, but also on the nerve cells of the peripheral ganglia and on the motor end-plates of voluntary muscle fibres; and that these latter actions were susceptible to the paralyzing effects of curare and of excess of the primarily stimulant nicotine.

Until a few years ago curarine and its substitutes were chiefly of interest as pharmacological curiosities and as technical aids in physiological experiment. It was only in recent years that the true meaning of curarine action was discovered and shown to be essentially a suppression of the normal sensitiveness of the end-plates to acetylcholine. This, together with the isolation of a pure tubocurarine by H. King, had made it possible to use curarine for the production of a paralysis of the voluntary musculature, as a supplement to anaesthesia in operative surgery.

He entered upon a detailed discussion of the paralyzing and transmission-blocking agents at the neuromuscular and ganglionic synapses, and referred in particular to the paper in the *British Medical Journal* of December 5 (p. 1237) on the use of an artificial hypothermia in conjunction with autonomic block and paralysis of voluntary muscles.

RETROSPECT AND PROSPECT

In concluding his lectures Sir Henry Dale spoke in somewhat wider terms of the progress of 50 years. After saying that not so many years ago he would have recoiled from the rashness of the forecast he had been making, he went on:

"I have seen so many cases, one after another, in which pessimism with regard to therapeutic possibilities has been suddenly put to shame by a courageous initiative. I have seen so many diseases, long regarded as beyond any reasonable hope of cure or relief, brought within the range of a medicinal treatment which has dealt with the primary cause directly, eradicating it or showing the way to prevent its occurrence, and thus banishing the disease from a whole community, or rendering it relatively innocuous. And I have seen these things happen so many times, and have been watching their frequency gather speed so continuously now for more than half a century, that, so far from finding myself subject to the disillusionment proper to my age, I feel bound to regard an attitude of hopeful, even of confident expectation concerning further developments in this direction, as not merely excusable, but as the only attitude which can be scientifically justified."

He went on to speak of the impressions left on his memory of the therapeutics of his student days at the turn of the century. His main impression was the lack of any effective medicinal remedies for almost all the serious illnesses, acute and chronic, which came to hospital for treatment—cases of *diabetes mellitus*, of pernicious anaemia, for example, admitted for observation or as subjects for teaching, without any hope of anything effective in the way of treatment, except, as one physician said, "to prolong the poor fellow's life by making the rest of it not worth living." In rickets there was at the time of which he was speaking a sound empirical observation waiting to be applied, but only fanciful aetiologies and treatments, till research showed the way much later. Diphtheria was the only infectious disease for which a specific treatment was then available. For the other acute infections—pneumonia, meningitis, erysipelas, septicaemias, or the common infections of childhood, none was yet in prospect. For none of these could anything be really done except to isolate the patient when necessary for protection of the community, and to keep him reasonably warm and quiet, and to administer anything likely to give him rest and keep up his strength. For the rest, the *vis medicatrix naturae*. Such therapeutic innovations as the newer types of remedies dealing with the proximate causes of symptoms were still far below any visible horizon. Only here and there were there any signs of the great change which was soon to begin; there was still but little general and positive advance from resources and methods which had been available 50 years earlier. The former drastic purgings and bleedings had been discarded, but there was little in the way of fresh therapeutic enterprise, and the prevailing mood was one of a placid acceptance, or of a cynical scepticism.

They had seen how all that had changed. Salvarsan, insulin, thyroxine, sulphanilamide, penicillin, the steroid hor-

none, the antihistamines—these and others he had mentioned as examples of the way in which therapeutics was now progressing.

Further Advances

What further advances were in prospect? An observer of the general situation would have the hope, if not the confident expectation, of further important advances in the curative or, better, the preventive treatment of the common virus infections. Anybody unacquainted with the technical difficulties might reasonably inquire why, after more than 150 years, we had not any method of preventive inoculation, comparable with Jennerian vaccination against smallpox, for most of the still common virus infections of our temperate zone. The real trouble was that hitherto the viruses which people had succeeded in cultivating outside the body happened, unfortunately, to be those like influenza for which no solid immunity was acquired, even from an attack. It could only be said that there was so much accumulated experience and trained ingenuity now employed on relevant researches that it ought not to be long before there was discovered a generally applicable preventive inoculation against one or more of the diseases of this group, or perhaps an effective treatment by some antibiotic or other remedy.

What was going to be done with all this new knowledge? The position had been transformed, as compared with that of only 20 years ago. The change had been, on balance, enormously for the better. The question was bound to arise, concerning the limits of the individual intelligence to absorb, to understand, and to apply all this swelling flood of genuine and potentially useful new knowledge. He had been conscious, during this lecture, when speaking of the intricacies of the different types of paralyzing and transmission-blocking agents at neuromuscular and ganglionic synapses, of his own difficulty in expounding, even of being certain that he himself understood completely some of these developments, although they were related to a range of physiology which had been that of his own special interest and concern. And he had wondered how the student of medicine was to be brought into contact with these things, and so to absorb them as to use them safely and intelligently in his practice.

This kind of educational problem, due to the increasing range and complexity of knowledge, was common, of course, to all branches of the medical discipline, and indeed to the learning of all the natural sciences; though it might be suspected that it was unusually acute in medicinal therapeutics on account of the rapid extension there from such small beginnings to this embarrassing abundance. Yet, here as elsewhere, the problem had somehow to be solved. He had himself long felt a strong conviction that the central aim of any scheme for a national health service ought to have been—ought still to be—to deal with this problem, of providing such technical facilities and assistance, such ease and regularity of access to expert advice and consultation, as would enable the individual practitioner to bring the highest practicable proportion of all this new knowledge that research is now producing, and would continue to produce, to the service of his patients, in the diagnosis and treatment of their ailments, with all the help that science could progressively offer.

THE DOCTORS' DISEASES

Addressing his fellow actuaries recently, Mr. E. A. J. HEATH, manager of the Medical Sickness, Annuity, and Life Assurance Society, was concerned mainly with the problems of "permanent" or "non-cancellable" (that is, by the Society) insurance for sickness. But he had also much of interest to tell about the cause of sickness among the members, most of whom are men doctors. Comparing two peacetime years, 1937 and 1952, there was actually a reduction in

the rate of claims for benefit owing to the occurrence of an influenza epidemic in the former year but not in the latter. Still, it was reassuring to hear that, unlike some industrial experience, there had been no general increase. Within this picture there were remarkable changes, however, that mirrored some of the recent trends of morbidity in the general population. Claims for septic infections were three times commoner in 1937 than in 1952; there were no claims for scarlet fever or diphtheria in the later year. Appendicitis was only half as common in 1952, and why this should be so was not at all clear. Surprisingly, pneumonia seemed to be commoner in 1952, though disability was probably much shorter, and as a cause of death pneumonia was now "practically non-existent." The speaker was dealing, of course, with a membership that ceases at 65 years of age.

A Fashionable Complaint

The other side of the balance sheet showed an increase in the claims for an assortment of conditions—for virus infections, for "disks," possibly for cancer, and, dominating the picture, for coronary thrombosis. This is what Mr. Heath had to say about "disks":

"In 1937 there were 47 claims for lumbago, sciatica, sacro-iliac strain, and so on, on the average of fairly short duration. In 1952 there were only 29 such cases—but no fewer than 35 cases of prolapsed intervertebral disks, with a definite increase in the average period of incapacity. I am told that prolapsed disks have been found in skeletons 2,000 years old, but they have only been rediscovered since the war, and very much to the cost of companies doing sickness insurance. Fortunately the drastic operation which was in vogue a few years ago has already fallen out of favour and disks tend more and more to be treated conservatively." It is not often that fashions in diagnosis—and treatment—are documented so neatly.

Coronary Thrombosis

The increase in coronary disease may be represented by these numbers: 9 claims in 1937, including 1 for angina pectoris, and 24 claims in 1952, including 4 for angina. (The figures given for 1952 were all "adjusted" figures, to allow for the changes in the number of members between 1937 and 1952 and the increase in the average age of the members.) Scrutiny of the other cardiovascular claims in 1937, and review of all the other information on the subsequent history of the claimants now available yielded another 6 cases in that year that might conceivably have been "missed coronaries." This procedure (which was not applied to 1952) permits a more conservative comparison of 15 claims in 1937 with 24 in 1952—similar figures to those of the deaths from coronary disease, 6 and 9 respectively. In addition there were 3 "chronic" cases of coronary thrombosis in 1937 and 8 in 1952. On the other hand, there was no apparent increase in these 15 years in the claims for intracranial vascular disease and high blood pressure.

Mr. Heath summed up the outlook in coronary thrombosis as "roughly speaking, one-third die within a day or two, one-third recover in 3 months, and one-third are incapacitated for 6 months or even for many years"—figures not unlike the results of the exhaustive analysis of prognosis in the same material reported previously in our columns.¹ Coronary thrombosis, he said, was probably "the biggest medical problem which life office actuaries have to face to-day, and it is even more important in the sickness field," which is not surprising in light of the observation of Morris and his colleagues that one in five members joining the society at the usual age may expect to suffer from coronary heart disease before reaching 65, and that a third of all the deaths are so caused.

Reports of Societies

USE AND ABUSE OF REST

On November 24 at the Royal Society of Medicine the Section of Medicine, with the president, Sir HENRY COHEN, in the chair, held a discussion on the use and abuse of rest as a therapeutic measure. In opening the discussion Dr. G. E. BEAUMONT extolled the value of rest in medicine. Although there was a modern tendency to emphasize rest for the mind as well as the body, it was remarkable how quickly a patient became indifferent to his worries when he took to bed with an acute illness. Even more remarkable was the mental tranquillity so often seen in chronic illness: indeed, the patient with an empty mind, who adjusted himself easily to prolonged rest, often derived most physical benefit from treatment. Patients in hospital were sometimes disturbed by visitors, visiting-hour often being followed by a rise in the patient's temperature.

Physical rest was of paramount importance in the early treatment of poliomyelitis. In pulmonary tuberculosis, many of the results obtained by prolonged bed rest in the old days compared favourably with the achievements nowadays attributed to chemotherapy. Treatment by pneumothorax or thoracoplasty was an adjunct to rest, but the physical exercises which had become part of the treatment in patients with pulmonary tuberculosis subjected to pulmonary resection were contrary to the basic principles of treating tuberculosis, and might activate latent foci in the opposite lung. Sciatica had once been treated vigorously though unsuccessfully by physiotherapy, but now it was suggested that prolapse of the intervertebral disk was the true cause of sciatica, and so patients were being successfully treated by rest. In rheumatoid arthritis treatment by complete bed rest for many months was better than subjecting the patient to the rigours of physiotherapy and spa treatment. It should be the physician's aim to treat fewer patients more thoroughly.

The Hazards of Rest

Professor W. MELVILLE ARNOTT emphasized the abuse of rest in treatment. Rest was often loosely applied to mean periods of relief from work. The erroneous belief that hard work caused disease was readily accepted by doctors who were reluctant to admit their ignorance about the cause of disease and by patients who avidly welcomed such a palatable explanation of their woes. The main drawback to rest was that it could be definitely harmful. Rest was a "drug of addiction," but unlike other such agents its prescription was untrammelled by law. It was traditional to rest sick people, but proof of its value was lacking. When young people were put to rest many adverse metabolic and circulatory changes could be demonstrated. In elderly patients the hazards were even greater. It was common knowledge that incontinence in the aged could often be cured by the simple expedient of getting the patient out of bed, and alimentary function improved when a bedside commode was substituted for the bed-pan. It was remarkable that bed rest was seriously considered as a therapeutic measure, since its use was not even backed by tradition. Rest was a habit which had arisen from the principles of Hilton's *On Rest and Pain* and which had been perpetuated by the influence of the hospitals where the bed-pan routine and thoroughness of nursing had encouraged treatment in bed. An excess of rest, like an excess of drugs, was a burden on the Welfare State.

The Surgical Patient

Professor C. A. WELLS thought that many of the principles underlying treatment by rest were out of date, since we were now able to alter the course of so many diseases by modern therapy. It was essential to distinguish between the need for local rest for a diseased organ and general rest for the

whole body. The symptom of pain could sometimes be treated by active means, as in the treatment of angina of effort by sympathectomy. Nowadays the main value of institutional treatment in pulmonary tuberculosis was to ensure that a complicated regime of chemotherapy was carried out, but the principles of resting diseased joints remained unchanged. A combination of rest and exercise was often the most successful way of treating orthopaedic disorders. In the field of general surgery early post-operative activity and ambulation had greatly reduced the risk of thrombo-embolic complications.

The newest approach to rest therapy was the process known as hibernation. By paralysing the heat-regulating mechanism and by cooling the body it was possible to produce a state of profound depression in which oxygen consumption was lowered without risk of cerebral or cardiovascular damage. In this state of almost completely suspended animation it was possible to carry out surgical operations while minimizing the risk of surgical shock and abolishing many of the harmful post-operative metabolic disturbances.

Rehabilitation

Group-Captain C. J. S. O'MALLEY discussed the place of rehabilitation in the treatment of disease. The need for rest in some diseases had decreased since the introduction of antibiotics. Although rest was still required in the acute phases of a disease, it was often found during rehabilitation that much effort was needed to overcome the apathy and ennui arising from too much rest. In rehabilitation centres it was vital to strike a careful balance between rest and activity. The timing of treatment was also important, especially in poliomyelitis, where complete rest was needed in the early stages. Active rehabilitation had reduced the length of disability after surgical operations in men on active service and in factory workers. During rehabilitation periods of relaxation were necessary: remedial games and work therapy helped to balance work with leisure. In many diseases, such as prolapsed intervertebral disk and osteoarthritis, exercises aimed at maintaining good muscle tone were most valuable. Patients with psychoneurotic disorders often responded well to rehabilitation, especially if they could be brought into contact with patients recovering from severe organic disabilities. Treatment in an active rehabilitation unit not only accelerated a good functional recovery but it was much more economical than prolonged treatment in hospital.

Nova et Vetera

TALES OF A POMANDER

The Gold-headed Cane. By William Macmichael, M.D. Seventh edition with foreword by James J. Waring, M.D., and preface by William J. Kerr, M.D. Containing the text and illustrations of the fifth edition, including the introduction by George C. Peachey. (Pp. 185; illustrated £2 7s. 6d.) Springfield, Illinois: Charles C. Thomas. Oxford: Blackwell Scientific Publications. 1953.

The title of this most readable of books on medical history may need explanation. Even within living memory the costume of doctors was almost as distinctive as that of the clergy. For centuries before that, part of their equipment was a long cane, the spherical head of which was a "pomander" and contained sweet-smelling herbs, thought to be preservative against infection. The pomander itself died out in the seventeenth century, but until the end of the eighteenth the doctor was distinguished by his elaborate and expensive stick. Such a cane was owned by John Radcliffe (1650-1714), most successful and least literate of the great doctors of the age, who, owning no books and reading none, left a fortune to endow a library. From him the cane passed successively to Richard Mead (1673-1754), Anthony Askew (1722-1774), William and David Pitcairn, uncle and nephew (1711-1791 and 1749-1809), and Matthew

Baillie (1761-1823). None except the last made any important contributions to medical science, but all in their day were famous and successful physicians, undoubtedly alleviated much suffering, and accumulated what seem to-day incredible sums from their practices. All were shrewd, far-seeing, kindly men of great personal prestige and peculiarly resourceful in relieving symptoms. Which of us in sickness would not wish to be attended by such a one?

It is the peculiar skill of the author of this work, William Macmichael (1784-1839), that he brings all this home to the reader. The method of endowing an inanimate object with the power to relate its experiences has been often tried, and by several good writers. With this one exception the result has always been failure. Macmichael alone, so far as the reviewer's knowledge extends, has been triumphantly successful in his handling of this clumsy and rigid device, and the book fully deserves its popularity. The first edition of it appeared in 1827; this, the seventh, has a preface by Professor J. J. Waring, director of the tuberculosis institute of the University of Colorado, and an introduction by Professor W. J. Kerr, of the University of California, together with the learned and amusing essay on the book by the late Dr. G. C. Peachey. It is by far the most beautiful of the seven editions, each of which is itself a bibliophile's piece. The ancient cane rests at the Royal College of Physicians of London. It is entertaining to learn that a replica of it is now awarded as a prize at San Francisco:

"To sounds that echo further West
Than its sire's Islands of the Blest."

CHARLES SINGER.

Preparations and Appliances

A MODIFIED WHITEHEAD GAG

Dr. A. OWEN-FLOOD, consulting anaesthetist, Hornsey Central Hospital, writes: Deciduous teeth extracted by means of a mouth gag during tonsillectomy can give the surgeon and anaesthetist cause for concern. The anaesthetic, of necessity deep enough for insertion of the gag, must at the same time allow a prompt return of the reflexes, and is thus, at the best, of a swinging type with a fairly stiff jaw.

The three danger points are: inserting the gag; the liability, when using the adenoid curette, of undue pressure on the front teeth; and taking out the gag with the jaw stiffening.

To a Whitehead gag, ideal for the partially toothless, giving an even pressure all round the jaw, I have fitted soft lead rollers where the gag is supposed to fit behind the front teeth (see illustration). This device makes insertion

of the gag simple and atraumatic, acts as a buffer against the shaft of the curette, and facilitates removal with a jaw beginning to tighten.

Any handy hospital engineer can fit these rollers, which are jointless, but care must be taken that they will not become loose and fall into the mouth. It is essential that they should be applied in a strip and be thick, so that on being bitten they do not alter their shape and thus cease to roll.

Correspondence

Because of the present high cost of producing the Journal, and the great pressure on our space, correspondents are asked to keep their letters short.

Carcinoma of the Female Breast

SIR.—Mr. David Patey's recent letter (*Journal*, November 7, p. 1046) raises a number of interesting points in connexion with our article on carcinoma of the female breast (*Journal*, October 10, p. 787).

The question of how effectively irradiation can destroy cancer in the axillary and internal mammary glands is a difficult one to answer and we, of course, did not investigate this directly. Elsewhere, one of us has jointly reported the results of histological investigation in a series of irradiated tumours and we would agree that irradiation does fail to sterilize the glands in a fair number of cases. It is, however, extremely difficult to decide about the viability of cells in histological sections. In so far as our recent series can give an indirect answer to this question, it seems possible that incomplete sterilization of the axilla is unimportant in a majority of cases, since so many of these already have more distant spread. However, a patient with a solitary deposit in a low axillary gland and no distant metastases should be better off with that gland removed. There can be no doubt that such cases are few in number, that clinical assessment can be most misleading, and that there is no way of recognizing them prior to operation and full pathological investigation. If we could confidently recognize these cases, then, notwithstanding the greater morbidity, it would be logical to do a radical mastectomy in order to offer them the best chance of survival and the least chance of local recurrence. We would largely agree with Mr. Hedley Atkins's view, reported in your leading article (*Journal*, October 10, p. 817), that in terms of survival it is likely that in a small fraction of cases only does the method of treatment really matter. In terms of morbidity, however, the method of treatment does matter to a much larger number of women.

Mr. Patey has also raised an important point about the technique of simple mastectomy. It is true that some of the axillary glands are bound to be removed if the axillary tail of the breast is properly dissected, and Mr. Patey is right in saying that it is a question whether axillary dissection should be complete or limited.

In turning to the subject of the internal mammary glands, Mr. Patey writes that we "appear to assume that irradiation of the internal mammary chain is efficient." We have no evidence on this point, but it is likely that irradiation of these glands is no more and no less efficient than of those in the axilla. It is likely, however, that the number of cases in which super-radical surgery can effect survival is very small, and once again we have no means of predicting these cases beforehand. If we are to do the greatest good to the greatest number it would seem likely that super-radical surgery is unjustifiable. We stand corrected if we seem to have condemned this method without trial, but we do submit that such signs as there are point strongly against any more heroic surgery. If the experiment is to be continued we would plead that it should be a carefully controlled one from the outset. The radical operation was accepted for many years without any proof of its value, and it would be regrettable if it took as many years and the suffering of many women to prove that super-radical surgery is unjustifiable as well as mutilating.

We are glad that Mr. Patey has questioned our local recurrence index. As stated in our paper, the method was put forward in order to stimulate comment and criticism. In a retrospective survey, such as we presented, it was very difficult to collect adequate and accurate information on many points. The simple surgery group included many cases which were treated by very limited local surgery and our numbers did not allow more detailed analysis. The local recurrences included a wide variety of circumstances—for example, a fresh or recurrent tumour in a case treated by local excision only, and recurrences in the skin or chest wall following mastectomy, as well as recurrences in the undissected and dissected axilla. If further investigation reveals that local recurrence is less common after radical than after adequate simple mastectomy (and we would emphasize the word adequate, since the latter operation is sometimes carelessly performed),

then this will be an important point in favour of radical surgery. It may be that in the past too much emphasis has been placed on survival figures and too little on morbidity and local recurrence. If two hypothetical and identical cases, A and B, are considered, the one treated by radical and the other by conservative surgery, it may eventually prove true that case A has the greater chance of a swollen arm, and case B the greater likelihood of local recurrence. If both cases survive for the same time it becomes extremely difficult to assess the merits and disadvantages of the two methods of treatment.

Though our own advocacy of conservative surgery may be partly demolished in the process, we would earnestly ask all workers to give very careful attention to this problem of local recurrence. In the meantime it is our considered opinion that, in the absence of any more exact method for really accurate pre-operative assessment of our cases, the greatest good and the least harm will be done to the largest number if less radical surgical methods together with radiotherapy are used in the great majority of cases.—We are, etc.,

R. S. MURLEY.

Malaria in Neighbouring Londoners

SIR.—The article by Drs. G. S. Crockett and K. Simpson (*Journal*, November 21, p. 1141) was of considerable interest to me. In 1950, with the co-operation of Mr. A. W. Leftwich, biology master, and the boys of the Wellingborough Grammar School, I carried out a survey of the different species of mosquitoes in the area. This area, which is a rectangle bounded by National Grid Lines E4/83 to E4/98 and N2/64 to N2/70, covers about 50,485 acres and includes the junction of the rivers Ise and Nene. The total number of specimens examined by us was 557, and of these 20 were of anopheline mosquitoes. The anopheline variety was *Anopheles maculipennis* and its subdivisions. Although the survey was far from being complete, it did show that the anopheline mosquito was no rarity in the district.

I appreciate the difficulty experienced by the writers of the article in finding the breeding ground of the anopheline mosquito, as we, too, experienced difficulty. We found the anopheline breeding in shallow reed-grown pools of overflow water from the river Nene. We also found some breeding in a water tank situated on the outskirts of a small town. The breeding grounds of the *Culex* variety were found much more easily. Adult anophelines were found to range one to two miles from their breeding grounds, and of course, if a swarm were caught by a wind, could be transported much further distances. This article brings to mind countries, given a certain period of warm weather for the malarial cycle to be completed, there is always the potential danger of primary malaria being contracted in England.

As a matter of interest, of the 30 or more known British species of mosquito, only six were found in this district. The species and numbers of specimens were as follows: *Theobaldia annulata*, 14; *Theobaldia (culicella) morsitans*, 18; *Aedes (ochlerotatus) rusticus*, 27; *Aedes cantans* (formerly *ochlerotatus housei*), 33; *Culex pipiens*, 445; *Anopheles*, 20. It is interesting to note that 60 specimens of *Aedes rusticus* and *Aedes cantans* were found. These specimens are related to the *Aedes aegyptus*, which is associated in Africa with the spread of yellow fever.

Considering the fact that mosquitoes are associated with the spread of diseases in tropical countries, one wonders if they could be the possible vectors of certain diseases in this country.—I am, etc.,

P. X. BERMINGHAM.

Wellingborough.

Costo-clavicular Compression of the Subclavian Vein

SIR.—I read with interest the article by Dr. R. Wyburn-Mason under the above title (*Journal*, November 28, p. 1198). It is true that in recent years the conception of costo-clavicular compression of the brachial plexus has been recognized as often giving rise to symptoms formerly attributed to the pressure of a cervical rib or to compression by the scalenus anterior muscle. Unfortunately, the impression that lesions causing drooping or drooping of the shoulder produce costo-clavicular compression of the neuro-

vascular bundle is still widely held. It is a fact well known to all anatomy students that when the shoulder descends the clavicle moves anteriorly away from the first rib. The further the shoulder descends the wider does the costo-clavicular interval become. Conversely, when the shoulder is raised, as by abducting the arm or retracting (bracing back) the shoulder, the clavicle moves upwards and backwards in the form of an arc, and the costo-clavicular interval becomes narrower.

The relationship of clavicular movements to costo-clavicular compression was pointed out by Professor E. D. Telford and myself in the *Journal* of March 15, 1947 (p. 325). The production of pain due to dropping of the point of the shoulder is caused by a dragging of the plexus across the tendinous anterior edge of the scalenus medius. Oedema is caused by a similar drag of the vein over the first rib, as shown by Dr. Wyburn-Mason. I quote the comment following the first two case reports in Dr. Wyburn-Mason's article: "It appears, therefore, that when the tip of the shoulder drops because of damage to or tearing of structures normally supporting it the subclavian vein may be compressed as it passes over the first rib, giving rise to venous oedema of the arm." It is significant that the author does not say "... compressed by the clavicle as it passes ...", and from this comment I think that he does not believe that the clavicle is an agent in this venous compression. The more unfortunate it is, therefore, that costo-clavicular compression is the title of this article.—I am, etc.,

S. MOTTERSHEAD.

Middlesbrough

Venepuncture

SIR.—In his article on venepuncture (*Journal*, October 24, p. 930), Dr. I. A. B. Cathie recommends the patient bending the elbow double tightly over the swab after the removal of the needle from the vein. I do not think that this common practice is the best. Not only does it dam blood back in the forearm, but it may also make a short, tight sleeve on a female patient into an effective tourniquet around the contracting arm muscles. In either case a propensity to bruising and bleeding is increased. It seems far better to leave the elbow extended and press the swab with the whole arm slightly raised. This is no more trouble than the usual method, and mishaps are less common.—I am, etc.,

Liverpool.

P. J. TAYLOR.

Fatality Following Penicillin Injection

SIR.—It seems desirable in the present state of our knowledge that every fatality following a penicillin injection should be given wide publicity. Here is another fatal case.

An apparently healthy woman, aged 31, who two years previously had been successfully treated in this hospital for phlebitis of the right leg (of unknown origin) with 53 injections of crystalline penicillin, was readmitted on September 21, 1953, for the removal of a chronic appendix. On the morning after admission she was prepared for operation, but on being given the routine pre-operative injection of morphine and atropine she passed into shock, and though she made a perfect recovery the operation was postponed for further examination of her general condition. Four days later, as nothing abnormal had been discovered, she was once more prepared for operation, but it was decided to omit the injection of morphine and atropine. A chronic appendix was removed under cinchocaine spinal anaesthesia (isotonic) and the patient left the theatre in apparently perfect condition, having had no fall of blood pressure or other untoward incident. One and three-quarter hours after being returned to the wards the patient received 50,000 units of crystalline penicillin into the buttock, and immediately, announcing that she was going to die, became cyanosed and pulseless. She succumbed 15 minutes later in spite of artificial respiration with oxygen, injections of nikethamide, caffeine, ouabain, and, finally, adrenaline into the heart.

This is the first fatal case following penicillin recorded by this hospital. Two years ago a severe case of shock was observed following the injection of 400,000 units of procaine penicillin given to a syphilitic patient.—I am, etc.,

E. H. R. ALTOUNYAN.

Aleppo, Syria.

The College of General Practitioners

SIR,—I rather gather that the movement for higher criteria for future membership of the College of General Practitioners is stronger at the moment in Scotland than it is in England. It is to be hoped that the desire for this will gain momentum in all quarters. It has been clear to me since the College was mooted in the early days of the Steering Committee that, if it is to secure equality for general practitioners with other sections of the profession, it must become, first, a royal incorporation, and, secondly, a licensing body able to issue a diploma or diplomas which will be recognized by the General Medical Council as a registrable higher medical qualification or qualifications.

Whether foundation or early members will automatically receive this diploma or not is of lesser importance at the moment. Nor is the form that the examination for the diploma should take at present in question. I do not wish to complicate the issues by referring to these disputable matters, but I do feel that at the moment the College enjoys widespread good will. To delay unduly in applying for a royal charter and in establishing a registrable diploma would, in my judgment, be most unfortunate.—I am, etc.,

Glasgow, W.3.

J. INGLIS CAMERON.

Research in General Practice

SIR,—The annotation entitled "Research in General Practice" (*Journal*, November 28, p. 1209) mentions herpes zoster as a suitable subject for study. It may be of interest to report that a small group of general practitioners working in rural areas of central Perthshire has been recording its observations on this disease for the past two and a half years. Our records are made on a standard form drawn up by Dr. P. L. McKinlay, the medical statistician to the Department of Health for Scotland.

As the majority of the members of our group are now foundation members of the College of General Practitioners it is our intention at an early date to explore the possibility of making our local inquiry the nucleus of a much bigger investigation conducted under the auspices of the College.—I am, etc.,

Pitlochry

JOHN M. HENDERSON.

Alcohol-induced Pain in Hodgkin's Disease

SIR,—Pain induced by alcohol is not peculiar to Hodgkin's disease. During the Libyan campaign of 1941 I suffered from a Brodie's abscess in the head of the right tibia. One half-glassful of beer was sufficient to cause pain of distressing severity in the region of the lesion. After confirming this curious phenomenon on two or three occasions with several types of alcohol-containing drinks, I was forced temporarily to become teetotal.

Before operative cure of the abscess I discussed the possible cause of such pain with Lieutenant-Colonel Graham, O.C. Surgical Division, 2/1 Australian General Hospital. He had himself suffered from a pyogenic infection of bone, and had experienced a similar alcohol-induced pain. We thought that the probable explanation was traction upon pain-sensitive structures (? vessels) caused by vasodilatation in osteoporotic tissue.

Growth of Hodgkin's tissue in bone may have been the cause of the pain in all instances quoted by Dr. Jan G. de Winter (*Journal*, September 12, p. 604). I have not known such pain to occur after alcohol in several other cases of pyogenic osteomyelitis, nor in cases of tuberculous osteitis and myelomatosis.—I am, etc.,

Victoria, Australia.

D. A. ALEXANDER.

Agonal Myokymia

SIR,—Recently I watched an old lady die of hypertensive heart failure. About half a minute after I heard the last heart sound the entire chest wall and shoulders rippled with fibrillary contractions of the muscle fibres. This went on for about a minute. The face was not affected and the

rest of the body was covered. The room was warm and there was no perceptible draught. It was a most striking sight.

I have never heard of this phenomenon and can recall no reference to it in the literature. One seldom sees the act of dying; one feels that were myokymia frequent at this time the ancients would have been well aware of it and that it would be described in classical writings. The only explanation I can suggest is that I saw during a minute an effect of anterior horn-cell degeneration which takes place over months in motor neurone disease.—I am, etc.,

Hutton Mount, Essex.

GAVIN THURSTON.

Medresco Hearing-aids

SIR,—Your leading article of October 24 (p. 929) dealing with Medresco hearing-aids states: "There is no doubt that the benefit extended to so many deaf people by the Medresco aid is ample return for the trouble and cost of providing a hearing-aid service on a national scale." The Medresco service has now been operating for nearly five years, and it would be wise to ask whether or not we are getting the best value for the money expended, this value to be determined in terms of hearing rehabilitation or the extent to which the hearing-aids distributed have enabled those who have received them to lead a normal life, free from the handicap of deafness. Judged in this way, the Medresco service may be found to have several serious shortcomings:

Mr. Gray and Miss Cartwright in a survey carried out for the Ministry of Health and summarized in the *Lancet* reported that the average daily use of the Medresco was 4.9 hours, and that only 18% of the aids issued were ever taken to work. The personnel of clinics have been consistent in their advice that only about one-third of the aids issued received any real use, one-third received occasional use, and the remainder were not used at all. The exclusion of commercial hearing-aids from the Health Service means that the hard-of-hearing are denied new developments as they become available. Bone conduction has just been introduced after being fully developed more than 20 years ago. Automatic volume compression, which has been featured in commercial hearing-aids for the last five years, has not yet been introduced, although it is essential in many types of inner ear deafness.

Might we not as a nation get better value for the money expended if some of this were devoted not to the giving away of free hearing-aids but to a determined drive to detect and treat deafness immediately it occurs, and particularly in school-children?—I am, etc.,

London, W.C.2.

A. EDWIN STEVENS,

President, Hearing-aid Manufacturers Association.

Lancet, 1951, 1, 1170.

Antibiotics in Bacteraemia

SIR,—I was interested to read the account of a fatal case of staphylococcal bacteraemia described by Drs. W. H. Jopling and F. D. Schofield (*Journal*, November 21, p. 1140). There are, however, two points which do not seem to have been considered by the authors. First, it is known that *in vitro* tests do not necessarily correspond to *in vivo* results. Thus it is perfectly possible for a patient to be cured of a bacterial infection by an antibiotic while *in vitro* tests demonstrate the organism to be insensitive to that antibiotic. Secondly, it is also known that bacteraemias respond more satisfactorily to bactericidal drugs such as penicillin and streptomycin rather than bacteriostatic ones such as aureomycin and chloramphenicol. Such a bactericidal action is probably particularly important when the cellulose-humoral response, as in this case, was apparently defective.

For these reasons it is difficult to understand why the authors should have persisted first with repeated courses of aureomycin and secondly with 57 days of chloramphenicol in spite of repeated positive blood cultures. Apparently it did not occur to them, in spite of the results of the *in vitro* tests, that it would have been worth trying the effects of a drug such as streptomycin. Furthermore, it might also have been of avail to have given the latter drug in combination with massive doses of penicillin and benemid.—I am, etc.,

Waltham St. Lawrence, Berks.

M. ANTHONY PEYMAN.

Succinylcholine Chloride for Casualty Anaesthesia

SIR,—Referring to the use of succinylcholine chloride ("scoline") in casualty practice, my personal technique varies from that of Drs. Terence Vaz and J. M. Bishop (*Journal*, October 17, p. 885). Instead of using gas for induction and then giving succinylcholine chloride, I use the bare minimum of thiopentone and give succinylcholine chloride as much as is needed judging by the age and weight of the patient. By this method I have done over 200 cases of casualty anaesthetics for minor operations. There has not been any ill-effect in this technique. Recovery has been quick, and the patients have looked very fit. Vomiting has not occurred in one single case. Those who have criticized Drs. Vaz and Bishop have not given the matter a thorough trial. If it was dangerous there would have been at least 1 case in 200 which would have shown some ill-effects.

The details of these 200 cases will, I hope, be published soon.—I am, etc.,

Sheffield.

RASHBEHARI GHOSE.

Insulin Zinc Suspensions

SIR,—In view of the correspondence regarding the new insulin zinc suspension preparations, the following observations may be of interest. After the investigation into the use of these insulins on 28 patients which were reported by Dr. R. B. Wilson and myself (*Journal*, November 7, p. 1023), a further 42 patients were tried on these insulins in the Victoria Infirmary, Glasgow, prior to their general release on November 16. The majority of cases were similar to those in the original series, many requiring large doses of insulin (from 80 to 140 units in nine cases), but also included were nine new patients who had not previously received insulin. In this supplementary series satisfactory control was obtained with "lente" in 32, with "ultralente" in 2, with a mixture of lente and ultralente in 3, and with lente and "semilente" in 2, while in 3 cases change to the new insulin resulted in much poorer control.

In the combined series, comprising 70 patients, control was effected with a single daily injection of lente in 47 (67%), of ultralente in five (7%), and of mixtures of lente with ultralente or semilente in 10 (14%)—a total of 63 (88.5%). We have found, therefore, that lente is suitable for a majority of patients, but that the proportions of crystalline and amorphous insulins must be altered in an appreciable number of cases. In this regard, however, individual variations appear to be very great. Whereas lente insulin contains 30% amorphous, we found that the proportion of this in the mixtures required to control 10 of our patients were: 12%, 15%, 15%, 16%, 19%, 37%, 47%, 53%, 57%. I would agree with Drs. A. Stuart Mason and D. Verel (*Journal*, November 28, p. 1215) that it would be at least very premature to advocate an alteration in the proportions present in lente. Nevertheless, as very different proportions are required by some patients, the fact that ultralente is not available in the strength 80 units per ml. is a real disadvantage, as Drs. J. D. N. Nabarro and J. M. Stowers (*Journal*, November 7, p. 1027) have already pointed out.

It will be noticed that five of our cases were regarded as failures and it was interesting to find that Drs. A. Stuart Mason and D. Verel had had similar experience. One of these failures has been studied further. She had formerly taken 44 units of protamine zinc insulin, but immediately developed acute symptoms when given 44 units lente. Later it was found she obtained very good control, in fact considerably better than that with the previous protamine zinc, with a dose of 72 units lente. This produced slight hypoglycaemic symptoms in the forenoon and she is now being tried on a mixture with less amorphous insulin.

It seems that there are difficulties in changing some patients on to the newer preparations, and these difficulties require further investigation. It is to be hoped that a solution will be found, since eventually it seems very desirable that, as Dr. W. Oakley has said (*Journal*, November 7, p. 1021), both protamine zinc and globin insulins should be withdrawn. Admittedly no one would wish to change the regime of a diabetic under perfect control and so these older insulins may have to be continued for a considerable time, but I would suggest that they be abandoned forthwith for all new cases.

In our original paper we recorded no local insulin reactions with the new insulins. That such can occur, however, is apparent from the observations of Drs. Stuart Mason and D. Verel. Recently I have encountered two patients who have shown quite troublesome local reactions; both were new patients who had just started to take insulin, and it is not yet known whether this sensitivity will be overcome. Finally, it may be of some interest to record that in two of our patients using lente insulin marked fat atrophy was observed at the site of injection.—I am, etc.,

Glasgow.

IAN MURRAY.

Medical Needs in the Gold Coast

SIR,—Having only recently returned from the Gold Coast after two tours of service, I was particularly interested in Mr. Ian Fraser's view (*Journal*, October 31, p. 987) on the shortage of medical officers there. I congratulate him on his keen appreciation of the causes of the present situation, following only a short visit to the colony. From the last paragraph of Dr. K. A. Taylor's letter (*Journal*, November 28, p. 1217) I can only assume that he has not had recent experience of the Gold Coast, and I hasten to assure him that conditions have drastically changed within recent years.

I think that the most important thing necessary to bring about an improvement is a change of heart and attitude in the non-medical administrators, not only in the Colonial Office, but also in the Gold Coast Government (which is now largely African). The present situation is that a European doctor is very unlikely to be offered a pensionable appointment, though he may easily obtain one under contract. From the specialist's point of view this is very important. To take up a post in the colonies is to cut your bridges behind you, for after spending several years outside the United Kingdom it is virtually impossible to be re-employed as a specialist on your return. Drs. G. L. Alexander and H. G. Calwell both make this point (*Journal*, November 28, pp. 1216 and 1217). If the Gold Coast wants specialists it must offer permanent posts. As Mr. Fraser states, "The expatriate specialist is more valuable to the colony the longer he stays."

Arising from this is the present rigid adherence to the "staff list," which lays down that there should be so many surgeons, so many physicians, etc. This adherence is quite absurd. One African surgeon who had his F.R.C.S., and who had been doing specialist work, was kept waiting for three years before being promoted from medical officer to a vacant specialist post. The administrators should realize that it is easier to alter staff lists than to obtain specialists.

Whatever our views are on self-government, it is undeniable that the new administration in the Gold Coast has greatly increased the burden of the ordinary medical officer. This is not made easy to bear by the application of discrimination against expatriates when it comes to study leave. It is now almost impossible for an expatriate to obtain much leave. This causes frustration to the individual and an overall loss of officers to the Service. This should be borne in mind by those who appear to find Africanization more important than their country's needs.

The Gold Coast remains a great challenge to our profession. Disease, curable disease, is there in plenty, and yet there is only one doctor to more than 50,000 inhabitants. But before going to work there we must be assured of our position, and that we will not be asked to practise alongside unqualified persons. Perhaps the B.M.A. can help, but in view of the glib but efficient way they were dealt with by the Colonial Office in the discussion on pay for medical officers in the Colonial Service, only a few years ago, they will have to improve their bargaining power. However, I feel that in Mr. Ian Fraser they have a powerful weapon, equipped as he is with first-hand knowledge and his grasp of the long-overdue improvements.—I am, etc.,

Edinburgh.

D. B. SCOTT.

Press Publicity

SIR,—Many must deplore the sickening vulgarity which so often invests newspaper accounts of medical matters, such as remarkable operations. To members of the medical profession there are other grounds for concern; I mean the way in which the principal figures in such exploits are made to endure an improper publicity, and even to appear, by implication, to have given a "story" to the press.

Journalists, of course, have their living to earn, and know what the public wants; but the newspapers of this country still have a reputation for fundamental decency. If it could be made plain that a doctor's career might be in jeopardy were the Disciplinary Committee to take notice of these seeming improprieties, surely such objectionable practices would cease.—I am, etc.,

Birmingham, 15.

B. M. WILLMOTT DOBBIE.

More Social Medicine

SIR,—I must beg the courtesy of your columns to clear up a misunderstanding on the part of Dr. C. Metcalfe Brown in the criticism he makes (*Journal*, December 5, p. 1254) of my statement in the book *Social Medicine*, on orthodox treatment of diabetes and asthma.

Dr. Metcalfe Brown ascribes to me the very view (the mechanistic approach to medicine) that I am criticizing. In fact, only a few lines later I write: "All these explanations and cures aim at the parts of the body which are mainly affected; none is aimed at the fundamental causes of the disorder as a whole; and we therefore cannot rely on an infallible cure from these methods."

On diphtheria immunization, the point I make is that its introduction on any effective scale in this country was not made until 1941. This, in fact, is the year in which it was introduced by the Ministry of Health, and is quoted in all their official publications. Indeed, it was not until after this date that any appreciable reduction in diphtheria was made in this country.—I am, etc.,

London, N.W.6.

S. LEFF.

What is Ennepilo?

SIR,—In a Report to the General Board of Health on a preliminary inquiry into the sewerage, drainage, and supply of water and the sanitary condition of the inhabitants of the township of Middleton in Lancashire, the following statement occurs at page 18: "Other diseases have also been very prevalent, and assumed a malignant form, such as scarlatina, rubula, and ennepilo."

The report is by Robert Rawlinson, Esq., C.E., Superintending Inspector, and was printed in 1854 for H.M.S.O.

Can any of your readers suggest what disease may have been referred to by the term "ennepilo"?—I am, etc.,

Purley, Surrey.

J. CAUCHI.

The Pain of Perurethral Manipulations

SIR,—As the *British Medical Journal* does not reach here until six to seven weeks after publication, my comments on Dr. E. C. Atkinson's letter (*Journal*, August 22, p. 440) are somewhat belated. If perurethral manipulations are carried out with gentleness and skill, an efficient topical anaesthetic can render them in most cases almost painless. The anaesthetic agent, however, must be efficient. It is surprising that some people still use, and that some writers of quite recent textbooks still recommend, procaine for this purpose. Procaine is not a surface anaesthetic.

I agree with Mr. H. P. Winsbury-White (*Journal*, September 19, p. 674) that the cocaine-sodium bicarbonate-chlorbutol combination, used as he advises, is most effective. I also have used it for years. It should be realized, however, that no matter how effective the topical anaesthetic agent, passage of instruments along the urethra will generally cause pain if the bladder neck is put on the stretch, or if the calibre of the instrument used is more

than about 20 Fr. Like Dr. Atkinson, I have often wondered why some urologists make things so difficult for their patients and themselves by not using adequate anaesthesia.

Finally, Sir, may I make a plea for the use of the word "perurethral," which I have used throughout this letter? You will agree with me, I am sure, that no analgesic agent could mitigate the agony of the "transurethral" passage of an instrument.—I am, etc.,

Sydney, Australia.

D. C. TRAINOR.

Lead in Lollies and in Water

SIR,—In commenting further on this question your correspondent, Dr. L. R. L. Edwards (*Journal*, November 21, p. 1160) asks: "Is this distinction of a decimal place dependent in the lollies controversy on whether we regard the ice lolly as a solid or a liquid?" The answer to this is that to an appreciable extent it is, because there is strong evidence that lead is absorbed by the body more readily from simple liquids than from foodstuffs generally, in which it is more likely to be in organic combination. Possibly this outlook may have been a reason for the comparison with drinking water in your annotation (*Journal*, September 12, p. 613). Some ice lollies have a substantial content of solid constituents, but a large proportion of them are mainly water; whatever their solids content, they melt, and it therefore seems reasonable to regard them as liquid supplied in a frozen condition. Lead in significant quantity is not a natural constituent of foodstuffs. A further point which seems important is that ice lollies are consumed almost exclusively by young children, which is another reason for supporting the attitude in your annotation that the amount of lead allowed should be very low.

For drinking water an especially low limit is required because of the comparatively large volumes consumed. However, in mentioning "generally accepted maximum permitted quantity of lead in drinking water as 0.02 p.p.m." Dr. Edwards misunderstands my mention of this figure (*Journal*, October 31, p. 993), which was not given as a limit. As a maximum permitted quantity in water I mentioned the United States standard of 0.1 p.p.m.; the same figure would be widely accepted in this country.—I am, etc.,

London, S.W.1.

ROY C. HOATHER.

The Human Foot

SIR,—It was interesting to read that 14.4% of the recruits in the survey reported by Mr. D. Hewitt and Drs. A. M. Stewart and J. W. Webb (*Journal*, October 3, p. 745) suffered from foot defects prior to enlistment, and it seems worth recording the amount of trouble to which foot defects gave rise in a recent survey of a planned cross-section of the Army. The survey was carried out by the Army Operational Research Group and recorded the number of men who reported sick with foot trouble during a period of four weeks. The results at present available show that 2.1% per week of 1,246 recruits reported sick with foot trouble (the figure compares with 1.8% per week which I reported from a smaller survey of 623 infantry recruits over a period of six weeks).¹ Of 3,578 trained men studied in north-west Europe 0.9% per week reported sick with foot trouble. If one considers only those who reported sick with foot defects similar to those considered by Mr. Hewitt and Drs. Stewart and Webb, the figure for recruits was 0.6% per week and for trained men 0.07% per week.

In order to reduce the incidence of foot defects, it appears that prophylaxis must begin in early life, as Dr. Doris Craigmile emphasizes (p. 749). Meanwhile there is much that can be done to prevent existing defects from getting worse and from causing symptoms. The Army lays particular emphasis on the following measures: (a) Careful fitting of all footwear; (b) education in the care of the feet and footwear; (c) personnel selection for various occupations (taking into account each man's medical category); and (d) the use of conditioning courses, where necessary, to develop the musculature and to correct postural defects.

I am grateful to the Director-General, Army Medical Services, to the Scientific Adviser to the Army Council, and to the Superintendent, A.O.R.G., for permission to publish this letter.—I am, etc.,

Bristol.

GEORGE HUDSON.

Distinguishing a Psychopath

SIR,—I hesitate to add to the correspondence on the above subject (*Journal*, November 28 p. 1224), but Mr. Justice Hilbery says that he is collecting definitions of the term "psychopath" from various psychiatrists. I would like to add what is, I think, a commonsense one.

Mental diseases can be divided up into three large groups—mental deficiency, the neuroses, and the psychoses. A psychopath may not suffer from any of these and yet there is present a disease of the mind which tempts him to act in a certain manner on certain definite stimulation; which manner is clearly abnormal to his usual state and mental condition. Further, he frequently gives in to temptation, and neither risk nor punishment is a deterrent, and both are at times insufficiently potent to make him throw to one side his abnormal behaviour.

I shall now sit back and watch the legal and clinical pundits pull this to pieces, and pray that something good will come out of it.—I am, etc.,

Bromsgrove.

ANDREW SHEPHERD.

Peritonitis and Antibiotics

SIR,—Mr. N. C. Lake (*Journal*, December 13, 1952, p. 1307) has mentioned the development of general peritonitis in patients being treated with antibiotics. Since 1948 I have seen in negroes, mostly women, 16 cases of general peritonitis with moderate or absent fever, slight general symptoms, and moderate distension of the bowels, proved by aspiration of pus through an ordinary syringe. These were treated by parenteral penicillin and streptomycin in large doses together with aspiration of the pus every day or every second-day. All recovered, 14 without any operation whatever. One had a relapse one year later, the infection stemming from chronic salpingitis. The aetiology of the majority could not be ascertained. It may be said, however, that appendicitis is an unlikely cause, as it is extremely rare in the Central African negro, in whom symptoms of acute appendicitis, when they are found, more often have their origin in an inflammation of the iliac lymph nodes. In the local type of general peritonitis of low toxicity I feel that antibiotics are safer than an operation.—I am, etc.,

Stan, Belgian Congo.

A. BARLOVATZ.

Florence Nightingale House

SIR,—Advanced work for nurses was an important aspect of Florence Nightingale's nursing policy. She wanted nurses of all nations to be what she called "missionaries of health" by training others and raising the standard of health wherever they went.

Next year will see the centenary of Florence Nightingale's mission to the Crimea. The National Florence Nightingale Memorial Committee in the United Kingdom is seeking funds to establish permanently a fitting memorial to her noble work and inspiration. It is proposed: (1) to endow a residence for 44 nurses of all nations while undergoing advanced courses in London; and (2) to further the advance of nursing education by the award of scholarships.

Throughout the world similar national committees are raising funds for the award of scholarships to nurses. They are all part of the Florence Nightingale International Foundation, which is concerned with nursing education internationally. The successful candidates come to Britain and reside at Florence Nightingale House at 173-175, Cromwell Road, London, S.W.5, during their postgraduate training, adding an additional responsibility to the committee in this country; but this is the land of Miss Nightingale's birth and we must not fail in our duty to her memory.

We therefore appeal to everyone who appreciates her magnificent work for the nursing profession, and to everyone who has experienced the kindness of a nurse, and to everyone who wishes to express in tangible form their gratitude. Please either send a donation or write for a copy of an informative and illustrated booklet to: The Florence Nightingale Memorial Committee of Great Britain and Northern Ireland, 12, Whitehall, London, S.W.1.—I am, etc.,

London, S.W.1.

LUKE,
Chairman.

POINTS FROM LETTERS

The Human Foot

Dr. R. C. GREENBERG (Harold Hill, Essex) writes: I would submit that it is very questionable whether a pathological condition of flat foot, *per se*, exists at all ("Any Questions?" November 14, p. 1114). It is very rare indeed that a truly flat foot is ever seen in childhood, and even then if one gets the child to stand on its toes the arch is clearly formed. Consideration of the treatment of the almost non-existent syndrome of flat foot in childhood can hardly be separated from the general problem of the treatment of conditions of the feet and legs, such as pigeon toes, knock knees, bow legs, valgus ankles, and so forth. It seems, from what information is available, that we doctors carry out a great many manoeuvres for such conditions and most of them "get better"—which seems to mean the patients approach a socially acceptable norm of appearance and gait, but in fact they would get better just as soon without anything being done at all. It would seem reasonable to reserve treatment for the more gross abnormalities of form and those malfunctions which are definitely pathological and not just physiological variations of normal. The amount of time and money involved is, by the way, not inconsiderable. Luckily we can all agree on one thing: that whatever is done for a child's feet will be set at naught if those feet remain encased in unphysiological, ill-fitting shoes.

Dr. A. B. PARTRIDGE (Northampton) writes: In 1947 and 1948 I bought two pairs of war-surplus Army boots which I was told had been designed for African infantry who had never worn boots before. The soles are perfectly straight along the medial border, and a pair standing together is as broad as it is long. They are the only boots in which my toes really reach to the tip when walking steeply downhill, instead of my feet being pinched across the heads of the metatarsals. My usual tendency to ingrowing toenails ceases when wearing them. I have only one regret: that I did not buy a dozen pairs while they were available. Dr. G. G. Sherriff's comparison with the binding of women's feet in China (*Journal*, November 7, p. 1048) is a perfectly fair one. We must continue, perforce, to "bind" until manufacturers and the public realize that the straight inner border is the normal shape for the normal foot.

Cataract and Blindness

Dr. M. W. BIRD (Wells) writes: I am surprised that the observation in your annotation (*Journal*, November 7, p. 1038) on Professor Arnold Sorsby's report concerning the high incidence of cataract as a cause of blindness has not brought further comment in the *Journal*. Anyone who has anything to do with senile cataract patients knows that the reason for blindness is not mainly on account of inoperability due to age or illness but to the stubborn unwillingness of such patients to leave their home surroundings and undergo the ordeal of an operation in hospital. Surely, if these patients will not go to hospital, the ophthalmic surgeon should make an effort to go to them. I would suggest a well-planned system of domestic surgery. A team consisting of a surgeon and his assistant with a number of nurses should go out "on circuit." . . . I am sure that such a policy of domestic surgery would not be a retrograde step. With the aid of modern antibiotics, anaesthesia, and analgesia the results should be as good as, if not better than, the satisfactory percentages reported for surgery in rural India.

Insurance Against Misfortune

Mr. T. B. FITZ GERALD (Ashton-under-Lyne) writes: Would it not be a reasonable and possible arrangement for the Health Service, or individual hospitals, to insure patients against unavoidable risks, somewhat on the lines of "third party" insurance for road risks? The provision of reasonable financial help to such individuals and their families would soften the sting of misfortune, and should do much to lessen the urge to desperate or vindictive claims for damages.

Obituary

WILFRED SHAW, M.D., F.R.C.S., F.R.C.O.G.

We record with regret the death on December 9 at the age of 55 of Mr. Wilfred Shaw, surgeon in charge of the gynaecological and obstetrical department at St. Bartholomew's Hospital.

Born at Birmingham on December 12, 1897, the son of Isaac Shaw, J.P., Wilfred Shaw was educated at King Edward's School in that city and at St. John's College, Cambridge, which he entered with an open scholarship. He continued a brilliant student career at Cambridge by winning a foundation scholarship and exhibition and Wright's prize. In 1918 he obtained a first-class in Part 1 of the Natural Sciences Tripos, graduating B.A. in 1919. He then went on to St. Bartholomew's Hospital with a Shuter scholarship, and later won the Matthews Duncan gold medal, the Lawrence research scholarship and gold medal, and the Cattlin research fellowship. After qualifying in 1921 he held house appointments at Bart's and then continued his postgraduate studies in Vienna and Dublin. He was admitted F.R.C.S. in 1923, graduated M.B. in 1924, and proceeded to the M.D. in 1928, being awarded the Raymond Horton-Smith prize for his thesis. In 1930 he received a certificate of honourable mention for his dissertation submitted for the Jacksonian prize of the Royal College of Surgeons of England. Elected F.R.C.O.G. in 1932—he was a founder member—he served on the museum committee of the College from 1939 to 1949 and on the pathology committee from 1949 to 1952.

Shaw, who saw service as a surgeon-probationer in the Navy in the 1914-18 war, was so outstanding as a house-surgeon to Sir Charles Gordon-Watson that many of his colleagues thought he would make a career in surgery. He had a remarkably wide range of knowledge, and was a sound craftsman. But his chief interest lay elsewhere, and it is probable that Dr. Herbert Williamson, then physician-accoucheur to St. Bartholomew's, influenced Shaw's decision to take up the work of which he became so distinguished an exponent, his contribution to gynaecological pathology being especially noteworthy. After holding the appointment of chief assistant in the gynaecological department at St. Bartholomew's, Shaw was elected assistant physician accoucheur, and in 1946 became surgeon in charge of the gynaecological and obstetrical department of the hospital. He was also a member of the board of governors. Among other hospitals at which he held appointments were St. Andrew's Hospital, Dollis Hill, and Brentwood Hospital. When the B.M.A. held its Centenary Meeting in 1932 Shaw was one of the honorary secretaries of the Section of Obstetrics and Gynaecology, and five years later he acted as a vice-president of the same section at the Belfast meeting.

While still a comparatively young man Shaw was appointed examiner in midwifery for both Oxford and Cambridge, and later he acted in a similar capacity for the Central Midwives Board, the London Conjoint Board, the University of London, and the Royal College of Obstetricians and Gynaecologists. His rapid rise to fame as a gynaecological surgeon never obscured his interest in physiology and research, as his many outstanding contributions to the literature of his subject made very plain. He was the author of many papers—the last one published in this *Journal* being on the subject of the Martius operation for vesicovaginal fistula—and several books. His *Textbook of Gynaecology* reached its sixth edition in 1952 and his *Textbook of Midwifery* has run to three editions.

Shaw's approach to his subject was essentially that of a scientist. He was quiet in manner and retiring in nature, yet he had an inexhaustible interest in his students and their subsequent careers, and a devotion to his own hospital that found an outlet in many ways that were deeply appreciated by those who knew him well. The tragic death of his old chief, Dr. H. Williamson, came as a great shock to him at the time, and in a sense left him with a feeling of isolation. Those who belonged to the Decennial Club of Bart's which included his year will long remember his persistent but unobtrusive efforts as one of its secretaries to keep it alive and active.

He is survived by his widow, three sons, and a daughter.

We are indebted to Dr. MALCOLM DONALDSON for the following appreciation: The death at an early age of my friend and colleague, Wilfred Shaw, is not only a great loss to all his friends but deprives gynaecology of one of its most scientifically minded members. "Wilfred," who was nearly always spoken of by his Christian name, was never more happy than when he was working in his laboratory, where he did his classical work on the histology of the ovary. This is not the time to recite a list of all the scholarships and gold medals that he was awarded, but mention must be made of his two textbooks, which are so popular that many editions have been published: he was just completing yet another edition at the time of his death. He will be mourned by his colleagues, many friends, and patients, and our heartfelt sympathy goes out to his widow and children.

J. H. writes: The untimely death of Wilfred Shaw has deprived British gynaecology of one of its best brains. Scientist, investigator, anatomist, pathologist, surgeon, and author are titles to which only one or two men in his specialty can lay claim: his versatile genius achieved them all.

Others will have chronicled the long and brilliant list of his academic awards. His best-selling *Textbook of Gynaecology* and his many famous publications in this and other journals made his name a household word not only to every student but to a wide international public. His operative sessions at Bart's were thronged with a polyglot and many-coloured audience, and here he delighted to demonstrate his latest modifications of some operation for prolapse or stress incontinence. On these occasions he invited and enjoyed criticism, and always maintained that he learned as much from his juniors as he taught them.

Essentially a shy, modest, and sensitive person, he was at his most natural when alone with one or two friends, with whom he would discuss a bewildering and fascinating range of subjects. He had a great sense of humour and never tired of pulling his own leg, as well as those of his beloved students, though nothing pleased him more than a deft repartee from his victim. His memory was remarkable, and he never forgot the name of any of the vast

number of students who passed through his hands. This uncanny gift enabled him to imprint indelibly upon his mind the published work of his specialty, so that his erudition and accuracy startled and confounded his opponent.

He knew and loved every stone and shadow in the Square at Bart's; here of a summer's afternoon he delighted to stand by the fountain and receive the greetings of all who passed that way. As we approached, his face would light up with a welcoming grimace and we would tarry a while in conversation. Having a word with Wilfred often implied more than pleasant chatter, and a few minutes of his shrewd advice and sound wisdom have resolved many a problem and helped many a career.

That a spirit so young and gay should be mortally wounded for the last two years did not daunt his matchless courage. Knowing his days numbered by a disease whose advance he observed almost weekly, he set himself the task of writing one last book. It was a race against time, but he was always a quick operator, and he has fulfilled his contract.

T. Y. FINLAY, M.D., F.R.C.P.Ed.

Dr. T. Y. Finlay, former maternity and child welfare medical officer in Edinburgh, died there on November 28 at the age of 71. Of Scottish parentage, Thomas Yule Finlay was born in Paris, where he spent his early years. When the family returned to Edinburgh he attended the Royal High School and then proceeded to the University, where he graduated M.B., Ch.B. in 1907, taking the M.D. in 1912 with a thesis on haemophilia, for which he received a high commendation. He was elected F.R.C.P.Ed. in 1927.

After graduation Finlay held resident posts at many of the hospitals in the city, where he came under the influence of such stalwarts as John Wyllie, J. W. Ballantyne, John Thomson, and Claude Ker, of whom he often spoke, and always with affection and gratitude. From 1913 till 1919 he was principal medical officer and medical superintendent of the Craiglockhart Poorhouse and Hospital, Edinburgh, where he carried out much valuable and original work among the children resident there. In 1915 he became associated with the Edinburgh Infant Health Centres Committee and acted as one of that organization's medical officers for infant welfare work.

Finlay was the unanimous choice of Edinburgh Corporation for the post of medical officer in charge of the maternity and child welfare section of the public health department when that section was brought into being in 1919. Under his wise guidance and direction and his happy knack of knitting voluntary and official activities into a co-ordinated whole, the section steadily extended its field, and the results achieved were remarkable. When he retired in 1947 well-deserved tributes were paid to his outstanding services on behalf of the mothers and young children of the city.

In 1919 he was appointed a member of the Scottish Committee on Child Life of the Medical Research Council and carried out nutritional studies on infants and young children for that body. In 1922 he was elected an assistant physician to the Edinburgh Royal Hospital for Sick Children, a post he held until 1932, when he was appointed senior assistant physician to the local municipal hospitals' children's unit. From 1939 till 1947 he was also honorary associate paediatrician at the Simpson Memorial Maternity Hospital. He was lecturer and examiner on diseases of children and child welfare at the university and at many other teaching organizations in the city. Though he may not have

published a great deal, his papers were always carefully prepared and were accurate and well expressed.

Recognition of his sterling work on the care of children came when he was elected a member of the Association Internationale de Pédiatrie Préventive in 1933, and an honorary member of the British Paediatric Association, of which he was an original member, in 1947, and of the Scottish Paediatric Society. Throughout his whole medical career in Edinburgh he was closely associated with many local voluntary organizations concerned with the care of mothers and children, and after his retirement he flung himself wholeheartedly into the work of many of these. He was one of the founders, in 1923, of a voluntary committee to promote adoption of children, and this committee had its headquarters in a room in his department. Later it became known as the Scottish Association for the Adoption of Children, and he was its honorary medical officer and, for a few years after he retired, its treasurer. He was a member of the committee appointed this year by the B.M.A. to consider the present law in relation to adoption, and his wide experience was of great value during its deliberations.

The pioneering spirit of Dr. Finlay was doubtless kindled by his brother-in-law, Gaston Variot, of Paris, one of the leaders in France of the infant welfare movement, but it was certainly set aflame by Ballantyne and Thomson, to whom he always acknowledged his deep indebtedness. He spent his whole life among children, whom he loved and to whom he gave of his best. His approach to the child, well or sick, was gentle and sympathetic, his examination thorough. Diagnosis was based essentially on the clinical findings, supplemented where necessary by laboratory and other aids. With difficulties in infant feeding he was at his best, and his management and supervision of marasmic infants were models of care and patience.

Simple in his faith, he was a keen and active member of the Church of Scotland. A staunch upholder of family life, he was supremely happy in his own family circle, and the sympathy of his colleagues and friends goes out to his widow, daughter, two sons, and grandchildren.

By the death of Dr. CHARLES HOPE WADDELL at Coseley on October 21 at the age of 74 the Black Country of South Staffordshire loses one of its outstanding practitioners. Although born in California, he spent his boyhood in Northern Ireland, and qualified in 1906 from Queen's College, Belfast, with the Irish triple licentiate. After holding a resident appointment at the Royal Victoria Hospital, Belfast, he came to England and learnt the disciplines of general practice as an assistant at Hednesford, Staffordshire. Forty years ago he entered his real life's work when he took over the practice at Coseley, an industrial village in the heart of the Black Country, and there he continued till he handed over the reins to a younger colleague two years ago—apart from a period of service with the R.A.M.C. in the war of 1914-18. A man of outstanding personality, Dr. Waddell exemplified the immense influence for good that can be wielded by a practitioner long resident in, and devoted to, his locality. Not only did he serve his patients to the utmost of his ability and with untiring energy, but he also controlled them, and his affectionate nickname of "the King of Coseley" reflected this paternal relationship, which indeed is one of the hallmarks of a good doctor. Apart from his professional work, he played a leading part in the public life of the district, serving as medical officer of Coseley for a time

and later as a councillor, and in the days of the voluntary hospitals he was the mainspring of many local activities devoted to their support. A loyal member of the British Medical Association, there was no more regular attendant at meetings, and he was chairman of the South Staffordshire Division in 1926-7, as well as being for many years a member of the local insurance committee. Dr. Waddell was a man of great though sometimes rugged integrity, whole-hearted and untiring in all he did, occupying a niche of his own in our affections, so that his death leaves those of us who knew him well with a sense of permanent loss. At the funeral service the parish church of Coseley was packed by colleagues and friends from hospital and practice and local authorities, and by his old patients, all of whom were there to pay respect to the passing of a great personality.—J. H. S.

Dr. D. R. ALLISON, consulting physician to Withington Hospital, Manchester, died suddenly on November 9 at the age of 50. David Rhodes Allison, who was a Yorkshireman, was born on November 25, 1902, and was educated at Leeds University, where he graduated M.B., Ch.B., with honours, in 1925. In the same year he obtained the London conjoint diploma, and in 1926 proceeded to the M.D. After holding the post of house-physician at the General Infirmary at Leeds he went into general practice at Filey, in Yorkshire. In 1939 he obtained the M.R.C.P. with the object of becoming a consulting physician, and shortly afterwards he left Filey on being appointed chief clinical assistant at Manchester Royal Infirmary. Early in 1942 he entered the R.A.M.C. as a lieutenant and saw service in West Africa and India. He relinquished his commission in 1945 because of ill-health, having attained the rank of lieutenant-colonel. On return to civilian life he became for a time honorary physician to the Manchester Northern Hospital and visiting physician to Oldham Royal Infirmary, and was then elected consultant physician to Stockport and Withington Hospitals, and, more recently, to Stepping Hill Hospital, Stockport. Because of his ability, integrity, and warm personality he soon built up an extensive consulting practice. He was especially interested in cardiology and in the psychiatric aspects of medical conditions, and was the co-author with the late Dr. R. G. Gordon of a book entitled *The Uses and Limitations of Psychotherapy*. In 1950 his paper on pain in the chest wall simulating heart disease was printed in this *Journal*. His fatal illness was sudden and quite unexpected, for right up to the day of his death he was apparently in good health and the full vigour of life. He will be remembered by his friends as a kind and loyal colleague who would take infinite pains to help, and by his many patients as a good and kindly doctor of outstanding ability and integrity. He leaves a widow, a daughter, and a son, who is also a doctor.—E. H. K.

Dr. F. W. JOHNSON died at his home at Bawtry, near Doncaster, on November 17, at the age of 77. The son of the late Dr. W. J. Johnson, Frederick William Johnson was born at Tickhill, Yorkshire, on October 14, 1876, and was educated at King Edward VI School, Retford, and at the Yorkshire College, Leeds, then a constituent college of the Victoria University of Manchester, where he graduated M.B., Ch.B. in 1899. After working as house-surgeon to Mr. Berkeley (later Lord) Moynihan at the General Infirmary at Leeds he went to South Africa to serve as a civil surgeon in the South African war, but was invalided home in 1901 after an attack of enteric fever. He then joined his father in practice at Bawtry. Always an enthusiastic member of the volunteer movement, he had remained attached to the Sherwood Foresters after his return from South Africa, and on the outbreak of war in Europe in 1914 he went to France with the R.A.M.C. From 1917 to 1919 he commanded a field ambulance, and was demobilized with the rank of lieutenant-colonel. In the last war he joined the Home Guard as medical officer to the South Yorkshire sub-area, with the rank of lieutenant-colonel. An active member of the British Medical Association for some 40 years, Dr. Johnson was chairman of the Doncaster Division from 1929 to 1936, and he was a former president of the Doncaster Medical Society.

It was very seldom that he allowed anything to interfere with his attendance at meetings. He had the cheerful ruddy complexion of the countryman, a figure which always conveyed the hint of a military training, and the shrewdness and sagacity of the very best type of general practitioner. Many of his colleagues had the privilege of serving under his chairmanship of the Ministry of Labour and National Service board at Doncaster from 1939 to 1952, and were always impressed by his rapid and accurate clinical assessments: few men can ever have made fewer mistakes. A devoted churchman, he was for many years a churchwarden at Bawtry. In his early days he enjoyed playing football and cricket, and throughout his life he was a keen naturalist and gardener. The B.M.A. has lost a staunch supporter, general practice a wise, unassuming, and sterling character, and his colleagues a loyal friend. He leaves a widow, one son, Dr. F. H. W. Johnson, who carries on the practice, and three daughters.—R. W. L. W.

Dr. CAROLINE WALKER, who died suddenly on November 26, was one of those who helped pioneer the way for women to be doctors, and one of the oldest medically qualified women in the West of England. She was the trusted friend of many. Theodosia Caroline Green was born in January, 1872, one of the eleven children of the Reverend John H. B. Green, rector of Normanton-le-Heath, Leicestershire. From school days she was always one who was prepared to plough a new, and at times an unconventional, furrow. At school she studied geology on her own, as there was no one to teach it. When she decided to study medicine she again found difficulties in her way, and had to study in various places, first in London at the London School of Medicine for Women (now the Royal Free Hospital) and later at the Rotunda Hospital, Dublin, where she obtained a licence in midwifery in 1895. Later in the same year she took the Scottish triple qualification, and then went on to Brussels, where she graduated M.D. in 1896. After qualification she took a post as junior assistant medical officer at the Lincolnshire County Asylum, an event which evoked a newspaper headline, "Woman Doctor Comes to Lincoln." In 1900 Caroline Green married Mr. Cyril H. Walker, then an ophthalmic surgeon practising in Bristol. For the next 30 years, especially during the first world war, she busied herself with infant welfare work, and acted as medical officer at several clinics in Bristol. For some years she lectured in hygiene in the department of education of Bristol University. She became well known, not so much for academic achievement or clinical skill as for her very sound advice, which was often sought and freely given on a wide range of subjects related to medicine. She was the much respected member of many committees, some medical and some connected with social welfare. Most of all, perhaps, her wise and balanced advice was valued during the 15 years that she was chairman of Walker Dunbar Hospital Committee. However, it was not only hospitals and welfare organizations which received her help: her friendly counsel was sought by many, particularly young women doctors, in whom to the end of her life she had a special interest. After an accident in 1938 she became a partial invalid, but in spite of increasing pain and disability from arthritis she remained resolutely cheerful, her courage and fortitude encouraging many in similar circumstances. Her generosity, sense of humour, and high Christian principles brightened every part of her life and work, whether for medicine or for her local church. We offer our deepest sympathy to her husband and to their two sons, one a doctor, and three daughters. One grandson is also a member of the medical profession.—D. H. T.

Professor HANS ISELIN, the eminent Swiss surgeon, died at Lörrach, Baden, on November 22, at the age of 75. He was born on February 21, 1878. His family were well known in Basle, and on his mother's side he was a descendant of Hans Holbein the younger. He studied medicine at Geneva and Kiel, graduating in 1902, and then joined the staff of the medical faculty at Basle University and later became chief of the surgical polyclinic in that city. He was

also surgeon to St. Clara-Spital and to St. Elisabeth Hospital, Lörrach, Baden. In 1918 he was given a professorial chair at Basle to develop the teaching of traumatic surgery, and he served for a time as dean of the medical school. Iselin was a pioneer in the use of radiotherapy in surgical tuberculosis and in the post-operative treatment of cancer of the breast. He made notable investigations on growth disturbances in rats after parathyroidectomy and published many papers on fractures and dislocations, bone and joint diseases, and traumatic surgery. He remained in active practice to the end of his life and was operating at the hospital in Lörrach on the day before he died.

Medico-Legal

CHOKED BY FAULTY MAGILL TUBE

[FROM OUR MEDICO-LEGAL CORRESPONDENT]

At an inquiry held recently by the Sheriff-Substitute of Lanarkshire into the death of Miss Margaret Elliott, aged 32, in the Southern General Hospital, Glasgow, death was found to be due to a defect in the Magill tube used for the administration of a general anaesthetic which had never previously been known to the consultant anaesthetist, Dr. J. R. Gallie.

Miss Elliott was suffering from a recurrence of symptoms of cervical rib which had previously been much improved by operation, and was admitted to hospital for further operation to relieve pressure on the nerves running down from the neck to the left arm. Anaesthesia was induced by thiopentone, nitrous oxide, and oxygen, and 1.5 ml. "scoline" intravenously, and the assistant anaesthetist, after inflating the patient's lungs with oxygen, passed a cuffed Magill's endotracheal tube connected to a semi-closed anaesthetic apparatus. The tube was visually inspected on removal from the sterile drum in which it was stored, and the cuff on test inflation with the standard 10 ml. of air appeared to be in good condition. It had probably been used only once before. A throat pack was inserted round the tube to keep it in position, and anaesthesia was maintained with nitrous oxide, oxygen, and "trilene."

After some thirty minutes the anaesthetist noticed a sudden diminution in the volume of tidal air indicating obstruction of the airway. He deflated the cuff of the Magill tube, which caused the obstruction to disappear, and called the surgeon's attention to the obstruction. The operation was suspended, and cardiac massage restored the pulse, which had stopped. Voluntary respiration, which had also stopped, was re-established within a few minutes, but although the patient survived for eleven days her condition gradually deteriorated and consciousness never returned.

Section of the brain on necropsy showed mottled pink degenerative changes of the cortex and basal nuclei, and Dr. W. P. Weir, pathologist to the Royal Alexandra Infirmary, Paisley, concluded that death was due to anoxaemia of the brain following cessation of respiration and circulation during the general anaesthesia for the operation.

When the Magill tube was examined after the operation it was found that the rubber of the cuff was perished and that when the cuff was inflated the perished rubber blew up into a soft blister or bulb. Dr. Weir thought that this must have slid down the trachea and either pressed the open end of the tube against the side of the trachea and so blocked it, or else must itself have covered and blocked the end of the tube. A movement of the tube during the operation would have been sufficient to move the blister in this way. The tube had been kept after sterilization in the autoclave in the recognized way, and the only cause suggested for the deterioration in the rubber of the cuff was that a drop of ether or trilene, both of which are rubber solvents, might have got on it. This would explain why the defect was not shown by the test inflation of the cuff before the tube was used. Dr. Gallie in his evidence at the inquiry said that it was the first time that he had ever seen a rubber cuff fail in this way.

Medical Notes in Parliament

Fluoridation Experiments

Mr. IAIN MACLEOD, Minister of Health, informed Mr. C. R. HOBSON on December 10 that before fluoride was added to the water supplies of selected communities baseline information on the incidence of dental caries in those communities would be obtained and any comparable communities that could be used as controls. Other matters receiving consideration included whether a survey of fluoride excretion in the urine of representative children and adults of all age groups throughout the country should be made in order to assess the required dose of fluoride to be added to water supplies; how adequate supplies of fluorides in the most suitable form will be obtained; and what safeguards there will be against errors in dosage and undue exposure of the operating personnel to the materials handled.

Vaccination Deaths

Mr. S. P. VIANI asked the Minister of Health, in regard to the age group 0-5 for each of the years 1938 to the latest date available, how many death certificates were received on which the words vaccination, vaccinia, post-vaccinal encephalitis, or any other association with vaccination appeared, and how many of these deaths were assigned to vaccinia, generalized vaccinia following vaccination, post-vaccinal encephalitis, or other complications of smallpox vaccination. Mr. IAIN MACLEOD on December 8 gave him the following details:

Year	Death Certificates with mention of Vaccinia, etc.	Deaths Assigned to Vaccinia, etc.
1938	6	5
1939	1	1
1940	7	6
1941	4	4
1942	5	3
1943	4	4
1944	9	8
1945	6	5
1946	3	1
1947	10	6
1948	6	4
1949	1	1
1950	—	—
1951	6	4
1952	3*	3*

*Includes one infant who had not herself been vaccinated.

Health in British Guiana

Mr. RONALD RUSSELL asked the Secretary of State for the Colonies what improvement had been achieved in the health of the people of British Guiana in recent years. Mr. LYTTLETON stated on December 8 that, of the major communicable diseases in British Guiana, malaria had decreased substantially from 15,490 notified cases and 290 deaths in 1947 to 181 cases and 28 deaths in 1952. There had also been a decline in the number of notified cases of enteric fever and pulmonary tuberculosis. Other detailed improvements were too complex to summarize, but over the past eight years the infant mortality rate had fallen from 101 per thousand live births to 82, and over approximately the same period the expectation of life at birth had increased by four years.

Welfare Foods

Major G. LLOYD-GEORGE, Minister of Food, who was asked what he was doing to encourage the consumption of welfare foods, replied on December 7 that he welcomed the opportunity of assuring the House that by all the means at his disposal the Ministry continued to emphasize the importance of welfare foods. Mr. SOMERVILLE HASTINGS asked him to state in a few words how he was going to encourage an increased consumption of welfare foods. Major LLOYD-GEORGE said that many methods had been used for a considerable time—posters, talks, and full information to

expectant mothers. Every possible method was still being used, and the percentage of take-up of the various welfare foods remained much the same and had sometimes increased.

Student Nurses' Call-up

Mr. R. J. MELLISH asked the Minister of Labour on December 8 whether he proposed to exempt from national service all those employed as student nurses in mental hospitals, in view of the shortage of mental hospital staff. Mr. HAROLD WATKINSON, the Parliamentary Secretary, replied "No," but the call-up of such students could be deferred until they had completed their training.

Rejections

The numbers of men called up for national service, and the numbers rejected on medical grounds, in the past five years, it was stated by the Parliamentary Secretary, Ministry of Labour, on December 1, have been: 1948—150,900 (rejected, 27,750); 1949—166,600 (rejected, 36,370); 1950—174,200 (rejected, 47,314); 1951—168,651 (rejected, 43,856); 1952—170,384 (rejected, 42,829).

Hospital Service Reserve

Mr. IAIN MACLEOD, Minister of Health, announced on December 3 that the Queen had been graciously pleased to assume the title of Head of the National Hospital Service Reserve in the United Kingdom, thus extending to that Reserve the honour already conferred upon the Civil Defence Corps.

Universities and Colleges

UNIVERSITY OF OXFORD

The Theodore Williams Scholarship in Physiology has been awarded to Roger James Robinson, scholar of Balliol College, and Kenneth Bryson Roberts (Lincoln College) has been re-elected to the Philip Walker Studentship in Pathology for two years from October 1, 1953.

UNIVERSITY OF CAMBRIDGE

Dr. B. H. G. Hayward has been elected into a second John Lucas Walker Studentship for one year from June 1, 1952, and into the same studentship for two years from June 1, 1953.

In Congregation on October 17 the degrees of M.B., B.Chir. were conferred on G. G. K. Parsons.

UNIVERSITY OF ST. ANDREWS

At a Graduation Ceremony held on October 9 the degree of M.D. (with commendation) was conferred upon J. A. Gillespie.

UNIVERSITY OF LONDON

The following candidates have been approved at the examinations indicated:

ACADEMIC POSTGRADUATE DIPLOMA IN CLINICAL PATHOLOGY.—P. B. Adamson, J. D. Arneaud, L. R. Chapman, S. K. Chopra, B. R. Davis, N. U. C. Godfrey, W. F. Hunter, S. Jatinandana, N. C. March, Mary Ralston, W. A. Russell, M. P. K. Shoorbridge, J. C. Squires.

EXTERNAL DIPLOMA IN CLINICAL PATHOLOGY.—M. C. Berenbaum, M. Datta, H. J. Woodliff.

The following candidates at the London School of Hygiene and Tropical Medicine have been approved at the examinations indicated:

ACADEMIC POSTGRADUATE DIPLOMA IN PUBLIC HEALTH.—P. P. M. Browne, J. Clearkin, K. A. Rahman, J. T. Subramaniam, D. R. Thomson, D. Ungar.

ACADEMIC POSTGRADUATE DIPLOMA IN TROPICAL MEDICINE AND HYGIENE.—P. Sirivorasarn.

UNIVERSITY OF WALES

The Council of the Welsh National School of Medicine has appointed Cecil Wilfred Dickens Lewis, M.Ch., F.R.C.S., who is at present Lecturer in Surgery, to be Senior Lecturer in Surgery at the School.

INFECTIOUS DISEASES AND VITAL STATISTICS

Summary for British Isles for week ending November 28 (No. 47) and corresponding week 1952.

Figures of cases are for the countries shown and London administrative county. Figures of deaths and births are for the 160 great towns in England and Wales (London included), London administrative county, the 17 principal towns in Scotland, the 10 principal towns in Northern Ireland, and the 14 principal towns in Eire.

A blank space denotes disease not notifiable or no return available. The table is based on information supplied by the Registrars-General of England and Wales, Scotland, N. Ireland, and Eire, the Ministry of Health and Local Government of N. Ireland, and the Department of Health of Eire.

CASES in Countries and London	1953					1952

* Measles not notifiable in Scotland, whence returns are approximate.
† Includes primary and influenza pneumonia.
‡ Includes puerperal pyrexia.

Vital Statistics

Northern Ireland—Second Quarter

According to the Registrar-General's return of vital statistics for the quarter ending June 30 the birth rate was 22.9 per 1,000 population, an increase of 0.7 over the rate for the same period of 1952. The general death rate was at 10.8 per 1,000 of the population as compared with 10.7 for the corresponding period of 1952, but it is 0.4 below the average rate for the second quarters of the previous five years. The infant mortality rate of 37 per 1,000 live births was the lowest ever recorded for the June quarter, as was the death rate from tuberculosis (0.22 per 1,000 population).

Graphs of Infectious Diseases

The graphs below show the uncorrected numbers of cases of certain diseases notified weekly in England and Wales. Highest and lowest figures reported in each week during the nine years 1944-52 are shown thus -----, the figures for 1953 thus ———. Except for the curves showing notifications in 1953, the graphs were prepared at the Department of Medical Statistics and Epidemiology, London School of Hygiene and Tropical Medicine.

Infectious Diseases

An increase of 98 in the number of notifications of whooping-cough, from 2,510 to 2,608, and 82 for measles, from 793 to 875, and a decrease of 129 for scarlet fever, from 1,613 to 1,484, were reported in England and Wales during the week ending November 28.

The largest variations in the trends of whooping-cough were a decrease of 49 in the number of notifications in Lancashire, from 276 to 227, and a rise of 33 in Essex, from 153 to 186. The largest rises in the incidence of measles were 59 in Norfolk, from 16 to 75, due to an outbreak of 65 cases in Norwich C.B., and 32 in Southampton County, from 6 to 38, due to an outbreak in Southampton C.B. with 21 notifications. The only large variation in the trends of scarlet fever was a fall of 32 in Middlesex, from 84 to 52. 16 cases of diphtheria were notified, 12 fewer than in the preceding week. The chief feature of the returns was a fall in Birmingham C.B. from 7 to 3. 5 cases were notified in Staffordshire. In Scotland 12 cases of diphtheria were notified; of these 9 were reported from Glasgow.

During the week 77 cases of acute poliomyelitis were notified. These were 4 fewer for paralytic and 7 fewer for non-paralytic cases than in the preceding week. The largest returns were Somersetshire 12 (Wincanton R.D. 7), Lancashire 8, London 7, Dorsetshire 6 (Poole M.B. 3, Wimborne and Cranborne R.D. 3), Staffordshire 5, Warwickshire 5, and Yorkshire West Riding 5.

399 cases of dysentery were notified, being 37 more than in the previous week. The largest centres of infection were Yorkshire West Riding 73 (Bradford C.B. 45), London 64 (Islington 12, Southwark 17), Lancashire 52 (Manchester C.B. 15, Bolton C.B. 14), Norfolk 42 (Norwich C.B. 42), Essex 35 (Braintree R.D. 14, Colchester M.B. 11), and Middlesex 34 (Willesden M.B. 34).

Week Ending December 5

The notifications of infectious diseases in England and Wales during the week included scarlet fever 1,549, whooping-cough 2,595, diphtheria 13, measles 886, dysentery 445, acute poliomyelitis 65, paratyphoid fever 1, and typhoid fever 3.

The Services

A Supplement to the London Gazette has announced the following awards:

Second Clasp to the Army Emergency Reserve Decoration.—Major W. H. Valentine, O.B.E., R.A.M.C.

First Clasp to the Army Emergency Reserve Decoration.—Major (Honorary Lieutenant-Colonel) A. W. Davidson, M.C., and Major R. L. Sadler (retired).

Army Emergency Reserve Decoration.—Major C. M. Fraser (retired).

The names of Captains E. D. Mackie and C. L. Tutty, R.A.M.C., appear in a list of those mentioned in dispatches in recognition of gallant and distinguished services in Korea during the period July 1 to 27, 1953.

Medical News

Nuffield College of Surgical Sciences.—At a meeting of the council of the Royal College of Surgeons on December 10 it was decided to proceed at once with the building of the Nuffield College of Surgical Sciences. It is almost exactly five years since the announcement of Lord Nuffield's magnificent gift of £250,000 for the purpose of building a residential college where young surgeons, particularly from overseas, could live while undertaking advanced study or research. The new college will adjoin the present premises of the Royal College of Surgeons, on its east side. A drawing of it was printed in our issue of July 2, 1949 (p. 27).

Dope-peddling in Britain.—The extent of the illicit traffic in narcotic drugs in Britain is much less than reports in the lay press might suggest. According to the United Kingdom's annual report to the United Nations on the subject, last year there was no evidence of any regular or organized traffic in Britain. Hemp and opium remained the drugs most frequently encountered by the police; of the 87 persons convicted of having hemp 67 were of African, Indian, or West Indian origin, while all except three of the 60 convictions relating to opium concerned Chinese, most of them in Liverpool. It is clear that regular "doping" by adolescents is not the problem here that it is in New York. The case of an 18-year-old plumber's mate, if the statements made in court were true, is said to be the "first recorded instance in the United Kingdom of an adolescent regularly smoking hemp." The report states that 297 addicts were receiving drugs from medical sources in 1952. In the non-professional classes women addicts outnumbered the men by nearly two to one, but among 75 addicts from the professional classes (72 doctors, 2 dentists, and one pharmacist) only three were women.

Buckston Browne Prize Essay.—The Council of the Harveian Society of London has selected "The Medical Problems of the Overweight Patient" as the subject for the Buckston Browne Prize essay. The prize, which consists of a medal and £100, is open to any member of the medical profession registered in the British Isles or Dominions and is limited to candidates under 45 years of age. Essays must be sent in by December 1, 1954. Further particulars may be obtained from the hon. secretaries, Harveian Society of London, 11, Chandos Street, Cavendish Square, London, W.1.

Scientific Exhibition, Glasgow, 1954.—Those proposing to exhibit at the B.M.A. Annual Meeting in 1954 should apply as soon as possible. In view of the joint meeting with the Canadian Medical Association in Toronto in 1955 there will be no other B.M.A. Scientific Exhibition in this country until 1956. Full details and application forms are obtainable from the Secretary, British Medical Association, B.M.A. House, Tavistock Square, London, W.C.1.

102 Not Out.—At the Whittington Hospital, London, on December 5 an operation was performed to repair a fractured femur in an old lady of 102. The next day this remarkable patient was up for 20 minutes, and the latest news is that nine days after her operation she is up for three hours each day.

Dangerous Drugs Act, 1951.—By an Order under this Act, which came into force on December 14, the salts of N-allylnormorphine and any preparation containing this substance have been brought within the provisions of Part III of the Act.

David Anderson-Berry Prize.—On December 4 the president of the Royal Society of Edinburgh, Professor James Kendall, F.R.S., announced the award of the David Anderson-Berry Prize to Dr. John Read, of the Dunedin Medical School, New Zealand, for his work on the relationship between oxygen tension and the effect of x rays on the tissues.

Council of the Royal Society.—In addition to the president, Dr. E. D. Adrian, the following members of the medical profession are among those who have been elected to the council of the Royal Society: Professor E. G. T. Liddell, Professor R. A. McCance, and Sir Edward Mellanby.

British Association of Otolaryngologists.—The following have been elected officers for 1953-4:—*president*: Mr. V. E. Negus; *immediate past president*: Mr. H. V. Forster; *vice-president*: Mr. I. Simson Hall; *honorary secretary*: Mr. Myles L. Formby; and *honorary treasurer*: Mr. W. A. Mill.

Medical Golfing Society.—At the annual general meeting Mr. George Armitage was elected president and Brigadier H. L. Glyn Hughes captain for the coming year.

London Medical Orchestra.—The Orchestra is now holding rehearsals on Thursdays at 7.45 p.m. at the George Eliot School, Marlborough Hill, London, N.W.8. More playing members are wanted, and should apply to the secretary, Dr. E. V. Slaughter, 6, Oxford Court, Queens Drive, London, W.3.

COMING EVENTS

A Seminar on Foot Health will be held by the Central Council for Health Education at St. John House, Collingham Gardens, London, S.W.5, from February 23 to 27, 1954. The programme will include a lecture on "Foot Function" by Mr. T. T. Stamm, films and discussions, and visits to London shoe factories.

The Ophthalmological Society.—The annual congress will be held at Durham University from April 22 to 24, 1954. The main subject for discussion will be "Inflammatory Vascular Diseases Affecting the Eyes." There will also be short symposia on "Cyclodiathermy," "Changes in the Incidence of the Eye Affections of Coal Miners in the Past 25 Years," and "Gonioscopy."

British Association of Physical Medicine.—The annual meeting will be held at King's College Hospital, London, S.E.5, on April 30 and May 1, 1954. Further information may be obtained from the honorary secretary, 45, Lincoln's Inn Fields, London, W.C.2.

Association of Surgeons of Great Britain and Ireland.—The annual meeting will be held in Leeds from May 13 to 15, 1954. The subjects to be discussed include: "Hiatus Hernia," "Ulcerative Colitis," "Exophthalmos," and "Duodenal Diverticula." Further information may be obtained from the honorary secretary of the association, 45, Lincoln's Inn Fields, London, W.C.2.

The South African Medical Congress will take place in Port Elizabeth from June 21 to 26, 1954. Part of the programme is expected to take the form of a symposium on rehabilitation. Those who would like to contribute papers at the Congress are asked to communicate as soon as possible with M. G. Woolf, Organizing Secretary, P.O. Box 1137, Port Elizabeth, South Africa.

International Association of Gerontology.—The third congress of the association will be held in London from July 19 to 23, 1954. Further information may be obtained from the organizing Secretary, Mrs. A. Humpage, B.M.A. House South, Tavistock Square, London, W.C.1.

SOCIETIES AND LECTURES

A fee is charged or a ticket is required for attending lectures marked ●. Applications should be made first to the institution concerned.

Monday, December 21
ROYAL EYE HOSPITAL.—5 p.m., Dr. T. H. Whittington: *Convergence, Heterophoria, and Factors Affecting Binocular Vision.*

Tuesday, December 22
INSTITUTE OF DERMATOLOGY.—5.30 p.m., Mr. A. K. Monro: *Hypostatic Eczema and Ulceration.*

APPOINTMENTS

ANDERSON, T., M.B., Ch.B., D.P.H., County Medical Officer of Health and Principal School Medical Officer, Oxfordshire.
BODMAN, R. I., M.B., Ch.B., D.A., Anaesthetist (Consultant Grade), St. Peter's, St. Paul's, and St. Philip's Hospitals, London.
BROWN, H. MORROW, M.D., M.R.C.P.Ed., Consultant Chest Physician, South Derbyshire Area.
DONALDSON, RAYMOND JOSEPH, M.B., B.Ch., D.P.H., Deputy Medical Officer of Health for the City of Stoke-on-Trent.
ESSEX-CATER, A. J., M.R.C.S., L.R.C.P., D.P.H., D.C.H., F.R.A.I., Deputy Medical Officer of Health, Swansea County Borough.
EVANS, W. G., M.B., B.Chir., D.P.H., Medical Officer of Health for Scarborough Borough, Scarborough Rural District, and Scabby Urban District; Assistant County Medical Officer, North Riding County Council; and Divisional School Medical Officer.
GIBSON, J. BAIRD, M.B., Ch.B., D.A., Consultant Anaesthetist, Alnwick and Wansbeck, Hospital Management Committee.
HOSPITAL FOR SICK CHILDREN, Great Ormond Street, London, W.C.—R. N. Twistington Higgins, M.B., B.Chir., Part-time Registrar to the Department of Psychological Medicine; S. M. Singh, M.B., B.S., House-surgeon to Orthopaedic and Plastic Departments; C. H. MacD. Walker, M.D., M.R.C.P.Ed., D.C.H., Senior Medical Registrar to Thoracic Unit; E. D. R. Campbell, B.M., B.Ch., Part-time Registrar to Department of Physical Medicine; Teresa M. Coyle, M.B., B.Ch., D.O., Part-time Senior Registrar to Ophthalmic Department; A. L. Jeanes, M.B., B.Chir., M.R.C.P., D.C.H.; I. S. Wallman, M.B., B.S., M.R.A.C.P., and Joan Angus, M.B., Ch.B., M.R.C.P., House-physicians; A. F. Ferguson, M.B., Ch.B., F.R.C.S., and Anne M. Calder, M.B., Ch.B., F.R.C.S.Ed., House-surgeons; Mary F. Thomson, M.B., Ch.B., Assistant Resident Medical Officer, Tadworth.
LIVERPOOL REGIONAL HOSPITAL BOARD.—R. B. Taylor, M.R.C.S., L.R.C.P., D.P.M., Whole-time Consultant Psychiatrist to Rainhill Hospital; T. P. Smith, M.R.C.S., L.R.C.P., D.P.M., Assistant Psychiatrist to Ormskirk and Southport areas; F. G. Anderson, M.B., Ch.B., D.M.R.D., Assistant Radiologist to Aintree and Walton Hospitals; Lucy M. B. Nelson, M.B., B.S., M.R.C.P., Assistant Chest Physician.
MANCHESTER REGIONAL HOSPITAL BOARD.—Betty Hargreaves, M.B., Ch.B., M.R.C.O.G., Consultant Obstetrician and Gynaecologist, Wigan and Leigh Hospital Centre; J. D. Glynn, L.R.C.P.&S.I., D.P.M., Assistant Psychiatrist, Whittingham Hospital.
MASON, S. JOAN, M.B., B.Ch., D.O.M.S., Assistant Ophthalmic Surgeon for Newport and East Monmouthshire, North Monmouthshire and Rhymney and Sirhowy Valleys Hospital Management Committee.
MILNE, JOHN COURTIS, M.B., Ch.B., D.P.H., D.T.M.&H., Assistant County Medical Officer and District Medical Officer of Health for Wells Urban District Council and Docking and Walsingham Rural District Councils, Norfolk.
MOORHOUSE, DOREEN, M.B., Ch.B., Resident Medical Officer, the General Infirmary at Leeds.
NORTH-WEST METROPOLITAN REGIONAL HOSPITAL BOARD.—W. W. Bridgen, M.D., F.R.C.P., Consultant Senior Cardiologist, Special Unit for Research into Juvenile Rheumatism, at Canadian Red Cross Memorial Hospital, Herta Graz, M.D., D.P.M., Consultant Child Psychiatrist at Portman Clinic.
R. W. Rowan, M.D., M.R.C.P., Assistant Chest Physician, (S.H.M.O.), Edgware, Ealing and Harrow Chest Clinics. R. D. Young, M.B., Ch.B., M.R.C.P.Ed., Assistant Chest Physician (S.H.M.O.), Bedford Chest Clinic.
SOUTH-WESTERN REGIONAL HOSPITAL BOARD.—L. V. Martin, M.B., B.S., D.A., Consultant Anaesthetist in North Gloucestershire Clinical Area; S. Muscat, M.D., D.Obst.R.C.O.G., Registrar in Obstetrics and Gynaecology to Bath Group of Hospitals; D. R. Richard, B.M., B.Ch., Surgical Registrar at Weston-super-Mare General Hospital; E. J. Sanders, M.B., Ch.B., Surgical Registrar at Cheltenham General Hospital; C. D. R. Pengelly, M.B., Ch.B., M.R.C.P.Ed., Senior Medical Registrar to West Cornwall Clinical Area.
ZWIRBACH, E., M.D., F.R.C.S., D.L.O., Consultant Ear, Nose, and Throat Surgeon, West Middlesex Hospital.

BIRTHS, MARRIAGES, AND DEATHS

DEATHS
Ashby.—On December 1, 1953, at the Mercy Home, Cork, William Joseph Ashby, M.D., of Ashgates, Hettfield Park, Cork, Eire.
Burt.—On December 1, 1953, at Pinderfields Hospital, Wakefield, Hutchison Burt, M.B., Ch.B., D.P.M., of Greenbank, Bar Lane, Wakefield, Yorks, aged 49.
Campbell.—On December 8, 1953, at the Windmill House, Ramsey, Essex, Samuel Marcus Dill Campbell, M.B., Ch.B., aged 77.
Cochrane.—On December 7, 1953, at home, Pinner, Middlesex, Thomas Cochrane, M.B., C.M., late of Peking, China, aged 87.
Greenwood.—On December 1, 1953, at his home, Birch House, Droydsden Road, Newton Heath, Manchester, Archer Greenwood, M.B., Ch.B.
Schofield.—On December 1, 1953, at Vine Cottage, Guildford, Surrey, Arthur Reginald Schofield, M.B., Surgeon Rear-Admiral, R.N., retired.
Sutton.—On November 27, 1953, at The Old Cottage, Long Melford, Suffolk, William Henry Arthur Douglas Sutton, O.B.E., L.R.C.P.&S.Ed., L.R.F.P.S., Colonel, late R.A.M.C., retired, aged 63.
Walker.—On November 29, 1953, Arthur Samuel Walker, M.D., D.P.H., of Middlesbrough, Yorks.
Warwick.—On December 4, 1953, in a nursing-home, Oxford, James Warwick, O.B.E., M.D., of Pull Croft, Sutton Courtenay, Berks, formerly of Chapel Allerton, Leeds, Yorks, aged 74.
Williams.—On November 27, 1953, in a nursing-home, Kirkby Lonsdale, Westmorland, Richard Geoffrey Williams, M.R.C.S., L.R.C.P., J.P., of Burrow, Camforth, Lancs, aged 77.
Wilson.—On December 1, 1953, at Moorcroft, West Moors, Dorset, Arthur Harold Wilson, L.R.C.P.&S.Ed., L.R.F.P.S., D.P.H., formerly of East Wills, aged 70.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Telling about Adoption

Q.—What is the right age to tell a child that he has been adopted? How should it be done? How should the matter be broached if the telling has been delayed, for instance until the child is 10 or 12 years old?

A.—The essential requirement is that at no time in the life of the child should there have been concealment of the fact of his adoption, or any untruth told about it. If this is observed, he will have become aware of the fact, without any surprise or shock, at the earliest age when the information would have any meaning for him. At some time he will have asked whether Aunt Jane is Mother's sister, or have made some similar inquiry, when, as part of an explanation that Aunt Jane is a courtesy aunt, he can be told of his adoption. In the same way, when questions are asked about how children are born, he could be told that Mother and the mother who bore him are different persons.

If the child has reached the age of 10 or 12 without being told, then the sooner he is told the better, with the minimum of fuss, though some formality will now scarcely be avoidable. A frank confession, with the statement that it was thought best to keep the truth from him till now, seems called for.

Persistent Laryngitis and Tracheitis

Q.—What is the best treatment for persistent laryngitis and tracheitis?

A.—First of all it must be clearly established by mirror laryngoscopy that there is no growth or paralysis of the larynx to account for the symptoms. When these causes have been excluded it is advisable to inquire into the state of the upper and lower respiratory tracts, as acute or chronic disease in the sinuses or lungs can perpetuate laryngitis or tracheitis.

Though tobacco rarely by itself causes irritation or infection of the respiratory tract, it can and does aggravate any inflammation of the mucosa lining the respiratory tract. Therefore, in any stubborn case of laryngitis and tracheitis it will be necessary to abandon tobacco. Avoidance of dusty, smoke-laden, or stuffy and over-heated atmospheres is also advisable. Local treatment can include any simple antiseptic throat, lozenges in which may be incorporated a local analgesic such as benzocaine. The troublesome night cough can often be allayed by a hot drink, and inhalation of steam with Friar's balsam just before retiring may prevent it. In more stubborn cases a course of inhalations with a vaporizing attachment on an oxygen cylinder may be tried.

Inverted Nipples

Q.—What is the best treatment for inverted nipples? Is the local inunction of oestrogen ointment effective?

A.—Oestrogen ointment tends to develop the nipple and to make it more supple, and might help in the treatment of inverted nipples. In addition, however, during the second half of pregnancy some mechanical treatment is necessary, and this may take the form of daily digital manipulation or of periodic suction by an electric pump. One of the best lines of treatment, with or without the above measures, is to instruct the patient to wear "Waller"-type glass or plastic nipple-shields regularly.

Facial Disfigurement after Dental Extractions

Q.—What measures can be taken to avoid the development of the disfiguring vertical grooves in the skin of the lips which appear a few years after dental extractions? They are particularly noticeable in middle-aged women and usually get progressively worse. Cannot dentures be built to avoid this, or will wearing them at night help? Alternatively, can established furrows be removed either by surgery or other means?

A.—A deepening of the naso-labial fold invariably follows the extraction of all the teeth, the loss of the upper canines being the main cause. The effect can be minimized by the construction and wearing of "immediate dentures" and the continuous use of well-fitting plates: rarely can a denture be worn for more than a few years without requiring some alteration if the soft tissues are to remain fully supported. The dentures should be worn continuously, only being removed for cleaning.

Established furrows cannot be eliminated by prosthetic means, though much can be done to minimize them by judicious plumping of well-fitting dentures. For complete removal a plastic surgeon should be consulted.

Rectal Ether for Asthma

Q.—Can you give me full instructions on the administration of rectal ether in oil for asthma? When is it indicated?

A.—The usual dose is 5 to 7 oz. (140 to 200 ml.) of equal parts of olive oil and ether, depending on the weight of the patient ($\frac{1}{2}$ to 2 oz.—14 to 57 ml.—in children). The olive oil and ether must be thoroughly mixed, and are given slowly over about 20 minutes. Some authorities advise a cleansing enema first; others do not.

It is indicated, or rather was indicated, in status asthmaticus after adrenaline had failed. Introduced in 1931 and advocated as a life-saving measure, it came into very general and widespread use, but since the introduction of intravenous aminophylline in status asthmaticus the use of rectal ether and olive oil has declined to such an extent that it is now rarely used. At one time widely advocated in the literature, it is now seldom even referred to.

Rations for an Endurance Test

Q.—What rations would be most suitable for a fit man undergoing a 25-hour endurance test in a canoe? The rations must be as light as possible, since they must be carried in the canoe during the test.

A.—There may be good reason for a plentiful supply of protein to build up muscle and to replace wear and tear during training, but there should be no attempt to supply the energy for an endurance test from the body's proteins. Carbohydrate and fat are the most suitable sources of energy, and, since the metabolic cost of fat is thought to be greater, the ration for the test should consist mainly of carbohydrate. How much is required? If the athlete could maintain an oxygen consumption of one litre of oxygen a minute throughout the 25-hour test, his total energy expenditure would be 7,500 calories; this could be provided by approximately 1,300 g. of carbohydrate, with about 400 g. of fat and 200 g. of protein in addition. In simple terms, the energy requirements would be met approximately by a diet of $1\frac{1}{2}$ lb. (0.68 kg.) of glucose and $1\frac{1}{2}$ lb. of bread made up into sandwiches with butter and a ham or cheese filling. This spartan regime could be partly replaced by more attractive substitutes, according to the whim of the athlete, provided the proportions of the three basic foods were maintained. As much as possible of the carbohydrate should be taken in the form of sugar, and common sense will suggest that such slowly absorbed forms as potatoes should be avoided. It may be useful to make up the glucose with fruit juice. Several pints of this fluid may be taken during the test, and

will help to make up the fluid and salt loss of the body, increase the alkaline reserve, and provide an immediate source of energy. A minimum requirement of fluid would be about 4 pints (2.3 litres), but thirst is as valuable a guide to water requirement as any other. It might be worth in addition taking two 5-gr. (0.32 g.) salt tablets at 8 and 16 hours, although the fruit juice would probably contain enough.

Selenium for Baldness

Q.—Is selenium sulphide of value in the treatment of alopecia? If so, what are the indications for its use?

A.—Selenium sulphide in the form of "selsun lotion" certainly appears to be useful in the control of dandruff of the scalp. However, although dandruff is often followed or accompanied by baldness (calvities) it cannot be assumed that the baldness has been caused by dandruff or that the suppression of dandruff will prevent the development of baldness.

While, therefore, this treatment has hardly been in use for a sufficient length of time to enable a judgment to be made, it seems unlikely that it can be expected to influence baldness.

NOTES AND COMMENTS

Pendulous Breasts.—Sir ARCHIBALD MCINDOE (London, W.1) writes: The rather old-womanish answer to the question on pendulous breasts ("Any Questions?" November 28, p. 1230) suggests that either they should be properly supported or the patient should go in for breast-stroke swimming, which is precisely what a woman would not want, and is almost invariably the reason why she seeks relief from the condition. Of course, the answer should have been that a surgical breast reduction should be performed by a competent plastic surgeon. This is an everyday operation and gives excellent results.

OUR EXPERT writes: This question and answer concerned the treatment of pendulous breasts immediately after cessation of breast-feeding, at which time there is much to be said for conservative measures—particularly if the patient is young and likely to have more children. Sir Archibald McIndoe's comment applies more to the treatment of breasts which remain pendulous after involution is complete and which are unlikely to be exposed again to the stimulus of pregnancy and lactation.

Causes of Failure of Contraceptive Diaphragms.—Dr. LILIAS M. JEFFRIES (Hove) writes: Referring to the question about the causes of failure to prevent conception by the use of the Dutch cap ("Any Questions?" November 28, p. 1229), I have found that a common cause is constipation. Scybala distort the shape of the vagina. Patients are often unconscious that the rectum is loaded, and need to be warned that the cap has been fitted when the bowel is empty, so that it will not fit otherwise. It is well worth while drawing attention to this point.

"Any Questions?" Book.—The second book of selected "Any Questions?" is available, price 7s. 6d. (postage 6d.). Copies may be obtained either direct from the Publishing Manager, B.M.A. House, Tavistock Square, London, W.C.1, or from booksellers.

THE NEPHROTIC SYNDROME*

BY

JOHN R. SQUIRE, M.D., F.R.C.P.

Leith Professor of Experimental Pathology, and Director of the Division of Pathological Studies, University of Birmingham

Massive oedema unfits numbers of people, young and old, for their normal daily life. In a fair proportion heavy proteinuria is present, and this group includes the patients to be discussed here. The subject is familiar, but, it must be admitted, a completely successful treatment is not known, so that patients with the nephrotic syndrome often languish for many months or even years in hospital, or closely tied to their homes. The syndrome invites study, not only from the desire to do more to help these patients but on account of its basic scientific interest; further research into the mechanism of the disorder seems likely to extend our knowledge of renal and circulatory physiology and of human protein metabolism.

This account is not to be regarded as a full review, such as the excellent article by Bradley and Tyson (1948); rather it is a preliminary report on some of the work of the last three years undertaken by a team in Birmingham, composed of Drs. J. D. Blainey, D. B. Brewer, J. Hardwicke, D. S. Rowe, Mr. H. J. Yardley, and myself. Though the results are incomplete, the usefulness of certain ideas and techniques can be illustrated. Especially we would emphasize the need for the quantitative collection and analysis of factual data from patients of this kind. We have studied some 20 patients, a few very completely over periods of many months of illness. Other similar studies are needed, and, since the syndrome is not rare, there is no lack of clinical material.

Definitions

There is at present a risk that students of renal disease will use different names for the same condition, or, worse, the same name for different conditions. It seems reasonable to reserve the term "nephrotic syndrome," unqualified, for patients with oedema, definite proteinuria, and hypo-albuminaemia, without hypertension, without electrolyte disorders or retention of non-protein nitrogen, and without an appreciable excess of red blood corpuscles in the urine. These excluding qualifications help, especially in discussions of treatment and prognosis, without denying the possibility that some of these features may appear as late sequelae, at least in certain forms of the syndrome. In addition, the nephrotic syndrome may appear in association with other definite disorders, when one may speak of, say, "constrictive pericarditis with an associated

nephrotic syndrome," "hypertension with an associated nephrotic syndrome," etc. This form of description, of course, begs the question of common or dissociated aetiology, which seems advisable in our present state of ignorance.

Other associated disorders included in this series are congestive cardiac failure (often previously treated with mercurial diuretics for long periods), subacute nephritis (i.e., hypertension and some excess of red blood corpuscles in the urine, with a history suggesting previous attacks of more acute renal disease), and femoral thrombosis. In Table I the series is described by diagnosis, sex, and age. Classifications based on the morbid anatomical structure of the kidney have been avoided, since but few of these patients have died, and since, in those that have, our ability to predict the structural changes from studies on living patients has proved to be quite limited.

TABLE I.—Diagnosis of Patients Studied in Present Series (Common Feature—Proteinuria)

Diagnosis	Age of Females	Age of Males
Nephrotic syndrome (uncomplicated)	7 years 14 " 17 " 20 " 30 " 42 " 48 "	7 years
Acute nephritis		31 " 36 "
Subacute nephritis with associated nephrotic syndrome	20 "	36 " 37 "
Hypertension with terminal renal failure, associated nephrotic syndrome		55 " 65 "
Congestive cardiac failure, associated nephrotic syndrome	35 " 59 "	
Femoral (and ? caval) thrombosis, associated nephrotic syndrome	55 " 58 "	

* Constrictive pericarditis.

Prime Cause of Oedema

Various suggestions have been made regarding the prime cause of oedema in the nephrotic syndrome. The most widely held view, following on the publication of Starling's (1896) work, has been that the reduced colloid osmotic pressure of the plasma, a function of the hypo-albuminaemia, is responsible. Our studies support this idea, though some qualifications and extensions are necessary in the light of current knowledge. The evidence in favour of the hypothesis is largely based on the following observations.

*Based on a lecture delivered by invitation of the Academic Council of the University of London on November 30, 1953.

(1) The colloid osmotic pressure (C.O.P.) of nephrotic-syndrome plasma is greatly reduced below the normal average, at least so long as oedema is present. With normal values of 40–50 cm. of water in our measurements, nephrotic plasmas have given readings of 5–25 cm. of water. This evidence is of positive association between a lowering of C.O.P. and oedema formation.

(2) Samples of oedema or ascitic fluid have shown low protein values (less than 0.2 and 0.1 g.% respectively), and, when measured, a negligible C.O.P. (This is true even when pseudo-chylous effusions are found.) This evidence may be regarded as excluding gross capillary permeability to colloid as a cause.

(3) Infusions of salt-free colloid (e.g., 50–100 g. of human albumin, 40–80 g. of transfusion dextran) have almost always led to an increase during the ensuing 24 hours of water and sodium chloride excretion. This is interpreted as a mobilization of oedema fluid with its elimination in the urine. The albumin infusions, for example, cause a rise in C.O.P. (from 10 to 20 cm. of water) over this period. (A concomitant increase in plasma volume is usually found.) The diuresis is usually transient, the C.O.P. falling rapidly to the pre-infusion level, though exceptions to this result are noted in a later section. This evidence provides an instance of positive association between rising C.O.P. and oedema reduction.

Two accessory factors operating in oedema production needing discussion are sodium chloride retention and plasma volume reduction. Retention of sodium has been blamed as the primary cause of the oedema by a school of workers, and, indeed, it is a pronounced feature of the disease. Whether on moderate (100 mEq/day) or low (30–40 mEq/day) intakes of sodium, patients are observed who lose less than 10 mEq of sodium daily for week after week. This is a remarkable tribute to the efficiency of at least one component of the tubular reabsorptive capacity of diseased kidneys, for the constancy of the sodium content of the oedema fluid is closely maintained at about 125 mEq/litre. (The plasma level is often about 135–140 mEq/litre, a little below the normal value of 145 mEq/litre. This is probably attributable to the hypo-albuminaemia, since the normal plasma albumin level binds some 10 mEq of sodium/litre.) Clearly, if chemical constancy of the internal environment is to be maintained, retention of sodium must be effected when oedema is forming. It seems, then, that the sodium retention in these patients is a secondary physiological adaptation to meet the situation of oedema formation. This view is strengthened by the immediate response, already mentioned, to colloid infusions when as much as 70–100 mEq of sodium may be released in a day. Chloride metabolism is, of course, similarly affected.

C.O.P. Measurements and their Interpretation

Our measurements of colloid osmotic pressure have been done with an instrument (Fig. 1) with some novel features which make it well adapted to clinical studies. The use of a mechano-electronic transducer valve makes it possible to decide in one minute or less whether fluid is being transferred from the Ringer compartment of the osmometer to the serum sample, or vice versa. By a few successive trials the pressure which has to be applied to the serum to prevent any movement between the compartments is found; this is the C.O.P. Parallel tests on plasma and serum have shown no significant difference, and serum is usually tested as a matter of convenience.

The effect on C.O.P. of diluting a normal serum specimen with Ringer's solution is shown in Fig. 2. It can be seen at once that the relation between C.O.P. and protein concentration is not the simple straight line passing through

the origin expected from solutions obeying the simple gas-laws of physical chemistry. The graph is markedly curved, being concave upward, so that at the order of concentrations present in normal serum the C.O.P. is about double that predicted from the molecular weight of its constituents. (Transfusion dextran solutions show a similar or greater

Fig. 1.—Principle of rapidly acting osmometer (D. S. Rowe). When tap is closed osmotic pressure of serum draws fluid through semipermeable membrane, causing upward bulging of diaphragm and changed resistance of transducer valve, which is electrically recorded. The air pressure which has to be applied to the surface of the serum to nullify this effect is equal to the C.O.P. of the serum.

effect.) The accurate determination of this curve is important in several ways. To the chemist the form of the curve at very low concentrations is of interest. From this region, where complications such as intermolecular forces, Donnan effects, etc., are negligible, the mean molecular weight of serum proteins can be calculated. (In Fig. 2 this is shown as the dotted line "limiting gradient.")

The physician is more concerned with two characteristics of the curve at and near the concentrations found in the blood. In the first place, the natural level of C.O.P. is important, for it must be related to the level of hydrostatic pressure at which there is no net movement of fluid through the capillary wall. In addition, the slope of this curve (shown by the dotted line labelled "physiological gradient" in Fig. 2) should be considered. This slope must affect the precision of the homeostatic mechanism governing the relation between plasma and interstitial fluid volumes. Suppose that a little fluid is ultrafiltered from the plasma into the interstitial space, some haemoconcentration will result and the C.O.P. will rise to an extent depending on the physiological gradient. This rise in C.O.P. will tend to oppose further ultrafiltration and so to maintain homeostasis. Conversely, haemodilution will be opposed by the fall in C.O.P. induced. Thus the steeper the physiological gradient the more exact the homeostatic control.

In Fig. 3 the state of affairs with a nephrotic syndrome serum is shown. Again dilutions with Ringer's solution have been prepared and the C.O.P. of each measured. This has made it possible to show that not only is the C.O.P. diminished greatly (to 19.1 cm. of water in this instance),

Fig. 2.—C.O.P. of normal serum, full-strength and at various dilutions. The limiting gradient at zero concentration is inversely proportional to the mean molecular weight of the serum colloids. The physiological gradient of full-strength serum is steeper, and is important for the maintenance of constant plasma volume *in vivo*.

but that the physiological gradient is also much less steep. Other factors being equal, not only will the nephrotic-syndrome patient be tending to lose fluid from plasma to interstitial space, but he will also, when some form of balance has been obtained, have a greatly diminished power of regulating the volume of either compartment—a small rise in, say, capillary pressure will tip the balance towards oedema formation, and a much larger fluid shift than normal will occur before a sufficient rise in C.O.P. has occurred to counterbalance the effect. At this stage it may be noted that the measurements here set out are made with semipermeable membranes completely impervious to the serum colloids. In that the blood capillaries are known to be normally slightly permeable, at any rate to the smaller proteins of the plasma (e.g., albumin), the physiological osmotic pressures will be fractionally less than those shown here.

Fig. 3.—C.O.P. of nephrotic serum for comparison with Fig. 2. C.O.P. and physiological gradient considerably reduced. Limiting gradient (cm. water/1 g. protein per 100 ml. serum) somewhat reduced.

It is thought that this difference is not likely to be appreciable, in that the speed of transmission of protein through capillary walls is many thousand times less than the speed of transmission of its Ringer-like solvent.

A further extension of the Starling theory is indicated by the knowledge now current that the interstitial space is occupied by a colloid gel, histologically seen as "ground-substance" lying within a network of collagen and other fibres. In Starling's time the interstitial space separating the vessel wall from the cellular contents tended to be thought of as a potential space analogous to the peritoneal and pleural cavities—assuming appreciable dimensions only in pathological states like oedema, ascites, or pleural effusion. To-day, estimates of the interstitial space in normal subjects suggest a volume perhaps about four times as great as the plasma volume, and that in health this volume is maintained with fair constancy. This state of affairs is inconceivable on the simple Starling hypothesis—the slightest

Fig. 4.—Illustration of two factors postulated as minimizing plasma volume alterations in normals (a), with reduced effectiveness in the nephrotic syndrome (b) (for explanation, see text).

discrepancy of mean capillary hydrostatic pressure and mean plasma C.O.P. would produce a progressive alteration in interstitial volume. Mechanical tissue tension in the sense of skin tightness cannot be responsible for interstitial space volume maintenance, as this tension is absent in various anatomical regions. Another factor which must be taken into account in the qualitative difference between oedema fluid and normal interstitial fluid is the tendency of oedema fluid to gravitate and to pit on pressure. This feature is prominent in patients with only, say, 5 litres of oedema—an increase in total interstitial fluid volume of less than 50%.

These difficulties are removed if the interstitial space is regarded as being occupied by a gel. It is known that such gels have a "swelling pressure," analogous to the C.O.P. of a soluble colloid. This swelling pressure tends to attract aqueous solutions into the gel up to a certain limit. At this level the swelling pressure is zero, imbibition ceases, and further addition of water leaves free fluid. This point, it is suggested, corresponds to the level at which oedema is found. Removal of water from a gel is resisted by the swelling pressure, which can be overcome by the exercise of mechanical pressure or by opposing the swelling pressure by C.O.P. In general, swelling pressures tend to rise rather steeply with progressive removal of water. Actual values for the swelling pressure of the interstitial gel have not, so far as is known, been measured. In Fig. 4a the swelling pressure for a normal man has been marked as a hypo-

thetical line. In Fig. 4b the situation in the nephrotic syndrome with oedema present is depicted—no swelling pressure is available to oppose the tendency of fluid to shift to and from the plasma. This, together with the reduced physiological gradient of C.O.P. already described, must make the regulation of plasma volume much more precarious than in the normal subject. In quantitative terms, $(X_1 - Y_1)$ is much less than the corresponding normal difference $(X - Y)$ (Fig. 4).

Insufficient measurements have been made of plasma volume or of red-cell mass in the nephrotic syndrome. According to Borst (1948) the plasma volume is usually reduced below normal and the few determinations we have made, using the dye T.1824, confirm this. The reduction is not always great (usually 5–25%), assuming significance only when related to the plasma volume of patients with a comparable degree of anaemia. This is necessary because the plasma volume tends to rise above normal with anaemia (thus tending to lessen the reduction in overall blood volume which would otherwise result). In the anaemia commonly found with the nephrotic syndrome a similar rise occurs, but of less degree. The plasma volume may also be somewhat reduced by salt deprivation even of the degree induced by therapeutic diets.

To conclude this discussion of the relation between the oedema of the nephrotic syndrome and the reduced C.O.P. associated with hypo-albuminaemia, we must agree with other workers that diuresis may occur before any definite rise in serum albumin concentration is found. This is demonstrated in Table II. The patient had been on a low-

TABLE II.—Factors Concerned in Diuresis

	1952		1953		
	Nov. 14	Nov. 29	Jan. 7	Jan. 22	Jan. 31
P.C.V.	39	40	25	25	41
Serum albumin, g./100 ml.	0.47	0.51	0.50	0.77	0.99
Plasma volume, ml.	1,780	1,710	3,360	3,360	2,610
Total circulating albumin g.	8.4	8.7	16.8	25.8	26.2
Mean daily weight change g.	+180	+300	-66	-300	-280

Female, 55 kg. High protein intake from November 14, blood transfusion 720 ml. packed cells on January 29, 1953.

In November, 1952, oedema was accumulating. Diuresis began at the beginning of January, 1953 (see weight changes). Note that serum albumin concentration had shown no appreciable change by January 7, but the packed cell volume (P.C.V.) had fallen greatly. This is interpreted as being due to a considerable increase in plasma volume and total circulating albumin.

salt and high-protein diet for many weeks; a markedly positive nitrogen balance was recorded throughout the period shown. Until the middle of December, 1952, steady accumulation of oedema and ascitic fluid continued, making paracentesis repeatedly necessary. This oedema formation is shown for simplicity in Table II by records of weight change: sodium, chloride, and water retention confirmed its nature. Then the trend was gradually reversed, until at the beginning of January a large diuresis occurred. At this point the serum protein concentrations were essentially unchanged. But the packed red cell volume had fallen from 40% to 25% in a matter of weeks, no evidence of haemorrhage or haemolysis being noted. Apparently, therefore, a considerable increase in plasma volume had occurred. The diuresis was not a function of a rise in glomerular filtration rate, as judged by creatinine clearance, which actually appeared to fall, only to rise again when the diuresis was completed. Only towards the end of January, when the diuresis was more than half completed, the serum albumin concentration rose somewhat, no further plasma volume increase being noted.

At this point a transfusion of packed red cells was given for therapeutic purposes, and this enabled the approximate estimate of actual plasma volume, shown in Table II, to be made. It seems that between November and January the total circulating albumin increased about twofold. Unless protein is added very rapidly to the circulation as by transfusion, an increase in plasma volume rather than in protein concentration is what might be expected to follow an increase in total circulating albumin when free oedema is

present. When the oedema has been removed, on the other hand, further abstraction of water from the interstitial space into the plasma will result in increased swelling pressure of the interstitial gel, and can only be achieved by reduction in capillary blood pressure or by a rise in serum C.O.P.

In conditions other than the nephrotic syndrome, alterations in interstitial gel may occur. Myxoedema involves its presence in exaggerated amounts (and perhaps in abnormal quality). A reduction in the interstitial gel may be a contributory factor to the production of famine oedema, and perhaps also to oedema in patients with the nephrotic syndrome after prolonged underfeeding.

Changes in Other Serum Proteins Associated with Hypo-albuminaemia

The introduction of paper electrophoresis for the separation of serum proteins has for the first time made possible numerous and repeated examinations of nephrotic syndrome sera and urines. In our department, Dr. Hardwicke has paid particular attention to validating the quantitative results. Differential analysis is made by elution of the dye bromphenol blue from the sites clearly stained by adsorption on to each component. Elution is also carried out from intermediate areas, and allowance is made for tailing of the serum albumin—the fastest-moving component which has travelled over the areas of paper eventually occupied by each globulin fraction. Total serum proteins have been estimated by a biuret method, while the fibrinogen in plasma samples is estimated by the Folin and Ciocalteu method after collection as a clot and redissolving in soda.

Without doubt the protein which is reduced to the greatest extent in the nephrotic syndrome is the serum albumin. As already described, there is fair correspondence between the serum albumin concentration and the C.O.P. Albumin levels have therefore been taken as an index of the severity of the condition from patient to patient and from time to time. Other serum constituents and other features of the syndrome (e.g., the degree of proteinuria) have been compared with the serum albumin level.

In Fig. 5 the total concentration of plasma proteins is plotted graphically against the serum albumin concentra-

FIG. 5.—Total plasma protein and serum albumin concentrations in patients with proteinuria (J. Hardwicke). For serum albumin levels falling below 2 g./100 ml. there is little further reduction in total plasma protein level. (Contrast findings in malnutrition, liver disease.) In this and subsequent figures the first determination on each patient is shown ●, subsequent readings being shown ○.

on, each being expressed as g.% (15 patients, 59 determinations). The results show that down to a serum albumin concentration of 1.5–2 g.% the level of total serum proteins falls from its normal range of 6.5–8 g.% to about 4.5–6 g.%. Below this value of serum albumin level there is little further fall in total protein, patients with serum albumin levels of below 0.5 g.% maintaining a total protein concentration of 4.5–6 g.%. In this series only one patient showed a total serum protein level of less than 4 g.%—in other words, very low levels of serum albumin concentration are accompanied by a rise in concentration of some globulins. This result contrasts with the findings in other forms of hypoproteinaemia due, for instance, to malabsorption of food from a diseased intestine, when the total protein level may fall to 1 g.%.

In Table III the relation between hypo-albuminaemia of increasing severity and other changes in plasma constituents is shown. Values have been expressed in terms of % of

TABLE III.—Relation Between Hypo-albuminaemia of Increasing Severity and Other Plasma Changes

Plasma Fraction	Molecular Weight	Normal		Nephrotic		
		g./100 ml.	% Normal	Mean Values and Range		
Albumin	69,000	4.0	100	50	26	14
				(45–53)	(23–29)	(12–19)
α_1 -globulin	45,000	0.3	100	103	84	57
				(66–140)	(33–150)	(17–113)
γ -globulin	156,000	0.9	100	86	81	63
				(44–187)	(38–140)	(39–72)
β -globulin	90,000 and 1,300,000	0.6	100	129	157	136
				(80–170)	(83–193)	(100–183)
α_2 -globulin	300,000	0.6	100	152	228	295
				(100–240)	(145–347)	(133–400)
Fibrinogen	450,000	0.3	100	197	286	354
				(123–323)	(197–400)	(280–460)
Cholesterol	—	0.3	100	170	288	330
				(104–194)	(103–395)	(259–478)

Each column is based on 10–15 observations. Note that the smaller proteins (α_1 - and γ -globulin) fall with albumin, whereas the other fractions rise.

normal averages to facilitate ready appreciation of the relative extents of the changes involved. The ranges observed are also shown beneath each mean. In spite of fairly large variations, some due to experimental error and some to case-to-case variation, all the patients conformed to clear-cut trends. This is notable in view of the probable diversity of aetiological agents concerned. With albumin levels reduced to below 30% of normal, α_2 -globulin, fibrinogen, and cholesterol concentrations were invariably raised, increases to 300% of the normal average being the rule with severe hypo-albuminaemia. By contrast, the globulin fractions with smaller molecular weights (α_1 - and γ -globulin) tended to fall with (though not so much as) the albumin; usually the α_1 -globulin falls to a greater extent than the γ -globulin. The β -globulin rises somewhat, usually to between 100% and 200% of normal. (This finding in particular differs somewhat from the picture described by others using classical free boundary electrophoresis where concentrations are measured by refractometry—a method which estimates the lipids associated with the β -globulin along with the protein.)

As, unfortunately, little is still known even of the normal functions of the various serum proteins, these changes cannot be said to cause or to correct any definite abnormality. The plasma viscosity is raised rather than reduced, for the proteins which rise in concentration are large, and in some instances probably asymmetric. It is tempting to associate the fall in γ -globulin with the known tendency of these patients to develop infections. The small degree of fall of the globulin would be unconvincing in this respect were it not known that the γ -globulin fraction is composite, and that some antibodies may perhaps be reduced more than the main γ -globulin fraction. β -globulin is complex also; the small metal-carrying β -globulin is probably reduced more than the larger lipoprotein associated with this fraction. Certain negative conclusions can be drawn. The rises in α_2 -globulin, fibrinogen, and total cholesterol are far too great to be accounted for simply in terms of reduced plasma

volume with ensuing concentration of some constituents. On the other hand, α_2 -globulin and fibrinogen, having molecular weights five times greater than serum albumin, cannot compensate directly for the reduction in colloid osmotic pressure associated with a reduction of serum albumin from, say, 4 g.% to 0.5 g.%. To do this the α_2 -globulin and fibrinogen level would need to rise to some 15 g.%—and the resulting solution would resemble treacle in consistency.

Extent of Dependence of Serum Abnormalities on Proteinuria

The clinical association between reduced serum albumin levels and severe proteinuria has often been held to show that the serum abnormality depended directly upon the urinary loss. An alternative view has been that some serum proteins, in particular the albumin, are produced in inadequate amounts in the nephrotic syndrome. These two views are, of course, not mutually exclusive.

Urine samples collected during 24-hour periods and serum obtained on the same day have been subjected to electrophoretic analysis. The same protein fractions—albumin and four globulin components—appear in each, having similar mobilities, and showing only these same fractions when electrophoresis is carried out on a mixture of urine and serum. There seems no reason to doubt, therefore, that the protein found in the urine has “leaked” from the blood via the kidney. The relative amounts of the different fractions, however, is not the same—the urine/serum ratios being always in descending order—albumin, α_1 -globulin; β - and γ -globulin; α_2 -globulin. (In acute nephritis the ratios may be almost identical, as discussed below.) In other words, the losses of albumin and α_1 -globulin tend to be large while that of α_2 -globulin is small. No doubt these losses are dependent on molecular weights—the small proteins, like albumin, passing readily through the glomerular wall, the large molecules of α_2 -globulin being restrained. It is also tempting to associate the facts that the albumin and α_1 -globulin are the proteins most reduced in nephrotic plasma as supporting evidence for the idea that serum changes in the nephrotic syndrome depend largely upon the urinary losses.

More evidence is obtainable from comparing the daily urinary losses of protein with the degree of hypo-albuminaemia on repeated examinations of a number of patients. This comparison is shown in Fig. 6, in which serum albumin concentration is plotted against daily albumin excretion (Fig. 6a) and daily total protein excretion (Fig. 6b). Losses are plotted as g./kg. normal body weight so as to make valid comparisons between large and small patients. A clear association is seen with low serum albumin levels accompanying large urinary losses. Statistical analysis shows this association to be highly significant, and regression lines have been calculated and drawn to show the most likely average relationship in these patients. It should be noted that all the patients from whom these values were derived had longstanding proteinuria; all were on a good hospital diet—in one or two instances only on very high protein diets (over 120 g. of protein a day).

A tentative interpretation may be put forward to explain the relation between albumin excretion and plasma (=serum) albumin level. Normally plasma albumin levels are constant at about 4 g./100 ml., production and utilization being equal. If urinary loss of albumin occurs and production remains steady the plasma level must fall; if utilization also remains steady the fall would continue until no plasma albumin was left. But if utilization is dependent upon plasma albumin concentration in some way, a new balanced state can be envisaged, hypo-albuminaemia being dependent on the degree of albuminuria. Most of these patients showed, in fact, remarkably steady levels of plasma albumin and of albumin excretion in the urine over periods of many weeks. In other words, they were in dynamic equilibrium so far as plasma albumin was concerned—albumin production being equal to the sum of albumin loss by excretion and albumin utilization. In a normal person, with a negligible excretion

FIG. 6.—Relation between hypo-albuminaemia and daily loss in urine of (a) albumin, and (b) total protein (J. Hardwicke). Regression lines are in each case highly significant, indicating close association of the blood changes and the extent of proteinuria.

of albumin, production is entirely balanced by utilization, which amounts to some 0.25 g./kg./day according to published studies using radioactive techniques (e.g., Sterling, 1951).

Several of the patients excreted 0.25 g./kg./day with constant serum albumin levels; even if utilization had fallen to zero their rate of albumin production was clearly not grossly impaired. If one were to assume that utilization of albumin had remained normal, their production must in every case have been greater than normal, in some instances reaching over 200% of the normal figure. In fact, it seems more plausible to suppose that albumin utilization in hypo-albuminaemia lies between these wide possibilities of zero and normal values. Interesting results are obtained if the assumption is provisionally adopted that albumin utilization is directly proportional to plasma albumin concentration; a similar hypothesis is known to be applicable in various situations with the utilization of glucose at different plasma glucose levels. If albumin utilization is taken as 0.25 g./kg./day with normal plasma albumin levels (4 g./100 ml.), utilization for any level of plasma albumin (P) is given by: $(\text{utilization} = \frac{P}{4} \times 0.25)$. Production is then calculated from $(\text{utilization} + \text{excretion})$. From the 53 determinations charted in Fig. 6a, calculated production levels fall between 48% and 124% of normal, with a mean value of 92% as shown in Table IV.

These figures should be treated with considerable reserve; they are, indeed, little superior to an informed guess. It is perhaps opportune to make such an estimate, for techniques available for accurate estimation in occasional patients are being used in other laboratories. In other words, the figures can be checked. They further emphasize that patients are not constant in this respect; indeed, protein production can apparently vary at least between production levels 60% of normal in severe cases and 120% of normal in convalescence on a liberal protein diet. When quoting experimental determination of albumin production, therefore, it is most desirable to give details of the diet, the daily albumin excretion, and the plasma albumin level.

TABLE IV.—Albumin Production Values in Nephrotic Patients Calculated from Albumin Excretion and Plasma Albumin Concentrations (53 Observations)

Calculated Albumin Production (% of Normal)	No. of Observations

108-115	7
116-123	7
124-127	4

(Based on assumptions:—1: Production = utilization + excretion. 2: Utilization = $\frac{\text{plasma albumin}}{4} \times 0.25$. 3: Normal production of albumin = 0.25 g./kg./day.) Data as for Fig. 6.

The automatic control of plasma albumin level by means of an albumin utilization rate which rises and falls with this level is presumably the main factor leading to steady levels of hypo-albuminaemia when underproduction occurs without proteinuria (e.g., liver disease). But in renal disease a further factor which determines the plasma albumin level is the marked rise in proteinuria which, without any change in the permeability of the kidney, accompanies any increase in plasma albumin. Such increases may occur naturally with increasing production or be artificially produced with albumin infusions. A rise of plasma albumin by 10% increases protein excretion by about 15%. (Taking into account the increased utilization, the plasma albumin level will rise only 10% in this way if production is stepped up by about 25%.) The effect of such plasma alterations in proteinuria gives useful indications of the exact kind of renal damage in individual patients.

Analysis of Renal Defect which Results in Proteinuria

For many years now there have been debate and confusion about the relative importance of glomerular and tubular lesions in disease processes affecting the kidneys. Histological evidence has focused attention on the glomerular

lesions in acute nephritis, but has shown obvious tubular changes, including pronounced fatty degeneration in patients who showed severe proteinuria and oedema as the chief abnormality before death. In this nephrotic group glomerular changes have been difficult to find; a special form of thickening of the glomerular basement membrane has been described as occurring in what is now often known as Ellis "type II nephritis" (Ellis, 1942), but even these changes are often slight.

The conclusions to be drawn from urinary abnormalities during life have been less definite. The excretion of red blood corpuscles in acute nephritis is reasonably interpreted as severe damage in limited areas of the glomerular membrane. Specific tubular defects are now well recognized in patients able only to a very limited extent to alter the concentrations of certain ions or other substances of low molecular weight in the urine. But the relative contribution of glomerular and tubular defects to severe proteinuria has remained unknown. So long as the normal glomerulus was supposed to produce a protein-free ultrafiltrate, opinion was naturally inclined to the view that proteinuria depended entirely on a glomerular defect. If one accepts the evidence from direct sampling of glomerular fluid that both cold- and warm-blooded animals pass some protein into the glomerular filtrate, tubular reabsorption of protein must be recognized as a normal process. Proteinuria therefore could theoretically arise from glomerular damage, allowing so much protein to be filtered that the tubular mechanism was saturated before all protein was reabsorbed, from tubular damage alone or from a combination of glomerular and tubular damage. At present our ability to correct either defect is limited (or in most instances non-existent), but establishing the degree of damage to glomeruli and tubules in each individual patient is a prerequisite of a rational assessment of the problem.

From electrophoretic estimation of proteins in urine and serum, an "apparent" (or urinary) clearance can be calculated for each fraction—that is, the ratio of the quantity excreted (expressed as mg./min.) to the serum concentration of the fraction under consideration. Now if no reabsorption of protein occurred in the tubules these apparent clearances would represent the "true" (or glomerular) clearances of each protein fraction. If reabsorption does occur, these apparent clearances will be less than the true clearances by an amount depending on the proportion of the protein reabsorbed during any particular test.

Both true and apparent clearances of protein fractions will depend directly upon the glomerular filtration rate. This has been estimated in all tests on the patients considered here from the clearances of endogenous creatinine. With the precaution of adsorbing serum creatinine on to kaolin to eliminate errors due to other substances giving similar colours with the Jaffé reagent, we believe this test gives a reasonably reliable indication of the glomerular filtration rate, at least with results of over 30 ml./minute. The disadvantage of the small errors which probably remain is offset in clinical studies by the minimal disturbance of the patient, the test requiring only a single venepuncture and an accurately timed collection of urine over a four-hour period. Creatinine clearances are also of considerable value in assessing the progress of patients. In agreement with other workers, we find that clearances of less than 20-30 ml./minute, if maintained over a period of weeks, indicate a poor prognosis.

From the apparent clearance of a protein fraction divided by the creatinine clearance, a value can be obtained for the "apparent relative clearance" of each protein fraction. This value will similarly be less than the true relative clearance in each case by an amount depending upon the proportion of protein reabsorbed by the tubules. In the absence of knowledge of this proportion, we have adopted certain hypotheses, capable of subsequent testing by measurements. These are:

(a) The amount of protein which can be reabsorbed each minute (T_{Mr}) in the tubules of each patient is limited and fixed.

Over any period of two to three days (except in acute conditions) this amount does not fluctuate. When proteinuria is present this potential reabsorption is fully active.

(b) The tubules do not distinguish between different protein fractions—the reabsorptive channels for, say, albumin and for γ -globulin being the same. It follows that if, say, 40% of the total protein in the glomerular filtrate is being reabsorbed, 40% of the albumin and 40% of the γ -globulin present are reabsorbed. The amount (as opposed to the proportion) reabsorbed will depend on the amounts of each protein in the glomerular filtrate.

Since the amount of protein per minute which can be reabsorbed is fixed, the proportion of the protein passed into the glomerular filtrate and then reabsorbed is less the greater the amount passed. It follows that the apparent relative clearance is lower than the true relative clearance of any protein fraction by an amount depending on this proportion reabsorbed; the apparent relative clearance will rise to approach the true value as the amount of protein excreted in the urine per minute is increased—for example, as the result of increasing the concentration of any serum protein. Furthermore, if exact measurements are made of apparent relative clearances of, say, albumin every few hours when total protein excretion changes and is measured, the true relative clearance and the amount of protein reabsorbed per minute can be calculated. This has been achieved by measurements made before and after abruptly increasing the serum albumin level by an infusion of human serum albumin. The calculation depends on the expression:

$$\frac{(\text{True relative clearance of albumin})}{(\text{Apparent relative clearance of albumin})} = \frac{(\text{Protein passed in glomerular filtrate/min.})}{(\text{Protein passed in urine/min.})} = \frac{(\text{Protein reabsorbed by tubules/min.} + \text{Protein passed in urine/min.})}{(\text{Protein passed in urine/min.})} = \frac{(\text{TMP} + \text{protein passed in urine/min.})}{(\text{Protein passed in urine/min.})}$$

or by rearrangement:

$$(\text{True relative clearance of albumin}) = (\text{TMP} + \text{protein passed in urine/min.}) \times \frac{(\text{Apparent relative clearance of albumin})}{(\text{Protein passed in urine/min.})}$$

Since each clearance estimate is subject to a degree of experimental error, successive clearances and total protein excretions over four-hour or eight-hour periods are measured. The results are shown graphically in Fig. 7, the protein excretions per minute being plotted vertically, and the ratios of (protein passed in urine)/(apparent relative clearances) on the horizontal axis. It can be seen that, in fact, for albumin a straight line is obtained, in agreement

FIG. 7.—Use of albumin infusion to measure glomerular permeability to albumin (calculated from gradient) and rate of protein reabsorption by tubules (from intercept on vertical axis). (Female patient, C. J., 54 kg. Albumin infusion 45 g., June 5, 1952.) Explanation of method is given in text.

with the hypothetical reasoning set out above. The slope of this line represents the true (glomerular) relative clearance of albumin, while the negative intercept on the vertical axis represents the amount of total protein reabsorbed each minute by the tubules.

The general form of result shown in Fig. 7 has been confirmed by five other tests on a total of three patients with the nephrotic syndrome. In all, the relationship has been a straight line within the limits of experimental error, as predicted from the argument already given. In all, a negative intercept has been obtained, indicating that some protein was being reabsorbed by the tubules. When a substantial increase in proteinuria occurred in association with the raised serum albumin, it disappeared with the return of serum albumin to pretransfusion levels—that is, no fresh renal damage followed the infusions. Although the serum globulins showed little tendency to alter after the albumin infusion, during the period of increased proteinuria the apparent relative clearances of these globulins increased in proportion to the increase in apparent relative clearance of albumin. This supports the concept that the tubules' capacity to reabsorb protein is uninfluenced by the nature of the protein presented to them in the glomerular filtrate, as was suggested above. The different proteins compete with each other on equal terms, as it were, for reabsorption.

If this method of investigating the renal defect resulting in proteinuria is accepted, tentative answers may be given to some salient questions. Is the tubular capacity for protein reabsorption affected in the nephrotic syndrome? Is a glomerular defect present? If so, what different forms of glomerular damage occur in different kinds of renal disease? This kind of investigation has not yet been carried out often enough for broad generalizations. In one patient tested, protein reabsorption was very low as compared with the other two patients. Grossly defective tubular reabsorption, on occasion, then, occurs, and it is worth noting that in this patient there was other evidence of tubular dysfunction. Serum electrolyte levels became disordered, and after death, some months later, very severe damage to tubule cells was shown by histological examination. This patient was suffering from subacute nephritis with malignant hypertension, accompanied by the nephrotic syndrome. Slighter degrees of tubular defect are possibly present—for example, in patient C. J., illustrated in Fig. 7—but this remains uncertain until more knowledge of normal tubular reabsorptive capacity for protein is obtained.

Some degree of glomerular defect appears to be present in all of the patients so far studied. If we are correct in assuming that tubular reabsorption of protein is substantially non-selective, and depends only on the relative concentrations of the different proteins in the glomerular filtrate, it follows that the ratios of, say, the apparent α_2 -globulin clearance to the apparent albumin clearance is identical with the ratio of the true (glomerular) clearances of these proteins. If the various globulin clearances are expressed as percentages of the albumin clearance in each patient tested, some information is given about the nature of the glomerular defect. In uncomplicated examples of the nephrotic syndrome, typical values found are: α_1 -globulin (70–150%), α_2 -globulin (2–20%), β -globulin (10–50%), and γ -globulin (5–40%). In acute nephritis, on the other hand, the globulin clearances mostly range from 50 to 150% of the albumin clearance, with slightly lower values for α_2 -globulin on occasion. Apparently, therefore, the defective areas of the glomeruli in acute nephritis transmit the different plasma proteins indiscriminately, the larger molecules of, say, γ -globulin being passed into the glomerular filtrate as readily as albumin.

If the glomerular membrane be regarded as a kind of sieve, in acute nephritis a few of the "holes" must be grossly enlarged. From clearance studies with dextran molecules of various sizes, it is known that the holes in the normal glomerular membrane are not all of equal size—all being permeable to molecules of molecular weight 5,000,

some 20% transmitting molecules of about 30,000 molecular weight, and very few being capable of transmitting molecules of 60,000–70,000 molecular weight. This state of affairs is apparently largely preserved in the uncomplicated nephrotic syndrome kidney, in that considerable selection is still exerted on the size of molecule which is transmitted. But there is enough "stretching" of many of the holes to permit increased filtration at any rate of the smaller plasma protein molecules such as albumin and α_1 -globulin. These

Fig. 8.—Possible glomerular membrane pore sizes as deduced from protein clearance studies. Normal: variations in pore size, but only occasional pores large enough to transmit protein. Acute nephritis: as normal, with occasional pores greatly enlarged. Nephrotic: many pores large enough to transmit smaller plasma proteins, only few transmit larger proteins. Reduced glomerular filtration rate may be associated with reduced numbers of pores.

variations in the size of hole in the glomerular sieve are illustrated diagrammatically in Fig. 8. Our findings in patients with subacute nephritis are intermediate between those described for acute nephritis and for the nephrotic syndrome.

Studies of Nitrogenous Metabolism

The patients in this series in whom proteinuria had been present for at least several months were grossly depleted in body protein. This feature of the nephrotic syndrome does not immediately attract attention for several reasons. The depletion develops insidiously, the muscular wasting is masked by oedema, and generally there is no marked loss of fat, so that the contours of the face, arms, and chest are not obviously abnormal. After loss or drainage of oedema, the calf muscles are often seen to be greatly reduced in bulk, and unequivocal evidence of protein depletion can be obtained by nitrogen-balance studies during convalescence. As an example, we have studied a girl of 19 (J. R.) who was severely affected with the nephrotic syndrome in July, 1952. Normally 55 kg. (8 st. 9 lb.) in weight, so much oedema was present by the end of October, 1952, that she weighed 87 kg. (13 st. 10 lb.), further increase being prevented only by repeated paracenteses. At this stage her appetite improved, and by December she was taking a diet containing more than 100 g. of protein each day. Daily nitrogen-balance studies were then carried out until her discharge from hospital 98 days later. During this period she gained over 3.6 kg. of protein (representing

with its associated water and minerals about 11 kg. of "flesh"). Since there was no slackening in this regain of body protein during the latter period of hospital treatment, and since the convalescence continued for several months after return home, this 11 kg. must represent only about two-thirds of the flesh lost at the height of illness, suggesting a maximum loss of 17 kg. In other words, a girl of 55 kg. normally (with no oedema) had wasted at the height of her illness to a person of (55–17 kg.)=38 kg., encumbered by (87–38 kg.)=49 kg. of oedema fluid. Now the normal body of a female of 55 kg. contains about 15% or 8 kg. of protein. This patient lost and regained at least half and probably nearly two-thirds of this total amount.

Much work has already been devoted to the study of nitrogenous metabolism in the nephrotic syndrome, Farr and MacFadyen's (1940) analysis of their findings in children being specially important. Nevertheless, it seemed worth while adding further studies. For the present, two findings are of interest—the nature and amounts of the nitrogenous metabolites found in the urine, and the effect of various levels of protein intake on these metabolites and on the nitrogen balance.

The daily output of urea is abnormally low in nephrotic syndrome patients of long standing. Whereas a normal person on an average English diet excretes each day about 25 g. of urea ($\equiv$ 11.7 g. of urea nitrogen), a severely affected nephrotic patient of similar size excretes only about 10 g. of urea daily ($\equiv$ 4.7 g. of urea nitrogen) on an equivalent food intake. This deficient output is not due to inability of the kidneys to excrete urea, for the urea output remains at this level for weeks or months without any progressive rise in blood urea concentration. As a practical consequence, simple urinary function tests based on specific gravity or urea content of early morning urines are unreliable in the nephrotic syndrome, especially as it can be shown that extra water taken by mouth does not produce a prompt diuresis in these patients, but tends to be excreted during a period spread over 24–48 hours. The low urea output in the nephrotic syndrome is a manifestation of the need to use all amino-acids derived from food so far as possible to synthesize new protein—especially the plasma proteins being lost in the urine. Even lower outputs of urea have been recorded in experiments when normal subjects have been maintained on diets containing little or no protein for long periods but otherwise adequate in calories and essential supplements. These normal subjects were, of course, sustaining the same continual loss of specialized protein in the urine. The 10 g. of urea being excreted each day by the nephrotic patient presumably represents the degradation product of certain amino-acids which cannot be used for plasma protein synthesis owing to relative deficiency of other essential components (probably other complex amino-acids).

While making daily measurements of nitrogen excretion by the nephrotic patient (J. R.), an unusually high difference or "gap" was found between the overall non-protein nitrogen values and the nitrogen present as urea + ammonia.

On the same 24-hour urine specimens, total osmolarity estimates disclosed an unusually large departure from the sum of estimated constituents. As these combined discrepancies led to a simple discovery, it seems worth describing the sequence in which they were noted.

In Fig. 9 is shown the Hill-Baldes thermo-electric device for measuring the total osmolarity of a solution. In principle it depends on the lowering of vapour pressure of dilute aqueous solutions in proportion to the number of dissolved particles (molecules such as urea or glucose, and ions such as sodium, sulphate, etc.). In use, the two loops shown are as loaded with a drop each of distilled water and urine, and then lowered into the thermostatically controlled chamber with walls lined with filter paper soaked in water. The condensation of minute amounts of water vapour on to itself,

and so becomes warmer. This continues for a few seconds until the urine is warm enough to have a vapour pressure equal to that of the water, when equilibrium is restored. This steady temperature difference between the loops, each of which is made up by a small manganin-constantan thermocouple, is measured directly on a specially sensitive galvanometer. The reading is directly proportional to the osmolar strength of the solution on the "urine" loop, so that only simple calibration of the instrument with three or four salt solutions of known strength is required.

Fig. 9.—Thermo-electric apparatus for measuring total osmolarity, as described by Baldes and Johnson (1939). The loops loaded with urine and water settle to a steady temperature difference which is proportional to the osmolar strength of the urine, and is measured directly with the galvanometer.

In normal urine the main non-electrolyte is urea. Protein has a negligible effect on osmolarity, as such large molecular-weight substances consist of very few particles in solutions of the order of 1 g. or 2 g./100 ml. The electrolyte cations, sodium and potassium, are readily estimated with the flame photometer, and with ammonium, also readily estimated, constitute the main cations. The anions are more various, and in this study were approximately estimated as equivalent to the cations divided by a factor of 1.1, their usual average valency, for conversion from milliequivalents per litre into milliosmols per litre. In other words, the electrolyte strength in milliosmols due to cations + anions was calculated approximately from:

$$\text{(main cations)} \left(1 + \frac{1}{1.1}\right) \\ \text{or (main cations)} \times 1.9$$

This sum of (urea) + 1.9 (combined cations) was compared with the total osmolarity measured with the Hill-Baldes instrument, and in normal urine was only about 5% less—a gap which on rough calculation was not unsatisfactory in view of the various minor constituents (creatinine, uric acid, calcium, magnesium, etc.) not considered. In the urine specimen from the nephrotic patient, however, this osmolar gap was much greater, and was found to increase as convalescence advanced. Similarly, the nitrogen gap (non-protein nitrogen—urea + ammonia) increased. This is shown in Fig. 10b, the values obtained by the research worker in 24-hour samples of his own urines being shown

FIG. 10.—“Nitrogen gap” in 72-hour urine specimens between total non-protein nitrogen and its major component (urea + ammonia). The gap (represented by the horizontal distance between the observed points and the line) is small in the normal (a). This confirms other workers' findings with high- and low-protein diets (e.g., Folin, 1905; Deuel and others, 1927). In the nephrotic patient, J. R. (b), the gap is often considerable, especially with larger values of non-protein nitrogen excretion following high-protein feeding.

in Fig. 10a. In Fig. 11 the two forms of gap as found on three-day averages, week after week, are plotted against each other on log. log. scales. There is a considerable scatter, due no doubt in part to errors of estimation, in part to the assumption of a constant valency of 1.1 for the anion constituents of the urine. But the results are consistent with the true relation between the gaps being a straight line rising positively at an angle of 45 degrees. This implies that the two gaps are only separate measurements of the same unidentified constituent or group of constituents. The position of the line accords with molecules each containing between one and four atoms of nitrogen. At this stage amino-acids become suspect as the unanalysed constituents, and paper chromatography recorded their presence in large variety and amount. Nearly all the common amino-acid constituents of protein were found to be present. It may well seem that a rather

FIG. 11.—Relation between osmolar gap and nitrogen gap in nephrotic patient J. R. (72-hour specimens). Both values are plotted on similar logarithmic scales. The lines indicated show the values expected if the bulk of the unanalysed constituents contained 1 or 4 atoms of nitrogen/molecule—the range observed in 20/26 specimens.

long way round was taken to a simple discovery: the method has been detailed, as it seems to be generally applicable to the search for unknown constituents in the urine in a variety of diseases.

Testing other nephrotic patients for amino-aciduria has shown that its presence is not an isolated occurrence, but that it is not found in every case. In the patient already described, the quantity of amino-acids wasted in the urine was very considerable, increasing on the higher protein diets so that on intakes of about 150 g. of protein daily the equivalent of 20–30 g. was excreted as amino-acids. With severe proteinuria also present this patient was “wasting” about one-third of her protein intake. The amino-aciduria was apparently due to deficient tubular reabsorption resulting in a lowered renal threshold for amino-acids, as the blood amino-acid concentration was not raised above the normal.

Estimation of the nitrogen balance is probably the best criterion on which to choose an optimum diet. High-protein intakes have in the past sometimes been observed to result in increased proteinuria (see Berglund, Scriver, and Medes, 1935), but this is not necessarily a contraindication to their use if it reflects an increase in plasma proteins. Similarly, an increase in amino-aciduria merely seems to reflect an increased absorption of protein. By allowing a patient to take more protein in some balance periods than in others, it is possible to choose the optimum intake for maximum retention of nitrogen. In our studies with adults, the highest intake which we could persuade the patients to take (up to about 180 g. of protein a day in 60 kg. patients, or about 0.5 g. of protein nitrogen per kg.) gave the most strongly

TABLE V.—Effect of Varying Protein Intake on Nitrogen Excretion and Balance

	Normal On Protein Intake of:			Nephrotic On Protein Intake of:		
	0.2	0.3	0.4	0.2	0.3	0.4
Excretion of: Urea + ammonia Protein	0.19 0	0.29 0	0.39 0	0.09 0.06	0.09 0.06	1.10 0.06
Nitrogen balance	0	0	0	+0.04	+0.11	+0.18

All values expressed as g. nitrogen/kg./day.

positive balance results. Table V summarizes some typical findings. Whereas a normal person put on such a diet increases urea output in a few days and so balances the extra intake by a rise in nitrogen excretion, the nephrotic patient shows very little increase in urea output over periods lasting several weeks. Slowly, however, the urea output does rise somewhat, suggesting that after retention of large amounts of nitrogen the depleted reserves of body protein are restored to more normal levels, and the nitrogen metabolism of the nephrotic approaches that of the normal.

Prognosis and Treatment

Renal diseases associated with sustained hypertension, electrolyte disorders, or rises in blood urea or creatinine levels are known to have a poor prognosis. The outlook seems to be far better for uncomplicated examples of the nephrotic syndrome, especially now that intercurrent infection is so much more readily controlled by the use of antibiotics. These drugs also make reasonably safe the drainage of oedema fluid by paracentesis or Southey's tubes, procedures which may afford symptomatic relief to severely affected patients. Low-sodium diets delay the formation of oedema and, with dialysed milk or animal serum as supplements, can be maintained in conjunction with high levels of protein intake.

Measures aimed at directly raising the colloid osmotic pressure of the plasma seem to meet with varying success. Albumin transfusions (e.g., 50 g. in water) have only a transient diuretic effect, and some of the material administered is rapidly lost into the urine. Salt-free dextran infusions have been given to eight patients on two occasions each, under our observation, in six a similar transient response being observed. In two patients a more satisfactory result was obtained with the second infusion of 1,200 ml. 600 ml. having been administered seven days and ten days previously. Considerable saline diuresis lasting two weeks and three weeks ensued, both patients being entirely cleared of oedema. No relapse followed, the proteinuria diminished, and the chemistry of the plasma slowly reverted towards normal. Certainly, similar results have been obtained in the past with other remedies, gum acacia having been prominent at one period. A task of future research is to discover which patients or what stage of the illness is likely to respond in this fashion.

Gradual recovery may also follow a lengthy period of high-protein intake, diuresis occurring after some two months of positive nitrogen balance. Though the flood of diuresis seems to occur suddenly, a preceding trickle may be detected several weeks earlier in the form of an increased sodium chloride loss. It is possible that the very beneficial results sometimes obtained with colloids like dextran are obtained when patients are in this borderline state, so that, in effect, a hastened convalescence is achieved. In the present state of knowledge it is desirable to emphasize the need for maintaining nephrotic patients on a high-protein intake. Several reports from other centres have suggested that rapid recovery may follow the administration in high dosage of specific food constituents such as methionine or choline. In view of the large overall protein deficit commonly found, it seems very likely that some patients are especially deficient in sulphhydryl or labile methyl groups, but more work is needed to find out the relative frequency of general and specific forms of depletion.

Evidently gradual repair of renal defects, glomerular or tubular, can follow conservative treatment. If a drug could be found which reduced proteinuria without diminishing glomerular filtration of substances of smaller molecular weight, much more rapid recovery could be anticipated. Such effects have been claimed for A.C.T.H. and cortisone, though relapse may follow. Again, it seems that favourable results are not universally obtained. Our own experience with these drugs is too limited as yet for useful comment. In one patient an appreciable effect on proteinuria was not obtained with either drug, but cortisone appeared to con-

tribute to an increased appetite, making the institution of high-protein feeding practicable, and so indirectly leading to gradual recovery.

Theoretically, mercurial diuretics seem out of place in the treatment of patients already afflicted with severe proteinuria. In practice, they are used when other measures fail to remove oedema, and may enable a patient to carry on limited activities which would not otherwise be possible.

Summary

The nephrotic syndrome is characterized by oedema, proteinuria, and hypo-albuminaemia without certain signs of other forms of renal disease. Similar syndromes may also occur in association with other diseases.

A reduced colloid osmotic pressure seems to be the prime cause of oedema, and so of saline retention. Plasma volume is also reduced; it may rise and diuresis occur before the colloid osmotic pressure rises. Homeostasis of fluid volumes is discussed in relation to C.O.P. and interstitial gel swelling pressures.

With proteinuria and hypo-albuminaemia, other plasma constituents show characteristic alterations, the smaller-molecular-weight proteins tending to be reduced, the larger to be increased.

The amount of albuminuria is correlated with the degree of hypo-albuminaemia; albumin synthesis and utilization is discussed in relation to this finding.

The effect of albumin infusion on proteinuria can be used to assess glomerular permeability and tubular reabsorption of protein. The relative clearances of albumin and other plasma proteins differ in various types of disease and imply different disorders of glomerular permeability.

Nitrogen metabolism and balance studies contribute to an understanding of pathogenesis and treatment. Large deficits of body protein have been observed; low urea excretion values are found and interpreted partly as a manifestation of nitrogen conservation. Amino-aciduria of considerable extent may accompany the nephrotic syndrome, especially on high-protein intakes.

The prognosis of uncomplicated nephrotic cases is probably not as bad as is often thought. The achievement of a positive nitrogen balance by high-protein feeding is recommended.

Grants from the Medical Research Council supporting Dr. Hardwicke, Dr. Rowe, and Mr. Yardley (studentship), and from the United Birmingham Hospitals Endowment Research Fund supporting Dr. Blainey, are gratefully acknowledged. Serum albumin has been given by the Lister Institute for special trial under the auspices of the Medical Research Council Blood Transfusion Research Committee. Special thanks are due to the physicians of the United Birmingham Hospitals and of Selly Oak Hospital for co-operation in investigation and treatment of their patients. Dr. H. Bickel kindly carried out some special investigations of amino-acids in blood and urine specimens. We are grateful to Mr. A. C. Downing for considerable help in constructing the Hill-Baldes thermo-electric instrument.

According to the World Health Organization's Expert Committee on Mental Health the following should be the essential characteristics of the modern psychiatric hospital : (1) The hospital should be designed by a town planner on the model of a small village in which patients should be placed in groups of not more than 10. (2) A hostess endowed with intelligence and an attractive personality should receive the patients. (3) The personality of the patient should be respected ; he should be considered as a sick person like any other sick person, worthy of trust and capable of responsibility and initiative. (4) The psychiatric nurse should be a specialist technician and should not be obliged to attend more than three to six patients. (5) Patients should be encouraged to form themselves into clubs (sports clubs, holiday clubs). (6) Patients who are on the way to recovery should be helped in the renewal of their relations with the community by being accorded leave of absence, or by employment. (*W.H.O. Technical Report Series, No. 73.*)

THE CLINICAL SPECTRUM OF OBESITY*

BY

J. H. SHELDON, M.D., F.R.C.P.

Senior Physician, the Royal Hospital, Wolverhampton

My contribution to this discussion is an attempt to survey the clinical field of obesity in the light of recent knowledge. The underlying point of view is that appetite plays the fundamental part and that, although endocrine factors are capable of causing changes in weight based on internal rearrangements of protein and fat, the usual reason for gain of weight is an excess of calorie intake over expenditure.

Experimental Obesity

Probably the most important recent contribution has been the direct production of experimental obesity by damage to certain nuclei in the medial hypothalamus, which has been shown by several workers and confirmed for several species of animals (Hetherington and Ranson, 1939; Brobeck, 1946). The essential feature of this obesity is that it is based on an enormous increase in appetite, and the close dependence of appetite on hypothalamic function has been further demonstrated by the discovery of lateral nuclei, destruction of which leads to total loss of appetite. In fact, it is possible to make an animal obese by first destroying the medial hypothalamic nuclei, and then to convert this into a fatal anorexia by subsequent destruction of the lateral nuclei (Anand and Brobeck, 1951a, 1951b). Clinically, this is reminiscent of the fat girl who subsequently develops anorexia nervosa, which, unless treated, may prove fatal.

The course of the increased appetite and consequent obesity in animals with hypothalamic damage is of great interest. Immediately after operation the appetite is voracious and indiscriminate, so that a rat may double or even treble its previous intake, and the gain of weight is very rapid. Both the appetite and the rate of gain then gradually decrease until a plateau is reached, on which extra weight can be maintained on a diet not significantly greater than normal. If these animals are starved and their weight is reduced they immediately return to their previous high level when allowed to refeed. In such animals fat may account for as much as 70% of their total weight, and water retention plays no part. Their appetite is now more capricious, and in this they appear to resemble both older rats and those that are naturally fat (Kennedy, 1950).

Maternal Obesity

These experimental findings may well have a direct application to some forms of human obesity, and indeed clinical study of maternal obesity shows so close a parallel to the experimental condition that there must be factors in common. The agreement covers the initial stage of voracious appetite, the plateau stage, and the amount of final gain achieved.

As clinicians we have undoubtedly been too ready to accept fat people as they are without a close inquiry into the rate of onset of the condition. The case literature is in fact extremely meagre on this point. It is, of course, difficult to obtain accurate information concerning weights in relation to time in the past, but individual accuracy can to some extent be replaced by multiple case histories, and in 80 cases of maternal obesity I have been able to collect 19 records of weight gain over different but definite periods (see Chart). It is remarkable how the rates of gain of these different women appear to be following a common path. They were all women whose gain of weight began after the birth of a baby, and the available information consisted of

*Read at a Plenary Session at the Annual Meeting of the British Medical Association, Cardiff, 1953.

a weight record taken during the puerperium and a subsequent record at a known but haphazard interval of time, which of course varied from patient to patient. It will be obvious that the general picture bears a close resemblance to that which has just been described in rats after hypothalamic damage; the gain of weight may begin with the same dramatic rapidity and then gradually tail off until a more or less steady state is reached, which in the case of these patients appeared to take about a year. Subsequent gain, if present at all, is extremely slow.

Records of weight gain (pounds per week) in cases of maternal obesity.

Thus, a woman had her baby in January, 1940, and weighed 133 lb. (60.3 kg.); in April, 1940, she weighed 168 lb. (76.2 kg.)—a gain of 35 lb. (15.9 kg.) in approximately 16 weeks, or a little more than 2 lb. (about 1 kg.) a week. She then refused to face the scales until April, 1944, when she weighed 218 lb. (98.9 kg.) so that in the interval she had gained 50 lb. (22.7 kg.) in some 208 weeks—less than $\frac{1}{4}$ lb. (0.11 kg.) a week. Over the whole period, however, she had gained 85 lb. (38.6 kg.) in 224 weeks, approximately 0.4 lb. (0.17 kg.) a week.

Development of Obesity

When one discovers that other individuals, who knew their weights only at the beginning and the end of a similar period of years, had not only experienced the same average rate of gain but also said that they remembered having put on weight very rapidly to begin with, one cannot help surmising that they may have followed a similar course. There is no doubt that some fat people have gained their weight slowly and steadily, but there are others who do so with a great initial rapidity which tends subsequently to be forgotten, and I would plead for more extensive studies of the actual rate of development of obesity. Not only does the rate of increase in these cases of maternal obesity parallel the experimental one, but in the very few cases that I have been able to see I have satisfied myself that the period of rapid gain was accompanied by an excess appetite.

Thus one woman who was gaining at a rate of slightly more than 3 lb. (1.36 kg.) a week not only ate her full ordinary meals with second helpings but also consumed sweets and raided the larder during the intervals. This is common enough, but when in addition it was found that after partaking of a special supper immediately before retiring she also took food to bed with her knowing that she would wake up ravenous in the night, and then required her husband to bring up bread and cheese with the morning cup of tea, one is justified in ascribing the gain of weight to a voracious appetite. It is of interest that she herself refused with some anger any suggestion that she was overeating, as she never had "more than her fill," and in response to later questioning would undoubtedly have denied any excess intake—for the patient is apt to deal with questions on this point as if the implied an accusation of greed.

When the rate of gain is at its steepest hunger seems to arise immediately after a meal and there is no feeling of satiety, however much has been eaten. As the rate slows off the intervals before hunger reappears seem to lengthen the progression being from "I'm never satisfied" to "get hungry again an hour after a good meal," and so on. It is as if a satiety mechanism which is nil at the start gradually increases as the weight approaches a target already set

Calorie Intake

When the woman has reached a plateau in which either the added weight is steady or is subject at the most to a very slow increase, clinical observation shows quite clearly that many of them are not taking an excessive diet (Sheldon, 1949) and that, in their own words, they "do not deserve to be fat"—which agrees with the experimental findings (Kennedy, 1950). Their eating habits are often unusual; they may cut out some meals altogether—usually breakfast—and depend on one or two very large meals, and many of them admit to an almost irresistible appetite in the presence of articles of food for which they have a partiality. In their study of actual diets consumed Widdowson and McCance (1936) found no significant correlation between body weight and calorie intake, and we should remember that fat individuals may very well not deserve to be fat in the light of their present intake, but they have undoubtedly at some time in the past deserved to become fat, and may since have been able to maintain their added weight on a reasonable intake. Since their basal metabolism is normal, and this is calculated on a bigger surface area, the only way they can achieve this result is by a diminution in activity. This has been shown to occur in the experimental animal (Brobeck, 1946), and, although it is virtually impossible to demonstrate clinically, yet I think that general observation suggests it may be true.

Since the final gain achieved may be as much as 150% of the original weight, simple calculation shows that some 60% of the total weight would be due to fat, and this again is in keeping with the experimental findings.

Hypothalamic Regulation

The general concordance between experimental obesity produced by hypothalamic damage and the clinical findings in maternal obesity is so close that one must assume a hypothalamic mechanism to be concerned in the latter, and, if so, its possible role in other types of human obesity has to be considered. The cases in which obesity develops after inflammation of or injury to the lower brain, as an occasional complication to encephalitis or chorea and to a fractional base or subarachnoid haemorrhage, would seem to be the direct human equivalent of the experimental damage. The interesting syndrome of periodic somnolence and morbid hunger (Kleine-Levin) is also a close analogue and serves as a link with those instances which are to be associated with alterations in hypothalamic function rather than with actual structural damage. In view of their close functional relations, one naturally looks to the cortex as one possible source of such alterations in hypothalamic function, and clinical experience does indeed reveal several types of obesity in which a cortical factor must be assumed. The obesity which sometimes follows frontal leucotomy undoubtedly belongs to this group, as also does the increased appetite which is well known to occur in some people in response to emotional states (Shorvon and Richardson, 1949). One wonders also whether the well-known gain of weight that follows abstinence from tobacco may not have a similar origin.

It is an interesting commentary on the difficulties of clinical medicine that an obesity of apparent emotional origin may often arise in the midst of a disturbed endocrine background. Bruch (1940) has shown that fat children are apt to have an emotional tension which is eased by the taking of food, and at the same time their bone growth is in advance of their age—which may, nevertheless, be a derivative from rather than antecedent to the increased intake. Maternal obesity begins immediately after the birth of the baby, when there is a considerable endocrine stress associated with the establishment of lactation. When such obesity occurs in the first and only pregnancy or in the last pregnancy, boy babies are no fewer than four times as common as girl babies, and one cannot avoid the speculation that it is the appearance of the male infant which has released an emotional state in the mother, leading in turn to the increase of appetite.

Other Types of Obesity

The types of obesity already mentioned are, of course, only a part of the whole clinical spectrum, and an application of the same point of view to other forms is not immediately obvious. They are characterized essentially by the fact that the obesity presents itself to the clinician in company with other features which imply an abnormal endocrine state, and in the latter it is natural to seek for an explanation of the former. This may be hazardous, for we have as yet no full understanding of the many factors involved in the established state of overnutrition. It is, of course, well known that insulin is involved and that obesity leads to hypertrophy of the islet tissue, but the endocrine adaptations are certainly complex, and probably involve both the anterior pituitary and the adrenal cortex in addition. When clinical evidence of ostensible endocrine derangements therefore are found to accompany obesity, it is well to remember that they may derive from rather than be causative of the obesity. Neglect of this aspect led to the mistaken view, held for many years in many quarters, that patients with anorexia nervosa were suffering from an organic hypopituitarism—a warning that should make one cautious.

Nevertheless, it is true in general to say that obesity tends to arise at three periods—growth and puberty, maternity, and the menopause—all of which have in common an endocrine departure from a relatively static state. It would be interesting to know more about the menopausal middle-age spread than we do. Accurate information is curiously lacking at a minimum, and there is certainly here an untapped field of clinical observation. One's general impression is that the gain is a slow one, which suggests that it may be due to a continuance of previous dietary habits at a time when energy expenditure has become somewhat less.

Relation to Growth Factor

The obesity which is so common an accompaniment of late adolescence in association with growth and puberty has been more closely studied, although the occasional excesses have proved more congenial than the normal development of "puppy fat," which never gets to the doctor at all. The work of Young (1951) on the relation of obesity to growth factor of the anterior pituitary may well be relevant here. In dogs the hormone causes a deposition of protein accompanied by an increased catabolism of fat. If the diet be controlled the animal can gain weight on a diet that previously only kept the weight static, owing to the different calorie values of protein and fat. The normal animal, however, does not keep his intake steady, but responds by a great increase of appetite, and this may be so big that the excess fat laid down more than compensates for the energy lost to the body by growth. The appetite response is, in fact, a coarse one and leads to the taking in at this time of life of an unnecessarily large calorie total—an experimental observation which would appear to be in harmony with both the insatiable appetite and the "puppy fat," which are so common in adolescence.

The effect of growth hormone has also been invoked as an explanation of maternal obesity. It is a well-established observation that women who develop diabetes in middle life are apt to have given birth to larger babies than non-diabetic women, and these women are also often obese; it has been suggested that overproduction of growth hormone has led to the large baby and, in the course of time, to the appearance of diabetes.

Nevertheless a general clinical review of these two types of obesity suggests that even at these epochs it is unlikely to be the only factor, for if growth factor were the sole agent one would justifiably expect the extreme cases to show clinical appearances tending towards gigantism or acromegaly. It is a remarkable fact that, on the contrary, these are conspicuous by their absence, and where there is evidence of endocrine excess in the obesities of growth or maternity the clinical appearances are those associated with abnormal function of the adrenal cortex. Thus striae distensae are very common, and I am in complete agreement with Simp-

son (1950, 1951) in the stress he lays on their importance. Although they can appear in diverse clinical states, the available evidence suggests that they derive from an altered or excessive adrenal steroid metabolism, and they can certainly occur in the course of treatment with A.C.T.H. Simpson (1951) has described some of these cases of pubertal obesity under the names of adipose gynism and adipose gynandrium, and there is no doubt that they constitute a definite clinical picture which we have all seen, although Le Marquand (1951) may well be right in regarding them as extremes of the continuous spectrum of childhood obesity rather than as isolated entities. However this may be, it would appear to be impossible to understand them without regard to the adrenal cortex, and the same applies to maternal obesity, for when endocrine abnormalities occur in these women their trend is always in the direction of a Cushing syndrome and never in that of acromegaly. Indeed, pregnancy is a well-recognized precursor of the Cushing syndrome.

Our present knowledge, however, does not enable us to go much farther than the general statement that the adrenal cortex is undoubtedly concerned in the mechanism of obesity. Apart from the possibility that it may affect the site of the deposition of fat, and that Kendall's compound A (11-hydroxycorticosterone) and compound B (corticosterone) may cause a decrease in weight accompanied by an increase in the percentage of fat, there is some clinical evidence that the gland may have a direct effect on appetite, and, if so, this may provide a link with what has already been said concerning the hypothalamus. It is well known that the use of both cortisone and A.C.T.H. may occasionally be accompanied by a marked increase of appetite and gain of weight; in my experience this is particularly true of A.C.T.H., and I well remember one child, given it for nephrosis, who immediately developed an appetite so insatiable that it was like that described for rats after hypothalamic damage; for if food were not at hand she would consume her chalks, and so long as food was available she would go on eating. Simpson (1952) has described the case of a child with a tumour of the adrenal cortex who developed a similar appetite with resultant obesity. The link between the adrenal cortex and such appetite is still a mystery.

We have no understanding of how the hypothalamic regulation of appetite is itself controlled, but Kennedy (1953) has suggested that hypothalamic damage leads to an increased appetite by interference with the satiety mechanism, which may normally be actuated by a sensitivity in the appropriate hypothalamic cells to metabolites in the blood stream. No single metabolite has been proved to be capable of exerting this control, though glucose has been suggested. One cannot avoid the speculation that adrenal steroids may influence appetite by a direct effect on the hypothalamic cells concerned, and that an excess of certain steroids may provide the hypothalamus with entirely false information, causing it to legislate for a state of need in the presence of a state of plenty. For this is essentially what happens when the hypothalamus is injured or a child with an adrenal cortical tumour develops an insatiable appetite.

Speculation is hazardous; nevertheless it seems fitting to end on such a note, for the problem of obesity has not yet disclosed all its secrets.

ASSESSMENT AND RESULTS OF OBESITY*

BY

H. M. SINCLAIR, D.M., B.Sc., M.R.C.P.

Laboratory of Human Nutrition, University of Oxford

For my purpose I shall define obesity as the condition in which the amount of body fat is greater than normal: the tiresome question of normality I have discussed at length elsewhere (Sinclair, 1948). The term "overweight" merely means that the body weight is greater than normal, having regard to such factors as race, sex, somatotype, height, and age.

Assessment of Obesity

A common but highly erroneous method is to obtain the weight and height of a person and compare the former with so-called standards of weight for given sex, age (if not adult), and height. The basis of the standards is seldom considered. When nutritional surveys were conducted in Germany for the Control Commission immediately after the war considerable attention was paid to body weight, and especially to longitudinal studies of body weight in individuals. Some 100,000 persons in a wide variety of categories were weighed monthly, and these weights were compared by the Hollerith method with the previous weights; unfortunately the Control Commission had these monumental results pulped in a moment of lightheartedness. Such longitudinal studies on single individuals are very valuable, although it must be remembered that undernourished persons may adapt by doing less work, thereby conserving their body weight, and that extracellular fluid may increase and mask a decrease in the weight of the fat and tissues. But a single estimate of body weight in cross-sectional studies did not give much information.

The standard tables available were those of Hassing-Schall; it was very difficult to discover their origin, which in fact proved to be unimpressive. Since the standards were much higher than those in the use of the U.S. Army, it was not surprising that Germans appeared in many cases to have lost a considerable amount of weight, and the possibility that Hassing's subjects were obese had not been considered. Further, his male figures (Brugsch, 1922) contained the common error of being the average or arithmetic mean of a large number of observations (his female figures were obtained by subtracting an arbitrary 0.89 from the male figures): since body weights are not normally distributed about the mean but are skewed to the right, the average weight of a group of persons is more than the centre of the distribution (or mode).

A very important variable in considering the assessment of obesity from overweight is the somatotype. As W. H. Sheldon (1940) has shown, every person has a greater or less degree of endomorphy, mesomorphy, and ectomorphy. Those persons in whom one or other of the first two predominates will tend to be overweight. The endomorph will tend to be overweight. The endomorph has excessive fat, and his overweight indicates obesity; but the mesomorph has large muscles and bones, though he may not be tall, and the amount of fat is not necessarily excessive. Indeed, a mesomorph

*Read at a Plenary Session at the Annual Meeting of the British Medical Association, Cardiff, 1953.

such as 163 would normally weigh much more and have much less body fat than an ectomorph such as 425 of the same height. So the measurement of body weight will not necessarily tell us much about obesity.

Methods of Measuring Body Fat

The easiest way of estimating the amount of fat in the body is to measure the amount in the subcutaneous tissue, where about half the total is located. This method has been used by clinicians for a long time. Quantitative studies have been made since the end of the last century; sometimes one site has been used, but Edwards (1950) tried 93 points and site has been selected 53. In wartime studies in England, and subsequently in the famine in the Netherlands and in post-war Germany, we used a simple form of calliper and two sites—over the top of the biceps and midway down the back of the forearm. It was found that there was a correlation between the thickness of subcutaneous tissue and relative weight (as judged from standards for given sex, age, and height) of the order of 0.5; this, though highly significant and indicating that fat persons tend to be overweight, does not mean that overweight is necessarily an accurate measure of obesity. The measurement of subcutaneous fat from soft-tissue x-ray films (Stuart, Hill, and Shaw, 1940; Reynolds and Asakawa, 1948) does not seem to have any advantage over that of skin-fold thickness.

Professor McCance has mentioned methods of determining the composition of the body. The most accurate way of measuring the total body fat is by determining the density of the whole body (Kohlrausch, 1930; Behnke, 1942; Rathbun and Pace, 1945; Keys, 1953). Keys (1950), in a study of young and middle-aged men, found a correlation between abdominal skin-fold and relative weight of 0.475 (similar to our correlation); but the correlation between density and relative weight was only -0.24, indicating again that overweight does not necessarily afford a good index of obesity. His correlations between abdominal skin-fold and density were -0.84 for the young men and -0.60 for the middle-aged men (Keys, 1953), so we may reasonably be content to measure obesity by the thickness of subcutaneous tissue.

Assessment of Obesity in Children

The assessment of obesity in children is more complicated. There are two well-known spurts in growth that do not necessarily occur at the same ages, and the problem of what is normal growth is difficult to solve; further, the distribution of subcutaneous fat varies with age. There has been a tendency to regard maximum growth of children as the optimum. In lower animals it has been shown by various workers that overnourishment during growth leads to early maturity and a shortened life-span. A characteristic of the genus *Homo* is the relatively long time taken to shorten maturity; there is no evidence that it is desirable that it is this period of development and some evidence that it is harmful. Some children appear to put on weight much more readily than others, and endocrine glands are often blamed. We may perhaps agree with Rynearson, who is co-author of an excellent book on obesity (Rynearson and Gastineau, 1949), that "the only glands involved in obesity are the salivary glands"; yet some facts are not easily explained. For instance, Peckos (1953) claimed to have found that endomorphic children ate less than ectomorphic; but her dietary methods are not beyond criticism. It is a common observation that some endomorphs, whether children or adults, appear to eat relatively little and yet gain weight, whereas some ectomorphs appear to remain thin on large calorie intakes. The matter requires careful investigation. It must be remembered that endomorphs have relatively less surface exposed and therefore lose less heat, and they tend to be less active with slower movements and fewer gestures than the "lean and hungry" ectomorph; on the other hand, more work is done by the endomorph for a given movement.

Effects of Obesity

If obesity were unimportant there would be little need to measure it. Apart from mechanical inefficiency and aesthetic undesirability, it is the cause of disease and premature death. It is somewhat trite to mention that a person who is 40 lb. (18 kg.) overweight carries around an extra 40 lb.; this means that extra energy is expended, extra food is eaten, and there is some muscular hypertrophy (Keys, 1953). There is an increased incidence of degenerative arthritis of the lumbar spine, hips, and knees (Harmon, 1942; Danowski and Winkler, 1944; Faust, 1946), and of hernias, varicose veins (Dublin, Fisk, and Kopf, 1925), and fractures (Coombs, 1936); accidents are more frequent, presumably because the obese are slower in their movements and clumsy (Dublin and Marks, 1930). The postural changes cause respiratory and circulatory inefficiency, with emphysema (Kerr and Lagen, 1936) and decreased vital capacity (Short and Johnson, 1939).

The careful statistics presented by Dublin and his colleagues of the Metropolitan Life Insurance Company, New York (Dublin and Marks, 1930; Armstrong, Dublin, Wheatley, and Marks, 1951), have shown that at all ages men and women who are overweight have a higher mortality than the average; and the greater the degree of obesity the greater the mortality. Obese men had higher death rates from degenerative cardiovascular and renal diseases, diabetes mellitus, and cirrhosis of the liver; obese women had relatively the greatest excess mortality from diabetes mellitus and diseases of the gall-bladder, especially gallstones. The mortality is relatively worst among those under 45; among both men and women the number of observed deaths from degenerative diseases of the circulatory system and kidneys is 70% more than the expected, and it is at least double the expected among those under 45 (Armstrong *et al.*, 1951). In the course of pregnancy and childbirth obesity is a hazard; there is a greater frequency of complications, deaths, toxemia, and large babies (Matthews and Der Brucke, 1938; Odell and Mengert, 1945; J. H. Sheldon, 1949; Gilbert, 1949).

Biochemical Aspects

I wish to mention in particular two conditions—diabetes mellitus and atherosclerosis—in which there is an increased formation of cholesterol, and to make a few brief remarks about biochemical aspects. According to Joslin, obesity is a forerunner of diabetes from middle life onwards in fully 90% of the cases, and only 5% are underweight before the

Chart showing process of formation of cholesterol.

onset (Joslin, Root, White, and Markle, 1940). Further, after the age of 40 the mortality from diabetes among overweight women insured at substandard rates was eight times as high as that of average or underweight women. There are two distinct biochemical mechanisms to be considered.

First, fatty acids are formed in cells from 2-carbon ("active acetate") fragments arising from pyruvate and hence from glucose, or from other sources such as oxidation of fatty acids. Though insulin promotes the synthesis of fatty acids, probably by making energy available within the liver cells for this synthesis, it is known not to be essential: liver slices from depancreatized cats will

convert C^{14} -labelled acetate into fat at a normal rate if the hypophysis is removed (Brady, Lukens, and Gurin, 1951). These workers also found that pituitary growth hormone or cortisone decreases the synthesis of fat, and in the intact animal growth hormone or A.C.T.H. depresses the synthesis (Welt and Wilhelmi, 1950). But the reverse process—the breakdown of fatty acids into 2-carbon fragments—is increased in diabetes as it is in fasting, and from these fragments acetoacetic acid and hence cholesterol are formed (Brady and Gurin, 1951); this accounts for the ketosis and hypercholesterolaemia of diabetes. It in no way accounts for the association of obesity with diabetes; indeed, if there is decreased formation of fat from carbohydrate and increased oxidation of fat one might be tempted to expect diabetics to be thin.

Dr. Meiklejohn has suggested that chronic excessive output of insulin by the islets of Langerhans might produce obesity and lead eventually to failure and atrophy of the islets, with resulting diabetes. But the characteristic middle-aged obese diabetic belongs to the insulin-resistant type and shows no atrophy of the islets after death. When we cannot explain a mechanism in man it is useful to turn to rats and mice. This has been done with success by Jean Mayer, of Harvard, who has studied obese patients and hereditarily obese mice (Mayer, 1952). He believes that appetite is conditioned by the effective blood-glucose level, or the amount of sugar that can pass into and be used by cerebral cells in unit time. Food intake is regulated to keep the effective blood sugar constant.

The inheritance of obesity in the mice is a Mendelian recessive; the adult animals weigh up to three to four times the normal, they become diabetic by the ninth or tenth week of life, and they die prematurely with very much enlarged islets of Langerhans. The diabetes is characterized by a high degree of insulin resistance, and it is caused by a blocking by pituitary growth hormone of the action of hexokinase upon glucose. In the pre-diabetic phase in these animals, as in hypothalamic obesity, increased lipogenesis causes overeating; in the diabetic phase, the blood glucose is raised but the impaired phosphorylation of glucose keeps the "effective" blood glucose from increasing correspondingly. Mayer concludes that there is a suggestive analogy between the obesity-diabetes syndrome in mice and the insulin-resistant diabetes often encountered in obese individuals. The obese diabetic mice, like insulin-resistant middle-aged obese diabetics, have hypercholesterolaemia, and it remains to consider the relation of overweight to cholesterol metabolism and atherosclerosis.

Correlation between Obesity and Atherosclerosis

The agreed facts about obesity and atherosclerosis seem to be as follows. There is a correlation between overweight and hyperpiesis: for instance, a study of 74,000 industrial workers showed at every age and in both sexes a steady progression in both systolic and diastolic pressures with increase in body weight for height (Master, Dublin, and Marks, 1950); at necropsy, advanced atherosclerosis is much commoner in the overweight (Wilens, 1947). The development of atherosclerosis is related to the serum cholesterol level (Davis, Stern, and Lesnick, 1937; Keys, 1951a; Katz, 1952). In general, there is a steady increase in the mean serum cholesterol level of well-fed men from adult age to the mid-50s, the average annual increment being about 2 mg. per 100 ml. (Keys, Fidanza, Scardi, and Bergami, 1952). There is no relation between the serum cholesterol level and the habitual dietary intake of cholesterol (Keys, 1949; Gertler, Garn, and White, 1950), but the serum cholesterol level is altered by substantial changes in the dietary fat (Keys, Mickelsen, Miller, and Chapman, 1950; Hildreth, Mellinkoff, Blair, and Hildreth, 1951). There is a correlation between the concentrations in serum of cholesterol and of Gofman's lipoprotein molecules (Keys, 1951b). Therefore Keys, whom we were fortunate to have working with us for a year in Oxford recently,

has been led to suggest that increased dietary fat raises serum cholesterol and produces atherosclerosis: since increased dietary fat will tend to cause obesity it is not surprising that atherosclerosis is commoner in overweight persons.

In many of these studies it is important to avoid the *post hoc* fallacy and the danger of confusing the cart with the horse. Because degenerative arthritis is commoner in the obese, we cannot necessarily conclude that obesity causes it: it might be maintained that arthritis limits movement and so causes obesity. Perhaps arteriosclerosis diminishes the blood supply of the hypothalamus and thereby increases appetite, with consequent obesity. In this connexion the recent work of Dublin (1953) is pertinent: he has shown that there is a substantial lowering of mortality amongst overweight persons who reduce their weight, and various disorders that are commoner in the obese can be diminished by slimming.

Ninety years ago William Banting (1863) began his *Letter on Corpulence* with the following words: "Of all the parasites that affect humanity I do not know of, nor can I imagine, any more distressing than that of obesity, and, having just emerged from a very long probation in this affliction, I am desirous of circulating my humble knowledge and experience for the benefit of my fellow man, with an earnest hope it may lead to the same comfort and happiness I now feel under the extraordinary change,—which might almost be termed miraculous had it not been accomplished by the most simple common-sense means." We know that obesity is very common, causes discomfort and ill-health and early death, and can be corrected by simple common sense. Since it also represents a waste of food, renders its subjects more prone to accidents, and can be measured, perhaps the Welfare State will consider taxing it.

Summary

Overweight and obesity are not synonymous. The estimation of obesity by comparing the weight of a person with standards of weight for given sex, age (if not adult), and height is often fallacious for several reasons: first, the basis of the standard is often doubtful; secondly, body weights are skewed and the average weight in a group is higher than the central weight; thirdly, somatotype is very important, since mesomorphs (muscular persons) may be heavier than endomorphs (fat persons) of the same height, and yet have much less body fat.

Obesity is satisfactorily estimated by measuring the thickness of a skin-fold. This correlates highly with the density of the body.

Overweight is particularly difficult to estimate in children because of the two characteristic growth-spurts and because there is doubt about what represents optimum nutriture: the maximum rate of growth is not the optimum, since overnourishment causes early maturity and probably early death.

Obesity shortens life and is accompanied by an increased incidence of accidents and of various disorders, including atherosclerosis, hyperpiesis, diabetes mellitus, chronic nephritis, arthritis, gall-stones, and complications of pregnancy and childbirth.

Hereditarily obese mice have increased lipogenesis, with consequent overeating; they are analogous to patients with hypothalamic obesity. Later they develop diabetes and are analogous to the middle-aged obese insulin-resistant diabetic.

Increased dietary fat (but not increased dietary cholesterol) tends to raise the serum cholesterol level and to produce atherosclerosis.

Reduction of body weight lowers mortality in overweight persons, and various disorders that are commoner in the obese can be diminished by slimming.

"Health in Hot Countries" is the title of a British Council study booklet, edited and introduced by Professor J. M. Mackintosh. It is based on a series of broadcasts given in the Overseas Service of the B.B.C., and is intended for the use of medical and auxiliary staff training for public health work. The booklet presents British Commonwealth experience and achievement in the field of tropical medicine. The opening chapter by Professor G. Macdonald, director of the Ross Institute of Tropical Hygiene, is concerned with the collection and interpretation of community health statistics. Then follows a chapter by the professor of physiology at Khartoum, Professor Dean Smith, on nutrition and health, which discusses the causes of malnutrition and their conquest. Dr. C. G. Pandit, secretary of the Medical Research Council for India, contributes a chapter on tropical diseases, in which he gives a brief account of the treatment of malaria, plague, filariasis, kala-azar, and leprosy. The health services of Pakistan and Nigeria are the subject of the fourth chapter, the former being described by Lieutenant-Colonel Muhammed Jafar, director-general of health for Pakistan, and the latter by Dr. Oladéle Ajose, professor of preventive and social medicine at Ibadan. Finally there is a chapter on "health engineering," written by Mr. J. W. Wright, a sanitary engineer, and Dr. J. A. Logan, director of medicine and public health, the Rockefeller Foundation, London. This chapter deals with the control of the environment and the vital problem of enlisting local co-operation in such work.

THE MAYLARD-SONNENBURG METHOD OF INTESTINAL ANASTOMOSIS

BY

WILLIAM JAMES MOORE, F.R.F.P.S.

Formerly Surgeon to Out-patients, Victoria Infirmary,
Glasgow

AND

JOHN FORREST-HAMILTON, M.D.

Warden, the Order of St. John Foundation Hospital,
Glasgow

In 1951 Kimbarovskij proposed "a new method of anastomosis of the small and large intestine." We believe that this method was devised and practised many years ago by Professor Sonnenburg, of Berlin, possibly in the late 'nineties, as told to us in a personal communication by the late W. D. Macfarlane, who was with Sonnenburg at that time.

Unaware of Sonnenburg's work, Maylard (1913) practised and developed the technique independently in Glasgow in the early part of the present century, probably about 1910. He introduced the method on account of its simplicity, safety, rapidity of execution, and immunity from leakage at the line of suture. The possibility of the establishment of a valve action comparable to the ileo-caecal valve of Taenius was regarded as a physiological possibility. Early sealing of the suture line was anticipated. His views were confirmed by post-mortem examinations. He found, in a patient who died of cardiac complications, that as early as six hours after operation the line of junction was sealed, no leakage had occurred, and regenerative processes had already begun.

His interest in this form of anastomosis was originally aroused by the difficulty he had experienced in dealing with faecal fistulae, especially those associated with the caecum and lower third of the ileum. He extended its use to cases in which he hoped to perform a partial or complete colectomy at a later date. In cases where there was an irremovable colonic tumour he performed an ileo-colic anastomosis in preference to any type of colostomy. He preferred it to a lateral or end-to-side anastomosis, the main reason being that by this method the possibility of leakage was substantially reduced.

With the exception of Bickham (1924), who gave a relatively accurate description of the method, no one appears to have described the technique.

The method is applicable to any condition in which the receiving tube is of greater calibre than the entering one. It may be practised as the first stage to colectomy, the colon being removed either in part or as a whole at a subsequent operation. It has been found useful in the treatment of ileo-caecal fistula, where it is necessary to re-route the intestinal flow from the ileo-caecal junction, as also in the treatment of obstruction of the alimentary canal proximal to the pelvic colon. It may be employed with advantage as a preliminary to subsequent operative procedures.

Principles

Technical simplicity, speed in execution, and immunity from peritoneal contamination owing to rapid sealing of the cut edges are the special attributes of this method. The

passage of the intestinal contents helps to tighten the union rather than to strain it. One row of sutures only being necessary, the amount of foreign material introduced is lessened. Only one, or at the most two, clamps are required; therefore tissue trauma is kept to a minimum and interference with the normal peristaltic action largely eliminated. The valve action tends to prevent regurgitation of the intestinal contents, and thus diminishes the incidence of post-operative complications.

Da-Costa (1931) states that at least 250 methods of intestinal anastomosis have been described, and he gives the essentials of a good method as one which can be speedily performed, which leaves an even and reliable line of suture, which avoids a considerable permanent septum, and which reduces to a minimum the use of mechanical contrivances. It is hoped to show that the Sonnenburg-Maylard method fulfils these requirements.

Technique of Operation

Maylard's *métier* was abdominal surgery, and he is rightly regarded as one of its foremost pioneers. At an early stage in his career he showed an originality in thought and practice which brought him international recognition. For a time he practised the orthodox methods of the day, but it was not long before he developed a technique which did much to eliminate the risks of abdominal surgery. The first of his many refinements and innovations was the introduction, in 1901, of the transverse abdominal incision, which he consistently used until his retirement in 1923. Upon the situation of the lesion depend the position and extent of the incision. An incision of adequate length allows of greater precision and of economy in operating-time.

The advances of modern radiology have largely eliminated the exploratory laparotomy, but it still has its place, for the abdomen remains the "temple of surprises." In obscure cases a transverse incision at the umbilical level gives free access and, by adjustments in the position of the patient, renders all regions of the peritoneal cavity operatively accessible.

Stage 1

With the patient in the recumbent position on the table, a transverse incision of the requisite length is made through the skin and subcutaneous tissue. Should it be necessary, there should be no hesitation in dividing the rectus muscle transversely. Haemorrhage is then controlled by passing a ligature on a round needle through the rectus sheath, embracing the muscle and tied upon the anterior wall of the sheath, thereby fixing the muscle at the line of section. In the upper two-thirds of the abdomen the posterior wall of the sheath is incised transversely, but in the lower third the sheath is deficient posteriorly. The peritoneum is incised transversely and the abdominal cavity entered.

Stage 2

The lesion is now located. When it is at the ileo-caecal junction the terminal portion of the ileum may be implanted into the ascending or transverse colon according to circumstance. Should the lesion be in the transverse or descending colon the ileum is anastomosed with the iliac or pelvic colon.

The portion of ileum chosen for anastomosis is stripped and doubly clamped at an appropriate distance from the ileo-caecal junction. The intestine is divided so as to leave 6-8 in. (15-20 cm.) of the ileum free for anastomosis with the colon.

The proximal portion of the divided ileum is closed by a temporary purse-string suture—the ends of which are left long—and the part wrapped in gauze, which is lightly fixed. The distal portion is permanently closed by a Lembert suture, invaginated into the caecum, and the serous coat is overstitched with a fine silk suture for further safety.

The part of the colon chosen for ileal implantation is immobilized by placing two pairs of tenaculum forceps 4 in.

(10 cm.) apart on the taenia coli. Any appendices epiploicae which may be present in this area are removed. The colon is incised in its long axis exactly in the middle line to the extent of 2 in. (5 cm.). At each end of the incision a No. 2 catgut suture is placed (Fig. 1).

The suture temporarily controlling the proximal extremity of the divided ileum is threaded into an intestinal needle, which is introduced into the lumen of the colon and brought out two inches beyond the distal end of the incision in the colon and held by forceps. The free end of the ileum is guided in the colon until about two inches lies free within the lumen (Fig. 2). The ileum is now fixed in position by the sutures which were previously placed at each end of the colonic incision. It is advisable to reinforce this suture at the upper and lower extremities of the wound by a Lembert mattress suture as a further safeguard against possible slipping (Fig. 3).

Fig. 1.—Sutures at each end of the longitudinal incision in the colon for the reception of the ileum.

Fig. 2.—The ileum invaginated.

Fig. 3.—Transverse section of the colon, showing the invaginate ileum.

The suture holding the free end of the ileum in the lumen of the colon is now withdrawn and the needle puncture in the anterior wall of the colon closed by a purse-string Lembert suture.

Stage 3

The incision in the abdominal wall is closed in layers by continuous catgut sutures, and the skin by interrupted silkworm-gut sutures or Michell's clips. If the rectus muscle has been divided the posterior and anterior walls of its sheath are closed by continuous catgut sutures: the muscle itself is not stitched and tension sutures are unnecessary.

Comments

The advantages of the transverse abdominal and of the electro-surgical incision have been fully described elsewhere (Moore, 1922; 1940). As only two clamps are used to control the intestinal contents, tissue trauma is largely avoided. The transverse incision affords free and adequate exposure of the peritoneal cavity.

The peristaltic action of the ileum and the colon being similar, the passage of the contents is not adversely affected, and this diminishes the possibility of regurgitation and of the development of ileus.

Leakage does not occur at the anastomotic line, for the greater the pressure of the contents of the ileum the tighter the union. The peristaltic waves travelling in the same direction still further lessen the risk of leakage and regurgitation.

Results have fully justified the operation both in the method of approach and in the reconstruction of the alimentary canal. Most prominent of the beneficial effects observed were the early passage of flatus, the absence of marked abdominal distension, the early return of normal peristalsis, the absence of ileus, the diminution of post-operative sickness and vomiting, and the early restoration of normal appetite.

When the operation was performed in the treatment of faecal fistula, but especially that of the ileo-caecal variety, early and permanent closure of the fistula resulted. In cases of colonic obstruction post-operative comfort was notable. The patient was saved the embarrassing discomfort of colostomy, and a second operation could be performed in a clean field.

Conclusion

Maylard made use of the axiom that "there is nothing new under the sun" when it was mentioned that the transverse abdominal incision had been practised by Paulus Aegineta of Alexandria. It is possible that future research may reveal that this method of anastomosis was practised at an equally early date, but it was undoubtedly originated in this country by Maylard of Glasgow in the early part of the present century.

We were Maylard's assistants. That we assisted him with the operation on many occasions refutes any modern claim to priority. Sonnenburg undoubtedly performed the operation in Berlin some years earlier, as was stated by Professor Macfarlane, whom we also assisted. The credit for this excellent operation must be awarded to Sonnenburg and to Maylard, who, working independently and unknown to each other, devised the method in Germany and in Great Britain respectively. Apart from the substitution of the active electrode for the scalpel there has been no modification of the original technique.

PENTA-ERYTHRITOL TETRANITRATE IN TREATMENT OF ANGINA

BY

DAVID WEITZMAN, M.D., M.R.C.P.

Senior Registrar, Institute of Cardiology, National Heart Hospital

Penta-erythritol tetranitrate* (P.E.T.N.) is said to be a vasodilator with a prolonged action. It was first used in Sweden during the recent war, when erythritol tetranitrate, which has a similar action, became unobtainable. Subsequently it has been used in France and the United States.

The chemical properties of P.E.T.N. have been described by Van Oettingen *et al.* (1944). At that time this substance, in use as an explosive, was investigated for any harmful effects on its handlers. Its composition is shown by the formula

It is more stable than glyceryl trinitrate and erythritol tetranitrate, and liberates nitrite more slowly than either of these. Absorption from the alimentary tract is slow in animals. In two human volunteers an insignificant rise only was found in blood nitrite up to three hours after the oral administration of 64 mg. No long-term toxicity was noted in animals given P.E.T.N. for one year.

Marche (1950) states that P.E.T.N. acts more strongly on the coronary vessels than on the peripheral circulation; the effect starts 10 minutes after ingestion, and the protective action against angina persists for four to five hours.

Bjerlov (1943) found that the effects of P.E.T.N. in 165 cases were as good as, or better than, those of erythritol tetranitrate. The dose used varied from 45 to 180 mg. daily. Headache appears to have been the most troublesome side-effect. Balatre *et al.* (1949) treated 24 cases, with marked improvement in 12 and moderate improvement in nine. In their series a fall in blood pressure was often seen, and was greater in hypertensive patients. Dailheu-Geoffroy (1950) reported 10 excellent and 69 moderate responses out of 97 cases.

Winsor and Humphreys (1952) gave P.E.T.N. to 125 cases of angina and 125 patients with pain from other causes—arthritis, gall-stones, etc. They found improvement in 78.4% of the anginal patients as compared with 4% of the others. The dose ranged from 10 to 70 mg. daily, averaging 30 mg. (10 mg. thrice daily). Higher doses brought no greater improvement and increased the liability to side-effects (headache, nausea, skin rashes). In three patients with acute coronary insufficiency the resting E.C.G. returned to normal.

Plotz (1952) used 10 mg. three times a day with the occasional addition of 10 mg. at night. He too found that larger doses were not well tolerated. Of 39 cases, 29 were improved (including five in status anginosus), but only four were able completely to discontinue gly-

*The tablets of penta-erythritol tetranitrate used in this investigation were kindly supplied by Bayer Products Ltd., under the name of "mycardol."

ceryl trinitrate. No effect was observed in four patients with cardiac infarction. Talley *et al.* (1952) were not impressed with the effects of P.E.T.N. as compared with a placebo in 14 patients. Perlman (1952) and Samuels and Padernacht (1952) report favourably on the use of P.E.T.N. in peripheral vascular disease.

Materials and Methods

A clinical trial of P.E.T.N. has been carried out on 65 cases with angina pectoris. The series comprised 54 males and 11 females; their ages ranged from 36 to 74, and averaged 56. The diagnosis of angina pectoris was unquestionable in all. In 37 the resting E.C.G. showed evidence of cardiac ischaemia. In three others there was bundle-branch block, and eight patients with normal resting E.C.G.s showed ischaemic changes after exercise. In the remainder the history was classical.

The cases were graded according to their severity as follows:

Grade I: pain only on strenuous effort (2 cases).

Grade II: pain on going uphill, or hurrying, or on walking after a meal or in the cold (27 cases).

Grade III: pain on walking at ordinary pace on the flat (30 cases).

Grade IV: pain on walking at ordinary pace on the flat, in less than 100 yards (6 cases).

Grade V: acute coronary insufficiency—that is, pain at rest and/or on the slightest activity.

Two other grades—0, indicating remission of pain, and VI, denoting fresh cardiac infarction—were also used in the assessment of progress. Only patients whose effort tolerance had remained unaltered for six months or more were included in the trial. Evidence of positive response to the drug was provided by an increase in effort tolerance, so that the case moved into a better grade, or by a decrease in the pain brought on by the same amount of effort.

Tablets containing 30 mg. of P.E.T.N. were used, dummies identical in appearance and taste with these being also supplied for control purposes. Each patient was instructed to swallow two tablets three times daily, at regular intervals. In some cases this dose was later increased. Thirty-four patients were given P.E.T.N. and 31 had dummy tablets. Approximately 50% of the patients in each effort grade were put into each group. After two to three months 15 patients whose condition remained unaltered while taking dummy tablets had P.E.T.N. substituted without their knowledge. Another group of 15 patients, who were apparently improved while taking P.E.T.N. were switched to dummy tablets or had their P.E.T.N. tablets discontinued. In most cases the results were assessed after a period of not less than three months; in nine cases treatment with P.E.T.N. was maintained for longer periods in order to determine the development of any tolerance or of long-term

TABLE I.—Results

	Cases Treated Primarily with P.E.T.N.	Cases Treated with P.E.T.N. after Serving as Controls without Change	Total Results in All Treated Cases	Control Group
Effort grading improved	8 (24%)	1 (7%)	9 (18%)	3 (10%)
Pain less severe and or less glyceryl trinitrate needed	6 (17%)	2 (14%)	8 (17%)	3 (10%)
No change	11 (33%)	11 (73%)	22 (44%)	23 (74%)
Pain more severe, or less effort possible, or further ischaemic E.C.G. changes	6* (17%)	1 (7%)	7* (15%)	2 (6%)
Treatment discontinued because of side-effects	3 (9%)	0	3 (6%)	0
Total	34	15	49	31

* One of these patients died of fresh occlusion, but this did not occur until two months after discontinuing treatment.

toxic manifestations. All patients had glyceryl trinitrate if an attack of pain occurred. The results are shown in Table I.

In addition, two in-patients with acute coronary insufficiency were given P.E.T.N. for short periods without any apparent effect on their progress. In a third case in this group P.E.T.N. was shown to influence effort changes in the E.C.G. (See Fig.).

Dosage.—The dose was 60 mg. thrice daily in most cases, but in 9 patients who failed to show improvement it was increased to 60 mg. four times a day. This resulted in some relief in two cases. A further increase to a daily total of 300 mg. proved intolerable, because of side-effects, in all but one case. This patient has been able to tolerate 360 mg. daily for over six months, with definite improvement in effort tolerance.

Side-effects.—Undesirable side-effects were experienced by eight patients. They comprised lethargy (often with a sense of depression) in five, digestive upset in three, headache in two, and visual disturbance in one. In three of the cases these side-effects resulted from the routine daily dose of 180 mg. and were troublesome enough to necessitate withholding the drug. In one of these patients toxic symptoms reappeared when treatment was recommenced with only 90 mg. daily. In the remainder side-effects were seen only with higher doses. No long-term toxic effects have been observed in 10 patients who have taken the drug for periods of six months up to one year, and no diminution of effectiveness has been seen in these cases.

P.E.T.N. and the Electrocardiogram

The effect of P.E.T.N. on the electrocardiogram was studied in six cases. In three of these the ST segment depression induced by effort was abolished by oral ingestion of 120 mg. of P.E.T.N. The illustration shows how this effect is present 15 minutes after taking the drug. It is seen to persist for four hours but not for five.

There was a definite relationship between E.C.G. patterns and response to P.E.T.N. in the 46 cases in which treatment was maintained (Table II). Thus of 30 cases with

TABLE II

E.C.G.	No. of Patients	No. Improved (Effort More or Pain Less)
Normal	11	3
Normal at rest, effort test positive	3	1
Ischaemic	11	6
Infarction	16	7
Others (3 bundle-branch block, 2 auricular fibrillation)	5	0

electrocardiographic proof of coronary disease, 14 (48%) responded to P.E.T.N. as compared with 3 out of 16 (19%) without such proof. It therefore seems that the more severe the ischaemia the more likely is the case to benefit from P.E.T.N. Winsor and Humphreys (1952) state that the worst cases show the greatest improvement. However, in the present series there was no correlation between severity of symptoms and response to the drug.

The E.C.G. was repeated in 12 patients under treatment with P.E.T.N. In one it was found to have reverted to normal; in two others the ST depression after exercise was abolished or lessened; in five there was no change; and in four the E.C.G. showed deterioration.

Effect on Blood Pressure

Casual readings were made in the out-patient department two to four hours after the last dose. In no case was there any significant fall in pressure. Other authors have described definite hypotensive effects from P.E.T.N. Thus Bjerlov (1942), after 30 mg., found a fall of from 10 to 45 mm., lasting two to five hours in 10 patients; Balatze

Electrocardiographic record (Lead V5) before and after taking P.E.T.N.

et al. (1949) state that 20 mg. can provoke a fall of 30–35 mm. in the systolic and 15–20 mm. in the diastolic pressure in man. This was not confirmed in the present series, nor was there any significant fall in basal pressures measured over three hours in two normal subjects after taking 60 mg. These findings are in agreement with those of Plotz (1952), who found no notable fall in 35 cases.

Other Conditions.—The series included two cases with syphilitic aortic incompetence and one with rheumatic valvular disease. In these, P.E.T.N. had no effect on effort pain.

Discussion

One may regard the improvement that occurred on dummy tablets as indicating the extent to which natural amelioration and psychological factors affect results. Taking this into consideration, the improvement rate is significantly greater in the treated group. Furthermore, it was shown that P.E.T.N. could abolish electrocardiographic changes due to effort, and that this effect could persist for four hours. Winsor and Humphreys (1952) have demonstrated the same phenomenon.

It was therefore rather surprising that the response was so poor in the 15 patients who were given P.E.T.N. after a period on dummy tablets, as compared with the group primarily treated with P.E.T.N. Since this finding cast doubt

on the validity of the results, a further check was made in another 15 patients who had improved with P.E.T.N. In seven all tablets were stopped, and in five of these the symptoms returned to their previous severity; but no deterioration was noted in five out of eight cases in which dummy tablets were substituted for P.E.T.N.

This finding detracts still more from the significance of the results. However, another explanation is worth considering. It is possible that the maintenance of improvement in the treated patients subsequently given dummy tablets was the result of an increase in collateral circulation induced by P.E.T.N. Zoll and Norman (1952) have shown that sodium nitrite stimulates the development of anastomotic vessels in the pig's heart after experimental coronary occlusion: a significant increase in collaterals is seen after as little as two days' treatment. There is, however, no direct proof that P.E.T.N. does cause any increase in the number of coronary anastomoses in man; and the finding, already stated, of progressive ischaemic change in the E.C.G.s of four cases under treatment shows that any such effect is not invariable.

The evidence is thus seen to be inconclusive, and further study would appear to be indicated. The results obtained by direct comparison of the two primary groups in the trial show a significantly greater improvement rate in the treated cases. The subsidiary studies throw doubt on this finding. Nevertheless, unquestionable and sustained improvement in effort tolerance was observed in about one-fifth of the treated cases, and some symptomatic relief in a like number. Objective evidence of improvement in coronary blood flow has also been furnished by effort tests.

Conclusions

P.E.T.N. would appear to have a place in the treatment of cardiac pain. In a small number of cases its routine prophylactic administration may replace the necessity for glyceryl trinitrate. Patients whose sleep is disturbed by nocturnal angina may benefit from a dose of P.E.T.N. taken before retiring. If patients find that routine P.E.T.N. diminishes but does not obviate the need to take glyceryl trinitrate for anginal attacks, there is probably little purpose in their taking two drugs rather than one. An exception to this is the case in which angina is most troublesome on first rising. Such patients often find that a tablet of glyceryl trinitrate chewed first thing may enable them to dress and get to work without pain. In such cases the combination of early morning glyceryl trinitrate with routinely spaced doses of P.E.T.N. may result in almost complete freedom from anginal attacks. P.E.T.N. seems to have little or no influence on acute episodes of increasing ischaemia.

Summary

Penta-erythritol tetranitrate (P.E.T.N.) is an anti-anginal drug with a prolonged action, lasting up to four hours after administration. This effect has been confirmed by electrocardiographic studies.

Forty-nine patients have been treated with this substance for several months. The usual dose employed was 60 mg. thrice daily. In nine patients effort tolerance was improved, and a further eight patients noticed diminution in the number and severity of anginal attacks.

This response was significantly greater than that of a control group taking dummy tablets; but the results after substituting drug for dummy, and vice versa, were not entirely in keeping with the original findings.

The use of P.E.T.N. for preventing angina is of value in some patients, but seldom replaces the need for glyceryl trinitrate.

This investigation was undertaken at the instigation of Dr. Paul Wood, Director of the Institute of Cardiology, and the majority

of the patients were under his care. I would like to express my gratitude for his advice and encouragement. My thanks are due also to other members of the staff of the National Heart Hospital for their assistance in the selection and observation of cases.

APPENDICITIS IN THE COURSE OF
MEASLES

BY

W. H. GALLOWAY, M.B., Ch.B., F.R.C.P.Ed.
D.C.H.

Consultant Paediatrician

(From the City Hospital, Aberdeen, and the Department of
Child Health, University of Aberdeen)

Having personally seen seven cases of appendicitis occurring during the course of measles in the space of 18 months, I searched for any report on this matter in a British journal. No such report was found, except for a most interesting letter from Dr. Leak (1935). Several papers on this subject have been published in the German and American literature. In several standard works, gastro-intestinal lesions are described. Nothnagel (1902) discusses the pathology of individual organs as affected in measles as follows. "Although no anatomic changes are demonstrable in the intestines, the occurrence of frequent evacuations during an attack of measles bears a close relation to the underlying infectious process. Diarrhoea may appear as an early symptom, ushering in the enanthemic stage or even preceding it, but may also persist until after the conclusion of the eruptive stage. . . . The diarrhoea is ascribed to the specific inflammation of the intestinal mucous membrane, to the eruptive process by which it is affected."

In *Modern Practice in Infectious Fevers* (1951) lesions of the gastro-intestinal tract are described thus: "Inflammatory catarrh with desquamative changes extends the whole length of the digestive tract. Koplik spots may appear anywhere, including the vermiform appendix, which is often swollen and congested and may undergo suppurative or necrotic changes. Multinucleated giant cells may be found similar to those in the spleen, tonsils, and lymph glands."

Harries and Mitman (1951) also make reference: "Some observers have claimed that tenderness over the appendix region or a definite attack of appendicular colic is not infrequent during the prodromal stage of measles, and would correlate this occurrence with the demonstration of giant cells in the mucosa of the appendix. Laparotomy in such cases has revealed an appendix normal to the naked eye or showing catarrhal

changes only. On the other hand, acute perforative appendicitis has occurred, probably as a fortuitous complication."

A brief description of seven cases is given below.

Case Reports

Case 1.—Male aged 4 years. *History*:—Two days before admission the child developed severe right-sided abdominal pain of colicky nature. He did not eat his evening meal. The attacks were spasmodic. He still had pain the next day. On the day of admission he awoke screaming with right-sided pain, and occasionally drew up his legs. A loose stool was passed. There were no urinary symptoms. *Examination*:—Tenderness in right iliac fossa. P.R., marked tenderness on right side; T. 99.2 (37.3° C.), P. 120, R. 24. *Operation*:—Gridiron incision. Peritoneum healthy. Acutely inflamed pelvic appendix found and removed. Rash appeared four days after operation.

Case 2.—Male aged 11 years. *History*:—Four days before admission, developed cough and sore throat. Twenty-four hours before admission, measles rash appeared. Eight hours before admission, he awakened with colicky pain localized to the right iliac fossa; vomited once and passed a stool. Further pain two hours later. *Examination*:—Definite tenderness in right iliac fossa—localized. P.R. tender on the right; T. 98.6 (37° C.), P. 80, R. 22. *Operation*:—Gridiron incision; appendix showed slight redness. Rash appeared one day before admission.

Case 3.—Male aged 5 years. *History*:—Twelve hours before admission, while at school, he developed right-sided abdominal pain, not severe enough to make him leave. Pain became worse on way home and he vomited. *Examination*:—Tender in both iliac fossae. P.R., tender on both sides; T. 98 (36.7° C.), P. 112, R. 26. *Operation*:—Gridiron incision. Apparently healthy appendix—no fluid. One small gland felt. Appendix removed. Rash appeared four days after operation.

Case 4.—Male aged 5 years. *History*:—Forty-eight hours before admission, developed pain in right side and across lower abdomen; colicky. Vomited twice. *Examination*:—Tender in right iliac fossa with muscle-guarding. P.R., tender. *Operation*:—Gridiron incision. Slightly inflamed appendix removed. T. 99.4 (37.4° C.), P. 96, R. 20. Rash appeared four days later.

Case 5.—Male aged 4 years. *History*:—Four days before admission, developed measles. Twelve hours before admission, onset of acute abdominal pain. Pain recurred eight hours later and he had a third spasm just before admission. *Examination*:—Well-marked measles rash. Abdomen held rigid. Definite tenderness in right iliac fossa. *Operation*:—Gridiron incision. Perforated appendix with small quantity of purulent fluid in peritoneal cavity. Appendix removed. Rash appeared four days before admission.

Case 6.—Male aged 2½ years. *History*:—Three days before admission, complained of abdominal pain and vomited. Vaguely "out of sorts" for a day or two before this. Next day pain localized to right iliac fossa. Vomited three times. Fevered. Passed one loose stool. Observed overnight at Children's Hospital. Measles rash next morning. Transferred to City Hospital. Abdominal symptoms attributed to measles. Very definite signs of acute appendicitis, but operation postponed again because of the measles. T. 102.6 (39.2° C.), P. 160, R. 30. By the next day the child had obvious peritonitis and a mass could be felt high in the right iliac fossa. *Operation*:—Gridiron incision. Purulent fluid in peritoneal cavity. Retrocaecal appendix with early abscess formation. Appendix removed and peritoneum drained. Rash in this case appeared two days before operation. The child developed pneumonia and died six days after operation.

Case 7.—Female aged 5 years 11 months. *History*:—Abdominal pain four days before admission. Slight pain present next day, when child vomited on three occasions.

Two days before admission, pain disappeared, but recurred on the day she came into hospital. Mainly para-umbilical. *Examination*:—Tender on deep palpation in the right iliac fossa. P.R., very tender. *Operation*:—Right paramedian incision. Apparently normal appendix found and removed. Ileocaecal mesenteric adenitis present. Rash appeared two days after operation.

Pathology

Davidsohn and Mora (1932) drew attention to a type of giant multinucleated cell found in appendices removed during the prodromal stage of measles. This type of cell had been previously reported by Warthin (1931) in tonsils removed at the same stage of the disease. Hudson and Krakower (1936) quote Finkeldey (1931) as describing them originally. Others who found them in the appendix include Hathaway (1935) and Avancini (1948).

It was thought by Davidsohn and Mora (1932) that the abdominal pain was due to changes in the lymphoid tissues in the gastro-intestinal tract. This reaction was thought to be directly attributable to measles. In some appendices many of these multinucleated cells were found, especially in those not showing much naked-eye evidence of inflammatory change. In others showing obvious inflammatory change very few of these cells were found, although they were present in regional lymph nodes. One theory to account for this, put forward by Davidsohn and Mora, was that the swelling of the mucosa of the appendix prepared the way for secondary invaders. By the time these true inflammatory changes had occurred the giant multinucleated-cell reaction had passed. A parallel can be found in tonsils removed during the prodromal stage of measles.

In the present series only one appendix (Case 4) was sectioned. At operation the appendix was thought to be slightly inflamed. The histological report, by Professor Young, was:

"The appendix had been opened from base to tip by the surgeon before fixation, and it was bisected longitudinally for microscopical examination. No notable abnormality was visible to the naked eye."

"Microscopically, the mucosal lymph follicles showed a peculiar hyperplasia of their reticulum cells, culminating in the formation of numerous giant cells, the largest of which were crammed with 100 or more small vesicular nuclei, while smaller forms contained as few as two or three relatively large nuclei with prominent nucleoli; in all cases, the cytoplasm was extremely scanty. Chromatin fragments resulting from karyorrhexis were often observed in the germinal centres, but there was no focal necrosis, and the general architecture of the lymphoid tissue was remarkably well preserved. No inclusion bodies were identifiable. The muscularis was normal in appearance apart from the presence of a very few perivascular round cells, but the serous coat showed a minor degree of fibrous thickening, with increased vascularity. There was no evidence of pyogenic inflammation."

"Comment: The changes in the lymphoid tissue of the appendix conform in every essential respect to those described by Warthin (1931) in the tonsil in the prodromal stage of measles."

The findings at operation in the seven cases reported were that two appendices were normal, three were acutely inflamed, and two were perforated.

Koch (1937) described two cases, in both of which the appendices were acutely inflamed. Angel and Kizinski (1938) described three cases and reviewed the literature. Their three cases all showed acute inflammation at operation. With the seven cases here reported, I have found 49 described in the literature, mostly in the United States of America, with a few contributed from Germany. Of these, 26 showed subacute or acute inflammatory changes, 12 showed abscess formation, 4 were gangrenous, 5 were perforated with pus in the peritoneal cavity, and 2 showed no naked-eye inflammation. The histology of one of these is described above.

Onset with Relation to the Rash

Hudson and Krakower, reviewing the literature, found 40 cases. Of these, 15 developed the symptoms during the pro-

dromal stage, 12 during the period of eruption, and 13 in the immediate convalescent stage. Koch's two cases occurred during the eruptive period. In the present series, four occurred during the prodromal stage and three during the eruptive period. Thus, of 49 cases, 19 developed the symptoms during the prodromal stage, 17 during the eruptive period, and 13 in the immediate convalescent period.

Discussion

While it is admitted that appendicitis and measles are both very common diseases in childhood, it is felt that the occurrence of the two together is not fortuitous. For many years appendicular colic has been a known concomitant of measles. Several workers have shown that it is dangerous to assume that the abdominal pain is part and parcel of measles. Most of the appendices removed showed acute inflammatory processes, and of the 49 reported 26 showed acute inflammatory change and 21 had gone on to the gangrenous stage and had ruptured, causing peritonitis or local abscess formation.

The case histories here reported show that abdominal symptoms had been present from 12 to 72 hours before the rash became obvious. All of them were most suggestive of acute appendicitis, and on clinical examination the findings were also in favour of this condition.

The pathology has been briefly outlined, and also the relationship of the abdominal condition to the stage of measles. In view of the acute nature of the appendicitis in this condition, and the speed with which abscess and/or perforation can occur, any sign or symptom of appendicitis in the course of measles should not be lightly dismissed. On the contrary, if, during the course of measles, abdominal symptoms should be equivocal, repeated examinations should be carried out. Angel and Kizinski (1938) advocate this, and Davidsohn and Mora (1932) are of the same opinion. The latter also quote Trepel as emphasizing that appendicitis occurring during the prodromal stage is a more acute and fulminating process. Case 6 had operation postponed as measles developed. When this case was discussed with surgical colleagues, in retrospect, their feeling was that, had measles not developed the day after admission, operation would have been carried out then. If operation had been carried out shortly after admission instead of 72 hours later, perhaps the inflammatory process would not have advanced to local abscess formation with peritonitis.

It is felt that measles probably initiates subsequent infection of the appendix. Thenebe *et al.* (1933) suggest that there may be ischaemia of the appendix, due to pressure of the enlarged lymphoid tissue in the submucosa and, for the same reason, interference with the flow of lymph. This leads to a local or a more extensive area of necrosis. This in turn is followed by bacterial invasion, probably from the ever-present intestinal flora.

From the above discussion and for the reasons given, it is strongly recommended that any child with measles in whom a diagnosis of acute appendicitis is made should be operated upon forthwith. Where the signs are less definite repeated examination at short intervals should be carried out.

Summary

Seven cases of appendicitis occurring in the course of measles are described, with one death.

A brief review of the literature is given.

The pathology of one case is given in detail, showing the typical findings during the prodromal stage of measles. This consists in an intense lymphoid reaction and the presence of multinucleated cells and a type of giant cell. It is confirmed that the presence of these cells is pathognomonic of measles in the prodromal stage.

During the course of measles, symptoms of acute appendicitis warrant immediate operation.

I would like to express my thanks to Professor John Craig for his help and advice and to Professor Young for the histological report.

THE LARYNGEAL MICROPHONE AS AN AID TO TREATMENT OF BULBAR POLIOMYELITIS

BY

F. D. STOTT, D.Phil.

Electro-medical Research Unit (Medical Research Council),
Stoke Mandeville Hospital, Aylesbury, Bucks

In the treatment of bulbar poliomyelitis the prime requirement is the maintenance of a clear airway. Failure to keep the airway free from obstruction results in anoxia and hypercapnia. McDowell and Wolff (1953) have advocated early tracheotomy as a prophylactic measure in bulbo-spinal cases. Galloway (1947) recommends tracheotomy in bulbo-spinal cases, and also in other types of the disease whenever there is difficulty in maintaining a clear airway. The frequency with which tracheotomy may be needed should be much reduced if the technique of detecting and removing obstruction is improved. Ritchie Russell (1952) has stressed the need for a continuous watch over the patient to detect obstruction at the earliest possible moment. If this can be done, and adequate postural drainage in the prone position is used, most cases of bulbar poliomyelitis uncomplicated by failure of respiratory muscles can be kept fully ventilated without tracheotomy.

The first indications of obstruction are not, however, easily detected even by experienced nurses, especially if there is much other noise in the ward. In order to eliminate this source of danger, an instrument has been developed to amplify respiratory sounds so that the slightest obstruction is immediately apparent. It has been tried out in two epidemics and has proved to be of the greatest value.

The instrument, as constructed here, consists of a standard pattern of U.S. Air Force laryngeal microphone;* together with an amplifier and loudspeaker. Details of the construction of two models, one mains-operated and the other battery-operated, are given below.

The method of using both instruments is the same. The microphone is placed over the patient's larynx and held in place by an elastic band. If the laryngeal position is inaccessible, as may be the case when the patient is prone, the microphone may be placed on the back of the neck, over the temple, or even on the occiput, when the sounds will be picked up by bone conduction.

*Type ZA.19734, readily obtainable from many shops dealing in radio equipment, and advertised in *Wireless World*.

Light pressure only is required, just enough to prevent displacement by the patient's movements. The volume is then adjusted until the intermittent rushing sound produced by normal unobstructed respiration is just audible without being obtrusive. Under these conditions the sound caused by obstruction of the airway is loud enough to draw attention from the far end of the ward. The bubbling sound, accompanied by loud rhonchi so produced, is quite unmistakable, and quite distinct from the more clattering or clicking noise produced by swallowing.

Construction of the Instruments

The circuit diagram of the mains-operated instrument is given in Fig. 1, and of the battery model in Fig. 2.

FIG. 1.—Circuit of mains-operated unit. R_1 , 100 K Ω . R_2 , 1,500 Ω . R_3 , 250 K Ω . R_4 , 100 K Ω . R_5 , 100 K Ω . R_6 , 1,500 Ω . R_7 , 1 M Ω . R_8 , 500 K Ω . R_9 , 100 K Ω . T_2 , Speaker output transformer, 300-0-300 V, 5 V. C_1 , 0.1 μ F. C_2 , 0.1 μ F. C_3 , 0.1 μ F. C_4 , 0.001 μ F. C_5 , 8 μ F. C_6 , 8 μ F. C_7 , 0.01 μ F. C_8 , 0.01 μ F. C_9 , 0.01 μ F. C_{10} , 0.001 μ F. C_{11} , 0.001 μ F. C_{12} , 0.001 μ F. C_{13} , 0.001 μ F. C_{14} , 0.001 μ F. C_{15} , 0.001 μ F. V_1 , 524. P_1 , 500 K Ω . L_1 , 5H, 100 mA. L_2 , 100H, 5 mA.

FIG. 2.—Circuit of battery-operated unit. R_1 , 30 K Ω . R_2 , 1 M Ω . R_3 , 500 K Ω . R_4 , 100 K Ω . R_5 , 100 K Ω . R_6 , 1,500 Ω . R_7 , 1 M Ω . R_8 , 500 K Ω . R_9 , 100 K Ω . R_{10} , 100 K Ω . R_{11} , 500 K Ω . R_{12} , 500 K Ω . R_{13} , 50 K Ω . R_{14} , 50 K Ω . R_{15} , 50 K Ω . T_1 , Microphone input transformer, 100:1. T_2 , Speaker output transformer, 300-0-300 V, 5 V. C_1 , 0.1 μ F. C_2 , 0.1 μ F. C_3 , 0.1 μ F. C_4 , 0.001 μ F. C_5 , 8 μ F. C_6 , 8 μ F. C_7 , 0.01 μ F. C_8 , 0.01 μ F. C_9 , 0.01 μ F. C_{10} , 0.001 μ F. C_{11} , 0.001 μ F. C_{12} , 0.001 μ F. C_{13} , 0.001 μ F. C_{14} , 0.001 μ F. C_{15} , 0.001 μ F. V_1 , 524. P_1 , 500 K Ω . L_1 , 5H, 100 mA. L_2 , 100H, 5 mA.

As will be seen, the mains amplifier is a three-stage type, with push-pull output to an 8-in. (20 cm.) loudspeaker. This provides a maximum output volume much greater than is normally needed. The highest and lowest notes are attenuated, as the required diagnostic sounds are mainly in the middle frequency range, from 100 to 2,000 cycles approxi-

* Counts taken during course of pyogenic pneumonia.

leucocyte count of 5,500 was recorded on one occasion, coinciding with some clinical improvement, but consolidation appeared in the left lower lobe soon after. Folic acid did not affect his condition. Three weeks after admission his temperature had settled and he was much better, but there were still signs of consolidation, and radiologically there was cavitation. The only organisms isolated from his sputum were *Proteus vulgaris* and *Bact. coli*. The signs gradually cleared over the following month, but some residual fibrosis remained. During convalescence transfusion of 1 pint (570 ml.) of fresh blood did not affect his white-cell count.

He was discharged in January, 1951, and readmitted two months later for splenectomy, with a view to correcting his neutropenia, to which the severity of his pneumonia was attributed. He was then a rather pale man with rheumatoid changes of moderate degree in his joints, ulnar deviation of his fingers, and a spleen which extended below his umbilicus. There was no lymph-node enlargement, his liver was not palpable, he was not pigmented, and there was no ulceration of skin or mucous membranes. Red-cell fragility was normal, reticulocytes 2%, and liver function showed abnormal flocculation reactions, while his serum albumin was 3.6 g. and globulin 3.7 g. per 100 ml. Splenectomy was performed by Mr. J. R. M. Whigham. The spleen, which measured 29 by 12 by 9 cm., was removed fairly easily, there being only a few adhesions. Sections showed congested sinusoids, increase of reticular tissue, and heavy plasma-cell infiltration. Biopsy of liver showed no significant histological abnormality. Bone-marrow biopsy at operation showed slight increase of erythropoiesis over leucogenesis and evidence of delay in polymorph maturation. Recovery from operation was uncomplicated. Since operation his joints have shown little or no improvement, his E.S.R. has remained high, and the abnormal liver function is unchanged. However, the leucocyte count is at normal levels, his haemoglobin is significantly improved, and he looks and feels much better.

COMMENT

Hutt and his colleagues noted an improvement in the general well-being of their patients. One was described after operation as "full of pep and working better than for years." A very noticeable feature of the present case was a change of disposition. Before operation he was a morose and taciturn man who appeared to care little whether he improved or not. He seems to have acquired a new zest for living, and for the first time shows interest in his future progress and in finding a job.

I am greatly indebted to Mr. J. R. M. Whigham and Dr. D. W. G. Smith for permission to publish this account and to Dr. Louis Steingold for the pathological reports.

mately. Amplification over this range, which is roughly the minimum required for comprehensible speech, is adequate. As the loudspeaker and microphone are usually fairly close together, amplification of higher frequencies is very apt to cause oscillation from acoustic feedback; this will, in any case, happen when the microphone is removed from the patient, and it should always be switched off by the switch, S_1 , when not in place on the patient.

The microphone used with this instrument is an electromagnetic type which is particularly robust and reliable, and gives excellent results. The battery model uses a carbon microphone; although this does not give quite the same frequency response, and has a rather higher noise level, it was chosen for this purpose because it gives a much larger output, so that a simpler amplifier, with correspondingly reduced drain on the batteries, could be used. A simple two-valve amplifier, using a DF92 voltage amplifier and a DL92 output valve, is all that is needed.

The same precautions with regard to acoustic feedback are desirable, though the oscillation is not so offensive in the battery model as in the mains one, because the maximum output power is so much less.

An instrument of similar performance and specification to the mains-operated model, but lighter and more compact, is now available from Isis Equipments, Broad Street, Oxford.

Acknowledgment is made to Dr. W. H. Kelleher for his assistance in testing this instrument in clinical use at the Western Hospital, Fulham, and to Dr. W. Ritchie Russell and the staff of the poliomyelitis unit, Stoke Mandeville Hospital, for carrying out extensive trials during the 1952 epidemic.

Medical Memorandum

Felty's Syndrome Treated by Splenectomy

Felty's syndrome is the name given to a rare but characteristic triad of arthritis of rheumatoid type, splenomegaly, and leucopenia, with which generalized lymph-node enlargement and hepatomegaly may be associated. The leucopenia has been regarded as a hypersplenic manifestation, and since it may give rise to disabling symptoms a number of patients have been treated by splenectomy. Hutt, Richardson, and Staffurth (1951) report four cases, two of which had corneal ulceration, and a third chronic leg ulcers. After splenectomy there was a continued improvement in the neutrophil count in all and a significant increase in the haemoglobin percentage in three. The ulcers healed, and one patient had lasting improvement in his arthritis.

CASE REPORT

A male radiographer now aged 35 first noticed joint pain in 1937. In 1940 he joined the R.A.M.C. and remained in the regular Army until he was invalided out with a diagnosis of Felty's syndrome in June, 1950. He had first come under medical supervision in 1943 when a diagnosis of rheumatoid arthritis with leucopenia was made. In 1950 his joints became worse and the investigations which led to his discharge revealed, in addition to the leucopenia, a spleen enlarged to 6 in. (15 cm.) below the costal margin.

He first attended hospital on November 6, 1950, for a blood count. He became unwell a few days later, and was admitted to hospital critically ill with a right upper lobe pneumonia. He was treated with large amounts of penicillin, but response was very poor. On the third day in hospital his temperature was still very high and there were signs of massive consolidation, but his leucocyte count was only 1,800 per c.mm., with 79% neutrophils (see Table). Streptomycin and aureomycin were given in full doses, and his temperature and clinical condition slowly improved. A

Reviews

PARIETAL LOBES

The Parietal Lobes. By Macdonald Critchley, M.D., F.R.C.P. (Pp. 480; illustrated. 70s.) London: Edward Arnold and Co. 1953.

The functions of the parietal lobes have been the subject of much interest and even more speculation, but this book is one of the first to be devoted wholly to the subject. The opening chapter on anatomical considerations is excellent, and, as Critchley emphasizes, the parietal lobes are really "empirical conceptions rather than autonomous entities in the anatomical or physiological sense," for they are merely those parts of the cerebral hemispheres which happen to be covered by the parietal bones. He traces the comparative anatomy, and includes surmises on the probable parietal configuration of *Pithecanthropus erectus* and Neanderthal man as judged by the markings on fossil cranial bones. The sensory defects found with parietal lesions are discussed in detail, and there is an interesting section on the controversial subject of localized muscle wasting, a physical sign which, although it was first described in England, has attracted little attention since then in this country.

The greatest value of the book is the exhaustive account of the more subtle disturbances which may occur with parietal lobe lesions and of the special techniques which may be necessary to demonstrate and evaluate them. They include constructional apraxia, visual disorientation, tactile inattention, the Gerstmann syndrome, and disorders of the body image and of symbolic thought. A study of these chapters reveals the rich diversity of parietal symptomatology and makes clear what is meant by some of the inelegant words which are at times used to denote these symptoms.

This monograph is a most important contribution to neurology. Critchley has collected a vast amount of information on the parietal lobes, much of it published in French and German journals, and has brought a good deal of order out of a chaos of observations by the application of his highly critical and, as the last chapter especially shows, constructive mind. The book is most interestingly written, is illustrated by numerous diagrams and by photographs of men who have made major contributions to the subject, and contains nearly 1,100 references, the title of each being given in full. It is essential to the neurologist, and should prove of the greatest value to everyone interested in psychology and psychiatry.

J. W. ALDREN TURNER.

CARBOHYDRATE METABOLISM

Ciba Foundation Colloquia on Endocrinology. Volume VI: Hormonal Factors in Carbohydrate Metabolism. General Editor, G. E. W. Wolstenholme, O.B.E., M.A., M.B., Ch.B., assisted by Jessie S. Freeman, M.B., B.S., D.P.H. (Pp. 350; 94 illustrations. £1 15s.) London: J. and A. Churchill. 1953.

The sixth volume in the series of the Ciba Foundation follows the same general plan as its predecessors. Internationally famous experts are gathered together, they present their formal papers, and then the ensuing informal discussion is recorded in full. The result is a revealing indication of the present state of informed opinion on the subjects under discussion. At the present Conference nine nations are represented, with five visitors from Switzerland, twelve from the United States, and eighteen from Britain. Although many of the papers are reports of rather specialized research work, yet there are many more general reviews which should prove of great value to all clinicians who have an interest in carbohydrate metabolism.

The volume starts with a series of three papers on enzyme systems in intermediate carbohydrate metabolism, and in glycogen synthesis. These are by well-known authorities, including C. F. Cori, and are for those with a

specialized knowledge of intermediate carbohydrate metabolism. There follows a series of papers on the conversion of carbohydrate to fat. Modern studies by means of radioisotopes show clearly that insulin has a major role in the conversion of carbohydrate to fat in animals. This work is well reviewed, as also is that showing how A.C.T.H. and growth hormone impede this conversion.

There is plenty here of clinical interest. The role of insulin is discussed in many papers, which give an account of the evidence for two types of human diabetes, the response of the human liver, normal and diabetic, to insulin, the mechanisms of obesity, and the effects of adrenal steroids on carbohydrate metabolism in man. There is an excellent review of the effects of insulin, growth hormone, and A.C.T.H. on the rate and manner of glycogen deposition in muscle of different types. It is clear that the action of insulin is far more complex than was at first thought. Finally several papers discuss the influence of sex hormones and of pregnancy on carbohydrate metabolism, and two the significance of fructose in semen.

As is inevitable in such a compilation, the papers vary considerably in their appeal, but this volume contains a high proportion of first-rate quality and of wide clinical interest. The volume sustains well the high standard of the whole series.

C. L. COPE.

SPORT MEDICINE

Sport Medicine: Proceedings of the International Symposium of the Medicine and Physiology of Sports and Athletics at Helsinki, July 17-18, 1952. Edited by M. J. Karvonen, M.D., Ph.D. (Pp. 229. \$3.) Obtainable from Suomalainen Kirjakauppa-Finnish Bookshop, Helsinki, Finland.

Delegates from 30 countries attended the conference whose proceedings are recorded here, and communications were received from the U.S.A., Finland, Belgium, Germany, Norway, Sweden, Italy, Greece, Czechoslovakia, Spain, Bulgaria, Japan, the Argentine, and Hawaii. Circumstances unfortunately prevented participation by any of the British representatives who had arranged to attend.

Finland provided many of the most valuable papers from the Institute of Occupational Health, Helsinki. These included one on menstruation in Finnish sportswomen, where it was concluded that exceptional nervous and physical strain of competitive events may disturb the normal menstrual cycle, but so slightly as to necessitate no limitations of activity in healthy well-trained women.

In a paper on the course of delivery of Finnish baseball players and swimmers no obstetrical disorders of any kind were identified; better development of abdominal muscles appeared to be of advantage.

Elbow injuries in javelin-throwers were discussed in another paper; all traumatic changes were found to be extra-articular, the structures injured including the capsule, ligaments, and the tip of the olecranon. These injuries occurred during the first year of competition, compelling a period of rest: later, activity could be resumed free from pain, presumably because of insensitiveness of the injured part.

The effects of heavy muscular work on the mineral composition of sweat were discussed, and no significant difference was found between champion athletes and sedentary men at rest. Hard muscular work caused a decrease in the Na and Cl concentration of thermal sweat in the physically fit, who were regarded as possessing much larger reserves of the adrenocortical function. It was suggested that sweat might be analysed as a check on an athlete's progress during training. A significant drop in the eosinophils and lymphocytes was related in another paper to the adrenocortical mechanism and to changes in water balance.

As to E.C.G. investigations in athletes, variations from the normal were found to provide no indication of pathological states. Electroencephalography and head injuries in boxers was a subject exhaustively discussed by E. Jokl, who is perhaps the greatest authority in the world on the physiology and pathology of exercise. Other interesting papers

included an elaborate synopsis of the psychological and physiological changes in physical training from Professor T. Cureton, of Illinois.

The value of ascorbic acid in minimizing post-exercise soreness and stiffness was advanced in a paper from the U.S.A. It was agreed, however, that no convincing evidence of any such biological attribute of vitamin C was forthcoming in relation to this familiar disability, which appears to be an aseptic tissue inflammation. Well-controlled observations, also reported from the U.S.A., were said to have failed to identify any benefit from the effect of glucose or blood alkalizers upon competitive endurance performance.

In a paper from Spain on the respiration value in sportsmen pulmonary capacity alone was concluded, as expected, to be no guide, since oxygen transport is an elaborate co-ordination of respiratory, circulatory, and metabolic interchanges. Selye's general adaptation syndrome was introduced in papers on muscular exercise (Belgium) and sports injuries (Germany).

ADOLPHE ABRAHAMS.

HUMAN SENSES

The Human Senses. By Professor Frank A. Geldard, Ph.D. (Pp. 365; 104 figures. £2.) New York: John Wiley and Sons, Inc. London: Chapman and Hall. 1953.

No English publication attempts to cover the ground of this book—that is, to bring within the covers of one book the anatomy, histology, physiology, and psychology of the senses. It contains fifteen chapters, including an introduction, and a bibliography of 330 references. There are four chapters on visual sense, three on auditory, four on cutaneous, and one each on labyrinthine, olfactory, and gustatory senses. In the account of each sense the physical nature of the stimulus is described and then the anatomy of the organ. An excellent account of the observed phenomena follows. Not only is the physiology treated as a simple straightforward account of functional findings, but it is also interpreted in terms of general physiology and biophysics.

The author recounts the current (but not the older) theories of perception and gives a few instances of the applications to problems arising out of Service conditions in the war.

This straightforward account makes the book useful to the more intelligent undergraduate student or doctor wanting to refresh his mind with up-to-date knowledge. The avoidance of discussion on the growing points of the subject—the parts where polemics exist—makes the book unobjectionable for the Honours or Part II Tripos student. It has a good account of the early German and the modern American literature, but except for that of a few outstanding European workers it is weak otherwise.

A. ST.G. HUGGETT.

BRONCHIAL CARCINOMA

Das Bronchuscarcinom. By Dr. G. Salzer, Dr. M. Wenzl, Dr. R. H. Jenny, and Dr. A. Stangl. (Pp. 143; illustrated. £6 13s.) Vienna: Springer-Verlag. 1952.

This volume is a tribute to Professor Denk presented by members of the staff of the clinic who were his pupils. It is based on 1,200 cases of bronchial carcinoma admitted to the clinic for the period 1947-52 and treated by the Professor and his pupils. It is a fine example of what can be achieved by organization and collaboration even under the difficulties of life in Vienna at the present time.

The cases are described in full detail, and everything that could be learnt from clinical and pathological study is discussed and analysed. Particular attention is devoted to the use of tomographs in radiodiagnosis and to bronchoscopy, and the conclusion is reached that by these two methods the question of operability can be decided in the great majority of cases. The view is expressed that in doubtful cases it is better to carry out a radical operation, since with modern procedures recovery is rapid and the results well worth the risk taken.

For those who can read German the whole volume is worthy of the closest study, but for those who have not that facility the second half of the book can be of value. Here are gathered together radiographs, tomographs, and pathological photographs of typical cases from which one can learn much of the diagnosis, progress, and treatment of bronchial carcinoma. The whole forms a pictorial manual of real value in the study of one of the most important problems of surgery at the present day.

HENRY SOUTTAR.

AMOEBIASIS

Amoebiasis: Pathology, Diagnosis and Chemotherapy. By Professor Hamilton H. Anderson, M.D., Warren L. Bostick, M.D., and Professor Herbert G. Johnstone, Ph.D. (Pp. 431; 48 figures. 83s.) Springfield, Illinois: Charles C. Thomas. Oxford: Blackwell Scientific Publications. 1953.

In this book the authors "attempt to present the environmental background, modern methods for detection, and modern methods for control" of amoebiasis, which, they consider, is of increasing importance in temperate as well as in tropical climates. It may fairly be stated that this object has been accomplished if by this it is meant that the literature on these subjects has been reviewed and summarized. A vast amount of information is presented to the reader, but it is seldom critically appraised, so that some sections are little more than bibliographies. The danger which amoebiasis constitutes to populations in temperate regions is perhaps exaggerated, and many of the statements made will not go uncontested by the majority of physicians with tropical experience. Thus, the authors say that "approximately half of the cases of amoebic colitis can be detected by the use of the sigmoidoscope. The remainder, namely those involving the caecal area, can be more easily detected by the use of barium enema together with other roentgenographic studies."

Confusion results from failure to distinguish between emetine hydrochloride for parenteral use and emetine bismuth iodide for oral administration. In the preface the authors remark that "the British still contend that emetine is useful, despite the fact that accumulated evidence in the United States denies this contention." If by emetine they mean emetine bismuth iodide, few will agree that this drug is no longer useful, whereas if intramuscular emetine hydrochloride is meant the statement will again be contested on the grounds that the British do not, and have not for the past decade or more, considered that it alone is adequate for treating amoebic dysentery. Standard British practice has been to give no more than two to three injections of 1 gr. (65 mg.) each as a preliminary to a course of emetine bismuth iodide. Though in the United States emetine derivatives have largely been replaced by antibiotics for the treatment of amoebiasis, and many favourable reports of their value in the disease have been made, it is clear that a high proportion of these, particularly those concerning aureomycin, are more favourable than has been justified by subsequent events. It is now known that the relapse rate after treatment with this drug is very high. Thirty-five years ago Dobell reported a cure rate of 90% after the treatment of intestinal amoebiasis with emetine bismuth iodide, and his results have been confirmed by many subsequent observers. It now appears that few if any of the antibiotics can produce results as good as this, while a course of even the cheapest is very much more expensive than one of emetine bismuth iodide. Accumulating evidence is showing, therefore, that emetine bismuth iodide, far from being no longer useful, is still probably the most valuable drug in the treatment of the infection.

This is a book which research workers in the Tropics and those interested in protozoal infections will find invaluable as a review of the literature, but it is not one in which doctors unfamiliar with the disease can be sure of finding guidance or a clear enunciation of the principles which should govern their practice.

SATURDAY DECEMBER 26 1953

OBESITY

The quest for a successful treatment of obesity has always overshadowed the search for its causes; it is only of recent years that painstaking scientific investigation has thrown much light on aetiology. The first interest, outside that in gluttony, arose in the thyroid gland, and thence embraced all too uncritically many other glands of internal secretion, especially the pituitary and gonads. Hereditary obesity remained a puzzle, as it does to-day. The recent upsurge of knowledge sprang from a study of salt and water metabolism, and fluid retention was found on occasions to be responsible for persistent overweight even in those whose calorie intake was certainly small. It was noticed that this form arose chiefly in women and that fluid retention was most noticeable when they were active, whereas mere bed-rest would be accompanied often by diuresis and always by loss of weight—thus confirming in part observations by Leonard Williams nearly half a century earlier.

Few writers on obesity have failed to preface their observations by the statement that adiposity is essentially due to excess intake over output. Timely as this reminder is to most of our obese patients, yet it has not really explained many bizarre features of the problem. Why, for instance, do so many slim women become obstinately fat after childbirth? How is it that nervous shock, cranial injuries, and, in the old days, chloroform anaesthesia preceded and possibly caused a sudden increase of weight? Why does abstinence from smoking often lead to the putting on of weight? Increase of appetite is the immediate and correct answer, but at once calls forth a search for the mechanism that can account for psychic and organic factors producing a like result. Elsewhere in this issue Dr. J. H. Sheldon summarizes experimental and clinical evidence pointing to the important functions of the hypothalamus in weight control, and lays stress on the constancy of the time-weight pattern which is apparent in maternal obesity to those who trouble to look for it.

The general physician who is faced by a patient worried by increasing weight usually finds that co-operation is readily accorded, and all he has to do is

¹ *British Medical Journal*, 1864, 1, 99.

to prescribe the type of diet best suited for the patient's circumstances. Thus the young can well tolerate, even when active, a diet of 600 to 800 calories, composed of egg or lean meats and lettuces: quick results are obtained to the satisfaction of all concerned. The true starvation diet is wellnigh impossible to accept unless the patient be at rest, and is suitable only for those who can devote time for this purpose and who are free from cardiac disease. The patient who comes for advice about conditions other than obesity but who is urged by the physician to reduce the body weight will resent severe restriction of meals, but can be coaxed to more graceful contours by allowing one good meal a day only, or even by a generous regimen from which starch and fat are largely excluded.

It is as well that the doctor should be able to give convincing arguments in favour of weight reduction. Dr. H. M. Sinclair (p. 1404) stresses the undoubted fact that obesity shortens life and is accompanied by a high incidence of atherosclerosis, diabetes mellitus, gall-stones, arthritis, and other diseases. Fortunately the patient's difficulties have been simplified by the finding of agents which depress the appetite yet which engender a sense of well-being. Dexamphetamine used with discrimination has proved a boon to the obese, but it should never be given in the second half of the day lest it cause insomnia. Unfortunately there are some patients who are so sensitive to its cerebral stimulant action that it cannot be used.

Dr. Sinclair quotes from William Banting's *Letter on Corpulence*, written ninety years ago. Mr. Banting weighed 202 lb. when he began dieting and a year later weighed 156 lb. His girth meanwhile had lessened by 12½ in. The *British Medical Journal*,¹ giving the following outline of his diet, described it as "not untoothsome" (and, we might add, not entirely unsuitable for the festive season):

"For breakfast, four, or five ounces of beef, mutton, kidneys, boiled fish, bacon, or cold meat of any kind except pork, a large cup of tea (without milk or sugar), a little biscuit, and one ounce of dry toast. For dinner, five or six ounces of any fish but salmon, any meat except pork, any vegetable except potatoes, one ounce of dry toast, fruit out of pudding, game or poultry; two or three glasses of claret, sherry, or Madeira, but neither champagne, port, nor beer. For tea, two or three ounces of fruit, a rusk, and a cup of tea without milk or sugar. For supper, three or four ounces of meat or fish (as above), and a glass or two of claret; and, if required, a tumbler of grog for a 'nightcap,' or another glass or two of claret or sherry. (Soak the rusk in spirits, if you please.) In fact, avoid sugar-containing foods."

William Banting's achievement of the miraculous by common-sense means should still be our guide.

THE NEPHROTIC SYNDROME

The nephrotic syndrome is characterized by oedema, often sufficiently marked to constitute anasarca, heavy albuminuria, and a decrease in the concentration of plasma albumin. Usually there is an increase in serum lipids, the blood cholesterol exceeding 500 mg. per 100 ml., and often neither hypertension nor nitrogen retention. This clinical picture may be caused by several different diseases. It may occur during the course of glomerulo-nephritis, in diabetes mellitus complicated by intercapillary glomerular sclerosis (Kimmelstiel-Wilson syndrome), in syphilitic nephrosis, in amyloidosis of the kidneys, after thrombosis of the renal veins, and after poisoning by various drugs, such as troxidone. In some cases, especially children, no underlying cause is apparent and the duration of the disease varies from weeks to years: there is a particular liability to infection and remissions, several of which may occur before the albuminuria finally ceases, the anasarca clears, and the patient remains permanently well. It is this complete recovery with absence of residual renal damage that distinguishes this so-called true (or lipid) nephrosis, which some authorities are loath to accept as a disease *sui generis*, from the nephrotic stage of glomerulo-nephritis.

In addition to the disagreement about the aetiology of the nephrotic syndrome, there has been much discussion and speculation on the cause of the oedema. As long ago as 1896 Starling¹ showed that the factors controlling the transfer of fluid across the capillary wall are the hydrostatic pressure of the blood in the wall, the hydrostatic pressure of the blood in the capillary tending to force fluid out; the colloid osmotic pressure of the plasma proteins tending to hold the fluid in; the integrity of the capillary wall, which prevents the loss of plasma protein to any great extent, thus conserving the colloid osmotic pressure of the plasma; and the pressure in the interstitial space. In 1917 Epstein² suggested that the oedema of the nephrotic syndrome was secondary to the reduced colloid osmotic pressure consequent upon the decreased concentration of plasma proteins. The lowered plasma protein concentration was attributed to the heavy and continuous proteinuria. This explanation had much to recommend it, but it does not entirely fit the observed facts. A marked and prolonged diuresis has been seen to occur without any measurable increase in the serum albumin level. Often the diuresis is spontaneous, but sometimes it

follows an infection, and in recent years this has led to attempts to induce a diuresis by infecting the patient with measles or malaria.

Current interest in electrolyte metabolism has led to the suggestion that sodium and water retention are important factors in the causation of nephrotic oedema. In animals the concentration of plasma albumin can be severely reduced without oedema appearing provided sodium is eliminated from the diet; oedema appears promptly as soon as salt is given. Certainly nephrotic oedema can be partially reduced by sodium restriction, but this is common to practically all types of oedema, and it is generally conceded that oedema fluid cannot accumulate without concomitant salt retention. Sodium retention and consequent water retention could hardly explain the hypoalbuminaemia unless there were considerable haemodilution and expansion of the vascular compartment, and these are not present.³ Thus it has seemed most likely that hypoalbuminaemia is the major cause of oedema, but because quantitatively the loss of protein in the urine does not always appear to be sufficient to cause hypoproteinaemia it has been suggested that in the nephrotic syndrome the synthesis of protein in the body is impaired.

In our opening pages this week we publish a paper by Professor Squire, who with his colleagues in Birmingham has been studying the nephrotic syndrome with a commendable originality of mind and method. Since his report is a review of three years' work, of necessity it lacks some of the details which would allow a complete critical appraisal. Professor Squire first turns his attention to the mechanism of oedema formation and considers in turn the various factors influencing the transfer of fluid across the capillary wall. He confirms that the osmotic pressure of the oedema fluid is low, indicating that the capillary wall is not abnormally permeable. A new instrument has been used to study the relationship between the concentration of plasma proteins and the osmotic pressure they exert. Contrary to expectation, the relationship is not linear but curved, with the result that in normal serum small changes in the protein concentration are accompanied by considerable changes in osmotic pressure. No explanation is offered for this observation, which shows that with a plasma protein concentration of 7 g. per 100 ml. the osmotic pressure is twice that predicted from the molecular weight of the plasma constituents. Thus in a normal subject loss of fluid from the capillaries will cause an increase in plasma protein concentration, and, such is the relationship between plasma protein concentration and osmotic pressure, there will be a considerable increase in osmotic pres-

¹ Starling, E. H., *J. Physiol.*, 1896, 19, 312.

² Epstein, A. A., *Amer. J. med. Sci.*, 1917, 154, 638.

⁴ Peters, J. P., *Amer. J. Med.*, 1952, 12, 66.

⁵ Rather, L. J., *Medicine*, 1952, 31, 357.

⁶ Farr, L. E., and MacFadyen, D. A., *Amer. J. Dis. Child.*, 1940, 59, 782.

⁷ Luetscher, J. A., et al., *J. Amer. med. Ass.*, 1953, 153, 1236.

sure, which will oppose the loss of more fluid. This sensitive regulator for adjusting the movement of fluid into and out of the capillaries is impaired in nephrosis. Not only is the colloid osmotic pressure much reduced, as would be expected from the low plasma protein concentration, but the steepness of the gradient relating osmotic pressure to plasma protein concentration is flattened. The patient with nephrotic plasma loses fluid from the capillaries, and a much larger fluid shift than normal can occur before there is a sufficient rise in osmotic pressure to oppose the fluid loss.

Another factor concerned in the transfer of fluid across the capillary wall is the pressure in the interstitial space. The original concept of Starling has required modification, since it has been shown that the interstitial space is largely occupied by a colloid gel, the ground-substance. This gel has an affinity for water and tends to draw water out from the capillary and to resist its reabsorption. This "swelling pressure" of the gel is reduced from a theoretical negative value to zero if the gel's affinity for water is fully satisfied. The arrival of more fluid from the capillary then results in a collection of free water lying in the interstitial space and the appearance of oedema. In nephrosis the gel is saturated with water and no longer exerts any pressure to oppose the tendency of fluid to shift to and from the plasma.

Professor Squire finds good correlation between the degree of proteinuria and the protein concentration in the plasma. He confirms that the proteins present in the urine are lost in accordance with their molecular weight, and that albumin with the lowest molecular weight is present in the greatest amount. In the plasma the total amount of protein and the albumin fraction fall in parallel until the albumin level reaches about 1.5 g. per 100 ml. Thereafter there is no further decrease in the total protein concentration, although the albumin may fall as low as 0.5 g. per 100 ml. The total protein concentration is maintained by an increase in globulins of high molecular weight, and it is possible that these to some extent sustain the plasma colloid osmotic pressure.

Although Squire considers the hypoalbuminaemia the most significant factor contributing to oedema formation and has confirmed that elevation of the plasma osmotic pressure by infusing salt-free albumin or dextran may cause a diuresis, he also finds, as other workers have done, that a spontaneous diuresis may occur without any measurable increase in the plasma protein concentration. He points out, however, that the plasma volume is decreased, and that any increase in circulating albumin would probably cause an increase in plasma volume rather than an increase in

albumin concentration. His data indicate that a gradual increase in plasma volume does occur before diuresis sets in. This finding will be welcomed by those⁴ who believe that a reduction in plasma volume despite normal plasma tonicity leads to retention of salt and water in an attempt to restore the depleted vascular compartment.

Professor Squire then turns his attention to the nature of the renal lesion. By infusing albumin intravenously a novel technique has been evolved for measuring renal protein-clearance. In all patients there was a glomerular defect whereby many of the "pores" in the glomerular membrane were sufficiently enlarged to allow the escape of proteins with small molecular weights (for example, albumin) and a few more enlarged to allow the passage of larger proteins (for example, globulin). In normal subjects the small amount of protein which crosses the glomerular membrane is reabsorbed in the tubules.⁵ In some patients with nephrosis there is evidence of tubular inability to reabsorb proteins, and further evidence of tubular dysfunction was confirmation of the finding of Farr⁶ that there may be a considerable loss of amino-acids in the urine.

Squire's work re-emphasizes the importance of a high-protein diet in the treatment of patients with the nephrotic syndrome. Some patients show evidence of increased ability to synthesize protein and they must be given the raw materials to make good the protein and amino-acids lost in the urine. Although infusion of salt-free albumin (which is not generally available) or dextran usually causes only a temporary diuresis, repeated infusions of dextran may clear the oedema, and further investigation is necessary to discover which patients will respond to this form of treatment. Another promising line of treatment, particularly studied in the U.S.A., is the administration of A.C.T.H. or cortisone. Luetscher⁷ and his colleagues have treated 42 patients with these hormones and obtained satisfactory results in nearly half. But they are careful to point out that the natural course of the disease is so variable that no definite conclusions can yet be drawn.

THE SMALLER THE BETTER?

Behind the dissatisfaction with wages that was the main reason for the recently threatened railway strike some observers have thought they saw another cause of unrest—namely, a lowering of morale as a consequence of the large-scale amalgamation wrought under nationalization. If contentment has indeed ebbed somewhat, that is no criticism of nationalization as such, but of the size of the new organization,

and huge industrial concerns have been created without State intervention. The idea that men may work better and also be more contented in a small organization than a large one is not new. It is common belief that to be a member of a small firm increases the individual's sense of importance and purpose, and inspires a loyalty to the firm which is lacking, or at least not so conspicuous, in a vast industrial concern. Large organizations are advocated by their supporters on economic rather than on social grounds. But until recently there has been little scientific study of the proposition that industrial morale is associated with the size of the industrial unit. Marriott¹ found in two motor-car factories a slight but definite decrease in output with increase in size of the working group from fewer than 10 to 50 or more workers. A survey by the British Institute of Management² showed lower rates of labour turnover in small than in large factories. Hewitt and Parfit³ found that absence rates in a hosiery factory, both from sickness and from other causes, were greater in the larger working units. Each of these studies seems to point to lower morale in the larger group.

The Acton Society Trust has now initiated an inquiry into the whole subject and given some preliminary results from a variety of sources.⁴ Two industrial concerns (one of which is the coal industry) and a commercial organization have been studied. In the coal industry there were definite associations between the number of miners working in a pit and attendance records, accident rates, and improvements in output between 1949 and 1950. For each measure the figures tended to be less satisfactory in the larger pits. So far as could be judged from the available evidence, morale was not associated solely with the size of the pit, but also with the number of miners working in a seam, and with the number under the immediate control of a single supervisor. A similar inquiry was made into lost-time records in an industrial group with nearly 100 separate units ranging in size from 8 to 11,000 male employees. Certified-sickness and accident rates, and absences from other causes, all increased with size of the industrial unit, but it was a surprise to find no corresponding relationship between absence without leave and size of unit. Of all forms of absence, this might have been expected to reflect morale more clearly than any other. When the commercial organization, which controls 230 stores throughout the country, was

studied, a much slighter connexion was found between size of store and absentee rates, and there were other differences between the pattern of absence in the commercial and in the industrial field.

There are enough anomalies in these preliminary findings for it to be clear that the Trust has so far touched only the fringe of an interesting subject; there is also no doubt of its complexity. For example, other investigators have found that bacterial contamination of the air,⁵ and the incidence of specific diseases^{6,7}—notably tuberculosis—are greater in workrooms containing large numbers of people than in smaller rooms, and it is understandable that this should be so for infectious diseases. But this specific association adds considerably to the difficulty of using records of sickness absence as an indicator of morale in relation to size of industrial unit. Again, as the Trust is already aware, the "size" of an industrial unit is a vague concept; it may mean the number of men in a compact working group under a single supervisor, the number in a single workroom, the number doing a specific job, or the number employed in the whole organization.

To discover the social psychology which is at the root of the broad tendencies that have already been observed will be a slow and laborious study and call for considerable research ability. Yet the findings should have valuable practical applications. It should prove possible to alleviate, if not to remove, some of the social disadvantages of the large organization without sacrificing its economic advantages. This may be expected to increase output and thereby contribute to the solution of the continuing economic difficulties which face Britain. But in addition it should make life and work more tolerable, more interesting, more worth while for many people caught in the complexities of modern society, and to the doctor that is at least as important an aim. The Acton Society Trust is to be congratulated on the start it has made in investigating this problem, and the later reports will be awaited with interest.

CARBOMYCIN

We referred a year ago to the introduction into therapeutics of erythromycin,¹ a new antibiotic with a range of activity resembling that of penicillin, although quite distinct from it in other ways. This discovery has been closely followed by that of carbomycin (magnamycin), first reported from the laboratories of Chas. Pfizer & Co. by Tanner and his colleagues.² Accounts of its activity *in vitro* and in the treatment of experimental infections have since been given by English and his colleagues.^{3,4} Like erythromycin, it is highly active against many Gram-positive bacteria, including streptococci, pneumococci, staphylococci, and diphtheria bacilli.

⁷ Acheson, F., and Hewitt, D., *Brit. J. soc. Med.*, 1952, 6, 68.

The only sensitive Gram-negative organisms belong to the two fastidious and delicate genera also exhibiting susceptibility to penicillin—namely, *Neisseria* and *Haemophilus*. Minor differences are that *Str. faecalis* and *N. catarrhalis* are highly sensitive to carbomycin, whereas to penicillin they are usually less so than their cousins. It was evident from the original papers on erythromycin and carbomycin that their range of activity was similar, but the work of Finland and his colleagues⁵ has shown that the relationship between the two antibiotics is close. They tested the sensitivity of 74 strains of various species of bacteria to both, and thus demonstrated a common range of activity—that is, the relative susceptibility of different species to the two was constant, although there were some absolute differences, the minimum inhibitory concentration of erythromycin often being lower. Further, there was invariable cross-resistance between them, an organism made resistant to one becoming equally so to the other. This relationship has been confirmed by Fusillo and his colleagues.⁶ These two antibiotics even share the peculiar property of rendering staphylococci coagulase-negative when resistance is acquired *in vitro*. This means that for dealing with staphylococcal infections resistant to other antibiotics—perhaps the most serious problem in the future of chemotherapy—we have not two further lines of defence but for practical purposes only one. Unfortunately resistance to these drugs can not only be induced readily *in vitro*, but has been observed to develop *in vivo* during the treatment of obstinate infections such as bacterial endocarditis.

Clinical evidence of the efficacy of carbomycin has hitherto been scanty, but two recent reports of clinical trials, although their conclusions are not in close agreement, enable this drug to be seen in better perspective. Finland and his colleagues⁷ review earlier findings, recapitulate the results of *in vitro* tests showing that carbomycin is less active than erythromycin, and describe the treatment of 45 cases of pneumonia with carbomycin. A prompt response such as is usually obtainable with other antibiotics occurred in only six: pneumococci often persisted for several days in the sputum, and persisted in the blood of five out of seven patients who initially had a bacteraemia. Two patients actually developed meningitis, and in 12 it was necessary to abandon the treatment and resort to penicillin. Very low drug concentrations were attained in the blood, and sometimes none could be detected. Hewitt and Wood, of Los Angeles, confirm that blood concentrations are low except after intravenous administration, and find that remarkably little of the drug appears in the urine (1% or less of an oral dose, and 2.5% of an intravenous dose), but their results in a smaller series of cases of pneumonia were better. They specifically state that the rate of improvement, as judged by several criteria, was equivalent to that observed after treatment with other antibiotics, and also that pneumococci disappeared from the sputum of all but 1 out of 12 patients within

forty-eight hours. The effect of carbomycin was also uniformly good in acute tonsillitis: in severe staphylococcal sepsis it was disappointing, and in bacterial endocarditis a failure. Five patients with amoebiasis responded well. It has also to be remembered that this drug is effective, to a degree which has yet to be clinically assessed, in infections due to rickettsiae and some of the larger viruses. The general impression left by these findings is that carbomycin has a limited sphere of usefulness, perhaps not yet fully defined, and that as a substitute for penicillin in coccal infections it is inferior to erythromycin.

EMOTIONAL REACTIONS

For about the last 50 years attempts have been made to measure emotional reactions to psychological stress stimuli. The instruments used have included the pneumograph, the sphygmomanometer, the skin galvanometer, and, most recently, the electroencephalograph and electromyograph. Some of these techniques, in the popular press and in courts of law, have become glorified with the name of lie detectors. Such sensational applications are almost automatically suspect, for all that these methods can show is the occurrence of emotional changes; they cannot show what was the nature of the emotional change or what was its relation, in terms of ideas, with the psychological stimulus which had called it out.

Even so, the techniques already available may provide clues in the individual case which will be helpful in psychological and psychiatric investigation. One of the latest of them is also one of the more interesting. Newman¹ has reported the use of the electroencephalograph for purposes of electromyography. It had been previously observed² that, in word association tests, stimulating words were associated with depression of the alpha rhythm of the E.E.G. Newman's interest was not in alterations of the alpha rhythm occurring during a word association test, but in variations of the amplitude, frequency, and duration of muscle action potential: in leads from the scalp. During the test the subject was not required to answer to test words, but only to lie relaxed on the couch and to listen. It was found that stimulating words brought out muscle spikes appearing in bursts of rapid oscillation owing to action current in the scalp muscles. The subject was unaware of this effect and showed no outward sign of emotion. The volunteers were asked afterwards to comment on the words which had brought out these signs of emotion and in some cases were able to recall affectively tone experiences in their past lives which had some connexion with them. Others were not able to recall anything relevant.

In a second series, the subjects were asked to name any object or situation which was particularly distasteful to them: or one that aroused a feeling of passion, revulsion, or horror. These incidents were then described by the operator in a way to build up a vivid emotional picture. One young woman who had a particular horror of spiders was given the series of suggestions that she saw a spider on the wall, that

suddenly jumped on to her leg, crawled on to her arm and neck, that it was big and hairy, that she was unable to brush it off, and finally that it was dead and out of sight. The subject showed no visible sign of emotion, except on the electromyographic record; and pulse and respiration rates were constant throughout the experiment. Similar results were recorded from other subjects.

From these experiments it seems likely that electromyography, probably best when applied to the scalp muscles rather than the neck, trunk, or limbs, provides a sensitive instrument for detecting emotional changes. It may also provide means of measuring them, since variations in amplitude, frequency, and duration of the muscle discharge are easily read off from the record. For really useful application in the problems of clinical psychiatry it would be desirable to find out what are the emotions likely to produce changes of these kinds, and whether they are only those of horror and fear. As Newman comments, the value of the method in clinical diagnosis will depend on the development of a systematic technique; and the work, which has so far been restricted to normal subjects, could well be extended to patients suffering from psychiatric abnormalities of many kinds.

LENGTH OF AMPUTATION STUMPS

Amputation of a limb was originally a life-saving measure, and the mutilation was accepted by both the patient and the surgeon when a cure was impossible. It was not until the campaigns of Napoleon that wounded limbs were amputated in large numbers and often for preventive purposes. Larrey, to prevent gas gangrene, performed one thousand amputations after the Battle of the Nile, and it is reported that most of the men survived, while those treated by his more conservative colleagues nearly all died. The satisfaction with life left surgeons little time for dissatisfaction with their surgery, and the limb-makers were individualists who were in general content to provide end-bearing peg legs—though some were capable of magnificent work, as shown in the iron hand of Gotz von Berlichingen made to replace a hand lost in battle in 1504. This system underwent little change until 1914. The sudden demands placed on the limb-makers as a result of the work done at Roehampton Hospital during and after the first world war brought about the needed close co-operation of surgeon and limb-fitter. At Roehampton, where 41,000 patients who had had a limb amputated were treated, and at other limb-fitting centres, the individual responsibilities of the limb-maker and surgeon were fused together under the Ministry of Pensions. Experimental studies were carried out first in the Ministry of Munitions inventions department and then at Roehampton. Experience soon established minimum and maximum length of stumps to which limbs could be successfully fitted. Wooden legs of a standard pattern for below-knee amputations were first introduced in 1921. Standard patterns for other amputations followed.

With the development of standard limbs based on functional and economic factors the demand for standard stumps to fit them inevitably arose. Wider experience showed that certain amputations were eventually followed by deformity or the breakdown of skin due to a combination of factors—muscular imbalance, circulatory deficiencies, and appliance pressure. All these were carefully analysed by Muirhead Little¹ in 1922, and his evidence resulted in the discredit of certain amputations. Stephen Smith's suggestion that the menisci should be left in the stump to cover the end of the femur was due to the use of the end-bearing stump. In the Gritti-Stokes operation the patella is used for a similar purpose. Both amputations failed, since the stump was too long. Syme's amputation through the lower ends of the tibia and fibula had an average life of seven and a half years, though some patients did manage to bear weight on the end for up to sixteen years. Some of the defects of Syme's stumps were in fact due to sepsis, and the clean Syme's amputation has possibilities which English surgeons still find attractive. The Pirogoff, Lisfranc, and Chopart stumps all showed similar disadvantages. End bearing had to be largely discarded as being too impermanent.

European surgeons from countries which are members of the Brussels Treaty Organization—namely, Britain, Belgium, France, the Netherlands, and Luxembourg—have discussed the length of amputation stumps earlier this year at a meeting in Utrecht of the Prosthetic Working Party Subcommittee. General agreement with British experience was voiced. Above-knee stumps should be 10–12 in. (25–30 cm.) in length from the top of the great trochanter, below-knee stumps 5½ in. (14 cm.) from the inner edge of the tibial plateau. Minimum lengths were 6 in. (15 cm.) in the femur and 2 in. (5 cm.) in the tibia. No other country than Britain favoured the Syme's amputation, and Netherlands surgeons alone thought a Pirogoff or Lisfranc should be occasionally considered. No country favoured disarticulation at the hip, and Britain alone advocated disarticulation at the knee in selected elderly patients and in children. The ideal upper-arm stump measured 8 in. (20 cm.) from the tip of the acromion and the lower-arm stump 7 in. (18 cm.) from the tip of the olecranon. The Netherlands alone favoured occasional amputation from the wrist.

The influence of stump length is primarily on the type of prosthesis and its control. Standard lengths enable the most efficient limb—functionally and aesthetically—to be worn and so simplify limb-fitting. Surgeons faced with amputation must, when circumstances permit, have these lengths in mind and conform to them where possible. Even a naturally conservative surgeon must accept the fact that a good below-knee amputation is better than a bad Syme or Lisfranc. From the patient's point of view, standard stump lengths do not necessarily mean stump comfort, and great care must be devoted to the site of the scar, preservation of healthy skin, sound healing, and stump bandaging and control if prosthetic discomforts are to be avoided. Stump lengths are easily memorized, though stump scars may not be so easily forgotten by the patient.

CLINICAL PATHOLOGY IN GENERAL PRACTICE

EVIDENCE OF GOUT

BY

OSWALD SAVAGE, O.B.E., M.R.C.P.

Physician, Arthur Stanley Institute, Middlesex Hospital; Assistant Physician, Rheumatism Department, West London Hospital

Gout has been a recognized disease since the beginning of the civilized world. It was described as podagra by Hippocrates in the fifth century B.C., long before chemical pathology had been envisaged. It has been an accepted fact up to the present day that the history and signs of gout are far more important in the diagnosis than any pathological estimation.

Gout occurs predominantly in males after puberty and much more rarely in females at or after the menopause. The typical story is of an acute onset first in a big toe and later in other joints, often at night, with excruciating pain developing in a few hours. Intense pain is the hallmark of gout and has led to many colourful descriptions, such as "tearing the joint asunder," and the well-known quotation of Sir Thomas Watson: "Place your joint in a vice and screw the vice up until you can endure it no longer—that represents rheumatism; then give the instrument another twist and you will obtain a notion of gout." The site of the attack gives a classical appearance, with the skin for some distance around the affected joint rapidly becoming shiny, bright red or mauve in colour, but remaining dry, and with distension of the neighbouring veins. Early attacks occur commonly in spring and autumn and are usually confined to the metatarso-phalangeal joints of the big toe but may later spread to almost any joint in the body.

A description of such an attack, which may be brought on for the first time by local injury or an operation, will lead to a diagnosis of gout without supporting pathological evidence. When the attacks are atypical, or when treatment has been applied without relief, further evidence of the disease may be sought with the aid of the pathologist.

Plasma Uric Acid

The pathological evidence most frequently required by the doctor to support a diagnosis of gout is an estimation of the uric acid in the blood or serum. Garrod in 1848 showed that the blood of gouty subjects contains abnormal amounts of uric acid, and to demonstrate this he devised the "thread experiment": when a thread is placed in the blood of such a patient the sodium urate crystallizes and adheres to it. In 1913 Folin introduced a reliable method for determining the uric acid content of the blood, and modifications of it are used to-day by most laboratories, though the uric acid content of the serum is now more often estimated. This is preferred by pathologists because anticoagulants tend to produce errors in the test. The estimation can be carried out by most laboratories. For serum estimations the pathologist requires 10 ml. of venous blood collected in a plain bottle. Your local laboratory may prefer the blood in oxalate bottles and it would be as well to inquire about this point.

Difficulties of Interpretation

There are certain points about the significance of the plasma uric acid estimation which should be understood by any doctor using this test as an aid to diagnosis in gout. The figures given for a normal level of uric acid in the blood vary from textbook to textbook and from laboratory to laboratory, and unless the normal figures are indicated in

the result the practitioner should ask the pathologist for them. Most textbooks in this country give a figure of 5 mg. per 100 ml. of blood as the highest normal, and the American normal figures of below 5 mg. per 100 ml. for women and 6 mg. per 100 ml. for men for the serum uric acid are regarded as too high by most British pathologists.

Another difficulty is that the level varies from day to day, and even in cases of gout a normal figure may result from an isolated estimation. It is suspected that a normal figure is more likely to occur in this disease during or immediately after an attack, though this is by no means proved. One reason may be that during an attack the patient is often given salicylates, which cause an increased urinary output of uric acid and so a lowered blood level. The reason for changes in blood uric acid levels is not properly understood because the mechanism of urate metabolism is still not clear. Recent work with isotopically labelled uric acid which has been injected intravenously into normal and gouty subjects has shown that there is a pool of uric acid spread throughout the body. The size of the pool in the normal subject is about 1,200 mg. and in gouty patients may be fifteen times as high as this. In the normal man 50 to 75% of the uric acid in this pool is replaced each day. Such studies may in time explain the variation in blood uric acid which occurs from day to day.

Although isolated estimations in gout may give a normal figure, in most cases the blood level will be raised enough to support the diagnosis. Hench has stated that an abnormally raised figure is found at some time in 75% of cases.

Other Causes of Hyperuricaemia

One of the curious anomalies of this disease is the fact that the high level of uric acid in the blood has apparently no connexion with the attacks of gout. If in fact uric acid is injected either into a vein or into a joint it will not produce an attack. Other causes of hyperuricaemia are leukaemia, polycythaemia, lead-poisoning, and chronic nephritis. In none of these are attacks of gout common, though they have been reported in both leukaemia and polycythaemia. It has also been shown that hyperuricaemia is a familial condition and that in such families the level of uric acid in the blood rises at puberty in the males and at the menopause in the females. Stecher, of Cleveland, has made a careful study of the hereditary aspects of gout and has shown that hyperuricaemia is a common finding in the families of patients with gout, though in fact many members may never suffer an attack in the whole course of their lives.

Tophi

One of the clinical findings in long-standing cases of this disease is the appearance of deposits of urates in articular, peri-articular and subcutaneous tissues and in bursae. They occur most often upon the helix or antihelix of the ear and less commonly in the olecranon and prepatellar bursae and in the tendons

Gouty tophi.

of the fingers, wrists, toes, ankles, and heels. They may break down and ulcerate, discharging a white chalky material which can be identified by the recognition of the typical needle-like crystals of monosodium biurate under the microscope.

Tophi can also be identified chemically by the murexide test, which is carried out as follows. Heat the removed contents of the tophus with five drops of dilute nitric acid until evaporation is complete; a reddish residue remains (alloxan); add a few drops of ammonia solution to the residue when cool; the result is a purplish red colour owing to the formation of ammonium murexide.

Other Tests

The sedimentation rate is raised during an attack of gout, but as this rate is raised in so many conditions it is of no particular help in diagnosis. There is a moderate leucocytosis during an attack, and unless this is recognized it may raise difficulties when a septic condition of the joint is suspected. Liver-function tests in gout have not shown any constant impairment and are of no value in diagnosis.

In conclusion, the history and clinical findings form the basis for a diagnosis of gout and are more important than any laboratory investigations. A raised level of uric acid in the blood or serum will support a diagnosis, but a normal result does not necessarily exclude it. The severity of an attack can be better judged by the physical appearance and the degree of pain than by chemical data.

PHYSIOLOGICAL CHANGES IN BLOOD IN THE ANTARCTIC A PRELIMINARY REPORT

BY

OVE WILSON, M.D.
Lund, Sweden

During the Norwegian-British-Swedish Expedition to the Antarctic in 1949-52 I spent two years in Queen Maud Land as medical officer of the wintering party. While there I made continuous physiological investigations on the expedition members, who numbered 15 men the first year and 14 the second. My investigations included basal metabolic rates and blood tests, the intention being to register the changes that occurred during acclimatization to the Antarctic climate and then back to temperate conditions. The blood tests were begun at home, and, with minor interruptions, were conducted monthly throughout the two-year stay, even on long sledge trips into the interior during several months of field work, and during the sea voyage south and back again.

Difficulties

I soon realized that the planning of physiological research on a polar expedition to an unknown country with an adverse climate is one thing, and the carrying out of it under extreme and unexpected conditions is quite another.

Cramped quarters, limited resources, primitive working conditions, the small restricted number of test subjects, and, above all, the human factor in these persons made large-scale investigations impossible, especially as all the other scientific programmes had priority when time and assistance mattered. Because of the extreme and primitive experimental environments even normally simple tests became time-consuming. During tests solutions and pipettes had to be kept at temperatures quite different from that of the surrounding air, which was often near freezing-point.

Owing to the fact that all scientists on the expedition had to do their part as handymen during the building of the base and afterwards, the tests planned could be done only when time permitted. Those that were thought most important were started first. This procedure was also of psychological importance, as the impact of all the blood tests begun at once would certainly have been to dismay some of the members and make them hesitate in giving "such quantities" of blood. In the way it happened they were coaxed into one series of tests after another with suitable intervals, and in the end they were all willing, though grumbling, guinea-pigs.

During sledging trips, to carry out only red-cell and white-cell counts, blood smears, and blood-sugar estimations on four persons usually took 10 to 12 hours. Consequently such tests had to be made when weather prevented sledging and outdoor work, which of course increased difficulties still more. The morning air temperatures in the tent varied from -5° to -30° C. (20° to -20° F.) before heating with the primus stove; this necessitated the thawing of frozen solutions, and in addition there was constant condensation in glass tubes and pipettes. The struggle to get from one tent to the other in drifting snow and subfreezing temperatures with half-full test-tubes to take blood samples in the early morning from shivering comrades who had just got out of their sleeping-bags in a cramped and poorly lighted tent is fun to tell about—afterwards!

Scope of the Tests

The blood investigations included: red-cell count, haemoglobin content, adrenaline in blood, blood sugar (fasting), white-cell count (morning and afternoon values), and white-cell differential count. The tests were made monthly, sometimes oftener, with three interruptions: (1) during landing operations and the month during which the base was established no tests could be done; (2) during the first summer's field work all tests at base were discontinued, as I went sledging inland for four months; however, while sledging I continued making regular blood tests on a small field group; and (3) during the second summer's field work tests were similarly discontinued for one month.

To avoid the influence of the prevailing extreme working conditions much trouble was taken to standardize the tests in every detail. As the same person did the tests all the time, the personal bias in colorimetric readings and laboratory operations can be disregarded. The morning tests were taken between 7.30 and 10 o'clock, and the afternoon tests between 4 and 6 o'clock. To avoid the influence of the daily variations in blood cells the tests on each particular individual were taken approximately the same hour every time, the procedure being made easier by the divergent times of getting up in the morning owing to the different personal jobs.

Samples were always taken from the ear-lobes, alternating between left and right, because wounds in finger-tips healed slowly and became painful. It was also more difficult to get blood from the finger-tips, which more often were cold and ischaemic because of the climate. For psychological reasons I did not take the blood samples on myself, but let them be done by any of my comrades who liked to try their skill. In this way some of them took a "cruel revenge" on their torturer, often inspired by the spectators' delighted remarks. Most of my comrades attained considerable skill in blood-letting during those two years.

Red-cell Count

The counts were made according to Ellerman's method. The number of red cells remained unchanged throughout the two and a half years. Only during summer field work inland in high altitudes did red cells react with a normal physiological increase, which showed that the method used was reliable. The men at the base at sea-level did not, of course, show this increase during summer.

Isachsen (1911) demonstrated in Norway a seasonal change in red cells with a maximum in the summer and a minimum in the winter. No such seasonal change was found by me in the Antarctic. The irregular red-cell changes shown by Frazier (1945), during Byrd's Antarctic Expedition, 1939-41, do not contradict my findings, as there is reason to believe that the red-cell variations shown in his curve are within the limits of experimental error.

Haemoglobin Content

Determination was made with a Zeiss haematometer. In spite of the red cells remaining unchanged in number, the Hb curve showed characteristic seasonal fluctuations. During both polar winters the Hb stayed at a high level, but when spring set in (September-October) the curve of both years declined steeply owing to increased outdoor activity. With greater muscular strain the Hb was used to form myohaemoglobin as musculation increased. This was also illustrated by the weight curve. Fat was first lost when outdoor activity started; the weight then went up as muscles increased during summer, and more fat was added during the second polar winter. Thus both Hb and weight curves became indicators of outdoor temperatures. This drop in Hb in the second spring could not be prevented by continuous prophylactic administration of iron, but it seems that Hb regeneration was accomplished quicker and to a higher degree because of this medication.

Finsen (1894), Isachsen (1911), and Odin (1937) have demonstrated a seasonal fluctuation of Hb with a minimum in the winter (December-January) and a maximum in the summer (June-August). The rise in Hb is regarded as being due to the influence of ultra-violet rays on the formation of Hb (Odin) as well as to the diet. The seasonal variations were found to be greater in North Sweden (Luleå) than in the south (Lund), attributed to the long winter nights in the north. Grimsgaard (1910), in northern Norway, showed

a decrease in Hb during the dark winter months. Contrary to this, Høygaard (1937, 1940) found the average winter values (December-April) of primitive-living Eskimos in Greenland to be higher than the summer values (June-July), although these were taken when summer food conditions were extraordinarily good. The winter values (men) were 4.5% above those of the summer. In accordance with this, Gyllencruz (1884), of the Swedish Spitzbergen Expedition, 1882-3, found no decrease of Hb during winter (September-February); and Ekelöf (1904) of the Swedish Antarctic Expedition, 1901-4, found an increase of Hb during the second winter. MacLean (1919), of Mawson's Antarctic Expedition, 1911-14, showed a rise in Hb during midwinter and reported that several Arctic expeditions had found no diminution in Hb during the dark months. Howe, in Alaska (Mikkelsen, 1910), and Koettlitz (Scott, 1905), of Scott's Expedition, 1901-4, had reported similar observations.

My investigations show the same increase in winter values, with a marked drop on the arrival of spring, in spite of the increased influence of exceptionally strong ultra-violet light. The diet can be regarded as unchanged, but with additional fresh seal meat and liver in the spring. Thus it seems that the seasonal decrease in Hb during winter found by Scandinavian workers has no correspondence in polar regions. On the contrary, winter values are high, with a marked decrease towards summer.

Adrenaline in Blood

It has been stated by many that the blood adrenaline increases in the polar climate. The raised blood-sugar level should indicate this. Frazier noted an increased liability to adrenaline shock following injections of local anaesthetics with small amounts of adrenaline. He claims this to be due to an increased amount of adrenaline in the blood stream. Butson (1949) investigated this possibility by injecting 1 ml. of 1/150,000 adrenaline intravenously over a period of 90 seconds. A slight increase in sensitivity was noted.

To investigate this further, attempts were made to determine the blood adrenaline by fluorescence according to Pekkarinen's (1948) absorption method. Less than 0.5 mg. of adrenaline per 100 ml. cannot be demonstrated in blood with this method. Tests were done during several periods of our stay: when arriving in Antarctic climate; after mid-

winter, when blood sugar was at its peak; and just before leaving. No measurable amount of adrenaline in the blood could be shown.

Blood Sugar

Fasting blood sugar in the morning was determined according to the Crecelius-Seifert method. As a result of acclimatization the fasting blood-sugar level was increased on an average 9% compared with home values, with incidental peaks averaging 17% increase. This confirms the usual assumption that fasting blood sugar is increased in Antarctic climate.

Frazier (1945) reports that Lockhart, of the U.S. Antarctic Service, 1939-41, found a blood-sugar increase above normal in 13% of the group tested. Butson (1949), of the Falkland Islands Dependencies Survey, found an average increase of 10 mg. per 100 ml. in fasting blood sugar in his subjects (Hagedorn-Jensen method). Heinbecker (1928), by means of the Shaffer-Hartmann method, found the average fasting blood sugar of Eskimos to be 120 mg. per 100 ml. Rabinowitch and Smith (1936) found 137 mg. per 100 ml. by means of the picric-acid method, which is considered to give values 10 to 15% higher than the Shaffer-Hartmann method. They therefore came to the conclusion that Eskimos have a higher fasting blood-sugar level than people living elsewhere. This was not confirmed by Høygaard (1937, 1940), who found an average fasting blood sugar of 88 mg. per 100 ml. (Hagedorn-Jensen) in Greenland Eskimos.

The most interesting result of my blood-sugar investigations, however, is the demonstration of a characteristic curve during adaptation to a different climate. The peculiar feature of this curve is the first great dip in the blood-sugar level (see Chart—compare with the morning white-cell curve). This dip seems to be characteristic for acclimatization. An obvious tendency towards a similar dip is found in the last part of the curve during reacclimatization to temperate conditions. This second dip is well developed in the morning white-cell curve, but would probably have shown equally well in the blood-sugar curve had not tests been discontinued on arriving home, as blood-sugar changes seem to lag one to two months behind white-cell changes. Later tests at home showed that blood-sugar values have returned to normal—the same as before leaving for the Antarctic—thus marking the completion of the second "dip of acclimatization." To illustrate this the assumed continuation of the blood-sugar curve has been drawn (dotted line in Chart).

White-cell Count

The counts were made according to Ellerman's method. Blood was taken while fasting, in the morning, as well as later in the afternoon. The morning white-cell curve shows the same characteristic "dip of acclimatization" as the blood-sugar curve (see Chart). In the first part of Frazier's white-cell curve the corresponding "dip of acclimatization" can be seen. He attributes this to the isolation of the group and the absence of infections and colds. However, the rest of his curve showed a marked difference from mine, because his values were not fasting morning values, but were made from blood taken two hours after meals, and therefore were influenced by activity and prevailing weather. Temperatures at the American base were also quite different from those at ours. A similar but less accentuated "dip of acclimatization" can also be seen in the white-cell counts done by MacLean (1919), of Mawson's Antarctic Expedition.

After acclimatization, morning white-cell values stayed at an even level 25% below normal with only slight variations. There were no pronounced tendencies towards seasonal changes. Ekelöf (1904) found a marked decrease in the number of white cells during a stay in the Antarctic. Isachsen (1911) showed that no seasonal fluctuations are normally found in white-cell counts.

After our return from the Antarctic the values were still 25% below normal (after the reacclimatization dip), prob-

ably owing to the long period with absence of infections. These low values may explain the wide susceptibility to all kinds of infection which most members showed for a long time after coming home. It is curious that the values have remained low also after the men had had a series of infections.

Afternoon white-cell values followed the same trend as the morning values, but were obviously more influenced by the incidental fluctuations of climate and activity at the time of the tests. Thus the morning values were more stable and showed the general trend, while afternoon values were more sensitive indicators of temporary conditions. In fact, if afternoon values are divided by morning values and the

curve is smoothed by applying the formula $\frac{a + 2b + c}{4}$ the curve (after acclimatization) almost accurately, but with a slight drag, follows the inverted temperature curve, and thus reflects the influence of weather (temperature) and the correspondingly varying strain (activity). After we returned from the Antarctic the afternoon values did not remain at the correspondingly low level, as the morning values did, but increased somewhat.

By making a two-way breakdown of the white-cell values, the reliability of the method used with such a small number of subjects can be demonstrated. An arbitrary but convenient division is into smokers (8) and non-smokers (7). This breakdown is interesting, because the smokers seem to represent the high white-cell values, while non-smokers have constantly low values. The morning white-cell curve for smokers (high values), as well as the curve for non-smokers (low values), follows the "normal mean curve" (total values) amazingly well, which goes to show that even with only half the number of test subjects a characteristic and applicable curve could have been obtained. The same applies to the afternoon values. Another interesting fact is that at home the mean morning values for smokers and non-smokers were about the same. When landing in the Antarctic both groups still differed very little, but from then on there was an appreciable difference. The white cells of the smokers seemed to react considerably more to acclimatization and showed a more accentuated "curve of acclimatization." Perhaps smoking makes white-cell values less stable and more liable to react to other stimuli, as the uneven swinging individual curves of the "great smokers" tend to show.

Differential Count.—Blood smears were mostly taken each time white-cell counts were made. The results of these differential counts have not yet been worked out, but there is reason to believe that the counts will show a decrease in eosinophil cells. Stein *et al.* (1949) report that the eosinophil count is significantly depressed on exposure to cold. This was not confirmed by Sapin-Jaloustre, of the French Adelle Land Expedition, 1949-51 (verbal communication, 1945).

Other Tests

Additional blood tests (mainly blood-sugar levels and white-cell counts) were taken on individual members each time they had been away from base any number of days, and therefore had been more exposed to the cold. During the first half-year these tests almost invariably showed a temporary increase in the blood-sugar levels and white-cell counts. In exposing fasting men to cold in a refrigerator Swift (1932) determined the blood sugar just before and immediately after exposure. The blood-sugar level remained unchanged. When exposing cold-adapted men to low temperatures for brief periods of time, Miller and Miller (1948) could not find any significant variation in blood-sugar levels and white-cell counts.

The basal metabolic rates taken in conjunction with the blood tests have not yet been worked out.

I should like to add that after two and a half years of almost continuous blood-letting under trying conditions my comrades are worth all the appreciation that can be given to them.

Summary

Continuous monthly blood tests were made on 15 (14) members of the N.-B.-S. Expedition to the Antarctic, 1949-52, during the two-year stay and the trip there and back.

Red-cell counts showed no changes or seasonal fluctuations. Haemoglobin values showed a typical seasonal fluctuation as a function of outdoor activity, not related to the usual summer maximum and winter minimum shown in Scandinavia. No measurable increase of adrenaline in the blood was found. During acclimatization to Antarctic climate and back again to normal climate fasting blood-sugar values as well as morning white-cell counts showed a characteristic dip of acclimatization in their curves. After acclimatization the fasting blood sugar showed an increased level of 9%, while morning white-cell counts stayed 25% below normal. Morning white-cell values were more stable and showed the general trend of acclimatization, while afternoon values were more sensitive indicators of temporary conditions. The white cells of smokers seemed to be more sensitive to reactions in the Antarctic and stayed at a considerably higher level.

I would welcome any criticism or helpful information about the problems mentioned here.

Reports of Societies

PSYCHOTHERAPY IN PRISONS

At a meeting of the Section of Psychiatry of the Royal Society of Medicine on December 8, with Dr. E. B. Strauss, president of the Section, in the chair, the subject of discussion was "Psychotherapy in Prisons and Corrective Institutions."

Group Treatment

Dr. J. C. MACKWOOD, for many years psychotherapist to H.M. Prison, Wormwood Scrubs, said that in 1946 a ward for psychotherapy was set apart in the prison hospital grounds. Here the selected prisoners were given the status of sick persons. The ward enabled group treatment to be undertaken, it constituted a kind of family setting, and it sheltered the prisoner from the additional punishments which he might be liable to incur when housed amongst those not getting this treatment. This social group was a potent stimulus for starting respect for the majority verdict. All kinds of offenders responded to this approach and became readjusted, including those with associated psychopathological (functional) disturbances that required analytical psychotherapy which could be provided within this group framework. When the offenders were first seen in prison it was not always easy to determine the cases which

would not respond to treatment, and the acceptance or rejection of a particular individual by the group was often a very useful guide.

Several ex-prisoners had written of the struggle within themselves they had encountered after discharge; a well-organized psychiatric social service for helping the prisoners after leaving prison was essential. In the final analysis this was more a sociological problem than an individual one.

Dr. W. F. ROPER, principal medical officer, Wakefield Prison, said that institutional life was often considered a barrier to successful psychotherapy, but it could be made of assistance. For many years there had been a movement towards enlightened man-management, the object being to liberalize the regime to the greatest extent possible. This was predominantly a lay achievement, but it had provided a background against which useful psychological work had been done. In 1947 a psychiatric unit was set up at Wakefield. At the moment there were two full-time visiting psychiatrists, a psychologist, and a psychiatric social worker. Prisoners were subject to a periodical review by the whole-time medical officers, and, when considered desirable, were referred to the psychotherapist for treatment. The prisoner was given an opportunity to work out new and more successful attitudes in his personal relationships.

The difficulties attending psychotherapy in prison were those of selection and timing, those associated with after-care, with relatives and the domestic environment, with occupation, and with the attitude of the group. Aftercare was a great problem, not made easier by the fact that in many cases the prisoner wanted, after his discharge, to have no reminder of his prison experience. The psychiatric social worker could do something to mitigate the difficulties following discharge. Relatives might be a great help or a great hindrance. They could help if they remained loyal or reverted to loyalty, and a great hindrance if they fostered ideas of innocence and injustice. Group treatment had worked very well in the hands of medical officers. It was no hardship to work with and through the existing prison staff, who were good colleagues, but the psychiatrist must "fit in." The results of psychological treatment at Wakefield were difficult to assess, but not unpromising.

Approved Schools

Dr. CHRISTOPHER LACK, visiting psychiatrist to the Magdalen Hospital Classifying School, introduced the subject of psychotherapy in approved schools. Girls, committed by a juvenile court in the southern half of England and who were between the ages of 14 and 17 years, were admitted to the classifying school for observation and investigation, before being sent on to the training school best suited to their needs. In selecting girls for psychotherapy, it was important to bear in mind not only their need for treatment but whether they were capable of adjusting to the life of a small community in an open school. A few approved-school girls were so violent as to disrupt the community in which they lived. Special provision was needed for the management and treatment of the aggressive, unstable adolescent, some of whom were psychopaths.

A greater number of girls would be amenable to training and to psychotherapy if they were committed earlier. The approved school should not be used as a last resort. Many of the girls had a history of disturbed behaviour and emotional difficulties dating back over several years, and the problem was intensified if they were not committed until the approach of their 17th birthday. Only a small percentage of girls were recommended for psychotherapy. The latter was only one weapon in the war against juvenile delinquency. Nowhere in the field of psychiatric endeavour was it more necessary to be modest in their claims than when they intruded upon the domains of the Law.

Discussion

Dr. PETER SCOTT, physician at the Maudsley Hospital, spoke of the value of the visiting psychiatrist who was able to link the prison with the mental health service. He mentioned the similarities between offenders referred

Treatment of Tetanus

SIR,—The short paper by Dr. J. H. McIntyre on the treatment of tetanus (*Journal*, October 17, p. 866) raises a number of points of considerable practical importance. There can be no disagreement with the advice offered by the author that where tetanus is unusually prevalent in a community, as it appears to be in New Zealand, and as it certainly is in this Western state of Australia, antitetanus immunization should be carried out at the time of immunization against diphtheria. Bigler and Werner,¹ Miller and Ryan,² and North and Patterson³ have demonstrated that highly protective titres of tetanus and diphtheria antitoxin develop after simultaneous inoculation with the two toxoids.

Dr. McIntyre's gloomy views on treatment—"present methods of treatment of tetanus in cases occurring within a week of injury are ineffective"—cannot, however, be accepted without qualification. Recent literature on this subject has stressed the use of this or that relaxant, and a tendency to place reliance on these pharmacological agents as the only life-saving measure worthy of consideration has unfortunately arisen. It would appear that we are in danger of losing perspective on this therapeutic problem. The immediate cause of death in tetanus is often an academic question not easy to answer; certainly exhaustion and anoxia caused by a prolonged apnoea due to severe spasms may be incriminated in many cases. In the inhibition of these spasms relaxants most assuredly must be regarded as a significant advance in therapy, obviating the use of heavy doses of centrally depressing soporifics. But a constant finding at necropsy is also the presence of excessive quantities of mucus in the bronchial tree with associated collapse and infection of one or other lobes of the lungs. In a recent paper my colleagues and I⁴ have adduced evidence that lives may be reclaimed if attention is paid to the prevention of the pulmonary complications of severe tetanus. When, by virtue of a short incubation period and the early onset of symptoms, a stormy course can be predicted, early and timely tracheotomy is to be recommended. Two cases, one a boy of 17 with an incubation period of only 3½ days, and the other an elderly lady who presented with signs of complicating pneumonia, were quoted in support of this contention. They were both treated in the conventional manner with, in addition, tracheotomy: both patients survived.

The problem in tetanus is to support life over the weeks when the toxin is exerting its pharmacological effect on the synapses of the central nervous system. Inhibition of synaptic excitation may be achieved with one or other relaxant; large doses of penicillin and antitoxin are useful in attacking the living micro-organism and neutralizing unfixed toxin in circulation; intragastric feeding sustains the nutrition of debilitated patients and lessens the risk of tracheal aspiration of food particles. In addition to these measures, concerning which there can be no room for debate, judicious tracheotomy with intratracheal suction and the usual posturing measures can reasonably be expected to prevent, in many cases, pulmonary collapse and sepsis. For some reason physicians are apt to adopt a conservative view towards tracheotomy, an attitude of mind which can no longer be held justifiable.

There can indeed be no place for therapeutic nihilism in an infection which continues to carry, even in this antibiotic age, a high mortality rate among young and healthy people. The statistical assessment of the results of treatment of tetanus is admittedly difficult; in the meanwhile we must be guided by experience in individual cases. In the minds of many of us there is little doubt of the value of tracheotomy.

for treatment in prison and those seen in a clinic for offenders at the Maudsley Hospital. The frequency of long spontaneous remissions indicated special care in assessing results in these cases.

After some further discussion, Dr. ROPER said that one point which he had found effective in group treatment was to challenge a prisoner at the very beginning to bring forward all the grouses he wished. All that they had to say in criticism of the general set-up was then heard. Perhaps three or four different sessions were devoted to this subject, and then they settled down to a fair amount of steady work.

Dr. MACKWOOD, also in reply, said that regression was the great bugbear in delinquency, but regression was a vague term unless one had in mind a fixation point to which the person regressed. One had, of course, to adjust the psychotherapeutic work in prison to the length of the sentence, which to a large extent determined the possibilities. It was important to assess the character structure of the individual as quickly as possible, and then set about canalizing his energy into useful channels.

MEGALOBlastic ANAEMIAS IN EAST AFRICA

At the meeting of the Royal Society of Tropical Medicine and Hygiene, held at Manson House, London, on December 10, Dr. HENRY FOY, of the Wellcome Trust Research Laboratories, read a paper on the influence of the intestinal flora on the synthesis of haemopoietic factors in the megaloblastic anaemias of Africans. He was describing some of the research carried out by Dr. Athena Kondi and himself in Kenya in recent years.

Some of these cases of megaloblastic anaemia responded to penicillin or to vitamin B₁₂ given by mouth, he said; some did not respond to these but responded to intramuscular B₁₂ (and these had histamine-fast achlorhydria and signs of gastric atrophy); some responded only to folic acid. These anaemias were uncommon in the coastal areas of Kenya, but were seen in the highlands. The patients were not undernourished, but there was evidence to suggest that one factor in the aetiology might be a diet containing too much starchy food and too little protein, and that such a diet favoured an intestinal flora inimical to the synthesis and utilization of B₁₂.

The Role of Penicillin

Administration of penicillin probably altered the ecological equilibrium of the gut flora, upsetting the balance between those organisms which synthesize B₁₂ and those which compete for it, and probably caused changes in bacterial metabolism for other bacteria or for the host. Penicillin might also destroy bacteria containing B₁₂, and thus make this substance available for the host. The acceleration of growth in animals following the administration of antibiotics, the prevention of liver damage in animals given necrogenic diets, and the development of megaloblastic anaemia in *Diphyllobothrium* infections were probably all related phenomena associated with changes in the flora and fauna of the alimentary tract and connected with the synthesis, absorption, and utilization of vitamin B₁₂. It was known that biosynthesis in the gut produces a wide range of essential metabolites, including nicotinic acid, riboflavin, folic acid, inositol, and tocopherol, which become available either for the host or for the organisms inhabiting the gut. The megaloblastic anaemias which accompany infection with *D. latum* could always be cured by removal of the worm, which would be found to contain large amounts of B₁₂, clearly obtained at the expense of the host.

In the discussion which followed the paper, Professor A. W. WOODRUFF commented on the fact that some of the cases had responded to intramuscular B₁₂ but failed to do so on oral B₁₂. He suggested that the amounts given might have been insufficient. Only the bound form of B₁₂ was effective. He also discussed the possible effects of bacterial infections high in the intestine. In West Africa macrocytic anaemias were associated with deficiency of protein.

in conjunction with the use of antitoxin, antibiotics, sedatives, relaxants, and intragastric feeding, in saving many cases.—I am, etc.,

Perth, Australia.

Treatment of Acute Pancreatitis

SIR,—As a result of my experience of 24 cases of acute pancreatitis in the last three years I have formulated opinions which differ in several respects from those expressed by Mr. R. M. Davies, Mr. F. T. Moore, and Mr. D. Wynn-Williams (*Journal*, December 5, p. 1251). Of my 24 cases, 21 were women and only 10 occurred in the fifth and sixth decades, the youngest being aged 22 and the oldest 83. Unlike the authors, who express the view that biliary calculi are an incidental finding in acute pancreatitis, I believe that there is in some way a direct association with gall-stones, as I have seen two cases occurring after cholecystectomy and drainage of the common bile duct, one in the immediate post-operative period, where the duct had contained purulent bile, and the other six months after operation. I have also operated for unsuspected acute pancreatitis on a young woman of 27—an age at which gall-stones are uncommon—and found a gall-bladder which appeared outwardly normal but contained many stones.

I cannot agree with the authors in their statement that exploratory laparotomy is indicated even if there appears to be no doubt about the diagnosis. I am convinced that operation is contraindicated and that, if the abdomen is opened in error, the pancreas should be disturbed as little as possible, and no drainage of the pancreas or gall-bladder should be established. My figures show that, of nine cases which were submitted to operation, four died, and of 15 cases which were treated conservatively, four died. Two of these latter were fulminant cases and died within 14 and 24 hours of the onset of symptoms; the other two followed cholecystectomy and partial gastrectomy respectively and occurred in the immediate post-operative period. The one difficulty which I have encountered in the conservative treatment is the control of pain, and the reported results of the administration of hexamethonium, if they are confirmed in a larger series of cases, represent to me a major advance in the therapy of acute pancreatitis.—I am, etc.,

Liverpool, 1.

W. M. BEATTIE.

SIR,—By their success in treating four proven cases of acute pancreatitis, Dr. Russell M. Davies and his colleagues have made out an appealing case (*Journal*, December 5, p. 1251) for the use of the ganglion-blocking drugs in this distressing, and sometimes fatal, condition. However, while they discuss Marion's rather impractical treatment by repeated splanchnic blockade,¹ they make no mention of the well-tried continuous technique by means of a fine indwelling epidural catheter.² The latter method of inducing analgesia and vasodilatation is at least as effective as the methonium drugs, and in severe cases may provide a more satisfactory measure of pain-relief, without the same degree of vascular hypotension that accompanies complete ganglionic blockade with the methonium salts.

When an epidural catheter is in place analgesia can be controlled according to the needs of the patient by varying the concentrations of injected drugs, without the need to extend the limits of the spinal block above the sixth thoracic segment; in this way a considerable degree of vasomotor stability is retained. With the methonium drugs, on the other hand, if analgesia is insufficient one must increase the dose and thereby inflict a greater degree of vasomotor paralysis upon the patient. Moreover, the ileus that tends to accompany acute pancreatitis may be aggravated by large doses of the methonium drugs.

I gave pentamethonium iodide to the last case of acute pancreatitis that I was called upon to treat, instead of insert-

ing an epidural catheter, but the patient obtained only partial relief of pain in the presence of an alarming fall of blood pressure. It was my intention to change the treatment to a continuous epidural block the next day, as being a more efficient method, and less disturbing to the patient's physiology. But the patient died during the night, and at necropsy the degree of pancreatic destruction and retroperitoneal haemorrhage made it seem unlikely that any treatment could have saved her.

Dr. Davies and his colleagues are to be congratulated upon their results and for recalling attention to the methonium drugs, but it would be unfortunate if their lack of comment on the epidural technique were taken to indicate that the continuous method does not merit consideration.—I am, etc.,

Chichester.

SIR,—We were very interested to read the important paper on the treatment of acute pancreatitis with hexamethonium bromide by Dr. Russell M. Davies, Mr. F. T. Moore, and Mr. D. Wynn-Williams (*Journal*, December 5, p. 1251). We were particularly intrigued by the apparently detailed literature suggesting the possible aetiology of this condition.

May we point out that in our book, *The Liver*,¹ we put forward a new concept of the aetiology of this disease which agrees with and explains the aetiology put forward in this stimulating paper? In brief, we postulated a thrombophlebitis of the portal radicles draining the pancreas as the cause of gangrenous pancreatitis.

In view of this new communication we feel that in fairness we should direct attention to our publication of 1950.—We are, etc.,

London, W. 1.

Nodular Fibrosis of the Lung

SIR,—With reference to the aetiology of the new syndrome of nodular fibrosis of the lung in coal workers with rheumatoid arthritis (*Journal*, December 5, p. 1231), it is clear that the tuberculous association must be explored, and also whether it is a primary or secondary factor. It would be interesting to know whether any similar condition has been found in miners with sarcoidosis. I would, however, like to put forward another possible explanation. The nodules may be granulomata resulting from a slowed lymph flow and transmission of dust from the periphery of the lung.

Lymph node hyperplasia occurs in 70%¹ of rheumatoid patients, and there is evidence that it is present throughout the body and therefore presumably affects the hilar glands. My own observations are that men are far more frequently and severely affected by this than women. I commented in 1949² on the possible implications of Selye's³ work with "formalin arthritic" rats when he showed that Indian ink injected peripherally was transmitted to the lymph nodes more effectively when the nodes were small and under the influence of A.C.T.H. than when they were normal. Furthermore, in rats treated by L.A.P. (lyophilized anterior pituitary tissue), which caused hyperplasia of the lymph nodes, even less Indian ink appeared to reach them.

A possible line of research would seem to suggest itself here. Expose for a sufficient time three groups of suitable laboratory animals to atmospheres polluted with coal dust and/or stone dust: (1) normals; (2) L.A.P. or deoxycortone acetate treated; (3) A.C.T.H. treated. Meanwhile the effect of A.C.T.H. or cortisone used early might be noted in the disease itself.

Another granuloma (Whipple's disease) occurring in the jejunum and related lymph glands also has a high incidence of polyarthritis at the outset and a vastly predominant male sex incidence. I have suggested⁴ that this lipophag-

granuloma may be related to slowing of the fatty lymph flow, lymph node hyperplasia from stress and rheumatoid arthritis being the possible initiating factor.—I am, etc.,

Routine Lumbar Puncture in Primary Tuberculosis

SIR,—In the reply concerning routine lumbar puncture in primary tuberculosis ("Any Questions?" *Journal*, November 7, p. 1058), the author states that the incidence of tuberculous meningitis is very low in primary tuberculosis. Surely this is only true as a general statement and special mention should have been made of the disease in infancy.

It is well known that tuberculous meningitis and miliary tuberculosis are the two great complications of primary tuberculosis, occurring as they do as part of the accompanying haematogenous dissemination, and that the incidence of these complications is relatively much greater during the first three years of life. I think, therefore, that a tentative case can be made out for routine lumbar puncture in cases of primary tuberculosis in this age group, since the dissemination is likely to be more active, and the early symptoms of meningitis difficult to detect. It is agreed that at any age miliary tuberculosis and primary complex with persistent pyrexia are valid indications for routine lumbar puncture.

It seems very unlikely that rupture of a subcortical tubercle by release of pressure on lumbar puncture could have caused meningitis within five days in the case cited by Dr. Ian G. Wickes (*Journal*, December 5, p. 1271), since the very nature of the pathology of meningitis the condition takes some time to develop. It seems far more likely that the findings of Bernard et al.,¹ quoted in the reply, are correct, and that, if meningitis develops shortly after a lumbar puncture, it does so because the process was already active though preclinical, and the lumbar puncture purely coincidental.—I am, etc.,

Hexham.

Appeal for Specimens

SIR,—May I make use of your columns to appeal for specimens of kidney from cases of acute nephritis? This condition so rarely reaches the post-mortem room nowadays that it is extremely difficult to collect material. The work upon which I am engaged involves the elution of antibodies from the kidney, so that it is essential that the specimens are not fixed in the ordinary way, but preserved in a deep freeze or refrigerator. If any specimens are encountered and the pathologist or clinician concerned contacts me (preferably by telegram or telephone—Edinburgh 41001, extension 30), I shall arrange to have them collected or sent here.—I am, etc.,

B. CRUICKSHANK.

Pathology Department,
University New Buildings,
Teviot Place, Edinburgh, 1.

Amoeboma of the Caecum

SIR,—In reply to Dr. L. Everard Napier's criticism of my memorandum (*Journal*, December 5, p. 1269), may I point out that in my original account all the information he seeks was present? At your editorial request I cut down the article to two-thirds of its original length, and had not the privilege of Dr. Napier's expert advice in this pruning operation.

I gave the following information: (1) The patient had never been out of this country except during the war, when he was on military service abroad. (2) No history of diarrhoea was given before operation, but on specific questioning afterwards he admitted that he had diarrhoea on and off while in the Middle East. (3) The antibiotics used before operation were penicillin and streptomycin; aureomycin and

chloramphenicol were not available for general use in 1949, when the operations were performed. (4) The tumour was not removed until the affected part of bowel had been exteriorized for three days. By that time the mass was partly gangrenous and the pathologist was unwilling to give a firm opinion. I can only say that at operation the mass appeared to be inflammatory rather than neoplastic, but admit that the evidence is incomplete. (5) As regards "personal criticism," surely that is of secondary importance. Here we had a case simulating appendix abscess and found at operation to be a caecal mass. In a country where amoebiasis is not endemic the diagnosis at operation lay between neoplasm, Crohn's disease, or tuberculosis. Had I performed entero-anastomosis or a formal resection, or even taken a biopsy, the patient would almost certainly have died of peritonitis. The two-stage operation proved to be the only safe one and was done on general principles. I wrote to help my fellow surgeons and hence the details of "surgical interference." (6) In my original account I suggested a therapeutic test with emetine, but would add that the toxic effects of this drug should be appreciated.

I also have some good photomicrographs for Dr. Napier's perusal if he would like to see them.—I am, etc.,

Epsom.

E. N. CALLUM.

Insulin Zinc Suspensions

SIR,—I was interested in the observation by Dr. G. M. Wauchope (*Journal*, December 12, p. 1325) that when she transferred her patients from globin insulin to insulin zinc suspension "lente" she found it necessary to increase the dose in order to maintain a similar control as with the globin insulin.

A series of 15 patients, who were treated as in-patients in this hospital, were carefully stabilized on a minimum dose of protamine zinc insulin. After satisfactory control had been present for seven days, these cases were then given the same daily dose of lente insulin. Within two or three days it was found that the dose of insulin had to be increased in every case except one, the increase ranging from 6 to 22 units. All the cases in this series were mild diabetics requiring from 28 to 66 units of lente insulin. Of three patients suffering from allergic insulin reactions, two continued to have them with insulin zinc suspension.

I wish to thank Evans Medical Supplies, Ltd., for supplies of insulin zinc suspension used in this trial.—I am, etc.,

Llwynypia, Rhondda.

M. S. PATHY.

Unwrapping the "Journal"

SIR,—The letter from Dr. H. Lyndhurst Duke (*Journal*, December 12, p. 1326) was very interesting, and seems to justify the mention of a swift and safe method of extracting the *Journal* from its wrappings which I have used for some months and can recommend for serious attention. The little finger of the left hand is inserted through the open end of the wrapper into the central space in the rolled up *Journal*. The right hand grasps the wrapper gently but firmly. By rotating the little finger in such a way as to "wind up" the rolled *Journal* like a watch spring it can be felt to grip the little finger firmly and at the same time to relax its outward pressure on the wrapper, from which it can be withdrawn like a cork from a bottle. It is sometimes necessary to insert the little finger into the other end and try again. I have become so used to this manoeuvre that I use it for the *Lancet*, which still has the quick-tearing strip in its wrapper.

It is possible to reverse this process and replace the *Journal* in the wrapper unknown to the owner.—I am, etc.,

Accrington.

J. H. ARMSTRONG.

SIR,—Dr. H. L. Duke (*Journal*, December 12, 1953, p. 1326) may be interested in my method of extraction of the *Journal* from its wrapper. This method is simple, speedy, and tidy. Grasping firmly the *Journal* and its wrapper in the middle third with the left hand, insert the index and middle fingers of the right hand into the proximal orifice as

SIR,—Both the excellent article by Professor T. N. A. Jeffcoate (*Journal*, October 31, p. 951) and the letter from Mr. J. A. Chalmers (*Journal*, November 21, p. 1159) show the dangers that general anaesthesia carries for both mother and baby when used for instrumental delivery. It is true, as Mr. Chalmers points out, that local analgesia is unsuitable for the more difficult forceps deliveries, but there are other forms of conduction analgesia which avoid the risks of general anaesthesia. It may seem bold to advocate spinal analgesia for these cases, and perhaps to reopen a perennial argument, so soon after the appearance of a report on a medico-legal case involving sequelae from it in two patients. Your columns, however, from time to time report the complications of all kinds of anaesthetic methods. The position is well summed up by Professor R. R. Macintosh in his monograph on *Lumbar Puncture and Spinal Analgesia*.¹ This deals thoroughly with the technique of spinal analgesia while avoiding discussion of its advantages and disadvantages, and in the introduction the author states: "I do not intend to extol the virtues of spinal analgesia. The benefits of any method of pain relief, general or local, have to be paid for in terms of morbidity, and the price exacted of the patient in this respect depends little on the choice of method or agent but very much on the care, skill and experience of the anaesthetist himself." Another authority, Dr. Frankis Evans,²

has stated: "The method is quite safe if used properly, in the right circumstances and with proper precautions."

Much of the prejudice against spinal analgesia in obstetrics dates from the days when more toxic drugs were in use and its risks were not appreciated. Previous correspondence in these columns about its risks for caesarean section has shown the widespread fear of its use for that operation. The level of analgesia required for a forceps delivery, however, does not involve the risks of fall of blood pressure and respiratory disturbance which may occur with the higher analgesia required for caesarean section. The risks of infection and nerve damage should be avoidable by proper technique. The only troublesome complication is that of headache, which should occur rarely if a fine needle is used. The use of cinchocaine ("nupercaine") gives ample time for an unhurried delivery and repair. The recent report by Mr. Henry Roberts¹ on over 3,000 obstetrical cases in which saddle spinal analgesia was used in Walton Hospital, Liverpool, shows the great safety of the method.

It is unfortunate that this subject arouses such strong feelings when it is discussed, and it was well said by Dr. Langton Hewer² in his review of Professor Macintosh's book: "It is curious that a moderately scientific body of men, such as surgeons and anaesthetists would claim to be, seem unable to reason calmly and dispassionately on the subject of spinal analgesia." It may be that the development of sacral and lumbar epidural block will give us the advantages of spinal analgesia without its risks, but the chances with this method of an overwhelming spinal analgesia will always have to be weighed against the small risks of a deliberate low subarachnoid block.

The introduction of lignocaine ("xylocaine") has been a big advance in local analgesia and for the pudendal block sufficient for low-forceps deliveries. For the more difficult cases, however, in view of the evidence about the results of other forms of conduction analgesia I feel that it is the use of general anaesthesia which now has to be justified, especially with the present tendency to displace the supreme safety of open ether with other methods.—I am, etc.,

Middlesbrough.

Appendix in Hernial Sac

SIR,—Mr. Henry B. Young, reporting a case in which the appendix was strangulated in a femoral hernia (*Journal*, November 28, p. 1216), states that appendectomy was difficult as the caecum "could just be drawn into the [femoral] canal and no more." The implication is that he tackles his strangulated femoral hernias by the "low" approach.

Surely there can be little justification to-day for such an approach, when an extra 10 minutes on the duration of the operation is unlikely to be harmful. In particular the operative procedure described by McEvedy¹ has much to recommend itself. By McEvedy's approach the femoral canal is under direct vision, the hernial sac can be amputated as high as possible, and the strangulated contents of the sac can be handled with ease and safety.—I am, etc.,

Liverpool, 15.

Greater London Fund for the Blind

SIR,—On December 4 a pianoforte recital was given at the Festival Hall by Mr. Walter Gieseke on behalf of the Greater London Fund for the Blind, and a special appeal was made to colleagues in London. The hall was sold out, resulting in a sum of over £1,500, of which contributions from our profession amounted to over £500.

I hope you will kindly allow space to thank all those who responded so very generously to my appeal and who helped to achieve this magnificent result.—I am, etc.,

London, W.1.

B. W. RYCROFT.

Obituary

R. V. PAYNE, M.Chir., F.R.C.S.

With the death of Mr. R. V. Payne on December 10 at the early age of 45 the Windsor area has lost a brilliant and distinguished surgeon when at the height of his career.

Richard Vaughan Payne was born on July 16, 1908, and was educated at St. John's College, Cambridge, and at Guy's Hospital, qualifying in 1932. He graduated M.B., B.Chir. in 1934, took the F.R.C.S. in 1935, and proceeded to the M.Chir. in 1936. From Guy's, where he had held a number of house posts and the appointment of demonstrator in anatomy and physiology in the medical school, he went to Windsor in 1936, when he was elected to the staff of King Edward VII Hospital as assistant surgeon. Three years later he became full surgeon. He was happy to give all his time to the area in which he had settled, and within the first few years of his arrival in the district was elected as surgeon to the smaller hospitals at Maidenhead, Staines, Iver, Egham, and Windlesham. He served with the Royal Air Force in 1946-7, and during the course of his duties went to India and became adviser in surgery at Air Headquarters in that country, attaining the rank of wing-commander. With the introduction of the National Health Service he was elected as surgeon to the Canadian Red Cross Memorial Hospital at Taplow when that hospital was taken over by the State. About a year ago his right arm had to be amputated, but he continued to act in a consultant capacity to the hospitals with which he was associated. He leaves a widow and three children.

We are indebted to Mr. J. GAYMER JONES for the following appreciation: Vaughan Payne was a firm believer that a happy, personal relationship should exist between patient and consultant both in hospital life and in private practice, and did his best to embody the soul of the old voluntary system in the modern health service. He gave willingly of his time to the various committees connected with the Windsor group of hospitals, and was chairman of the King Edward VII Hospital medical committee. He was also president of the Windsor and District Medical Society during its jubilee year, 1949-50, and was elected a Fellow of the Association of Surgeons of Great Britain and Ireland. Vaughan Payne was a keen sportsman and was much admired for his skill with both the gun and rod. He was a lover of nature and, as might be expected, was fond of his garden. His courage during his last illness, and, indeed, also that of his wife, was remarkable. This young surgeon had to face many operations, including the removal of his right arm for a condition that he well knew would probably prove fatal, and he did this with a calm courage and happy demeanour that was nothing short of amazing. He was always willing to be interested, although in pain, in accounts of things that were going on in the area he loved, and it was never difficult for his friends to go in and talk to him, even about himself and of the things that were to happen. The sympathy of all will go out to his widow and three children.

S. D. MITCHELL, M.B., D.P.M.

Dr. S. D. Mitchell, consultant psychiatrist at Cane Hill Mental Hospital, Coulsdon, died suddenly in the grounds of the hospital on December 8.

A native of Birmingham, Sydney David Mitchell (formerly Isaacs) was born on July 10, 1902, and was educated at Clifton College and at Emmanuel College

Cambridge. He received his clinical training in the Birmingham Medical School and qualified in 1928, graduating M.B., B.Chir. in the following year. After holding a number of house appointments at Birmingham he worked for a time in general practice, but was soon attracted to psychiatry. After taking the D.P.M. in 1931 he became medical officer at Long Grove Hospital, Epsom. Later, after a period of training at the then London Child Guidance Clinic, he was appointed medical director of the Creighton House Clinic in Fulham. His interests at this time extended to psychosomatic medicine, and in 1936 he took part in research on the psychological aspects of rheumatism. During the last war he directed an E.M.S. neurosis clinic at Shotley Bridge General Hospital in County Durham. With this varied experience behind him, he accepted an appointment at Warringham Park Hospital. The comprehensive psychiatric services provided there gave him ample scope, and he took a very full part in the physical and social therapy for which the hospital is pre-eminent.

Mitchell's lifelong love of music led him to investigate its use in psychiatry, and he published a number of papers and became a recognized authority on the subject. His observations record the reactions shown by patients suffering from different forms of mental disorder to music of different periods and schools; these reactions he found of value in diagnosis, and also as a basis for discussion and elucidating interpersonal relations in group sessions. More directly he fostered the use of music as a source of delight and interest, sometimes using it as a means of resocializing patients to whom no other form of occupation or recreation made any appeal. This was seen especially in the patients' percussion bands, which he founded and conducted personally. When he was appointed consultant psychiatrist to Cane Hill in 1950 he brought his ideas and methods with him, so that the two hospitals soon became keen rivals in musical activity. Latterly he had extended his researches to the subject of combined music and art therapy.

Mitchell was a fine all-round psychiatrist with a mature and balanced judgment, therapeutic enterprise and sympathy, tolerance, and good humour—qualities which endeared him to patients and staff alike. His untimely and tragic death at the age of 51 deprives his hospital of a most loyal and trusted colleague and psychiatry has lost the further contributions which would certainly have come from him. He leaves a widow—Norah Gruhn, the operatic singer—and two children, to whom we offer our sympathy.—A. W.

Dr. PHILIP ELLMAN writes: I first met Sydney Mitchell over 30 years ago when he was a Cambridge undergraduate, and the qualities of loyalty, sincerity, and complete integrity for which so many friends, patients, and colleagues have since known him were already then apparent. There were three facets to his life and character—medicine, music, and his home—and the quality of his life was enriched, even created, by the integration of the three. As a young doctor, after several resident appointments in Birmingham, including the posts of house-physician to Professors P. C. P. Cloake and J. G. Emanuel, circumstances led him to general practice, where he was immensely beloved and respected, perhaps mainly because of his own insight into and sympathy with the psychological side of his work. More and more he was drawn to his beloved psychiatry, and with the outbreak of the war his real ambition was fulfilled when he became a psychiatrist with the Emergency Medical Service.

Initially music had been a hobby more than anything else, but with his marriage to Norah Gruhn, the well-known soprano, it became part of his complete life. Dr. Mitchell was a pioneer in the use of music as a form of therapy for mental patients, being a founder member of the Council for Music in Hospitals. Not only did he draw satisfaction from the good results achieved, but his active mind was constantly seeking new methods and new paths to explore. To conduct his hospital orchestra gave him intense satisfaction, and it is a happy thought that he was engaged in this less serious side to his work only a few hours before his death. Moreover, this aspect of psychiatry commingled most readily with his home life, and in it he was wholeheartedly encouraged and assisted by his devoted wife. Her wisdom and professional knowledge stood him in very good stead, and she herself was always ready to sing at concerts for mental patients. Music in medicine formed, indeed, a bridge between home and hospital.

All his friends will recall the fundamental peace and cheerfulness of the Mitchell home, and I recall the same warm hospitality of his parents' home before his marriage. At home his friends were able to penetrate the reserve that cloaked an intensely human, lovable, and understanding personality and to know him as a wise and sympathetic husband and father. There his wide interests and many-sided cultural pursuits were fully evident, and it is for these reasons above all that his untimely death leaves a void in so many hearts.

Dr. G. C. HARTLEY, who died at his home at Sutton Coldfield on November 6 at the age of 66, will be remembered as an unusually conscientious, kindly, and proficient general practitioner in the Erdington and Sutton Coldfield districts for some 27 years. In addition to conducting a general practice he was chairman of a National Service medical board in Birmingham, a part-time referee for the Ministry of Health, an examining medical officer to the Ministry of Pensions, and at one time medical officer at the Jaffray Hospital, Birmingham. Born at Montrose, Forfarshire, on January 11, 1887, the son of a Methodist minister, George Cleverdon Hartley had the advantages of a good education and the knowledge that for him success in life could come only as the result of hard work. After leaving Kingswood School, Bath, he was apprenticed to an engineering firm in Leeds, but a few years later he decided that medicine was to be his vocation and entered Birmingham University, where his fiancée, Miss Muriel Evans, was already a medical student. He graduated M.B., Ch.B. in 1916, and then, after holding the appointment of house-surgeon at Queen's Hospital, Birmingham, served in France during the first world war as a captain in the R.A.M.C. In 1917 he was awarded the Military Cross for "saving life under fire." Subsequently he saw service at Salonika and Constantinople for two years. On his return to civilian life he took the London Conjoint diplomas in 1920. Two of his three daughters also took up medicine as a career, both qualifying at Birmingham University, as their father and mother had done before them.—P. T.

Dr. A. S. WALKER died at Middlesbrough on November 29 at the age of 75 after a long illness. Arthur Samuel Walker was born at Middlesbrough on June 9, 1878, the younger son of Dr. Samuel Walker, and was educated at Uppingham and King's College, Cambridge, whence he went on to Edinburgh University to read medicine. He graduated M.B., Ch.B. in 1906, and proceeded to the M.D. in 1914. After holding the appointments of house-surgeon at Leith Hospital and at the Royal Maternity Hospital, Edinburgh, he became interested in preventive medicine, and took the D.P.H. in 1910, when he was appointed medical officer to the Leith education authority. On the outbreak of war in 1914 he was mobilized as a Territorial officer in the R.A.M.C., and served at home and in Italy until the end of the war, when he returned to Leith. Just over 30 years

ago he joined his brother in the family practice at Middlesbrough, and he also became police surgeon and medical officer to the Post Office. His keen interest in his fellow men led him to take an active part in freemasonry and in the Rotary movement. He was a man of great personal charm, and his warm-hearted humanity endeared him to a wide circle of friends. As a doctor he was interested in his patients as persons rather than as cases, and by them he will be sadly missed. Dr. Walker was unmarried and is survived by his brother, Mr. Harold Walker, F.R.C.S., and three sisters.—J. I.

Dr. W. J. ASHBY, who was for many years a well-known general practitioner in the Aylesbury district of Buckinghamshire, died at the Mercy Home, Cork, on December 1 at the age of 68. Born at Sandhurst on November 6, 1885, William Joseph Ashby was brought up in Ireland and was educated at Queen's (now University) College, Cork. He won distinction as a mathematician, and was selected for training as a teacher, but he chose medicine instead and graduated M.B., B.Ch., with honours, from the National University of Ireland in 1910, proceeding to the M.D. three years later. He was a sprinter of note and a good Rugby player, playing forward for Munster and for Ireland, and he was a member of the British Isles team which toured South Africa. After graduation he held house appointments at the Derbyshire Royal Infirmary and the Norfolk and Norwich Hospital before entering general practice at Aylesbury. During the first world war he served in the R.A.M.C. in France, during the battles on the Somme, and in Egypt and Palestine. Returning to his general practice in Aylesbury, he was appointed surgeon-in-ordinary to the Royal Buckinghamshire Hospital, and was also elected to the county council. His simple humanity, kindness, and good-natured humour and wit made him friends in every stratum of Buckinghamshire society, and these qualities, added to undoubted skill and knowledge, resulted in a thriving practice. Patients and friends alike found him a tower of strength at times when they most needed help, and he did not spare himself during sickness or sorrow. His later years were spent in Cardiff, where he continued to practise until his retirement early this year. Warning oedema had given him an inkling that the days to come were limited, and he returned to Ireland, salmon-fishing contentedly at Donnemare. It was characteristic of his spirit that after sustaining a Pott's fracture early this season he was back at the river with rod and sodden plaster within four days. His final illness was a short one, and he had a joke for everyone until the day before he died.

The premature death of Mr. J. W. F. RICHARDSON on December 14 at the age of 37 came as a severe blow to his many friends. James Walker Freer Richardson was born at Simla on September 12, 1916, the younger son of the late Dr. James Freer Richardson, and received his medical training at St. Thomas's Hospital. He qualified M.R.C.S., L.R.C.P. in 1941, and then held appointments at St. Thomas's and other hospitals before entering the R.A.M.C. in 1942 for service in the last war. On his return to civilian life he obtained the F.R.C.S. and then went into general practice. A colleague writes: Jim Richardson's death comes as a shock, particularly to all St. Thomas's men who were students at the beginning of the last war. He was one of the fittest men among us, and he played rugby with considerable zest. He served with distinction as a medical officer attached to the Royal Marine Commandos in the Far East theatre of war, being mentioned in dispatches, and on his return home he obtained the diploma of F.R.C.S. After his tenure as senior resident medical officer at Queen Charlotte's Hospital, Hammersmith, he went into general practice for a while, and just as he was settling into his future work he was called to higher service. He enjoyed life to the full, and he was a wholly delightful companion. He made friends wherever he went, and he will be sadly missed.

Medical Notes in Parliament

CARE OF THE AGED SICK

Mr. DAVID LLEWELLYN initiated a debate on December 14 on the provision for care and treatment of the aged sick. On the question where the fault lay, he said that any suggestion that the upper strata of the administration were less acutely aware of the problem than they should be was quite wrong. It was argued that now the poor law infirmaries were merged into the general hospital system comparisons with pre-Health Service days were no longer valid. But against this there was an impressive volume of demand from general practitioners for an extension of statutory powers. His questions to the Minister were: Was he content that the statutory powers are wide enough? What substance was there in the charge that general practitioners are exaggerating the gravity of cases, understating the ages of patients, and even resorting to dialling 999 to get an elderly patient into hospital? And was the Minister satisfied that his memorandum of November 2, 1951 (to the effect that those simply in need of care and attention should not be refused admission to hospital while other accommodation was sought), was being fully observed?

Mr. IAIN MACLEOD gave first the statistical background to a problem which he described as perhaps the most baffling in the whole Health Service. He agreed with Lord Amulree, and other members of the executive of the Medical Society for the Care of the Elderly, that the appointment of relieving officers was not the solution. If such an officer was under the local authority, would it be possible for him to direct that a hospital board should make a bed available? If he was a layman, it was difficult to see how he could decide between medical priorities; and, if not, it was not easy to see how that could be an improvement on the present position. They might delude themselves by too easy a comparison with the position before 1948, when local authorities had institutions. In many areas now there was simply no bed to which such a person could be allocated, and there was an immense problem of priorities in deciding between a person of the aged and chronic sick class and a younger person needing urgent treatment. The suggestion had been made that prefabricated institutions should be built, where simple care would be provided. Those who suggested that recognized the danger of a lower standard of medical care. Short-term solutions might remain longer than was intended, and it would be the final irony of the Welfare State if all they could find to solve this immensely difficult problem was to bring back the relieving officer and rebuild, in whatever form, the workhouses. That was not the road.

He thought the solution lay rather in the home than in the hospital. Progress must be seen as a whole—the additional hospital beds, the increased rate of turnover (to which he attached the greatest importance), the extension of out-patient services, increased provision of residential homes, development of welfare and voluntary services, the development of the geriatric service. While they should by all means ask whether the State had failed, they should also ask whether the family, the neighbours, the local authorities, the voluntary bodies, and the churches were doing all they could. It was a problem for all.

Fall in Prescription Costs

Mr. GILBERT LONGDEN asked the Minister of Health on December 17 whether he could give any information about the results of the steps he had taken to encourage doctors to reduce the cost of their prescribing in order to release funds for improvements elsewhere in the National Health Service. Mr. IAIN MACLEOD: While the average cost of prescription has hitherto increased progressively every year

Universities and Colleges

UNIVERSITY OF BIRMINGHAM

Dr. H. F. Humphreys has been appointed a governor of the University College of North Staffordshire for three years.

Enid Charles, Ph.D., Reader in Demography and Vital Statistics in the University, has accepted an invitation from the World Health Organization to advise the University of Malaya on the setting up of a department of demography and medical statistics, and has been granted leave of absence for one year from August 1, 1953.

Dr. W. T. Cooke, Reader and First Assistant in Medicine, has been granted leave of absence for the first quarter of 1954 to visit gastro-intestinal and metabolic clinics in the U.S.A.

The Rockefeller Foundation has made a grant of £28,800 to Professor J. J. Elkes for research in psychiatry and in the biochemistry and pharmacology of the nervous system. The grant will cover the five-year period beginning in July, 1953, and will be spent mainly on salaries, technical assistance, and supplies.

Professor A. B. MacGregor has been appointed Director of Dental Studies and Professor J. Osborne Deputy Director and Tutor.

Dr. David Mendel resigned the appointment of National Coal Board Fellow in the Department of Medicine on May 31, 1953.

The title of University Research Fellow has been conferred upon Dr. G. Holt, research worker in the Medical Research Council's unit for research on the experimental pathology of the skin, during the tenure of his present post.

Dr. K. Valteris, Research Fellow in Pathology, has been seconded to the service of the Regional Hospital Board for work in the Department of Pathology at Dudley Road Hospital.

UNIVERSITY OF LEEDS

At a meeting of the Council of the University on October 21 it was agreed to confer the title of Emeritus Professor on Professor R. D. Passey on his retirement from the Chair of Experimental Pathology.

Dr. Andrew Bogdan has been appointed Senior Registrar and Tutor in Paediatrics for one year in the first instance from November 1, 1953, and Dr. I. S. Bruce Lecturer in the Department of Anaesthetics from November 15, 1953.

ROYAL COLLEGE OF PHYSICIANS OF LONDON

At a quarterly comitia of the College held on October 29, with the President, Sir Russell Brain, in the chair, Dr. T. Jenner Hoskin, Dr. B. E. Schlesinger, Dr. A. M. Cooke, and Dr. J. C. Hoyle were elected Councillors of the College; Dr. J. Forest Smith was elected representative on the Committee of Management; Sir Russell Brain, Sir Harold Boldero, Dr. W. G. Barnard, Sir Allen Daley, and Dr. A. M. Cooke were re-elected members of the Standing Joint Committee of the three Royal Colleges; Dr. C. E. Newman was appointed representative on the Examination and Tuition Advisory Board of the Association of Medical Records Officers; and Professor A. A. Moncrieff was appointed representative at the Annual Conference on Maternity and Child Welfare for 1954.

The Registrar announced that Dr. J. A. Smiley had been appointed Milroy Lecturer for 1955, and that his subject would be "Personal Factors in Accident Proneness."

The following candidates, having satisfied the Censors' Board, were elected Members of the College: Y. K. W. Aboul-Dahab, M.B., Mary H. Aitken, M.B., Mary Bateman, M.D., D. B. Benazon, M.B., R. A. Bruce, B.M., W. Brumfit, M.B., J. P. Caley, M.B., Rosemary A. Cooper, M.B., R. F. A. Dean, L.R.C.P., A. E. Dormer, M.B., C. P. V. Evans, M.B., J. H. Evans, M.B., H. Foster, M.B., Major, R.A.M.C., L. Friedlander, M.B., J. F. Hale, B.M., D. R. Hay, M.B., F. E. Higgins, M.B., A. W. Johnston, M.B., E. N. M. Johnston, M.B., Lilian F. Jones, M.B., H. P. Lambert, M.B., G. Larkins, M.B., J. C. Leonard, M.D., A. Z. Abd-El Massieh, M.B., B. F. Robinson, M.B., A. Sachs, M.D., Brigadier, R.A.M.C., A. W. Steinbeck, M.B., L. V. Sthyr, M.D., J. D. Stride, L.R.C.P., Surgeon Lieutenant-Commander, R.N., J. H. Tyrer, M.D., B. W. Webb, M.D.

Licences to practise were conferred upon the following 106 candidates (including 20 women) who had passed the final examination in Medicine, Surgery, and Midwifery of the Conjoint Board and who have complied with the by-laws of the College: J. Anderson, M. E. Anfilogoff, Christine M. Armstrong, B. S. Beardsworth, P. J. Bell, J. A. Bevan, C. Bishop, R. J. Blow, C. W. W. Brown, L. F. Brunt, J. D. Campling, Patricia M. Carpenter, J. A. A. S. Chamberlain-Webber, H. J. Clarke, A. Clark-Jones, W. E. Clifford-Jones, J. T. Coals, R. J. C. Cobbold,

since the National Health Service started, I am glad to say that in August the estimated cost fell to about 1½d. less than in August 1952. This was maintained in September and there was a further reduction to 2d. in October. I am glad to have this opportunity to thank the joint committee on prescribing for their valuable work in classifying preparations, and the General Medical Services Committee of the British Medical Association and the whole body of general practitioners for their co-operation in producing this encouraging result.

Mr. LONGDEN asked whether this satisfactory result followed on the advice given to general practitioners about prescribing drugs of doubtful therapeutic value. Mr. MACLEOD said it seemed almost certain that the two were linked, because the letter was sent out by the Chief Medical Officer on July 18 and the first noticeable drop was in the month following. Asked by Dr. EDITH SUMMERSKILL whether he would consider giving instructions to doctors not to prescribe certain drugs if there was an equivalent in the National Formulary, Mr. MACLEOD thought this would be too big an interference with the ordinary discretion of doctors.

Mr. RICHARD ADAMS asked how far limitations were placed on prescriptions under the National Health Service in cases of tuberculosis, and in particular on the prescription of cod-liver oil and malt. Miss PAT HORNSBY-SMITH, Parliamentary Secretary, said that a general practitioner might prescribe any generally available drug or medicine which he considered necessary for the treatment of tuberculosis. Cod-liver oil and malt might be prescribed when it could properly be regarded as a drug for the treatment of a patient.

Health in West Africa

Mr. RONALD RUSSELL asked the Secretary of State for the Colonies on December 16 what improvement had been made in the health of the people of the West African Colonies, Protectorates, and Trusteeship Territories in recent years.

Mr. OLIVER LYTTLETON informed him that there had been a general improvement in the health of the peoples of these territories. For example, the use of new drugs in certain areas had drastically reduced the incidence of leprosy. In Nigeria mobile teams had been set up to deal speedily with outbreaks of epidemic diseases, and a large pilot scheme was in being to combat yaws. Trypanosomiasis had ceased to be a public health problem in the Gold Coast. In the Northern region of Nigeria a considerable area had also been cleared of the tsetse fly.

Artificial Limb Repairs

Mr. IAIN MACLEOD, answering questions by Mr. JAMES SIMMONS on December 17, stated that the average time taken for repairs to artificial arms during January-July, 1953, was 50 days, and during August-November, 1953, 70 days. Similarly, the average time for repairs to artificial legs had been 30 days and 35 days. Mr. SIMMONS said it was apparent that since the Ministry of Pensions had ceased to have responsibility for these repairs there had been a longer time lag, and asked the Minister to see that Roehampton was not penalized by the change in administration. Mr. MACLEOD said that he would certainly do his best, but it was quite unworthy to suggest that a firm which was providing artificial limbs for ex-Service men was going to alter its skill and time of delivery purely because there had been a departmental change. Mr. SIMMONS said that he made no imputation against the firm, but against the change in administration.

Major LEGGE-BOURKE asked if the Minister could give an absolute assurance that the fact that the two Ministries had merged had no relevance whatever to the increased time involved in repairs.

Mr. MACLEOD: None at all.

C. W. M. Cooper, Violet G. Cousins, Shirley A. Crockatt, J. Crook, I. D. Davies, W. C. Davies, Jose A. Day, J. D. Devitt, Eva M. Dilling, M. S. G. Douglas, D. R. Elam, J. I. Evans, P. Field, C. V. Foll, Gillian France, P. J. Frost, T. Gibson, L. Goldie, Rosemary A. Grange, A. N. Green, J. M. Green, F. V. Griffiths, S. T. Gunewardene, Dorothy J. Harden, Margaret M. Heley, E. J. Hill, H. Holden, W. J. Jackson, Elsie Jaques, I. R. Jenkins, J. J. Jones, Elizabeth M. H. Kennett, P. Konfortion, G. E. T. Lawley, I. V. Lishman, D. Longbourne, K. Loucas, T. M. McAneny, J. G. Macdonald, M. A. McDonald, G. F. Mackenzie, T. D. M. McNeill, Patricia S. Matthew, Bridget d'E. Matthews, C. Mawdsley, Jean E. Moffat, Margaret L. M. Monro, R. J. Morgan, F. J. Morley, C. E. Nelson, M. R. Oates, R. C. Oliva, Patricia M. O'Sullivan, R. B. Pardoe, D. J. Parry, D. M. Paul, J. D. W. Peck, J. W. Prout, J. E. G. Rault, A. D. Richardson, J. A. V. Riley, A. A. Roe, W. A. St. John, S. C. C. Scott, D. E. Sharland, Jean M. Shields, A. J. Slim, Marguerite L. Sloper, P. C. Smart, C. J. Stephens, R. L. G. Sutcliffe, G. W. Sykes, M. Tack, A. Talalla, R. W. H. Tavenner, E. M. Thomas, C. P. D. Tong, E. A. M. Tuck, H. M. Turner, J. C. S. Turner, F. B. Valentine-Hagart, H. W. C. Ward, Isabel M. P. Ward, W. H. Waters, J. H. H. Webster, P. H. Wiesendanger, Lee Yoke Hyam, G. W. G. Yule.

Diplomas were granted, jointly with the Royal College of Surgeons of England, as follows:

DIPLOMA IN CHILD HEALTH.—Elizabeth A. Martin, K. R. Mombert, and to the other successful candidates whose names are printed below in the report of the meeting of the Royal College of Surgeons of England.

DIPLOMA IN MEDICAL RADIO-DIAGNOSIS.—K. M. C. de Silva, H. K. T. Fernando, P. G. Keates, L. Langton, Kee Loo Lim, E. A. H. MacLaughlin, O. D. Macnamara, W. B. D. Maile, A. C. Mitra, B. O'Hare, A. W. Robinson, A. Roy, H. Tayebbhoy, J. A. Watson.

DIPLOMA IN MEDICAL RADIOTHERAPY.—D. M. T. Cones, G. McK. Crawford, D. A. L. Dick, Marjorie O. Dunster, G. B. Goodman, B. T. Hale, F. E. Neal, J. D. Reeves, M. Samiullah, J. G. Stewart, Elsie N. K. Wallace.

DIPLOMA IN OPHTHALMOLOGY.—J. M. Ferries, R. Smith. Diplomas were also granted, jointly with the Royal College of Surgeons of England, in Tropical Medicine and Hygiene, in Anaesthetics, in Industrial Health, and in Laryngology and Otolaryngology, to the successful candidates whose names are printed below in the report of the meeting of the Royal College of Surgeons of England.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

At a meeting of the Council of the College held on October 8, with Sir Cecil Wakeley, President, in the chair, Sir James Learmonth was appointed the Sir Arthur Sims Commonwealth Traveling Professor for 1954, and it was reported that Sir Cecil Wakeley had been appointed the Hunterian Orator for 1955.

The Sir Gilbert Blane Naval Medal was presented to Surgeon Captain J. G. Holmes.

Dr. E. Rohan Williams (St. Mary's) was admitted as the co-opted Member of Council representing radiology.

The ophthalmological research unit, which has been in existence for ten years under Professor Arnold Sorsby, was admitted to the status of a department of the College.

Dr. R. Wyburn-Mason was awarded a Proffit Research Studentship; the Handcock Prize was presented to Mr. J. J. Jones (King's College Hospital); and Mr. G. Hass (London Hospital Medical College) was admitted as a Macloghlin Scholar.

The Council approved the institution of a Mitchiner Medal, in memory of the late Major-General P. H. Mitchiner, to be awarded annually for outstanding services to military medicine by an officer of the Army Medical Services or the R.A.M.C. A similar medal, presented by Sir Stanford Cade for award to a medical officer of the Royal Air Force, was instituted in memory of the late Lady Cade.

The Council agreed, on the recommendation of the trustees of the Hunterian Collection, to publish *The Life of William Clift*, by Miss J. Dobson, Recorder of the College.

The Council received a number of interesting gifts, including a portrait of Sir Henry Newland presented by the Royal Australasian College of Surgeons; a portrait of the late Sir Robert Jones and various relics of Hugh Owen Thomas presented by Mrs. Hilda Watson; and part of the manuscript of Wilfred Trotter's *Instincts of the Herd in Peace and War* presented by Mr. H. Morrison Davies.

Diplomas of Membership of the College were granted to F. J. Morley (St. Thomas's) and S. C. C. Scott (Guy's).

Diplomas were granted, jointly with the Royal College of Physicians of London, to the following successful candidates:

DIPLOMA IN TROPICAL MEDICINE AND HYGIENE.—A. Ahmad,

Fatima S. Ahmed, J. A. S. Amos, R. P. Bradshaw, T. M. W. D'Arcy, M. W. Dhurandhar, J. M. Dube, J. R. Eley, J. I. T. Glover, G. H. V. Keshani, H. D. Madsen, T. C. H. Mathews, R. Mortimer, G. A. Real, S. Rehman, A. D. Ross, J. G. Slater, S. G. Talpade, Margrit Zuber, S. Rao, Majuree Sundaravej.

DIPLOMA IN CHILD HEALTH.—C. A. L. Abrams, A. Ahmad, R. N. Akeel, A. Allibone, Kooki N. Bharucha, H. C. H. Bird, Irene F. A. Blakeney, M. Braudo, N. Broughton, Dorothy F. M. Burnett, Joan M. Cashman, Margaret J. Cox, Marian E. Cox, Diana F. J. Duncan, C. N. Faith, Eva O. Faulkner, Carol A. Foxell, Margaret J. Francis, Jessie S. Freeman, A. K. Ghosh, J. C. Gillespie, Bandana Gupta, D. T. G. Harris, W. B. McN. Howie, Jasmine R. Jacob, B. Jaffe, F. E. James, K. V. Jones, Winifred A. Kane, A. J. Keay, P. J. E. Lewis, Joo Lee Lim, Daphne H. Line, A. D. Macdonald, K. W. Matheson, Joan M. Mawer, Margaret B. Mearns, J. L. Miller, B. J. L. Moss, J. W. Muller, C. W. A. Murray, Gwendoline D. Newman, M. N. Orton, V. Pillai, Dafne E. MacG. Plowman, Theresa Posner, O. C. Raffel, Myrtle J. Raynor, Ellen L. M. Rhodes, Nancy M. B. Robertshaw, Hilary G. Rubin, D. Satya Nand, M. K. Sawday, D. H. Shennan, Priyani E. Soyva, Sara I. Stinson, T. E. Stockley, Elsie G. Taylor, Katharine J. Thicknesse, A. J. Thomas, Elizabeth S. Tomlinson, Pamela S. Triplett, Joan E. Walton, Sheila M. Watts, J. Wessels, Enid M. Whitfield, T. K. Williams, Irene H. Winick.

DIPLOMA IN ANAESTHETICS.—J. C. Richardson.

DIPLOMA IN INDUSTRIAL HEALTH.—K. B. Roy.

DIPLOMA IN LARYNGOLOGY AND OTOLARYNGOLOGY.—J. B. Blacklay.

DIPLOMA IN OPHTHALMOLOGY.—R. Smith.

ROYAL COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS

At a meeting of the Council held on September 26, with the President, Mr. Arthur A. Gemmell, in the chair, the following awards were made: *Leverhulme Research Scholarships for 1954*, I. Donald, J. Gardiner, M. L. Paterson. *William Blair-Bell Memorial Lectureships for 1954*, T. E. C. Barns, I. Donald.

Vital Statistics

Infectious Diseases

Only quite small variations occurred in the number of notifications of infectious diseases for the week ending December 5 in England and Wales; the largest were increases of 65 for scarlet fever, from 1,484 to 1,549, 57 for acute pneumonia, from 557 to 614, and 46 for dysentery, from 399 to 445.

The largest increases in the incidence of scarlet fever were 38 in Essex, from 81 to 119, and 30 in Yorkshire West Riding, from 175 to 205. 2,595 cases of whooping-cough were notified, being 13 fewer than in the preceding week. The usual fluctuations in the local trends were recorded, the largest being decreases of 54 in Yorkshire West Riding, from 239 to 185, 53 in Essex, from 186 to 133, and 40 in Durham, from 97 to 57, and increases of 41 in Warwickshire, from 138 to 179, and 40 in Lancashire, from 227 to 267. The number of notifications of measles increased from 875 to 886. The largest variation in the returns was a decrease of 40 in Lancashire, from 168 to 128. 13 cases of diphtheria were notified, being 3 fewer than in the previous week. These cases were reported from 5 administrative areas—Warwickshire, Birmingham C.B. 5; Staffordshire, Coseley U.D. 3, Sedgley U.D. 2; Lancashire, Liverpool C.B. 2; Devonshire, Plymouth C.B. 1.

The notifications of acute poliomyelitis numbered 65 and were 1 fewer for paralytic and 11 fewer for non-paralytic cases than in the preceding week. The largest returns were Lancashire 8, Devonshire 6 (Totnes R.D. 3), Staffordshire 6 (Cannock U.D. 3), Gloucestershire 5 (Bristol C.B. 5), London 4, Yorkshire West Riding 4.

The largest centres of dysentery were Yorkshire West Riding 74 (Shipley U.D. 23, Bradford C.B. 21, Leeds C.B. 13), London 57 (Hackney 12), Lancashire 56 (Bolton C.B. 32), Leicestershire 45 (Leicester C.B. 37), Norfolk 34 (Norwich C.B. 32), Middlesex 25, Essex 23 (Barking M.B. 10).

Graphs of Infectious Diseases

The graphs below show the uncorrected numbers of cases of certain diseases notified weekly in England and Wales. Highest and lowest figures reported in each week during the nine years 1944-52 are shown thus -----, the figures for 1953 thus ———. Except for the curves showing notifications in 1953, the graphs were prepared at the Department of Medical Statistics and Epidemiology, London School of Hygiene and Tropical Medicine.

INFECTIOUS DISEASES AND VITAL STATISTICS

Summary for British Isles for week ending December 5 (No. 48) and corresponding week 1952.

Figures of cases are for the countries shown and London administrative county. Figures of deaths and births are for the 160 great towns in England and Wales (London included), London administrative county, the 17 principal towns in Scotland, the 10 principal towns in Northern Ireland, and the 14 principal towns in Eire.

A blank space denotes disease not notifiable or no return available. The table is based on information supplied by the Registrars-General of England and Wales, Scotland, N. Ireland, and Eire, the Ministry of Health and Local Government of N. Ireland, and the Department of Health of Eire.

CASES in Countries and London	1953					1952				
	Eng. & Wales	Land	Scot.	N. Ire.	Eire	Eng. & Wales	Land	Scot.	N. Ire.	Eire

* Measles not notifiable in Scotland, whence returns are approximate.

† Includes primary and influenza pneumonia.

§ Includes puerperal pyrexia.

Medical News

Westminster Abbey.—The national banks have agreed to assist in the transfer of the odd shillings and pence remaining in their clients' accounts at midnight, December 31—the last day of Coronation Year—to the Westminster Abbey Appeal Fund. The Abbey is appealing for a million pounds for desperately needed repairs and restoration. So far just over £700,000 has been collected. All that a donor needs to do is to sign a form, available at his bank, authorizing the transfer. Although the most that an individual can give in this way is 19s. 11d., the last time such a collection was made on a national scale—for the King George V Memorial Fund—£100,000 was obtained. Christmas is a time for giving, and it is certain that doctors will not be backward in responding to this appeal.

Professor R. Bastianelli, 90.—It gives us great pleasure to congratulate Professor Raffaele Bastianelli on reaching his 90th birthday. The doyen of Italian surgeons, he is an honorary fellow of the Royal College of Surgeons of London and a foreign corresponding member of the British Medical Association. He was born on December 26, 1863,

and from the day he entered the medical faculty of Rome University he has remained at work in that city right up to the present time. For 25 years he was professor of clinical surgery in Rome, and to-day he is still active and still operates. He has been a general surgeon all his professional life, though his special interests have been in brain and abdominal surgery. During the first world war he directed a front-line surgical unit treating wounds of the head, abdomen, and chest. One of the earliest qualified pilots in Italy, he flew his own aeroplane for many years, only giving up about 10 years ago when his plane was destroyed during the war. Leading the life of a surgeon, a farmer (quite recently he conducted an extensive investigation into the literature of chestnut tree disease), and an art connoisseur, Professor Bastianelli still exerts a powerful influence in his own country. His many friends in other countries will be glad to hear that old age has proved such a minor hindrance to one who was always noted for his intellect, open-mindedness, courage, and humanity.

Medical Research in the Colonies.—One section of the Colonial Office publication *Colonial Research, 1952-3* (Cmd. 8971, 7s. 6d. net), is devoted to the work of the Colonial Medical Research Committee, the body which advises the Colonial Secretary and the Medical Research Council on all matters of medical research in and for the Colonies. Since 1940 £12m. has been allotted (£6½m. spent) to Colonial development and research schemes of one sort or another. Medical research has had 14% of the total allotted, but in addition a further 28% has been provided for research on trypanosomiasis and insecticides and rather more for agricultural schemes, all of which play an important though indirect part in promoting the health and well-being of the Colonial peoples. Malaria, filariasis, loiasis, guinea-worm infestation, yellow fever, and leprosy are some of the principal diseases being studied, often in several colonies simultaneously. There is also work proceeding on hot climate physiology and metabolic problems. The latter type of investigation is often carried out by visiting workers from Britain, a development which the committee is keen to foster. New research grants during the year reviewed have included £106,000 for the Medical Research Council's field research station at Fajara, in the Gambia, £90,000 for

insecticide research in East Africa, and £77,000 for the Colonial Microbiological Institute at Trinidad.

A Novel Out-patient Department.—The Earl of Onslow, deputizing for the Minister of Health, opened the new out-patient department at St. James's Hospital, Baltham, on December 11. The building is constructed of brick piers supporting specially toughened glass, the floors being tiled with cork. The unusual feature is that the plastic partitions between the various clinics are all movable so that the number, size, and shape of the clinics can be altered at will. To facilitate this each internal pier contains within it steam, water, and gas services, to allow equipment to be sited almost anywhere required. A similar provision has been made for electricity supplies, telephones, and clocks. There are three floors, with a waiting space on each, and as well there is a large hotel-like lounge for the convenience of friends accompanying patients and those who arrive too early for their appointments. Outside is a lawn on which stands the statue by Wayne Hobson which has aroused so much local controversy. The department has cost £178,000 and is designed to deal with 200,000 patients a year.

Local Medical Societies.—Recent meetings have included the following: *Ulster Paediatric Society.*—On October 30 Mr. James Robertson showed the society his film "A Two-year-old Goes to Hospital." *Manchester Medical Society.*—In an address to the Section of Medicine on November 4 on "Inquiries into the Cerebral Basis of Temperament and Personality" Dr. Denis Williams described current work on the functions of the "silent areas" of the brain. This had been made possible by advances in neurosurgical and electronic techniques. Clinical disease and electrical stimulation of the silent areas produced complex disorders of thought, feeling, behaviour, and memory, so that now it was becoming possible to establish a physiological basis for some processes previously explicable by psychology alone. *Liverpool Medical Institution.*—On November 26 there was a discussion on emergencies in newborn infants. Dr. F. P. Hudson, who opened the discussion, stressed that infections in the newborn besides spreading rapidly were often caused by organisms not responsive to penicillin. He advocated as a routine a combination of penicillin and streptomycin, with chloramphenicol later if these failed. He also described the emergency treatment of haemorrhage, jaundice, and respiratory obstruction in the newborn. Mr. P. P. Rickham followed with an address mainly concerned with congenital malformations and their diagnosis. *West Midlands Physicians Association.*—At a meeting in Birmingham on November 28 Professor A. P. Thomson was elected president in succession to Dr. J. H. Sheldon.

Langley Memorial Prize.—This prize, valued at about £17, is open to competition among officers of the Colonial Medical Service who are serving, or who have served, in West Africa. The prize will be awarded for the best paper on one of the following subjects, special consideration being given to original work: tropical medicine or surgery; tropical hygiene and sanitation; or tropical entomology and parasitology. Papers, which may consist of either published or unpublished work, should be sent to the Dean, London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1, not later than October 1, 1954.

Research in Eire.—The Medical Research Council of Ireland has recently issued its annual report for 1952. It received £19,600 during the year from the Hospitals Trust Fund, by arrangement with the Minister for Health, and grants amounting to £1,500 from Messrs. Arthur Guinness, Son and Co., Ltd. The Council's most important activity is research on the chemotherapy of tuberculosis. A new project which is receiving support is a survey of the incidence of congenital abnormalities in children born in Dublin.

British Association of Plastic Surgeons.—The annual general meeting of the association took place at the Royal College of Surgeons, Lincoln's Inn Fields, on December 11, when the following officers were elected for 1954: *president*, Mr. D. N. Matthews (London); *hon. treasurer*, Mr. R. P.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Spread of Crab Lice

Q.—Is it possible for crab lice to be acquired other than by sexual intercourse? If so, what are the commonest ways in which this may happen?

A.—The crab louse is a sedentary ectoparasite and does not survive easily away from the human body. Since it commonly infests the pubic region, there is little doubt that sexual intercourse provides its simplest means of spreading from one person to another; indeed, it is sometimes known in France as *papillon d'amour*. On the other hand, it is clear that there are other means of transmission. Thus, infants may become infested from their mothers, usually on the scalp, which is their only hairy region. In older children and adults infestation of the scalp is rare, but the eyebrows or eyelashes may be invaded in the absence of pubic infestation. There is a tendency for *Phthirus* to spread through small groups of men living very closely together—for example, among crews of small merchant ships or soldiers in camp.

While these facts prove that there are modes of dissemination other than sexual contact, there is very little evidence as to which are the most frequent. There are stories of crab lice being found on the seats of public water closets and in beds; and it is very likely that they or their eggs may be spread on loose hairs dropped by infested persons, particularly if towels or blankets are shared. The larval and mature lice die within a day or so of removal from the body. On analogy with *Pediculus*, the eggs would probably survive about a week, but would not hatch unless warmed to body temperature.

A Developing Moustache in a Young Girl

Q.—A girl aged 9 years began to develop a moustache a year ago, and it is increasing slowly. She appears healthy otherwise, and there is no hirsuties elsewhere. What is the likely cause, and should she be investigated further?

A.—The development of a moustache indicates an androgenic stimulus above normal, and the adrenal itself is most likely to be the source of the stimulus. In this connexion it should be remembered that the adrenarche, as distinct from the menarche, normally occurs over a number of years and may precede the menarche by some years. In fact the adrenarche bears the same relationship to the menarche as the climacteric to the menopause. The biological basis of the adrenarche is the augmentation (via the pituitary) of adrenal cortex function involving both androgens and glucocorticoids, either predominating according to the genetic endocrine constitution of the individual.

As in all endocrine processes, the physiological may become the pathological and the borderline be indistinct. In the case described we are probably dealing with a hyperplasia rather than a neoplasia of the adrenals, but the latter should be borne in mind as a possibility; there is also the possibility of an ovarian neoplasm, but I would regard this as unlikely.

Investigations should consist in urinary assays of the 17-ketosteroids and the 11-oxysteroids and, depending upon these results and the clinical evaluation of the condition, such further investigations as intravenous pyelogram, carbohydrate tolerance, blood count, etc. The family history may indicate a similar genetic tendency in other members, and also the probability of the type of evolution.

Osborne (Liverpool); *hon. secretary*, Mr. J. P. Reidy (London); and *Council*, Mr. W. Hynes (Sheffield), Mr. Rainsford Mowlem (London), Mr. P. H. Jayes (East Grinstead), Mr. Mortimer Shaw (Leeds), Mr. J. N. Barron (Salisbury), Mr. J. S. Tough (Glasgow), Professor T. P. Kilner (Oxford), Mr. A. B. Wallace (Edinburgh) (*Editor*), and Mr. B. K. Rank (Melbourne).

Scientific Exhibition, Glasgow, 1954.—Those wishing to exhibit are reminded that the last day for receiving entries is December 31. Details and application forms are obtainable from the Secretary, British Medical Association, B.M.A. House, Tavistock Square, London, W.C.1.

Honorary Degrees at Leeds.—In congregation on May 14, 1954, the honorary degree of LL.D. will be conferred on Professor Evarts A. Graham, professor of surgery in Washington University, St. Louis; Professor F. W. Rankin, President of the American College of Surgeons; and Sir Cecil Wakeley, President of the Royal College of Surgeons of England. The ceremony will take place during the period of the meeting at Leeds of the Associations of British and American Surgeons.

Dr. Pierre Lépine, director of the department of virology at the Institut Pasteur, Paris, and internationally renowned for his research on viruses, has been elected to the French Academy of Medicine.

Professor T. J. Mackie, Irvine Professor of Bacteriology, has been elected dean of the faculty of medicine at Edinburgh in succession to Sir Sydney Smith.

COMING EVENTS

Institute of Dermatology.—The fourth in the series of semi-permanent exhibitions will be available from January 1 to 23, 1954. It is given by Dr. H. Haber on "Cytological Diagnosis."

International Organization Against Trachoma.—The next meeting will be held at Montreal on September 11, 1954. Further information may be obtained from the secretary-general, 45, Lincoln's Inn Fields, London, W.C.2.

SOCIETIES AND LECTURES

A fee is charged or a ticket is required for attending lectures marked ●. Applications should be made first to the institution concerned.

Tuesday, December 29
INSTITUTE OF DERMATOLOGY.—5.30 p.m., Dr. H. Haber: Cutaneous Syphilis.

Wednesday, December 30
INSTITUTE OF DERMATOLOGY.—5.30 p.m., Dr. H. Haber: Specific and Foreign Body Granulomas.
ROYAL EYE HOSPITAL.—5.30 p.m., Mr. L. H. Savin: Ophthalmic Operations and their Indications (1).

Thursday, December 31
INSTITUTE OF DERMATOLOGY.—5.30 p.m., Dr. R. W. Riddell: Subcutaneous Mycotic Infections.
ROYAL EYE HOSPITAL.—5.30 p.m., Miss M. Savory: Differential Diagnosis of Diplopia.

Friday, January 1
INSTITUTE OF DERMATOLOGY.—5.30 p.m., Dr. A. D. Porter: Disorders of the Skin Affecting the Hair Follicles.

Saturday, January 2
MIDLAND TUBERCULOSIS SOCIETY.—At Birmingham Chest Clinic, series of short communications.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Carstairs.—On December 9, 1953, at the Churchill Hospital, Oxford, to Jean, wife of Captain J. R. L. Carstairs, R.A.M.C., a daughter—Alison Frances Elizabeth.
McGrigor.—On November 27, 1953, to June (formerly Casswell), wife of Ronald Buchanan McGrigor, M.B.E., F.R.C.S., of 34, Prince Albert Road, London, N.W., a son—Alastair.
Warren.—On December 12, 1953, to Josephine Barnes, D.M., F.R.C.S., F.R.C.O.G., M.R.C.P., wife of Dr. Brian Warren, 46, Chester Square, London, S.W., a son.

DEATHS

Courtenay.—On December 9, 1953, at The Patch, Warcham, Dorset, Kilcourse Jocelyn Courtenay, L.R.C.P.&S.Ed., L.R.F.P.S., aged 89.
Davis.—On December 3, 1953, John Warren Davis, M.R.C.S., L.S.A., formerly of 75, Gloucester Place, London, W., aged 93.
Duncan.—On November 17, 1953, Norman Alistair Duncan, M.B., Ch.B., of The Gables, Long Melford, Suffolk.

Indirect Hernia in Children

Q.—Is it sufficient when dealing with a small indirect inguinal hernia in a child or young adult simply to excise the sac?

A.—For the great majority of such cases most surgeons regard simple excision of the sac as quite adequate. However, even in a child or young adult it is important to correct any stretching of the internal ring. Repair of the transversalis fascia is therefore important in any case in which there is a broad-necked sac with a large internal ring.

Professional Secrecy in Evidence

Q.—Is it still necessary to remind the judge of the absolute secrecy enjoined on a medical man when called as a witness in a case involving V.D. patients (*Garner v. Garner*, "Times Law Reports," 1919-20, 36, 196)? If so, has this formal protest to be lodged before being sworn in, and what wording would you recommend?

A.—Notwithstanding the rule of professional secrecy, a medical man has always had an overriding obligation to answer questions put to him in the witness box; the law in this respect has not changed. Nevertheless, if a medical witness is asked a question which, if answered, would in his opinion constitute a breach of professional confidence, it is desirable to remind a judge of the rule of professional secrecy observed by medical practitioners. This situation arises when the witness does not hold the consent of the patient to disclose information gained during his professional relationship with that patient. The right time to appeal to the judge is when a question is asked the answering of which would involve a breach of secrecy. The appeal might be in the following form: "My Lord, to answer this question would involve a breach of professional secrecy; am I compelled to answer it?" Most practitioners accept the judge's ruling and follow his directions. There are some practitioners, however, who are so firmly attached to the ethical rule that they would rather accept imprisonment for contempt of court than disclose the secrets of their patients in the absence of consent.

Catabolic Foods

Q.—I have read that certain foods such as some vegetables are catabolic because they require energy for their absorption. Is this view correct?

A.—This statement is probably true, although not necessarily in relation to absorption. A drink of cold water is catabolic in the sense that a corresponding amount must be lost either as urine, at body temperature, or as sweat, which during drying will cool the body by the absorption of latent heat. Some vegetables, such as melons, radishes, and lettuce, provide only about 50 calories per lb. (110 per kg.), and if all their water were evaporated from the skin nearly 300 calories would be absorbed, either from the body or from the surrounding atmosphere. In hot weather, therefore, these vegetables may cool the body rather than warm it. We must not forget, however, that tortoises can keep going for years on a diet of nothing but lettuce.

The Imperial Eunuchs

Q.—Can you tell me the Chinese method of making eunuchs? How were they selected, and at what age were they castrated? What was the reason for their great influence in the imperial courts?

A.—Castration in China goes back, so it is said, to about 1100 B.C., although it did not become what perhaps can be called an official practice till much later. Persons permitted themselves to be made eunuchs either from necessity (when they were compelled to submit under threat of force) or through poverty or even through choice. The age at which the operation was performed varied from childhood up to about 25 or later, and the methods employed do not seem to have varied much, according to the reports that have been made available to us. It is said that sometimes a form

of local analgesia was employed, but few details appear to be available. The method most usually adopted was to remove the whole of the external genitalia either with a sickle-shaped knife or by some other means. A plug was then inserted into the urethra and the wound covered in paper soaked in cold water. Healing was said to take place within about 100 days, and the mortality has been reported as being something like 4%, or even less. The influence exercised by the imperial eunuchs was doubtless due to their knowledge of court intimacies and intrigues, and to the fact that they often acted as intermediaries between the emperor and his concubines.

Will a Wig Stop Hair Growing?

Q.—Does the temporary use of a wig prejudice the regrowth of hair in a case of alopecia?

A.—The answer is no.

NOTES AND COMMENTS

Abortifacient Pastes.—Professor Andrew M. CLAYE (University of Leeds) writes: I am interested in the reply in "Any Questions?" (*Journal*, November 28, p. 1229) to the query on abortifacient pastes. The last sentence but one reads: "These pastes are neither as safe nor as efficient as is often stated, but it has to be remembered that the same can be said of nearly all methods for inducing abortion." From the use of the word "nearly" I infer that perhaps the writer knows some safe and efficient method. What is it? I am glad to say that I have no extensive experience of inducing abortion, but I have had enough to acquire a great dislike for the method of dilatation and curettage, partly because I am some fear of perforating the uterus, but even more because I am rarely certain that the uterus is empty when I have finished. In my experience, it is seldom that uterine paste fails to produce expulsion of the uterus within 48 hours, and abortion is nearly always complete. From Mr. David Maxwell's remarks at the Royal Society of Medicine on November 27, I gather that his experience has been like mine.

OUR EXPERT writes: I agree with Professor Claye that the word "nearly" could with advantage have been omitted from the sentence mentioned. It is also true that many in this country have used abortifacient pastes with satisfactory results over several years. When this matter was previously a subject for a question and a cautious answer one doctor wrote to say how surprised he was to learn of the dangers of the method—having himself used it without ill effect for more than 10 years. Within one week of writing the letter, however, he encountered two fatal cases, and he was good enough to write again immediately and to report the full details of these cases. The post-mortem findings were of the kind indicated in the warning given in the original reply (see also "Any Questions?" August 23, 1947, p. 317).

Causes of Failure of Contraceptive Diaphragms.—MARIE STOPES, D.Sc. (London, W.1) writes: May I add to your reply ("Any Questions?" November 28, p. 1229) about the fantastic failure rate of three in twenty? It suggests in addition to a six possible causes you give another also—that is, trust in a jelly instead of a grease. As the essential supplement to a diaphragm cap there is no contraceptive jelly in the world which can be relied on to give approximately 100% security, but a low-melting-point grease does give this.

Correction.—In the obituary notice of Dr. K. E. Eckenstein (*Journal*, September 12, p. 630) we were in error in saying that he was born in Alsace; he was, in fact, born in Liverpool.

The B.M.A. in Committee**SCIENCE**

"The wish has . . . been warmly expressed and widely circulated that the members of the profession residing in the provinces should unite themselves into an Association friendly and scientific; that this Association should have for its main object the diffusion and increase of medical knowledge in every department of science and practice."

Thus wrote the *Midland Medical and Surgical Reporter* in May, 1832, as part of the announcement of the proposed formation of a medical association. The prospectus of the Association, which was advertised in the *Lancet* of July 7 of that year, twelve days before the meeting at Worcester at which the Association was inaugurated by one means or four of its five objects the dissemination of medical knowledge and the promotion of medical science. The fifth object was the honour and respectability of the profession.

No word was said in all these proceedings about medico-political activities, which have so largely preoccupied the British Medical Association, especially since the advent of National Health Insurance, or, before that, the establishment of the new constitution with its Representative Body. The compulsion of events soon made such activities necessary. But it is well to recall that the Association in its origin was a scientific body concerned primarily with the collection and publication of medical knowledge. The diversion of much of its energy into the medico-political field has led many outside people who were imperfectly informed on the subject to regard the Association as a professional union, working almost entirely for the economic and other status of its members. This impression is the more unfortunate, because it overlooks the vast amount of scientific work which the Association has undertaken, even during some of the most controversial periods in its history. Some of its greatest leaders, occupied closely as they were in their time with medico-political activities, declared that they looked forward to an era when the medical services in this country would be so satisfactorily adjusted that conflict might die down and the Association resume more completely its primary role. Even as it is, despite change and struggle, it has managed to carry out scientific activities on a scale rivalled by few, if any, other professional bodies.

Early Scientific Activities

For nearly 80 years the Association has had among its standing committees a Scientific Committee, formerly called the Scientific Grants Committee. In the seventies of the last century the Council resolved to allocate a definite proportion of the Association's income for the encouragement of direct scientific investigation, and it did so in the first place

by the award of grants and scholarships which were almost the first of their kind in medicine. The sum originally allocated was small, but it grew under the careful recommendations of the committee. Within a few years the grants were numerous, and some of the recipients bore names which afterwards became famous.

The Science Committee consists now of 11 members, four of whom are elected by the Representative Body and six by the Council, with one other appointed by the Journal Committee. Its powers and duties are defined as the consideration of questions concerning the work of the Association for the promotion of medical and allied sciences, including the award of scholarships and grants and the management of the library. The library itself, with its more than 65,000 volumes and its unrivalled collection of 1,600 medical periodicals every year, is an undertaking which might well absorb the energies of a committee.

Prizes and Scholarships

Of the Association's prizes and scholarships which the committee has in its charge the most noteworthy is that which bears the name of the founder. The Sir Charles Hastings prize is awarded annually for the best essay by a general-practitioner member of the Association on a theme which is the result of systematic observation, research, and record in general practice. To this has been added, for the next best essay, a second prize bearing the name of a former chairman of the Representative Body, Dr. C. O. Hawthorne. Two prizes offered biennially bear the names of a former treasurer of the Association and his wife, the Nathaniel and Katherine Bishop Harman prizes, the former for research in consulting practice, and the latter to encourage study and research directed to the diminution and avoidance of the risks to health and life which are apt to arise in pregnancy and child-bearing. The Stewart prize, also biennial, is in recognition of important work done on the origin and spread of epidemic disease. In its time this prize has been awarded to men like Patrick Manson, Robert McCarrison, and Almroth Wright. A prize is also offered to encourage interest and research in the field of occupational health. The Middlemore prize is offered biennially for the best essay or work in ophthalmology. It has been gained in past years by such ophthalmologists as Herbert Parsons, Treacher Collins, and Duke-Elder. There are also annual prizes for medical students on subjects chosen by the Council on the Committee's recommendation and annual prizes for nurses in various categories.

Of the scholarships awarded, two—one of them named after Ernest Hart, a former editor of the *Journal*, and the other after Walter Dixon, a great pharmacologist, who was himself one of the chief advisers of the Association in regard to scholarships and scientific grants—are of £250 each, and there are up to four research scholarships, each to the value of £200, but the question of these scholarships is at present under review. Another award is the Insole

scholarship of the value of £250, awarded biennially for research into the causes and cure of venereal disease.

Famous Names

In the long list of Association scholars one notices such famous names as Watson Cheyne, Ralph Stockman, E. N. Starling, J. S. Risien Russell, G. Elliot Smith, John H. Parsons, and scores of others who afterwards attained an international reputation.

Among its other duties the Science Committee has the arrangement of Association lectures. It is a court of reference for innumerable questions attaching to medical science which reach Headquarters. For example, a current problem concerns access by the public to hormone preparations. The Science Committee took part in a meeting with representatives of the Royal College of Nursing and the Pharmaceutical Society to discuss the availability to the general public, without a medical prescription, of sex hormone preparations and the possibility of safeguards for the future against a too easy availability of these substances. It also co-operates with the British Standards Institution, and with the British Pharmacopoeia Commission in connexion with proposed inclusions in new editions of the *British Pharmacopoeia*.

Collective Investigations

One of the great contributions the Association has made to medical science has been by means of collective investigations. These investigations have sometimes been very highly organized, at other times more loosely, and they have usually been entrusted to special committees set up for the purpose, with some members at least who are experts in the special field. One of the first of such inquiries, undertaken as long ago as 1874, concerned the special dangers of chloroform, and this was followed by a series of inquiries into anaesthetics in general. The matter was put on a more effective basis after 1880, when the then President of the Association, Sir George M. Humphry, suggested in his address at the Cambridge meeting that the Association should undertake the collection of facts relating to diseases in a careful and systematic manner. A year or two later this work was begun, and inquiries into pneumonia, chorea, and acute rheumatism were the first undertaken. Among the many subjects which have since been investigated and made the subject of special reports have been ophthalmia neonatorum, the early recognition of uterine cancer, rheumatic heart disease in children, the causation of puerperal mortality and morbidity, psychoanalysis, mental deficiency, the care and treatment of the elderly and infirm, the cause and treatment of arthritis, aspects of nutrition (especially in wartime), and many others.

Three noteworthy investigations took place at the end of the 'twenties, one of them on the treatment of varicose ulcers, another on the after-history of gastro-enterostomies, and the third on the treatment of cancer and its history after treatment. In 1935 there appeared the report of a committee on fractures, and other reports have been on miner's nystagmus, on the spa in medical practice, and, after the 1939-45 war, on rehabilitation.

Work of Divisions and Branches

In any survey of the work done by the Association under the category of science the work of the Divisions and Branches should be remembered. In the Branches, as in the Association in general, the original emphasis was on scientific work, which is not surprising, as many of the Branches were formed from local medical societies which devoted their meetings to clinical and scientific subjects. This went on until about fifty years ago, at the time of the reform of the Association, when, with the necessary formulation of medico-political policies, more and more local meetings came to have a medico-political character. Later, however, the clinical and scientific meetings re-asserted their interest, and they now form a great factor in keeping the local practitioner familiar with medical progress.

GENERAL MEDICAL SERVICES

MEDICAL EXAMINATION OF STUDENT NURSES

From time to time the General Medical Services Committee receives inquiries about whether a fee is payable for a report to a hospital on the state of health of a girl wishing to be accepted for training as a student nurse. From discussions with the Ministry of Health and inquiries which have been made it is clear that a large number of hospitals do not ask for a report from the applicant's own doctor but rely on examination at some stage by the hospital's own medical staff.

Fee Payable

The Ministry does not wish to interfere with the arrangements and requirements of individual hospitals, but it has assured the Committee that hospitals have full authority to pay a fee up to a maximum of one guinea for reports which they require from an applicant's general practitioner. This fee is payable by the hospital either to the applicant or direct to the doctor furnishing the report.

Notification of Cause of Death

There has been doubt about whether it is part of a general practitioner's terms of service to obtain details of the cause of death and to insert these details on the medical record envelope.

The G.M.S. Committee has been informed by the Ministry of Health that there is no specific obligation on doctors to obtain the details of the cause of death. Provided that when forwarding the medical record to the executive council the general practitioner gives all the information readily at his disposal, he will be regarded as fulfilling his terms of service.

Correspondence

The G.P. and the Industrial Medical Officer

SIR,—Dr. F. H. Tyrer's letter (*Supplement*, June 27, p. 314) appearing in the issue of the *Journal* containing at page 1437 your leading article on "Teamwork in General Practice" calls for some comment. Perhaps it is not inappropriate that some should be offered by a fellow industrial medical officer with a high regard for Dr. Tyrer's organization, and one who works in an area in which a significant general-practice experiment is being started. I refer to the Corby Diagnostic Centre projected by the Nuffield Provincial Hospitals Trust to provide facilities for the general practitioner going far to meet the ideal suggested by the Minister of Health. Modesty may forbid the general practitioners to draw attention to the fact that the concept of the diagnostic centre, and the acceptance of more work and greater responsibility therein, is their own idea. Here is a new conception put forward by the general practitioners, endorsed by the consultants, with general support from the regional hospital board, and broad-minded acceptance by the local health authorities. This is teamwork with the general practitioners in the centre if not the lead.

This brings me to my criticism of Dr. Tyrer's letter, and possibly of the attitude of many industrial medical officers. It has been stated by many of these and, if I understand him rightly, it is implied by Dr. Tyrer that the good of the patient comes before ethical rules. The rules of medical ethics and, I believe, of etiquette, which are sometimes confused with them, act always in the long run towards this end. Often the worst harm that can befall a patient is that his doctors should quarrel over him. Unless the present rules are applied by the industrial medical officer this will sooner or later happen.

The rigidity of the rules is modified by the relationship of the industrial medical officer to the general practitioner which will, in turn, depend on the confidence of the latter in the loyal co-operation of the former. No harm can be done despite difficulties from present inadequacies in the Health Service if the industrial medical officer regards the general practitioner as the "leader of the team" and treats him with due courtesy and, above all, understanding. By no means all industrial officers have sufficient experience of general practice to realize that one of the arts of that sub-ject is to know when to examine, when to defer examination, and when to ignore a demand for examination. Without this experience the industrial medical officer may find himself unwittingly proffering an implied insult in examining another man's patient. He may unknowingly find himself encouraging that bane of general practice—the disloyal patient—and be himself entrapped.

There is an attitude of mind which we cultivate in our industrial medical service which renders the present rules, if not ideal, at least acceptable—i.e., "Everything that we can do for a patient we do on behalf of his own doctor." When we accept this the mark of our success is not the number of patients that find it "convenient" to consult us, but the number of general practitioners who welcome our co-operation and advice on matters affecting work. If we succeed we have not only worked towards keeping the general practitioner as leader of the team, but justified our inclusion in the side.

I should like to be allowed to add a word from experience, lest I be thought to be advocating "working to rule." My for the usual motives of that method in bargaining. My experience, which I know Dr. Tyrer shares, possibly with more frequent success, is that when the right relationship is achieved with a general practitioner he regards us as partners in his work. In such a case the rules of etiquette are applied as though between friendly partners, and the ethics remain as those governing the whole conduct of our profession.—I am, etc.,

G. MACBAIN.

Gretton, Northants.

Extraordinary General Meeting

SIR,—Dr. R. W. Cockshut's reply (*Supplement*, July 4, p. 9) to Dr. W. J. Grant is, unintentionally, amusing and revealing. His "main contention" is that the requisitionists "called a meeting of 67,905 people, in a hall capable of holding 775, in an attempt to upset the policy of the Association."

Are requisitionists, then, to wait until a hall capable of holding 67,905 people has been built, before calling for an Extraordinary General Meeting? And if spontaneous and sustained anger among doctors throughout the kingdom in a matter so important as their livelihood is not sufficient reason for such a meeting, what is? The weather?

In fact, the policy of the Association was upset—not by the requisitionists, but by those selfsame people who had established it, our leaders. It was upset (or ignored, which amounts to the same thing) because our leaders assented to the Minister's assertion that he would not be bound to the Danckwerts award unless there was agreement in the Working Party. What a weapon our leaders put then into the Minister's hands! It became for him a case of "Heads I win, tails you lose." And lose we did. For, despite the larger cheques many are receiving now, we did lose; the Association was obliged to jettison its declared policy of loading payment for the first thousand patients. Up to the moment of the Working Party's first meeting—and it needed very few meetings, since our leaders had already surrendered power—the declared policy of the British Medical Association was for loading on the first thousand patients. The General Medical Services Committee, the Special Conference of Local Medical Committees, and the Annual Representative Meeting, all of them in 1949 (the only time when the profession ever gave—and never again will be able to give—unbiased consideration to the matter) adopted and urged loading on the first thousand. Drs. Dain and Wand, to name only two, spoke forcefully for it. But it was discarded amid the loud jubilation; the small-list man was silently betrayed.

If, as Dr. Cockshut says, there was sharp practice, surely it was there and then. And I suspect it is his troubled conscience that makes him turn so vehemently on the requisitionists. I am reminded of the East European newspaper which, describing a scene when a man tackled an escaped lion, carried the headline: "Liberal attacks defenceless lion."—I am, etc.,

London, E.8.

CHARLES SCHIFF.

SIR,—True, other speakers voiced their own personal views, as they had every right to do, when the meeting was thrown open to general discussion. I hold no brief for those. Nevertheless, Dr. Charles I. Schiff and myself had been chosen by the committee, representing the requisitionists and the aggrieved practitioners, as seconder and mover respectively of the resolution to be presented to the meeting; and the Association, being so informed, accepted this arrangement and officially allotted to us our times for our speeches. When, therefore, Dr. R. W. Cockshut in two early paragraphs of his letter (*Supplement*, June 13, p. 279) criticized what he wrongly purported to be the case put by the signatories without indication of what speeches he was criticizing, the legitimate inference was that he was opposing the arguments voiced by the requisitionists' specifically accredited speakers. I therefore corrected Dr. Cockshut's erroneous paraphrase of our arguments. He now replies (*Supplement*, July 4, p. 9) that he was not criticizing my presentation of the aggrieved practitioners' case, and says he has not the knowledge "necessary to deny, defend, or resolve anything." In this case, it is difficult to understand why he mentioned me by name in the penultimate paragraph of his first letter, attributing to me views I do not hold. I will not, therefore, further pursue this aspect of his letters.

Further, he alleges something sinister in the calling of the meeting, incorrectly stating that the requisitionists called it at a hall which would not accommodate 67,000 people. We did nothing of the sort. We sent a requisition to B.M.A. Council for a general meeting, as provided for in the Act of Parliament

governing limited liability companies' conduct of their affairs; but it was the Council which decided the venue of the meeting. Nevertheless, quite contrary to Dr. Cockshut's unworthy insinuations, we were genuinely disturbed lest the venue might not accommodate the numbers who might attend; and we addressed a letter to the Secretary to this effect. We were told the accommodation would presumably prove ample, as in fact it did. B.M.A. Council has now called another Extraordinary General Meeting for July 13 in City Hall, Cardiff. Does Dr. Cockshut see anything sinister in the fact that that hall also will accommodate only a fraction of 67,000 people? If so, why? If not, what was sinister about the May meeting venue?

Nor was there anything sinister in asking our Association to reconsider the distribution scheme. If, as we are prepared to argue, that scheme diverts to other purposes large sums of money which, under the Danckwerts award, we contend should rightfully be paid to small-list practitioners in some proportion to the numbers on their lists (so honouring the declaration of the present Minister of Health that "doctors have an unanswerable case for increased remuneration" and the declaration of the G.M.S. Committee that the Danckwerts award had "made it clear that general practitioners had been substantially underpaid since the Health Service began"), what was there of wrong in the calling of a general, perfectly legal meeting of our colleagues to present the case for their consideration and endeavour to secure at least a postponement of the implementation of what we consider to be an injustice until a more equitable scheme might be considered? Under what moral or other canon is it wrong for some thousands of honourable professional men to seek redress, by utterly legal and orderly methods, for what they consider to be a great injustice? If such a course be denied them, what means have they available to secure their rights? Possible legal action in the Courts would be highly undesirable.

We are not seeking something for nothing for those who, under the Working Party's scheme, are left with no share in the award their numbers have attracted to the central payment pool. They ask only an increase of remuneration, to which the Minister has by clear implication indicated they are entitled. If Dr. Cockshut applied himself to assisting to ensure that increase, it would be more creditable than imputing to others motives and intentions they neither consciously nor unconsciously entertain.

Finally, I would seriously advise Dr. Cockshut not to formulate or express in writing any charge of "sharp practice" to which he obliquely refers. If he does so, my answer will be swift, certain, and definite.—I am, etc.,

Shrewsbury.

W. J. GRANT.

SIR,—Dr. W. J. Grant, in his reply (*Supplement*, June 20, p. 291) to Dr. R. W. Cockshut (*Supplement*, June 13, p. 279), states: "If 1,500 patients are to draw a 'bonus' of £500 per year to their practitioner, why not at least £250 'bonus' for the practitioner with a 750 list? If not, will Dr. Cockshut tell us why?"

I can tell him why. They are both drawing the same rate of "bonus" after the first 500. Therefore why should the G.P. who is getting his £500 "bonus" on 1,500 patients (2,000 total) look after the first 500 at the low rate, and the G.P. with the 750 list look after his total number of 750 at the "bonus" rate?

Please keep to the point, Dr. Grant.—I am, etc.,

Cosham, Hants.

E. SLADEN.

The B.M.A. and the Public Health Service

SIR,—I have read the article on public health, in the series "The B.M.A. in Committee" (*Supplement*, June 20, p. 289), with no little amazement. In it, the claim is made, no doubt correctly, that many advances in the country's public health arrangements have resulted from suggestions made by the Association. No mention is made, however, of the Association's responsibility for suggesting a national health service, nor for omitting to secure Spens Committee conditions for its members in the public health branch of that service. This omission has led directly to the tardy and meagre pay award to this branch.

Probably the facts of the case are not generally known to the profession. Briefly they are as follows. Every assistant

medical officer of health, from June 1, 1953, receives a salary similar to that of a senior registrar, and this is the grade from which the majority of public health recruits eventually retire on pension. No senior assistant medical officer is as well paid as those in the S.H.M.O. grade, though their qualifications, experience, and responsibility often exceed those required of the S.H.M.O. A very large number of medical officers of health, who are doing specialist work and are in charge of their departments, do not receive the salary of the S.H.M.O. Nobody in public health received the benefit of retrospection when the salary award was made, it only operated in full from April, 1951. No, there was no Danckwerts award for public health. To refer to this award as "disappointing in some respects" is to be guilty of a terminological inexactitude. In fact, the award is the direct and inevitable consequence of the failure of the Association in its duty toward a section of its members. And it bids fair to be the death blow to the public health branch, which has served the country so well for so long. If this is the Association's "considered public health policy," the sooner the Society of Medical Officers of Health puts its trust elsewhere the better.—I am, etc.,

Elgin.

- 13 Mon. Annual General Meeting (at Cardiff), 12.30 p.m.
- 13 Mon. Extraordinary General Meeting (at Cardiff), at conclusion of A.G.M.
- 13 Mon. Council (at Cardiff) at conclusion of A.R.M.
- 13 Mon. Board of Trustees, British Medical Guild (at Cardiff), at conclusion of Council.
- 13 Mon. Adjourned Annual General Meeting and President's Address (at Cardiff), 8.15 p.m.
- 22 Wed. Transport Medical Standards Subcommittee, Occupational Health Committee, 2.30 p.m.
- 23 Thurs. G.M.S. Committee, 10.30 a.m.
- 29 Wed. Executive Subcommittee, Joint Formulary Committee, 2 p.m.

OCTOBER

- 2 Fri. Joint Committee of B.M.A. and the Magistrates' Association, 11 a.m.

Branch and Division Meetings to be Held

MID-ESSEX DIVISION.—At Nurses' Dining Hall, St. John's Hospital, Wood Street, Chelmsford, Saturday, July 18, 7.30 for 8 p.m., annual supper followed by annual general meeting.

MONMOUTHSHIRE DIVISION.—At St. Mellons County Club, Tuesday, July 14, 5.30 to 7 p.m., cocktail party.

SOUTHAMPTON DIVISION.—At Royal South Hants Hospital, Wednesday, July 15, 8 for 8.30 p.m., general meeting. Address by Dr. G. S. Graveson: "Poliomyelitis."

WEST NORFOLK DIVISION.—At Ingoldisthorpe Manor Hotel, Friday, July 10, 7.30 for 8 p.m., dinner. After-dinner speech by Sir Archibald McIndoe: "Plastic Surgery."

Meetings of Branches and Divisions

SOUTH ESSEX DIVISION

The annual general meeting was held at Oldchurch Hospital on June 12, 1953. The following officers were elected:

Chairman.—Dr. R. D. Milford.

Vice-chairman.—Mr. John Watt.

Secretary and Treasurer.—Dr. P. S. Steen.

A vote of thanks to Dr. E. Anthony, the late secretary, for his services to the Division since its inception was passed unanimously.

ANNUAL MEETING, CARDIFF

The Section of Child Health will meet in room 127 in University College, Cathays Park, and not in room 28 as previously notified.

British Medical Association

PROCEEDINGS OF COUNCIL

A meeting of the Council was held in the Council Chamber of the City Hall, Cardiff, on July 11, Dr. E. A. GREGG in the chair.

Congratulations were accorded to the members of the Association whose names had figured in the Coronation honours, and also to Sir Hugh Linstead, M.P.

The deaths were announced of Mr. R. G. Hogarth, Vice-President of the Association and a former President, and of Lieutenant-Colonel Arthur Martin-Leake, V.C. and Bar, and Gold Medallist of the Association. The members stood in silence as a tribute.

The Chairman of Council reported that he had sent a telegram of congratulation to Dr. L. G. C. Pugh, senior member of the Association in the Mount Everest Expedition.

A letter was read from the Honorary Secretary of the Worcester and Bromsgrove Division expressing thanks to the Council for the opportunity of looking after the silver tray which was originally presented to Sir Charles Hastings, and which the Association has acquired. "We will cherish it and see that it is on display at every local B.M.A. function."

The following names were put forward for the consideration of the Minister in connexion with the filling of vacancies on the General Nursing Council caused by the expiration of the term of office of certain members of the Council in September next: Mr. A. Staveley Gough, Dr. T. Rowland Hill, Mr. H. H. Langston.

Dr. G. Clark Trotter was appointed the Association's delegate to the forthcoming conference of the National Smoke Abatement Society.

It was reported that a group consisting of the Chairman of Council, the Chairman of the Representative Body, and the Chairmen of certain interested committees had met and considered the evidence to be given to the Ministry of Health Committee which has been set up to review the cost of the National Health Service. The group considered that it was necessary to invite the standing

committees specially interested in the problem to express their views on the evidence to be given. It was also proposed that the Scottish Committee should prepare evidence relating to the Service in Scotland, and present it to the Guillebaud Committee when it was sitting in Scotland. The group of chairmen is to be kept together as a steering and co-ordinating committee.

Arrangements were reported for a dinner to be given at B.M.A. House to the members of the World Medical Association Council meeting in London in August.

Preliminary reports from the Arrangements Committee for the Glasgow Meeting, 1954, and the Toronto Meeting, 1955, were approved.

The Science Committee submitted revised conditions which should apply to B.M.A. essay competitions, and these were approved.

The Central Ethical Committee brought forward a recommendation for submission to the Representative Body on the question of the loan of hospital records to Government Departments. This matter subsequently came before the Representative Body (see report of Monday's proceedings, *Supplement*, July 18, p. 49).

The catering establishment at B.M.A. House was the subject of a report from the Office Organization Committee. Certain recommendations were agreed to under which the management of the whole catering establishment is to be vested in a special committee composed of the officers of the Association and five members appointed by the Council, at least one of whom should be a woman.

Appreciation was expressed by the Council to Messrs. Harold Whitehead & Partners for their valuable services in connexion with the investigation of the departments at B.M.A. House.

The business of the Council had to be compressed within one hour in view of the early start of the Representative Meeting, and consideration of certain parts of the agenda was deferred to the next meeting on July 13.

First Meeting of New Council

The first meeting of the new Council was held in the Council Chamber, City Hall, Cardiff, on July 13, at the conclusion of the Annual Representative Meeting. The reports of certain committees which had been postponed owing to pressure on time at the meeting of July 11 were presented by the respective chairman and approved. The Council then proceeded to the election of its Chairman, and on the proposition of Mr. A. M. A. MOORE, Dr. E. A. GREGG was unanimously and with acclamation re-elected.

The CHAIRMAN proceeded to welcome and introduce the new members of Council—namely, Sir John McNee, the President-Elect, Dr. H. D. Chalke, Dr. T. W. Davies, Dr. Neil Douglas, Dr. H. G. Dowler, Dr. J. O. M. Rees, and Dr. J. T. Rice Edwards. He also expressed regret at the retirement from the Council of an equivalent number of members, and thanked them for their services.

The Council adopted Standing Orders and resolutions relative to its business. The minutes of the Annual Representative Meeting were examined and it was decided that there was no reason to take a referendum on any of its decisions. The members then proceeded to vote by ballot for the election of Council members on Standing Committees, and to reappoint the Special Committees. The work of each of the Special Committees was reviewed, and where the reference was still undischarged they were reappointed, in some cases with a slight rearrangement of personnel. The number of Special Committees, including Joint Committees with outside bodies, was 26.

With regard to the Constitution Committee, which a resolution of the Representative Body instructed the Council to set up, it was decided to postpone the appointment until the next meeting of Council in order to give time for consideration as to the best selection of members.

The Council discussed at some length the policy with regard to meetings of committees during the session 1953-4. The practice in the last session was that, apart from the Central Consultants and Specialists, General Medical Services, Public Health, and Finance Committees, only two firm dates should be allocated to committees for meetings during the session, on the understanding that any committee could be called at additional dates if found necessary, and that any urgent business between meetings should be delegated to a small executive subcommittee with power to take action and to report to Council. The necessity of continuing economy despite the improvement in Association finance was stressed. On the motion of Dr. WAND, seconded by Dr. I. D. GRANT, it was agreed to revert to the normal number of meetings in the schedule of committee dates for the new session, but to include certain dates in brackets to indicate that meetings arranged for these dates would be cancelled if not found absolutely necessary.

Dr. Frank Gray and Dr. W. Woolley were reappointed as representatives on the council of the Society of Medical Officers of Health, and Dr. H. Guy Dain (or his deputy), Dr. K. Cowan, and the Secretary of the Association as representatives on the Civil Service Medical Officers Joint Committee.

A letter was read from the General Secretary of the Canadian Medical Association accepting the invitation for a meeting conjointly with the British Medical Association in England in 1959, and adding that his Association had instructed him to invite the B.M.A. to nominate one of its members as President of the Canadian Medical Association for that year. It was requested that the nomination should be made before June 1, 1957. The Council agreed that a letter of thanks be sent to the Canadian Medical Association and that consideration be given to the question of nomination at a later meeting.

The Secretary also read a letter which had been received from the New Zealand Branch suggesting the holding of the Annual Meeting in that Dominion in 1959 or 1961 in conjunction with the New Zealand Biennial Conference. It was

agreed to thank the New Zealand Branch and to inform them that the earliest date that could be considered was 1961, and that the matter would come forward at the next meeting of Council.

BRITISH MEDICAL GUILD

A meeting of the Trustees of the British Medical Guild followed the Council meeting. Dr. Gregg was reappointed chairman, Dr. Frank Gray treasurer, and the executive committee was re-elected. A statement was made on the financial position of the Guild Trust Fund.

ADJOURNED ANNUAL GENERAL MEETING

The Adjourned Annual General Meeting was held in the Park Hall Cinema, Cardiff, on the evening of July 13. The President of the Association, Mr. J. W. TUDOR THOMAS, presided, and was accompanied on the platform by the Lord Mayor of Cardiff (Sir James Patrick Collins), the immediate Past President (Dr. P. T. O'Farrell), the President-elect (Sir John McNee), and the principal officers of the Association. Most of the members in the very large assembly were in their academic robes.

Introductions

The CHAIRMAN OF COUNCIL (Dr. E. A. Gregg) introduced to the President the following delegates from kindred Associations:

Austrian Medical Association, Dr. W. DEMUTH
Danish Medical Association, Dr. JACOB RAFT
Irish Medical Association, Professor W. J. O'DONOVAN
Medical Association of South Africa, Dr. J. P. DE VILLIERS and Dr. M. H. DE VILLIERS
Medical Association of Thailand, Dr. SMAI CHIANDAVIMOL
Pakistan Medical Association, Dr. MUNAWAR ALI
West German Medical Association, Dr. RUDOLF WEISE and Dr. J. KEHRINGS
Swedish Medical Association, Professor A. WALLGREN

This was followed by the introduction of representatives of Overseas Branches of the Association:

AFRICA

Dr. K. V. ADALIA, Kenya Branch
Dr. A. F. TUBOKU-METZGER, Sierra Leone Branch
Dr. A. A. LOVELL, Tanganyika Branch
Dr. A. B. RAPER, Uganda Branch
Dr. KEITH D. YOUNG, Zanzibar Branch

AUSTRALIA

Dr. E. A. TIVEY, New South Wales Branch
Dr. J. G. HUNTER and Dr. L. D. WALTERS, Queensland Branch
Dr. C. H. DICKSON and Dr. W. J. FLANAGAN, Victoria Branch

FAR EAST

Dr. J. MACKINTOSH and Dr. F. PARAMPALAM, Malaya Central Division
Dr. R. A. PALLISTER and Dr. LOH GUAN LYE, Malaya Northern Division
Dr. R. J. GROVE-WHITE and Dr. MARY GROVE-WHITE, Malaya Southern Division

MEDITERRANEAN AND MIDDLE EAST

Dr. N. H. SKELTON-BROWNE, Aden Branch
Dr. W. M. FORD-ROBERTSON, Middle East Branch

WEST INDIES

Dr. WILBERT J. S. WILSON, Jamaica Branch
Dr. L. R. WYNTER, Leeward Islands Branch
Mr. J. HENRY PIERRE, Trinidad and Tobago Branch

Mrs. O'Farrell then invested Mrs. Tudor Thomas with the President's Lady's Badge.

Presentation of Prizes

The PRESIDENT presented to the recipients the various Association prizes as follows:

The Sir Charles Hastings Clinical Prize to Dr. M. J. Cookson, of Gloucester, for an essay on "A Survey and Commentary of Certain Aspects of Obstetrics of Importance to the General-practitioner Obstetrician."

The Occupational Health Prize to Dr. R. McL. Archibald, of Northwich, Cheshire, for an essay on "Perforation of the Nasal Septum due to Soda Ash."

The Dawson Williams Memorial Prize to Dr. Helen M. M. MacKay, of London, in recognition of her researches on nutritional disorders in early life.

Prizes were presented to the following student nurses for an essay on "Is Nursing a Vocation?": Mildred P. Simson, Royal Northern Hospital, London, and Barbara M. Jamieson, West London Hospital; to the following State-registered nurses working in a hospital, for an essay on "The Role of the Married Nurse in the Hospital Service": Phyllis M. Kynaston, University College Hospital, London, and Gertrude E. Prior, Leicester General Hospital; and to the following State-registered nurse not working in a hospital, for an essay on "The Psychological Approach to the Patient": Mrs. Ethel Forrest, Heston, Middlesex.

Prizes were presented to the following medical students for an essay on "A Good General Education is a Necessary Preliminary to a Medical Career": Mr. T. R. Boyde, University College Hospital, Mr. R. D. Hyde, St. Thomas's, Mr. R. Portal, Middlesex, Mr. P. J. Taylor, St. Thomas's.

President's Address

The PRESIDENT then delivered his address from the Chair. The address was published in the opening pages of the Journal last week.

At the close of the address Dr. S. WAND, Chairman of the Representative Body, in moving a vote of thanks, said that Mr. Tudor Thomas had had a very distinguished academic career, and had done great work in ophthalmology. But he was also a man who had endeared himself to everyone with whom he came in contact. He had found time to help in the work of the Association, and had served on local and central committees and on the Council. Cardiff was very proud of the honour bestowed on him that day, and they in the Association were proud to have him as their President.

The remarks of Dr. Wand were endorsed by hearty applause.

President's Reception

The President's Address was followed by a reception at the National Museum of Wales, where Mr. and Mrs. Tudor Thomas received 1,250 guests. The museum, a treasure-house of Wales, was open for inspection, and for the entertainment of those attending a selection of Welsh music, with the harp, was given by Osian Ellis in the Wilson Gallery, and cinematograph films depicting Wales were shown. Refreshments were served in a marquee.

OVERSEAS CONFERENCE

UNQUALIFIED PRACTICE IN THE COLONIES

The Overseas Conference in connexion with the Annual Meeting was held at the City Hall, Cardiff, on July 15, with Mr. J. L. GILKS, Chairman of the Overseas Committee, in the chair. The President of the Association and the Chairman of the Representative Body were present.

The SECRETARY of the Committee (Dr. E. Grey Turner) gave his usual annual survey. He first explained the composition of the Overseas Committee. It consisted of the four officers of the Association *ex officio*, seven representatives of overseas constituencies elected by the ordinary democratic machinery of the Association, two by three years, two members appointed by the Council, two by the Representative Body, and one by the Organization Committee, with power to co-opt two additional members for areas not otherwise represented. The Chairman of the Committee for some years had been Mr. J. L. Gilks, to whom the overseas members owed a tremendous debt. The work of the Committee consisted principally in looking after the affairs of the overseas Branches in the Colonies and the foreign countries. It had no need to worry much about the affairs of the corporate Branches in the Dominions, which seldom required any assistance from Headquarters. The

Committee, however, always had to bear in mind that quite a large number of members were living in areas where there was no Association Branch.

With regard to the representation of overseas constituencies in the Representative Body, the old system of representation whereby each Division was a constituency for the Representative Body gave rise to curious anomalies. For example, the New Zealand Branch included seventeen Divisions, each of which was entitled to send a representative, yet the powerful New Zealand Branch itself was not entitled to send anybody. The same applied to Malaya. By resolution of the recent Representative Meeting, the Branches had been made the units for this purpose, with the same plan of representation as Branches in the United Kingdom, but with an upper limit of three.

Future of the Colonial Medical Service

Dr. Grey Turner went on to say that hitherto the British Commonwealth had consisted of (1) self-governing countries which had their own universities and medical schools, and (2) non-selfgoverning countries which had no medical schools or very small ones, and were not able to meet their own requirements for doctors. A new phenomenon was about to appear. In the near future countries which had not been able to supply their own requirements for doctors were going to be promoted politically into the self-governing category. This was the case with the new Central African Federation, consisting of the Rhodesias and Nyasaland, which had no medical schools, the Gold Coast, which could not afford a medical school for some years to come, and certain other areas. On the other hand, in the Caribbean, where it was possible that in the near future the Colonies would federate and form a new self-governing dominion, West Indian doctors had for many years past come to Great Britain and qualified, and they had their own medical school. Thus the future Caribbean Federation, and Malta also, did not fall into the category he was discussing.

A country which was independent and self-governing but could not supply its own requirements for doctors could adopt one of two policies. It could adopt a policy of self-sufficiency, making use of such qualified doctors as it had, and in addition granting a bare legal recognition to semi-trained doctors, registering dispensers, osteopaths, herbalists, and so forth. There was a proposal now before the Legislative Council of the Gold Coast to carry out precisely that policy. This created a situation such as they had never had to face before. Let it be assumed that in spite of protests this proposed law in the Gold Coast came into force. If the Association condoned it, it was all against their traditions. Moreover, association with an unqualified practitioner was a serious ethical offence for which the practitioner was liable to be summoned before the General Medical Council. On the other hand, supposing the Association black-listed the country, it might be argued that that was only making matters worse. A decision on this question would not be taken until events required it, but his Committee would be glad to have any views on the subject from the present Conference.

The second policy which such a country might follow was that of recruitment from abroad. It could recognize that it was not self-supporting, and must bring in doctors from other countries. Such a policy had certain implications. If a country wanted to attract doctors from abroad it must offer terms which would make it worth their while to settle there. For example, it might be found that it could obtain its own doctors for posts in the Government Medical Department at a certain starting salary, that salary might not be nearly sufficient to attract doctors from Great Britain or America, and the consequence might be that they would have two rates of pay, one rate for their own people and the other for people from abroad. Not only must the salary be sufficient but the conditions of service must be attractive. Libya, for example, last year became an independent self-governing country, and the British doctors

who had been working there were asked to remain on as employees of the Libyan Government. Quite quickly reports reached the Association of considerable dissatisfaction in the medical service and some resignations. It was found that in a new Dominion the medical service was treated in a thoroughly unsatisfactory way, what was the Association to do? Was it to condone the unsatisfactory conditions or to black-list the country? If the conditions were condoned they would be recruiting doctors for service which they regarded as intolerable; on the other hand, if they black-listed the country they were cutting off a country with which they had a tradition of friendship. For some weeks now the *Journal* had refused to accept advertisements for the Libyan Medical Service.

Thus there was a state of considerable uncertainty in some countries—the Gold Coast, Malaya, Nigeria—about the future of Government medical services. One solution suggested was short-term engagements, but these had the disadvantage that a man went out to a Colony, say in Africa, for three years, spent the first year getting acclimatized, the second year learning the language, and came back in the third year. Another possibility was to offer a full career in the Colonies, but the only way in which the Secretary of State could do that might be to form a general colonial service, employed by H.M. Government, and seconded to the various Colonies, with pay and conditions guaranteed. The whole situation bristled with difficulties. It cut right across the whole tradition of self-determination in the British Commonwealth. There might be other solutions—some middle road—and the Overseas Committee was giving deep thought to this very serious problem and had made an approach to the Colonial Office.

Geographical Survey

Finally, Dr. Grey Turner gave a brief geographical survey of the Branches. The Overseas Committee had received an agreed scheme for the unification of the Malayan Medical Service and had been hoping to receive some views from the Malaya Branch about this. The Committee had also successfully negotiated an improvement of remuneration in Borneo. The Seychelles furnished an example of a little group of unattached members whose interests the Committee had been trying to serve. The salaries of the officers there were too low. Mauritius had had a salary revision. Kenya was passing through a troubled period. One of the causes of the Mau Mau uprising had been the rapid growth of population in East Africa. The Kenya Branch had directed attention to this subject as long ago as 1947, and could claim to be six years ahead of the Kenya Government in this matter. The three protectorates in Southern Africa—Basutoland, Bechuanaland, and Swaziland—which had British doctors recruited from the United Kingdom, had been passed by in the recent salary revision and the Committee had been trying hard to put the matter right, so far without success.

The Association had three Branches in foreign countries—namely, the Sudan, the Egyptian, and the Middle East Branches. The Sudan was passing out of the Anglo-Egyptian condominium. The Committee was trying to give it all the help it could in this time of transition. The Middle East Branch, which rose from the ashes of the Mesopotamian Branch, had held an annual meeting at which a first-class scientific and clinical programme was arranged.

Cyprus was at present included in the "Important Notice"—a very regrettable state of affairs. The decision had been taken only as the last possible resort. When the Committee finished its negotiations on salaries on behalf of the large Colonies it turned its attention to the small, and as long ago as 1950 it had a preliminary discussion with the Colonial Office about Cyprus. In August, 1951, the Association submitted a comprehensive memorandum to the Colonial Office. No reply was received for nine months, and in May, 1952, the bald announcement was made of new salary scales, which had been arrived at without any proper consultation with the medical profession. The sala-

ries were considered much too low in relation to the rest of the Colonial Empire, and certain medical officers were not put on the new salary scales but on other special terms. The Chairman of the Representative Body, on his way to another conference, spent a short time in Cyprus in October, 1952, but he was not enabled to meet the Governor. Some slight improvements were made, including a recognition by the Cyprus Government that the Branch could make representations to them concerning alterations, but alterations in the scale were refused, and on May 20 the Government of Cyprus was included in the "Important Notice." The Committee felt that it was its duty after this long consideration to include Cyprus under this ban.

With regard to other Branches, the Malta Branch had produced an interesting memorandum on the future condition of the medical service in that country. They were fully alive to the problem. In the Caribbean Branches a considered reply from the Colonial Office was still awaited on the Association's proposals for a federal medical service. The Branches were well ahead in this matter.

General Discussion

Dr. P. T. O'FARRELL said that it might be necessary in some regions to employ in the medical service people who were not fully qualified, but he insisted that they should be on a separate register and not allowed to call themselves doctors. He also suggested that the Overseas Committee, owing to economic considerations, held too few meetings.

Dr. S. WAND said that the suggestion had been made that a sort of central pool should be created for the seconding of doctors in the Colonial Service. He thought that the present system could be integrated with such a pool. If there were a nucleus from which men could be seconded to certain areas it would solve some of the problems of those areas and also relieve the difficulties of absorbing these men when they came back to this country. Dr. R. A. PALLISTER and Dr. R. J. GROVE-WHITE spoke of the conditions in Malaya and the need for doctors in the Colonial Service to be assured of opportunities for appointment when returning to Britain. Some men could not get a job if they had been a number of years abroad and, so to speak, were off the ladder of promotion.

Dr. K. V. ADALIA (Kenya) spoke, as did others, on the question of training medical auxiliaries in certain regions. Dr. GREY TURNER said that the proposal lying on the legislative table of the Gold Coast was to register and grant legal recognition to people who had not had an orthodox medical course at all. Dr. W. DEGAZON said that there had been political pressure in Jamaica to put osteopaths on the register, with full status. This had been resisted, but their dental colleagues were now subject to similar pressure, the idea being to bring in unqualified dentists. It all emphasized the importance of having strong B.M.A. Branches. On this question of unqualified practitioners there could be no compromise. Mr. J. HENRY PIERRE (Trinidad and Tobago) said that on this question of unqualified practitioners, whatever the British Medical Association might do, people who had that attitude towards medicine would persist in it. The aim should be to ensure that the qualified and non-qualified were kept in separate compartments, in distinct registers. Dr. WAND suggested that registration for the non-qualified should be only for a limited term, with, if necessary, provision for extension. Dr. N. H. SKELTON-BROWNE (Aden) said that in Aden they were relatively well doctored, but the thought of unqualified practitioners being allowed to practise caused him perturbation. He had in mind some Arab practitioners in his Colony, who, when they carried out operations for cataract, for instance, obtained remarkable immediate results, but the final results were deplorable. The law in Aden allowed a dispenser to run a dispensary, but not to call himself a doctor. Dr. GREY TURNER said that what Mr. Pierre wanted was a register of medical auxiliaries, but if these unqualified people had a register nothing would stop them from getting full registration.

Dr. J. G. HUNTER (Queensland) said that the problem of the unqualified was not unknown in Australia. He spoke also of the difficulty of dealing with alien practitioners, mostly displaced persons, in Australia, in view of the large entry from Australian medical schools. In New South Wales during the last few years the average output had been 330 graduates a year, and the wastage was under 100. Dr. C. H. DICKSON (Victoria) also spoke of this problem. In New Guinea medical assistants were being employed under supervision and were doing very good work.

Empire Medical Advisory Bureau

Dr. H. A. SANDIFORD, Medical Director of the Empire Medical Advisory Bureau, spoke of the facilities which the Bureau at B.M.A. House had to offer and expressed the hope that overseas members would tell their colleagues about them and advise them to get in touch with the bureau when coming to this country.

A vote of thanks to the Chairman concluded the proceedings, and afterwards the overseas delegates attended an "At Home" given at Cardiff Castle.

The luncheon to Overseas representatives was held at the Angel Hotel, Cardiff, on July 10, when Dr. S. WAND, Chairman of the Representative Body, welcomed the visitors and Dr. J. G. HUNTER, Federal Secretary of the B.M.A. in Australia, replied.

REPRESENTATIVES' DINNER

At the conclusion of the first day of the Annual Representative Meeting, the representatives dined together at the New Continental Café, Cardiff, Dr. S. Wand presiding. Later they were joined by the ladies for a dance.

The speechmaking was by tradition limited to the proposal of the toast of the health of the Chairman. Dr. A. S. Wilson, in proposing the health of Dr. Wand, said that he did not suppose that any person had made a more extended tour of this country attending celebrations in his honour than Dr. Wand had done in recent months. It seemed strange to see Dr. Wand sitting in the Chair of the Representative Body, because it was not so many years ago that he first appeared in that assembly as a very determined critic and even something of a menace to the platform. It was never possible to smash him, for he always knew what he was talking about. He was also a man eager to enter into battle at any time and one who bore no malice afterwards. His ascent to high office in the Association was perhaps a surprise to himself. They in the General Medical Services Committee greatly regretted his departure from the Chair of that body, but they already had a deputy chairman in Dr. Talbot Rogers who had all the advantages of Dr. Wand's assistance and was proving a very worthy successor. Alluding to the number of chairmen who had come from Birmingham, Dr. Wilson said that no doubt when better chairmen could be built Birmingham would build them. Finally he paid tribute to Dr. Wand's modesty, his disclaimer of undue praise, and his ready acknowledgment of the services of predecessors and colleagues.

The toast was accorded musical honours. Dr. Wand said that they had had a memorable day. It had been suggested to him that this should be called a Royal Meeting. Some of them had been privileged to be present at the ceremonies in the City Hall, and the meeting itself that morning had elected H.R.H. the Duke of Edinburgh an Honorary Member of the Association. This was also a historic occasion on other grounds, inasmuch as it was the fiftieth meeting since the constitution of the Representative Body in 1903. To go still further back, he recalled some of the peculiar features of the organization of the Association 100 years ago, when the membership of its Council was reputed to be over 300. Much had been made of the number of Association chairmen who came from Birmingham, but in its early years the Association was governed not from Birmingham but from a neighbouring city—Worcester. A great deal had happened since then, and he thought it

could be said that those who were present at the Swansea meeting 50 years ago did a good job of work.

At gatherings of this kind in the past it had been the duty of the Chairman to make some reference to those who had formerly held office. He would content himself with referring only to a few of those who had worked as whole-time officials within the organization—Alfred Cox, George Anderson, who died in the Association's service, and then Charles Hill, during whose term of office the Association grew more rapidly than at any other period. Dr. Wand then referred in terms of warm appreciation to present members of the Headquarters official and clerical staff. He then concluded by saying that during his own experience of the Representative Meetings there had been a great improvement in the standard of speaking. He had been struck in recent years by the extremely high quality of the speeches, which were terse, well thought-out, and usually not long enough to incur the warning of the red light. He believed that the quality of speaking in the Representative Body would compare favourably with that of any other assembly in the country. He begged the younger men to come forward and serve the Association. Any sacrifice which such service involved would be more than made up by the satisfaction which the work afforded. He was grateful to the representatives for putting up with some of the difficulties which he might create from time to time, and he begged a continuance of their good will.

THE ANNUAL DINNER

The Annual Dinner at the Cardiff Meeting was held in the Assembly Room of the City Hall on July 16. About 520 members and guests assembled under the presidency of Mr. J. W. Tudor Thomas, who had on his left the Lord Mayor of Cardiff and on his right the Lord Lieutenant of Glamorgan. Grace was said by the Archbishop of Wales (Most Rev. Dr. John Morgan). Immediately after the toast of "H.M. The Queen," the President announced that a telegram had been received from Buckingham Palace:

"The Duke of Edinburgh accepts with great pleasure your invitation to him to become an Honorary Member of the British Medical Association. His Royal Highness trusts that your meeting in Cardiff has been a great success."

The toast of "The Duke of Edinburgh, the Earl of Merioneth" was then drunk.

"The City and Port of Cardiff"

Dr. S. WAND, Chairman of the Representative Body, proposed "The City and Port of Cardiff." He spoke of the unexpected beauty of the city. Its history was the history of the industrial revolution, and on this his first visit to Cardiff he had rather expected to find it shrouded in industrial gloom. Instead he had been greatly impressed by the cleanliness even of its smaller streets, while Cathays Park was perhaps the most beautiful civic centre in the world. The men who had contributed to the stateliness and prosperity of Cardiff had combined with industrial enterprise true civic pride. Cardiff had welcomed the Association in a grand way, for which they had first of all to thank the Lord Mayor and Corporation. He had attended many Annual Meetings, but never one at which the chief citizen had been more helpful or more frequently with them. It had been a wonderful meeting, and one of the most memorable things about it had been the magnificence of the civic hospitality.

The LORD MAYOR (Sir William Collins), in responding, said that they in Cardiff were indeed grateful to those who had served before them and had brought the city to its present dignity. Unfortunately Cardiff was now faced with a crisis at the docks, but they were not despondent, they accepted it as a challenge to their day and generation, and the trouble would be overcome. Cardiff was a particularly healthy city. It happened that this was the centenary year of the appointment of its first medical officer of health. In 100 years the city had had only four such officers, two of whom were still with them—Provost Ralph Picken and

the present medical officer, Dr. Greenwood Wilson. It had been a great pleasure to have the British Medical Association in their midst. He and the Lady Mayoress would be very lonely next week, for they had had the privilege of entertaining at the Mansion House nine of the medical visitors. He begged the Association not to wait 25 years before it came again.

"The University of Wales"

Sir DANIEL T. DAVIES, in proposing the toast of "The University of Wales," said that when the Association last met in Cardiff, in 1928, the Welsh National School of Medicine, one of the constituent parts of the University, was only eight years old. On that occasion the then President, Sir Ewen Maclean, had delivered an address on the theme of the increased responsibility of the medical profession in the unknown to-morrow. His words had indeed been fulfilled by subsequent events. The University of Wales, said Sir Daniel, was the first university in the Empire to establish a chair of international relationships, also the second in Britain to establish a chair of tuberculosis. He mentioned the names of some of the sons of the university, such as Sir Thomas Lewis, who had made a great name in medicine.

LORD HARLECH, Pro-Chancellor of the University, said that the University was in fact a very small institution, but it was very proud that it had brought people from the wage-earning classes into touch with all the modern techniques of science and with the study of the humanities. It was a university democratic in origin and in structure and activity. The School of Medicine was itself the great result of local effort and interest. He went on to speak of the extraordinary advances in curative and especially in preventive medicine as he had observed them during his travels in Africa.

Sir CLEMENT PRICE THOMAS proposed the toast of the University College of South Wales and Monmouthshire and the Welsh National School of Medicine, and said how grateful he was, as a Monmouthshire man, that that sometimes forgotten county was included in the title. He spoke with pride of the medical school.

PRINCIPAL ANTHONY STEEL, replying for University College, remarked that it was in University College that medical training first began in Wales, and, together with the Cardiff hospitals, it was the parent of the Welsh National School of Medicine. Like many parents, it was astonished at its offspring—its vigour from birth, and the fact that it spoke with a strong Scottish accent!

PROVOST R. M. F. PICKEN, who also replied, condensed his speech, in view of the lateness of the hour, into one sentence in which he acknowledged the compliments paid to the Welsh National School of Medicine.

"The British Medical Association"

Sir ROBERT WEBBER proposed the toast of the British Medical Association, saying that he did so at the behest of his old friend, their excellent President. What he lacked in knowledge of the Association was made up by the sincerity of his admiration for the profession as a whole, which he looked upon as the greatest in the world. Doctors spent their lives halving the sorrows and doubling the joys of the sick, the lame, and the blind, and he knew that the British Medical Association had done great service in safeguarding the profession and enabling it to carry out its task in freedom. He had recently returned from Canada, where he had been interested to observe the tremendous pride which the medical men he met there felt in the British Medical Association and their own. Incidentally, he had found them very anxious to learn about the effect of the National Health Act in Great Britain upon the profession and upon the patient. Finally he spoke of his great delight in seeing Tudor Thomas in the Presidential Chair. His name was worthy to rank with other great names in contemporary Welsh medicine—names like those of the late Sir Thomas Lewis, Sir Horace Evans, Sir Daniel Davies, and Sir Clement Price Thomas.

The CHAIRMAN OF COUNCIL (Dr. E. A. Gregg), in responding, said that notwithstanding the late hour it would ill become him, speaking on behalf of the Association, if he did not say at any rate some of the things it was his duty to say on that occasion. This was a great event in the history of the British Medical Association; it was the jubilee of the foundation of the Association in the form in which it now existed. The first meeting under its present constitution was held in South Wales 50 years ago, and it was felt most appropriate that in 1953 they should meet again in the Principality.

This was a great occasion also because their friends in Wales had nominated as the President of the Association for this year their very good friend and councillor, Tudor Thomas, who had already done a great deal for the Association. Under his guidance they had had an excellent Annual Meeting, discussing many matters, and preparing a programme of work for the coming year which they would do their best to carry through. But, apart from that serious aspect of the meeting, the surrounding atmosphere and the social occasions which belonged to a meeting of that kind had been unusually happy. They had received a wealth of hospitality. The preparations which had been made for the visit had astonished him, and the warmth of the welcome had touched their hearts and was something they would never forget. They were going away with the happiest memories, and hoped to be able to come back again soon.

"The Guests"

Professor GILBERT I. STRACHAN proposed the health of the guests. The guests could be divided into various categories. The first consisted of those who came from overseas, whom they were very glad to welcome. Then there were a number of others associated with Cardiff and Glamorgan, to whose hospitality the success of the meeting was very largely due. There were the representatives of the City and the University who had provided such excellent accommodation and other facilities for the meeting. Another guest was the immediate Past-President, Dr. O'Farrell, who was to be congratulated on the way in which he had discharged his presidential duties during the past year. He associated two names with the toast, the Lord Lieutenant of the County, Major Traherne, who came of a family distinguished for a strong sense of public spirit, and had shown himself a man of outstanding ability in county affairs, and Dr. Wilder Penfield, O.M., who had been a Rhodes Scholar and had done great work at McGill University which had given him a world-wide reputation.

The LORD LIEUTENANT, in responding, said that Glamorgan had been glad to have this memorable meeting of the British Medical Association within its borders. This had been a great year for Cardiff, and one of the events to be remembered would be the visit of the Association.

Professor WILDER PENFIELD said that in acknowledging the toast he could speak for his Canadian colleagues. At this time there was perhaps a greater feeling of fellowship among the profession on both sides of the Atlantic than ever before. In Britain they had had a great occasion in the Coronation of the Queen, but perhaps it was not realized in this country how much this had meant to English-speaking people throughout the world. In saluting his British colleagues he thought he could speak also to some extent for the American Medical Association. The British Medical Association was regarded on the North American continent with respect and affection.

"The President"

The final toast was that of "The President," which was proposed by Mr. ROBERT D. OWEN, of Cardiff. He congratulated Mr. Tudor Thomas on accepting the responsibility of this great office and also on the way in which he had carried through the Annual Meeting. The name of Tudor Thomas was a worthy one to add to the list of Presidents over the last 120 years. He also paid a tribute to Mrs. Tudor Thomas. Tudor Thomas was a man greatly loved

by his colleagues, one who had never said an unkind word about his fellows, and as President he knew that he would maintain the dignity of the Association.

Mr. TUDOR THOMAS, who was loudly acclaimed on rising to respond, which he did just before midnight, thanked the company for the generous way in which this toast had been received and also thanked Mr. Owen for his kind reference to his wife. The British Medical Association was world-wide and stood for great ideals. Many great men in the profession had devoted themselves to its service. Some of them would spare an affectionate thought on this occasion for the distinguished Cardiff citizen who was President of the Association when it last met in South Wales in 1928—Sir Ewen Maclean.

The President went on to express his appreciation of the secretariat of the B.M.A. for all that they had done in the work of the Annual Meeting, and then mentioned some who had been prominent in the local arrangements, in particular Dr. J. D. Spillane, the Honorary Local General Secretary, and Mr. R. A. Mogg, his deputy, Professor G. I. Strachan, the Honorary Local Science Secretary, and Mr. A. S. Aldis, his deputy, also Mr. R. D. Owen himself for his work on the Local Arrangements Committee. Indeed, all the members of the various committees whose task it had been to look after the various parts of the meeting were to be thanked, not forgetting the ladies responsible for many of the social arrangements. Finally, for himself, he expressed his deep indebtedness to the civic and university authorities for their co-operation.

The dinner concluded with the singing of "Land of our Fathers."

CHRISTIAN MEDICAL FELLOWSHIP BREAKFAST

The annual breakfast of the Christian Medical Fellowship was held at the Continental Café, Cardiff, on July 15, with the President of the Association, Mr. J. W. TUDOR THOMAS, in the chair. In introducing the speaker to the large company, the President mentioned that the Rev. D. Martyn Lloyd-Jones was a member of the medical profession before becoming a minister. He had worked at St. Bartholomew's and in close association with Lord Horder. He was now the minister of Westminster Congregational Church.

Dr. MARTYN LLOYD-JONES said that he had pondered much on the subject to choose for his address. Should it be about faith-healing or the relationship of the Church and medicine? Finally he had decided to be governed by a medical dictum, and give the "patient" what he thought was the best thing for him, taking as his theme the doctor's personal approach to life and to death. Those in the medical profession had certain peculiar temptations, perhaps the most serious being a proneness to objectify everything and take a detached view. In a way this was inevitable, because a doctor obviously could not allow himself to be affected emotionally by every case he treated. He had to put up a protective barrier against the troubles and the suffering of others, and especially perhaps against the fact of death. The danger lay in this objectiveness becoming a fixed habit, so that he might fall into the terrible error of never really facing himself and his life at all. The speaker adapted an epitaph of which he had heard—"Born a man, died a doctor."

For this complaint he had no need to prescribe for the patient. The prescription was ready to hand in the Bible. All that he, as a minister, had to do was to dispense it. He proceeded to read the story from St. Luke of the man who had laid up for himself riches on earth and when the time came to take his ease and enjoy himself death came to him, for which he had made no provision at all. Dr. Lloyd-Jones said he had no intention of speaking about riches. He read the newspapers and was therefore familiar with the fact that during the last five years doctors had become semi-paupers. What he was interested in was the kind of man this was in the story. He was a man who had prided

himself on his hard-headedness, his worldly wisdom; he was a wise man who looked ahead, particularly proud of his foresight and carefulness, one who took an objective view of everything. And Christ had said that this man was a fool. He had failed at the very point where he had always thought himself strong; he had looked ahead and catered for every eventuality except one—he had not catered for the thought of death.

It was a fact that in this world we very often failed to see the thing that was most clearly before us. One might say that doctors were not interested in death, but in life and health. That was true, but was there anything that tended to affect life more than death? The fear of death and the thought of death was one of the most potent factors affecting our health and our well-being from day to day. It was indefensible to refuse to face up to it.

The man in the story was a fool because he had thought of himself in terms of possessions and success. This was an insult to his being and to his Creator, in whose image he was made. Man was more than a reasoning animal, he was destined for communion with God. This man had refused to face the fact that he would come face to face with God and justify himself. What had he done with the gifts God had given him? All gifts came from God and must be used as God intended. The only way by which a man could face the meeting with God was through belief that in Christ he had been offered forgiveness for all his wrongdoing.

Again, the man was a fool because he was a poor judge of riches. True riches consisted in peace of conscience, not in the measure of possessions gathered in this world, and were to be found in the Gospel of Christ—the knowledge that death is not the end of life but the beginning of eternal life.

Dr. Lloyd-Jones concluded: "I suggest to you that these are the things which the doctor needs to think of. You are gathered together to think of the patient and his needs and his diseases and the cures and the problems. It has been my humble privilege to say these few words, to beseech you, as a one-time medical man who still loves the profession and every man and woman who belongs to it, not to allow the profession to make you forget yourself. You are a man, and not merely a medical man. Face yourself and what is inevitably true about you, as it is true about every other human being."

The PRESIDENT, in thanking Dr. Lloyd-Jones for his inspiring words, said that his rhetoric and delivery had kept the rapt attention of everyone, and all must have been struck, as he had been, by the obvious sincerity in every word he had spoken.

CIVIC RECEPTION

The City Hall, Cardiff, which for several days had resounded to medico-political discussion, transformed itself into an arena of gaiety on July 15, when a civic reception and dance was attended by a company of about 1,000. The guests were received by the Lord Mayor (Sir James Collins) and the Lady Mayoress and by the President of the Association (Mr. J. W. Tudor Thomas) and Mrs. Tudor Thomas.

Many of those attending were in academic robes. Among those present were the Chairman of Council and Miss Gregg, Dr. and Mrs. P. T. O'Farrell, the Archbishop of Wales (Most Rev. Dr. John Morgan), Sir Russell Brain (President of the Royal College of Physicians) and Lady Brain, Professor W. J. O'Donovan, of Cork, President of the Irish Medical Association, Sir Frederick Rees, former Principal of University College, Dr. R. M. F. Picken, Provost of the School of Medicine, and Dr. David G. Morgan, medical superintendent of Llandough Hospital.

During supper in the Lord Mayor's parlour a representative from Hawaii, Dr. W. B. Quisenberry, director of the Bureau of Hygiene, assisted by his wife, performed the picturesque ceremony of Hawaiian welcome and farewell. Dr. Quisenberry garlanded the ladies of the company and

his wife the gentlemen, the garlanding being accompanied by the customary kiss and the Hawaiian salutation, "Aloha."

Dancing continued until a late (or early) hour, and for the more serious-minded the civic treasures of Cardiff were on display. The flood-lighting of the City Hall and the adjacent buildings in Cathays Park, and the wealth of flowers and Coronation decorations made a brilliant spectacle for the visitors and for the crowd who watched their arrival.

POPULAR LECTURE

SIR RUSSELL BRAIN ON DR. JOHNSON

The Popular Lecture which concluded the proceedings of the Annual Meeting at Cardiff was given on July 17 by Sir RUSSELL BRAIN, P.R.C.P., whose subject was "Dr. Johnson as Scientist and Patient." The chair was taken by Mr. Tudor Thomas, the President, supported by the Lord Mayor of Cardiff and by the Chairman of Council and the Chairman of the Representative Body. The Reardon Smith theatre was well filled.

Johnson and Science

Dr. Johnson, said the lecturer, was famous, not so much because of his literary achievements as because of his personality, particularly as revealed by Boswell. But Boswell did not invent Johnson, he only reported him, and some of the less familiar aspects of Johnson were revealed from other sources and showed a mind wider in scope and richer in interest than the Johnson of Boswell. Boswell, for example, never suggested that Johnson knew anything of science, and yet from casual observations it was evident that Johnson had an eager interest in and some acquaintance with the scientific and philosophical discussions of the eighteenth century. The best account of Johnson's interest in chemistry was given by Hawkins. At Streatham, apparently, Johnson contrived some chemical experiments until these were banned by Mrs. Thrale. At the close of his life he interested himself in and gave learned descriptions of the principle of the air-bladder or balloon, which was then evoking much public interest. He evidently had a grasp of both chemistry and physics. His limitless curiosity found scope also in natural history. He measured the rate of growth of his nails and hair. He was concerned about the disappearance of swallows in winter. He was vastly interested in the kangaroo, first described by Captain Cook in 1773, the year of Johnson's tour of the Highlands, and there was a humorous account of Johnson's imitating the shape and motion of the kangaroo, gathering up the tails of his big coat and making vigorous bounds about the room. One of the specimens taken by Captain Cook's party was given by Sir Joseph Banks to the Royal College of Surgeons, and it was only a few years ago that bomb damage at the College brought about the end of Johnson's kangaroo. Johnson seemed to have been in touch with physiological research; in the *Idler* he revealed himself as an antivivisectionist, and he also entered into evolutionary controversies concerning the orang-outang and the human tail which in some way anticipated Darwin. Sir Russell Brain quoted an instance in which Johnson revealed himself as an "unqualified practitioner," prescribing for a lady, of whose complaint he had been told by her physician, a remedy which consisted of taking one ounce of dried orange peel, finely powdered, and divided into scruples, each scruple being drunk in a glass of red port—a medicine, he said, which was not disgusting.

Johnson's Infirmities

In early life Johnson received the "royal touch" from Queen Anne, and he was a sufferer from many infirmities, but he had a strong constitution which enabled him to survive to the age of 75. During the last ten years of his life he suffered increasingly from shortness of breath and cardiovascular incompetence. He took opium, two or three grains a night, for his dyspnoea. Sir Russell Brain showed

portraits of the doctors who attended Johnson in his later years—in particular Richard Brocklesby, Dr. Warren, Dr. Heberden, and Mr. Cruickshank, the surgeon.

The singular appearance and nervous habits of Johnson had often been remarked. He appeared to be in a state of constant agitation. Miss Reynolds, sister of Sir Joshua, described his extraordinary gestures, such as stretching out his arm in any direction with a full cup of tea in his hand, to the peril of the clothing of his neighbours, also the continual movement of his head, hands, and feet, all in motion at the same time. Some people thought it was a nervous disorder, but had that been so he could not have controlled the movement when he wished, and this he certainly could do. Boswell suggested some form of St. Vitus's dance, but Sir Joshua Reynolds declared that it came from habit in which he indulged by accompanying his thought with some form of physical action, and Sir Russell Brain believed that Reynolds and not Boswell was right. A Miss Hunter once, with great temerity, asked Johnson why he made such strange gestures, and his answer was, "From bad habit."

Johnson was afraid of death and afraid of many things. He had a consciousness of guilt and sin, and periodical attacks of severe depression. It seemed ironical that a man of such disordered mind should have come to be regarded as the embodiment of British common sense. But his mind must have been of exceptional quality. Was his mental gloom or disorder a handicap or was it the necessary accompaniment, so to speak, of so virile an intelligence, a memory so remarkable, a habit of thought capable of such richness of association and verbal discrimination as made him the author of so famous a dictionary? Madness was common, genius was rare, and Johnson with all his infirmities was a genius who had achieved greatness and immortality and was secure in the affection of mankind.

On the motion of Dr. E. A. GREGG, Chairman of Council, a resolution of thanks was accorded by acclamation to the lecturer.

OFFICIAL RELIGIOUS SERVICE

The official religious service in connexion with the Annual Meeting was held at St. John's Church, Cardiff, on July 14. Members assembled and robed at the City Hall and walked in procession to the church. The service, conducted by the vicar, Canon T. M. Hughes, included thanksgiving for the advance of medical science and prayers for the medical profession and the hospitals and nursing services. The First and Second Lessons were read by the Chairman of Council and the President respectively.

The preacher was the Archbishop of Wales (Most Rev. John Morgan, D.D.). After a reference to St. Luke, the beloved physician, he went on to describe the ideal doctor, adding that he could not suppose he would be as successful as Chaucer in depicting the ideal parson:

"... Cristes lore, and his apostles twelve,
He taughte, but first he followed it himselfe"

—but it was a task worth attempting. In the first place, the doctor must have a sense of vocation. This needed explaining because the word "vocation" had become precious; it was usually restricted to the ministry, and it had come to be regarded as something rare and strange, possibly visionary. But "vocation" was exactly what the word meant—a calling by God, a kind of request that each man or woman will do some particular work. The call, of course, might come in some dramatic way, but ordinary people were usually called to their work in some ordinary way, and the mistake must never be made of assuming that the extraordinary was necessarily more valuable than the ordinary. For each of them, happiness in his work came largely through the belief that he had been called upon to do it. No doubt a doctor could carry on his task without vocation. He might do so for a variety of reasons, some of them good, and others indifferent. But if a doctor had had no sense of vocation there would be a sense of frustration and disappointment.

He would be called upon to undertake monotonous and depressing tasks, to see people under conditions which emphasized their failings rather than their good qualities, and if he was not fortified by the sense of vocation he would be tempted to ask himself, "Is it all worth while?" A man could rise above this only if he knew that he was not only doing good work but work to which God had called him. A real sense of vocation was a great protection. It was easy to see the harm that could be done by the exercise of mere competence without this higher calling. There were teachers who were able to impart knowledge to their pupils without giving them a love of knowledge. There were priests who could be silver-tongued in the pulpit and yet had no love for souls.

In the world as it was at present there was probably a greater amount of philanthropy and care for the unfortunate than ever before in history, but whether that state of things was likely to continue with the decay of Christian belief was very doubtful. The Christian faith began with one commandment—"Thou shalt love the Lord thy God and thou shalt love thy neighbour as thyself." Christ was the first person who had put together these two sentences from the Law of Moses. Through the centuries the two things had sometimes become divided again; it was rather like a candidate faced with an examination paper which bore the note, "Attempt either." Man could take his choice, either serve God or serve his fellow-man. And the next step would be inevitable. We saw around us many examples of kindness and good nature, but we might not be far from the truth if we regarded them as remnants of the more Christian past. They were rather like the brightness that lingered in the sky after the sun had set. The goodness to be seen in this country was not a rock on which we could build a brave new world; it was rather a legacy from the past, because you could say "I believe in man" only after you had said "I believe in God."

The ideal doctor must also have imagination; but what was meant by imagination? To quote a dictionary definition: imagination was a mental faculty for forming images of external subjects not present to the senses; a creative faculty of the mind. Having imagination did not really mean seeing things that were not true, it was rather a gift of seeing things from the point of view of someone else, of getting outside oneself and taking the larger view. It was often more than this, he knew, but he thought he had said enough.

In conclusion the Archbishop said that he had made no reference to professional training, nor had he touched upon the necessity for a high standard of morality, and these omissions had been deliberate. By making such omissions he was paying the profession the greatest possible compliment. "When one is ill and sends for the doctor it is taken for granted that he will be both competent and honourable, and this assumption springs from the experience, not just of one person, but of thousands over many years. Is not the fact that this is taken for granted the highest praise that society can give you in your great profession?"

ROMAN CATHOLIC SERVICE

Holy Mass was celebrated at St. Peter's Church, Cardiff, on the morning of July 14. Roman Catholic members attending the Annual Meeting assembled and robed at the Mansion House, where a reception was held after the service.

The celebrant was His Grace the Archbishop of Cardiff (Most Rev. Michael McGrath), and the sermon was preached by the Rev. Barrett J. Davies, B.D. In his sermon Father Davies devoted himself to the theme that the use of created things must not frustrate the purpose for which they were created. To the agnostic, he said, things might be used for any purpose for which they could be used. This led to the complete exploitation of Nature. In the modern sphere agnosticism produced humanism, a rejection of God as the last end of the universe, and the substitution of human convenience as its final purpose.

"As doctors you are in the forefront of this conflict between humanism and Christianity. The campaign for euthanasia, contraception, and so forth is increasing, and the agnostic cannot understand our objection to these evils because he sees no final purpose in human life or its functions. There is no common ground on which he is prepared to meet us, precisely because he has been brought up in this modern heresy. To those who reject the revelation the existence of a Creator and the knowledge of the final purposes of the universe must remain unknown."

"If we can do nothing as individuals to bridge this unfortunate gulf between agnosticism and Christianity we can at least safeguard our own position. We can change belief into conviction. We must make it clear to ourselves as well as to others that we reject these evils not because they are forbidden by the Church but because they are intrinsically wrong; they violate the divine order of the universe. The half-hearted Catholic accepts the Church's ruling on these matters reluctantly. He is torn between his loyalty to the Church and his desire to conform to the pattern of this world. This will not carry conviction to others. The agnostic will respect true conviction whenever he finds it. He will not ask his Christian colleague to do anything which violates his conscience if he feels that that conscience is formed, not by the prohibition of any external authority, but by a deep inner conviction. Such conviction comes only from a fully integrated personality."

The death of Christ, said the preacher in conclusion, was a consecration of the whole human race to God, reconciling us and restoring the final purpose for which we were created. "On the Cross Christ offered Himself once for all; in the Mass I fulfil my part in that sacrifice, I offer the divine Victim for myself. He has already made Himself my Victim by dying for me. I also make Him my Victim by my co-operation. I declare that He truly represents me. I offer myself to God in union with Him. We may say that it is Christ who is sacrificed in the Mass, but it is ourselves that we offer."

OPENING OF EXHIBITIONS

The exhibition of medical and surgical appliances, drugs, foods, and books, and the scientific exhibition, both of which were housed in Sophia Gardens Pavilion, Cardiff, were opened by the President of the Association, Mr. J. W. Tudor Thomas, on Monday morning, July 13. In the trade exhibition 64 exhibitors had stands.

The President, who was supported by the President-elect and the principal officers, said that they were very fortunate in Cardiff in having a large hall in which both exhibitions could be accommodated. The scientific exhibition was in the centre, and the trade stands grouped around.

The nature of the trade exhibition was set out in the official catalogue. The firms exhibiting were of the highest standing, and, indeed, firms which were known all over the world. The quality of the goods displayed, from a minute thing like a hypodermic needle to a complicated piece of apparatus, was of the highest. They were carefully packed and attractively displayed, and everyone would find the greatest interest in looking round at what was on view on the stands. He thought he could say that the firms were out to please medical men, who were not always easy to please, but, in endeavouring to please them, what they were really trying to do was to produce something which was best for their patients. He expressed gratitude to the exhibitors, who had taken great pains and trouble in putting before them everything they needed. He hoped the exhibitors would derive some measure of benefit from the trade which would naturally and properly result from their efforts.

In the centre was the Scientific Exhibition. Here there were 32 stands representing a great deal of carefully prepared work—research work—the result of much thought and planning. He knew, personally, in the case of some of the exhibits how much care and thought had been put into their planning. Here one could see the results of a great deal of modern thought in medicine, surgery, and pathology. The wide range of subjects covered by the exhibition was outlined in the Handbook of the Meeting. He expressed gratitude to the individual doctors and institutions whose medical departments had gone to so much

trouble to put these things together in a very attractive form in the exhibitions, and he declared both exhibitions open.

The Representative Meeting was put back for a short time in order to permit of representatives making a tour of the exhibitions.

THE TRADE EXHIBITION

Seldom at an Annual Meeting has the exhibition of surgical instruments and appliances, drugs, foods, books, and other equipment of interest or necessity in medical practice been so pleasantly housed as at Cardiff. The Sophia Gardens Pavilion is built for utility, but its architectural plan is pleasing, and it comfortably accommodated the stands of the trade exhibitors, and also, in an enclosed centre, the scientific exhibition, to which various schools, public health departments, laboratory services, and research institutes had contributed. At the end of the hall, on a dais, was the registration counter for members and a display by the British Medical Association of the many journals which it now publishes. The exhibition had a uniform scheme of general decoration, leaving plenty of scope for individual arrangement. As space is insufficient to give a description of each stand, and to mention some exhibitors and not others would be invidious, only a visitor's impression can be given.

Antibiotics and Hormones

Almost half the stands were devoted to the products of the laboratory in the form of drugs, pharmaceutical preparations, and dietetic foods. Here were to be seen the whole range of antibiotics, hormone products, antiseptics, vaccines and prophylactics, and so on. One of the stands was almost wholly given up to terramycin. Combinations were much in evidence, such as an oral preparation of streptomycin combined with sulphaguanidine, or tablets containing penicillin and a sulphonamide. A.C.T.H. freeze-dried for rapid solubility was exhibited. One firm concentrated on glucose in various forms, included a glucose barley-sugar base into which halibut oil was incorporated. Among the anaesthetics was one product which it was claimed would maintain local analgesia for a week or longer after a single injection.

Appliances and Equipment

The appliances and equipment section revealed again the ingenuity which goes to the making of instruments. Here were anaesthetic apparatus in new patterns, operation tables, and stainless steel instruments. Nylon was in evidence as a material for unbreakable hypodermic needles. Attention was drawn to a monocular ear-microscope, a portable instrument developed by the otological unit of the Medical Research Council. At one stand an appliance was shown designed for the purpose of promoting breast-feeding. This device, for initiating and maintaining lactation, takes "feeds" from the breasts exactly as if it were a real baby; indeed, it does better, for the "feeds" can be taken from both breasts at once. The visitor was faced with a bewildering variety of plasters, dressings, and the like, including a new form of tubular gauze bandage. At least four stands had an elaborate display of ophthalmic instruments. An intraocular acrylic lens was in evidence. Devices to ease the doctor's burden included a new form of dictating unit and a mobile radiotelephone.

Auxiliary Services

The Board of Registration of Medical Auxiliaries exhibited the current registers of its six sections and much other literature concerning the various branches of medical auxiliary work, and at an adjoining stand the N.O.T.B. (Medical Eye Section) offered particulars of its services to a membership which is open to ophthalmic medical practitioners and dispensing opticians. The Medical Insurance Agency was there to offer expert advice on all insurance matters, and the London Association for Hospital Services explained its plan for providing for the expense of private ward or recognized nursing-home treatment. Finally there were seven book-

stands which tempted one to linger, and evoked the reflection that here in the world of medical publishing was an elegance which matched that shown elsewhere in the Exhibition by the pharmacists and the instrument designers. Altogether the exhibitors are to be congratulated on a fine piece of work and perhaps commiserated with on the fact that the fullness of the programme of the Annual Meeting allowed members only a limited time for inspection.

HEARD IN CATHAYS PARK

Badges for All

The most unobservant citizen of Cardiff could not have helped noticing that something of unusual interest was taking place in his city, for every second person was badged. Sixteen different sorts of badges were worn on the various lapels, from the dark red of the local committee men, the dark blue of the members of Council and Headquarters staff, the dark green of officers of the scientific sections, to the light red of the Press, and the cream of the ladies. The streets themselves were badged, having been admirably sign-posted by the Automobile Association in collaboration with the chief constable. Then, again, academic robes were worn on six distinct occasions in Annual Meeting week, and academic robes give both colour and dignity to any setting. Even in a year of pageantry the church procession from the City Hall to St. John's and from the Mansion House to St. Peter's was grateful to the eye.

Official Receptions

After the President's reception in the National Museum of Wales on July 13 (see p. 57) it was the University's turn the following night. Joint hosts were the University College of South Wales and Monmouthshire and the Welsh National School of Medicine. The guests were received by Principal Anthony Steel and Mrs. Steel on behalf of the University and by Dr. R. M. F. Picken, Provost of the Welsh National School of Medicine, and Mrs. Picken. This was a colourful occasion, for as a background to the academic robes of the men and the evening dresses of the women there were flowers in profusion.

In fact, the floral decorations everywhere were a feature of the meeting: even the table on the platform at the Plenary Sessions was graced with an armful of roses. On July 15 there was a Civic Reception and Dance at the City Hall. The Lord Mayor of Cardiff, Sir James Collins, and Lady Collins welcomed the guests.

Parties and Dances

The scale of the Cardiff hospitality was set at the beginning of the meeting by the sherry party given by the Cardiff Division (Chairman, Professor A. G. Watkins) on July 8. About 1,000 people were present. A few days later, on July 14, the Monmouthshire Division (Chairman, Dr. B. A. Thomas) gave a sherry party at St. Mellon's County Club. Here again a very large number of guests greatly enjoyed themselves in the pleasant surroundings of this well-known club, which most generously offered honorary membership to members of the B.M.A. attending the meeting.

One of the functions held in the newly opened B.M.A. House in Cardiff was a sherry party for women representatives given by the South Wales Association of the Medical Women's Federation. This was on July 10.

Of the two large garden parties held during the meeting, the first was on July 16 at Margam, by invitation of Mr. and Mrs. Evans Bevan.

Strangers to Glamorgan usually underestimate the beauty and interest of the county. A pleasant surprise was in store for the many members of the Association and their ladies who accepted the generous invitation of Mr. and Mrs. Evans Bevan. Fortunately the weather remained fine and guests were able to enjoy the fine setting of Margam Abbey and the

Castle. After being received by their host and hostess, guests climbed a beautiful slope bordered by trees and crowned by the Castle, about 120 years old and unfortunately unoccupied. The view of the Bristol Channel from the Castle terrace was admired, and guests then descended to the oldest Orangery in Europe for a generous and perfectly organized tea, ended by one of the briefest and most agreeable speeches of the Annual Meeting (the speaker was the President, Mr. Tudor Thomas). The very fine Abbey, dating from 1147 and still filled with worshippers every Sunday, was visited after tea as well as the ruins of the adjacent Chapter House of the monastery, which once had 2,000 monks attached. As the garden party ended, a sudden shower drove the visitors to their cars and buses—and so back to the preparations for the Annual Dinner.

On the next day, July 17, the Board of Governors of the United Cardiff Hospitals gave a garden party at Duffryn House, where the guests were received by Mr. Gilbert D. Shepherd, chairman of the Board of Governors of the United Cardiff Hospitals, and Mrs. Shepherd. Among other notable occasions was a complimentary luncheon in honour of the President, Mr. J. W. Tudor Thomas, given by Sir Robert Webber, managing director of the *Western Mail*.

For those fond of dancing there was no lack of opportunity: the Representatives' Dance on July 8; a dinner-dance at St. Mellon's County Club on July 10; a dinner-dance at Porthcawl on July 11; a dance after the Civic Reception on July 15; a dinner-dance at St. Mellon's on July 18; and finally the B.M.A. Summer Ball in aid of the Ladies' Royal Medical Benevolent Guild at Cardiff Castle on July 17.

Excursions

Thanks to the efforts of the Entertainments and Excursions Committees many interesting excursions were arranged both for members and for their wives. On Sunday, July 12, there was an all-day excursion to St. Donat's Castle. One of the first to encourage others to try the swimming-pool by sampling it himself was the chairman of the Representative Body. Later in the evening Representatives had the opportunity of listening to Welsh choral singing at a concert in the New Theatre.

South Wales at Work

One greatly admired those members who, declining such events as garden parties and other pleasant outings, and remaining aloof from golf courses and tennis lawns, betook themselves to one or other of the three great steelworks of South Wales which opened their gates to the Association. Some of them conscientiously went through the pattern shops, the blooming mills, and the tin-plate plant, and got as near they could to the blast furnaces, or accepted the National Coal Board's invitation to go down the most modern colliery in the country, the name of which—Nantgarw—few ventured to pronounce, and to visit the coke ovens and by-product plant there, which is said to be the finest in the world.

The Annual Dinner

Wonderful as was the setting for the Annual Dinner under the barrel roof of the City Hall—as fine a hall as there is in this country—the visitor on looking at the toast list, with six separate toasts and fourteen speeches, felt his stomach sink. As it happened, in spite of the amplifying equipment, some of the speeches were heard only with difficulty. The speaking began at 10.15 p.m. and ended a couple of hours later. The dinner this year was not so well attended as it should have been, and two hours of after-dinner speaking is likely to discourage members and their wives from being present at such an important function.

The Ladies

The smoothness and efficiency of the arrangements made for the entertainment of the lady visitors to Cardiff testified to the great efforts which must have been put in to all the

organizational work by the various ladies' committees, especially the executive committee of which Mrs. J. W. Tudor Thomas was the chairman and Mrs. J. D. Spillane the secretary.

The Ladies' Club in the university, at which about 350 ladies registered, was a haven of rest and refreshment, and from it the ladies were escorted, as their fancy took them, to mannequin parades at St. Mellon's County Club, to tea parties at country houses, or to places of historic interest, such as Caerphilly Castle and Caerleon. The Ladies' Dinner on July 9 was a gay and friendly affair.

Golf

The golf competition for ladies was played on the Barry Links on July 15, the Notts Ladies' Challenge Cup being won by Mrs. Jack Matthews, of Cardiff. The competition for the Treasurer's Cup was played on the Royal Porthcawl Links on July 16. The winner was Mr. L. P. Thomas, F.R.C.S., of Cardiff, with a net score of 77. The Leinster and Childe Cups were played for on the Southerndown Links on July 19, the winner of the former being Dr. J. L. Jones, of Bridgend, who was two down on bogey, and of the latter being Dr. W. J. Lewis, of Maesteg, Glam., also two down on bogey.

PUBLIC HEALTH

REMUNERATION OF ASSISTANT MEDICAL OFFICERS OR MEDICAL OFFICERS IN DEPARTMENTS

The following circular (M.D.C. Circular No. 17, dated July 9, 1953) has been issued to all local authorities in England, Wales, and Scotland, by the joint secretaries of Committee "C" of the Medical Whitley Council.

1. As negotiations upon revised salary scales for assistant medical officers or medical officers in departments failed to result in agreement the matter was referred by the two Sides of Committee "C" to the Industrial Court for determination in accordance with the provisions of the Industrial Courts Act, 1919. After hearing the parties, the Court made the following award:

(a) The salary scale of assistant medical officers or medical officers in departments shall be £950 by £50 to £1,300.

(b) Paragraph 13(c) of Award No. 2321 shall apply as before, the scale for assistant medical officers being adjusted to £950 by £50 to £1,300.

(c) The new scale shall be applied to the present holders of such appointments, assimilation being at the point on the new scale corresponding with the medical officer's position on the old scale. A medical officer now at the maximum (£1,150) of the old scale shall be placed at the sixth point (£1,250) of the new scale and shall thereafter proceed to the new maximum (£1,300).

(d) The operation of the new scale shall not in any circumstances result in reducing the salary of any medical officer in post.

Effect shall be given to this award as from June 1, 1953.

2. This award (No. 2452) has been considered by Committee "C" of the Medical Whitley Council. The Committee has accepted the award and recommends all local authorities to put it into operation.

3. Printed copies of the Industrial Court Award No. 2452 may be obtained from H.M. Stationery Office.

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

Metropolitan Borough Councils.—Fulham, Southwark.
Non-County Borough Councils.—Crewe.
Urban District Councils.—Houghton-le-Spring.

Correspondence

Because of the present high cost of producing the Journal, and the great pressure on our space, correspondents are asked to keep their letters short.

Cost of Prescribing

SIR,—I address you both as a physician and as a taxpayer. Digitalis folia and digoxin have similar effects on the heart except for that of speed of action. Digoxin in full doses by mouth has a good pharmacological action within a few hours, and by intravenous injection it acts more quickly still. Digitalis folia in full doses is not fully effective within two to three days. Thus in acutely ill patients there is no question as to which drug should be used. But for ordinary maintenance therapy there is nothing to choose between the two.

From a large experience I know that many doctors, perhaps a majority, prescribe digoxin as a maintenance drug, either because they mistakenly think that it constitutes more scientific therapy, or, as I rather suspect, because of laziness. Digoxin is one word and digitalis folia is two.

As a taxpayer addressing taxpayers I would like to remind them that the retail price of 100 tablets of digitalis folia 1 gr. (65 mg.) is 1s. 8d., and of 100 tablets of digoxin, 0.25 mg., is 4s. 2d.; and that the equivalent special wholesale price to hospitals is 2s. 6d. for 1,000 tablets of digitalis folia and 24s. 7d. for 1,000 tablets of 0.25 mg. digoxin. I suggest that it is to their financial advantage to write two words instead of one.—I am, etc.,

London, N.W.1.

GEOFFREY BOURNE.

SIR,—It looks as if we are being rushed once more over the question of prescribing, with special emphasis on proprietary preparations, the reason given being the cost of them *vis à vis* the *National Formulary*. I hope long and deep consideration will be given to this, as there are very grave implications involved. We are astonished at the cost mainly because the cost of the whole service was based on valueless statistics worked out by experts for a totalitarian service.

The cost of prescriptions seems excessive, and if it really is excessive—I am not admitting that it is—the blame must be shared equally by the Government, the patient, and the doctor—the Government because of shocking under-estimating, the patient because of excessive demands on the doctor, and the doctor for satisfying the excessive demands of his patient, who was assured that he could have anything and everything for curing or alleviating his ill-health; and here let me suggest very forcibly that the patient must have a considerable say as to whether his demands are excessive—or hasn't he?

The question of proprietary preparations being expensive has of course many facets. A firm may spend thousands on research and clinical tests, etc., and this will have to form part of the cost. Another firm may just copy the formula and manufacture it—without any research—at a much lower cost.

We should not accept too readily the statement that the drug bill of £40m. for 50 million people is excessive, considering the price of such things as cotton-wool, bandages, lint, and the antibiotics, etc. If we accept too readily and too easily that we are prescribing too expensively we may be putting back curative medicine many years, for, after all, we are the part of the research department of health which is best placed to test the therapeutic value of any preparation. It should be up to the Government to tell the manufacturers to reduce their prices. We seem to be moving towards the dictation of a group of Government experts on what we must and must not prescribe.—I am, etc.,

St. Osyth.

R. E. CLARKE.

Demands of Whole-time Specialists

SIR,—The cause of the whole-time specialist is dear to many of us. It is much to be regretted that at this late date there is still confusion as to the relative importance of many of the points at issue. All of the points expressed by Dr. Leo Gilchrist (*Supplement*, June 27, p. 314) are relatively insignificant in comparison with the importance of implementation of the Spens recommendations. Let us not ignore the wood for the trees.

Until recently the claim for income-tax reliefs could without distortion be interpreted as an attempt to obtain preferential treatment, however justified, over and above every other class of wage and salary earner, professional and otherwise, throughout the country. The present claim for consideration is now only properly based on the judgment of Mr. Justice Gerrard in the case of *Crawford v. Charing Cross Hospital* (*Journal*, May 2, p. 1001). Dr. Michael Ashby in his letter (*Journal*, May 9, p. 1051) quotes from the judgment as follows: "Nice questions might arise as to how far a medical man could excuse his ignorance of a technical development that he had not met in his reading of his professional journals." "It was the anaesthetist's duty to follow up the writings on a subject which concerned him closely." "I think it was regrettable slackness that left Dr. X in ignorance of the opinions of distinguished men on an important subject so closely affecting his own work at the time he came to administer the drip to the plaintiff." Of course some of us feel strongly about these many points, but first things must come first, and at present the first thing must be Spens.

But for Dr. Gilchrist to state that the Government is "paying him less than one-tenth of the cost of using it (his car) on official business" is a greater disservice to the cause of the whole-timer than even its worst enemy could concoct. We are not asking for the travelling allowances to cover the wages of the chauffeur and the gardener who keeps the drive weeded. Informed opinions seem to agree that one-half is probably nearer the figure. The Staff Side of Whitley "B" has an almost unendurable task as it is. But for them to be harassed by wild fantasies of this sort makes it just about impossible.—I am, etc.,

Worcester.

ANTHONY A. VICKERS.

Branch and Division Meetings to be Held

WEMBLEY DIVISION.—At Wembley Hospital, Fairview Avenue, High Road, Tuesday, July 28, 9 p.m., meeting. Report on Annual Representative Meeting, speaker Dr. McConnell Thomson.

Meetings of Branches and Divisions

COUNTY ARMAGH DIVISION

The annual meeting was held in Armagh on June 23, 1953. Dr. F. M. J. McFerran was in the chair. The following officers were elected:

Chairman.—Dr. H. A. McCaffrey.
Vice-chairman.—Dr. T. A. Spence.
Hon. Secretary and Treasurer.—Dr. D. L. Hemmingway.

WESTMINSTER AND HOLBORN DIVISION

At the annual general meeting the following office bearers were elected for the session 1953-4:

Chairman.—Dr. J. L. McCallum.
Vice-chairman.—Dr. Alice E. N. Gilby.
Secretary and Treasurer.—Dr. Arthur A. Bradley.

The B.M.A. in Committee

OCCUPATIONAL HEALTH

Occupational health is by no means a new concept, and the subject, in one form or another, has had the attention of the British Medical Association all through its history. To come to quite recent times, in 1941 the Association set up a Committee on Industrial Health in Factories, which made a useful report, influenced, of course, by the special war conditions then prevailing. The formation of a special committee devoted to this subject as one of the standing committees of the Association dates back only for a few years. Formerly questions affecting practitioners engaged wholly or partly in industrial medical service were dealt with by a subcommittee of the General Practice Committee (which, with the coming of the National Health Service, bequeathed its functions in part to the General Medical Services Committee and in part to the Private Practice Committee).

Outside Nominations

The constitution of the Occupational Health Committee is unusual in that as many as seven of its twenty members serve on the nomination of bodies outside the British Medical Association. It is true that the Public Health Committee has two members nominated by the Society of Medical Officers of Health, and the General Medical Services Committee includes nominees from the Medical Practitioners Union and the Medical Women's Federation; but the Occupational Health Committee has seven members from outside—three of them nominated by the Association of Certifying Factory Surgeons (the term "Certifying Factory Surgeon" is now replaced by "Appointed Factory Doctor"), and four by the Association of Industrial Medical Officers, a body which represents those engaged both whole-time and part-time in industrial medical services.

This representation brings a valuable addition to the experience available to the Committee, but it has also led at times to some conflict of points of view. From a long experience of the committees of the Association the present writer would say that the Occupational Health Committee is a difficult committee to steer. Its admirable chairman, Dr. J. A. L. Vaughan Jones, of Leeds, who has piloted it from the beginning, has been able to bring different points of view into an area of agreement.

Apart from the members nominated by the two bodies just mentioned, there are four elected by the Council of the Association and four by the Representative Body, and one appointed by each of the four Association committees whose territory is contiguous to or overlapping that of industrial health—namely, General Medical Services, Central Consultants and Specialists, Private Practice, and Public Health.

As industrial dermatitis has been a subject much before the Committee there is also one member nominated by the Dermatologists Group Committee.

An Uneven Field

The Committee has a difficult task to discharge. The industrial medical service is not a compact uniform organization like, for example, the medical services in the defence Forces. Great Britain is a country of small factories. Out of more than a quarter of a million of them, only some 20,000 employ more than 20 people. Few industrial establishments are of a size to justify a whole-time medical officer of their own, and even among the larger establishments relatively few have definite arrangements for medical services, apart from some provision for first-aid and perhaps the appointment of a nurse. Many working communities are not within the scope of the Factories Acts of 1937 and 1948, and only about 350 inspectors are available for visiting the 280,000 work-places covered by the Act. A survey conducted in 1949 by the Ministry of Labour and National Service showed that the number of doctors with whom arrangements had been made for factory medical services in Great Britain was just over 3,000, and only 235 occupied whole-time appointments, though another 200 were giving a substantial amount of their time to factory work.

In spite of obvious difficulties the Committee has achieved a very large amount of excellent work. A report from the Council was approved by the Representative Body in 1949 recommending the establishment of a comprehensive occupational health service of a national character, integrated with the National Health Service, and planned and supervised by the Ministry of Health, after preliminary surveys to ascertain the special needs of different areas. Definitions and general principles were set out, and the problems envisaged by this report have since been under study in greater detail by the Occupational Health Committee.

Status of Industrial Medical Service

The Committee has laid down scales of salaries and increments for industrial medical officers. It has drawn up a concise statement of duties and ethical rules for the guidance of practitioners engaged in this service. Its latest task has been the production, after long travail, of a memorandum on the future of occupational health services, though at the moment this has not yet been approved by the Council. Its agenda contain matters involving the medical services in the mining, transport, or shipping industries, or public utility undertakings. On the initiative of the Association a number of joint councils of industrial health have been set up in appropriate areas. The Committee has made recommendations on the resettlement of tuberculous persons in industry. Many fields of occupational health research have been explored. Questions relating to the

examination of workers to determine fitness for employment, the notification of industrial diseases, the opportunities for careers in industrial medicine, postgraduate education for practitioners working in industry—all these matters and many others come continually in one form or another before the Committee. Like other committees also, it is called upon to give an opinion on, or sometimes to take action in, questions or disputes involving individuals or groups.

Possible difficulties in the relation between the industrial medical officer and the general practitioner have to be borne in mind. While ideally there should be perfect co-operation between the two, this is not always attained, owing to faults (or, more likely, inadvertences) on one side or the other. The workman at the factory whose temporary illness or injury is attended by the works doctor is also on the list of a general practitioner in the National Health Service. There is nothing to hinder a common-sense approach, but delicate situations do sometimes arise.

The Committee has also helped to maintain liaison with industrial leaders, on the one hand with the Trades Union Congress and on the other with the Employers Federation. For some years the Association has had a joint committee with the T.U.C. A panel of 16 members has been set up from whom a number are selected, according to the nature of the business to be discussed, to meet representatives of the trade unions, and in this panel several members of the Occupational Health Committee are included.

The work of some Association committees may well lessen or even disappear as time goes on, with the achievement of what they have set out to do; but the Occupational Health Committee has a very long way to go, and one can foresee for it an increasingly important role in Association counsels and in industrial affairs.

GENERAL MEDICAL SERVICES

DISCLOSURE OF CLINICAL DETAILS TO LOCAL MEDICAL COMMITTEES

Executive councils have a duty to recover the cost of a preparation prescribed if it appears to them that it was not prescribed as a drug. When an investigation into the facts is required a formal reference of the case is made, under the regulations, to the local medical committee, who then has the duty of making a finding which it communicates to the council.

Patient's Consent

In the past difficulties have occasionally arisen because the practitioner concerned has been unable to obtain the patient's consent to the disclosure of certain clinical details which are necessary if he is to be able to justify his prescribing. The objection is usually to the disclosure of medical information to the lay officials and lay members of the executive council. The General Medical Services Committee has therefore discussed with the Ministry of Health the best method of obviating the difficulty in the rare cases in which it arises.

The local medical committee, when the case is referred to it, are required to give the practitioner the opportunity of appearing before it or of submitting a statement in writing. The General Medical Services Committee and the Ministry feel that where the practitioner decides to submit a written statement including clinical details of a case no objection can be raised if the following procedure is adopted.

Suggested Procedure

The practitioner sends the details of the case to the secretary of the local medical committee, who is, in most cases, himself a doctor, or to the chairman of the committee. The secretary or chairman, as the case may be, discloses to his committee the clinical details which he receives, but without holds the name of the patient. The committee, in informing

the executive council of its findings, suppresses these clinical details, but the council will, of course, be in possession of the name of the patient through their clerk. Thus the secretary or chairman of the local medical committee is the only person who is in a position to connect the patient by name with the clinical details, and the objection to the disclosure of medical information to lay members and officials of the executive council is avoided.

CERTIFICATION FOR CREMATION

In view of the many inquiries received about cremation certificates the following statement is published to clear up misunderstandings which appear to have arisen.

Procedure of Certification

A special form is supplied by the crematorium company to be completed by an executor or the nearest relative, who must state, *inter alia*, that the deceased expressed no objection orally or in writing to cremation of his or her body.

A certificate ("B") of cause of death must be given by the doctor who attended the deceased during the last illness. A confirmatory certificate ("C") must be given by another medical practitioner of not less than five years' standing, provided that he is not a relative of the deceased or a relative or partner of the doctor who has given certificate B. The Home Office has advised that, when Form B is given by a house-officer in a hospital, Form C signed by another doctor of the hospital staff should be accepted only if given by the medical superintendent or, in the absence of such a post, by a consultant or senior hospital medical officer not in charge of the case. Failing these, Form C should be completed by an outside doctor. Both certificates B and C are also on a special form supplied by the company.

The Medical Referee

Certificates B and C are submitted to a "medical referee" appointed by the Secretary of State. If the medical referee is satisfied that the requirements of the Act have been complied with, that the cause of death has been ascertained, and that there exists no reason for any further inquiry or examination, he issues an "authority to cremate" and under this the superintendent of the crematorium is authorized to cremate the remains.

Fees

In 1951 the Annual Representative Meeting approved the following policy:

A suitable fee for the completion of either Certificate B or Certificate C is £2 2s., plus a mileage allowance, where applicable, at the rate of 1s. per mile or part of a mile, each way, outside a radius of two miles.

Special reference is made to cremation certificates in the Terms and Conditions of Service of Hospital Medical and Dental Staff (England and Wales). The furnishing of Certificate B is categorized as work within the scope of the hospital and specialist services provided under Section 3 of the Act, and therefore to be performed by members of hospital medical staffs as part of their hospital duties without charge. On the other hand, completion of Certificate C is deemed not to fall within the scope of the hospital and specialist services and may be given by members of hospital medical staffs on payment of an appropriate fee.

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

Metropolitan Borough Councils.—Fulham, Southwark.
Non-County Borough Councils.—Crewe.
Urban District Councils.—Houghton-le-Spring.

GENERAL MEDICAL SERVICES COMMITTEE

COST OF THE N.H.S.

An all-day meeting of the General Medical Services Committee was held on July 23, Dr. A. TALBOT ROGERS presiding. The President of the Association (Mr. J. W. Tudor Thomas) was welcomed on his first attendance. A welcome was also given to the new members of the Committee.

One of the principal items of business was the consideration of a memorandum by the London Local Medical Committee on the cost of the N.H.S. Dr. N. Levitt and Dr. N. Fisher attended to present the memorandum. They stated that when the Minister announced the appointment of an extra-Parliamentary committee to inquire into the cost of the Service the London L.M.C. considered it important that the profession should conduct an independent parallel inquiry. They suggested that a suitable set of questionnaires should be sent to a random sample of specialists, general practitioners, hospital administrators, and others, and that the returns should be studied by statisticians. The result would be available for comparison with the report of the Guillebaud Committee.

The deputation was asked how London proposed to obtain the very detailed information it expected from the hospital service. Obtaining it would give the administrative people in the hospitals a great deal of trouble. Moreover, hospitals were not likely to pass on information until after their figures had been sent to the Ministry and collated into the annual report laid before Parliament. The reply of the deputation was that the questionnaire was only a suggestion, but it was thought that a well-run accounting system would enable any hospital to answer such questions straight away. They asked the Committee not to fasten on the details of the scheme, but to consider whether such an investigation was desirable.

The CHAIRMAN asked what a committee of the sort proposed could find out which the Guillebaud Committee itself would not already have found out. Most of the conclusions of the Guillebaud Committee when they came forward would be debatable on the ground of opinion rather than of fact. Dr. S. WAND said that he was averse to starting an inquiry which would necessitate bringing in statisticians and so become a public inquiry with the expression of majority and minority opinions.

Dr. M. SORSBY, on the other hand, considered that an inquiry ought to be undertaken, with all the branches of the Service participating, so that the profession might be prepared to meet all possible contingencies.

The SECRETARY of the Association (Dr. A. Macrae) described the steps which the Association had taken after the announcement of the Guillebaud Committee. A small group had been formed consisting of the chairmen of the Council, the Representative Body, and of a number of standing committees. So far it had not been possible to obtain any indication from the Guillebaud Committee as to topics on which it would welcome evidence from the Association. This committee of chairmen was to meet again in September to draw up a list of topics for the various standing committees to which the task of preparing evidence was to be referred. The committees would then decide for themselves how they would prepare their part of the evidence.

In view of the action already proposed, the Committee decided that no useful purpose would be served by embarking on an independent inquiry on the lines suggested by London.

Subcommittees Reappointed

The CHAIRMAN said that the Committee had sustained the loss of one of its most useful members, Dr. Frank Gray, who had failed to secure re-election through the Representative Body. A vote of thanks was accorded to Dr. Gray for his past services.

Subcommittees were reappointed, including the Scottish, Rural Practice, Health Centres, and Protection of Practices, and the Committee's representatives were also appointed on certain other committees of the Association. The 14 representatives of the Committee on the Working Party were reappointed, and seven members were nominated to act as the Committee's representatives on the Medical Functional Council and nine on its Committee "A" (General Medical Services). On the question of the Joint Formulary Committee, on which the Committee appoints four representatives, two others being appointed by the Consultants and Specialists Committee and two by the Science Committee, it was pointed out that, although this was a committee which was intended solely for the help of the general practitioner, the Association representatives were in a minority. It was agreed to ask the Council to look into the composition of this committee.

The CHAIRMAN stated that the report of the subcommittee which had been concerned with service committee and tribunal procedure had been adopted, with a few amendments, by the Conference, and he suggested, and it was agreed, that the subcommittee be reconstituted to look at these amendments, and to take the report, as amended, to the Ministry.

Conference Resolutions

The Committee then turned to the various resolutions of the Annual Conference and decided the action to be taken on each. A lengthy discussion took place on the resolution concerning the allocation of patients to general practitioners, that a practitioner should not, by reason of his terms of service, be compelled to take or retain a patient who was accepting treatment from an unregistered practitioner or from another registered practitioner with whom he was not acting in consultation. The difficulty of doing this, particularly in sparsely doctoring regions, was mentioned. One member suggested that the help of the General Medical Council should be invoked, in view of the liability to a charge of "covering" in a case in which an unregistered practitioner was concerned. Dr. GUY DAIN, however, a member of the G.M.C., pointed out that the G.M.C. could act only in the disciplinary cases which came before it on information received, and would not be prepared to lay down general directions. It was agreed to discuss the matter further with the Ministry.

Employment of Salaried Assistants

At a previous meeting the Committee had considered a recommendation from the Assistants and Young Practitioners Subcommittee that, save for a period of three years, no principal in single-handed practice should be permitted to have a list of over 3,500 patients by virtue of the employment of an assistant. This had been referred back for further consideration, and the subcommittee now brought forward a recommendation that the extra list of patients allowed in any given practice by virtue of the employment of an assistant should be 1,000 for any length of time, but that once the principal's list exceeded 4,500 he should, within a period of two years, be required to take a partner, or at the end of the two-year period again to bring his list within the 4,500 limit.

Dr. ROSE said that this imposed another restriction on the freedom of the general practitioner, and it would be one of their own making. After all, assistantship was a very necessary phase in the making of a general practitioner. Dr. J. C. ARTHUR said that there were infrequent instances of exploitation of assistants under the specious promise of a partnership, and the only way to put the matter right was by local check. Dr. M. SORSBY supported the proposal, saying that something must be done to satisfy the just demand on the part of these young practitioners. Dr. J. A. PRIDHAM said that there were, no doubt, infrequent cases of a man who had no ambition to be other than an assistant, but in the ordinary way it was natural to look forward to prin-

cialship and partnership. He thought that the proposition should not be turned down, but that some statistics should be obtained in order to discover the extent of the problem. Dr. A. D. JAVIES thought that three years would be more reasonable than two, and also took exception to the word "required," which meant regulation. Dr. WAND pointed out that during the past five years, having regard to economic circumstances, a great deal had been done to meet the case of the assistant aspiring to be a principal, and it should not be forgotten that the whole effect of this was to eat into the final income of the practitioner. Dr. BRUCE CARDEW thought the proposition on the right lines, and suggested that it would be a good idea if some local body was charged with the duty of seeing that assistants were not unfairly treated.

The CHAIRMAN thought that what the subcommittee had now brought forward was a considerable advance upon their earlier proposition, and he reminded the committee that an undertaking had been given to present some scheme to the next conference.

Finally, it was agreed that the proposition be referred back to the subcommittee with a view to obtaining more facts and figures which might help the Committee in reaching a decision, and that the subcommittee be assured that the matter would receive further sympathetic consideration.

Other Business

A long discussion took place on the question of the declaration of practice vacancies. A resolution from Wolverhampton stated that executive councils and local medical committees, in considering whether a vacancy should be declared, were entitled only to take into consideration the circumstances of the district, and that they exceeded their statutory duty if they took account of such matters as whether a partnership was bona fide or not. The Committee listened to legal arguments by Dr. J. A. GORSKY, but in the end reaffirmed its concurrence in what was stated in para. 75 of its recent Annual Report (*Supplement*, May 2, p. 165). This was, in brief, that agreement had been reached with the Ministry and the Medical Practices Committee that the latter should not, unless there were special circumstances, accept one partner as the logical successor of another who had died or resigned if the partners had not been in active practice together for at least about a year.

It was reported that representatives of the Committee had met officers of the Ministry with a view to exploring ways and means of utilizing the £100,000 set aside by the Working Party for the encouragement of group practice. The Ministry had undertaken to set out draft proposals, which would be considered by the committee at its next meeting.

The Ministry had expressed a wish to encourage some improvement in the standard of accommodation in surgeries and waiting-rooms, and it was intimated that at the September meeting of the Committee a draft memorandum on this subject would be presented to the Committee for information and criticism. The office would prepare this memorandum.

Ten members of the Committee were appointed representatives to constitute with the Ministry a working party for discussions on further ways of securing economies in the prescribing field, and to draw up a list of points for discussion.

The Committee received with appreciation a copy of a letter which had been sent by the College of General Practitioners to the Secretary of the Guillebaud Committee, in reply to a request from that body to submit evidence. The College had replied that it was not concerned with terms and conditions of service, and that if any points did arise which concerned the College they would be submitted through the General Medical Services Committee.

The Committee sat from 10.30 a.m. to 5.30 p.m.

Correspondence

Because of the present high cost of producing the Journal, and the great pressure on our space, correspondents are asked to keep their letters short.

Medicines Classified

SIR,—We have now been issued with the classified list of proprietary medicines and, after a preliminary gasp of amazement, have had time to appreciate the burdens which have been added to our prescribing difficulties. Included in category 6 are a number of remedies which have frequently been recommended by consultants of repute and which have stood up to the clinical test of usage in general practice over a number of years. For some of them there are no *National Formulary* equivalents. We are told in the accompanying letter from the chief medical officer that, of course, we may still prescribe what we think best; but behind this is the hardly veiled threat that, if we do, we are likely to be called to account.

I am not, in general, addicted to the prescribing of proprietaries, but some are not only convenient but even appear to be effective in that the patient is relieved. Are these old and tried remedies now to be cast aside? Are the clinical impressions of 20 years entirely worthless? And must I now produce to the local medical committee a controlled series with full laboratory data to support my prescription of "coramine" by mouth? This is, indeed, too large an encroachment upon our clinical liberty, and the patient is likely to suffer.—I am, etc.,

East Horsley, Surrey.

BASIL S. GRANT.

Cost of Prescribing

SIR,—May I be one of the first "self-confessed digoxin addicts" (Dr. Geoffrey Bourne's letter, *Supplement*, July 25, p. 66) who promise to save 2s. 6d. on each 100 tablets by ordering digitalis folia in the future as a maintenance dose?

I would save less than £1 a year, whilst the chap who orders "penidural," 12 oz. (372 g.), at 12s. 6d. per oz., mixtures of 40 oz. (1.2 kg.) at a time, and 36 capsules of "chloromycetin" for a simple afebrile sore throat wastes about £18 per week. No, Dr. Bourne, this will not do. Great economy was exercised when doctors dispensed medicines they paid for before '48, and only rigid inspection into wastefulness will curb the habit, fortunately exhibited by a minority only.—I am, etc.,

Luton.

H. JARVIS.

The A.R.M.

SIR,—I attended recently at Cardiff my first Annual Representative Meeting of the British Medical Association as a representative of the Manchester Division, and would like to record my two outstanding impressions of the meeting.

The first was the wonderful job of preparatory work and organization which made possible the amazing smoothness of the entire proceedings; and I wish to congratulate on this both our Welsh hosts and the staff of the British Medical Association, both lay and medical. The second was the democratic way in which the entire meeting was conducted. To me, a newcomer, it was a revelation how the body of the meeting could control the time allotted to speakers, how simple it was for any delegate to speak to any motion or amendment, how readily last-minute amendments were received, and how the decision whether or not they should be discussed again lay with the representatives. I would also like to pay tribute to our very able Chairman, Dr. S. Wand.

I would like to point out an omission in the report (*Supplement*, July 18, p. 27) of the few remarks I made

H.M. Forces Appointments

ROYAL NAVY

Surgeon Commanders T. L. Cleave and J. H. Nicolson to be Surgeon Captains.
Surgeon Lieutenant-Commanders (Acting Interim Surgeon Commanders) C. A. St. C. Hiley, P. G. Rowsell, G. S. Irvine, P. S. Fuller, P. B. Nicol, and W. M. Davidson, O.B.E., to be Surgeon Commanders.
Surgeon Lieutenant-Commander C. M. Lamont, V.R.D., to be Surgeon Commander.
Acting Interim Surgeon Lieutenant-Commanders B. Geoghegan and W. Cullen to be Surgeon Lieutenant-Commanders.
Surgeon Lieutenant R. H. Cowling to be Surgeon Lieutenant-Commander.

ROYAL NAVAL VOLUNTEER RESERVE

Surgeon Commander K. Forsythe, V.R.D., to be Surgeon Captain.
Surgeon Lieutenant-Commanders J. F. Foulkes, V.R.D., A. R. Harper, V.R.D., and T. S. Eimerl, D.S.C., to be Surgeon Commanders.
Surgeon Lieutenants J. C. E. Peshall and R. R. Wilson to be Surgeon Lieutenant-Commanders.

ROYAL ARMY MEDICAL CORPS

Captain W. L. Sanders to be Major.

REGULAR ARMY RESERVE OF OFFICERS

Major-General (Honorary Lieutenant-General) Sir Gordon Wilson, K.C.S.I., C.B., C.B.E., M.C., Major-Generals D. C. Monro, C.B., C.B.E., D. T. Richardson, C.B., M.C., W. C. Hartgill, C.B., O.B.E., M.C., Sir Alexander G. Biggam, K.B.E., C.B., L. T. Poole, C.B., D.S.O., M.C., R. E. Barnsley, C.B., M.C., Q.H.S., C. M. Finney, O.B.E., Brigadier H. T. Findlay, and Colonel G. O. F. Alley, M.C., late R.A.M.C., having attained the age limit of liability to recall, have ceased to belong to the Reserve of Officers.

ROYAL ARMY MEDICAL CORPS

Major D. C. Muir, having attained the age limit of liability to recall, has ceased to belong to the Reserve of Officers, and has been granted the honorary rank of Lieutenant-Colonel.

Major A. Torrie, having attained the age limit of liability to recall, has ceased to belong to the Reserve of Officers, and has been granted the honorary rank of Brigadier.

Captain (War Substantive Major) (Honorary Lieutenant-Colonel) J. Neill, O.B.E., having attained the age limit of liability to recall, has ceased to belong to the Reserve of Officers.

Captain C. R. M. Greenfield, having attained the age limit of liability to recall, has ceased to belong to the Reserve of Officers, and has been granted the honorary rank of Major.

ARMY EMERGENCY RESERVE OF OFFICERS

ROYAL ARMY MEDICAL CORPS

Lieutenant (War Substantive Captain) G. S. Tupman, from Emergency Commission, to be Captain, and has been granted the acting rank of Major.

TERRITORIAL ARMY

ROYAL ARMY MEDICAL CORPS

Lieutenant-Colonel R. J. S. Doherty has been granted the acting rank of Colonel.

Major F. H. Blackburn, T.D., has been granted the acting rank of Colonel.

Majors J. Baxter and H. B. Lee, T.D., have been granted the acting rank of Lieutenant-Colonel.

Captain (acting Major) J. Petrie has been granted the acting rank of Lieutenant-Colonel.

Captains G. I. Cameron and W. Lees have been granted the acting rank of Major.

Lieutenant (Honorary Major) M. J. McSwiney has retired.

TERRITORIAL ARMY RESERVE OF OFFICERS: ROYAL ARMY MEDICAL CORPS

Colonel J. G. Morgan, C.B.E., T.D., from Active List, to be Colonel, and has been regranted the honorary rank of Brigadier. Colonels D. L. Kerr, O.B.E., T.D., and M. H. Summers, D.S.O., T.D., from Active List, to be Colonels.

Lieutenant-Colonels C. K. Sconce, T.D., and D. W. E. Lloyd, M.C., T.D., from Active List, to be Lieutenant-Colonels.

Major (Honorary Lieutenant-Colonel) H. B. Porteous, M.B.E., T.D., has ceased to belong to the T.A.R.O.

Major F. C. Rodger, from Active List, to be Major, and has been granted the honorary rank of Lieutenant-Colonel.

Majors J. H. Green, W. B. Evans, G. Savill, G. Lancaster, and D. M. Williamson, from Active List, to be Majors.

in the discussion on the "Remuneration of Hospital Medical Staffs." I stated that the consultants and specialists in the Manchester area were of the opinion that "an adequate betterment factor" (Nottinghamshire motion) would be 100%.—I am, etc.,

Manchester.

T. D. CULBERT.

Capitation System Unsatisfactory

SIR,—To my mind not only do the proposals of the Working Party fail miserably to satisfy its terms of reference, but they are bound to fail as long as they do not accept the fact that the present capitation system, with its competition between doctors for patients, is an unsatisfactory basis for medical organization.

In the first place the capitation system, by rewarding quantity rather than quality, tends to encourage and indeed depends for its rationale on a maldistribution of work. It exerts a constant insidious economic pressure on those who are able to take on more work than the dictates of reason or optimum efficiency would otherwise suggest. It tends to overwork one half of the profession and underwork the other half. In neither case is true justice or full efficiency being achieved.

The fundamental problem of the small-list practitioner is his small list, not his small income. The solution therefore will not be found merely by loading the first 1,000 patients as opposed to any other 1,000, even though some modicum of justice may thus be satisfied. The solution will only be found when we have a system which ensures, so far as humanly possible, that every practitioner is working to optimum capacity. Not until then can it be said that the best possible service is being made available to the public.

In the second place, competition between doctors for patients, rather than competition for posts, is in its present form the main obstacle to rational organization and full co-operation between practitioners. It leads to isolated and therefore relatively less efficient work. It prevents the widespread promotion of group practice and ultimate unification with the hospital and local authority services. It perpetuates a negative *laissez-faire* attitude to medicine which is the antithesis of that preventive and social outlook which should complement the individual approach and inspire a vigorous National Health Service.

In this connexion "freedom of choice" should not be claimed as an absolute rule, but only as one important relative principle to be followed as far as circumstances permit. Absolute freedom of choice never did and never can exist. No one can choose a doctor in John o'Groats who himself lives at Land's End. Most people are content with a convenient doctor so long as they are free to change should they wish. This is the most that freedom of choice usually necessitates. There is no reason therefore why in a planned medical service practitioners should not be ensured an optimum list, at the same time as patients are ensured reasonable freedom of choice. If one doctor in a group tended to attract more patients than his optimum, then a waiting-list or some such device could be instituted so that patients could transfer when a vacancy occurred.

In short I would plead for the leaders of our profession to consider anew whether they could not devise some more rational organization of our work, such as a modified salaried service which would maintain the maximum of freedom compatible with reasonable efficiency, to the benefit of both the profession and the public.—I am, etc.,

Bransgore, Hants.

A. C. McLEISH.

POINTS FROM LETTERS

Extraordinary General Meeting

Dr. W. J. GRANT (Shrewsbury) writes: Dr. E. Sladen (*Supplement*, July 11, p. 14) asks why I contend that "the G.P. who is getting his £500 'bonus' on 1,500 patients (2,000 total) should look after the first 500 at the low rate, and the G.P. with the 750 list look after his total number at the 'bonus' rate." I made no such contention, and Dr. Sladen's question seems to arise from a misunderstanding of the distribution scheme, as would appear from the figure 2,000 which he inserts in brackets. It is a 1,500 list which qualifies for the £500 bonus. I asked why a 750 list did not attract at least half that "bonus." It draws only one-quarter that amount. . . .

The notifications concerning Lieutenant-Colonels S. W. Barber, M.B.E., T.D., and S. R. Trick, O.B.E., T.D., published in *Supplements* to the *London Gazette* dated March 20 and May 1, respectively, have been cancelled.

Captain (Honorary Major) I. N. MacIver has relinquished his commission, retaining the honorary rank of Major.

Major E. H. Markly has relinquished his commission.

Captain J. H. B. Livingston, T.D., has relinquished his commission and has been granted the honorary rank of Major.

Notes and News

Hospitality Wanted.—A Yugoslav surgeon who speaks English seeks hospitality in the London area for one or two months in return for hospitality in Dalmatia. Suitable dates could be arranged. Any reader interested should first communicate with Dr. H. A. Sandiford, International Medical Visitors' Bureau, B.M.A. House, Tavistock Square, London, W.C.1.

Emergency Equipment at Home.—When life-saving equipment—for example, oxygen tents, respiration machines—is needed from a hospital for use in a patient's home, hospitals are to supply it on the application of the patient's general practitioner. They are not to wait for the recommendation of a hospital specialist, which is the usual course when there is no urgency (R.H.B. (53) 81).

PRIZE ESSAY COMPETITION FOR MEDICAL STUDENTS, 1954

The Council of the British Medical Association is prepared to consider the award, in 1954, of prizes to medical students for essays submitted in open competition. The subject of the essay will be: "Is the Medical Curriculum too Heavily Loaded?"

The purpose of this competition is to promote systematic observation among medical students. In awarding the prizes due regard will be given to evidence of personal observation. No study or essay that has previously appeared in the medical press or elsewhere will be considered eligible for a prize. Previous prizewinners are eligible for a second award of a prize.

Any medical student who is a registered member of a medical school in the United Kingdom or the Colonial Empire at the time of submission of the essay is eligible to compete for a prize. If any question arises in reference to the eligibility of a candidate or the admissibility of his or her essay, the decision of the Council of the British Medical Association will be final. Should the Council decide that no essay entered is of sufficient merit, no award will be made. In determining the number and amount of prizes to be awarded, the Council will take into consideration the number and standard of essays received.

It is suggested that essays should consist of from 2,000 to 5,000 words. Essays must be typewritten or legibly written in the English language on foolscap paper, on one side only, must be unsigned, and must be accompanied by a note of the name and the medical school of the entrant. Notice of entry for this competition is necessary and a form of application can be obtained from the undersigned.

Essays must be forwarded so as to reach the Secretary of the British Medical Association not later than December 31, 1953. Inquiries relative to the Competition should be addressed to the Secretary, British Medical Association, B.M.A. House, Tavistock Square, London, W.C.1.

A. MACRAE,
Secretary.

Association Notices

FORMATION OF NEW WEST LOTHIAN DIVISION

Notice is hereby given by the Council to all concerned that it is proposed to reconstitute the existing Lothians Division into two separate Divisions as follows:

- An East and Mid Lothian Division comprising the Counties of East and Mid Lothian.
- A West Lothian Division comprising the County of West Lothian.

Any member affected by this proposal and objecting thereto should write to the Secretary of the Association by Monday, August 31, 1953.

A. MACRAE,
Secretary.

Diary of Central Meetings

- SEPTEMBER
16 Wed. Guillebaud Evidence Committee, 11 a.m.
30 Wed. Occupational Health Committee, 11 a.m.

Meetings of Branches and Divisions

SOUTH STAFFORDSHIRE DIVISION

The annual meeting was held in Wolverhampton on June 5, 1953. The following officers were elected:

- Chairman.—Mr. W. Leslie Thomas.
Vice-chairman.—Dr. Jessie E. Pringle.
Hon. Secretary and Treasurer.—Dr. L. C. Rutter.

WAKEFIELD, PONTEFRAC, AND CASTLEFORD DIVISION

The annual divisional meeting was held at the Clayton Hospital, Wakefield, on May 17, 1953. With Dr. T. Gardner in the chair, there were nine members present. The following officers were elected for 1953-4:

- Chairman.—Dr. Marjorie Steven.
Vice-chairman.—Dr. L. Watson.
Hon. Secretary and Treasurer.—Dr. A. G. James.

The B.M.A. in Committee

MEDICAL SERVICE IN THE ARMED FORCES

During the greater part of its existence the Association has had, under one name or another, a committee charged with the interests of doctors in the medical services of the defence Forces. Until recent years this was known as the Naval and Military Committee; it now appears under the name of the Armed Forces Committee. At present it consists of 17 members, apart from the principal officers of the Association, who are members *ex officio*. The members include high-ranking officers of all the three Services and civilian practitioners with Service experience, together with one representative from the Medical Branch of the Royal Navy, the Royal Army Medical Corps, the Medical Branch of the Royal Air Force, the Territorial Army R.A.M.C., and the Royal Navy and Royal Air Force Volunteer Reserves.

Backroom Committee

Not much is said, usually, when the reports of this Committee come forward to the Council, and through the Council to the Representative Body. They are generally taken towards the end of the proceedings, and evoke little or no discussion, because, except during the times to which that inadequate word "emergency" applies, the affairs of this Committee are of direct interest only to a small section of the profession—that is to say, the men and women who have commissions in the Services—although, to be sure, many civilian doctors carry out part-time or occasional work in some form for Services personnel.

The Association has never relaxed its vigilance concerning the position of its members who are in the defence Forces. It is realized that many of them, by reason of their location and their frequent change of place, are outside ordinary Branch and Divisional organization; moreover, they are subject to regulations and discipline and are not allowed to combine in the way which is open to people in practically every other form of employment. The Association has always been, and still is, the obvious body to take a comprehensive view of the conditions of medical services in the Forces as compared with services outside, and to make the necessary representations to the defence departments. Indeed, the history of the Association is full of instances of effective intervention on behalf of these officers, and, although obduracy on the part of the powers that be has often been encountered, the position of these officers and the efficiency of the service that they can give to those under their charge have—to use a hackneyed phrase—improved out of all recognition.

Balaclava Surgeons

To appreciate this it is necessary only to glance at the very different position of these men a hundred years ago. To take the Army alone—though a similar state of affairs obtained in the Navy—the ordinary medical officers in the middle of the nineteenth century suffered many injustices. They were not really regarded as part of the Army at all, but only as camp followers, although they shared the perils of Army campaigns and had their share of wounds and disease. The conditions of admission to the Service and promotion in rank would now be regarded as intolerable. The successful candidate in an examination might have to wait for years for a commission as assistant surgeon with the rank and pay of a lieutenant, plus a shilling a day.

The Struggle for Status

At a time when that "bothering woman" (her own description), Florence Nightingale, was preparing herself to undertake the gigantic task of reforming the health administration of the British Army, and moving heaven and earth (which included Queen Victoria and the Prince Consort, as well as the Panmures and other "bullyable mortals") to secure the setting up of a Royal Commission to investigate the administration of the Army Medical Department, the Commission to be filled with her own nominees, while she arranged who should *not* be the next Director-General of the Department—at the time this was happening the Association was also moving, presenting in 1857 a comprehensive memorial on a thorough reorganization of the medical services. It was urging that none but properly qualified medical men should be engaged; that, once commissioned, they should enjoy absolute equality with other officers and have like authority over those serving under them, and that they should be equally well provided in respect of pensions and eligibility for distinctions and rewards of good service. In 1858 new Army regulations were issued which remedied the position to some extent, though in practice they were often rendered ineffective as a result of the resentment of combatant officers on seeing a subordinate department raised to relative independence and power.¹

For many years Army medical reform continued to be a live subject in the Association, and the status and security of the medical officer were a matter of constant argument between Great Queen Street or the Strand, where the Association had its offices, and Whitehall. For a long time the Army surgeon was still regarded by the authorities as not quite a civilian nor quite a soldier, and suffered from the disadvantage of the worst of both worlds. His promotion was blocked; the conditions which awaited him on retirement were most unsatisfactory; when working in hospital he had no authority even over his own orderlies; his work

¹The full story is told by Mr. Russell Coombe in a short history published in the *Handbook* of the Association in 1921.

compelled him to have a horse, but he was never sure of his forage allowance. A new code of Army regulations came in in the 'nineties, thanks again to an Association committee which was still considering Army medical reform.

The Royal Corps

The creation of the Royal Army Medical Corps, which was announced in 1898 by the Secretary of State for War, Lord Lansdowne, may be said to be an Association achievement. The Service was further improved after the South African War, again largely on the initiative of the Association, which made important recommendations concerning promotion, increase of pay, and pension rights. The work of the Association during the two great wars deserves a separate chapter, or many chapters, to itself. A word may be said about the work of the Naval and Military Committee, as it then was, in connexion with the many problems arising from the demobilization of medical officers after the war of 1939-45. Release leave, allowances, disability pensions, absorption into civilian work, and refresher courses for released officers were among the questions that crowded forward.

The Interests of Service M.O.s

To-day the Committee is perhaps more pedestrian but none the less useful. On Service pay and recruitment it has lately prepared and submitted a memorandum through the Council to the Working Party set up by the Ministry of Defence. The idea has been to secure for medical officers in the Services a position as comparable as possible to that of the civil practitioner. The inadequacy of widows' pensions has also recently been a matter for representation. The Association's Medical Practices Advisory Bureau offers its services to medical officers on retirement if they are seeking to take up civil appointments. The Committee keeps in close touch with the Medical Directorates of all three Forces. It does not intervene in cases of individual grievance unless the individual concerned has availed himself of the internal machinery open to him in his Service and apparent injustice still remains. The Committee gets little publicity, but it is performing a most useful function in the tradition of the Association from its very beginning.

REVIEW OF THE N.H.S.

NO DRASTIC CHANGES—Minister

The Minister of Health gave an assurance last week that he has no intention at present of making any drastic changes in the basic structure of the Health Service. Introducing the annual report of the Central Health Services Council,¹ he draws attention to what he and the Council consider to be its most important single piece of work in 1952—namely, the study of medical research in relation to the National Health Service. It was carried out by the Standing Medical Advisory Committee and the Medical Research Council. The fruits of this study—recommendations greatly to expand clinical research—were published recently and discussed in the *Journal* of July 18 (p. 140). Most of the Council's work was reported in these columns when it was first published, and may be briefly summarized here.

A number of recommendations were made on improving the welfare of patients in hospital, and daily visits from parents of children in hospital were also advocated provided that adequate safeguards are taken against infection. The Council considers that cancer education should be carried out locally by voluntary bodies, not by any central government organizations. Some action should be taken to ensure that people seeking work in this country from abroad should be free from infectious tuberculosis when they arrive.

¹Report of the Central Health Services Council for the Year Ended December 31, 1952. H.M.S.O. 1s. 3d.

Minister-Hospital Consultation

With the Council's recommendation that regional hospital boards should be fully consulted by the Minister on the application of policy in the hospital service, Mr. Macleod expresses his whole agreement. He adds that, "while ultimate direction from the centre is unavoidable, I am satisfied that it should be kept to the minimum and that those responsible for running the Service should have as much say as possible in its development. I hope it is fair to say that this conception of partnership is given effective expression in the regular consultation between members and officers of the hospital authorities and my Department."

He also makes the point—of special topical interest—that hospitals should take full advantage of the help they can get from medical officers of health in investigating outbreaks of infectious diseases and food-poisoning, and admonishes those "too many hospitals" whose practice "has been defective in this respect." The dental services in hospitals are described as being "generally most inadequate, for patients and staff alike."

Correspondence

Cost of Prescribing

SIR,—The chief medical officer of the Ministry of Health is assured of the loyal support of all medical men concerned in response to his recent appeal to them to help reduce the huge N.H.S. drug bill. It is encouraging also to learn that the right to prescribe whatever we think necessary in any individual case is not to be taken from us, subject to justification of the cost to our colleagues on the local medical committee, if called upon to do so.

In the exercise of this right fellow-practitioners may, however, be unaware of the time, trouble, and expense to which unwittingly they may be committed, as the following example will show.

In December, 1950, a medical consultant, in whose judgment I have every confidence, found a patient of mine, an agricultural labourer, to be suffering from an active gastric ulcer, confirmed radiologically. To heal this he advised a period of strict bed-rest at home on the Witt 3 hospital diet. He gave the patient a copy of this, and in his report to me asked if I would supply the (only) medicaments named therein—namely, vitamins A, C, D, and "marmite." In accordance with the ethics of medical consultation I did so, prescribing on the E.C.10 form a liquid combination of A and D, ascorbic acid tablets, and—since the patient had read the sheet—the B complex as "marmite," an 8-oz. (240-g.) jar.

A year later I was invited by the local medical committee to justify the prescription of this marmite. I explained that the specialist had advised it, and sent a copy of the diet sheet. The committee decided they had no alternative but to have me surcharged the marmite, as it is classified as a "food" in the First Report of the (Cohen) Definitions of Drugs Joint Subcommittee. In forwarding this decision their secretary explained my right to appeal to the Minister, and I elected to exercise it. Inadvertently I omitted to lodge the appeal within the month allowed, but the secretary of the Ministry then wrote to remind me and accepted the appeal a few days later.

Another year passed before I was invited to appear personally or be represented legally 50 miles away at Cambridge, so that the referees, a lawyer and two doctors, could decide whether the marmite was or was not a drug in the circumstances in which I had prescribed it.

I duly appeared, supported by a solicitor from a firm commissioned by my defence union. We were accorded a careful and courteous hearing. I reiterated the explanation given to the local medical committee, stated that the specialist had since confirmed that the patient "really needed" these medicaments, and added that—since reading

up the subject—I now thought the diet advised was probably deficient in the B vitamins. I also explained that it is now thought that there is a greater need of the B complex vitamins in cases of peptic ulcer, owing to their beloved increased local destruction in that disease. In this connexion I invited the referees to consider the third sentence in the section on vitamins on page 36 of the (1952) *National Formulary*, and other references.

A copy of their report to the Minister has just been received. They state that it is clear to them from perusal of the diet sheet that the marmite and other vitamins were intended as part of the diet, so my appeal is disallowed. I am sure they are as anxious as I am that this decision should have publicity.—I am, etc.,

Mattishall.

CHARLES S. THOMSON.

SIR,—I would respectfully point out to Dr. Geoffrey Bourne (*Supplement*, July 25, p. 66) that his criticism of digoxin on economic grounds omits certain important facts. As a dispensing practitioner, I find fault with tablets of digitalis leaf on two grounds, economic and therapeutic. There is considerable wastage in the dispensing pack and in the pillbox from disintegration to powder. In many households I have seen these tablets spoilt by damp. These drawbacks are totally avoided by the use of a hard, stable, polished tablet. Allow me to disclaim any proprietary interest in digoxin.—I am, etc.,

Sedburgh.

H. THISTLETHWAITE.

The G.P. and the Industrial Medical Officer

SIR,—I am grateful to Dr. G. MacBain (*Supplement*, July 11, p. 13) for his friendly and courteous criticisms of my letter (*Supplement*, June 27, p. 314). There is no fundamental divergence between our views, for I agree with him that it is not in the patient's interest that doctors should quarrel over him, and that reciprocal courtesy and understanding should ensure that conflicts do not occur. I know of the inspiring project of the Corby Diagnostic Centre and of the very happy relationship between Dr. MacBain's organization and his general-practitioner colleagues. Ideally, this kind of relationship should exist wherever there is an occupational health service. I believe that in Corby there are special conditions—a very large works which dominates the town, and a small number of general practitioners—which have facilitated personal contact; though this does not make his achievements any less praiseworthy.

But can it honestly be said that in Corby, or in any other place where similar good relations exist, the credit should be given to the ethical rules for industrial medical officers? In these circumstances the doctors concerned, because of their personal regard for each other, have tacitly agreed between themselves that the rules are superfluous, and shall not in fact govern their relations, which are founded instead on ordinary professional courtesy. Do the rules then help to improve a less happy situation? There is abundant evidence that they frequently have the opposite effect. Not every doctor is uniformly courteous, either in industry or in general practice. The rules are apparently aimed at teaching manners to the industrial medical officer, but have nothing to say about the discourteous general practitioner.

There is more involved in this discussion than mere considerations of the status and prestige of the industrial medical officer. The establishment of a comprehensive occupational health service is accepted B.M.A. policy, and employers and employees alike will expect such a service to provide for treatment, so far as this can reasonably be given at the place of work, with a view to minimizing loss of working time. It is they, rather than the medical profession, who are the final arbiters, although there is every reason to think that they will recognize, as they have always done in the past, that there is such a thing as medical etiquette. The trend is illustrated by a recent press report that a large general hospital in the Midlands, unable to fill two vacancies for casualty officer and house-surgeon, has appealed to those factories with medical departments not to refer cases to hospital, but to treat them as far as possible in the works surgery.

The Ethical Rules, though revised in 1949, are still inspired by the same spirit as the original ones, drawn up when most industrial medical officers were in general prac-

tice. The drafters appear to have been dominated by the fear that the works doctor might induce his colleagues' patients to transfer to his practice, and the rules were intended to guard against this. Since then things have changed; occupational health services have played an increasingly important part in our national life, and will continue to do so. Whatever branch of the profession we practise in, we owe it to our patients to collaborate for their good; but this must surely be on a footing of equality, a relationship engendered by the quality of the work we do, and not one prescribed by an anachronistic code.—I am, etc.,

Birmingham.

F. H. TYRER.

Sweated Doctors

SIR,—The following vacancies have been publicly advertised during the current month by hospitals in the Home Counties:

Job	Age	Pay/Week	Weekly Hours			Notes
			Duty	Free	Total	
Junior house-officer (first 6 months)	Any	£6 15 0	136	32	168	Whether provisionally or fully registered
Hospital clerk	25	6 15 0	Unstated			
Gardener's labourer	—	6 2 0	48	120	168	
Theatre orderly (shift)	—	6 11 0	48	120	168	
Kitchen porter	—	6 2 0	48	120	168	
General porter (shift)	—	6 2 0	48	120	168	
Shorthand typist	25	5 10 0	Unstated			

In the same period the Industrial Court has raised to £7 5s. a week the wages of general clerks aged 25 employed in the London office of the National Society of Painters. Into the comparative earnings and hours of such workers as miners, dockers, market porters, and skilled transport men of similar age I hesitate to delve.

Of all the above N.H.S. jobs, which can compare in responsibility, difficulty, anxiety, wear and tear, and risk with that of the house-officer, with the lives of patients on his hands, night as well as day? In which other of them is the holder obliged, as a condition of his employment, to insure himself against actions for damages? Who but he can earn no overtime, and never be sure of an unbroken night except on six or seven days a month?

Look at the figures. Obvious underpayment (both relative and absolute) on the one hand; overwork no less obvious on the other—what are conditions such as these but the merciless exploitation of young doctors, especially when aggravated by the increasing and very intelligible difficulty of filling resident vacancies?

The house job at the top of my list (which offers only one free week-end in four) is possibly an extreme case; but in the common cases of one free week-end in three, or even in two, the total hours of freedom (to compare with the 120 granted to all the other listed jobs) are still only 36 and 41 respectively.

How in such conditions can a young doctor look after his patients properly even if he ignores his own health? Is the B.M.A. asleep?—I am, etc.,

Hove.

W. B. MANLEY.

Ophthalmic Services

SIR,—In the reports of the Cardiff meeting of the B.M.A. I have failed to see any reference to the inconsistencies of the Supplementary Ophthalmic Services. How many of our G.P. and specialist colleagues realize that the O.M.P. has to provide his own establishment and equipment himself for which he gets no compensation and no pension? His only alternative is to work in an optician's shop, where the medical atmosphere of eye symptoms as part of ill-health is replaced by the commercial one of whether or not a nice new pair of spectacles should be purchased.

How much longer are we going to tolerate the numerous patients who, while retaining a private general practitioner, come for a sight test on the N.H.S. and proceed to purchase an expensive pair of spectacles from the optician made up to our National Health prescription? Was there ever a better example of cut-price medicine?

It is surely time that this abuse of our profession be stopped. It should be made possible for anyone needing glasses to receive a free test and a free pair of glasses made to a limited but adequate specification of frame under the N.H.S., but any person wanting anything more elaborate than this should pay for both the sight test and the glasses.

The only alternative is to restore the State sight-testing fee to a proper level, but this would cost the Exchequer considerably more.—I am, etc.,

Redhill.

F. J. CURTIS.

Use of Health Visitors

SIR.—The following is an extract from a letter sent to general practitioners in this area recently:

"If you have not already read the report of the Annual Representative Meeting of the B.M.A. concerned particularly with the Public Health Committee and under the heading 'Health Visitors,' I hope you will do so. It is to be found on pages 25 and 26 of the *Supplement* to the *British Medical Journal* of July 18. The meeting carried the following motion:

"That the Association welcomes health visitors working under the guidance of general practitioners as a means by which such practitioners may increase the help they can give to patients, and that the Council be requested to consider ways whereby the help given by health visitors to general practitioners may be increased."

"Dr. W. E. Dornan (Sheffield) said that his group of medical practitioners had the services of a health visitor placed at their disposal and working to their orders in co-operation with the services provided by the local health authority.

"In this Division the health visitors are available to visit cases at the request of medical practitioners and to assist patients in carrying out the advice and orders of their doctor and to report direct to that doctor any matters of which he should be informed. Health visitors have been instructed that they are to carry out this work if and when requested and to do their utmost to co-operate with general practitioners. Doctors in this area have in the past made little use of health visitors, and I find it difficult to believe that there are not cases where a report of a test feed or other services of the health visitor would not be useful. I hope, therefore, that you will consider whether it is not possible for general practitioners and the local health authority to make a better use of health visitors in the future than in the past."

I shall be gratified if it elicits a favourable response.—I am, etc.,

Otley, Yorks.

R. A. W. PROCTER,
Divisional Medical Officer.

Notes and News

Housing of Nurses.—The Ministry of Health questions whether an unduly large share of the available resources is not being spent on nurses' accommodation, to the prejudice of some other important developments. The practice of "living in," it says, is established by tradition as normal for nursing staff, and it asks whether it continues to be justified by the conditions of the nurses' work or the needs of the service. The Standing Nursing Advisory Committee has now come to the conclusion that, subject to certain reservations, "There are no factors inherent in the work of a hospital nurse that make it necessary that she should live in the hospital in which she works or in near-by accommodation provided by the hospital authority." The chief difficulty is obtaining accommodation at a reasonable cost and reasonably accessible to the place of work. So the Ministry indicates in R.H.B. (53) 83 that hospital authorities should help their nurses and other employees to find suitable living accommodation, and they might consider following the example of university authorities by maintaining registers of approved lodgings to which nurses and others in need of accommodation could be referred.

Assistance to Pay Charges.—The total amount of national assistance granted in 1952 to meet charges raised under the National Health Service was just over £600,000. Of this, £209,000 represented the refund of shilling charges for prescriptions from June 1 onwards, when the charges began.

H.M. Forces Appointments

ROYAL ARMY MEDICAL CORPS

Captains F. L. Holroyd and I. M. Grant to be Majors.

REGULAR ARMY RESERVE OF OFFICERS

ROYAL ARMY MEDICAL CORPS

Major W. Mackenzie, having attained the age limit of liability to recall, has ceased to belong to the Reserve of Officers.

REGULAR ARMY: EMERGENCY COMMISSIONS

ROYAL ARMY MEDICAL CORPS

Lieutenant (War Substantive Major) A. Kirshner has relinquished his commission, and has been granted the honorary rank of Lieutenant-Colonel.

COLONIAL MEDICAL SERVICE

The following appointments have been announced: M. A. Byer, M.B., Ch.B., M.P.H., Medical Officer of Health, Barbados; H. C. Foster, M.D., D.T.M.&H., Assistant Director of Medical Services, Tanganyika; K. Sperber, M.D., D.P.H., Medical Officer, Gold Coast; L. J. Miller, L.M.S.S.A., Medical Officer, Zanzibar; D. R. Gunn, M.B., F.R.C.S., Orthopaedic Surgeon, Federation of Malaya; L. H. Hatcher, M.B., Medical Officer, Fiji.

Association Notices

SCHOLARSHIPS IN AID OF SCIENTIFIC RESEARCH

The Council of the British Medical Association is prepared to receive applications for research scholarships as follows:

An Ernest Hart Memorial Scholarship of the value of £250.
A Walter Dixon Scholarship of the value of £250.

These scholarships will be awarded to candidates whom the Science Committee of the Association recommends as qualified to undertake research in any subject (including State medicine) relating to the causation, prevention, or treatment of disease.

Each scholarship is tenable for one year commencing October 1, 1954. A current scholar may apply to be re-appointed for an additional year. No scholarship may be held for more than three years. A scholar is not necessarily required to devote the whole of his or her time to the work of research, but may be a member of H.M. Forces or may hold a junior appointment at a university, medical school, or hospital, provided the duties of such appointment will not, in the opinion of the Science Committee, interfere with his or her work as a scholar.

Applications for scholarships must be made not later than March 1, 1954, on the prescribed form, a copy of which will be supplied on application to the Secretary, British Medical Association, B.M.A. House, Tavistock Square, London, W.C.1.

Applicants are required to furnish the names of three referees who are competent to speak as to their capacity for the research contemplated.

Diary of Central Meetings

SEPTEMBER

11 Fri. Public Health Committee, 2 p.m.
23 Wed. Arbitration Committee, 2 p.m.

Correction.—We regret that in our report of the Annual Representative Meeting (*Supplement*, July 18, p. 26) we attributed to Dr. A. Y. Cochran (Edinburgh) the contribution to the discussion made by Dr. N. J. Cochran (Burton-on-Trent).

The B.M.A. in Committee

PRIVATE PRACTICE

Several of the committees of the Association are inadequately named in view of the range of work which falls to them. It is not possible to put into a short title what they do. This is conspicuously true of what is now called the Private Practice Committee—a committee of 16 or 18 members dealing with matters affecting private practice which do not come within the purview of those other committees whose concern is with the various medical services under the National Health Service Act. It would be difficult to hit upon a name which could describe in a word or two the miscellaneous agenda which confront the Private Practice Committee at its (normally) quarterly meetings. It must not be assumed that it is a committee which deals with the left-overs—the odds and ends which the National Health Service has failed, or scorned, to pick up. Many of the items, numbering perhaps thirty or forty, which come before it at its meetings may appear to be matters of small detail, but all of them have their importance, general, local, or individual. Moreover, some of the questions have a habit of recurring again and again, cropping up in new guises and requiring a modification of a previous decision or a reaffirmation of it. If one looked up the records of the committee or of its predecessor ten years back one would find many of the questions, such as points on certification, fees for medical reports for assurance companies, and so on, very much as they keep presenting themselves to-day.

The fact is, of course, that the work which a practitioner may be called upon to do, outside the National Health Service as well as within it, is so various and complex, so much dependent upon the particular situation, that it cannot be reduced to a rigid pattern, either of obligation or of remuneration. The committee which looks after the interests of the practitioner on the private side of his work must be flexible and prepared to consider many similar cases from the point of view of each particular one. The doctor's work is not a fit field for the methods of quantity surveying. The assessment of fees, the decisions on conditions of appointment, and innumerable other matters have to be reviewed again and again, and in the Private Practice Committee the Association has a fit instrument for this task.

Typical agenda may cover such questions as fees for examination and report for life assurance corporations, for certain services to public authorities, for witnesses in courts, for varied forms of certificates, for the occasional treatment of certain special classes in the community, for the examina-

tion of "drunks in charge," the remuneration of ship surgeons, and so on. The committee, of course, is not preoccupied merely with fees. Such questions come before it as those relating to the appointment and powers of coroners, the forms of certificate required by Government departments or other public bodies, points arising on work undertaken for local authorities, right down to the remedy for the unattended telephone, or the doctor sign on the car, or the line to be drawn between day and night calls—small matters, some of them, but helping to smooth out the corrugations in daily practice.

Liaison

The Private Practice Committee consists of twelve elected representatives and up to three co-opted, together with one member from the General Medical Services, one from the Consultants and Specialists, and one from the Public Health Committees. This liaison between the various committees is one of the most important features in B.M.A. committee structure. The Journal Committee, for example, has representatives from the Central Ethical, the Organization, and the Science Committees. The Organization Committee includes a representative from the Colonies and Dependencies Committee, and the latter has a representative from the Organization Committee. The Private Practice Committee has representatives on the Occupational Health, Public Health, Consultants and Specialists, and Finance Committees, and on the Consultants and Specialists Committee there are representatives from four other standing committees, not to speak of others from the Specialist Group Committees.

This interlacing of representation, while it means double attendances for the members concerned, is a very necessary contrivance. The boundaries of committee work can never be exactly defined.

Origins of the Committee

The former Medico-Political Committee was the progenitor of the Private Practice Committee. The Medico-Political Committee, from the early years of this century, played a very important part in Association affairs. In that committee the first steps were taken towards putting right various inequities from which practitioners suffered, and many useful changes to the advantage of the practitioner in establishing his status and ensuring him a proper remuneration for various services were made. The term "medico-political," which equally applied to some other committees, was later dropped, and the committee became the General Practice Committee. For some years it had the advantage of having Dr. S. Wand in its chair, but when the National Health Service started he became chairman

of the General Medical Services Committee. At the same time the General Practice Committee was reborn as the Private Practice Committee, and since 1948 Dr. Ian Grant, of Glasgow, has guided its work. He has done so with a gentle and yet a firm hand, checking the unreasonable demands which are sometimes received from members outside, but standing for a proper recognition of the services which the doctor renders to the community in many directions outside the National Health Service. It is a highly interesting committee to serve, partly because of the diversity of its work. Sometimes it touches on medico-legal matters, and here it has the advantage that at least two of its present members have legal experience. During the last five years it has had many solid achievements to its credit—achievements which have eased the burden and improved the reward of many practitioners.

NEW MATERNITY BENEFITS

Cash maternity benefits under the National Insurance scheme are to be increased, and changes made in the conditions of payment, from October 26, 1953. The new maternity grant and home confinement grant will be payable for confinements which take place on or after this date; the new maternity allowance is payable for confinements which are expected on or after October 26.

Terms of Payment

The maternity grant of £4 will be increased to £9. There will be an additional new grant of £3 for home confinements. For women not employed outside their own home duties the home confinement grant of £3 will take the place of the former attendance allowance of 20s. a week for the four weeks immediately after the date of confinement. Women ordinarily working for an employer or self-employed will receive the £3 home confinement grant, and a maternity allowance of 32s. 6d. for the 18 weeks starting 11 weeks before the expected week of confinement, with additions in certain circumstances for dependants. This is instead of the present maternity allowance of 36s. a week for the 13 weeks starting six weeks before the expected week of confinement (or attendance allowance of 20s. a week for the four weeks immediately after the date of confinement).

Qualifications for Home Grant

The home confinement grant will also be awarded for confinements which take place in any other institution or accommodation, such as a private nursing-home, so long as the cost of accommodation and maintenance does not fall on public funds. Occupiers of amenity beds will not be entitled to the home confinement grant.

IRISH HEALTH BILL PASSED

On July 30 the Dail passed the Government of Eire's Health Bill by 79 votes to 40. Dr. Ryan informed the House that the Bill would cost £2,000,000 a year to implement, half the amount to be expended by local authorities and the rest by the Department.

I.M.A. Comment

Dr. P. J. Delaney, secretary of the Irish Medical Association, is reported to have stated that the association found it necessary at this juncture to remind the public that it had already expressed dissatisfaction with the principles of the Health Bill, 1952, basing its opposition on the fundamental grounds that "State medicine is bad medicine." Notwithstanding apparent modifications to the Bill during its passage through the Dail its basic structure remained the foundation stone of a system of nationalized medicine.

He added: "The association remains convinced that the solution of the needs of our health services will be found in the adoption of a system of State-aided voluntary insurance."

HOSPITAL PRIORITY FOR WAR PENSIONERS

After transfer of the functions of the Ministry of Pensions on August 31 priority will be given at all National Health Service hospitals to war pensioners needing examination or treatment as out-patients or admission as in-patients in respect of their "accepted disability"—i.e., for any condition related to the disability for which they are pensioned. This priority will be given subject only to the needs of emergency and other urgent cases which must take precedence, and hospital authorities are being asked in a Ministry circular (RHB (53) 94) to ensure that it is afforded in all cases where a condition related to an accepted disability is involved. Civilian and mercantile marine pensions will be dealt with in the same way as Service pensioners.

Ex-officer Patients

The Ministry of Pensions has hitherto provided private accommodation for ex-officers requiring in-patient treatment. In N.H.S. hospitals this will be arranged by the use of Section 4 beds, where available, subject to the overriding needs of cases urgently requiring private accommodation on medical grounds. Any charges payable for ex-officer patients will be borne by the Ministry of Health, and no charge will be made to the patient or to the Ministry of Pensions and National Insurance.

Indication of Pensioner Status

General practitioners are asked by the Ministry of Health to state clearly when referring war pensioners to hospitals in the National Health Service if the reference is in connexion with an accepted disability, so that the necessary priority may be given.

Correspondence

The Drug Bill

SIR,—Surely the time has come for us to look at the nation's drug bill under the N.H.S., with due regard to its short and economically alarming history, to certain basic principles, and to the future.

The Santa Claus beginning at least had the merit of idealism, although it was clearly doomed to suicide. The first serious amendment, popularly known as "a bob a job" (more, of course, for a rupture or varicose veins), lost the idealism without gaining in practicability.

The following are the basic facts, as I see them, which should be borne in mind. The object is to ensure that nobody is deprived of adequate medical treatment because of financial hardship. It is impossible to draw any hard-and-fast line between medical products on the one hand and toilet preparations, foodstuffs and food substitutes, and beverages on the other. It is undesirable solely for N.H.S. economy to stigmatize certain medical proprietaries as ineffectual. They may benefit the peculiar mixture of body and mind of a particular patient, and the most that an overseeing political organization should do is to refrain from subsidizing them. There is the human fact that a person values a thing and derives benefit from it to some extent proportionally to what, in a broad sense, he pays for it. Effective medical products are not commercial—that is, a rich man may wish to buy an aeroplane or television set, but not penicillin.

Instead, therefore, of this endless, hopeless, thankless task of sorting out the possibles and probables from the unlikelys and the unspeakables, would it not build for a better future if we could have, say, three big categories? (a) The really important therapeutic agents, which are made unpurchasable and are made free to all patients (N.H.S. and private) on medical prescription only. This category would be small in number, large in power, and would include the antibiotics, sulphonamides, hormones, D.D.A. scheduled

drugs, and, of course, others which would have to be decided on (by doctors, please). (b) A thorough selection (*vide supra*) of effective palliatives, made inexpensive by heavy State subsidies. This list of approved palliatives and dressings, linctuses, analgesics, laxatives, etc., would be purchasable without prescription. The patient would not buy more than he needed, he would value his medicament proportionally, and he would not have to return to his doctor each time he needed more. (c) For the remainder—the ineffective or doubtful medicaments, the "frills," for example, palatability (and surely this is advantageous only in paediatrics)—let the commercial firms compete and the laws of supply and demand operate.

Unless some such outline scheme is adopted I cannot see how it is possible to restore a sense of proportion and dignity to the medical aspect of life, which recently has been oppressed with the impracticable and sentimental idealism of "where health is concerned no expense must be spared." And who but the medical profession can enlighten the misguided, albeit well-intentioned, politicians of the true place of medicine in society?—I am, etc.,

Littlestone, Kent.

P. M. VICARY.

SIR,—We are asked to boycott so far as possible the proprietary medicines. If we do this, the drug houses will be unable to afford the employment of research chemists, and that would be a calamity. Also the patients do not believe our "But this is just as good as the medicine you are used to." Yet there is insufficient money for the present rate of prescribing to continue.

The provisions of the health scheme were never properly thought out, and it would be much more sense to change the worst parts completely than merely to modify them. In Australia life-saving drugs (insulin, penicillin, vitamin B₁₂, etc.) only are free, although pensioners have a wider range of free medicines. Anything outside these categories must be paid for by the patient. If we introduced the same scheme here, not only would the demand for unnecessary medicines be reduced, but there would probably be sufficient people who prefer medicines in elegant preparations to keep the drug houses happy. Also we would be saved the painful task of dealing with the patients who bring "grocery lists" of the purgatives, antacid preparations, etc., they say they need. Very little hardship would be caused. Those of us who do not take medicines when we have a cough get better as quickly as our patients who take pints. Persons with, say, proved bronchiectasis could be allowed extra sick benefit money to cover the cost of their B.P. cough medicines, or the chronic sick could be put into the same category as the pensioners and receive certain "non-life-saving" medicines free.

The introduction of this scheme would certainly cause an outcry, but sooner or later this will have to be faced.—I am, etc.,

Harrogate.

BETTY J. BATT.

Succession to Single-handed Practices

SIR,—The paragraph (75) of the G.M.S. Committee's report (*Supplement*, May 2, p. 159) concerned with this problem was referred back by the Conference of Local Medical Committees in June (*Supplement*, June 27, p. 293). Then, in July, the corresponding section of Council's report was also referred back by the A.R.M. (*Supplement*, July 18, p. 15). This shows that there is a large measure of disquiet with the solution which has been agreed by the Ministry, the G.M.S. Committee, and the Medical Practices Committee.

It is even more disquieting, therefore, to read that when the G.M.S. Committee came to reconsider the matter, despite long discussion, they were unable to suggest any alternative. If, despite the disapproval of both the Conference and the Representative Body of the existing scheme, the G.M.S. Committee will not take up the matter with the Medical Practices Committee, that existing scheme will remain in operation for another year, and perhaps indefinitely, if the same thing happens next year—or do the G.M.S. Committee hope that the matter will be forgotten by next summer?

I am sure that the representatives at both meetings realize the practical difficulties involved in this thorny problem, but nevertheless they could not accept, as a question of principle, the agreed scheme. Would it not be better if the wording of the relevant paragraphs were altered to this effect: "The Medical Practices Committee will normally accept the remaining partner as the successor, unless there are special circumstances which, in the opinion of the local medical committee, render such succession contrary to the best interests of the Service?"—I am, etc.,

Stevenage.

DAVID L. GULLICK.

Capitation System Unsatisfactory

SIR,—Dr. A. C. McLeish (*Supplement*, August 1, p. 71) has put a finger precisely on one of the major obstacles to the full and efficient employment of all members of the profession in general practice—the capitation system. As he so rightly points out, a doctor is paid on the number of patients he can attract, while the quality of his work goes unheeded. It is manifestly wrong that patients should have to wait one or two hours for the privilege of two minutes of the doctor's time, while hundreds of general practitioners are unable to enter practice.

There seem to me to be two possible solutions—limitation of lists, or a salaried service. I am aware that there is a nominal limitation of N.H.S. lists at present, but I do not think that a doctor can provide conscientious service for 3,500 patients all the year round even if he does nothing else, and certainly not in addition to midwifery, private work, vaccination clinics, dental anaesthetics, etc.

The second solution, supported by Dr. McLeish, is the introduction of a salaried service. I have heard various objections to this—that the doctor-patient relationship would be endangered, that freedom to choose one's doctor would be lost—but I feel the strongest reason is the conviction that the State would not pay a salary on the scale at which a full list is now paid for.

My submission, therefore, is that until general practitioners reduce their valuation of themselves the present unsatisfactory state of affairs will continue.—I am, etc.,

Petts Wood, Kent.

H. HILDITCH.

SIR,—I am writing to support the earnest plea of Dr. A. C. McLeish (*Supplement*, August 1, p. 71) that the time has come for the introduction of some form of salaried service.

A salaried service, under a corporation like the B.B.C.—that is, devoid from politics—would have many obvious advantages. It would reduce the soaring drug bill by 50% at least, if not more, if the doctor were relieved from the pressure of the exacting patient and cut-throat competition. Medical practitioners are not free agents as regards certification nowadays. Stricter certification (not under pressure) would save the country many millions, and would bring back some dignity to the profession. Nothing has contributed more to the degradation of the profession than the "easy certificate."

A salaried service would put an end to the bitterness which has torn the profession in two in recent times, and which manifested itself in the Extraordinary General Meeting. A salaried service would welcome the young practitioners, instead of exploiting them or looking on them with suspicion as potential competitors.

With a salaried service, group practice could be introduced immediately and would succeed. Group practice with doctors competing within the group will never work. A salaried service, under an independent corporation, would improve the intolerable conditions of practice nowadays, would introduce a new spirit of co-operation, and would raise the dignity of the profession.

Finally, for your information, I have never been a socialist or communist—but, in view of the fact that the Health Service has come to stay, a salaried service would be preferable from every point of view to the chaotic conditions which prevail at present.—I am, etc.,

Manchester.

Association Notices

FORENSIC PATHOLOGY

Petition for the Formation of a Group

The following petition for the formation of a Group of Forensic Pathologists (specialists in forensic pathology) has been addressed to the Council.

"We, the undersigned members of the British Medical Association, engaged in the practice of forensic pathology, hereby make petition for the formation within the Association of a Group of Forensic Pathologists (specialists in forensic medicine).

"We are engaged in a branch of professional work which has always been of great importance both to the medical profession and to the public. In recent years it has become more specialized and, on account of crimes of violence and increase in litigation, plays each year a more prominent part in the security of the community as a whole. The number of pathologists practising the subject in one Division is too small adequately to represent the medico-political problems of our specialty or to advise the profession, and we are of the opinion that the formation of a group would be an advantage not only to the specialty but also to the Association. We feel that at present forensic pathology (medicine) is not adequately represented within the existing framework of the Association by the Pathologists Group, which must perforce cover the whole of that large subject; at the same time we could, as a body, assist the interests of the Association and especially of its general pathologists by reason of our particular training and experience."

SIR CHARLES HASTINGS CLINICAL PRIZE
ESSAY COMPETITION

The Sir Charles Hastings Clinical Prize Essay Competition was established by the Association for the Promotion of systematic observation, research, and record in general prac-

tice. The Competition has been extended by the addition of a second prize known as the Charles Oliver Hawthorne Clinical Prize. The following are the regulations governing the awards:

- (1) The Sir Charles Hastings Clinical Prize, consisting of a certificate and 50 guineas, will be awarded for the best essay submitted.
- (2) The Charles Oliver Hawthorne Clinical Prize, consisting of a certificate and 40 guineas, will be awarded for the second best essay submitted.
- (3) Any member of the Association who is engaged in general practice is eligible to compete for these Prizes.
- (4) The work submitted must include personal observations and experiences collected by the candidate in general practice, and a high order of excellence will be required. If no essay entered is of sufficient merit no award will be made. Candidates in their entries should confine their attention to their own observations in practice rather than to comments on previously published work on the subject, though reference to current literature should not be omitted when it bears directly on their results, their interpretations, and their conclusions. It is suggested that essays should consist of from 3,000 to 10,000 words.
- (5) Essays, or whatever form the candidate desires his work to take, must be sent to the Secretary, British Medical Association, B.M.A. House, Tavistock Square, London, W.C.1, not later than December 31, 1953.
- (6) A prizewinner in any year is eligible for an award of either of the prizes in any subsequent year. A study or essay that has been published in the medical press or elsewhere will not be considered eligible for a prize, and a contribution offered in one year cannot be accepted in any subsequent year unless it includes evidence of further work.
- (7) If any question arises in reference to the eligibility of the candidate or the admissibility of his or her essay the decision of the Council on any such point shall be final.
- (8) Preliminary notice of entry for this competition is required, on a form of application to be obtained from the Secretary.
- (9) Each essay, which should be unsigned, must be typewritten or printed and accompanied by a note of the candidate's name and address.
- (10) Inquiries relative to the prizes should be addressed to the Secretary.

Meetings of Branches and Divisions

GLASGOW DIVISION

A meeting was held in the Glasgow Regional Office on May 29, 1953. With Dr. W. D. Anderson in the chair, there were 21 members present. Arrangements for the Annual Meeting to be held in Glasgow in 1954 were discussed. Dr. J. I. Cameron Joint General Secretary, reported considerable progress by the Arrangements Committee dealing with the scientific side of the Meeting. A draft letter was approved to be sent to members of the Division appealing for support for the Hospitality Fund and co-operation in arranging private hospitality for overseas, foreign and United Kingdom visitors.

NORTH LANCASHIRE AND WESTMORLAND BRANCH

The fourth annual meeting of the Branch was held at Blackpool on May 21, when Dr. T. S. Blackledge, of Blackpool, was installed as President for 1953-4. In his presidential address Dr. Blackledge spoke of "the show of gold" which had fallen into the lap of the general practitioner a reward not in any way undeserved and which emerged from the determination of a small compact minority of the profession to insist on the fulfilment of promises previously given. This was achieved in a manner consistent with the dignity of the profession and without holding society as a whole to ransom. O the N.H.S. Dr. Blackledge said: "There is no field in which is more incumbent upon us to remember that the price of liberty is eternal vigilance. . . . Administrative dockets and bureaucratic files can become an abomination. Medicine has a humanistic background, and one must not lose sight of the individual as such."

Dr. Ian M. Dove, of Blackpool, and Dr. J. R. Turner, of Furness Division, were elected Vice-Presidents and Dr. John Wilkie, Lancaster, was re-elected Honorary Secretary. The members were the guests of the Blackpool Division at lunch, and golf and excursions were enjoyed in the afternoon.

Correspondence

Because of the present high cost of producing the Journal, and the great pressure on our space, correspondents are asked to keep their letters short.

Limited Lists

SIR,—Some of your readers, not directly concerned, may be unaware of the arrangements for payment for limited lists under the recently introduced distribution scheme.

The essential points are that loading shall not be payable, and the capitation payments shall be reduced by 20%. This figure is presumably based on a reduction of 10% as the practitioner is relieved of his liability to have persons assigned to him under the allocation scheme, and a reduction of a further 10% as the practitioner is exempted from liability of emergency calls to persons not on his list. It goes without saying that, if practitioners with limited lists were to be allowed to accept such additional responsibilities and receive the full capitation payment, they would be a great deal better off for very little additional work. To assess the total reduction at 2% rather than 20% would surely be a more accurate and realistic estimate.—I am, etc.,

I. M. BROWN.

Eastbourne.

Monthly Payment

SIR,—My partners and I have recently had to apply to our executive council for a payment on account on grounds of hardship. The nature of the hardship is one probably experienced by a great many general practitioners at the present time. The purchase of houses and cars is, in the majority of cases, made out of income. The Chancellor's policy of restricted credit, together with higher rates of interest and the diminished value of the pound, has affected all walks of life, and not least the medical man. Prior to the inception of the National Health Service, many practitioners relied upon the National Health Insurance for only a small part of their income. Nowadays the position is reversed, and in our own case 90% of our present income comes from the National Health Service.

I feel, Sir, and I am sure the majority of my colleagues agree with me, that it is time that the exceptional method of payment to general practitioners, payment at the end of each quarter, was reviewed and that a method of fact that Prime payments was devised. It is a matter of fact that Prime Ministers, Cabinet Ministers, Members of Parliament, judges, members of the armed Forces, Civil Servants, and indeed all other people whose source of income is the Exchequer, are paid by the month. University professors are, I believe, an exception to this rule among professional men.

I have it on good authority that there would be no real difficulty or expense involved in paying general practitioners monthly. It would be possible to send to each practitioner at the end of each quarter two pay warrants amounting to 30% of his previous quarter's earnings, payable on the last day of each of the following months; the balance of 40% could follow at the end of each quarter, leaving ample margin for any depreciation in his list, etc. I am also told that any representation made by the profession to the Ministry of Health would be sympathetically received.

I would be interested to read the views of my colleagues in this matter.

A RURAL PRACTITIONER.

Domiciliary Anaesthesia

SIR,—I beg to call attention to an anomaly in the N.H.S. Many dental operations are performed in the patient's own home. These fall, as a rule, into one of the following categories: (1) Cases where intratracheal anaesthesia is indicated either by the prospective duration of the operation or by the possibility of heavy bleeding. (2) Cases of cardiac or pulmonary disease which add to the anaesthetic risk. (3) Cases where the patient is extremely nervous and anaesthesia in the dental chair is not a pleasant prospect for patient or operator. It would be impracticable to deal with all these patients in hospital even if the large number of beds involved were available, because this would interfere with the patient's free choice of dentist.

In many of these cases the patient's own doctor is asked by the dentist to administer the anaesthetic. He may very well consider that he is not qualified to administer an intratracheal anaesthetic or an anaesthetic to a bad cardiac case. In this event he may call in a consultant anaesthetist to anaesthetize the patient. It appears that in such a case no domiciliary consultation fee can be claimed because "the patient is not unfit to go to hospital." The criterion of the patient's unfitness to go to hospital was laid down to prevent a consultant being called to a patient who was fit to visit him in his out-patient department, and clearly has no bearing in these cases.

I consider that this matter should be brought to the notice of the Ministry of Health and cleared up as quickly as possible.—I am, etc.,

East Boldon, Co. Durham.

M. RUSHTON.

Cost of Prescribing

SIR,—In advocating the more extended use of digitalis folia, Dr. Geoffrey Bourne (*Supplement*, July 25, p. 66) has not taken into account the ravages which time and climate can play on such a tablet. During inspections of smaller hospitals in East Africa I frequently found tablets of digitalis folia that had been on the dispensary bench for as long as 10 years. They would remain undisintegrated in

a tumbler of water overnight and appeared to be therapeutically quite inert. A well-made product of a pure glucoside such as digoxin would appear to be free from these disadvantages.

A drug which may fail to achieve its purpose is not cheap at any price. Is there not a danger that pharmacists in England, as a result of Dr. Bourne's exhortations, may be dispensing stocks of tablets of digitalis folia which have long been uncalled for, since the wider use of digoxin has been customary?—I am, etc.,

London, S.W.12.

DONALD LATHAM.

SIR,—Economy in prescribing is seemingly the burning topic of the hour and the target for attacks from Members of Parliament. With it goes the implied allegation of waste and carelessness on the part of the doctors.

Publication of the list of 650 proprietary preparations, use of which is discouraged, has received considerable publicity, and tends to create the impression that there is much room for improvement in the work of the family doctor. When one considers that of that list of 650 the majority are so obscure that neither my dispensing chemist nor I had even heard of them, it reduces itself to a farce. In actual fact, it is impossible to believe that the problem of waste is being realistically approached. No doubt a small reduction of expenditure on dispensing will follow the use of the list, but it will only be achieved by throwing the onus on the family doctor—he gets "the dirty end of the bamboo" as usual.

The situation which has arisen over dispensing can be fairly ascribed to the vapourings of politicians who flung open the chemists' shops in 1948 and encouraged the public to help themselves. Everything was to be "free"; then the bills began to come in, the chemists' profit was cut, the doctors were blamed, and the public continued to expect all their old favourite proprietaries at the new rate, free, gratis, and for nothing. Naturally they had been taught to expect them. But the one step that could be taken (and would be taken if politics had nothing to do with the matter) remains untried. So far nobody has had the courage to say to the public that a mistake was made, that after all we cannot afford to give them at State expense their favourite remedies, and that they must buy their own or accept the N.H.S. dispensing.

No attempt has yet been made to wean the public from their attitude of expectancy of "free for all and never mind the cost." The politicians started this trouble; the public cannot be blamed for swallowing their familiar ration of political half-truths, untruths, and promises that cannot be fulfilled; yet there is no particular reason why the family doctor should have the task of satisfying an insatiable demand he has not aroused. Nor is there any particular reason why he should face up to the unpleasantness of saying "No" to patients who have looked upon him as a friend rather than as a watch-dog of the Ministry.

Had the Ministry played fairly and done their part, honestly trying to re-educate the public out of their mistaken conceptions, whilst calling upon us to economize, we could have seen some sign of their sincerity. As it is, we are to take the blame for the politicians' mistakes and are expected to do their distasteful cleaning up after them. And the queer part of it all is that as a profession we do it—face our patients' disapproval on one side and veiled Ministerial threats on the other side, and do it without a murmur.

There seems nobody in the profession shrewd enough to realize the part thrust on us by the Ministry, no one wise enough to give the Ministry our assistance at the price of a ministerial campaign of public re-education, and no one with backbone enough to stand up for the family doctor in his daily tussle with an impossible job. We let the Ministry give us a bad name at the very moment when a vigorous handling of the situation would nail the blame where it belongs, and the time has come for us to declare our stand. We shall be pretty small if we don't.—I am, etc.,

carehead.

K. T. BROWN.

Sweated Doctors

SIR,—Dr. W. B. Manley's comparative analysis of various N.H.S. workers' earnings (*Supplement*, August 8, p. 75) indicates a deplorable state of affairs. When it is considered that the keep of a house officer can scarcely be less than £3 and his laundry another 10s. it will be realized how little of his £6 15s. is left at the end of each week.

I can well remember the £1 per week that I and my contemporaries received for early house jobs a quarter of a century ago. At that time the earnings of employees mentioned by Dr. Manley were actually in excess of ours. We were ridiculously docile wage slaves, most of us holding the absurd notion that a house appointment was in reality a part of our training and should be paid for accordingly. Nor is it quite fair to compare past and present. In those days it was the custom of hospitals to provide full board and lodging.—I am, etc.,

Gillingham, Dorset.

G. E. ELLIS.

Meetings of Branches and Divisions

BURY DIVISION

At the annual general meeting held at the Bury General Hospital on June 22, 1953, the following officers were elected:

Chairman.—Dr. F. M. Braithwaite.
Vice-chairman.—Dr. D. Brown.
Treasurer.—Dr. J. S. B. Mackay.
Secretary.—Dr. E. Smalley.

DORSET DIVISION

A meeting was held at the Clinic, Dorchester, on June 9, 1953. With Dr. H. G. Harvey in the chair, there were 14 members present. Dr. C. Hollins gave a talk on his experiences in the Colonial Medical Service in Nigeria, with particular reference to trypanosomiasis.

SALISBURY DIVISION

The annual general meeting was held at the Salisbury Infirmary on July 17, 1953. Dr. P. Greenstreet was in the chair and 10 members were present. The following officers were elected for 1953-4:

Chairman.—Mr. A. Duff.
Vice-chairman.—Mr. Brian Reeves.
Secretary.—Dr. A. L. L. Silver.
Treasurer.—Dr. I. E. Jameson.

SUFFOLK BRANCH

The annual meeting was held at Everard's Hotel, Bury St. Edmunds, on June 18, 1953. With Dr. C. B. Bevis in the chair there were 22 members present. The following officers were elected for 1953-4:

President.—Dr. J. W. E. Cory.
Vice-president.—Dr. C. Grantham-Hill.
Immediate Past-president.—Dr. C. B. Bevis.
President-elect.—Dr. D. M. Craig.
Secretary.—Dr. W. P. Grieve.

Dr. W. Hedgcock, assistant secretary of the B.M.A., spoke on current medico-political matters.

Dangerous Drugs Act: Withdrawal of Authority

The Home Office announces that Dr. Thomas Bertram Whitehead (Oldham) is no longer authorized to be in possession of or to prescribe those drugs to which the Dangerous Drugs Regulations apply.

ISLE OF MAN COMMISSION ON SALARIES AND EMOLUMENTS DISCOURTEOUS TREATMENT OF B.M.A.

The Isle of Man has its own Health Service modelled on that of Britain. It is governed by the National Health Service (Isle of Man) Act, 1948. In this Act the administration of the Service is entrusted to a Health Services Board. In 1950 the Health Services Board gave an undertaking that the remuneration and terms of service of doctors would not be less than those in Britain. It was added that, at any time be less than those in Britain. It was added that, should any deviation be suggested at any time, three months' notice would be given to allow time for discussion of the proposal.

On March 31 of this year the Health Services Board notified the Isle of Man Branch of the B.M.A. (the Isle of Man Medical Society) that as from June 30—the requisite three months—it would no longer consider itself bound by the agreement on remuneration and terms of service made in 1950. This was followed by an undertaking that the Danckwerts award would be applied up to June 30, 1953, and retrospectively to 1948. There are about 30 general practitioners in the island.

Commission Appointed

The Manx Government has been perturbed for some time about the cost of its social services, particularly the Health Service, and has been looking for ways in which to economize. What payment doctors are to receive subsequent to the termination of the Government's yet to be decided, but an indication of a Commission to inquire into salaries and emoluments with the following terms of reference: "To consider how far it is equitable and in the general interest of the Isle of Man that different conditions appertaining here (with particular reference to income tax) should be taken into consideration when applying English emoluments to positions in the Isle of Man and to recommend in what way such emoluments can best be adjusted to Manx conditions." Income tax in the Isle of Man is at present considerably less than in Britain.

B.M.A.'s Action

As soon as he heard of the Commission the Secretary of the Association wrote and made an application for the B.M.A. to make oral or written representations to it. The Association's application was acknowledged on July 8 with a statement that "a further communication will be addressed

to you in due course." On July 31 a further letter was sent to the Commission asking when evidence would be required and stating that the Association could submit a memorandum in the latter part of September. On August 4 a letter was received from the Commission: "I have to request that you be so good as to forward me your Association's written representations for submission to the above-named Commission. I shall inform you later of the date when the Commission will hear your Association's oral representations."

To this the Secretary of the Association replied immediately, repeating a previous explanation of the difficulty of preparing evidence during the holiday season and asking for the latest date on which the Commission would be prepared to receive a memorandum.

There was no reply until August 12. On this day the Secretary of the Association received a letter from the Commission: "The above-named Commission has fixed Tuesday, August 18, 1953, at 2.30 p.m. as the date for hearing the oral representation of your Association. I am to point out that it would cause great inconvenience to alter this date and it would suffice if your Association's written representation could reach me not later than Monday, August 17, 1953." In spite of strong protest by telephone the Chairman of the Commission, Sir Sidney Wadsworth, refused, in a telegram received on August 13, to postpone the date. Within two days and nights the Secretary of the Association had flown to the Isle of Man for local consultations, consulted an eminent economist, and, on his return to London, had prepared a memorandum which reached Douglas on the morning of Sunday, August 16. This memorandum is printed below.

Casual Reception

At considerable inconvenience, Dr. Talbot Rogers, Chairman of the G.M.S. Committee, accompanied the Secretary on a difficult journey to appear before the Commission in Douglas on August 18. Also present were the President, Chairman of the Representative Committee, and assistant honorary secretary of the Isle of Man Branch. Their protest at the lack of courtesy and consideration shown to the Association was casually received by Sir Sidney Wadsworth, the Chairman. Equally casually he remarked that he had not read the Association's evidence, as it had come to him only a minute before. The Commission agreed to receive

2536

within a week or so such further evidence as the Association could provide. After 90 minutes, instead of the 30 minutes only which had been planned by the Commission, the Association's representatives withdrew. The Commission will report to the Tynwald in due course.

There are about 50 medical practitioners in the Isle of Man who may be affected by any decision on the recommendations of the Commission by the Manx Government.

MEMORANDUM OF EVIDENCE SUBMITTED TO THE COMMISSION ON SALARIES AND EMOLUMENTS, ISLE OF MAN

INTRODUCTORY

1. The British Medical Association, of which Her Majesty the Queen is Patron, is a voluntary organization of doctors with a membership, at home and overseas, of some 67,000. Its membership includes more than 80% of the doctors in active practice in the United Kingdom. Its principal objects, as defined in its Memorandum of Association, are "to promote the medical and allied sciences and to maintain the honour and interests of the medical profession."

2. The Association is the chief representative organization of the medical profession in the British Isles and has long been recognized as such by Government Departments and by many public authorities and other bodies. On very many occasions it has been specifically invited to assist Royal Commissions and departmental and interdepartmental committees by providing both written and oral evidence.

3. Through the Health Services Medical Whitley Council, the Association takes part in the negotiation of the terms and conditions of service of members of hospital medical staffs and medical officers in the public health service. The General Medical Services Committee of the Association negotiates directly with the Ministry of Health on all matters relating to the terms and conditions of service of general medical practitioners in the National Health Service, and this committee is the only body with which the Ministry enters into such negotiations. An illustration of the standing of the Association in relation to the Government is afforded by the fact that no regulation concerning the general medical services is made and no instruction issued by the Ministry of Health to local executive councils until it has first been discussed in draft form with this committee of the Association.

4. The Isle of Man Medical Society is a branch of the British Medical Association, which is therefore properly concerned with the affairs of the doctors on the island no less than with those of the doctors on the mainland.

5. The Association is grateful for the opportunity of submitting representations to the Commission on Salaries and Emoluments, but it is with regret that it finds it necessary to state that the Commission has allowed insufficient time to permit of this memorandum being produced with the care habitually given to the preparation of a document of this kind, or being placed before the Council of the Association for the customary examination and approval before presentation to the Commission. The memorandum, however, carries the authority of the Chairman of the Council. No doubt it bears the marks of hasty composition, and certainly it could with advantage have been revised and amplified had more time been available—particularly for consultation with appropriate experts. The demand of the Commission for the document to be produced and posted at three days' notice and for representatives to submit oral representations at six days' notice is an occurrence unprecedented in the Association's long experience of dealings with governmental bodies. The Association therefore asks that the present document be accepted as merely an interim statement of its views and that an opportunity be given of making additional representations to the Commission after it has been possible to secure a detailed report from an expert in economics.

REMUNERATION IN RELATION TO INCOME TAX

6. Two committees which sat under the chairmanship of Sir Will Spens were charged with the duty of considering what should be the remuneration, in a publicly organized health service, of general medical practitioners in the one case and of consultants and specialists in the other. It is on the recommendations of these committees that the payments made to general practitioners and to consultants in the National Health Service are based.

7. The two Spens Committees expressed their recommendations in terms of the value of money in the year 1939, leaving to others the task of making the necessary adjustments to take account of the changed value of money and of changes in the incomes of other professions. Neither committee suggested any adjustment related to income tax or made any reference whatsoever to variation in rates of income tax as a relevant consideration in the assessment of proper levels of remuneration. The introduction of this consideration would be a departure from the principles of the Spens Reports, which have been accepted both by the Government and by the medical profession.

8. In March, 1952, the "betterment factor" to be applied to the Spens figures for general practitioners was decided by the award of Mr. Justice Danckwerts. The method established by the Danckwerts award of determining each year the size of the fund from which the capitation payments are made to general practitioners takes account of a number of variables, but takes no account of varying rates of income tax.

A Strange Proposal

9. The budget for the financial year 1953-4 included provision for a reduction in the rate of income tax; yet no suggestion has been made that there should be a corresponding decrease in the remuneration of any section of the medical profession.

10. The Commission on Salaries and Emoluments is now asked "to consider how far it is equitable and in the general interest of the Isle of Man that different conditions appertaining here (with particular reference to income tax) should be taken into consideration when applying English emoluments to positions in the Isle of Man, and to recommend in what way such emoluments can best be adjusted to Manx conditions." Presumably the doctors working in the health services in the Isle of Man would be included among those whose remuneration would be affected by any adjustment of the kind here envisaged.

11. The British Medical Association, having no special competence outside the medical field, hesitates to pronounce on a large economic issue, but the suggestion that the remuneration of persons who are paid from public funds should be subject to increases and decreases directly related to variations in the rate of income tax appears to it at first sight to be strange and, indeed, preposterous. Is it seriously contemplated that, because the present rate of income tax payable in the Isle of Man is lower than that payable on the mainland, the doctors, for example, on the island should receive for their work in the Health Service correspondingly lower incomes than are earned by their colleagues on the mainland? If this were brought about, it would seem to follow inevitably that their remuneration would require adjustment on each and every occasion on which income tax was either raised or lowered, whether on the island or on the mainland. If, for instance, world disarmament led to a reduction of the rate of tax on the mainland from 9s. to 6s. 6d., the authorities concerned in the Isle of Man would immediately be committed to a corresponding increase in the payment of the local doctors. The Association can see no justification for any such plan of measuring remuneration by a sliding scale in accordance with varying rates of tax.

12. It is a recognized obligation of the individual citizen to contribute a fair proportion, related to the size of his income, of the funds which must be raised by direct taxation to meet the cost of services which the Government elected by the community has provided for the benefit of

the community. If the cost of these services increases, the Government may reduce the extent of the services provided and thus reduce their cost, or it may call for a larger contribution from the citizen. If it chooses the latter course, the obligation of the citizen to pay his fair share remains, although his fair share now amounts to a larger proportion of his income. There appears to be no case for him to demand a measure of exemption from this obligation in the form of a compensatory increase of pay. Indeed, financial compensation for a rise in the rate of income tax would appear to reduce the system of taxation to absurdity.

The Economic Argument

13. If there is no justification for increasing earned incomes to protect the taxpayer against an increased rate of income tax, neither is there any justification for reducing these incomes to deprive the taxpayer of the benefit of a reduced rate of income tax. In such consultations—necessarily extremely hurried in the limited time available—as the Association has been able to hold with experts in economics, it has found no support for the theory that net earned income—in the sense of the amount of earned income remaining after the deduction of income tax—should remain constant. For example, Mr. George Schwartz, who is economic adviser to Kemsley Newspapers and was formerly Lecturer in Economics in the University of London, has informed the Association that he feels certain that no reputable economist would subscribe to such an argument. In his opinion, there is not the slightest justification for adjusting the remuneration from public funds of the doctors engaged in the health services, whether on the mainland or in the Isle of Man, in accordance with differences in the rates of income tax payable locally from time to time; nor is there the slightest justification for adjusting the remuneration of the doctors on the island in accordance with a difference between the rates of tax payable on the mainland and on the island at one and the same time. Mr. Schwartz goes so far as to describe any such proposal as "indefensible, impracticable, and absurd."

14. The Association therefore submits that, so far as income tax is concerned, the adjustment of "English emoluments" to Manx conditions envisaged in the terms of reference of the Commission on Salaries and Emoluments would be wrong in principle, and that the doctors working in the health services should continue to receive consistently, year after year, the recognized "rate for the job," contributing income tax from year to year at whatever rate the central Government or the Manx Government, as the case may be, may find it necessary to levy for the time being.

15. In view of the fundamental objection in principle to the plan contemplated, it seems scarcely necessary to prolong the argument; but brief reference should perhaps be made to certain anomalies which the adoption of the plan would entail if its adoption proved practicable. There would be the grave objection that one section only of the population of the island would be prevented from earning incomes comparable with those earned in corresponding circumstances on the mainland. In effect, those residents on the island who are paid from public funds would pay the mainland rate of income tax, while a large proportion of the local population would continue to pay the lower local rate of tax. Do the Manx hotel-keepers, for instance, because of the reduced charges to visitors to the island because of the relatively low Manx income tax? Are any Manx products sold on the mainland at prices below those generally obtaining on the mainland because of the relatively low Manx income tax? Do the British banks with branch offices on the island pay their staffs at rates below their standard rates because of the relatively low Manx income tax? Does even the local Manx Bank pay its staff at rates below those of the mainland banks because of the relatively low Manx income tax? The answers to these and other similar questions are understood to be in the negative; and the Association has difficulty in understanding the equity of paying a doctor less than the rate for the job on the ground that he enjoys the

comparatively favourable local conditions in respect of tax while a bank manager, for example, receives the full rate for the job although enjoying precisely the same local conditions.

Effect on Superannuation

16. A further illustration of the injustice of the plan under consideration is evident when one considers what its effect would be on the superannuation arrangements for doctors engaged in the health services. The pension granted to the general practitioner on retirement is related to the amount of his remuneration throughout the whole period of his service. It follows that a practitioner who, after 10 or 12 years of practice on the island, decided for one reason or another to move to a practice on the mainland would eventually receive a smaller pension than would be paid to a colleague whose circumstances were identical except that he had spent the whole of his professional life on the mainland. In the case of the consultant the retirement pension is related to the remuneration earned during the final years of service. Hence a consultant who took up an appointment on the island in middle life and held this appointment until his retirement would receive a reduced pension although he might have paid the higher mainland superannuation contributions (the standard 6% of the higher mainland salary) for a considerable period.

17. It appears to the Association that, under the plan contemplated, it would be a misfortune to be engaged in work for which payment was made by the Manx Government. It is unlikely that in such circumstances the normally competent and ambitious doctor would be attracted to service on the island. The probability is that the plan would have a detrimental effect on recruitment to the Manx health services and would therefore prove injurious to the interests of the local community.

COST OF LIVING

18. It is not known what other "Manx conditions" may be under consideration by the Commission as possibly justifying an adjustment of "English emoluments"—whether, for example, comparative figures relating to the cost of living on the mainland and on the island are being studied. The Association would not accept evidence of a lower cost of living on the island as warranting an adjustment of remuneration without first considering whether this advantage was offset by disadvantages connected with the relative isolation of the island doctors.

19. In fact the Association is aware of no such evidence. On the contrary, such limited information on the subject as it has been able to acquire suggests that the contrary position may be the true one. The Association, however, would welcome an opportunity of examining any relevant statistics on which the Commission might propose to base its recommendations.

CONCLUSION

20. The Association appreciates the fact that the function of the Commission is a purely advisory one and that it would be for Tynwald to put into execution any recommendations of the Commission which it might see fit to approve. Nevertheless, it is perhaps fair to state at this stage, for the information of the Commission, that the medical profession would certainly resist to the uttermost any proposal, based on considerations of income tax, to pay the doctors on the island at lower rates than those obtaining on the mainland, and would be forced to use every legitimate means at its disposal to prevent any such proposal from being put into operation or retained in operation.

21. The Association would again ask that it may be given an opportunity of submitting further written observations should the present hastily produced memorandum fail to convince the Commission. Meantime, if the Commission is studying any other matters on which it is thought that the Association's comments might be helpful, the Association would be very glad to afford any assistance in its power.

An Association Service

THE LIBRARY

The Library of the British Medical Association is not just a collection of some 65,000 books and a turnover of 1,600 journals regularly available. It is not even a spacious building with an ample reading-room and gallery and alcoves such as the present Librarian dreams about when some additional land at the back of B.M.A. House comes into occupation. It is a functioning thing—an expert service. Its staff of 10 are trained people. Librarianship is not learned in a day or a year; it is a highly skilled job, as everyone must appreciate who has been turned loose in a library and left to find his own way about. Moreover, the B.M.A. Library is not merely a place to which people come and look at books: the mountain goes to Mahomet, it is a place from which books and periodicals go out to them.

At successive Annual Meetings, on the presentation of the report on the science activities of the Association, the chairman of the committee has always given an appreciative nod in the direction of the Library as a useful branch of the Association's work, but never, in the writer's recollection, has it evoked discussion, either in terms of criticism or praise. It is too often regarded as one of the Association's side-shows, to be taken for granted. Someone once called it a Cinderella, but if it is that poor maiden she has no time to sit over the hearth, for she has to issue 30,000 books and journals in the year for home reading, and to dispatch nearly 12,000 parcels to all parts of the kingdom.

A Dip into History

For nearly 60 years of its history the Association had no library, and it was not until 1893 that a permanent full-time librarian was appointed. Incidentally, during the 60 years since then there have been only two such officers—Mr. Spencer Honeyman, who served until 1929, and Mr. T. J. Shields, the present Librarian, who was appointed in that year. The Library has had invaluable service, however, in an honorary capacity, notably by Mr. Walter G. Spencer, who was honorary librarian from 1923–9, and a generous donor.

When the Association entered its present premises in 1925 the Library was accommodated in what is now the members' lounge and later in the north wing; a few years ago it was transferred to more commodious quarters on two floors overlooking the garden court. But its premises are less ample than its contents and service deserve. Some day, when economic circumstances permit, the Library may come into its own with increased grants and be able to perform still greater service.

Hastings Collection

Sir Charles Hastings, the founder of the Association, was a bibliophile, and some part of his collection came into the possession of the Association as late as 1926. Four years after the Association was founded there was a proposal for a Library, but it was turned down and nothing was done about it for the ensuing half century. It is rather astonishing how many people, physicians and philosophers among them, have failed to appreciate the value of a library. There was John Radcliffe who deprecated "the rubbish of antiquity contained in musty volumes" and undertook to write down all necessary medical knowledge on a sheet of paper, though, to be sure, he left £40,000 to found a library at Oxford—as though, said a wit of the time, a eunuch had left money to establish a seraglio.

But it was probably practical considerations that determined the early decision not to have a library. So long as its headquarters were at Worcester the Association had no house of its own, and long after it came to London its headquarters were little more than the editorial and publishing

offices of the *Journal*. Again, to render a library available to members scattered all over the country may well have seemed a hopeless proposition.

The First Collection

In the 'eighties Mr. Ernest Hart, then Editor of the *Journal*, in a letter to Sir Walter Foster, Chairman of Council, proposed a reading room and reference library in the new home of the Association in the Strand. Hart was the first donor and the first honorary librarian. He started the practice, which has been continued by subsequent editors, of passing on to the Library, after the reviewers had done with them, books received for review. The Library was opened to readers in 1889, when it consisted of 2,600 volumes. Within a very short space of years the number had risen to 5,000, and the material was such, said a report at the time, "as to make one believe that it may eventually become one of the best medical libraries in the country." In 1892, 2,000 visitors entered their names in the admission book at the door of the reading-room. In the following year Spencer Honeyman, who had previously assisted Hart in forming the collection, was appointed full-time librarian (hours of attendance 10 to 5), at a salary of £150—a salary raised within two or three years to £200, with an acknowledgment of the efficiency and courtesy with which he discharged his duties.

When the Association, after occupying temporary quarters during rebuilding, went back to its new premises in the Strand in 1908, the Library was given quite a handsome setting in a lofty room pillared with Spanish mahogany, and with accommodation, including storage space, for 25,000 volumes, which was twice as many as it possessed at that time. As great an authority on librarianship as Sir William Osler paid it a great tribute at the Belfast Meeting in 1909, declaring it to be one of the most valuable of modern professional libraries.

The Library was at first maintained for reference purposes; a lending service was not developed until after the first world war. In 1922 the books lent to members numbered 3,700; by 1931 the number had increased to 15,000; and by now it has more than doubled that figure. By the time of the centenary in 1932, the Library, in the meantime installed at Tavistock Square, contained 40,000 volumes, and so it has gone on growing. Last year there were 35,000 attendances and borrowings, though the figure does not include the many who drop in at the library and look up a reference without troubling to sign the admission book, nor members of the Association staff who constantly have occasion to consult the Library. It is worth noting that twice as many country members as town members use the shelves. Books and journals in current demand are issued for 14 days; others for 28 days. But the current fasciculus of any periodical cannot be loaned, and not more than two issues of a particular periodical may be borrowed at any one time. There is no charge for borrowing, except postage.

With no end, as Solomon said, to the making of books (though he was corrected by old Thomas Fuller, who said that it was of the making of foolish books there was no end), space is the librarian's nightmare. The solution to the problem may lie in the microfilm, and the books of the future may not be within covers at all, but on reels of celluloid. That is a dismal prospect, but the B.M.A. Library has already a collection of microfilm, and two microfilm "readers" are available. There is a useful liaison between the Library and other leading medical and scientific libraries whereby they supplement each other.

A Modern Library

The Association's Library is a modern one—a working one. There is, of course, a great place for a library with literary treasures and ancient books, such as the Medical Society of London possesses. But to the man in busy practice, a member of a progressive profession, who knows that he must never cease to be a student, a modern library in which not only the latest textbooks (for, as someone has

said, textbooks nowadays are out of date before they leave the press) but journals are available is essential. The library is really an extension of the medical journal, a mirror of changes in thought and practice, a record of happenings in medical centres all over the world. That is why the Association library has specialized in periodicals, of which it has now probably as good a regular service as is to be found anywhere.

Mention must be made of one collection in the Library which is believed to be unique in this country. This is the medical *Thèses de Paris* (1892 onwards) and *Thèses de Lyon* (1894–1919). When Mr. Ernest Hart was in Paris soon after 1894–1919, the Library was founded he arranged for the receipt of a complete series of these theses. In France the professors in the various medical faculties make use of such theses as the mouthpiece for the teaching in the hospitals with which they are connected. When distinguished men are candidates for hospital appointments or professorships they give proof of their attainments in these essays, and thus many of them are *thèses d'agrégation*. The value of them, of course, varies, but some are of great importance, embodying the practice and matured opinion of leading teachers in the French hospitals, and they have been often consulted at the Association Library by British authors of textbooks.

Then, of course, there are those invaluable compilations, the *Index Medicus*, the *Quarterly Cumulative Index Medicus*, the *Index Catalogue of the Library of the Surgeon-General's Office*, and the *Current List of Medical Literature*, which are available in the Library, and enable the student to thread his way through the intimidating vastness of medical periodical literature. There is no printed catalogue of the Library, but there is a card index and additions are published in the *Supplement*.^{*} Members of the Association, the Library is at your service!

THE SMALL-LIST PRACTITIONER WORKING PARTY INQUIRY

The chairman of the G.M.S. Committee told the Special Conference of Local Medical Committees and the Extraordinary General Meeting of the Association in May (Supplement, May 9, p. 206) that it had been decided to invite the full Working Party to undertake an inquiry into the difficulties of practitioners with small lists and, in the light of the facts revealed, to consider whether any modifications should be made to the existing arrangements.

List Prepared

The Working Party has now considered the sort of information which it needs to make a general analysis of the circumstances of all small-list practitioners who might be adversely affected by the new distribution arrangements, and the Ministry has prepared a list of the names of single-handed practitioners who were recorded as having lists of less than 1,200 patients on January 1, 1953.

Executive councils are being asked to supply information from their own records which will enable the Working Party to examine some aspects of the circumstances of practitioners with small lists. This data, however, will not give the Working Party the complete picture which it needs for the purposes of its survey, since a number of those concerned will have substantial professional commitments outside general practice in the National Health Service.

Questionary to Small-list Doctors

In order to complete its survey, the Working Party wishes to supplement the information provided by executive councils by some knowledge of the work doctors are undertaking outside the Service. The G.M.S. Committee is therefore sending out through local medical committees a questionnaire to practitioners with lists of not more than 1,200. These prac-

^{*}Any presentation of medical books of the 16th to 18th century would be acceptable to the Association librarian.

tioners will not be asked to disclose details of professional remuneration. The questionnaire is designed to give an indication of the amount of time which is spent by them on professional commitments both inside and outside the Health Service. The information supplied by practitioners will be used solely for the purpose of building up a broad general picture and will not in any way be used when assessing the circumstances of those practitioners in regard to any scheme which the Working Party may decide to recommend in the light of the findings of the survey. The information will be treated in the strictest confidence and will be used only to form a survey for statistical purposes for the Working Party.

The General Medical Services Committee gave an undertaking that the Working Party would consider the problem of the small-list doctors as soon as the full facts were forthcoming, and it is hoped that the completed questionnaires will be returned to the Committee by the end of October.

MEDICAL PRACTICES COMMITTEE

The following amendments to the classification of areas (June 16 to August 1, 1953) have been issued by the Medical Practices Committee:

ENGLAND: COUNTIES

- Bedfordshire.—Dunstable, Intermediate from *Designated.
- Buckinghamshire.—Bletchley, Intermediate from *Designated; Marlow, Restricted from Intermediate.
- Cumberland.—Kirkbride, Restricted from Intermediate; Whitehaven with Rowrah, Intermediate from *Designated.
- Derbyshire.—Urban District of Clowne, Intermediate from *Designated.
- Durham.—Municipal Borough of Jarrow, Urban District of Washington, Intermediate from *Designated.
- Essex.—Urban District of Billericay, Intermediate from *Designated.
- Hampshire.—Rural District of Stockbridge, Restricted from Intermediate.
- Kent and Canterbury.—Borough of Margate, Intermediate from *Designated.
- Lancashire.—Urmston, *Designated from Intermediate; Tyldesley, Intermediate from *Designated.
- London.—Borough of Camberwell: Albyn, St. John's, The Rye and Nunhead Ward, Intermediate from *Designated. Borough of Islington: Canonbury Ward, Intermediate from *Designated.
- Middlesex.—Borough of Willesden: Manor Ward, Restricted from Intermediate.
- Northumberland.—Borough of Blyth, Borough of Wallsend, Intermediate from *Designated.
- Staffordshire.—Urban District of Willenhall, Intermediate from *Designated.
- Sussex (West).—Storrington, Restricted from Intermediate.
- Yorkshire (West Riding).—Borough of Pontefract, Urban District of Castleford, Urban District of Colne Valley, Rural District of Wakefield, Intermediate from *Designated.

COUNTY BOROUGH

- Croydon.—North Parliamentary Division, Intermediate from *Designated.
- Kingston-upon-Hull.—District No. 8, Intermediate from Designated.
- Stoke-on-Trent.—Fenton and Blurton, *Designated from Intermediate.

WALES

- Caernarvonshire.—Urban District of Penmaenmawr, Intermediate from Restricted.
- Denbighshire and Flintshire.—Cefn Mawr, Intermediate from *Designated.
- Cardiff.—Whole of County Borough, Intermediate from Designated.

*Areas in which the position is finely balanced and the admission of only one or two doctors may result in reclassification.

LOAN OF PATIENTS' RECORDS TO THE MINISTRY OF PENSIONS AND NATIONAL INSURANCE

The following circular (R.H.B. (53) 93, H.M.C. (53) 87, B.G. (53) 88, dated August 11) sets out revised procedures for the loan of patients' records to the combined Ministry of Pensions and National Insurance. The procedures operate from August 31, 1953.

1. Requests for patients' records will come from medical officers of the Ministry of Pensions and National Insurance in connexion with either claims for disablement benefit under the National Insurance (Industrial Injuries) Act, 1946, or the need for determining a person's entitlement to a disability pension (war pension) and the assessment of the degree of disablement on which the amount of that pension is based. The cases concerned are those in which a patient has received hospital treatment for wounds, injuries, diseases, or mental illness which may be due to, or aggravated by, enemy action or by service in the Armed Forces, Merchant Navy, Civil Defence Force, or Women's Auxiliary Services.

2. The Ministry of Pensions and National Insurance is prepared to give an assurance in each case that the consent of the patient to the loan of his records has been given in writing.

In the case of patients at mental hospitals or hospitals approved under Section 1 of the Mental Treatment Act, 1930, or under treatment at out-patient clinics associated with these hospitals, or in the case of mental defectives, the consent should be obtained by the medical officer in charge of the case at the request of the Ministry of Pensions and National Insurance. Where the patient is "certified" or "temporary," the consent of the responsible relative should be obtained, and also that of the patient himself if in the opinion of the medical officer he is able to give consent and ought to be asked to do so. Where the patient is "voluntary" his own consent should, of course, be obtained unless he is at the time incapable of understanding what is required, when the responsible relative's consent would be sufficient. Where the patient is a mental defective the responsible relative's consent should be obtained.

3. Case papers will not be asked for unless needed. Very exceptionally papers may be needed a second time, for an appeals tribunal. Because of the statutory conditions under which a pensions appeal tribunal works it is essential that the tribunal should have access to the full information and not only to copies or extracts.

4. Case papers will be treated as confidential and will be handled only by medical officers (and their confidential lay staff), by boarding doctors and consultants, and (on appeal) by the members of the appeal tribunal. An assurance has been given that if the papers include x-ray films special care will be taken of them. The case papers or any other copies or extracts that may be made are not accessible to unauthorized persons, and are not revealed to the patient except in case of appeal, when only the portions relevant to the appeal are disclosed subject to special scrutiny to ensure that no information which may be harmful is given to him.

5. In connexion with an appeal by a war pensioner to the Pensions Appeal Tribunal a statement of the case is prepared by experienced confidential lay staff of the Ministry of Pensions and National Insurance working in close collaboration with medical officers of that department, who scrutinize all reports obtained from N.H.S. hospitals which are to be included in the statement. This statement must, legally, be made available to both sides. Where, however, the evidence includes reports which the Ministry of Pensions and National Insurance medical officers consider might cause the appellant serious anxiety or distress or retard his progress, procedures which are provided for in the pensions appeal tribunal rules are operated, as follows, so that the appellant does not see these reports. When, as is usually the case, the appellant is to be represented by some organization at the hearing of his appeal, the representative handles the statement without showing it to the appellant and treats it as strictly confidential. When the appellant does not intend to be represented at the hearing, the Ministry of Pensions and National Insurance omits the harmful reports from the copies of the statement sent to him, though not from the copies sent to the tribunal, who are informed of the omissions and the reasons.

6. In paragraph 6 of R.H.B. (53)/H.M.C. (53)/B.G. (53) boards and committees are asked to furnish treatment reports on service pension cases to the War Pensions Office of the Ministry of

Pensions and National Insurance. These reports, which are not revealed to the patient or anyone else, are required only for the clinical records of the Ministry of Pensions and National Insurance medical staff to enable them to act on recommendations from the hospital, to follow up the case, and to take such action as is indicated on the pensioner's behalf. Consequently no question of consent arises.

7. If any records of treatment of Service men, civilians, or mariners under the E.M.S. scheme before the appointed day are still held by hospitals they may on request be released to the Ministry of Pensions and National Insurance.

8. Documents, etc., when called for are needed urgently, and in the interests of the patient hospitals are asked to comply with requests as quickly as possible.

HOSPITAL MEDICAL STAFF COMMITTEES MEDICAL ADVISORY MACHINERY

General guidance on the ways in which the Minister considers that medical staff committees can most usefully be constituted and organized is given in a circular dated August 15 (R.H.B. (53) 91, B.G. (53) 85, H.M.C. (53) 87). In a circular issued to boards of governors and hospital management committees by the Ministry early in 1948 a brief reference was made to the importance which the Minister attached to the appointment by different sections of hospital staff of staff committees, not only for the purpose of watching over the interests and welfare of the staff, but also to give advice on their respective spheres of the hospital's work to the board or management committee. During the succeeding years this expression of ministerial policy has, at any rate in some quarters, tended to be overlooked or ignored.

Although the present memorandum refers specifically to groups of hospitals administered by boards of governors and hospital management committees, it stresses the desirability of having staff committees at individual hospitals, normally to include the whole senior medical and dental staff. The memorandum is not intended to interfere with the discretion of the staff in deciding itself what sort of committee it wants, but makes suggestions which the Minister thinks will enable medical committees to advise hospital authorities most effectively.

Importance of Medical Committees

The guidance given by the Minister follows prolonged discussions between the Ministry and the Joint Consultants Committee, which repeatedly emphasized the value to the Service of suitable advisory committees, truly representative of the profession, at all administrative levels. It is hoped that the circular will result in a greater measure of co-operation between hospital authorities and their medical staffs and that the former will come to look to the hospital medical committees as their regular source of professional advice.

The suggestions for medical advisory committees are not extended to regional hospital boards. The Joint Committee and the Central Consultants and Specialists Committee consider that the need for satisfactory advisory machinery is greatest at regional board level, and this view will continue to be pressed upon the Ministry.

Constitution

The Minister suggests that a group medical advisory committee should consist of up to 30 members, representing the whole consultant and specialist medical and dental staff of the hospitals concerned, the general medical and dental practitioners on the staff and in practice in the area, and the medical officers of health. The committee should meet from time to time to enable the staff to form a collective

SUPPLEMENTARY OPHTHALMIC SERVICES

DIRECTION OF PATIENTS BY GENERAL PRACTITIONERS

The Minister of Health thinks that there may have been some misunderstanding about the position where doctors recommend patients who may need glasses to particular ophthalmic medical practitioners or opticians. A circular to executive councils and ophthalmic services committees (E.C.L. 66/53) points out that the regulations contain nothing to prevent a general practitioner from giving a patient the name and address of an ophthalmic medical practitioner or optician, and there is no objection to this provided nothing is said that might seem to override the statement on Form O.S.C.1 that the patient has a free choice in selecting the person who is to test his sight.

Provision of Toughened Lenses

The Minister has decided to include toughened lenses in the range of special type glasses supplied at the applicant's own request, and towards the cost of which the applicant pays an additional charge. Charges will be the same as for laminated lenses. Toughened lenses are not available in flat form or for any concave prescriptions in which the power exceeds -6.00 dioptres.

Notes and News

Found in the Home.—Large quantities of expensive or dangerous drugs are sometimes left over when patients die or are taken to hospital. *Prescribers' Notes* for July lists the following items which were found unused in the home of a patient who had died. All were prescribed on E.C.10: 8 1-g. vials streptomycin; 22 vials "distaquaine fortified," 400,000 units; 3 vials "estopen," 500,000 units; 20 tablets penicillin, 20,000 units; 50 1-ml. ampoules "vegolysen"; 14 25-ml. vials "vegolysen"; 30 1-ml. ampoules "lytensium"; 40 hypodermic needles.

The cost to the N.H.S. for these left-overs, excluding dispensing fees and container allowances, was about £15.

National Formulary, 1954.—The Joint Formulary Committee is now revising the *National Formulary*, 1952, with a view to the publication of a further edition in the summer of 1954. It has been suggested to the committee that a special edition be published for use by prescribers and that the preparations in this edition be listed in pharmacological order instead of under the various sections, such as mixtures and injections, used in the present edition. If this proposal were adopted it is probable that the prescribers' *Formulary* would be based upon the pharmacological classification contained in the 1952 edition. Before embarking on such a radical change of policy the committee would be glad to have the comments of prescribers, which should be addressed to the Secretary of the Joint Formulary Committee, B.M.A. House, Tavistock Square, London, W.C.1.

Trainee General Practitioner Scheme.—The report of the Trainee Assistants' Subcommittee of the General Medical Services Committee on the trainee general practitioner scheme (*Supplement*, September 1, 1951, p. 92) has now been circulated by the Ministry of Health to executive councils together with the Minister's recommendation that the council should ask the augmented local medical committee to consider carefully which of the recommendations are suitable to be adopted locally. The Minister, however, makes it clear that if arrangements were made for a full-

view on all major matters of policy. A smaller executive subcommittee could meet at frequent intervals and act for the full committee, but without committing it to advice on major items of policy without taking the collective view of consultants and specialists in the group into full account. Unless the staff prefer one of their own number to act as secretary of the committee, the secretary or other senior member of the administrative staff of the board of governors or hospital management committee might, it is suggested, accept responsibility for the secretarial work of the committee—the board of governors or hospital management committee providing any clerical or other assistance required.

Functions

The object of the medical committee is to advise the hospital authority on all matters of medical policy and all medico-administrative problems, which include maintaining a continuous review of all hospital facilities in the group to ensure their most effective employment. The committee should give advice without being asked if occasion should warrant it, as well as advice on matters referred to it. The hospital authority should consult it on all appropriate matters as early as possible.

Examples given of such matters are: (a) developments in the scope of a hospital's work, such as the formation of new departments, or extensions and modifications in existing departments; (b) allocation of beds; (c) criteria to be followed in deciding upon the admission of patients on the waiting-list; (d) arrangements to be adopted for emergency admissions; (e) procedure for dealing with complaints involving medical or dental staff; (f) procedure for making appointments of junior medical or dental staff (within the framework of such central guidance as has been given—for example, in relation to registrars); (g) types of medical and dental equipment and supplies to be obtained; (h) care of medical and dental records; (i) economies to be sought both generally and in relation to such matters as prescribing, use of x-ray films, etc.; (j) control of infection in hospitals; (k) recommendations of members of the staff to serve as members of the board of governors or hospital management committee; (l) the organization of such activities as clinical demonstrations or maintenance of a medical library.

Additional Function

The Minister considers that in addition a systematic review and analysis by the committee of the clinical work of the staff would be of the greatest value, a function not usually exercised by it at present. If the results of the work of all departments were regularly reviewed and where practicable subjected to statistical analysis and brought before the full committee at its periodic meetings, discussion of the results would, in the Minister's view, assist all the staff in achieving and maintaining a high standard of clinical work. Suitable opportunity for discussion of the clinical details of cases of special interest might also be provided. No question of clinical interference in the conduct of individual cases would arise; this would remain the sole responsibility of the consultants in charge of the particular cases. The object would be discussion and review of clinical results with the object of ensuring as high a standard of medical care as possible throughout the group.

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

Metropolitan Borough Councils.—Fulham, Southwark.
Non-County Borough Councils.—Crewe.
Urban District Councils.—Houghton-le-Spring.

time course in midwifery for trainee assistants, such as envisaged in paragraph 21 of the report, he could not undertake to provide additional funds for the purpose.

New National Insurance (Industrial Injuries) Act, 1953.—The Industrial Injuries scheme first came into operation on July 5, 1948. It replaced the Workmen's Compensation Act by a new system of compensation for accidents at work and for "prescribed" industrial diseases. Compensation took the form of insurance benefits. At present it can be paid only if the disablement resulting from the accident or industrial disease is assessed by a medical board as substantial (20% or more), or is likely to be permanent, or in some circumstances both substantial and permanent. Under the new Act, from August 26 the benefit may be paid wherever the disablement is assessed at 1% or more, whether it is permanent or not. This change does not affect the special rules relating to persons suffering from pneumoconiosis or byssinosis.

Questions Answered

Employment of Agent for Assistance in Tax Matters

Q.—Can I claim relief of tax on the cost of employing a chartered accountant to safeguard my interests against an erroneous claim by the income-tax authorities of underpayment of tax by me? During the years concerned my sole income arose from local government service and the Army, and deductions were made at source.

A.—The case of *Allen v. Farquharson Bros.*, which was decided in the High Court in 1932, dealt with legal rather than accountancy costs, but the judgment of Finlay J. is capable of application to this case. The learned Judge made it clear that objection would not be taken to "expenditures connected, for example, with the accounts" or to discussing them with the inspector of taxes, but he held that to be allowable the expenditure should be "made for the purpose of earning the profits of the trade." On the facts of that case it was decided that the expenditure incurred in an appeal to the Commissioners of Taxes was not incurred for purpose of earning the profits and therefore was not allowable. (Incidentally it would seem that the appeal to the Commissioners had in the main been successful.)

It is considered that the judgment referred to above gives ample support to the refusal to allow the questioner any relief for the expense incurred by him, not in the preparation of a professional account, but in the settlement of the amount of tax payable by him on an ascertained income.

Deduction for Rental Value of Premises

Q.—I do not live at my surgery, which is in a private house owned by myself. The whole house is devoted to professional purposes. Apart from the surgery and waiting-room the remainder is occupied by a housekeeper and husband who live rent-free. The net rateable value is £48. On this I pay Schedule A income tax and am allowed £48 off my income as well as £40 rates. The value of the house is £3,000, which I paid for it. I am allowed nothing for rent beyond the £48. Is this correct, or should I get a rental allowance equivalent to what I would rent this house for for professional purposes—for example, £120 per annum?

A.—It is provided by Section 136(3) of the Income Tax Act, 1952—a consolidation Act—that the deduction on account of the annual value of the premises used for the profession shall not exceed the amount of the assessment under Schedule A. In this case the limiting amount is therefore £48. This does not seem inequitable, because if the questioner could deduct £120 as being the amount of quasi-rent to be borne by the practice, then he as landlord would

have to be regarded as receiving a rent of £120; the net effect would be that his "unearned" income would be increased and his "earned" income decreased by the same amount, and that would presumably increase the tax payable by him.

Signature on International Certificates

Q.—The new form of International Certificate requires the stamp of one who is authorized to use a stamp. May a general practitioner obtain this authority? If so, to whom should one apply?

A.—The purpose of the authorizing stamp is to satisfy the overseas country concerned that the signatory to the International Certificate is a duly registered medical practitioner in Britain. In practice the stamp is issued by the medical officer of health for the area, who is not in any way countersigning the doctor's certificate. It is not possible for general practitioners to be authorized to use the stamp for the purpose of International Certificates.

Tax Liability on Retirement

Q.—I am advised that if I retire (at the age limit) during the present financial year from the regional hospital board and board of governors, I shall be liable to be assessed on my total earnings during 1953-4 for 1954-5. As my salary from the hospitals service is separate from my private practice I had imagined that my liability on this account would cease in 1954-5.

A.—It is assumed that the questioner has hitherto been assessed on the basis that the whole of his professional earnings have been regarded as coming within the scope of Schedule D—a course which is convenient both to the consultant and to the Inland Revenue, and often advantageous to the former, as it avoids the application of the stringent Schedule E rule on expenses. The view of the Revenue if the questioner gives up his appointment but continues his private practice is likely to be that he is committed to the treatment of his earnings as derived from a single source, and that the fact that that source for a particular reason has become less remunerative does not affect the application of the Schedule D basis of assessment—that is, calculation of the liability as determined by the earnings of the previous year. To counter that view the questioner would have to show that the practice after the termination of the hospital appointment was a different practice from that formerly carried on—not merely the same practice on a reduced basis of gross earnings. Success in that contention is doubtful, but it would assist if it could be shown that when the appointment was taken up the previous year's basis was not applied—that basis would of course have then operated in the questioner's favour.

Radiological Equipment

Q.—What annual depreciation is allowed by the Inland Revenue on x-ray apparatus and equipment in use in private radiological practice? Should domiciliary consultation fees be taxed under P.A.Y.E.—I have to provide my own apparatus and materials, and my accountant is of the opinion that these fees should be dealt with under Schedule D with the rest of my private practice?

A.—We are not aware of any officially approved standard rate of depreciation for x-ray apparatus, but we have known 15% (plus 4, that is, 18½%) allowed on the usual "written-down" basis. As regards smaller items of equipment, a depreciation allowance is not usually regarded as applicable, and in that case the cost of maintaining the equipment is allowable as and when the expense of repair and replacement is incurred.

The question of whether fees should be assessed under Schedule D or dealt with under the P.A.Y.E. system depends legally on whether the fees are the earnings of "employ-

ment"—if they are, then the employee is legally within the P.A.Y.E. system. But even in that case it is the approved practice of the Inland Revenue to include them in the Schedule D assessment on the practice (and of course to exclude them from the application of P.A.Y.E.) if they are a comparatively small portion of the total earnings of the practitioner. If the authorities insist on applying P.A.Y.E. then either the whole of the expenses should be deducted from the other earnings of the practice or the total amount should be divided proportionately between the two classes of earnings.

Tax Assessment on Unreceived Profits

Q.—I am asked to pay about 13s. in the £ income tax on the amount I received from the Danckwerts award for the time I was in partnership, apparently because the profits of the business in the year before I entered the practice were increased. I did not participate in these profits. Is it inevitable that I must pay this amount of tax on my share of the award?

A.—When the personnel of a partnership is altered the question whether the previous year's basis is to be applied as to a continuing partnership or whether, on the other hand, the practice is to be regarded as having ceased and recommenced—in which case the new firm will be assessed for its first year on the profits of that year—is one which is decided by the partners themselves. In this case it is assumed that they did not take action to have the cessation and commencement provisions applied as from February, 1951, and the questioner cannot now avoid the consequences that result from treatment of the firm's earnings as assessable on the previous year's basis, and therefore the bringing into the calculation of the firm's liability of the Danckwerts award as if they had been normal earnings of the firm of the years to which the award applies.

Taxation on Reprints

Q.—From time to time I publish lectures delivered before professional bodies and order reprints for distribution to various colleagues. Why should the cost of such reprints not be an allowable expense for income-tax purposes?

A.—The main difficulty in deciding the point raised is that so frequently the reasons for delivering and publishing lectures are mixed—including, for instance, a desire to advance general medical knowledge, to further a personal aim, to acquire a new and superior professional status, and (the relevant consideration for income-tax purposes) to ensure the maintenance of the lecturer's clientele and earning capacity. The argument for allowance of the printing costs is clearly stronger if the lecturer is a specialist and is dealing in that way with his specialty. One rather shrinks from using the word "advertisement" in this connexion, but that seems to be the fundamental consideration involved. In our view the questioner's prospects of appeal would not be good if he is in general practice, but might be good enough to justify an appeal to the Commissioners if he is in practice as a specialist.

Assistant with Rent-free House

Q.—In order to get a suitable full-time assistant, my partner and I had to purchase a house through a building society, which he will have rent free. Can we claim all the expenses associated with the house for income-tax purposes—that is, repayments to building society, rates and telephone, repairs and renewals?

A.—The cost of providing the accommodation—but not capital expenditure incurred in the purchase of the house—is an allowable expense in calculating the profits of the practice. As regards the payments to the building society, in so far as they consist of interest a deduction can be

claimed (as the society will account for income tax on interest), but in so far as the payments are in reduction of the loan they are "capital" sums and cannot be regarded as expenses. Payments of local rates and for the periodical telephone accounts are allowable, and in addition the amount of the assessment on which income tax is payable under Schedule A (the so-called "property tax") is also deductible as if it were rent. Repairs are allowable, provided that any expense of improving, as distinct from maintaining, the premises is excluded.

New Assistants' New Car

Q.—I start as an assistant in general practice in September. Is the set car allowance to cover all expenses, and is it tax free, or can I claim a further tax deduction in respect of a new car bought in this month?

A.—The £200 to be received for car expenses is not chargeable to tax, but will be considered by the Inland Revenue to cover wear and tear of the car as well as the running expenses. Consequently, no capital allowance can be claimed in respect of the cost of the car.

Sickness Benefits

Q.—Are sickness benefit payments liable for income tax?

A.—Sickness benefit payments are not liable to income tax. They are in fact benefits purchased by payment of premiums for which no income-tax allowance is given.

Correspondence

Succession to Single-handed Practices

SIR.—Dr. D. L. Gullick (*Supplement*, August 15, p. 79) may well be disturbed by the General Medical Services Committee's reaction to the reference back of paragraph 75 of its report (*Supplement*, May 2, p. 165), and is probably correct in his surmise that it hopes the real issue will be forgotten by next summer. His alternative suggestion, however, would not get over the objection that E.C.L. 11/53 asks local medical committees in making recommendations in respect of these practices to take into consideration matters for which they have no statutory authority, and consequently the local medical committee would not be able to plead it was performing a statutory duty if its action was subsequently questioned in a Court of Law. These and other legal objections which are supported by legal opinion caused the local medical committee of which I am a member to sponsor the reference back of paragraph 75 at the Conference of Local Medical Committees in June.

Neither the G.M.S. Committee nor the Ministry of Health seem willing to answer the questions asked them, but with hurt dignity used the old dialectic device of returning irrefutable replies to questions that have never been posed. My colleagues have for the moment confined their opposition to E.C.L. 11/53 to the legal aspects, which they consider make this letter quite impracticable and in need only of decent burial. If its sponsors will do this I do not think we will begrudge them a little harmless face-saving.

On grounds of policy also there are grave dangers in the proposals. If interference with partnership agreements in the way that is proposed is countenanced in one set of circumstances it cannot be long before the practice will spread, and soon all partnership agreements will cease to be worth the paper on which they are written. What then about the hopes of encouraging group practice and similar developments?

Once again it appears that the G.M.S. Committee has been prepared to agree to proposals aimed at remedying an

anomaly that will produce more anomalies than they remedy. They are in fact trying to work sections of the N.H.S. Act that are unworkable. The only remedy is, of course, repeal of Section 35 (Prohibition of Sale of Medical Practices) and related sections, but that is another story.—I am, etc.,

Wolverhampton.

R. S. V. MARSHALL.

PROGRESS IN AUSTRALIAN NATIONAL HEALTH

SIR EARLE PAGE ADDRESSES W.M.A.

On Wednesday last Sir Earle Page, the Minister for Health of the Commonwealth of Australia, in an address to the assembly of the World Medical Association at the Hague described the progress that had been made with the national health measures in Australia. At present many of the health services provided are subject to regulations. A National Health Bill will be introduced to the Commonwealth Parliament during the coming session. This Bill will aim at consolidating under one heading the various medical services carried out by the Federal Government.

Political Issues

Health schemes have been big political issues in Australia since the Federal Government was given full control of the social services at a referendum held in 1946. For three years after 1946 the Labour Government tried to get a health plan into action, but could not do so because of the objections of the British Medical Association to certain sections of the plan. But since 1949, when the present Liberal and Country Party Government came into office, Sir Earle Page, himself a doctor, has been working on a plan which involves some contribution by the people. This is the one which he will bring before Parliament. The whole range of the scheme was set out to the British Commonwealth Medical Congress in Brisbane in May, 1950, and gained the approval of the medical profession. The following is a summary of the account which Sir Earle Page gave of his plan to the World Medical Association.

Gradual Stages

The existing health provisions have been brought in gradually. In July, 1950, generous tuberculosis allowances were given to ensure that infectious patients would offer themselves for treatment in the knowledge that their homes would be able to be maintained. Mass radiography of the population was simultaneously carried out. In August, 1950, life-saving and disease-preventing drugs were made available free to the public on a doctor's prescription, and in December the Commonwealth Parliament passed an Act to inaugurate a free milk scheme for school-children under 13 years of age. In January, 1951, the Hospitals Benefits Insurance Scheme, based on a system of governmental aid to voluntary insurance, was offered to the Australian States. The following February saw the inauguration, for the first time in Australia, of free medical treatment for pensioners, and in May arrangements were made for pensioners to receive free medicines on a doctor's prescription. A Medical Benefits Scheme began to operate in July, 1953. Under this scheme the Commonwealth Government encourages voluntary insurance through approved organizations towards prepaid medical care by making available, throughout Australia, a

flat, uniform contribution for 600 medical and surgical services, on condition that the insurance organizations at least match the Government's contribution.

Government's Motives

The considerations which influenced the Australian Government in deciding upon its scheme of State-subsidized voluntary medical and hospital insurance are given in the following quotation from Sir Earle Page's address to the World Medical Association: "The most immediate problem exercising the minds of the public generally is how the advantages of modern medical science may be brought within the pecuniary reach of the people at large. The most crucial problem facing the medical profession is how can progressive improvement in the standards of treatment and practice of medicine (which are largely responsible for increased costs) be maintained at the same time as they are brought within the means of the people."

"The Australian Government does not believe that either or both of these problems can be solved by Government direction and action alone. The Australian Government believes, however, that a partnership of the medical profession, the community, insurance organizations, and the Government can evolve a method of retaining all the existing traditions and advances on the medical side and still bring the cost of a first-rate medical service within the means of the people."

Government Action

The Government has endeavoured to establish a partnership between the Government and the individual through the union of Governmental aid with voluntary effort. This partnership is, in its view, a recognition that both State and individual have obligations in a national health scheme, and that both will benefit by it. The individual will gain better health, longer life, and an easier mind about the expense of sickness; the State will gain more efficient production, greater national income, and social stability. The cost is distributed between the Government and the voluntary societies. Under this system the Government has strict control over its own costs. The patient and doctor both have a definite interest in preventing waste and abuse of time, skill, medicine, and equipment.

Grants-in-Aid

Preventive measures in Australia have been undertaken wholly by the Government because it felt that the resulting community gain might be as great as or greater than the individual benefit.

In the field of medical and hospital benefits, in which it feels that the individual gain is undoubtedly the greater, the Government's view is that this field should be covered by a system of prepaid voluntary insurance, operated by voluntary non-profit-making organizations experienced in that particular field. To encourage the development of such organizations and to make the benefits attractive to their members, the Australian Government makes available

substantial grants-in-aid. The Government believes that a wide extension of voluntary insurance to the community as a whole, and especially to the self-employed and rural elements in the community, can be secured by a basic grant of Governmental aid towards extending the actuarial benefits beyond those possible under existing insurance schemes. Insurance is thereby made so attractive as to induce many people to seek insurance cover without great expenditure, especially as members' dependants are also covered.

This grant-in-aid is given only if participating insurance organizations at least match the Governmental grant for each item of medical treatment. The Government grant, plus an equivalent amount of insured benefit, meets the major proportion of the fees charged to the lower-income groups. Higher-income groups can insure themselves for greater benefits, rendered more valuable by the existence of the Governmental grant. There is no direct connexion between the Government and the medical profession. The Government does not fix fees, which are left to the discretion and judgment of the profession itself.

Conditions of Payment

The Australian plan makes available to the patient, through his insurance organization, the appropriate amount of Governmental subsidy, even where the organization is precluded from paying a benefit under its own rules. In a number of circumstances an insurance organization in Australia, because of actuarial consideration, does not pay a benefit to its members. For instance, there is the condition that a member must go through a probationary period, usually two months in ordinary cases, and nine or ten months before confinement benefit is payable. Most organizations have a maximum amount which can be drawn on their funds during a year, and will not pay benefits for treatment symptoms of which were in evidence at the time of joining. In all these cases the Governmental subsidy is available. A man might become a member of an insurance organization on his way to the doctor and be eligible for the Governmental grant.

Hospital Benefits

Application of the principle of prepaid voluntary insurance backed by Governmental aid has already had results in Australia. Hospital revenues and patients' charges have been assisted by the Government's insurance scheme. Many hospitals showing a debt a year ago are already showing a surplus, and the total increase in hospital revenues over Australia is several million pounds. The total Federal Government subsidy is 12s. a day to any hospital patient who also insures for a minimum hospital fund benefit. In practice many patients insure for larger insurance organization benefits which, together with the Government grant, approximate to actual hospital costs.

As in the medical benefits plan, the Governmental grant is available to insured persons where actuarial considerations preclude the societies from paying benefits from their own funds.

Administration

The Government rejected the idea of a massive Governmental organization to control the insurance scheme, because, apart from the expense, it considered that such a scheme would not accord with the history of voluntary participation and organization of people for their mutual benefit. It thought that it would crush that spirit which caused people to unite voluntarily amongst themselves for mutual help and assistance. Already many large friendly society benefit funds and community hospital benefit funds are operating, as well as funds controlled by trade unions.

Extent of Cover

In its scheme the Australian Government has taken special care to give what it considers to be the widest possible health cover to the Australian people in the following ways: (1) It has provided a general-practitioner free medical service with free medicines to the pensioner group—that is, all persons or their dependants who are in receipt of an age,

invalid, or widow's pension, a Service pension under the Repatriation Act (but not a war pension), or an allowance under the Tuberculosis Act. War pensions are provided under the Repatriation Act. (2) Consideration is being given to the question of insuring at reasonable rates dependants of active service men and of war veterans who are not entitled to medical treatment under the Repatriation Act. (3) Special arrangements are made for the completely indigent. (4) Commonwealth benefits for hospital and medical care are payable as soon as patients are insured, without any waiting period that may be a condition of the insurance organization's rules. (5) Government medical and hospital benefits are given to insured patients both for chronic and for pre-existing diseases, even if benefit for these sicknesses is not given by the insurance organizations. The effect of this latter condition is to make voluntary insurance attractive. (6) The liberal Governmental grant will enable insurance organizations to review their previous exclusion conditions.

Professional Discipline

A committee of inquiry is set up through the recognized organization of the profession—the British Medical Association. This committee reports and recommends methods of dealing with the infringement of professional practice, ethics, or fraud associated with the action. It recommends the appropriate penalty to the Minister for Health, who decides what action should be taken by law or otherwise.

Professional Co-operation

Australia has developed Federal organization of its medical and pharmaceutical professions. There is a Federal Council, formed by election by State Councils from each State. The State Councils are based on regional organizations, and the individual members of the organizations elect their representatives. Close contacts are maintained between all the tiers in the organization, and it is possible to get representative opinion on all vital matters in a reasonable time. The Federal Government deals exclusively with the Federal Councils. The Royal Australasian Colleges of Physicians and Surgeons have delegated discussions on political and financial matters to the Federal Council of the British Medical Association, so that only one medical voice speaks on this matter to the Government.

Advisory Drug Panel

To determine what drugs should actually be on the free list the Australian Government invited the Federal Council of the British Medical Association and the Federal Pharmaceutical Guild to nominate a panel of specialist physicians and pharmacological experts from which an advisory council was drawn. The Bill states that this committee shall make recommendations to the Minister from time to time as to the drugs and medicinal preparations which it considers should be made available as pharmaceutical benefits, and shall advise the Minister upon any other matter concerning their operation referred to it by the Minister.

Examples of Benefits

The following table gives examples of medical benefits:

	Commonwealth Benefit	Fund Benefit at least	Total Benefit at least
	£ s. d.	£ s. d.	£ s. d.
Surgery consultation — general practitioner	0 6 0	0 6 0	0 12 0
Appendix operation	5 12 6	5 12 6	11 5 0
Tonsils (adult)	3 0 0	3 0 0	6 0 0
Tonsils (child)	1 17 6	1 17 6	3 15 0
Midwifery	3 15 0	3 15 0	7 10 0

The average cost of insurance for medical benefit for a man and his dependants is 2s. a week.

Commonwealth benefits to members of insurance organizations of £4 4s. a week are uniform over the whole continent. The organization benefits vary according to the rates of contribution. In some cases they provide sufficient to meet the hospital charges in the particular State, but they

must provide at least 6s. a day. This, with the Government benefit, makes a total of at least £6 6s. a week. An insurance organization benefit of 12s. a day can be obtained in most States for a contribution of 1s. a week. A larger or smaller benefit can be obtained for a correspondingly higher or lower contribution.

Additional Information

The Commonwealth population is given as 8,538,936. There are about 9,000 doctors. The annual cost of the Government subsidy to the Medical Benefit Scheme is £10m. and to the Hospital Benefit Scheme £12m. Except those which are private, hospitals are administered by the State Governments and not the Federal Government. Any doctor can participate in the Medical Benefit Scheme or the Pensioners Scheme. The free medicines available to pensioners are the scheduled life-saving drugs plus—broadly—those in the B.P.

About 55% of the people are voluntarily insured; 10% are covered by the Pensioners Scheme and 5% by the War Pensions Scheme; 3-4% are indigent and specially provided for. Thus nearly 75% of the population benefit from health schemes.

APPEALS MACHINERY IN NORTHERN IRELAND

DISCUSSION WITH THE MINISTER OF HEALTH

The Minister of Health of Northern Ireland, Dame Dehra Parker, accompanied by officials of the Ministry, recently received a deputation from the British Medical Association to discuss recommendations for the setting up of an appeals machinery for the profession in Northern Ireland similar to that now working in this country and to which differences could be referred. The deputation was led by Dr. Kenneth Cowan, chairman of the Association's Public Health Committee, who was accompanied by Dr. J. B. Young (president of the Northern Ireland Branch), Dr. N. S. Dickson (member of Council), Dr. Robert Marshall (chairman of the Northern Ireland Consultants and Specialists Committee), Dr. J. McKinney (representing the public health service medical officers, Northern Ireland), Dr. J. W. Chapman (assistant branch secretary), and Dr. A. V. Kelyack (assistant secretary, B.M.A.).

The principles of an appeals machinery were fully discussed, and the Minister expressed her interest and sympathy on certain points, though in doing so she was doubtful as to the need for such an appeals committee as was suggested, and asked for any example in Northern Ireland which might have been dealt with had such machinery been available.

The long-standing difference regarding the status and remuneration of the divisional medical officers employed in County Down was then discussed, not only with reference to the main issue of appeals machinery but also as an individual problem. The Minister was informed that the Council of the Association had already decided that the only solution of the difference was to refer the matter for independent arbitration, but in view of the meeting with her and in the hope that agreement could be reached, action to refer the matter under the Conditions of Employment and National Arbitration Order, 1940, had been deferred.

After a very full discussion the Minister promised to consider carefully the suggestions for a Northern Ireland appeals committee as put forward by the Association.

County Down Dispute to go to Arbitration

Further consideration has now been given to this matter, and in accordance with the decision of Council the Ministry of Health has been informed that the Association's solicitors are being instructed to take the necessary action on behalf of the five medical officers employed as divisional medical officers by the County Down health committee, to ensure that the difference regarding their status and remuneration is referred for independent arbitration.

ISLE OF MAN COMMISSION ON SALARIES AND EMOLUMENTS

ASSOCIATION'S SUPPLEMENTARY MEMORANDUM OF EVIDENCE

Prefatory Note

When representatives of the Association appeared before the Commission on August 18, the Chairman of the Commission stated that the Commission would be glad to receive any additional written evidence which the Association might be able to submit within a week (approximately). The Chairman was understood to say that the Commission would be interested to see any figures relating to comparative costs of living in the Isle of Man and on the mainland. The Chairman also indicated that he would welcome some further explanation of the statement by Mr. George Schwartz, quoted in paragraph 13 of the Association's original memorandum, that the proposal to adjust remuneration in accordance with varying rates of income tax was "indefensible, impracticable, and absurd."

The Association is advised that the suggestion of compiling, within the time allowed by the Commission, statistics showing the cost of living of doctors on the island as compared with the corresponding cost on the mainland is entirely impracticable. The Association has pleasure, however, in submitting a short explanatory memorandum which Mr. George Schwartz has most kindly composed at very short notice, and at considerable personal inconvenience. This memorandum is quoted below.

Memorandum by Mr. George Schwartz

1. The proposal to vary remuneration in accordance with the rate of income tax implies that income tax is a separate item in the cost of living. It is not. Income tax does not raise or lower either the cost of living or the standard of living. It alters the composition of both, but does not affect their magnitude. Income tax involves a reshuffle of the community's purchasing power and does not *per se* alter the volume of it. It does not therefore affect the general level of prices and incomes in the community. The citizenry redistributes it on behalf of the State, which thereupon, the result are no different from those which occur when a husband hands over housekeeping money to his wife. This doesn't raise the cost of living or the standard of living of the household. It is no answer to say that if the husband not take it out on his meals the household must suffer a corresponding reduction of other welfare.

2. This household analogy shows the fallacy of treating income tax as an item in the cost of living, and the double reckoning involved in the process. Suppose the price of carpets went up. This admittedly would entail a rise in the cost of living. Suppose an employee proceeded to argue: "Not only has the price of carpets gone up, but I have to give my wife more housekeeping money because of that. I want two increases in my salary, one to compensate for the rise in the price of carpets and one to offset the increase in the housekeeping allowance." It would be a very unsophisticated employer who was taken in by this double reckoning. And it would be a very unsophisticated employee who took a double cut in his salary, one because the price of carpets had fallen and the other because he thereby handed over less to his wife.

3. If remuneration really fluctuates with changes in the rate of income tax why does anyone grumble about the tax? An economic paradise would be a country in which with any increase in taxation the citizen was given additional income in order to pay the tax. Attempts have been made in some countries to achieve this paradise. What is achieved is inflation and currency disorder.

4. That prices and remuneration are determined quite independently of the local rate of income tax is clearly evident in the case of international commodities. Tin is

produced in Bolivia, Burma, Malaya, Indonesia, Nigeria, and Siam. Whatever the local rate of income tax, tin sells to-day at £600 per ton, and the income of tin-producers everywhere derives from that. In 1951 tin sold at one time at £1,620 per ton and in the same year at £805 per ton. What had these fluctuations to do with local rates of income tax? If lead, zinc, and copper were still mined in the Isle of Man the producers' incomes would be determined by the prices quoted on the leading metal exchanges, regardless of the rate of tax in the Isle of Man. Does a novelist living on the island get and accept a lower rate of royalties than authors on the mainland? Do investors get lower rates of dividend? Are interest rates lower because of the lower rate of tax?

5. The Health Services themselves provide a clinching refutation of the whole argument. Suppose the National Health Scheme was abolished in Britain. This would permit a reduction of the income tax by about 2s. in the £. On the thesis under discussion all salaries and wages could and should be reduced correspondingly. The citizen would then pay for medical service out of his own pocket. This trick can be performed only in public houses, and is known as "ringing the changes."

Heard at Friends House

A Well-organized Conference

During the whole of last week Friends House in Euston Road was thronged with delegates to the First World Conference on Medical Education. A journalist who has attended international conferences—not medical ones alone—in many capitals remarked that this conference was far and away the best organized in his experience. The system of earphones and simultaneous interpretation enabled those present to hear every man in his own tongue—at least if that tongue was English, French, or Spanish. But, the really excellent interpretations apart, the system of earphones at every seat in the four halls magnified the speaking to such perfection that even the whisperers and mumblers got the hearing they hardly deserved.

A Few Figures

Fully 80% of the speaking at the conference was in English, yet not much more than half the speakers were from the British Commonwealth or the United States. The number of announced papers and addresses (apart from contributions in the open discussions) was 153, and the proceedings were recorded on 200,000 ft. of magnetic wire. Talking of tape recorders, one speaker in the Section of Social Medicine mentioned that he took recordings of interviews between his patients and an experienced social worker, which proved very useful when replayed to him while he was considering the case. On one busy morning a patient was admitted, and he took her into the next room and asked her to talk to his tape recorder while he attended to other patients. Presently, going out to lunch, he found this patient at an adjoining table. On asking her what had happened she said, "Oh, I left my tape recorder talking to your tape recorder."

Points of View

In Section A, after the reading of an opening paper, another member got up and vigorously attacked it, whereupon he was joined by the "author" of the paper, who criticized it with equal vigour. It turned out that the paper, although he had read it as in duty bound, had been written by somebody else.

A professor from Uganda, who is also the head of the library of his school, surprised a section by remarking, "Nothing gives me greater pleasure than to find a student asleep in the library. It is true that he is not absorbing much learning, but at least when he wakes up he is in the right environment." This speaker pleaded for school libraries with deep comfortable easy chairs and a supply of works other than medical.

Another unusual method was mentioned by a teacher of medicine from Trinidad who had introduced his students to the study of vital statistics by encouraging them to play bridge and other games of chance and to study football pool coupons. To make them acquainted with the elementary facts of epidemiology he sent them to mingle with the crowds at football matches. There they learned that sickness might be a collective as well as an individual matter.

An Australian member told of a placard which he saw in a medical school: "The student retains 10% of what he hears, 20% of what he reads, 50% of what he sees, and 90% of what he does."

A professor of bacteriology at a London school: "The clinical teacher is the students' hero. I bring him in whenever I can. The students are far more likely to listen to him than to me."

A senior teacher at a London school: "I tried to find out from our students what they thought of the teaching at Hospital. They are a pretty bright lot. They found that the senior men were better than the registrars; the latter knew too much from textbooks, whereas we old fellows, educated in medicine 30 years ago, have forgotten all those details and keep more to general principles."

Correspondence

Isle of Man Commission on Salaries

SIR,—I should like to offer my hearty congratulations to our secretary for the fine bit of work he did in the Isle of Man. After the exhausting labours of an Annual Meeting this emergency must have put a great strain on Dr. Macrae. He rose to it nobly. I particularly admired the touch of righteous indignation he put into his memorandum (*Supplement*, August 29, p. 84).—I am, etc.,

London, S.W.7.

ALFRED COX.

Cost of Prescribing

SIR,—In reply to Dr. Donald Latham (*Supplement*, August 22, p. 81), the tablet of digitalis folia is not the only one which would not stand 10 years' exposure to a tropical climate without being used. My remarks, of course, have reference to the use of digitalis preparations in this country. It is quite possible that in certain English seaside areas the tablets would not keep well, but the obvious solution is to be found in using them regularly so that they are not kept too long in stock. It is surely advisable to use a cheap drug rather than a 10 times more expensive one, when the cheap drug is as efficient for maintenance purposes. After all, we are all taxpayers.—I am, etc.,

London, N.W.1.

GEOFFREY BOURNE.

A REVIEW OF GENERAL PRACTICE, 1951-2

REPORT OF THE GENERAL PRACTICE REVIEW COMMITTEE

From time to time the Council of the British Medical Association appoints special committees, the reports of which are subsequently "ordered by the Council to be printed." This does not mean that such reports have been subjected to detailed scrutiny and revision by the Council and are to be regarded as representing its views on the matters with which they deal. What is meant is that the Council, having received a report of an expert committee, has deemed it worthy of publication as a record of the findings and recommendations of a group of persons chosen because of their special competence in a particular field. The present report is not a report of the Council. It is a report "ordered by the Council of the Association acknowledges with gratitude the laborious work of the committee which drew it up. The Council of the Association acknowledges with gratitude the laborious and enthusiastic work of the chairman, members, and staff of the committee responsible for this report, and the sincere and illuminating account written by Dr. Stephen Hadfield of the personal investigation which he conducted.

E. A. GREGG,

Chairman of Council.

INTRODUCTION

In the summer of 1950, when the National Health Service had been in operation for two years and the British Medical Association's report on "General Practice and the Training of the General Practitioner" had just been published, the Council decided that an authoritative review of the actual conditions of general practice should be undertaken. For this purpose it appointed a Special Committee "to review the present position in general practice, its difficulties and its trends, both generally and with reference to the two years' experience of the National Health Service Acts, and to the B.M.A. report on 'General Practice and the Training of the General Practitioner,' and to make recommendations." The membership of the Committee is shown on the following page.

The Committee's preliminary discussions showed that, if the results of its review were to have significant value, it must make its inquiries on a large scale, and, further, that it must seek its information from general practitioners themselves—from the men and women in practice whose voices might not otherwise be heard. The Committee accordingly decided to invite assistance in its task from the whole body of general-practitioner principals in the National Health Service and in private practice.

On the advice of Professor A. Bradford Hill, of the Department of Medical Statistics at the London School

of Hygiene and Tropical Medicine, a small sample of general-practitioner principals was drawn at random for a field survey, and the remainder, divided into groups of 500, were communicated with by post. The table printed on the next page shows the classification of general-practitioner principals by age and type of practice. The Committee is very grateful for Professor Bradford Hill's help in the initial sampling procedures.

The practitioners who came into the field survey were visited personally by Dr. Stephen Hadfield, an Assistant Secretary of the Association who had been in general practice until 1948, and these provided material for an objective detailed study of a small number of practices. Dr. Hadfield's survey is published in the opening pages of this week's *Journal*. From the results of the postal inquiry (see *Supplement*, p. 105) there has been obtained a broad, though subjective, picture of the views of the general body of practitioners. The preparation of the questions put to the general practitioners and the interpretation of the results of the inquiry were the concern of the Committee itself.

It will be seen from the reports of the field survey and of the postal inquiry that the Committee covered a wide range of topics to ensure that its review was complete. On the whole the verdicts of both reports agree fairly well, though there are certain discrepancies. On some topics the investigator was able by personal questioning to obtain a more precise answer, while the replies to the postal inquiry must bear a broader interpretation. More-

Analysis of N.H.S. General-practitioner Principals

Total No. of N.H.S. Principals ..	17,916
No. selected for visits (with reserves) ..	390
No. invited to answer Postal Inquiry ..	17,657

		Totals ..	17,916	100	188	100	12,657	100

over, the field survey was objective, while the replies to the postal inquiry are subjective and more coloured by personal views, or even by the doctor's mood when he gave his answer. In reviewing the reports the Committee has been careful to avoid the conclusion that because a majority make no complaints on a particular matter all is well. The nature of complaints made by a minority has been carefully studied, in case the absence of complaint by the majority indicates an uncritical acceptance of a position which examination proves to be contrary to the interests of good medicine.

Having considered the two reports and other evidence, the Committee submits its own observations and recommendations (see *Supplement*, p. 131). In general, its object has been to compare the conditions and standards of general practice at the present time with the ideas set out in the Association's report on "General Practice and the Training of the General Practitioner," 1950, which, for the sake of brevity, is referred to as the "Cohen Report." It has found that a high proportion of general practitioners are doing good work, but many of them are handicapped in various ways, more especially by the lack of personal contact with consultants and hospital services. The Committee's recommendations are, in general, designed to secure for the practitioner all the facilities and contacts he needs if he is to exercise his

capacity to the full and to provide the best possible service for his patients.

The Committee wishes to draw the attention of the Council to one aspect of its research which it believes has proved of especial, though somewhat intangible, value. The very nature of the field survey demanded that an official of the Association should visit and discuss problems with members of the profession who are normally remote from the activities of professional bodies. It feels that much knowledge was gained on both sides, and understands that several practitioners, especially in the remoter areas, were very gratified that they should be thus visited.

Acknowledgments

The Committee wishes to place on record its grateful thanks to the 188 general practitioners who received Dr. Hadfield, and the 12,879 practitioners who, by replying to the questions put to them, enabled the views of such a large proportion of the profession to be assembled. The response of 72% from the National Health Service practitioners and of 56% from the private practitioners in the postal survey was not so large as had been hoped, but the Committee believes that the result does reflect the thoughts of the general body of practitioners.

The Committee also acknowledges the help given by the 167 consultants who answered questions on their relations with general practitioners, and by those practitioners who sent memoranda of their views in response to the invitation published in the *Supplement to the British Medical Journal*.

The Committee wishes to record its grateful thanks to all who worked with it to produce this report: to the pathologists who gave an account of the work in their laboratories, as well as to the other consultants who replied to specific questions; to all the general practitioners who answered the questionnaire and gave their opinions, and to those who sent in memoranda. The Committee has a special word of thanks for the general practitioners who allowed their practices to be surveyed.

It wishes to record its gratitude to its Secretary, Dr. S. J. Hadfield, who combined the labour of a Hercules with the wisdom of the Serpent, and whose enthusiasm and tact made it possible to complete both the Field Survey and the Report in reasonable time.

It is most deeply indebted to all those at B.M.A. House—the invaluable Miss Saxby, the secretaries, the typographers, and those in the card index and filing departments who worked long hours and who responded to the many and varied calls made on them by the Committee to make the Report as complete and accurate as possible.

That this Report has been achieved shows that unity of purpose in the profession is not only desirable but also practicable.

MEMBERSHIP OF THE GENERAL PRACTICE REVIEW COMMITTEE

The Committee appointed as its Chairman Dr. C. W. WALKER, M.B., B.Ch., a general practitioner in Cambridge.

The other members of the Committee were as follows:
Sir HENRY COHEN, M.D., F.R.C.P., Professor of Medicine, University of Liverpool. (President, 1950-1; co-opted to Committee, March, 1952.)
A. W. S. SICHEL, M.D., D.O., Capetown. (President, 1951-2.)
E. A. GREGG, J.P., M.D., General Practitioner, London. (Chairman of Council.)

J. A. BROWN, M.D., General Practitioner, Birmingham. (Chairman of Representative Body, 1950-1.)
S. WARD, M.B., Ch.B., General Practitioner, Birmingham. (Chairman of Representative Body, 1951-2.)

A. M. A. MOORE, F.R.C.S., Consulting Surgeon, London. (Treasurer.)
H. ALEXANDER, M.B., Ch.B., D.P.H., General Practitioner, London.
G. O. BARBER, M.A., M.B., B.Ch., General Practitioner, Great Dunmow, Essex.

LINDSEY W. BATTEN, M.B., B.Ch., M.R.C.P., General Practitioner, London.
ALEXANDER BROWN, M.B., Ch.B., General Practitioner, Linton, Cambridgeshire.

Sir ZACHARY COPE, M.D., M.S., F.R.C.S., Consulting Surgeon, London.
H. GUY DAIN, LL.D., M.D., F.R.C.S., General Practitioner, Birmingham.
N. S. DICKSON, M.B., B.Ch., General Practitioner, Co. Antrim.
H. R. FREDERICK, M.B., Ch.B., General Practitioner, Port Talbot, Glamorgan.

ANNIS GILLIE, M.B., M.R.C.P., General Practitioner, London.
A. STAVELEY GOUGH, F.R.C.S., Consulting Surgeon, Watford.
IAN D. GRANT, M.B., Ch.B., General Practitioner, Glasgow.
D. M. HUGHES, M.B., B.Ch., General Practitioner, St. Clears, Carmarthen.
G. W. IRELAND, M.B., Ch.B., General Practitioner, Pathhead, Midlothian.
J. A. L. VAUGHAN JONES, J.P., M.B., Ch.B., General Practitioner, Leeds.
W. JOPE, M.B., Ch.B., General Practitioner, Glasgow.
Dame HILDA N. LLOYD, D.B.E., F.R.C.S., M.R.C.P., P.R.C.O.G., Emeritus Professor of Obstetrics and Gynaecology, University of Birmingham and United Hospitals.
J. I. MILNE, M.B., Ch.B., General Practitioner, Manchester.
T. W. MORGAN, M.B., B.S., General Practitioner, New Malden, Surrey.
R. R. POWELL, M.B.E., M.R.C.S., L.R.C.P., General Practitioner, Reigate, Surrey.
J. O. M. REES, M.R.C.S., L.R.C.P., General Practitioner, Guildford, Surrey.
J. REVANS, M.B.E., M.R.C.S., L.R.C.P., D.C.H., Deputy Senior Administrative Medical Officer (Western Area), South-west Metropolitan Regional Hospital Board.
A. TALBOT ROGERS, M.B., B.S., General Practitioner, Bromley, Kent.
J. A. STIRLING, D.S.C., M.B., Ch.B., D.P.H., Medical Officer of Health and School Medical Officer, Chesterfield.
J. G. THWAITES, M.B., B.S., General Practitioner, Brighton, Sussex.

A POSTAL INQUIRY AMONG 12,879 GENERAL-PRACTITIONER PRINCIPALS, JULY, 1951

METHOD OF INQUIRY

When the sample of general-practitioner principals in the National Health Service required for the Field Survey had been drawn, there remained 18,346 who were invited to co-operate in the Postal Inquiry. These were divided so far as possible into groups of 500. Between the counting of the groups and the issue of the questions there were losses due to death, retirement, etc., giving a final figure of 17,616 practitioners from whom replies could have been received and reducing the sizes of the groups to between 468 and 489.

The Committee drew up a long list of questions, and each group was asked two of them, though some questions contained more than one part. The question papers were issued on July 12, 1951,* and the total number of practitioners who replied was 12,657, or 72%. A detailed classification of these is shown in the Table below.

In addition, 398 private general practitioners were divided into groups of 22 or 23, and each group was asked two questions appropriate to private practice. The number who replied was 222, or 56%.

In order that practitioners might feel free to make any comment they wished, each was given a serial number; no names appeared on the question forms, nor were they available to the Committee.

The report prepared for the Committee covered 230 typed foolscap pages and included full statistical tables. It is not possible, for reasons of economy, to print the whole of it, but it is believed that the summary in the following pages will indicate the scope of the inquiry and the character of the response to each question.

* This was before the announcement of the Danckwerts award and the subsequent improvements in the conditions of service for general practitioners in the National Health Service.

I. THE RANGE OF GENERAL PRACTICE

1. Continuity of Care

One group of general practitioners were asked questions about their arrangements for providing continuous care for their patients. The answers of the 357 (75% of the group) doctors who replied show that, in general, patients are attended by their own doctor personally, though there is a certain amount of overlapping between a practitioner and his assistant or between partners. Among those in partnership 68% state that, over a period, a patient may be attended by more than one doctor, but 59% also state that during the course of any one illness the patient will be attended by one doctor only.

Almost 70% of those doctors who were in practice before July, 1948, have not made any change in their methods in this respect on account of the introduction of the N.H.S. Five, however, stated that their partnership had been compelled, owing to increased work and longer surgeries, to "regionalize" their visiting-lists so that patients living in a particular district would be visited by a particular partner. "If one of us works on any one day to the north of the town, the other partners' cases in this area are seen by him. Bad for medicine, but what else can one do?" Three doctors commented that patients no longer expected a particular doctor.

2. Health Education and Preventive Medicine

Of the 338 general practitioners who replied to a question on this subject 50% stated that they take a real interest in this aspect of their practice; 43% give advice or inoculations when asked, but take no very positive steps in the matter of health education. Sixty-five practitioners, including 35 who classified themselves as keen on this work, commented upon the lack of time for health education in the N.H.S. This was the main adverse effect of the N.H.S. referred to in this connexion. Others among the 31% who thought the N.H.S. had had a bad effect mentioned the "mass introspection induced by a free service, and the lack of co-operation on the part of local health and school authorities." An urban doctor found that his discouragement came from his colleagues. He specified as a "bad effect" of the N.H.S.: "Less time to talk to patients, less energy to organize informal discussions and meetings. Fear of criticism by colleagues and executive if such meetings are organized."

3. Treatment of the Patient as an Individual

A group of practitioners were asked whether the N.H.S. had had any effect on their ability to get to know and treat their patients as individuals in the sense of paragraph 25 of the Cohen Report, which reads: "In order to arrive at an accurate diagnosis and to prescribe effective treatment the general practitioner must have regard to the 'totality' of his patient, his distinctive personality, his home environment, his occupation, his emotional make-up, his earlier medical history, and the rest. The doctor will consider the patient's illness in this background and perspective, for without this knowledge an illness may present difficulties in diagnosis and inappropriate treatment may be

prescribed." Of the 312 practitioners who replied, 38% state that the N.H.S. has had no effect, but another 38% (or 43% of those who were in practice before July, 1948) feel that they are not now able to give such full regard to the individual "totality" of each patient as they would wish. The reasons given most frequently are the great increase in work and the demands for medical treatment for trivial conditions, which leave insufficient time for the thorough investigation of patients who need it and for becoming acquainted with the background of each patient. One doctor sums up in the following way the views expressed by many: "Too many patients per day → less time per patient → no doctor-patient relationship → inadequate history, no explanation, no thought, no reading, → no diagnosis. Inadequate remuneration → undercurrent of dissatisfaction, little incentive → poor work."

Two factors were mentioned by several doctors as being partly responsible for denying to the general practitioner the opportunity of treating his patient as an individual. The first was the view held by many patients of the function of the general practitioner. They regarded the doctor as being there to sign certificates, to give prescriptions, to "sort" cases, and to give letters for hospital consultations. The other factor was the attitude of hospital staff towards general practitioners and the absence of liaison. This led, it was felt, to a lowering of the status of the general practitioner both professionally and in the eyes of patients. The complaint is illustrated by the following reply: "Any investigation requires the patient to be sent to a specialist, and if I am lucky I get a brief note after a considerable time telling me what the specialist thinks. If investigations are prolonged I am still responsible for the patient, and if anything acute arises I am quite unaware of what has been excluded by investigation."

The N.H.S. was considered to have had a good effect on this aspect of practice by 9% of the group who were in practice before July, 1948. They gave as a reason the earlier attendance of lower-income patients, which enabled the doctor to know the patient and to prescribe freely.

4. Diagnosis

Paragraph 26 of the Cohen Report described the function of the general practitioner in connexion with diagnosis. A group of doctors were asked what effect, if any, the introduction of the N.H.S. had had on their ability to exercise responsibility for diagnosis. Of the 367 who replied, 42% stated that the N.H.S. had had no effect, and 42% that it had had an adverse effect.

Most of the "good effects" observed by 9% related to the more easily available hospital services and domiciliary consultations. One doctor wrote: "I am now able to exercise a 'watching brief' without financial loss to my patients. Patients attend at an earlier stage of the illness, they attend more frequently, and I am able to make a thorough study of my practice. I find that intimate knowledge means better ability to diagnose any particular patient."

The "good effects," however, were greatly outnumbered by the bad. Two-thirds of those practitioners who replied "bad effect" referred to lack of time or the heavy demands for treatment for trivial ailments. The haste necessitated by crowded surgeries was said to induce mental fatigue and strain, diminish alertness of mind, and cloud clinical judgment. This led to a

tendency to "spot diagnosis" and to the reference to hospital of any cases requiring much thought. One doctor had had 40 patients in his surgery on the day he replied to the question and had been able to devote not more than three minutes to each.

A summary of the effect of lack of time and increased work is given by a young doctor in an urban partnership:

"1. The incredible amount of work one has to cram into 24 hours makes it impossible to examine people properly. This means that: (a) I have to jump to conclusions, and therefore may and do make errors which I would not otherwise have made. (b) I refer patients to hospital without having properly investigated them first. (c) I tend to congratulate myself on the speed with which I can polish off large surgeries and waiting-lists and not on any clever diagnosis or considered line of treatment. (d) I fight shy of treating a long-drawn-out case or a serious one if I feel I can get it into hospital. I just cannot fit them in. (e) I completely shun all minor surgery that I can get out of. Again, I just cannot find the time. (f) I cannot study the journals as I would like.

"2. The patient's attitude to me as a doer-out of cough mixtures, etc., and a pointer to hospital out-patients."

5. Minor Surgery

Of the 336 practitioners who replied to a question concerning their attitude towards minor surgery which is within the range and competence of a general practitioner, about 50% were anxious to undertake this work. Half of them also said that the introduction of the N.H.S. had had a bad effect on general practice, the main reasons being lack of time on account of increased work and the patients' expectation that minor surgical operations would be performed in hospital.

Seven practitioners complained that they were now deprived of opportunities for performing minor surgery in the local cottage hospital, and one that it was now difficult to make arrangements there owing to the increased number of consultants' sessions held. Another was unable to continue his fracture work as the local x-ray department had been closed. On the other hand, 14 doctors stated that they still undertake minor surgery in local or cottage hospitals. One of the latter added that, as his remuneration for hospital work was inadequate, the time spent on minor surgery was a financial loss.

The attitude of 22 doctors towards undertaking minor surgery is affected by the absence of extra remuneration which would provide an incentive. An urban practitioner in the middle-age group gives his view as follows:

"Before the Health Service, we did all our own minor surgery, including the reduction and putting up of fractures of the smaller bones. We had an immediate x-ray service kindly supplied by the local dental surgeon.

"Now, we refer most of it to hospital, retaining only that which our own pride and Christian charity require that we do ourselves.

"Why? Because we are not paid (1) for the skill needed, (2) for the responsibility of the job itself, or (3) for the responsibility of the aftercare. Even claims for the general anaesthetics so often needed are not popular with the 'keepers of the pool'."

About 4% of those replying thought that the N.H.S. had improved the position, mainly by providing better facilities for minor surgery in the hospitals. One doctor said that the work would be better done in hospital because a general practitioner attempting it would be too hurried.

6. Information to Consultants

It is noted in the Cohen Report that one of the duties of a general practitioner is to supply to consultants and specialists the fullest possible information about patients sent for an opinion or treatment. A group of practitioners were asked to describe their customary procedure in such cases. Of the 360 who replied, two-thirds write a short account of the history and their own findings, and 29% write a full letter giving details of the case, their own findings, and environmental factors.

7. Non-medical Advice

After enumerating the medical functions and responsibilities of the general practitioner, the Cohen Report adds a paragraph about the non-medical advice which patients frequently seek from their doctors. In order to ascertain the feelings of general practitioners on the matter, the Committee asked a group to indicate which of certain descriptions most appropriately defined their attitude towards the giving of non-medical advice to patients. Of the 348 who replied, 85% stated that they were prepared to give advice when asked, and regarded it as an incidental part of medical practice.

Three doctors mention that it is sometimes necessary to give such advice as part of treatment without its being asked for by the patient. "Non-medical advice is frequently given without it necessarily being asked for. Its need may not be appreciated by the patient till it is given. Conditions of work and environmental and social factors are often important in relation to psychological aspects as well as physical. I would not regard this as necessarily non-medical if medicine is viewed in any but the narrowest aspects."

8. Special Interests

In a group of 272 general practitioners 54% have some special interest within the scope of general practice. The branch in which the greatest number of practitioners take a special interest is midwifery, followed by paediatrics, anaesthetics, and minor surgery. Only one-third of those with some such special interest are able to develop it, the chief reasons being lack of time and lack of access to hospital beds and facilities.

9. Advances in Medical Knowledge

The range and methods of general practice are necessarily influenced by the general advance of medical knowledge and by progress or change in other fields of medical practice. The Committee accordingly included a few questions designed to ascertain how such factors had affected general practice during the last five years. The first of these asked what effect, if any, advances in the science and art of medicine had had on the doctor's practice.

It is clear that general practitioners are deeply appreciative of the new means of treatment placed in their hands by the discovery of antibiotics and the advances in chemotherapy. They enable the doctor to control infection, to shorten the duration of illness, and to treat at home patients who would previously have been removed to hospital. As one doctor replied, "One can now really treat disease. The day of the placebo is gone."

Of the 301 practitioners who replied to the question, 14% stated that advances in medical knowledge had had no effect on their practice, 63% a good effect, and 4%

a bad effect; 11% felt that, from the point of view of their practices, the benefits of the progress of medicine were tempered by disadvantages. Four of them considered that, while medical science had advanced, the art of medicine had declined. Two doctors expressed this more specifically by stating, as a "bad effect," the tendency of modern medicine, with its numerous investigations, to drive practice into the hospitals. Thirteen others mentioned this emphasis on the hospital as a bad effect. The remaining practitioners were unable to decide or gave an irrelevant answer.

That modern therapeutic methods made more work for the general practitioner was the opinion of 14 doctors, three of whom pointed out the time required for injections of penicillin and other drugs and for the sterilization of needles and syringes. One found that advances in medicine increased the number of patients coming for treatment, though they reduced the time required for each patient. The difficulty in the present conditions of general practice of finding time to keep abreast with advances in medical knowledge was mentioned by five doctors, and one said that he had no time to apply the new methods.

10. Increasing Specialization

Nearly half the doctors replying to a question asking whether they thought that increasing specialization had any effect on their general practice answered in the negative. The good and the bad effects were almost equally matched.

Most of the "good effects" concerned the new methods of treatment available, the higher degree of accuracy in diagnosis, and the readily available specialist advice.

Four practitioners refer to the narrowness of the field of certain specialties and the effect of this on general practice. One doctor writes: "Some specialists are so highly specialized that they cannot recognize or correlate facts which fall outside their own particular field." Another finds it difficult to obtain a "well-balanced" opinion. The multiplication of specialties is found by four doctors to retard diagnosis. They find, for example, that delays are caused by one specialist referring to another, and that "patients referred for simple matters, such as blood counts, find themselves encouraged by physicians to embark on long mechanical investigations quite apart from the original query."

A desire for more general consultants is expressed by one doctor who finds that "individual specialists are not interested in what might be termed 'allied' specialties. This throws extra work on both the general practitioner and the patient. The problem might be solved by a group of specialists working as a team." The multiplicity of specialties and what one practitioner called "sub-specialists" leads some doctors to lack confidence in the opinions given. For example, a doctor who, however, replied, "No effect," wrote as follows: "I employ as I have been used such specialists of standing as I think proper for each case. It is becoming more difficult to get a competent opinion in hospital owing to the numbers of specialists more or less in training. As regards the existence of clinics presided over by young doctors who confine themselves to part of a limited subject, these are not specialists and their existence is bad for the patients and worse for themselves, but they have not affected my work much."

A "bad effect" is specified by a rural practitioner as follows: "When I send a patient to hospital to see a consultant, in 75% of cases the case is seen by a registrar, from whom I either learn nothing or am blinded by science which is often wrong. The patient is disgruntled at being seen by a young man."

Two doctors found that increasing specialization helped them to keep abreast of advances in medicine. One replied, "Work more interesting by cross-checking my diagnosis with the specialist's, and so learning and by having to read to keep up." The other replied, "Increasing contact, both personal and in correspondence, with good specialists has the effect of a continuous postgraduate course."

The loss of access to the hospital in order to accommodate the specialties is bound up with the effect of increasing specialization on the range and interest of general practice. Fifteen doctors referred to this in such terms as the following: "The ever increasing sub-specialization of local teaching hospitals limits the scope of the G.P. Anaesthetics, minor surgery (occasional appendicectomy), fractures, psychiatry, midwifery and gynaecology were all in the day's work. There is a different picture to-day." "Narrowing of scope of work of G.P. with lessening of interest and responsibility—work in cottage hospitals curtailed—no anaesthetics, no assisting at operations, even minor surgery done by young specialists."

In the opinion of five practitioners increasing specialization results in the division of control of the case and in the general practitioner losing touch with his patient. Others feel that the limitation of the range of their practice by increasing specialization and the necessity for referring a large proportion of their cases to hospital through specialists reduces their professional status. "The general practitioner more or less runs a sorting office and has a mass of correspondence. He sees less actual treatment."

A "bad effect" mentioned by 24 practitioners is the demand by patients for a reference to a specialist even before the general practitioner has made his examination or given an opinion. Three others state that there is an increased tendency on the part of patients to distrust the general practitioner's judgment and to expect specialist investigation and treatment for comparatively trivial conditions.

11. The Public Health Service and the General Practitioner

From time to time the effect on general practice of the activities of the public health service has been the subject of discussion in the Association. As this may affect the range of service which the general practitioner is able to provide for his patients, the Committee asked a group of general practitioners whether their practices had been affected during the last five years by any development or deterioration of co-operation between the public health service and the general practitioners of the area. About three-quarters of the 339 who replied did not think that it had any effect. Ten per cent. thought the position had improved and 10% that it had deteriorated. Most of the criticism related to the maternity and child welfare and school clinics.

12. Public Education in Health

The theme of the replies to the question about the effect on general practice of public education in health was that "a little learning is a dangerous thing," the

line being quoted by many practitioners. The question asked whether the effects, if any, on the doctor's practice were slight or marked.

Of the 343 practitioners who replied, 28% thought it had no effect, 47% a slight effect, and 20% a marked effect. Of 203 comments, 38 specified good effects and 165 bad effects. Two practitioners who gave no opinion felt they could not give a reliable answer without making a special inquiry among their patients. One doctor considers that all health articles which deal with a specific disease are detrimental to the public morale, for "the lay mind is quite incapable of assessing the value" of such an article. He reports "a spate of cancer phobias" after a television health talk. Another refers to the television feature on slimming as "deplorable."

The difficulties of the general practitioner in dealing with patients who have been listening to radio health talks are illustrated by the comments of two doctors. "Has made consultations over illness, trifling and severe, more difficult because the patient's mind is filled with the little he has gleaned from the 'education.' He will, for example, show little faith in advice or treatment not mentioned in his 'education.'" "Some people become more nervous with regard to the various broadcast illnesses and themselves, and so visit the doctor unnecessarily. They place more stress, often, on what has been heard, especially in the way of treatment, than on what they are told by their doctor, and are inclined, therefore, when the two treatments differ to think they are not getting proper treatment from their own doctor."

The tendency to introspection and neuroticism is expressed as follows by one doctor: "Many patients trot out knowledge, usually ill-digested or distorted with an added anxiety component, sometimes marked. Frequently the question, 'What have you been reading or listening to?' brings things back to a healthy plane. The more aggressive type will argue and insist, with logical thinking in marked abeyance. Frequently requests or even demands for treatments or investigations selected by the patient follow the home-made diagnosis. In my opinion patients are becoming increasingly disease-minded and suggestible, and anxiety is increasing, largely attributable to matters read or listened to." Another says that the "public is scared stiff about 'polio' and reacts strongly to every publication and report, however slight"; and one gives as an example: "After a television talk on poliomyelitis I saw a number of patients complaining of headache lying in bed thinking they had the disease." The effect of Press articles during the influenza epidemic of 1950-1 is described by a doctor with a large rural practice: "The whole population became 'jittery' and our work increased by leaps and bounds. In fact, for two weeks the practice became almost unmanageable, with 90% of the patients only suffering from the common bronchial cold."

Demands for treatment or drugs read or heard about form a large proportion of the "bad effects." The following note from a doctor summarizes the attitude of patients of this type: "A tendency on the patient's side to suggest his or her own medical treatment—for example, Can I have penicillin or 'M. and B.'?—for complaints where it could not possibly be expected to help, such as chronic eczema. Requesting 'sight tests' (O.S.C.I) for every trivial headache, producing a feeling of lowered status

and inferiority in the general practitioner." Several doctors refer to the facts that treatment with many of the drugs asked for is still in the experimental stage, that some of the drugs are not available for general use, and that treatments available in America are not available in this country. The general practitioner's inability to provide the drugs desired causes distress to the patients, some of whom believe that the doctor is withholding from them what might be beneficial. Specialist investigations and auxiliary services are demanded before the general practitioner has examined the patient. One doctor says: "Most people now ask for physiotherapy if they have a pain in the back."

Most of the "good effects" mentioned related to increased requests for vaccination and immunization and the earlier attendances for treatment of serious disease.

Several doctors find the effects of public education in health are mixed, some being beneficial, others harmful.

A doctor who thinks that "generally speaking the public have not been well informed from above" adds: "There is only one way, in my opinion, to educate the public on health matters: by personal talks and discussions in the consulting-room or in the home by doctor to patients. By all means let the above-mentioned agencies start the ball rolling, but only the doctor-patient relationship can drive it home."

In spite of health education the public is still ignorant on the subject. One doctor estimates that 0.5% of his patients "seem to have been somewhat enlightened"; another finds that primitive ideas still exist.

Three practitioners point to the need for the doctor to keep himself up to date in medical knowledge if he is to be able to reply to the questions patients now ask. One writes: "It is more than ever necessary that the practitioner should be fully up to date in order to be able to digest the information that he receives. Mothers particularly are more worried and very much unnecessarily by the problem of 'polio': patients read of A.C.T.H., etc., and want to hear all about it. The practitioner has to be able to explain matters simply on a wide variety of topics if he is to avoid the persistence of constant underlying anxiety stress syndromes in his patients. I spend much time in preparation for explanation—I find this essential."

Several practitioners offer suggestions for topics of instructions:

(i) Emphasis should be laid on simple rules of health and general hygiene. In mentioning the latter a doctor says that housewives work themselves to death scrubbing doorsteps, but do not know how to handle food cleanly.

(ii) More instruction should be given in certain diseases. "There is tremendous scope for education about upper respiratory infections. These form at least 75% of one's work in the winter, and reassurance and encouragement to keep away from crowded surgeries would be of benefit."

"If tuberculosis were publicized as much as 'polio' it would do more in reducing the general mortality."

"Tonsillitis, with its common complication otitis media, could be minimized by some publicity—for example, 'Don't neglect sore throats or earache (especially in children).'"

Septic fingers and hands: "These usually arrive days too late at the surgery."

Cancer: "There are still too many late skin, breast, and uterine carcinomata reporting: this is only true for the 45+ age group."

Timing of propaganda for diphtheria immunization: "Publicity at the opening of the 'polio season' wastes a lot of time by having to postpone cases until the autumn."

13. The Effect of National Health Service on the Scope of General Practice

The last question in this group asked whether the operation of the N.H.S., disregarding any question of abuse or maladministration, had increased or diminished the scope of the doctor's practice. The replies sent by 336 doctors indicated: no change, 27%; increased, 31%; diminished, 30%; the remainder not having been in practice before July, 1948.

Expressed in this form, however, the figures are misleading, for inspection of the comment reveals that many of those who answered "Increased" interpreted the word "scope" as "amount," while those who answered "Diminished" interpreted it as "range," which was the Committee's intention. It seems likely that, had some of the 59 practitioners who replied "Increased" because of the large increase in attendances at the surgery carried their thoughts a little further, they would have arrived at the same conclusion as those who answered "Diminished" for the same reason. The preponderance of the replies would then have shown that the scope of general practice had diminished.

Lack of time is the dominant reason given for the reduced scope, time having to be given to the treatment of trivial conditions at the expense of the investigation of more serious illness and of the more interesting aspects of general practice. As one doctor put it, "The call is not so much for real medical investigation as for odds and ends, some of which are most unnecessary."

14. Midwifery

Questions addressed to one group of doctors were designed to ascertain the attitude of general practitioners towards midwifery. Of the 308 who replied 76% were general-practitioner obstetricians. Half of the 297 practitioners who classified themselves according to their attitude towards midwifery stated that they like it and wish to increase their experience of it; one-third undertake cases only when specially asked to do so; and the remainder wish to discontinue it. Lack of time was the most frequent reason given for wishing to discontinue it.

Eighteen practitioners indicated in additional comment that they found satisfaction in midwifery or regarded it as an essential part of general practice. "I feel it is the family doctor's duty and privilege to see his patients successfully through their pregnancy and childbirth." "The practice of obstetrics gives me a sense of satisfaction and achievement, and I feel that I can do the work to the patient's satisfaction also." "It is the key-stone of a successful general practice. It is the branch of medicine which allows me to exploit my skill and art to the fullest." Two stated that midwifery helped to establish the family doctor relationship. Some doctors thought midwifery "one of the few good things" left to the general practitioner, and one found it "a pleasant change from the minor ailments, etc., which appear to make up so much of general practice to-day." Another remarked, "A practitioner cannot undertake abnormal midwifery unless he is doing a certain amount of normal midwifery."

The difficulties of finding time for midwifery are mentioned by 18 doctors. For example: "The great increase in the volume of work caused by the introduction of

State medicine makes a large midwifery list an intolerable burden. On the other hand, I consider midwifery is an essential part of general-practitioner service, but the practitioner must have more time to devote to it." "I have a large general practice and find that midwifery interferes with ordinary work. I dislike undertaking the responsibility without having enough practice in the branch to keep myself up to date." Some young practitioners state their position as follows:

"I like midwifery a lot. Chiefly as a G.P. it increases one's meagre yearly salary. Unfortunately, as I have not attended 20 confinements I am not allowed to call myself a G.P. obstetrician, but as I am in partnership with an obstetrician I manage A1. Owing to G.P. work I have not time to fulfil local obstetrician committee's requirements."

"I would like to discontinue it as it is time-consuming and often at inappropriate times, and I don't like it. However, I must do it as it forms an important part of my income (an essential part). Therefore I am anxious to increase my experience in order to become more efficient and give good service, which I think I do."

The position in a country practice was described by another doctor, who wrote: "I undertake any midwifery that comes to me. I do not like midwifery now, for only abnormal midwifery is dealt with, usually in appalling conditions, which in the country takes a lot of valuable time, and the remuneration for doing abnormal midwifery, maybe 18 miles away in the hills in bad conditions, is not satisfactory. Most patients now book up in hospitals, as they can get little help in the home, and the public are beginning to realize that midwifery under bad home conditions is a menace. The majority of cases now seen are for antenatal supervision and any treatment; they are mostly confined in hospital and handed back for post-natal care. This works very well indeed and seems to please all concerned, I think."

15. Accommodation for Chronic Sick

Accommodation for the chronic sick was the particular subject of a question put to a group of practitioners who were asked whether they could command sufficient hospital accommodation for this class of patient. Of the 348 who replied 87% gave a negative answer. This may be compared with the 95% on this point in the group which was questioned generally on the adequacy of hospital beds.

Comment referred to the heart-breaking plight of some old sick people living alone without attention and unable to obtain a hospital bed. By the time a bed is offered the patient may be dead. A doctor replied: "Position has never been worse—I am told that chronic sick patients cannot be sent home once in hospital as relatives will not have them. The waiting-time seems to be months or years for the aged sick—many of these old people do not need full hospital services. They do require night attention and the attention of a warden and assistant nursing orderlies with a visiting district trained nurse—at present many of them on the waiting-list are living in crowded conditions with little care, and their condition is quite tragic. There should be more home helps and more financial compensation for relatives who tend the chronic sick at home." Another reported that in his town of 50,000 population there was now no accommodation for the chronic sick, though before the introduction of the N.H.S. admission to beds could be easily obtained through the relieving officer. Another, however, stated that the period of delay had been reduced from six months to two weeks.

16. The Care of Tuberculosis

Of the 313 practitioners who replied to a question asking whether they were satisfied with the present arrangements for the domiciliary care of tuberculosis in their areas, 46% replied "No," 44% replied "Yes," and 10% could give no opinion.

Fifteen practitioners (9 replying "Yes" and 6 replying "No") expressed appreciation of the helpfulness and co-operative attitude of the tuberculosis officer and his department. Two of the six replies which amplified the satisfactory arrangements may be quoted: "This is one bright spot in a rather gloomy outlook. I feel that to the county public health service is due every credit for an enormous advance in this aspect of the tuberculosis campaign. The improvement has been striking in the past ten years, and is not due to the N.H.S. Such defects as exist are outwith the control of the public health service—chiefly housing difficulties." "The appropriate health visitor calls regularly; the tuberculosis officer calls at any time on my request. The patients who can travel by themselves attend the local clinic regularly and those who cannot travel by public transport are taken by ambulance for x rays or refills. The tuberculosis officer is most helpful at all times."

The majority of the specified unsatisfactory arrangements fall under a few main headings. Several of them are combined in the following reply:

"(1) The great delay between notification and the first visit from the health visitor. (2) The infrequency of the visits by the health visitor and to the clinic so that I have to do the day-to-day treatment—which I do not mind—but I have no knowledge of the x-ray reports, B.S.R. or sputum reports except what I can glean from the patient. (3) The distance of the clinic is 3–5 miles with two bus changes for patients in this borough. (4) The tuberculosis officer rarely visits the patients. (5) In spite of having a large practice I have only once met the tuberculosis officer in a patient's house, and that by chance."

Examples of the lack of liaison between the general practitioner and the tuberculosis officer are given in the following replies:

"Initial treatment of the tuberculous patient gets under way satisfactorily, but further information as to progress and future treatment is too often lacking. The tuberculosis department is no doubt grossly overworked, but when the G.P. has no information to give his patient, following a repeat x-ray examination, etc., the patient is needlessly distressed and the important psychological angle is badly let down."

"In cases attending the chest clinic regularly, the physician does not lay down specific enough instructions in his reports to me, and does not report his findings and advice at regular intervals. In the few cases unfit to attend the clinic, I find they are not visited regularly, and again I lack specific and regular guidance. It could be said against my criticism that I could find out all this by a personal visit or telephone, but all this takes time."

Two practitioners remarked on the division of responsibility for the patient. One wrote: "It is difficult to know whether one is primarily responsible for the care of these cases or whether the local tuberculosis officer is. In some cases directions and prescriptions are left by the tuberculosis officer and in some cases the practitioner is left to his own devices."

The delay in providing specialist treatment may place the general practitioner in a difficult position. Thus, a doctor replied: "The patient falls between two stools. Admission to hospital is not usually possible for a long

period, during which time T.O. does nothing and patient relies on G.P. for treatment. G.P.'s treatment must be non-specific, and in many cases deterioration occurs. Since advent of streptomycin, with co-operation with T.O. treatment is sometimes started at home in suitable cases, and this has helped but by no means solves the problem." Another wrote: "With the increased demands already made on the general-practitioner service due to the Health Scheme, I find that my cases after reference to the chest clinic are sent home to bed and left there, and the only domiciliary care is the periodic visits of the G.P. Far too many of these cases clutter the visiting-lists and leave a sense of frustration as we feel we can do nil, and visiting week by week becomes monotonous in the extreme."

Several doctors complained that patients were not visited in their houses often enough by tuberculosis officers. One replied: "Not visited by tuberculosis officer often enough. Sent home to bed to await sanatorium bed and very little attempt made by authorities to show they are still interested in the case."

The difficulties of patients in present housing conditions appeared in many replies, as, for example:

"Cases of active respiratory tuberculosis are allowed to remain in dark airless basement flats waiting for months for admission to sanatorium."

"As methods of diagnosis have so vastly outstripped methods of 'disposal' of patients, and as the 'housing' problem and overcrowding are as bad in — as anywhere in U.K., 'domiciliary open tuberculosis' is a menace to all the remaining occupants of the buildings—often far too many of them. Many cases in consequence which are treated as domiciliary cases would in the 'bad old days' have been in sanatoria long before."

Seven doctors stated that, in general, they were opposed to the domiciliary treatment of tuberculosis.

"The shortage of hospital beds makes many difficulties for the general practitioner. The following are some illustrations:

"The dispensary side is good. The tuberculosis officer is most co-operative and helpful. We sadly lack beds for institutional care and for the later chronic or advancing case. The beds available are not even adequate for the early acute case group. The result is that the late case has to be nursed at home with considerable possibility of spread to other members of the household."

"Insufficient hospital beds to accommodate patients when complications arise that need hospital care—should be more beds allotted for such cases. Huts should be made more comfortable, so that patients will not sneak back into the house when winter conditions are rather harsh."

"Patients who are actually dying of tubercle are refused admission to hospital. Even though they cannot benefit from treatment, surely they should sometimes be admitted, from humanity?"

Two practitioners mentioned particular groups of patient. One stated that "elderly persons with chronic pulmonary phthisis are not catered for adequately." The other is dissatisfied because "there is no specific treatment available for the milder forms of pulmonary tuberculosis." Another doctor suggested that more tuberculosis patients "should have institutional treatment while they learn a way of life."

The official attitude towards the problem of the domiciliary treatment of tuberculosis and the administrative arrangements were criticized by several doctors. For example: "The magnitude of the problem here has dulled the appreciation of urgency in tuberculosis

officers and the hospital boards, and provides an excuse for inaction or dilatory action after much prodding by individual G.P.s." One doctor replied: "Dilatory, easy-going attitude to the problem by P.H. department still persists. Too great time-lag in putting into effect appropriate treatment—for example, pneumothorax. Delay in forwarding information—for example, x-ray result. The 'open' case still not regarded as urgent requiring immediate segregation (which is impossible in the overcrowded tenement dwelling). Expensive 'health visitors' set-up could be more usefully employed doing nursing duties in the district or in sanatoria."

The administrative changes which were made as a result of the introduction of the N.H.S. are commented upon by four practitioners. One found an improvement when a tuberculosis officer was appointed in the area. "Since July, 1948, there has been an all-round increase in the care of tuberculosis cases, due mainly to the fact that a tuberculosis officer is now centred in the area. Formerly this work was done by the M.O.H. along with countless other jobs. X-ray examinations are done more frequently, patients attend clinics more frequently, and domiciliary cases are visited more frequently by nursing staff." On the other hand, one doctor replied: "Have not noticed any such arrangements since responsibility was removed from the M.O.H. to a newly appointed chest physician." In the area of one doctor there is lack of co-ordination because the tuberculosis officer is employed by the county borough council and the health visitors by the county council. The following remarks are offered by a rural doctor: "The M.O.H., who is tuberculosis physician for the county, is employed on a basis of two-thirds by the regional hospital board and one-third by the county council. The cost of domiciliary treatment of tuberculosis in the shape of streptomycin, by a decision of the regional board, is charged against the I.D. hospital and constitutes a large part of the expenses thereof. The primary loyalty to the regional board appears to result in an attempt to keep down these expenses by reducing the number of patients under treatment. If this cost were to be removed from the regional hospital board to a separate account financed direct by the department of health I am sure that improvement would result."

II. THE DOCTOR-PATIENT RELATIONSHIP

A short series of questions was designed to find out how doctors felt about their relations with their patients, and any changes which may have taken place as a result of the introduction of the National Health Service.

1. Doctor and Patient

As the first question of this series a group of doctors were asked to indicate their general relations with their patients.

A summary of the replies of the 350 doctors who answered the question is given on the next page.

The predominance of the first category suggests that the traditional intimate relationship between doctor and patient persists through at least half the group. The "matter-of-fact" relationship has penetrated to only 8%, but that there is a danger of deterioration in consequence of conditions of practice in the N.H.S. is emphasized by the remarks of 25 doctors. As one of them expressed it, "In pre-N.H.S. times Category A applied to all my patients, private and panel. I regret to say that Category B is now the general rule, and it appears to be rapidly degenerating to C." Another doctor said that, while Category A applied to the older

	Total		Town		Country	
	No.	%	No.	%	No.	%
(A) Very friendly relations	188	52	121	51	67	57
(B) Moderately friendly relations	127	36	87	36	40	35
(C) Mainly matter-of-fact	27	8	22	9	5	4
No definite answer	14	4	9	4	5	4
	356	100	239	100	117	100

	25-39		40-59		60+	
	No.	%	No.	%	No.	%
(A) Very friendly relations	37	41	113	54	38	69
(B) Moderately friendly relations	42	47	70	33	15	27
(C) Mainly matter-of-fact	6	7	19	9	2	4
No definite answer	5	5	9	4	—	—
	90	100	211	100	55	100

patients to whom he had been family doctor for 30 years, Category C applied to the younger patients, who were determined "to get some return for their insurance."

Seven replies referred to the difficulty of maintaining a happy relationship when the demand for treatment for trivialities or the lack of time produced irritability and short temper in the doctor. One doctor, who gave Category C as his reply, wrote: "Since July, 1948, I have discouraged the relationship in A and B, as it leads to abuse, especially extravagant prescribing. Quite definitely, C is the basis since July, 1948, on which I insist." Another, on the contrary, replying in Category B, stated that the relationship on his part has to be apparently friendly, otherwise "the economic threat of transfer may easily become dynamic."

2. Servant or Friend?

Another question was an attempt to discover how doctors felt they were regarded by their patients—whether as an official, a professional man, a servant, or a friend.

A number of the doctors who were asked this question found it difficult to answer and were unable to decide, among the varying attitudes of their patients, which was predominant. For the large group who felt that they must reply both "Professional Man" and "Friend" an additional category was introduced in the tabulation. These three categories together account for 63% of the replies.

A doctor who gave no definite reply made the point that the answers would be "biased according to the doctor's own attitude towards the N.H.S.," and another said that the attitude of the patients would depend upon the behaviour of the doctor towards them. This latter view was expressed in a more positive form by the doctor who, replying "Professional Man and Friend," added: "A friendly professional relation still exists and has been deliberately encouraged. Argument and demand are practically non-existent." Another, who replied "Professional Man," disciplines his patients: "I do not allow my patients to treat me as an official or a servant; if they require an official or a servant they must find somebody else."

Two doctors stated that the patient's attitude often depended upon how ill he was. One who replied "Servant," said that in a case of serious illness he would be regarded as a professional man, and the other, who replied "Professional Man," said that if there were anything really wrong he would be treated as a friend.

A number of doctors remarked upon the general deterioration of the relations between doctor and patient. Some noted that, while the patients who had been in the practice for many years still maintained their friendly attitude, newcomers or the younger generation or "those with left-wing politics" or migrants from town to country tended to lower the standard. Five found that patients in rural districts were more friendly or considerate than those in or from the towns. Social class was also thought to have some bearing

on the difference of attitude; one reply was: "Professional man by professional and lower middle classes, servant by working class." Lack of time in N.H.S. practice caused one doctor to reduce his category from "Friend" to "Professional Man and Friend," as he now had no time to be friendly.

Nevertheless, deterioration is not everywhere prevalent. The following note from a doctor who replied "Friend" is worth quotation: "This was pre-Act a good lower-middle and working class practice, and the change-over made little difference in professional relationships or income. Of the old private patients who have come into the Service the majority make fewer demands on my time than before. A minority who do not like the scheme show their resentment by getting as much out of it as they can. I see a lot more children than before, and this is all to the good."

The presence of a minority of patients who made excessive demands on the doctor's time was mentioned by many who described their general relationship as that of "Friend" or "Professional Man." As one doctor put it, the "unnecessary work they cause is quite out of proportion to their numbers, and they are a cause of dissatisfaction."

3. The Family Doctor

In view of the oft-repeated statement that the day of the family doctor is over, the Committee asked one group of general practitioners whether they thought the idea of one doctor for the whole family desirable. The reply was overwhelmingly in the affirmative, 82% considering it desirable. Eight doctors qualified their affirmative reply by saying that the family doctor idea was desirable if the patients themselves wished it, and three of those who replied "No" gave as their reason the importance of free choice of doctor. One doctor thought the family doctor desirable when there were children under 18 years of age, but otherwise it was of no importance.

Among those who attached great importance to the idea of the family doctor, one said that it was essential for complete co-operation, and another replied: "It is extremely important, as most illness is linked up with the home background, and it is impossible to sort out the neuroses without knowing other members of the family. In my opinion, this is the strongest argument against health centre practice, which will encourage the patient to see different doctors, and continuity is lost." Another, who replied "Yes" wrote: "Ordinarily speaking, the word 'family' doctor implies this, but under the present N.H.S. set-up so much is impersonal and constantly changing on the least excuse that I don't think it matters a hoot. This is one of the tragic failures of the present Service."

One of those who replied "Yes" thought that in a group practice one family should be attended by one group of doctors rather than by one particular doctor.

Among those who thought the idea of no importance was a woman doctor who wrote: "It seems all right in practice for me to have the woman and children and the man to go to a male doctor. It is not good for public health to take over antenatal and school-age functions without my co-operation and knowledge."

4. "Suppliers" of Drugs

The Committee asked a group of doctors whether they found any widespread tendency among their patients to regard them as "suppliers" of medicaments rather than as medical advisers. The result was as follows:

	No.	%
No	55	15
A few patients so regard doctor	168	46
Many patients so regard doctor	143	39
Total replies	366	100

The figures suggest that this is a problem which worries many doctors to a greater or less degree. Even a few patients adopting this attitude may, by their frequent returns to the surgery, cause considerable annoyance and be a drain

supplies; one doctor, replying "A few," added: "At first I thought the answer would be 'many,' but the recurrence of 'few' makes them appear 'many.'" Eight doctors stated that they had taken a firm stand, at the risk of losing patients.

The complaint, where it is specified, is that the patients ask for drugs or appliances which they have prescribed for themselves or for medicine for a self-diagnosed complaint. Three doctors mentioned the written shopping-list presented to them, which made them feel like grocers. Two said that this type of patient seemed surprised or resentful when asked questions about symptoms or when the doctor suggested an examination. Another, however, remarked that the patient who comes for medicaments usually has symptoms, and the doctor is afforded the opportunity of viewing the disease, even if the patient is at first unwilling to submit to examination."

Two doctors stated that the problem existed before the N.H.S. began, and one added: "The N.H.S. tends to tempt the doctor to be a supplier of medicaments. It would be unfair to blame the patients, who seldom resent the doctor's exercise of his own judgment." Another blamed the government for telling patients only of their rights and not of their duties.

A doctor who replied that many patients regarded him as a medical supplier wrote: "My problem is to get rid of this type and pick out the patients who are truly reporting sick. When payment for prescriptions was announced in the wireless, my next surgery was of three patients, all old patients who said that now they could attend with a clear conscience."

5. Direct Resort to Consultants

It was reported to the Committee that a number of patients went direct to a consultant without an introduction from the general practitioner. It therefore included a question on this subject, with the following result:

	No.	%
No tendency	200	61
A few patients do	124	38
Many patients do	5	1
Total replies	329	100

There seems to be no widespread tendency among patients to seek a consultant's advice direct, for not only did two-thirds of the doctors in the group answer "No," but a third of those who answered "a few" inserted the word "very" before "few." Three stated that the tendency was no greater than before July, 1948, three that the local consultants would not see the patients direct, and two that if consultants did see the practitioner's patients direct they would cease to refer any patient to the consultant concerned.

The question, however, prompted eight doctors to make observations on the tendency of some patients to ask for a reference to a consultant or specialist.

6. The Ex-Private Patient

One group of doctors were asked a specific question about the attitude of their ex-private patients—that is, those N.H.S. patients who before July, 1948, were their private patients. They were asked whether they had observed any change of attitude and, if so, whether the change was slight or marked. Of the 349 who replied, 67% felt that some change has occurred in the attitude of their ex-private patients towards them. Most of the change is adverse, the specific changes mentioned most frequently being: the more "demanding" attitude; requests for treatment for trivialities which the patients would formerly have treated themselves; demands for visits when attendance at surgery would suffice. On the other hand, 31 doctors said that ex-private patients were more considerate than formerly or seemed reluctant to call him or apologetic (27 slight, 4 marked).

Some doctors found that the attitude of their ex-private patients varied with social class. Ten found that the better class patients were apologetic and reluctant to send for the

doctor, while the lower social classes took excessive advantage of the Service. One doctor estimated that his former private club patients now utilized his services four times as much as before July, 1948. Another said that "patients of the working class moving into new housing estates are much more careless of their attitude towards me than similar type people who were private patients before July, 1948." Groups of ex-private patients who are mentioned as demanding more attention are young mothers who shirk responsibility for the health of their babies, and middle-aged and elderly women who throng the surgeries for tonics.

One doctor thought the change was one of atmosphere. This view was supported by others who stated that their former private patients seemed to be less grateful for treatment, or to be ill at ease in the surgery, or distrustful of the doctor, or that the doctor-patient relationship had been spoiled.

7. Preferences for Private or N.H.S. Patients

Two groups of practitioners in the N.H.S. were questioned about private practice. The question put to one group attempted to ascertain whether general practitioners feel that the preservation of an element of private practice alongside the N.H.S. is desirable. The group was asked to indicate which of the following three statements most appropriately expressed their attitude towards private patients: (A) I should like my practice to consist of private patients only; (B) I like my practice to include both private and N.H.S. patients; (C) I like my practice to consist entirely of N.H.S. patients.

The result of the 353 replies was 15% for A, 66% for B, and 19% for C.

Three practitioners found that a proportion of private patients made a change; as one of them put it: "The comparatively few private patients one has remaining since July, 1948, offset most pleasantly the, at times deadly, routine of N.H.S. work." Another writes: "I am quite happy about the present position—that is, the vast majority as Health Service patients, and just a few private patients (about 4% of my total number) as variety. I should dread a return to the old days of accounting, unpaid bills, self-dispensing, and the extra time and 'fussing' that private patients expect as their right. I am now able to concentrate on the patients' ills alone, without the frills!"

Some embarrassment is expressed by one doctor: "I think the N.H.S. has made it more difficult to have private patients. One feels one should not charge too much, as they have to pay for their drugs (which I think unfair and unnecessary). Also it is difficult to be sure they get any extra benefit for it." One doctor replied under B "because it doesn't make any difference to me whether it is a National Health or a panel patient or a private patient. I am always ready to attend to any ill person no matter who it is or whether he can pay or not. I think this is our real duty."

A comparison is made by a doctor between the present position and his practice before July, 1948: "My original practice consisted of one-third National Insurance, one-third public medical service, and one-third private patients. This I think is probably in an urban district the best proportion. It worked easily and there appeared to be much less discord and discontent on the patients' part than I find at present, where the public, and I think particularly women who have become N.H.S. patients, appear to be very difficult."

The reasons given for replying under C include the lack of time for the kind of service private patients expect, the view that it is wrong for any section of patients to expect preferential treatment, and the absence of book-keeping and bad debts.

A few doctors made comparisons between the three statements. One, who replied under B, would like A if he could afford it, and would hate C. Another replied: "I don't want my patients to feel that they could have better service if they paid for it directly; I also don't like the shocking abuse of the N.H.S. But as A is impossible and B undesirable I reluctantly vote for C."

8. Drugs for Private Patients

The other group of practitioners were asked whether they thought that, in their own practices, the refusal of the Government to allow private patients to obtain drugs under the N.H.S. has been a factor in causing patients to claim treatment under the Service who would otherwise have preferred to remain private patients. They replied as follows:

	No.	%
No	91	24
A few	98	26
Many	89	24
Yes (unqualified)	95	26
No evidence	2	—
Total replies	375	100

III. PROFESSIONAL RELATIONSHIPS

Personal relationships with other general practitioners and practitioners in other branches of medicine form an important feature of the general practitioner's life. The Committee included in its review a series of questions on the present state of these relationships and the effect, if any, of the introduction of the National Health Service.

1. Neighbouring General Practitioners

The first question in the series asked a group of practitioners whether their relations with neighbouring general practitioners had improved, deteriorated, or remained the same since July, 1948. Of the 310 who replied, 63% replied "No change," 19% "Improved," and 6% "Deteriorated." The remainder were not in practice before July, 1948, and could therefore make no comparison.

The basis of good relations for many practitioners seems to be the rota or group system, which facilitates off-duty periods and help in emergencies. One doctor writes: "In 1948 I formed all the G.P.s into the — General Medical Practitioners Group. This group provides constant assistance and co-operation in all aspects of G.P. Regular monthly meetings are held, as well as social and clinical meetings. Personal relationship between all the G.P.s in a population of 25,000 could not be better." Another describes his "improved" relations as follows: "I began practice on my own in April, 1948, and now have become so friendly with neighbouring practitioners that we do week-end duties 'on and off' for each other, etc., and see each other's emergency cases at other times without sending 'emergency fee forms' to local executive council."

Local general-practitioner hospitals provide a focus for good relations in two cases. One reply reads: "The inter-doctor relationship here is very good, and the ethical tone is pretty high. I think all this is due in great part to the fact that we have a local G.P. hospital to which we all belong, and where we frequently meet." Improved relations are also attributed by eight doctors to local meetings of the profession for the discussion of common problems. One of them amplified his answer under "Improved": "Since July, 1948, G.P.s in this area have had monthly gatherings at one another's houses to have a drink and a 'natter.' This was unheard of before July, 1948, and one's neighbours were always rather an unknown quantity."

Another aspect was put by the doctor who replied: "We meet oftener and seem to have much more in common—even if it is only grumbling, or perhaps I am getting older and more philosophic." The conditions in the N.H.S., to which the "grumbling" presumably alludes, are mentioned by six other doctors as a cause of bringing general practitioners together. "We are companions in distress, as a poor, underpaid, overworked, maligned profession." The attitude, however, varies. One doctor writes: "All are fed up with the new Service and therefore all are more friendly," but another puts it more hopefully: "There is considerably less competition now than ever before. We general practitioners find that we have much more in common, in our general attitude towards the Health Service, and consider that good comradeship is essential before we attempt any beneficial changes."

Competition for patients is given as a cause for deterioration by ten doctors. One of them, who replied that there had been some slight improvement in relationships, added that "as long as there is competition for larger capitation lists on account of inadequate remuneration there will be little improvement in the relationship—this is regrettable, but it is nevertheless true."

2. Public Health Medical Officers

The report on this section should be related to that on p. 108, which dealt with the effect on the scope of general practice of developments in the public health service. The same group of general practitioners were asked whether their personal relations with public health medical officers had improved, deteriorated, or remained the same since July, 1948. Of the 342 who replied, 79% stated that it had made no difference, 8% that their relations had improved, and 4% that they had deteriorated. The remainder gave indefinite answers or were not in practice before July, 1948.

Among the tributes paid by general practitioners to public health medical officers was the following: "I consider that practitioners in the area in which I, too, am in practice are fortunate that we have a district M.O. who is conscientious and co-operative. His help and advice have been of great value to me, personally." One doctor finds that "the present personnel are more anxious to co-operate when help is asked for," and a young rural practitioner had a pleasant surprise when he first came into contact with public health medical officers: "Before the war I did an assistantship in general practice in between hospital jobs. Public health medical officers then were fierce ogres my principal told me about when he wished me to pull up my socks. After I came back from the war I did more hospital jobs and more assistantships until, at the end of 1949, I became a principal myself, only to find that now public health medical officers are human friendly souls only too willing to help and advise in any difficulty."

Personalities, of course, enter into the relationships. One practitioner complains of interference in purely personal concerns by the M.O.H., while another reports that since the M.O.H.'s powers have been curtailed he has become "more modest and human" in his contacts with general practitioners.

Although the introduction of the N.H.S. has improved personal relations in some ways, the transfer of certain functions to county authorities has hindered them for some practitioners, and the personal link has been damaged. Thus, one doctor writes: "Prior to July, 1948, all public health services (except midwifery) were under the district M.O.H., with whom one had direct personal contact. Now all the personal health services have been transferred to the county council, where contact is impersonal and always with clerks!" Another replied that relations had deteriorated because "our M.O.H. is now assistant M.O.H. and the M.O.H. is in another town. . . . Questions are 'referred' and personal relationship has been largely lost."

The absence of contact between general practitioners and public health medical officers was illustrated by a doctor who wrote: "Having been in practice here for the last 40 years, I have never even met my three district M.O.H.s. As chairman of the local medical committee I occasionally meet the county M.O.H. at committee meetings."

3. Midwives and District Nurses

Among the professional relationships included in this series of questions were those with midwives, district nurses, and health visitors. The first two were combined in one question, while the question concerning health visitors was addressed to a different group of practitioners.

The duties of midwife and district nurse are frequently carried out by the same person, but for the purpose of the present analysis they have been treated separately. The

replies of 310 practitioners showed that for 63% no change in relationships with midwives had occurred since July, 1948, for 8% they had improved, and for 11% they had deteriorated. In the case of district nurses the respective proportions were 76% no change, 12% improved, and 6% deteriorated.

The figures suggest that deterioration has occurred in the relations with midwives to a greater extent than with district nurses, the most frequent complaint being the lack of co-operation from midwives. Two doctors state that cases booked by them are taken by midwives, and another writes: "Less antenatal co-operation. Not only do the midwives dislike a general practitioner being 'booked' for a confinement; in some instances they actively try to dissuade the patient from doing so. We do not get the support of the divisional M.O.H. to the extent to which we are entitled. Little or no co-operation from antenatal clinic." Another reports that "midwives since the advent of gas-and-air appliances have taken over practically all midwifery, and even where one is expected by the patient to attend, the nurses confiscate practically all cases. There is also a complaint that midwives seem to resent a doctor's attendance at the confinement. 'I think midwives rather tend to resent doctors attending normal cases and would rather we only attended the abnormal.'" The deterioration specified by one doctor was that "midwives tend not to call me when I have specifically stated I wished to be called; they tend to ignore a lacerated perineum in unbooked cases, leaving the mother with a weakened 'frame.'"

The restriction of the scope of the general practitioner in midwifery is commented on by seven doctors, mainly because most women are confined in hospital. "In this district patients who have no facilities for confinement at home and cannot afford a private nursing home are forced to attend the local clinic in order to get into the county maternity home. The G.P. is out of the picture of this. I do not approve." "Almost all midwifery done in maternity home. Since State took over control scope has been restricted by consultants with some loss of status for G.P.s. More 'B.B.A.s.' and divided authority over patients *re* care and treatment."

Several of the doctors who reported good relations with midwives added that they had worked with the same women for many years. Two remarked that the younger ones seemed less co-operative.

Among the practitioners who amplified their statements that relations with midwives were good was the doctor who wrote: "The relationship with midwives is excellent in this practice. Three reasons I would put forward: (1) teamwork spirit; (2) prompt attendance at calls from midwives; (3) insistence on being present at birth in all booked cases." Specified improvements included the attendance of the midwife at the doctor's antenatal clinic.

There was less comment on relations with district nurses. Examples of improvement are quoted by a doctor whom the district nurse helps in giving liver injections, and by one who writes: "More help now given in country districts by district nurses, especially with post-operation daily dressings and injections for diabetics, pernicious anaemia, etc." Complaints are that district nurses are less willing now to take responsibility; that "frequently off-duty, half-days, full days, and week-ends" result in loss of contact and interference with the continuity of treatment; and that "too many unnecessary demands are made on the nurses, so they are often impatient."

One doctor thinks that "centralization of authority for appointment and general discipline seems to work less well than the old system of local nursing association." The administrative arrangements are criticized by a practitioner who replied "No change": "Whilst the service is less, as ever the personal contact with the nurse is less, due to the increased work done by nurses and their interference with the continuity of treatment; and that 'too change of duties resulting in their not being confined so rigidly to one district.'"

4. Health Visitors

The replies of a group of practitioners to the question whether their relations with the health visitors were satisfactory to them showed that among 334 practitioners the relations for 56% were satisfactory and for 20% unsatisfactory, while 24% had little or no contact with health visitors.

Most of the comments came from those practitioners whose relations with health visitors were unsatisfactory. Among those whose relations were good, two stated that they found health visitors useful in instructing young mothers in the care of their babies. As one doctor pointed out, "Good health visitors are very helpful; bad ones are a menace."

One of the most frequent complaints is the over-emphasis which health visitors place on attendance at clinics, even when the patient is being attended by a general practitioner. For example: "An effort is made to wean the patients to the clinics for vaccination and immunization, and it was recently suggested to a patient of mine that she was a 'bad mother' because she did not attend the clinic with her infant." "I hold my own antenatal clinic. The local health visitor tries to tell the patients that, though they come to me, they must attend the public clinic as well."

To some health visitors the "doctor" is the doctor at the clinic, not the general practitioner. "If I approach health visitors they are as a rule helpful, but they never seem to seek contact with the general practitioner or appear to be conscious of his or her part in the general scheme of things. To them a doctor seems to be the clinic doctor. I feel there should be more co-operation."

Thirty-eight doctors, specifying the unsatisfactory character of their relations with health visitors, complained that these women gave medical advice, often incorrect or in conflict with the general practitioner's treatment, and by their interference undermined the doctor's authority with his patient. As an example of the harm which can be caused by health visitors giving medical advice, a practitioner quotes a recent experience in a chicken-pox epidemic. "The health visitors have insisted on a return to school in 14 days and all contacts going to school; this was against my advice of three weeks roughly, until all the crusts had come away. As a result we had a widespread epidemic." A woman doctor writes: "The local health visitor recently told the mother of one of my backward, rather obese children, aged 15 months, who was slow in walking and whom I had ordered massage and exercise for his leg and back muscles, that the child had a T.B. hip and I had missed it!" The conflicting advice complained of often concerns infant feeding. For example, a doctor states that "one health visitor changed a baby's feed when I was in attendance because of difficulty of child's feeding (duration between my visits was three days)."

The annoyance caused to general practitioners by the conduct of some health visitors is expressed in such replies as:

"These persons are often officious, impertinent to patients, and ask questions about treatment which have nothing to do with them. I have even had suggestions made to patients by them! I will not tolerate interference by such people."

"Health visitors have visited patients who are under the immediate care of their own doctor, and on ascertaining this fact have persisted in their inquiries and visits, regardless of the fact that adequate supervision and advice is being given by the patient's own doctor. Furthermore, a conflict of views or suggestions *re* treatment is not calculated to improve the patient's peace of mind. It is suggested that such visits should only start either at the doctor's request or when he is no longer in regular attendance."

From the comments on the lack of co-operation the following illustration may be quoted: "I have no contact at all with health visitors. I have never met one. I am never informed when they intend to visit my patients. I have sometimes found that their advice on infant feeding in a particular case is wrong, and have had to overrule it as tact-

fully as possible, but there are no facilities for discussing the case with the visitor." Three doctors refer to the waste of their time in having to reassure patients who have been given contradictory advice or been caused needless anxiety by health visitors, "such that panic and quite unnecessary calls and consultations are made, increasing the G.P.'s work."

Twenty doctors thought that health visitors fulfilled no useful function or that the system was a waste of money.

Two practitioners remarked on the influence of health visitors in connexion with admissions to hospital. One writes: "I cannot understand why a health visitor can get a chronic patient into hospital fairly soon while I fail to do so." The other states that "when a patient is notified for removal to hospital, the health visitor is sent and on her recommendation, either way, the patient is admitted into hospital or not."

5. Consultants

Close contact and mutual understanding between general practitioners and consultants are essential to the efficient conduct of medical practice. Fears have been expressed that, since the introduction of the N.H.S., the relations between these two main branches of the profession have become less personal or more official. A series of questions put to groups of general practitioners was designed to ascertain whether there are grounds for such fears and what difficulties, if any, general practitioners experience in their relations with consultants.

(a) Personal Contact with Consultants

One group of general practitioners were asked whether their direct and personal contact with consultants had undergone any change since July, 1948. 360 replied. About half of those who were in a position to compare present conditions with those prevailing before July, 1948, found that no change had taken place in the degree of their contact with the consultants, and one-third found that they had less contact than formerly. Of the 55 practitioners who stated that they had more contact than formerly, 23 attributed the increase to the system of domiciliary consultations available in the N.H.S.

That more contact with consultants is not necessarily good for general practice was illustrated by a doctor who wrote: "Yes. But to the deterioration of the general practitioner. Formerly I could do my own x-ray work, minor operations—order physiotherapy, massage, and other treatments—under my own supervision at our small hospital. Now I have to send all of the above troubles to organized clinics which are grossly overcrowded—where they are crammed by visiting consultants. The entire system is deplorable. I am frustrated, losing interest, and ashamed of being akin to a grocer's assistant, making notes for consultants to deal with flatfoot, whitlows, fibrositis, etc."

Some doctors felt that, although there was more contact with consultants, it was less intimate. One wrote: "Domiciliary visits arranged through a consultant bureau, with an impersonal report and a form to fill up days later, are a poor substitute for a real consultation with a colleague by the patient's bedside; cases referred to hospital O.P. clinics are also dealt with impersonally."

For some general practitioners loss of direct contact with consultants has been accompanied by the disappearance of the former friendly relations. A practitioner wrote: "Consultants are now appointed on an area basis, and one makes little professional and no social contact with them—they are no longer one's friends. They have no local loyalty (as in a voluntary hospital) and their sessions are too infrequent for continuous care of in-patients." Another reports: "These new specialists seem to consider they are superior officers and to treat general practitioners as orderlies. Therefore I avoid them as much as possible."

The fact that consultants do not now need to depend upon the good will of general practitioners for their livelihood was mentioned by five doctors. For example, "Consultants are less dependent on private practice and less inclined to

bother with contacts. Far more consultants are more or less full-time and their income depends less on their own efforts. The personal factor counts so much in everything."

Seven doctors referred to domiciliary consultations without the presence of the general practitioner, one of the reasons for the increasing number of such consultations being the difficulty of arranging a time convenient for both consultant and general practitioner. On the other hand, eleven stated that they had no time to attend consultations.

The reference of more patients, often at their own request, to hospital out-patient departments has modified the relations between consultant and general practitioner. Of the nine practitioners who mentioned this factor, eight replied that it made contact less personal and direct, and one that it resulted in more contact, though it was also more indirect. A doctor writes: "Less contact, as all patients want their specialist through the out-patients department of hospitals. I hardly ever appear at a consultation to discuss a case personally with a specialist."

In the out-patient departments patients sent for consultations are frequently seen by registrars or juniors, and this was quoted by six doctors as a cause of loss of contact with consultants. For example, "Patients sent with letters to hospital O.P. are generally seen by registrars unless one happens to know the consultant personally and addresses a letter to the individual. The opinion of a registrar is not of the same value as that of a consultant, especially to a senior practitioner."

In another group of general practitioners, who were asked whether there had been any improvement or deterioration in their relations with consultants since July, 1948, about two-thirds of those who gave a definite reply stated that no change had occurred in their relations with consultants since July, 1948. Sixteen of them added that these relations were cordial and friendly. For 23% of those giving a definite reply, relations had deteriorated.

The comment is much the same as that on the question just considered. A few remarks which give a fresh angle are selected for quotation:

"Prior to 1948 I had all the means at my disposal to fully investigate my cases. The function of a consultant physician was judicial. A consultation in private practice gave opportunity to reassess the evidence. The great clinicians are a 'dying race.' We now send our cases to young men at hospital to set the x-ray department and clinical laboratory in motion. They rarely 'consult' with the G.P."

"From my point of view, specialists take no great personal interest in the patient as an individual. Letters take a long time to come. The consultants seem to regard the G.P. as a necessary evil."

"Deterioration in that there is a tendency among consultants to send brief instructions back, rather than an opinion."

"The difference is subtle and hard to define. I am still on the very best of terms with our local consultants, as before, but somehow there is a difference. In the old days one used to ring them up constantly and discuss cases and people. Now one feels they are no longer dependent on us, and they seem to be so much taken up with clinics here, there, and everywhere, and somehow one doesn't like to bother them."

To the question "Have you any complaints to make of the attitude of consultants and specialists towards you?" replies were received from 362 practitioners, 88% of whom said that they had no complaints.

To the further question asking the practitioners whether they had observed any alteration of attitude since July, 1948, replies came from 359. Of those who were able to make a comparison 83% had no complaints to make against the attitude of consultants toward them. Seventeen added a remark to the effect that their relations were friendly and co-operative; four of those who replied "Yes" to the second part of the question stated that the change was in the direction of improvement. One of these stated that he now received more letters "during continued treatment by consultants"; one observed that the obstetrics and gynaecological services had much improved; and one found consultants "rather more obliging." The other wrote: "They,

or many of them, are more aware of the problems and the importance of good general practitioners and seem willing to make efforts to improve general practice." A few who replied "Yes" did not specify whether the alteration was in the direction of improvement or of deterioration.

It is convenient to treat the adverse comment in the two parts of the question together. The complaint most frequently made (29 replies) concerned the failure of consultants to keep the general practitioner informed of the patient's progress while in hospital or of discharge or death, and the inadequacy of reports which were sent. The latter replies included statements that the general practitioner was not given a full report on the results of investigations or of the findings at operation, and he was consequently at a disadvantage when subsequently consulted by the patient. A doctor wrote: "Patients returning from hospital after operation are followed, perhaps a week later, by a printed form initiated by the H.S., merely giving a one-word diagnosis such as 'laparotomy.' No full letter from the specialist ever comes; most unsatisfactory."

In summary, it may be said that for the majority of practitioners their degree of personal contact with consultants is satisfactory, and the system of domiciliary consultations under the N.H.S. is valued. Where deterioration of relations has occurred it is attributed by some practitioners to the fact that patients are frequently seen by a registrar or a junior consultant and not by the consultant whose opinion is desired. Contact thus becomes more impersonal and the former friendly relations have been lost. Some general practitioners fear that the former friendly relations have been damaged by the fact that, under the N.H.S., consultants are no longer dependent upon the good will of the general practitioner for their income.

(b) Attendance of General Practitioners at Consultations

The figures below show the replies of a group of general practitioners to a question asking whether they customarily attended with their patients at consultations before July, 1948, and whether they do so now.

Consultations at Hospital					
	Total	Yes %	No %	Not in Practice before July, 1948	%
Before July, 1948	329	94 28	200 61	35	11
Since July, 1948	303	54 17	249 83	—	—

Domiciliary Consultations					
	Total	Yes %	No %	Not in Practice before July, 1948	%
Before July, 1948	329	284 86	10 3	35	11
Since July, 1948	311	295 95	16 5	—	—

The only comment to record is the following:

"In my opinion consultants and specialists in local hospitals pay too little attention to the local practitioners and their difficulties. In no local hospital do any facilities exist for attending along with patients. In addition, I can see no intention or desire by the specialists to have the practitioners present along with patients."

(c) Exclusiveness of Specialties

In order to ascertain, if possible, what general practitioners felt to be the causes of any deterioration in their relationship with consultants, five groups were questioned on possible specific causes. Thus the first group of general practitioners in this series were asked whether they found any tendency to exclusiveness among the specialties which diminished the contact and understanding between consultant and general practitioner. 343 practitioners replied, 324 giving a definite reply. Of the latter 30% found this to be a cause of diminishing contact, and 70% did not.

A doctor who replied "No" thought that the statement in the question had been repeated so often, though without evidence, that it had become accepted as a fact. The preponderance of negative replies suggests that "exclusiveness" among the specialties does not affect general practice adversely to any considerable degree.

Where it does have an effect, however, it can produce irritation and delay. For example, "There is a tendency to confine an examination of a patient to a particular specialty. A fresh appointment seems necessary for each system of the body. In the past a patient was examined completely when sent for an investigation." "Most particularly there appears to be no co-operation between one specialist department in hospital and another. The patient is constantly sent back to me to be sent to another at the same hospital. Common sense would direct the patient to all necessary departments at first instance. The result is weeks of delay for full investigations in all out-patients."

Another effect is the diminishing number of general consultants. A doctor who replied "No" added: "I still use in the main the consultants whom I have known for many years, and would only say that with increasing subdivision of specialties it is more difficult to find a consultant able to take a sound all-round view of a case, as the great physicians of the past seemed able to do. This is due to changes in medicine rather than deterioration in quality, and throws on the G.P. the increasing onus to correlate the contribution of different specialists and advise the patient himself."

Much of the comment in this group concerned the "exclusiveness" of consultants as a class and the degree of contact between them and general practitioners.

General practitioners' feelings about lack of courtesy from consultants are illustrated by the following comment: "Many consultants now exercise much less care or even courtesy in reference to the practitioner. The patient's confidence in his own doctor is of much more value to him in the long run than the occasional 'cleverness' of a consultant. This confidence is in the best interest of the patient and should be fostered and not destroyed."

(d) Effect of Alleged Decline in Numbers of the General Consulting Physician or Surgeon

It is sometimes suggested that the general consulting physician and the general consulting surgeon are gradually disappearing and are being replaced by consultants who specialize in a particular part or system of the body. It is said that this development is detrimental to medical practice. The group of general practitioners who were asked whether such a change was affecting the relationship between them and their consultant colleagues replied as follows: Yes, 13%; No, 29%; General consultants still available to 58%.

The replies indicate that the majority of general practitioners in the group are still able to consult general physicians and general surgeons and that any narrowing of the practice of consultants has not had repercussions on general practice.

(e) Premature Specialist Training

The replies of the group of general practitioners to whom was put the question, "Do you find that the fact that intensive specialist training begins immediately after registration has any effect upon the personal contact and understanding between consultant and general practitioner?" indicate that there is a strong feeling among them that the value of the help they obtain from the younger consultants is limited because the consultants, having had no experience of general practice, fail to appreciate the character of that branch of practice and the difficulties of the general practitioner. The response was as follows: Yes, 55%; No, 28%; No opinion, 17%.

The comment showed that, with one exception, the effect was considered to be adverse. The most frequent com-

plaint was that consultants do not appreciate the general practitioner's conditions of work, his problems and difficulties, or his point of view. It may be illustrated by a short series of comments:

"Less appreciation, especially by the young consultant, of the general practitioner's contribution to the history of the illness and background of the patient, to the patient's detriment; and, frequently, inadequate reports to the G.P., often leaving out the valuable and significant points from the G.P.'s point of view, and often not recognizing the G.P.'s rights and interests in the clinical side of the case, also to the patient's detriment. A widening gulf between the young consultant and the G.P., leading to a lack of mutual understanding and less incentive to the G.P. to approach and discuss the case with the consultant. If the G.P. has reasons to disagree with the consultant's opinion, in the patient's interest he is not given much opportunity to do so."

"The younger consultant who has obviously done little or no general practice has little idea of conditions under which G.P.s work; and is occasionally apt to prescribe treatment which is too elaborate and time-consuming to be carried out efficiently in a busy practice and under conditions which are rather far removed from the asepsis and efficient nursing found in a hospital environment."

"I feel that the average consultant does not appreciate the lack of facilities, the pressure of work, or the time wasted on trivial ailments that the G.P. has to contend with. Some consultants waste a lot of time in giving a long history of the patient in their reports to the G.P. of which he is already fully aware and has in most cases already given to them in his letters."

"The younger consultant is now much more detached, and often seems to ignore the fact that the G.P. is a colleague who seeks assistance but not instruction."

Another complaint is that consultants lack appreciation of the environmental factors, including home conditions, in a patient's illness. They tend to treat the patient as a "disease" or a "case" rather than as a human being. For example:

"It does prevent the specialist from viewing the patient *he* sees as a whole complete picture, including family background, environment, etc. It also prevents him from understanding human conditions and ailments not met with in hospitals or in textbooks. He only sees a minute fragment of the general make-up of the patient. He has little or no knowledge of general practice from the inside. To him the patient is a number, to the G.P.—a living and ailing entity."

"Some of the *younger* consultants do not seem to realize that what may seem routine investigation to them appears to the patient and his relatives as a vital operation in which the patient, and not the consultant, plays the leading role."

Several practitioners remarked that the consultant seemed to be becoming a "specialist" rather than a "consultant." One expressed the view that consultants placed too much reliance upon "photographic and mechanical investigations," and another stated that "many of the newer consultants seem to be technicians. They lack the breadth of view and, often, the cultural background of the older consultants."

Many doctors in the group are of the opinion that all prospective consultants should be required to have some experience of general practice. The periods suggested vary between six months and five years. One doctor thinks it should be spent "in one of the dirtier and more over-populated industrial areas." "An enforced period in general practice before specializing would give the specialist an understanding and appreciation of the work of the general practitioner, and an insight into home conditions and mode of life of patients. The general practitioner would then cease to be, in his opinion, merely an intermediary, and the patient would be a human being and not a number as at present." It would also, in the view of another doctor, enable the consultant to see the kind of help the general practitioner needs from the consultant.

Finally, a practitioner makes the following comment: "From my personal experience relations with consultants have been entirely harmonious. For this state of affairs to exist either the general practitioner must have considerable postgraduate hospital experience or the consultant *real experience* of general practice."

(f) General-practitioner Clinical Assistantships

Another group of general practitioners were asked, "Do you find that personal contact and understanding between consultants and general practitioners have been diminished by lack of opportunities for general practitioners to become consultants, for example, through clinical assistantships in hospitals?" Of the 352 who responded, 30% replied "Yes," 44% replied "No," and 26% had no definite opinion.

The lack of opportunity referred to in the question does not seem to disturb general practitioners to any great extent. Several of those who replied "Yes" observed that it was a less important cause than some others in separating these two branches of the profession. Some of the comments related to other causes of the loss of contact with consultants which have been dealt with by other questions.

Of the practitioners who replied three were clinical assistants, nine had appointments on the staffs of local hospitals, and one was an S.H.M.O. Five had formerly had access to the local hospital, and four had had to surrender clinical assistantships or other appointments.

One doctor wrote: "I would welcome clinical assistantship at hospital on sessional basis as the best idea yet put forward to restore the clinical status and interest of the G.P." One amplifies his negative reply: "Personal contact and understanding have not, in my opinion, diminished, but lack of contact with hospitals, owing to pressure of work, has increased. This makes it more difficult for the general practitioner to keep up to date with the march of medicine and so he is less conversant than he should be with what can be done by modern treatment for cases hitherto incurable. Clinical assistantships would help, but time must be found for them." Seven other practitioners, six of whom replied "Yes," stated that the general practitioner would have no time to visit hospitals. A doctor replying "Yes" added that "consultants have no time for clinical assistants who rank between registrars and junior housemen."

Two other opinions, both in the affirmative, may be quoted: "The standard of medicine in a particular area is much higher if the G.P.s are on the staffs of smaller hospitals—and their contact with the consultants contributes a great deal to their mutual benefit." "Lack of assistantships means less work in the hospital, much of which is undertaken by newly qualified men with less experience with the growing feeling that the G.P. cannot tackle even the simplest work."

The loss of the local hospital as a common meeting-ground was mentioned by two doctors, both replying "Yes": "Chiefly through loss of the personal touch which was fostered by the hospital being a common meeting-ground. The hospital now tends to be another Government administrative unit."

A practitioner replying "Yes," adds: "As Secretary of the Group Medical Committee I am very aware of this problem. We have recently elected to our committee a general practitioner (chairman of the local medical committee) to improve liaison."

(g) Administrative Separation of Regional Hospital Boards and Local Executive Councils

The last question in this series asked a group of general practitioners whether they found that "personal contact and understanding between consultants and general practitioners have been affected by the administrative separation, in the National Health Service, of the spheres of the regional hospital boards and the local executive councils." About one-half of the 355 doctors replying to the question stated that this administrative arrangement had had no effect on their personal contact with consultants. For one-third, personal contact had been diminished. Little comment was included in the replies.

IV. HOSPITAL FACILITIES FOR GENERAL PRACTITIONERS

Effect of National Health Service

A group of general practitioners were asked whether they undertook any hospital work immediately prior to July, 1948, and whether they undertake any now. Their replies are tabulated below:

	Total	No	%	Yes	%	Not in Practice	%
Before July, 1948	336	181	54	122	36	33	10
At July, 1951	301	210	70	91	30	—	—

Differences between Town and Country (among those replying "Yes" or "No")

	Town		Country	
	No.	%	No.	%
Before July, 1948:				
Yes	72	35	50	53
No	137	65	44	47
Total	209	100	94	100
At July, 1951:				
Yes	52	25	39	42
No	156	75	54	58
Total	208	100	93	100

Private Practitioners

The private practitioners who were asked this question replied as follows:

	Total	No	%	Yes	%
Before July, 1948	13	8	62	5	38
At July, 1951	6	3	50	3	50

General-practitioner Beds

It is part of the Association's hospital policy that beds in local hospitals should be available to general practitioners for the treatment by them of their own patients for conditions which are within the province of general practice. A group of general practitioners were asked questions designed to ascertain to what extent this facility was available to them and, if they had no such facility, whether they felt that their practice thereby suffered. The following tables show the result.

Access to General-practitioner Beds	Total	Yes	%	No	%	Not in Practice before July, 1948	%
Before July, 1948	373	117	32	222	59	34	9
At July, 1951	367	103	28	264	72	—	—

Of the 246 practitioners who had no access to general-practitioner beds and replied to a further question asking whether their practices thereby suffered, 24% said that they did suffer and 76% that they did not.

Differences between town and country are tabulated in the next column.

The replies show (i) that access to general-practitioner beds is not yet a customary feature of general practice; (ii) that the proportion of general practitioners enjoying the amenity is rather less than before July, 1948; (iii) that the proportion of practitioners with beds is higher in the country than in the towns; and (iv) that the majority of those who have no general-practitioner beds are not conscious of any adverse effect on their practices. Ten practitioners who have no general-practitioner beds indicated in their replies that they would like to have them. Six stated

	Town		Country	
	No.	%	No.	%
Before July, 1948:				
Yes	62	28	55	47
No	159	72	63	53
Total	221	100	118	100
At July, 1951:				
Yes	52	22	51	39
No	185	78	79	61
Total	237	100	130	100
Whether practice suffers by lack of beds:				
Yes	39	23	21	28
No	131	77	55	72
Total	170	100	76	100

that, although they have no beds, they visit their patients in hospital and discuss their progress and treatment with the consultants in charge.

One of the latter writes: "Knowing the medical and surgical staff and counting them as friends, I am perfectly at liberty to see my patients in hospital beds and can agree or disagree with investigations and/or treatment. We enjoy arguing about our cases and suggest (frequently) further investigations and treatment."

A practitioner who appreciates the advantages of general-practitioner beds doubts the attitude of his patients: "This practice was established sixty years ago, and the patients have always expected to be treated by specialists and 'students' in large general hospitals. They have never expected their family doctor, to whom they come for advice on all sorts of matters, to be associated in any way with their treatment in hospital. They would need to be educated along such lines if access were established in this region. My practice, therefore, does not suffer so far as my patients are concerned, but it does with respect to myself, for I find the treatment of many cases, with which I could deal, being taken out of my hands."

A doctor who has general-practitioner beds now, but did not have them before July, 1948, writes: "Little doubt exists in my mind of the superiority of general practice with access to beds in a local-practitioner hospital to that of practising where no such facilities exist." One practitioner who has never had beds and states that his practice thereby suffers adds: "I think that the principles of G.P.s having access to beds in local hospitals is the only way to keep up a high standard in general practice. I feel very strongly on this."

Several doctors replied that, although they could not say that their practices actually suffered, they were aware that access to general-practitioner beds offered advantages both for themselves and for their patients, such as continuity of care during hospital treatment, the sustaining of the practitioner's clinical interest, and the improvement of his skill and knowledge. "The practice does not suffer, as the hospitalized patients receive adequate attention, but one suffers oneself in 'losing' many medically interesting cases which, had the facilities been available, one could have treated oneself, retaining skill and interest."

The value of general-practitioner beds was summed up by a doctor who sent the following remarks: "I can only compare my present practice with (a) a practice in which I was first a locum and later an assistant, with G.P. beds, and (b) what I can do for my private patients in a good local nursing-home."

"1. *Surgical*.—I lose touch with the actual appearances of surgical pathology in my N.H.S. patients by not assisting at operation on lesions which I have tried to diagnose. This also adversely affects my after-treatment in a subtle way, (a) by loss of contact with their post-operative progress, and (b) by not always knowing when they come out of hospital."

"2. *Diagnostic*.—I do not usually see hospital x-ray films unless specifically asked for. (In this case they are always sent to

By far the most frequent difficulty mentioned was that caused by delay in obtaining appointments for hospital con-

sultations. One doctor described it thus: "I do not know if the hospital out-patient departments are crowded with minor cases, but my practice is hampered by the long wait for appointments and again for re-examination, because if a patient has to wait two, three, four, or five weeks that patient has to be visited and observed although both the patient and I know that nothing can be usefully done until the investigation or examination at hospital has been done first."

Although he could not say whether it was due to overcrowding, another practitioner stated that patients saw different doctors at each visit to some hospitals in his area. This resulted in lack of continuity and disturbed both his interest and his treatment of the patient.

One doctor suggested that "there should be some clinic for minor complaints, especially surgical—for example, lipomata requiring removal, renewal of surgical appliances: this would relieve the congestion at the main clinic." Another wrote: "There appears to be a need for urgent (not emergency) hospital consultation as a halfway house between domiciliary visit and ordinary four-weeks wait for hospital consultation."

Unnecessary Transport for Patients

It was suggested to the Committee that in some areas hospitals provided transport to convey patients to hospital for follow-up treatment which should properly fall within the province of the general practitioner. This, it was stated, was resented by the doctor as a form of encroachment. On the evidence, however, of the replies to a question on the subject put to a group of general practitioners, this procedure does not appear to be causing any serious disturbance to general practice, for 81% of the 339 who replied had no complaint to make, and the comment of some of those who replied in the affirmative showed that they were referring rather to the general question of follow-up treatment by hospitals than to the specific point of the question—namely, the collection of the patients by hospital transport.

Adverse Criticism of General Practitioners by Hospital Staffs

A group of general practitioners were asked whether, in their experience, members of hospital staffs, including almoners, gave patients the impression that better treatment could be obtained at a hospital than from a general practitioner. The result shows that 20% of the 371 practitioners who replied have some cause for complaint in this respect, though a few added that it was only occasional. Seven stated that only junior hospital staff were guilty of this fault, and two attributed it to nursing and lay staff. Three stated that it applied only to maternity departments.

For the attitude of some of the junior staff one doctor thought medical teachers were responsible: "As a medical student one was (and I expect still is) initiated into this attitude towards the G.P. by certain teachers, and as a houseman one may or may not (but very probably will) indulge one's self-importance in this way. I do not expect conditions in teaching hospitals have much altered recently."

A doctor who was doubtful of the value of patients' statements remarked that there were no means of verifying the factual correctness of such statements.

Some practitioners who answered "No" or "No knowledge" believed that the impression existed among patients, though not for the reason suggested in the question. Among these other reasons were N.H.S. propaganda, the frequency of reporting back to the hospital for follow-up treatment or inspection, and the knowledge of patients that general practitioners have no time for full examinations. "I think there is a general feeling among the more intelligent patients that, as a class, G.P.s are so overworked that they cannot expect much attention. If they suspect anything seriously wrong there is a definite tendency to just request a letter for hospital with no preliminary examination." "The

Government practice of issuing lists of practitioners in post offices, etc., without any letters after their names tends to lower prestige in eyes of public."

Waits for Minor Operations

The group of general practitioners who were asked to state whether patients referred by them to hospital out-patient departments for minor operations had to wait long before the operation was performed replied as follows:

Replies	Total	%
No	178	55
Yes	145	45
Reply indefinite	4	1
Total replies	323	100

Average Length of Wait, where Specified	Total	Average Length of Wait, where Specified, for Tonsillectomies Only	Total
Up to 2 weeks	2	3-6 months	4
2-4 weeks	7	6-9 "	12
1-2 months	14	9-12 "	10
2-4 "	19	12-18 "	7
4-6 "	30	18-24 "	5
6-9 "	21	2-3 years	4
9-12 "	19	3-4 "	
1-2 years	12		

Of those practitioners who replied that there was no wait, 26 added that they themselves performed most of their minor surgery either in their own surgeries or in local or cottage hospitals. Of these 18 were in rural partnership practice.

The most frequently mentioned suggestion for reducing the waiting period was the encouragement of general practitioners to undertake more minor surgery. This might be done by allowing them a special fee for minor operations for their own patients and/or by allowing them to participate in hospital work of this type. The direct access of general practitioners to pathological and x ray facilities was also suggested.

Among the difficulties encountered, apart from a shortage of hospital staff, was the absence of proper selection of cases from the waiting-lists. A doctor wrote: "There does not seem to be any selective method of choosing patients from the waiting-list; for example, a patient of mine with a hernia which was giving a lot of pain and had heavy work had to wait six months. He either had to keep lifting or stop work and starve. Too many cases are being seen by registrars who regard the patients as 'cases' and not as persons who work and have families to support. They have academic and clinical skill, but none of the common sense and experience of people that the G.P. has. They are also over-specialized in their own branches, and to them a hernia is of no interest and is put 'on the list' automatically and forgotten." The comment of another doctor was: "Hospitals vary in length of waiting-time; but the reason usually is that 'interesting' cases (that is, cases which are good for teaching or investigating) are admitted before those cases which are 'ordinary' but causing inconvenience to the patient."

Waits for Admission to Beds

The tables below summarize the information received in reply to a question asking a group of general practitioners whether their patients had to wait for admission to various groups of hospital beds:

1. Hospitals: Ordinary Cases			
Replies	Total	%	Length of Wait, where Specified
No	51	16	1-7 days
Yes	268	84	1-4 weeks
Reply indefinite	2	—	1-3 months
Total replies	321	100	3-6 "
			6-12 "
			6-24 "
			12-24 "

2. Hospitals: Semi-urgent Cases

Replies	Total	%	Length of Wait, where Specified
No	109	34	1-7 days
Yes	208	65	1-4 weeks
Reply indefinite	4	1	10 days-6 weeks
Total replies	321	100	1-3 months
			3-6 "
			6-12 "

3. Beds in Sanatoria

Replies	Total	%	Length of Wait, where Specified
No	22	7	1-4 weeks
Yes	280	87	1-3 months
Reply indefinite	19	6	3-6 "
or no experience			6-12 "
Total replies	321	100	1-2 years

4. Beds for the Chronic Sick

Replies	Total	%	Length of Wait, where Specified
No	13	4	1-7 days
Yes	305	95	1-4 weeks
Reply indefinite	3	1	1-3 months
Total replies	321	100	3-6 "
			6 months-2 years
			3 years
			Indefinitely

Emergency Admissions

A group of general practitioners were asked whether they experienced difficulty in obtaining hospital beds for emergency cases. Of the 385 who replied one-half found no difficulty. A further 36% found occasional difficulty.

On the whole it is usually possible to obtain a hospital bed for an emergency case, though sometimes admission may be achieved only after an expenditure of much time and effort by the general practitioner. The difficulty most frequently mentioned (17 replies) was that of making use of contact with a responsible officer at the hospital. The practitioners resented what one of them termed "a minor inquisition" by newly qualified house officers or having their applications dealt with by "a series of secretaries, porters, telephone operators, etc."

Twelve doctors suggested that beds which should be available for emergencies were "blocked" by their use for other purposes—for example, by specialist grouping, for the chronic sick and long-term cases, and for private patients. One of them amplified this as follows: "It is rarely possible to get a bed in the hospital of your choice—for example, local or teaching—and far too many cases under investigation at one hospital are admitted as emergencies to another (for example, cardiacs or perforated ulcers). This usually involves unnecessary investigations and expenditure of time and money by the hospitals. I think alternative but none the less essential arrangements should be made for the following types of cases blocking up hospital beds: (1) The sociological cases that cannot be nursed at home. (2) The terminal cases that cannot be nursed at home. (3) Cases undergoing routine hospital investigations as in-patients. (4) Cases awaiting disposal while room is found for them elsewhere."

The difficulty of defining an "emergency" sometimes results in differences of opinion between the general practitioner and the hospital officer. A doctor writes: "It is difficult to convey over the 'phone the nature of the emergency. A case diagnosed as 'acute bronchitis' in an afebrile patient over the age of 55 is in my experience a graver emergency than a pneumonia, yet this diagnosis does not carry enough emphasis to make admission by hospital more certain. G.P.s' requests for admission must be accepted as evidence of urgency unless the G.P. agrees to delay." Some of the difficulty of obtaining admission for elderly patients is due to the fear of the hospital authority that they may have to retain the patient as a chronic case when the acute illness has passed. A doctor writes: "The

difficulty arises mostly in winter and mostly for old people (70 or over), of whom there are very many in my region. There is a tendency of the bed bureau clerks (who, be it said, are most helpful and obliging when pressed) to fail to realize that over-70s can have acute illness from which they may recover and are not necessarily chronic cases."

In order to avoid the necessity of telephoning to a number of hospitals eight doctors recommend the establishment of a central bureau.

The appointment of a particular medical officer for an area with the responsibility of finding beds for all emergencies was suggested by three practitioners, and two recommended that if beds were not available temporary ones should be made up. Another suggested that "cases which a local G.P. feels are urgent should be admitted without question at least overnight, in a special 24-hour ward if necessary, and discharged, if hospital authorities think fit, next morning."

The Hampering of General Practice by Defects in Hospital Procedure

Eight groups of general practitioners were asked questions designed to ascertain whether general practice is hampered by any defects in hospital procedure.

Delayed Appointments

The tables below summarize the information received from a group of practitioners in reply to a question asking whether patients they referred to hospital for consultation had to wait for an appointment.

Is there Delay?			Length of Wait		
Replies	Total	%	Up to 1 week	2 weeks	19 cases
Yes	288	82	" 1-2 weeks	" 3-4 "	83
No	53	15	" 5-6 "	" 7-8 "	53
Varies	12	3	" 9-10 "	" 11-12 "	40
Total replies	353	100	" 13-14 "	" 15-16 "	7
			" 17-18 "	" 19-20 "	31
			" 21-22 "	" 23-24 "	16
			" 25-26 "	" 27-28 "	5
			" 29-30 "	" 31-32 "	6

The departments in which the longest delays occurred were stated to be the orthopaedic (66 replies), ear, nose, and throat (45), medical (30), and psychiatric (27).

In commenting on the length of the wait for an appointment three practitioners pointed out that after the initial wait for an appointment there was further delay before necessary specialist treatment or investigation was carried out. Secretarial delay might further lengthen the time that elapsed between the initial request for a consultation and the receipt of a report.

The length of wait may vary with the popularity and seniority of the consultant. One doctor estimates a wait of three or four weeks for "a good senior" and one week for a "junior." One doctor overcomes the difficulty by never specifying the name of a consultant. "Thus, for example, I ask for an appointment for 'a physician,' 'a surgeon,' 'a gynaecologist,' 'a throat consultant,' etc. This (a) ensures the patient gets the first available 'date,' (b) ensures the consultant is the least busy one at the hospital. I have pursued this line for years and so get a cross-section of all consultants and their views and methods (and can assess how much work they do!)." "The

The most frequently suggested cause of delay was that there were too few consultants and that they saw too few patients at each session. Comment which concerns methods of improvement includes the following: "It seems to me that the question is one of the attitude of approach to an appointments-system. It seems to me that such a system could be designed either (a) to improve the specialist's working conditions, or (b) to increase the patient's convenience. Regarding (a), we would all very much like to do better work by seeing fewer patients in a more leisurely way. But if the work is there to be done we have to scramble through

it as best we can. Whatever crowd is in his waiting-room the G.P. must see them all. In the past the hospital specialist had to do the same. He must now do it again. Regarding (b), if it can be arranged that a patient does not have to report at a hospital at 9 a.m. for a consultation at noon it should be arranged. This is the only proper purpose (under present conditions) of an appointments system. In my view every applicant for an appointment received by a given time (say 48 hours before a clinic) should be given an appointment for that week, at the available time divided up equally between the applicants. The consultant is then no worse off than without an appointments system, whilst the patient is better off. Carry-over from one week to another is almost bound to be cumulative, and should not be allowed." Other practitioners made a similar comparison between the general practitioner who, however hard pressed, must continue to work until he has finished and the consultant who sees patients only within the time limit of his session.

Appointments Systems

A group of general practitioners were asked whether an appointments system for out-patients operated in the hospitals in their localities, and, if so, whether it worked satisfactorily for their patients.

The replies of 370 practitioners indicate that most hospitals operate an appointments system, and that of these systems nearly 70% are reasonably satisfactory.

The main criticisms were that an appointments system creates a long waiting-list for consultations, which may be delayed for several weeks, and that, even though an appointed time may have been arranged, the patient still has to wait, sometimes for several hours, before he sees the consultant or his deputy. This waiting at the hospital is often due to the fact that many patients are given the same time of appointment.

The timing of sessions is sometimes inconvenient for patients. Five doctors mentioned the difficulties of country patients in reaching the hospital for an early morning session, and an urban doctor wrote: "Many patients attending O.P. departments are fit for their employment (for example, those attending for barium meals, massage, radiant heat, etc.) but remain incapacitated, as these special examinations, treatments, etc., can only be carried out during normal working hours (for example, between 9 a.m. and 5 p.m.). Suggest evening sessions."

A suggestion was made for a revised method of applying for a consultation: "In my opinion the easiest and best method is an application for appointment made on a form in part completed by the doctor and in part by the patient. The form is then posted by the patient in an official stamped envelope. Where the patient is left to 'phone the hospital for an appointment mistakes are common. If the doctor does this himself valuable time is wasted."

The following tribute was paid by a practitioner to the staff of his local hospital: "In so far as I am concerned, it may be placed on record that the O.P. system of the general hospital here is admirable. The specialists are a fine bunch, kind, tolerant, and helpful. They seem to take a personal interest in cases sent for their advice. My patients never fail to mention the fine impression left on them."

Delayed Reports

One group were asked whether they found that delay occurred between the discharge of a patient from hospital and the receipt of a report. Of the 387 practitioners who replied, 64% experienced such delay.

In considering the replies, however, allowance must be made for individual definitions of "delay." At least three practitioners answered "No" for reports which were received within a week, while of those who answered "Yes," 37 assessed the average delay up to one week, a few adding that this was not unreasonable. Of two

practitioners answering "Yes," one considered a delay of 7-10 days to be satisfactory, while the other found the same period "a source of annoyance to both doctor and patient." Specific periods quoted by practitioners answering "Yes" were as follows:

Delay up to 1 week	77	Delay up to 3 weeks	38
" " " 2 weeks	87	" " " 4 " "	9

Avoidable delay is attributed to secretarial routine and the failure of junior medical staff to appreciate the importance of reports to the general practitioner. Two practitioners refer to the delay caused when reports from several departments have to be co-ordinated. One finds teaching hospitals unsatisfactory in this respect: "As they are dealing with the unusual type of case this delay is particularly unfortunate. Occasionally the report on the 'follow-up examination' never comes at all."

A doctor who reports one to two weeks' delay states that he counteracts this by telephoning the R.S.O. or medical registrar in important cases: "the information so obtained is of more value than any written report." Another states: "Report from local hospital never received until I ring up to find out: (1) what was done; (2) when discharged."

A few suggestions for improving procedure are offered among the replies: "I can see no reason why every patient should not bring his discharge letter home with him. The saving in postage would even be worth while. A family doctor's letter always accompanies the patient, so it cannot be impossible to reciprocate." "I recommend most strongly that a patient who is to have a particular drug or treatment should either be given a proforma to show the practitioner, or given a sufficient supply of drugs to tide him over the period which must elapse before a report is sent out." "Might I suggest that when a patient dies in hospital the general practitioner should be notified immediately."

Notifications to General Practitioners

A group of practitioners were asked whether they were notified by the hospital if a patient sent for consultation was retained or sent to another department.

Only about 10% of the 345 replying fail to receive notifications, though many of those who replied in the affirmative categories added that notifications and reports were nevertheless much delayed.

A doctor replying "No" amplified his answer thus: "By and large, I am not notified if a patient is retained or transferred to another department. This does hamper me in my practice, in so far as one has got to question the relatives of the patients to find out what is going on. Also it does not inspire the patients' confidence in their own practitioner if he obviously does not know what is going on. Thirdly, one ultimately has to write to the consultant concerned in order to get the report required. Finally, operative procedure is often undertaken without the formal consent of the patient's own practitioner."

An example of the embarrassment caused by delayed notifications of discharge was given by one doctor: "Notification that a patient has been discharged from hospital is often most dilatory, sometimes 10-14 days elapsing before letter arrives. The patient is told on discharge that the doctor will visit in a few days, and is naturally annoyed when he does not come."

A doctor compared the methods of the larger hospital in his area, which does not notify, with a smaller hospital, which does: "The weakness in the hospitals is due to their large swollen staffs, both medical and clerical, working, it seems, on shifts with little continuity and less responsibility for the patient. This is a marked feature of the larger hospital. In the smaller hospital we are notified, and the standard of work, as far as it goes, is more satisfactory from our point of view than in the larger hospital."

VI. THE ORGANIZATION OF GENERAL PRACTICES

A series of questions was included in the review to obtain some information on doctors' methods of organizing their practices and on any changes which may have been necessitated by the introduction of the N.H.S. A report on the replies to another question concerning the effect of income on organization will be found in the next section.

1. The Effect of the N.H.S.

One group of general practitioners were asked whether the introduction of the N.H.S. had affected the organization of their practices, and a list of possible alterations was offered for them to mark "Yes" or "No."

Of the 315 practitioners who replied to the question on this subject, 36% had made no change in their organization as a consequence of the introduction of the N.H.S. The change most frequently mentioned was the employment of secretarial assistance, and next came the provision of new accommodation to meet the increased demands for service.

2. Non-medical Assistance in Surgeries

Of a group of 342 doctors, 63% employ some form of ancillary assistance in their surgeries, mainly clerical and secretarial. The help employed, however, was not always sufficient, and 162, or 48%, of the doctors who replied to the question felt handicapped by the absence of some particular form of help. Of the 126 doctors who had no help, 90 were thereby handicapped in their practice.

3. The Doctor's Wife

A separate question was devoted to the part played in the administration of the practice by the doctor's wife. The replies showed that in the practices of 277 married doctors the doctor's wife takes a considerable part in 39% and a moderate part in 58%. Only in 3% did she take no part at all.

4. Co-operative Arrangements for Relief

The Committee wished to ascertain to what extent neighbouring general practitioners co-operate to enable each of them to have some time off duty. A group of practitioners were asked whether they had any arrangements with neighbouring doctors or partners to permit some relief from duty, either regularly or occasionally, or arrangements for periods of holiday or illness. Of the 342 doctors who replied only 28, or 8%, have no arrangements whatever, and 17 of these are single-handed rural practitioners.

5. Employment of Locums

Of the 321 doctors who replied to a question asking whether they experienced difficulty in obtaining suitable locums, 57% had not needed to employ them. Difficulty had, however, been experienced by 86 doctors, or 29%. Among the 127 single-handed doctors who replied, 43, or 34%, had experienced difficulty.

6. Appointments Systems in General Practice

A group of general practitioners were asked whether they adopted an appointments system for all consultations or for private patients or special examinations. An appointments system for all consultations was adopted by only 8 out of 321 practitioners (2%) in the N.H.S. and by 5 out of 12 private practitioners. Among the N.H.S. practitioners 245, or 76%, arranged appointments for special examinations or, in some cases, for private patients.

An appointments system is rarely adopted in general practice. A few doctors in the group had tried it. One found that "patients had not the intelligence" to use it, and another stated that "on the whole 5 o'clock means any time between 5.30 and 7 in this area." A doctor wrote: "Appointments system was tried for 12 months. It worked well at first, but gradually the work increased up to 50% and the system was abused—discontinued when patients

complained they had to wait three hours if they had not previously made an appointment. Patients phoned at all hours of day and night for appointments for next day or in two to three weeks' time." An appointments system was considered to be administratively impracticable by a doctor who replied: "If we worked to an appointments system not one of three partners would ever be able to do any domiciliary visiting—our staff of three receptionists, etc., would have to be doubled, and a telephone exchange installed."

7. Health Centres

The Committee asked a group of practitioners whether they favoured, or did not favour, health centres as a basis for general practice for their areas or whether they were indifferent to the subject. Of the 362 who replied, 38% were in favour, 53% were against, and 9% were indifferent.

The majority opposed to the idea of health centres is maintained among both the town and the country groups and among all the age groups. The reason most frequently given for opposing health centres is the fear that such a basis of practice would disturb the doctor-patient relationship. "Health centres would mean the abolition of general practice and general practitioners. Space does not allow me to make this point clear, but it may suffice if I say the purpose of a doctor in a community is but little understood by the advocates of 'clinics and health centres.' We are little removed from the witchcraft of primitive societies, and to help the people to a way of life we should be with them, not apart, or separated by official centres." "Group practice—yes, but the essential of the G.P. is to see and advise his patients in his own surgery. The development of health centres and clinics, etc., would tend to take the patient away from the family doctor, who should be the friend and companion of his patients and not deal with them as mere numbers. The development of health centres is bound to make the contact impersonal."

The reason most frequently given by those who support the idea of health centres is that they would enable the doctor and his family to have more privacy in their own home.

Twelve doctors who replied that they were in favour of health centres added qualifications; for example, provided that the centres were conducted by the doctors themselves and not by an outside authority, or that they were better equipped than the average individual surgery. Three of them thought that, while health centres might raise the standard of medical practice, they might do so at the expense of the doctor-patient relationship.

Among those who were indifferent to the idea, a doctor wrote: "I do not think health centres would benefit the patients. They would enable G.P.s to have more leisure and their wives more freedom; but we would have to pay heavily for this (in cash). In this area any G.P. can have what leisure he wants, because there is no professional jealousy and we all willingly see each other's patients, etc., as it is now, and has been for many years." Another replied: "The answer depends too much on what solutions are found for other problems."

VII. WORK AND REMUNERATION IN THE NATIONAL HEALTH SERVICE

Although the Committee is not concerned with the actual amount of remuneration paid to general practitioners working in the N.H.S., it has endeavoured to obtain information on some aspects of the relation of professional income to services rendered and the effect of any inadequacy of income on the practitioner's efficiency.

It must be emphasized here once again that the inquiries from which these figures were obtained took place before the announcement and application of the Danckwerts award and of the recommendations of the

Working Party on the calculation and distribution of the Practitioners' Pool. It seems probable that the changes recently introduced will have affected these figures very considerably and will have restored, at any rate in part, some of the imbalances which they show.

1. Unnecessary Demands for Services

The series included three questions dealing, in a general way, with the amount of work required of practitioners in the N.H.S. The first asked a group of general practitioners whether unnecessary demands were made upon their time and services. Of the 351 who replied, 53% feel that excessive demands are made upon them to a considerable degree and 41% to a less degree.

Most of the practitioners who added comments stated that the excessive demands consisted of requests for treatment for trivial conditions and the demand for visits when the patient might be expected to attend the surgery. The next most frequent kind of excessive demand was the clerical work involved in issuing certificates and other forms. Some practitioners were especially irritated by the hindrance to their rounds when they were asked to prescribe for members of the family other than the patient visited, or when "buttonholed" by neighbours of the patient. To others the particular annoyance was the calls made unnecessarily late in the day or calls during the night which could wait until the morning.

Five doctors replied that there were a few unnecessary demands, but no more than before the introduction of the N.H.S.

From among the examples of unnecessary demands given by the doctors replying, three may be quoted:

"One Sunday in the middle of my lunch I received a message to come at once to a man who does get attacks of asthma. I left my meal to ruin and went immediately. His wife opened the door, looked rather startled, and said, 'I am sorry, we did not expect you yet, and he has gone out to have a drink.'"

"A patient attended at home with slight bronchitis sent for me two days later to ask was it in order for him to eat meat."

"Another woman asked me to visit her and wanted me, before doing so, to 'phone some of her friends in a town over twenty miles away and tell them she would not be there that day."

Several doctors made an estimate of the unnecessary demands on their time and services. One found that 5-10% of his patients were persistent offenders. Higher estimates include the following:

"50% of my 'visits' could attend the surgery, and 30% would never have seen a doctor if they had to pay."

"There is no doubt that 85% of the patients I see do not require medical attention."

"The practice has varied little in numbers for which it is at risk, yet I previously ran it alone, and now have a partner doing a full share of work and I give three times as many consultations and do twice as many visits as formerly. The increase is due to the influx of children and formerly uninsured women."

"At least 50% of my work in the surgery could be done by a qualified nurse."

Four doctors had disciplined their patients successfully, but another stated that he had lost patients since he had become firmer with them. One wrote: "I have tried to drill my patients, and I find that the exhibition of the B.M.A. notice on timing and urgency of calls is very valuable. This notice should be put up in every waiting-

room." Two found that unnecessary demands were reduced or eliminated through the help of a full-time secretary-receptionist or caretaker.

Two doctors mentioned the importance of recognizing that a condition which might seem trivial to the general practitioner might appear serious to the patient. "This is a difficult problem. We should not discourage patients consulting us with early symptoms of grave conditions. The average patient is not competent to decide the significance of certain symptoms."

The continuity of the insurance form of practice was mentioned. One doctor wrote: "In my district 'Club' medicine has been practised for many years, and both doctors and patients have become acclimatized to conditions rather similar to the present. The Health Service is not such a novelty to these patients as to those whose medical care was governed by financial factors." On the other hand, another replied: "This practice was almost entirely covered by colliery schemes or doctors' clubs before N.H.S., so the increase is not due to increased availability of attention without direct payment, but to an attitude that 'It's there for nothing, and that's what the doctors are for.' Tendency has much increased under N.H.S., and they will not bandage a cut finger for themselves."

2. Ex-Private Patients

It is sometimes alleged that many unnecessary demands come from those patients who formerly paid private fees for the services they required. The Committee therefore asked a group of practitioners: "Have you experienced any increase or decrease in the number of services required in the N.H.S. by patients who, before July, 1948, were your private patients?" Replies from 355 were as follows:

Replies	Total	%
No	20	6
Increase slight	74	21
Increase considerable	218	62
Decrease slight	7	2
Decrease considerable	3	1
Not in the practice before July, 1948	32	9
Answer irrelevant	1	—
Total replies	355	100

3. Relation between Income and Organization of Practice

A group of practitioners were asked whether they were able to organize their practices in the way they desired on the amount of remuneration they received. Their replies, which should be related to the summaries in Section VI (2), show that 72% of the 338 practitioners replying are handicapped by financial inability to organize their practices as they would wish. The most serious handicap is the absence of secretarial and other non-medical help. Others are unable to afford improvement or extensions of surgery or waiting-room accommodation or to buy new equipment, while some are unable to employ an assistant.

4. Effect of Financial Anxiety on Efficiency

A group of general practitioners were asked whether the efficiency of their practice was disturbed by personal anxiety about finance. A few of those who replied "No" seemed somewhat shocked at such a suggestion, but the number who replied in the affirmative shows that some reduction of efficiency on this ground does occur.

Of the 360 who replied, 64% feel that their efficiency is impaired, to some degree, by personal anxiety about finance. The causes of anxiety most frequently men-

tioned amongst the numerous comments were the heavy overhead expenses and the fact that too large a list has to be accepted in order to maintain income.

The following quotations have been selected to illustrate the comment:

"A continuing sense of frustration due both to the inadequacy of the capitation fee and to the uncertainty of the amount paid at any quarter (the sum may vary up to £25 for the same number of patients). The increasing cost of living plus anxieties about finding the money for children's education in an underpaid and overworked profession."

"My List is 2000+. I cannot afford a part-time dispenser or secretary. My telephone charge to ring the nearest hospital is 4d.—I would often like to ring the hospital and inquire from the house-surgeon if my diagnosis is confirmed. I cannot truly afford this. I would very much like to attend a monthly clinical meeting or medical dinner. I cannot afford to do this."

5. Size of Doctors' Lists

In view of the frequent complaints that many general practitioners in the N.H.S. have more patients on their lists, often for financial reasons, than they can efficiently care for, the Committee asked a group of practitioners for how many patients, both N.H.S. and private, they were at risk at the present time and how many they thought they could look after efficiently and to their satisfaction. They were asked, in estimating the latter figure, to disregard any consideration of remuneration. The optimum size of list for any particular practitioner will, of course, depend upon many factors, including the doctor's own temperament and skill, the age distribution of patients, the kind of district, and whether midwifery is undertaken.

The number of practitioners who replied to this question was 344, or 71% of the 487 addressed. The information provided is tabulated below. In analysing the present size of lists of practitioners in partnership, the average number per partner has been taken where it is clear that the number given by the practitioner applies to the partnership as a whole.

(i) Number of Patients at Present Time					
(a) N.H.S. and Private			(b) N.H.S. Patients		(c) Private Patients
No.	Total	%	No.	Total	%
Under 1,000	19	5	Under 1,000	76	8
1,000-1,999	67	20	1,000-1,999	66	19
2,000-2,999	115	33	2,000-2,999	115	33
3,000 and over	143	42	3,000 and over	137	40
Total	344	100	Total	344	100

(ii) Optimum Number of Patients					
Town			Country		
No.	Total	%	No.	Total	%
Under 1,000	1	—	Under 1,000	20	18
1,000-1,999	16	7	1,000-1,999	75	67
2,000-2,999	136	59	2,000-2,999	15	13
3,000 and over	77	33	3,000 and over	2	2
Answer indefinite	2	1	Answer indefinite	—	—
Total	232	100	Total	112	100

(iii) Comparison between Optimum and Present Numbers			
	Total	%	
Optimum	115	34	
More than now	139	40	
Less than now	86	25	
About the same as now	4	1	
No comparison available	—	—	
Total	344	100	

One doctor states that the optimum list would vary according to the standard of service expected:

"Under present conditions, about 500 really well; about 2,500 up to expected standard; about 4,000-5,000 if fully staffed and equipped health centres were provided."

A few other notes have been selected for quotation:

"A maximum of 2,500: beyond this number it is necessary to be a 'business man' doctor: the visiting speed of the 4,000-5,000 doctor is fascinating: he meets himself coming out of the house as he is going in. I would like to judge some of them by their reports to R.M.O. on R.M.2."

"Between 4,000 and 5,000. I have never looked after less, and I invite any sceptic to stay with me for a week to see if he thinks my practice is efficiently run."

"I was able to look after about 2,300 patients by diligence before 1948. But now I believe that the number should be almost halved for efficiency. For now work is slavery in a scattered area such as this, where, instead of an annual mileage of 14,000 miles, I must travel 22,000 miles. Work is two to three times as great as before July 5, 1948."

"I should say up to 2,200, which with a practice extending over 80 square miles of country would mean 35-50 miles a day, and from December 1 to end of May some 25-35 visits a day. I reckon 4½ visits an hour, and if I have no meals from breakfast to dinner and visit steadily from 10 a.m. to 6 p.m.—that is, surgery to surgery—34 visits."

6. Method of Remuneration

A group of general practitioners were asked whether the capitation fee system worked fairly for them as a method of payment, excluding from consideration the actual size of the Central Pool. The replies of 345 practitioners were heavily in favour of the capitation fee as a fair method, for the majority of those giving a negative reply and offering alternative suggestions favoured some variation of the method. The figures were as follows:

Replies	Total	%
Yes	224	65
No	118	34
Answer indefinite	3	1
Total replies	345	100

Those replying "No" and adding comments are classified as follows:

	No.	% of Total (345)
Some form of sliding capitation fee	33	10
Other variation of capitation fee	35	10
Item per service	23	7
Salaries service	4	1
Other methods	13	4
Total	108	32

By adding to the affirmative replies the 68 practitioners who, though replying "No," nevertheless think that a capitation fee should be the basis of remuneration, it is seen that about 85% of those replying to the question favour the capitation method.

Although the question excluded consideration of the amount of the capitation fee, 13 doctors replying "Yes" added that the present rate was inadequate, and at least four of those replying "No" showed that it was only the amount of the capitation fee to which they objected.

The sliding scale of capitation fee suggested usually meant a higher rate for the first 1,000 patients or for the small list. Two suggested up to the first 2,000. A few suggested also a reduced rate over a certain size of list. A more complicated scale was proposed by one doctor:

"Payment of £1 10s. per head on first 1,000 patients
" " £1 " " " next 500 "
" " 15s. " " " " 500 "
" " 10s. " " " " 1,000 "
" " 7s. 6d. " " " " 1,000 " and over
Also an additional 5s. per head per annum on people under 16 years and over 65."

The suggestion for a higher rate of capitation fee in respect of children, old people, or the chronic sick appeared in the replies of six doctors. Variations which took into account the factors of seniority or years of service were suggested by four doctors.

Criticism of the mileage scheme was the subject of the comment of seven doctors—five in the rural classes and two in urban areas.

Another doctor thinks that urban practitioners should receive a higher capitation fee than rural practitioners because they work harder, have more surgery hours, and see more of their patients. Nine practitioners wished to have a fixed capitation fee without deductions, and three stated that monthly, instead of quarterly, payments would cause them less inconvenience.

As will be seen from the second table above, 23 doctors in the group would like a fee for each item of service. Four others suggested a fee per service, paid partly by the Government and partly by the patient.

The "other methods" in the second table were usually combinations of methods, such as

- a small basic capitation fee, plus a fee for each item of service;
- a basic salary plus a fee for each item of service;
- a capitation fee plus a small payment by the patient for each attendance or visit;
- a basic salary plus capitation fee;
- an expenses allowance plus a capitation fee;
- an expenses allowance, allowance for length of service, and a capitation fee.

7. Recognition of Skill and Length of Experience

The capitation fee in the N.H.S. is paid at a flat rate for each person on a doctor's list, whatever the doctor's age or the length of his experience in general practice and whether or not he possesses some special skill in a particular branch of medicine. Suggestions are made from time to time that the incomes of general practitioners should be adjusted in some way which will take into account variations in these factors. The Committee endeavoured to ascertain the views of general practitioners on this subject by asking a group whether they thought that some financial recognition should be given to a practitioner in the N.H.S. for (a) special skill and (b) length of experience, and, if so, what method they would suggest for providing it. The answers of 340 practitioners were as follows:

(a) Recognition of Special Skill

Replies	Total	%	Age Groups					
			25-39		40-59		60+	
			Total	%	Total	%	Total	%
In favour ..	183	54	50	50	110	55	23	59
Not in favour ..	125	37	44	44	71	35	10	26
No opinion ..	31	9	6	6	19	10	6	15
Answer indefinite	1	—	—	—	1	—	—	—
	340	100	100	100	201	100	39	100

(b) Recognition of Length of Experience

Replies	Total	%	Age Groups					
			25-39		40-59		60+	
			Total	%	Total	%	Total	%
In favour ..	221	65	54	54	141	70	26	67
Not in favour ..	95	28	36	36	51	26	8	20
No opinion ..	23	7	10	10	8	4	5	13
Answer indefinite	1	—	—	—	1	—	—	—
	340	100	100	100	201	100	39	100

The figures indicate that of the doctors who replied 54% were in favour of the financial recognition of the possession of special skill and 65% of length of experience. Many suggestions were offered for the application of the idea, some detailed, others very general. A number of practitioners who submitted suggestions made a reservation that the additional money required should not come from the Central Pool.

Some of those who gave negative replies to one or both parts of the question did so because they felt that in general practice skill and experience bring their own reward through their recognition by patients. Others thought that any scheme would be too difficult to apply fairly. One replied that "a general practitioner is a specialist and should be paid as such."

The suggestions most frequently made for methods of recognition of special skill were the payment of a fee per item of specialist service rendered, with opportunities to undertake such work and extra payment for special qualifications.

Two of the ideas for special diplomas or examinations for general practitioners may be quoted: "For diplomas in medicine I feel that the universities could usefully institute an M.D. qualification attainable after five years in general practice in which the general practice aspect of all branches of medicine is especially stressed." "This would be a great incentive to do good work. Examinations should be held every three or five years in special branches, such as cardiology and chests; paediatrics; eye, E.N.T., and skins."

A higher capitation fee and a bonus or percentage addition to remuneration were the two methods most frequently suggested for the recognition of length of experience. Several practitioners made the point that in computing years of service experience in the National Health Insurance scheme should be included.

As his suggestion for recognition of length of experience one doctor wrote: "Make 15 years' G.P. experience a *sine qua non* for election to local medical committee—members of which could then be paid a honorarium—subject to satisfactory attendance at meetings. This would get an experienced body of practitioners actually competing for places on L.M.C., which at the moment is often run by an enthusiastic few."

8. Are Doctors Happy?

To one group of general practitioners in the N.H.S. the Committee put the question, "Are you reasonably happy and contented in your work?"

The replies of 345 practitioners indicate that 54% are reasonably happy and contented, though a number had qualifications to make. Four, who are included under "Yes," made a philosophical distinction: they are happy but not contented. The comment on present conditions of practice ranges from "Yes, would not go back to the old days for anything," to "No. If I could get out tomorrow I should."

Seven of those who replied "Yes" wished to make it clear that their answer did not imply that they were satisfied with the present rate of remuneration. Other reservations included the lack of time for study and leisure, overwork, and the excessive demands of patients. Three stated that they were happy in N.H.S. work only because they retained a certain amount of private practice or hospital work.

Some similar reservations were made by doctors who gave negative replies; they could be happy were it not

for the numerous trivial conditions they were called upon to treat. The excessive demands of patients were referred to by most of those who gave a reason for their unhappiness. The general sense of frustration expressed by seven doctors may be illustrated by the following answer: "Since the scheme, despite no real change in number of patients, my work is increased, my pay much less, and I have not the size of practice which I could undertake before in that it is financially not worth while doing minor surgery and giving physiotherapeutic measures and x rays. I feel frustration in my work and deplore the deterioration in relations between the patients and doctor, who no longer come for advice but for authority to gain benefits for which otherwise they would have gone elsewhere but paid directly." Another doctor wrote: "I like being a G.P.—I like my work—but consider conditions have deteriorated since N.H.S. Patients have not the same respect—I work harder and am paid less."

Of those who made a definite comparison with their degree of happiness before July, 1948, six replying "Yes" stated that they were not so happy now as before the introduction of the N.H.S., and four replying "No" stated that they were happy before 1948. One of the latter wrote: "I was very happy in my work prior to the New Health Act. The soul went out of medicine in July, 1948."

9. Effect of N.H.S. on Interest in Practice

Another group of general practitioners were asked whether they experienced any sense of gain or loss of interest in their work now as compared with the years before July, 1948.

Of the 341 practitioners who replied to the question 56% feel some degree of loss of interest in their work since the introduction of the N.H.S. This result may be compared with the replies to the preceding question. The comment suggests that one of the chief reasons is that the proportion of time spent on the treatment of trivial conditions and on routine work is so great that, in the words of one young doctor, "only rarely do I feel I am really practising medicine." Other reasons given are the changed attitude of patients, the loss of interesting cases to the hospitals, the lack of time for reading, and the lack of opportunity to continue special interests. An illustrative general statement was the following: "It has been chiefly loss. One tends to be more mechanical in one's attitude to patients. The undue proportion of trivial complaints, 'mass' consultations, and the feeling of being imposed upon for semi-medical articles have tended to make one a little 'sour.' On the other hand, I have been glad of the opportunities to prescribe much-needed preparations for people who could not previously afford them. In this practice, generally speaking, patients have behaved very fairly and there is still a good spirit prevailing between doctor and patient. I have been determined to preserve it, to prevent complete frustration." One doctor added to his reply: "Loss, yet not 'loss of interest'; it's just a loss—that one can't satisfy oneself, with everything so busy."

Among those who have experienced a gain of interest is a doctor who wrote: "I consider that closer contact with the family as a unit obtains under the N.H.S. and that this creates a warmer and better climate in which to work." Relief from financial considerations and book-keeping was mentioned by two practitioners. Another as found a new interest in his trainee assistant. Through the N.H.S. I am enabled to employ a trainee

assistant, which has given me a new interest in introducing the newly qualified to general practice, and I benefit from his new ideas."

VIII. THE CONTINUOUS EDUCATION OF THE GENERAL PRACTITIONER

1. Local Facilities for Postgraduate Education

The Association's Report on "General Practice and the Training of the General Practitioner" defined the postgraduate education of the established general practitioner as "a continuing process, extending throughout the practitioner's active life, whose object is to preserve and increase his technical competence and to provide a continuing contact with hospital practice and with advances in the diagnosis and treatment of disease." The Committee asked a group of practitioners some questions designed to ascertain whether local facilities for postgraduate education were available to them, whether they took advantage of such facilities as there were, and whether they wished for more facilities, and, if so, of what kind. The information obtained from 320 practitioners is summarized below:

1. Facilities Available Locally

(a) Clinical Meetings and Lectures			(b) Local Courses		
Replies	No.	%	Replies	No.	%
None ..	27	8	None ..	154	48
Occasional ..	185	58	Available ..	155	48
Frequent ..	100	31	No reply to this part ..	11	4
Available (unqualified) ..	6	2			
No reply to this part ..	2	1			
Total ..	320	100	Total ..	320	100

2. Use Made of Local Facilities

Replies	Total	%
Used occasionally ..	155	48
" frequently ..	67	21
" (unqualified) ..	10	3
Not used ..	79	25
No facilities ..	5	2
No reply to this part ..	4	1
Total ..	320	100

Of the 79 practitioners who did not use the facilities available 54 gave as the reason lack of time or pressure of work. Distance was the difficulty for 10 practitioners, and for 15 the times of meeting were inconvenient.

One doctor complained that general practitioners are not notified of opportunities, and another suggested that the Secretaries of B.M.A. Divisions might help by issuing local news sheets of forthcoming meetings and courses.

Eleven doctors did not find what they wanted in local arrangements. Two thought that direct consultations on their own cases were of more value than organized instruction. Four preferred to attend courses away from their own areas. "A fortnight's intensive course at one's old medical school or hospital (with locums provided) is a much more satisfactory way of doing postgraduate work, and is a greater stimulus to learn and put the lessons into practice than any number of half-daily sessions or lectures at local hospitals, many of the staffs of whom are not accustomed to any serious teaching."

Criticism of the standard of teaching came from three practitioners:

"I endeavour to keep up to date. There is not time to take advantage of all opportunities to learn. Many lecturers

hand out material that can be got from standard texts at home. What is needed is *not* spoon-feeding at medical students' standard, but new approaches."

"Apart from meeting other doctors (the chief reason for going to such meetings), I learn as much from the weekly refresher articles in the *British Medical Journal*. The courses I have attended are too like the rounds when a medical student, and frequently out of touch with the problems of general practice."

"We used to have consultants with whom we consulted and by whom we were taught. Now we only have specialists who have no time to consult or teach even if we had time to consult and learn."

To a further question asking whether more local facilities were desired, 62% replied "Yes," and 31% replied "No."

Of those who specified the kind of facility they desired, the majority needed some kind of clinical meeting. Thus 92 wanted clinical meetings, 54 hospital work, and 28 local courses.

Several practitioners emphasized the need for a clinical approach to all subjects of lectures, for the inclusion of the common conditions seen in general practice, and for the demonstration of cases of interest to general practitioners, including "general-practitioner cases" as well as hospital patients. One suggested lecture-demonstrations locally on the lines of the refresher courses in the *British Medical Journal*, and another similar suggestion was that there should be half-day "courses" on specific subjects, with instruction in the most recent developments.

One doctor made the point that clinical meetings should include free informal discussions with the hospital staff; and another replied: "I would like to have more clinical meetings with the local and personal factors emphasized—for example, based on a regional hospital with consultants and G.P.s using that hospital engaged in joint consultation *re* their own cases, rather than the more formal academic discussions which usually prevail."

The variety of times suggested for meetings—afternoons, evenings, week-ends, Sunday morning, summer time—indicates the importance of consultation between those responsible for arranging programmes and the local general practitioners. One doctor suggested that "direct teaching should be given at more than one hospital on more than one evening a month, so that if one is engaged on, say, a Wednesday one can get a tutorial on a Thursday. Meetings should not clash with one's surgery hours."

The most favoured forms of teaching through hospital work were ward rounds (13 replies), clinical assistantships (10), and attendance at out-patient sessions (10). Twenty practitioners desired more association with hospital work and closer liaison with consultants. The desire for continuous education through hospital contacts is illustrated by the reply of a doctor who wants "personal contact with doctors in hospital, socially as well as professionally, with a feeling of freedom to move about the hospital," and by the doctor who wrote: "Doctors should be able to go to out-patient clinics at times suitable to themselves and be given tuition and be able to take part in the session."

A few novel ideas were put forward, including the following:

"I suggest consultants spend an occasional half-day with a doctor, seeing, say, a morning surgery and a morning round."

"I would like to collect all my difficult cases at one surgery, about once a month, and have a physician go over them with me, showing points in detection of physical signs, etc."

"Continuous postgraduate education of the G.P. should be a duty of the regional hospital board. Each physician should have a number of G.P.s allotted to him. The physician would arrange for regular frequent meetings. He would keep his G.P.s in touch with all advances in diagnosis and therapeutics, he would be available to discuss with G.P.s their difficulties and problems. He would arrange for his other colleagues (E.N.T., obstetrics, paediatrics, etc.) to keep G.P.s familiar with their side of the picture."

2. Special Interests of General Practitioners

A group of general practitioners were asked whether they had any special interests within the scope of general practice, and, if so, whether they were able to pursue and develop those interests. The replies of 271 practitioners indicate that 54% take a special interest in some particular branch of medicine within the scope of general practice, but only one-third of these are able to develop their interest.

The branch in which the greatest number of practitioners take a special interest is midwifery, which was given by 51 practitioners, and 8 gave gynaecology. Then came paediatrics (18), anaesthetics (16), minor surgery (13), general medicine (9), psychiatry (8), cardiology (6), tuberculosis and chest diseases (6), and dermatology (5).

The main reasons for the practitioners being unable to develop their special interests are lack of time (33 replies) and lack of access to hospital beds and facilities (36). In midwifery there was also the lack of cases owing to bookings with midwives and attendances at local authority clinics. A doctor who is interested in obstetrics wrote: "I am able to practise only within the range of my own practice. I would favour a scheme in which a general practitioner interested such as I am would receive what one might call local consultant status, and thereby be given the opportunity to help with the more difficult cases of one's colleagues. One's experience and skill would thereby increase. I hold the D.Obst.R.C.O.G., but under the present scheme this is not much advantage to me, as officially one receives no added recognition or status."

Several practitioners complain that they are unable to obtain hospital appointments necessary for the development of their interests, and some who hold special qualifications are unable to make use of their knowledge. For example: "I possess M.R.C.P. and am interested in general medicine. I have no access to x-ray investigations or pathological ancillaries, which I have been trained to interpret. I have time in my work to pursue any interest I may have owing to group practice organization, but no hospital connexion. This would add interest to my work."

3. The General Practitioner's Reading

An important part of the continuous education of the general practitioner consists of his own reading. In order to obtain some information about the extent to which practitioners make a habit of reading medical literature, the Committee asked a group to classify themselves under the most appropriate of three categories; 322 replies are tabulated on the next page.

Some of the practitioners slightly amended the wording to suit their positions. The question of time arose. Ten of those who replied under Category C gave as a reason the lack of time, and six in Category B stated

Replies	Total	%	Age Groups					
			25-39		40-59		60+	
			No.	%	No.	%	No.	%
A. Reads a considerable amount of medical literature	50	16	10	10	31	17	9	26
B. Studies regularly one or two medical journals	211	65	71	72	119	63	21	60
C. Reads little or no medical literature	60	19	18	18	37	20	5	14
Answer indefinite	1	—	—	—	1	—	—	—
Total replies	322	100	99	100	188	100	35	100

that they found it difficult to find time for regular reading. Two others in Category C stated that they had read more before the introduction of the N.H.S. "Before the 1948 Act I managed to read a reasonable amount of medical literature, but now it's a quick look through the *B.M.J.*"

IX. INTERESTS OF GENERAL PRACTITIONERS OTHER THAN CLINICAL MEDICINE

The Committee thought it would be useful to include in its survey a question concerning the general practitioner's non-professional activities and his participation in what are known as medico-political activities which affect the profession as a whole. It asked a group of practitioners in the N.H.S. to compare the part they now take in medical politics, local politics, other communal activities, and hobbies with the part they took in them before July, 1948. Of the 339 practitioners who returned their forms 303 replied to one or more parts of the question, and 36 were not in practice before July, 1948, and therefore could not compare.

THE COMMITTEE'S REPORT

1. THE GENERAL PRACTITIONER IN THE HISTORY OF THE MEDICAL PROFESSION

1. The survey published in the opening pages of the *Journal*, and the postal inquiry preceding this report, present a picture of the general practitioner and his work at a particular period—the year 1951-2. It is appropriate to recall briefly how the general practitioner have developed in being and how he and his function have developed in relation to other branches of medical practice.

2. It is unnecessary for the present purpose to go further back into history than fifteenth- and sixteenth-century England, when the differentiation between the status and functions of surgeons and physicians was first clearly established in the rise of the Company of Barber-Surgeons and the Royal College of Physicians. A third group of practitioners was recognized in 1617, when the apothecaries, originally those members of the Company of Grocers who sold drugs, severed their association with the grocers and obtained a separate charter as the Society of Apothecaries.

3. The apothecary may be regarded as the ancestor of the modern general practitioner and the family doctor. Members of the new society prescribed as well as sold drugs, and, as their practice developed, they made considerable encroachments on the sphere of the physicians. The latter, who were cultured men moving in the highest circles, confined their practice largely to those who could afford to pay fees, and worked in the hospitals, while the apothecaries, less educated and inferior in social standing, practised among the poorer members of the public. The difference between the two groups was one of education, standing, and extent of knowledge and facilities rather

Replies	Medical Politics		Local Politics		Other Communal Activities	
	Total	%	Total	%	Total	%
No change	9	3	3	1	19	7
Smaller part than before	59	19	22	7	101	34
Greater part than before	97	32	14	5	51	17
Has never taken any part	138	46	261	87	124	42
Total replies	303	100	300	100	295	100

The figures above show that over half of the practitioners replying take some part in medical politics and in various communal activities, but only 13% participate in local politics. Since July, 1948, one-third of them have taken a greater part in medical politics, but at the same time a similar number have reduced their communal activities.

Doctors' Hobbies

Gardening is the doctor's most popular hobby according to this survey, for it was given by 115 of the 254 practitioners who responded to the Committee's invitation to state the nature of their hobbies. Next in order came golf (87), reading (44), music (36), tennis (35), motoring (27), photography (27), shooting (24), sailing (23), and fishing (22). Other hobbies which claimed smaller numbers of devotees ranged over a very wide field, from plumbing to philosophy, from mountaineering to small pet dogs.

The replies show that since the introduction of the N.H.S. 70% of the doctors replying have had to reduce the time they can devote to their hobbies. Twenty-seven stated that they had no time for hobbies.

than of essential function. In 1815 the Society of Apothecaries received the legal right to grant licences for the practice of medicine throughout England and Wales, and in 1858 its licence was made registrable equally with university degrees and the diplomas of the Royal Colleges.

4. The Apothecaries Act is important in the history of general practice, for it gave legal recognition to a body of practitioners who had hitherto existed on sufferance. It laid down regulations for apprenticeship and for examination in Latin, pharmaceutical chemistry, materia medica, and the theory and practice of medicine. Surgery and midwifery were not included, but licentiates frequently obtained the membership of the College of Surgeons, and the usual qualification of this class of practitioner became "M.R.C.S., L.S.A." The term "general practitioner" seems to have come into common use soon after 1815.

5. The best type of English general practitioner in the mid-Victorian period was described by Sir Clifford Allbutt in 1920 in his presidential address to the British Medical Association: "His university . . . was nature; in his clinical experience he enriched the instruction, half empirical, half dogmatic, of his medical school by the shrewd, observant, self-reliant, resourceful qualities of the naturalist. His science and his practice were of the naturalist, not of the biologist. In my early days a country drive with such a doctor used to be one of the rewards of the consultant; and a bedside talk with him a lesson in quickness of wit and hand, and of instructive inference and prognosis; his rules of thumb were not without their efficacy, and his flair for the issues of disease marvellous."

6. The general practitioner was steadily gaining ground during the period of the great reforms of the nineteenth century and the period of social revolution. His standard of education, both general and technical, improved. In 1832 a general practitioner, Charles Hastings, founded what was to become the British Medical Association. In 1859 the Royal College of Physicians, which had hitherto concerned itself only with the consulting physician, instituted a new class of licentiates with the right to dispense medicines for their own patients. The general practitioner now also began to take university degrees. Before the end of the century his function in medical practice had become clearly recognized. He was the family doctor, the personal medical adviser of his patient, exercising continuous responsibility and calling in specialist assistance when it became necessary.

7. The result of the various developments and reforms of the nineteenth century was to weld all medical practitioners into a single profession of medicine, but even while that unity was being achieved other forces, some of them outside medicine, were threatening the profession with disintegration of a different form. The increased momentum of these forces is one of the most difficult problems facing the profession to-day. Two main influences may be distinguished. First, the rapid growth of scientific knowledge, which, having extended the potentialities of medicine to undreamed-of horizons, necessitates specialization in particular fields of practice. Secondly, the interest of the State in the health and welfare of the people has led to the public provision of medical services.

8. These factors must be accepted as inevitable in modern society, but their effect on general practice has not been wholly good. The growth of specialism in the profession has tended to transfer to the hospital some parts of the general practitioner's work and to deprive him of these personal contacts with practitioners in other branches of practice which had come to mean so much to him. At the same time, however, it is recognized that the growth of medical knowledge has placed in his hands the means of treating at home conditions which formerly could only be treated in hospital.

9. The interest of the State in medical practice made its first impact on general practice in 1911 with the National Health Insurance Act, which introduced a third party into the relations between doctor and patient. The doctor's "list" and the capitation fee, applied then to the lower-income groups of wage-earners, have now been applied to the whole population, with the result that the environment of medical practice has changed from mainly private practice to mainly State practice. This change in itself is not necessarily a disadvantage, but certain fears for the future of good medicine have been felt. One is that the general practitioner working in a State scheme may be so overloaded with non-essential and administrative duties that his clinical enthusiasm may be curbed and consequently the field in which he exercises it may be contracted. Another is that administrators may tend to regard administration as of more consequence than the service they administer. Administrative convenience may sever the various branches of medical practice and so aggravate the isolation of general practice which specialization in medicine has already begun.

10. State activity in connexion with medical practice has also affected the attitude of the patient towards the doctor. With the increased literacy of the population medicine has naturally lost something of its mystery, but

some doctors feel that they are losing professional status in the eyes of their patients. The patient tends to come not for advice but for a tangible return for his contribution—namely, the "bottle of medicine." It has been said that Mr. Lloyd George introduced the "bottle of medicine habit" in 1911. A love of medicine is perhaps ingrained in human nature, whether it be the charms of primitive medicine, the pills and potions of the early modern period, or the bottle of medicine of the twentieth century, but the danger of the present attitude is that the patient is coming to regard the general practitioner not as his adviser but as a person to give prescriptions and certificates and to refer to a specialist any illness of more than a minor nature. It may be replied, of course, that if this happens the doctor is himself partly to blame because he fails to exercise proper discipline in his practice.

11. Besides the central government, local government authorities, since the Public Health Act of 1875, have concerned themselves with the prevention and treatment of disease. They have certain statutory duties to fulfil—for instance, the notification of disease and the control of infectious diseases—but they have also provided services which general practitioners feel encroach upon their sphere and attract patients away from the surgery to the clinic. It is true that some of these services, such as the school and maternity and child-welfare clinics, were originally instituted by the local authority because general practitioners displayed no desire to undertake the preventive work required, but the important fact is that there has been antagonism and division of responsibility where there should have been co-operation and integration.

12. It is the cumulative repercussion on general practice of all these events and developments which has made the general practitioner of to-day apprehensive of his fate. This uncertainty has been illustrated in numerous aspects of the Committee's survey, and it points to the need for a more precise understanding by the profession itself, by official quarters, and by the public, of the function of the general practitioner, the range of his practice, and the difference between medicine as practised in the home and as practised in hospitals. The terms of service of general practitioners in the National Health Service are, of course, under constant review by the General Medical Services Committee, which, in continuing the work of its predecessor, the Insurance Acts Committee, has already made a very substantial contribution to the improvement of general practice in the National Health Service. The recent establishment of the College of General Practitioners has also been noted with interest.

13. The general practitioner to-day holds a more important place in medicine than ever before, and the nation is receiving from him a more valuable service than ever before. With the modern aids to diagnosis and methods of treatment which the advance of medical knowledge has placed in his hands, sick people are restored to health and activity in a shorter period than formerly, and they can be treated, for a very wide range of conditions, in their own homes without the expense and disturbance of entering hospital. Moreover, the general practitioner is the only person whose view ranges over the whole complex field of modern practice. He selects, on behalf of his patients from his knowledge of the scope and potentialities of all the special branches of medicine, those services and those specialist practitioners most suitable for the individual needs of the patient.

14. Thus the humble apothecary, obscure and unrecognized, has evolved, by the sterling worth of his character and the work and the progress of knowledge, into a highly trained and indispensable practitioner upon whose care for his patient in the home rests the whole edifice of modern medical practice.

II. THE GENERAL PRACTITIONER AS AN INDIVIDUAL

15. The foundation of general practice is the mutual trust and confidence between the individual general practitioner and the individual patient. Each of them makes a contribution to this relationship, the precise nature of which will vary with the characters and temperaments of each. There are, however, certain personal qualities, many of them inborn, which most good general practitioners possess or acquire and which lead a man or woman to choose medicine, and more especially general practice, as a career. Conversely, general practice makes on the practitioner certain demands, both physical and mental, which call for the highest standards of personal character.

16. General practice requires in the practitioner, to a higher degree than many other fields of human activity, a sense of vocation. This call to a medical career may be felt at an early age, or the possession of the special aptitude and personal qualities required for general practice may be discovered only after a period of actual practice. The sense of fitness is most felt by the doctor, perhaps, in the patient's attitude and approach to him—in the confidence and trust with which the patient pours out his troubles to the doctor, and the consolation or courage which is seen to derive from the consultation. The doctor feels his power to cope with his patients' problems and to allay their anxieties, even when these are unexpressed.

17. The Cohen Report contains in paragraph 43 a fairly comprehensive survey of the personal qualities of the ideal general practitioner. It may usefully be recalled here: "An enumeration of the desirable personal qualities of the ideal general practitioner reveals that only a superman could possess them all. He should have an exhaustible tact, wisdom, patience, discretion, and that 'imperturbability' which Osler placed in the forefront of the qualities of a physician or surgeon. He needs to be gentle, yet firm in speech and action, and his manner must inspire confidence and trust. He should have a kindly, humane approach to his patients and, however pressed he may be for time, each patient should be made to feel that his illness is of real concern to the doctor. The general practitioner needs a deeply imaginative sympathy which enables him to understand his patients' fears, anxieties, pain and discomfort. . . . The general practitioner is all things to all men; he is guide, philosopher, and friend to patients of all classes, and shows himself equally at ease with the duke and the dustman, the bishop and the boilermaker. Such 'bedside' qualities must be supplemented by sound medical knowledge and efficient practical work, and the practitioner's art must be applied through scientific methods—observation, discrimination, selection, diagnosis and decision. His general conduct in professional and private life should be guided by high moral principles, and in his practice he should adhere steadfastly to the spirit of the Hippocratic Oath."

18. The Committee would lay stress on the qualities of versatility and adaptability in dealing with a wide variety

of situations, resilience in accepting with equanimity occasional failure and rebuffs, and a physical constitution to withstand the rigours of climate.

19. The general practitioner, in common with other members of the profession, must be trustworthy and possess integrity and a sense of honour and duty. He must be a "gentleman" in that broad sense of the term which, though undefinable, is nevertheless recognized by everyone. Insistence on the sterling and irreproachable character of entrants to general practice is important, for any weakening of the moral tone of the profession may damage the unique relationship between doctor and patient. Perhaps extra vigilance is needed at the present time, when, as is commonly acknowledged, the values placed by society in general upon the practice of religion, upon honour, duty, and moral rectitude are less strict than two or three generations ago.

20. The general practitioner is the patient's chosen personal medical adviser, and this position is the key to his professional function and standing. He is concerned for his patient in sickness and in health, and his interest continues even if it should become necessary for a time for a consultant to assume responsibility for the treatment of a particular condition. When his patient enters hospital the general practitioner does not feel that he is therefore divested of his relationship with the patient. He expects to know what measures are being taken, and perhaps to see his patient in the ward, so that he may subsequently resume his active responsibility with all the requisite knowledge. His position may be compared, in a general way, with the continuous responsibility of a ship's captain, who even when not in direct control on the bridge is still concerned for the safety of the ship and all those on board.

21. As personal medical adviser the general practitioner provides or obtains for his patient the best available diagnosis and treatment. He himself will give a wide range of service according to his skill and the facilities at his disposal. When he needs specialist help he must know where to find the best for his purpose and be able to appraise critically what is available. It follows that he must know the specialists, preferably personally but at least where they are to be found; he must know what each can do, and whether their work is fundamentally good. General practice is based, in this respect, on a series of personal relationships. On the one hand, there is the doctor's patient, with the continuous intimate relationship which is found in no other branch of the profession, and on the other are the specialists from whose ranks the general practitioner selects the help he needs for any particular purpose. It is this unique position which makes general practice a "special" or distinctive branch of practice. The Cohen Report made the same point, but it has been misunderstood by many readers. General practice is not a specialty in the sense that, say, major surgery is a specialty, but it is a distinctive branch with its own special outlook and problems.

22. It has been suggested that the general practitioner is the "all-rounder" of medical practice. He must possess a high degree of resourcefulness and initiative, for he has to be able to turn his hand to any medical task that needs to be done. He has to be competent to cope with influenza epidemics, accidents, aid raids, and any kind of unexpected situation; he must fill the gap when there is no one else to do the job; and he must take over when the specialist physician or surgeon can do no more for the patient.

23. General practice cannot be standardized. Each practitioner, within the commonly accepted traditions, works out his own methods and organization and his own characteristic relations with his patients. He is intensely individualistic, and the interaction of personality and environment needs full play. For his self-realization he must be allowed to choose the type of practice in which he can give of his best, whether single-handed or in partnership, and whether in town or country, and he must be allowed to choose his own partners or assistants. The breadth and variety of the general practitioner's culture and non-clinical interests are well illustrated by the replies to the Committee's question on hobbies.

24. The all-round character of the work of the general practitioner, the personal relationships which it involves, the demand for a sound understanding of human nature, and the necessity for the frequent exercise of common sense, emphasize the breadth of education needed for general practice. The Committee believes there has been a fall in the standard of general education of entrants to the profession due to premature specialization in scientific subjects. This may in time have an unfortunate effect on general practice, for, of all members of the profession, the general practitioner needs the widest possible general education. The foundations of a broad interest in general subjects must be laid before medical training is begun, and the Committee draws attention to the recommendations made in the Association's report on "The Training of a Doctor." It has heard with satisfaction and interest of certain schemes designed to inform medical students of the nature of general practice, including those where general practitioners have been invited to lecture to students in medical schools and where general practitioners have themselves received medical students as guests in their practices for instructional purposes.

III. THE GENERAL PRACTITIONER AND HIS PATIENT: THE DOCTOR-PATIENT RELATIONSHIP

25. The patient, who chooses his doctor of his own free will, has a right to expect from him the best service of which he is capable. At the same time he himself must bring to the relationship intelligent co-operation. There is no standard by which the doctor-patient relationship can be measured, and thus no absolute comparison can be made to show the effect of the introduction of the N.H.S. There is this difference, however. The fee paid by the private patient includes payment not only for the doctor's medical skill but also for the time spent by the doctor in suiting his practice to the patient's convenience. Under the N.H.S. the patient is required to conform to a certain amount of regulation, and, while he may well expect to receive the same standard of medical treatment as the private patient, he is under an obligation not to abuse the Service by making excessive demands on the doctor's time.

26. There is little doubt that there has been at least some deterioration in the doctor-patient relationship. It is surprising that there have not been greater difficulties when the magnitude of the change which took place in 1948 is taken into account, and also the extra work with which doctors have been faced and the fact that some patients appear not to understand that the N.H.S. is a medical service and not a "giving" service. It became apparent in the course of the Committee's discussions

that there has been less interference with the doctor-patient relationship in scattered country practice than in industrial practice. The smaller numbers of patients and the more numerous channels of contact between doctor and patient in such practice as compared with urban, particularly industrial, practice accounts for this difference. In the country personal knowledge of one another is closer and more detailed, and the traditional relations are more persistent. The population is more static and relations do not suffer, as they do in the towns, where loyalties to and preoccupation with mass interests count for more than personal contacts.

27. The Committee feels that the method of payment of practitioners may have a direct effect on the doctor-patient relationship. There seems little doubt that practitioners, on the whole, are happier in their relationships now that fee-charging and the rendering of accounts are almost entirely a thing of the past. Some practitioners, however, are finding difficulties in their relationships with their patients under the present system because there is no payment for individual items of service. Nevertheless, the Committee firmly holds the view that where the doctor is receiving payment for each individual patient by capitation fee, as at present, the relationship is better than it would be in a salaried service. Where the relationship was formerly sound, the institution of a capitation fee has made it sounder. At the same time, the possibility cannot be denied that where the doctor-patient relationship was defective the institution of a capitation fee might well tend to render the link weaker. The Committee believes that the institution of payment by salary would virtually deprive the patient of free choice of doctor.

28. The majority of practitioners find that their relations with the majority of their patients are friendly. By most the general practitioner is regarded as a professional man and friend. On the evidence from the field and postal surveys the Committee is satisfied that there has been exaggeration in the reports that doctors are commonly regarded as servants and officials. There is undoubtedly an increased tendency for the general practitioner to be regarded as a "supplier of medicaments" rather than a medical adviser. Some say a few patients so regard them, and others say many do. As a doctor in the postal inquiry wrote: "At first thought the answer would be 'many,' but the recurrence of the 'few' makes them appear 'many.'"

29. In this quotation seems to lie the general answer to a series of questions. There is a core of patients whose behaviour does not permit the proper functioning of the doctor-patient relationship. Their number may not be large in any one practice, but they are sufficient to cause the doctor irritation and annoyance and to obstruct his work. Taken over the whole country, the minority must be sufficient to give rise to the general impression that the N.H.S. has brought about a deterioration of the doctor-patient relationship.

30. Practitioners were also questioned to see whether any of the excessive demand for services which has been complained of since July, 1948, came from those patients who were formerly the doctor's private patients and are now on his N.H.S. list. Most of them have so transferred. There is a discrepancy here between the results of the field survey and the postal inquiry, though the slight variation of the wording of the question may have had some effect. In the former the number of doctors stating that ex-private patients required a disproportionate increase of services was 26%, while 61% of the

practitioners in the postal inquiry stated that the increased demands from these patients were considerable. In the field survey 16% stated that the increase came from a few patients, and in the postal inquiry 21% stated that the increased demand was slight. The Committee itself was inclined to disagree with statements that have been made to the effect that middle-class ex-private patients have been making excessive demands on the Service.

31. In both the field survey and the postal inquiry there was a heavy majority of practitioners (96% and 82% respectively) who were in favour of the conception of the "family doctor"—one doctor for the whole family. The Committee agrees with this majority, making allowance for the occasional cases where the female members of a family like to have a woman doctor, while a male doctor attends the men. The majority of women doctors customarily attend whole families in the same way as do the men.

32. While it would appear from the figures collected that the doctor-patient relationship is felt, on the whole, to be satisfactory, the Committee thinks it desirable to set down one or two aspects of this relationship which are apt to be overlooked. It is not enough that there should be absence of friction or that the doctor shall have satisfied the demands of his patients. The ideal doctor-patient relationship is dynamic. It needs time for discussion and confidence, and the doctor must be prepared to take infinite trouble to provide for his patient the best available diagnosis and treatment.

33. It is not wrong to expect financial reward for taking trouble, and the financial incentive is an effective means of encouraging good work. The attitude towards financial reward, however, is changing under the N.H.S. Formerly, in private practice, the doctor took an enormous amount of trouble on behalf of his patient, and he did not shirk the difficult or the old or the chronic patient, at whose bedside he would sit to give medical reassurance and consolation. He hoped he would be repaid financially, but he regarded taking this trouble for his patients as part of his practice. To-day in the N.H.S. there is some tendency to secure large lists of the more trouble-free and healthy members of the community, and doctors are left with no time, and perhaps with less inclination, to take trouble for their patients over and above the bare minimum required by their terms of service.

34. There are two ways, complementary to each other, of overcoming any such tendency, which is bad for medicine and bad for the individual doctor, because it weakens the doctor-patient relationship. First, a larger capitation fee and more competition in the form of free choice of doctor may be effective in securing for the practitioner his appropriate financial reward, and in encouraging him to take trouble on behalf of his patient. The investigator in the field survey estimated that, on a high standard, at least one in four of those visited, not content with discharging to the full their obligations under the N.H.S., appeared to be willing to go to great lengths in the interests of their patients.

35. The second way lies in the continuance of a certain amount of private practice. Many patients prefer the more elastic relationship of private practice, and they prefer, for their own reasons, to be independent of regulations which may, in their minds, prevent the relationship with their practitioner from attaining its fullest scope. They wish to be able to approach their practitioner without feeling that they are imposing upon

him in order to discuss their problems with him, even though these do not come apparently within the orbit of what is normally understood to be medical treatment.

Private and State Practice

36. Whether a particular doctor combines private with N.H.S. practice is a matter for individual decision, for it involves temperament and opportunity. A certain discrepancy is observed in the results of the field survey and the postal inquiry, though the wording of the questions differed slightly. The field survey shows that 35% of the practitioners like private patients and feel that there should always be some in the practice, while in the postal inquiry 66% like to include both private and N.H.S. patients in their practice, and a further 15% would like to have private patients only. Those who do not want private patients formed 43% of the field survey and 19% of the postal inquiry. On the lowest of these figures, slightly more than one-third of general practitioners feel that private practice has a definite value.

37. There is room for both N.H.S. and private practice. There will always be some practitioners who can work best outside a public service, as there will always be some who prefer to combine the two. Perhaps most of the 66% who replied to the postal inquiry in the latter sense would echo the practitioner who added: "Because it doesn't make any difference to me whether it is a National Health or a panel patient, or a private patient. I am always ready to attend to any ill person no matter who it is or whether he can pay or not. I think this is our real duty."

38. A further question asked practitioners whether they thought that the fact that private patients were unable to obtain drugs under the N.H.S. had caused many who would have preferred to remain private patients to claim treatment under the Service. In the field survey 50% thought there had been no such effect, and in the postal inquiry those who replied "No effect" and "A few patients only" represented 50% of the group. In considering this figure note should be taken of the reply of a doctor in the postal inquiry: "Many patients say that but for the drug bill they would be private patients, but, if put to the test, I doubt that many of them would return to private status; in my opinion it is just a convenient excuse for registering."

Relations with other Branches of Practice

39. In many parts of this Report attention is called to the effect on general practice of the inadequate liaison between the general practitioner and other branches of practice. The absence of personal contact adversely affects not only the quality of the service the general practitioner can provide for his patient, but it also touches the fundamental doctor-patient relationship itself. The patient notices when consultants or other hospital staff ignore or depreciate his own doctor, and this cannot but diminish his trust in his doctor's competence and his standing in the profession.

40. All medical practitioners, in whatever branch of practice, have the interests of the patient at heart, but some of them fail to realize that they are not serving those interests if they permit any action or omission on their part to threaten the relations between the patient and his general practitioner. This relationship should indeed be one of the strongest unifying influences in medical practice. The Committee is bound to point out that the general practitioner has a responsibility to do his share and should respond to such co-operation as is offered to him.

IV. THE GENERAL PRACTITIONER AND HIS PATIENT: THE RANGE OF SERVICE

41. The Cohen Report discussed in Chapter 3 the nature and scope of general practice, and it analysed, so far as was possible on paper, the functions and responsibilities undertaken by the general practitioner in modern medical practice. The General Practice Review Committee, accepting the description as a fair general statement, has endeavoured in its inquiry to ascertain the attitude of individual doctors to the various functions and responsibilities mentioned, and whether they felt that the introduction of the N.H.S. had had any effect on their ability or opportunity to provide their patients with the range and standard of service they would like to offer.

Continuity of Care and General Responsibility

42. The Committee views with favour any arrangement which permits and encourages the general practitioner to maintain a close contact with his patient during his stay in hospital. This is brought out to most advantage where the general practitioner is on the staff of a local hospital. Whereas an operation or the general direction of the patient's treatment is in the hands of a visiting consultant, the general practitioner is in the hospital each day and is, literally, seeing the patient through the illness. He not only bears but is also enabled to carry into effect the continuous responsibility of steering the patient through the period of trouble, even though he must enlist the aid of a consultant to act as pilot where expert knowledge is essential.

43. The tendency nowadays is to depart from this ideal. There is evidence that, even if the practitioner has time to call to see his patients in hospital, he may not be welcome and may be regarded as something of a nuisance. So often admission to hospital constitutes a break in the contact between the doctor and his patient, only to be restored at some uncertain date in the future, when the patient is discharged. Medicine must be practised as a unity, and this is an example of what happens when it is not.

44. It is just as absurd, or even more absurd, that a patient should be completely isolated from his own family doctor while in hospital as it would be were it decided that a consultant should never visit a patient in his own home.

45. It should be an accepted principle in all hospitals that reasonable opportunities are provided for general practitioners to visit their patients from time to time and to discuss their progress with members of the hospital staff. Such liaison between the general practitioner and the hospital should be regarded as a necessary part of the practitioner's postgraduate education.

46. In a single-handed practice continuous responsibility through a succession of illnesses is obviously exercised by the doctor chosen by the patient, even though an assistant may attend on occasion, but when a single-handed practice is replaced by a partnership a new situation, with both advantages and disadvantages, arises. Partnership arrangements are likely to be such that on some occasions a patient will be seen by a partner other than his own doctor, and the larger the partnership the greater the care necessary to preserve the principles of personal responsibility and continuity of care.

47. Arrangements for a division of work in a multiple practice should be such as will encourage the principle of responsibility for continuity of care. Both the field survey and the postal inquiry indicate that the majority of general practitioners endeavour to secure for their patients the greatest possible degree of continuity of care, though there seems to be no uniformity of method. Conditions in the N.H.S., with heavier and longer surgery hours, have made it desirable in some partnerships to "regionalize" visits—that is, one partner will visit on a particular day all the patients of the partnership living in a particular district, both his own and those of his partners. There can be no objection to these arrangements so long as the principle of

responsibility for continuity of care by the patient's own chosen doctor is preserved. There may, indeed, be some advantages in such a division of visits. It enables all the doctors in the partnership to become known to all the patients, and thus minimizes difficulty when a patient's own doctor is not available—and this must sometimes happen in the conditions of modern life. The interchange also provides an opportunity for the discussion of a case between the partners. This is often of much value to the patient.

48. The Committee recommends that the principle of "one illness, one doctor" should be regarded as the ideal. Such modifications of the ideal as do not conflict with personal responsibility should not be discouraged, but there should be no departure from the rule that a patient joins the list of an individual doctor. He is responsible for giving his patient continuous personal care or, on occasions when he cannot be at hand, for ensuring that the best available care is provided.

Health Education and Preventive Medicine

49. The combination of health education with medical advice is an important part of general practice. The majority of practitioners appear to give advice on hygiene and preventive measures when asked, but many lack the time to do more than this, and patients themselves are often uninterested. The general practitioner, with his intimate knowledge of the home and family circumstances of his patients, is in a strong position to advise on individual measures for the prevention of sickness or improvement of health. Probably much depends upon the skill of the practitioner in making his teaching of personal and individual interest to the particular patient. It is often found that, if the patient is told exactly what preventive measures he should take and why, he is more likely to co-operate than if he is given instruction in the form of general rules of health.

50. The general practitioner's aid can be invaluable in keeping the medical officer of health informed of community sickness trends, particularly, but not exclusively, in connexion with the notifiable infectious diseases and food-poisoning. The general practitioner should recognize that the public health department has an important part to play in health education.

51. There is another aspect of preventive medicine in which the Committee feels that the general practitioner should take an important part. This is in the field of occupational health and industrial medicine. The Committee is of the opinion that managements would achieve maximum results in the field of preventive medicine were they to employ, so far as is practicable, general practitioners, part-time, for advice and work in this field. The Committee notes the current tendency to regard industrial medicine as being unconnected with the curative and preventive medicine practised by the general practitioner. Believing that the general practitioner can be of the greatest assistance in this field, it urges upon those concerned the need to reverse this tendency. Should the general practitioner be excluded from participating in occupational health schemes a valuable opportunity will be lost.

52. General practitioners undertaking this work will realize that, although they are bringing to the task the knowledge and the special approach which they have learned in general practice, their relations with employees cannot be the same as those obtaining with their own patients in their practice.

Treatment of the Patient as an Individual

53. The Committee notes with concern the effect of lack of time in the N.H.S. which prevents a doctor from familiarizing himself with the "totality" of his patient, including his past history and his background. Knowledge of the personality and constitution of one's patient is essential to good medicine. Conditions of practice must be such as will give the practitioner the time he needs for each patient.

54. Part of the explanation of the lack of personal knowledge, however, seems to lie in the attitude of the patients themselves, who frequently misunderstand the functions of

the general practitioner and overemphasize the place of the hospital in medical treatment. Practitioners reported to the Committee that many patients do not expect their doctors to make any thorough examination, but simply to prescribe or refer them to the hospital. Both patient and doctor lose by this attitude.

55. Many patients come not for advice but to get something. They enter the consulting-room with a demand for some ephemeral proprietary preparation on their lips. Urban practitioners are experiencing these difficulties much more than are their country colleagues.

Diagnosis

56. The standard of history-taking and clinical examination is gratifyingly high according to the field survey, and the Committee was informed that among the youngest age group 70% of those visited were placed in the highest class, as against 54% in the middle-age group and 60% in the oldest group. It may be that, while the young man tends to place more emphasis on physical signs, the older man is in a position to rely more often on his clinical instinct, his experience, and his knowledge of his patient. The observer made allowance for this in his assessment, however.

57. Against this good result of objective observation must be set the subjective feeling expressed by a large number of doctors in the postal inquiry that they are unable, through lack of time, to examine patients as thoroughly as they would wish.

Minor Surgery

58. Minor surgery appears to be one of the branches of general practice which have suffered by the conditions of practice in the N.H.S. Both the field survey and the postal inquiry show that there are many doctors who used to do minor surgery and want to do it now, but who are unable to undertake it because the pressure of work in the N.H.S. is too great to allow time for it, because they have lost the hospital facilities which they formerly used for their minor surgery, or because patients think they ought to be sent to hospital for any surgical procedure, however slight. There are, of course, general practitioners who dislike minor surgery or who feel that they do not possess sufficient skill and therefore prefer to send such cases to hospital. There are also others who seem to welcome the excuse of extra work in the N.H.S. for sending all minor surgery to the hospital and thus shedding some of their responsibility. A reason given by some is that no special remuneration is received for minor surgical procedures. The Committee deprecates this attitude. It is of the opinion that general practitioners should undertake for N.H.S. patients those minor operations which, before the Service was introduced, they performed as part of clinical treatment in the ordinary course of general practice.

59. The habitual transfer of minor surgery to the hospital is neither necessary nor desirable. The training of the doctor has included instruction in this work, and, in the view of the Committee, it is a part of general practice. The constant sending of cases to hospital results not only in the loss of practical experience but also in a belief on the part of the hospital staff, especially the junior staff, that general practitioners are not competent to perform minor operations. Moreover, in present hospital practice, especially in towns where there are large hospitals in the immediate neighbourhood, the general practitioner frequently loses contact with his patient because the hospital retains the patient for any aftercare required instead of returning him to his own doctor. Sometimes the reason is simply that some young house officers, eager to see their cases through, forget the general practitioner and their duty to return the patient to him. Whatever the reason, the general practitioner is deprived of his patient and of clinical material.

60. Unless a practitioner really dislikes minor surgery he should be expected and encouraged to undertake it, and he should endeavour to organize his practice in such a way

as to enable him to do so. It is indeed in the interests of his own prestige that he should be prepared to perform this service for his patients. Admittedly it may be difficult in a single-handed practice, but it should be possible to arrange for minor surgery to be undertaken in partnership practices.

61. The Committee is aware of the reasons underlying the efforts of certain organizations to impress upon practitioners the legal risk incurred in undertaking surgical operations of any kind. It considers, however, that it is undesirable for any outside body to attempt to restrict a practitioner in performing for his patient any service he feels competent to undertake. The decision is a personal one, which each practitioner must make for himself in each particular case. He will consider whether the risk is one which he, as a general practitioner, would be expected to accept, and whether, in the interests of the patient, he should perform the operation himself or send the patient to hospital.

62. The remedy for the threatened divorce of minor surgery from general practice lies in the association of the general practitioner with hospitals and consultants. General practitioners should be allowed the use of facilities in local hospitals where they may perform minor surgical procedures and give the necessary immediate aftercare, as was formerly the case in cottage hospitals. Their work should be under supervision of a member of the hospital staff. It seems to the Committee, on the face of it, that the casualty department of a hospital is the ideal place for a general practitioner to do minor surgery. It is realized, however, that there are administrative difficulties. These should not be insuperable, and are worth overcoming in the interests of preserving minor surgery in general practice. Further, much of the present uncertainty about which minor operations ought to be sent to hospital for specialist attention and which the general practitioner can quite well perform himself could be removed by local discussion and agreement between hospital staffs and general practitioners.

Certification

63. Administrative duties, on the whole, seem to cause little difficulty to most practitioners, though certification sometimes presents a problem. The Committee believes that some practitioners do not regard certification with due seriousness, while others find more difficulties than they need. If these doctors would study the current regulations they would find them not so irksome after all. Only a minimum of certification should be necessary, and the practitioner should bear in mind that his primary duty is his clinical work.

64. Not all the blame, however, should be laid on the doctor. He is, to some extent, at the mercy of outside influences. The public generally has little regard for professional ethics and cannot, or will not, understand the doctor's hesitation. Patients are quick to take advantage of any weakening on his part. Further, the practitioner is subjected to pressure by the Ministry of National Insurance, which, regardless of practicability, demands certificates on a particular day of the week. Many practitioners do not seem to realize what the regulations are. The second certificate of incapacity for work must be given within seven days of the first. Thereafter the weekly certificate may be given on any day between Sunday and Sunday of each week. If there is hardship caused by uneven payments of sickness benefit the problem for solution is administrative, not medical. The Committee is of the opinion that more account should be taken of the difficult position in which the pressure of events has placed the general practitioner. Doctors could help themselves if all those in an area could meet together from time to time in order to determine and agree upon a "common certification front."

Non-medical Advice

65. Little comment need be made on the last of the functions of the general practitioner listed in the Cohen Report. The great majority of general practitioners are prepared to

give, when asked, advice which, though not strictly of a medical character, yet has a bearing on the general well-being of the patient and may be regarded as incidental to general practice.

Special Interests

66. Both the field survey and the postal inquiry show that about one-half of the doctors concerned take a special interest in a particular branch of general practice. Sometimes, indeed, the interest tends to become a specialty. In the N.H.S., however, about one-third of these practitioners are unable to develop their interests, mainly through lack of time or lack of access to hospital beds and facilities.

67. The Committee is of the opinion that general practitioners should be encouraged to develop special interests within the scope of general practice. This is most easily arranged in a group practice, and it is one of the arguments used in favour of health centres. It also raises again the need for the association of general practitioners with hospital work. One way of providing facilities would be by clinical assistantships which would interfere as little as possible with the management of the practice.

68. It should be emphasized that the development of the special interest should not necessarily be a step towards transferring to a specialty, but it should add variety to general practice and enable the practitioner to provide a fuller service for his patients. In some areas the local doctors find it an advantage to have among their number one who has made a special study of a particular aspect of practice and who can help with difficult cases.

Midwifery

69. The Committee has devoted much time to the consideration of the place of midwifery in general practice and the repercussion on general practice of outside events in the field of obstetrics. It is firmly of the opinion that midwifery is an integral part of general practice and that every possible encouragement should be given to general practitioners to undertake it. The coming of a new baby is an important event in the family, and the family doctor should be closely concerned with it. Many long-established doctors have found midwifery to be the most satisfying part of their experience. They believe that, generally speaking, a general practitioner who does good midwifery makes a better all-round doctor than one who does none. During recent years there has been a tendency to divorce midwifery from general practice. Much of this is due simply to the fact that the interest and competence of the family doctor have been ignored by those responsible for obstetric services.

70. There has been a gradual diminution in the amount of domiciliary midwifery carried out by general practitioners. The Committee considered it important to discuss the reasons for this diminution and to suggest methods of encouraging domiciliary midwifery.

71. One reason for the diminution was that, even before the war, expectant mothers were becoming more "institutionally minded." In the post-war period this outlook, coupled with housing difficulties and with the fact that institutional confinements are a good deal cheaper for the patients than home confinements, made institutional confinements more popular. Then there is the tendency among mothers to hold the hospital in higher esteem than the general practitioner, and to feel that in the hospital everything will be at hand in the event of an emergency.

72. The general practitioner thus loses contact with his patient at an important moment of her life, and responsibility passes for the time to a consultant. Present arrangements for institutional midwifery, it has been said, tend to place normal cases in an environment suited to abnormal cases. An event which should be a natural physiological process supervised by the family doctor takes on the aspect of a major illness requiring the care of a special department. Responsibility is divided and continuity of care is

broken, for, while antenatal care has been given by the general practitioner or clinic medical officer, a member of the hospital staff is responsible at the confinement.

73. It is apparent to the Committee that a high proportion of general practitioners like midwifery and wish to do as much as possible. A few comments are quoted in the report of the postal inquiry to illustrate how some practitioners feel that midwifery is, as one puts it, "the keystone of a successful general practice." There has been a great deal of argument in recent years for and against general-practitioner domiciliary midwifery, but the Committee feels that, in the light of opinions expressed to it, it must put forward a further plea on behalf of the general practitioner.

74. It seems likely that steps will be taken to adjust monetary considerations as between institutional and domiciliary confinements. It is also likely, however, that the housing problem will be with us for a considerable number of years. The Committee is of the opinion that if, owing to unsuitable home conditions, the confinement must take place in an institution and the woman would like to be attended by her own doctor, there should be a number of beds available for this purpose.

75. These beds, forming maternity units for cases which clinically could be domiciliary cases, need not be in general hospitals and need not carry the full established staff of a specialist maternity unit. The midwife who would have attended in the home would attend the case in such a unit. Consultant advice should be readily available if required by the general practitioner. The Committee believes that, by this provision, the expectant mother would receive adequate care during her confinement. Such provision may have the additional advantage of reducing the present high cost of institutional confinements.

76. Such domiciliary midwifery as remains tends to be undertaken by midwives, the general practitioner being called in only in an emergency. The result is that the general practitioner, excluded from institutional obstetrics and restricted in domiciliary obstetrics to emergencies, is placed at a disadvantage, for his loss of contact with normal midwifery reduces his ability to deal with the abnormal. This explains the reluctance of many general practitioners, both young and old, to undertake midwifery. The Committee believes that many practitioners are content to leave domiciliary confinement to the midwives, but part of the responsibility for this situation must be attributed to the attitude of some midwives who attempt to exceed their proper function and are unwilling to co-operate with general practitioners. This is not in the interests of the patients, and deeper thought should be given to the relations between doctors and midwives.

77. Particularly since the coming into force of the National Health Service Act, the more general booking of general practitioners by expectant women has tended to alter this. This has caused grave concern to midwives, who feel that their status is being attacked and that they will in future become "maternity nurses" rather than midwives, thus tending to create a feeling of resentment and competition rather than co-operation between midwives and general practitioners.

78. The Committee wishes to place on record its high appreciation of the splendid work midwives have done in the past, and would like to assure them that general practitioners are just as keen as midwives to encourage an efficient and satisfactory domiciliary midwifery service. It feels, however, that it is important for the good of both professions and for the patients that any gulf between general practitioners and midwives, imaginary or real, should be bridged.

79. The Committee believes that, if general practitioners and midwives could work together as a team, each with his or her own function and responsibility, much of the present difficulty in domiciliary midwifery would disappear. The trouble is that, with the depleted number of domiciliary confinements, some midwives are reluctant to take on the

attendance at the confinement. There need be no such antagonism if the relative functions are understood and observed. The midwife is highly trained in a restricted field. The doctor is trained in the wider field of medicine, surgery, and obstetrics, and, as the family doctor, he is intimately concerned with all that happens to his patient. To him the pregnancy and the confinement are events in the life of his patient with environmental, psychological, and medical implications.

80. This indicates the character of the team-work, and it also suggests a line of procedure. At an early date in the pregnancy the patient, her family doctor, and the midwife should meet together in the doctor's surgery and decide whether the doctor should attend at the confinement in any event or only if the midwife finds his attendance necessary. In a normal case the decision must depend largely on the wishes of the patient. Some women like to have their doctor present; others are satisfied if they feel assured that he will come if he is needed. At this early meeting the doctor will also make arrangements for antenatal care. He should examine his patient as often as he considers necessary. According to generally accepted standards he will see her at least once every month until the 36th week and thereafter more frequently. The more care he gives during the antenatal period the fewer will be his abnormal confinements. The midwife, of course, will also make her routine visits. The doctor may or may not attend at the actual confinement, but if the delivery is left to the midwife he should attend within a stated period to satisfy himself regarding the patient's condition. Finally, he will make at least one post-natal examination.

81. If young practitioners were made to realize that midwifery comprises all this care, it is likely that they would feel more encouraged to undertake it. Midwives also, when they appreciate this view of midwifery, are more likely to be willing to co-operate with the doctor.

82. It should be appreciated by the general practitioner, the midwife, and the public that where doctor and midwife are working together as a team this in no way relegates the midwife to an inferior status; she is a midwife and is working as such. The Committee feels strongly that this situation is not fully appreciated by either doctors or midwives and that it has an important bearing on the present confused ideas about the correct professional relationship between doctor and midwife.

83. The Committee feels that clarification of the situation is necessary, and that responsible professional and administrative bodies at all levels should take steps to clear up the misapprehensions which exist. For example, the use of the term "maternity nurse" should be discontinued when a midwife is working with a doctor.

84. A further point in the problem of general-practitioner midwifery is the tendency, among administrators, consultants, midwives, and others, to underestimate the competence of general practitioners to undertake midwifery. This is seen in their exclusion from institutional midwifery and, in England and Wales, in the requirement of approved postgraduate experience for admission to local obstetric lists. The Committee will not enter into the long-drawn-out argument of whether admission to undertake midwifery implies the same degree of competence to undertake midwifery as to treat patients for any other condition, but it takes its stand with those who would allow any registered medical practitioner to provide a midwifery service for his patients if he wished and who would encourage him to increase his experience. In saying this it emphasizes two points. The first is the view already expressed that midwifery consists of much more than the conduct of a confinement. The second is that present planning is for the future, and in the future newly qualified practitioners who are interested in obstetrics will have an opportunity of improving their knowledge and experience during the post-qualification year of resident appointments. It is to be hoped also that there will in the future be an increasing measure of co-operation and mutual understanding among

the different branches of the profession. It is against this background that the Committee recommends that any general practitioner who wishes to undertake midwifery should not be precluded from doing so by administrative restrictions. The present obstetric lists maintained on a basis of varying criteria by local obstetric committees in England and Wales should be replaced by the Scottish procedure—that is, that every registered medical practitioner should be eligible to have his name included, if he so desires, in a list of practitioners undertaking to provide midwifery services, and should receive the full fee.

85. Finally, the relations between the general practitioner and the public health service in connexion with midwifery are at present somewhat confused and unsatisfactory. The Committee has been informed of attempts to persuade women to attend local authority clinics rather than their doctors for antenatal examinations. If the midwifery service develops on the lines suggested in the foregoing paragraphs there will be no need for antenatal examinations to be made by any doctor other than the one who is to be called in in the event of emergency at the confinement, thus preserving continuity of care.

86. The Committee is aware of the history of local authority clinics and the reasons for their existence, but it believes that the time has now come for some reorientation of the local authority maternity services in conformity with the general practitioner's outlook. Possibly antenatal clinics might be staffed by general practitioners provided that, normally, the antenatal examinations would be undertaken by the doctor who was to be responsible for the confinement. In any case, the question whether the patient will attend at the clinic or the doctor's surgery during the antenatal period is best decided in consultation between the patient and the practitioner. The clinics will still exercise an educational function, for many matters in the field of mothercraft may be better taught by midwives or others in such clinics than by the doctor in his surgery. It is important, however, that co-operation with the general practitioner should be maintained.

87. That there are difficulties is hardly surprising, for, as has been said elsewhere, to have three separate administrative bodies dealing at once with one event in a patient's life is to invite confusion, trouble, and, consequently, misunderstanding and bewilderment on the part of those actually attending the patient.

The Care of Tuberculosis

88. In some areas, as a result of the lack of institutional accommodation, the domiciliary care of patients suffering from tuberculosis falls increasingly heavily on the general practitioner. About half of the general practitioners in both the field survey and the postal inquiry are satisfied with the arrangements for the domiciliary care of tuberculosis. The main complaint of the remainder was the insufficient visiting by the chest physician and health visitor.

89. The domiciliary care of tuberculosis has been affected by the transfer of responsibility for treatment from the local health authority to the regional hospital board. The former tuberculosis officer, whose outlook was mainly preventive and one of whose duties was the visiting of patients in their homes, has been replaced by the chest physician, whose outlook is mainly clinical and who is more interested in institutional treatment. Moreover, the tuberculosis officer was concerned wholly with the care of tuberculosis, while the chest physician's interest lies in all diseases of the chest, of which tuberculosis is only one. The chest physician, who usually sees the patient at a clinic, knows little of the home environment, and domiciliary care is left to the general practitioner, who has little or no personal contact with the chest physician.

90. There should be more co-ordination between provision for the diagnosis and the treatment of tuberculosis and between out-patient and domiciliary treatment. This implies more co-operation between the public health officer,

the chest physician, and the general practitioner. In both diagnosis and treatment the chest physician should be available to the general practitioner for consultation in the same way as other consultants, and when a patient is discharged from hospital the general practitioner should be notified. The district nurse should work under the direction of the general practitioner, with whom she should keep in constant contact.

91. The Committee believes that co-ordination on these lines, together with a fuller service of home help, would place the domiciliary care of tuberculosis on a better basis than exists at the present time, but there is also urgent need of more beds in hospitals and sanatoria. All the domiciliary care that can be given by general practitioners cannot take the place of institutional treatment for those who need it, or prevent the spread of infection to other members of the household when isolation or removal from unsuitable housing conditions is necessary. Apart from the long waits for beds in sanatoria, there is difficulty in securing the admission to hospital of cases of acute tuberculosis. The Committee recommends that provision should be made in each area—for example, the area of each hospital management committee—where practicable, for a certain number of beds reserved for acute tuberculosis.

Care of the Chronic Sick

92. One of the social problems of the day which have an important repercussion on general practice is the need for the provision of care and treatment for the elderly and infirm. The Association published a report on this subject in 1947, mainly in connexion with the planning of hospital services. It quoted one of the members of the Committee who prepared the Report: "What is needed more than anything material is an awakening of the whole community to the existence in their midst of a state of affairs often tragic in its melancholy and suffering." No one is more aware of this suffering and also of the hopelessly inadequate means of relieving it than the general practitioner and the district nurse. They see the heart-breaking plight of the aged sick living without domestic help in unsuitable accommodation and the reluctance or inability of younger members of some families to look after them. Although very often the general practitioner can do little more than ease pain and bring consolation, the burden of frequent visits imposes a serious strain on his practice, and there is no one to whom he can turn for help.

93. More institutional care on the lines of the Association's earlier report is certainly required, and there should be some means of ensuring that those most in need are admitted. An old person who is acutely ill should be treated in a general hospital in the same way as a younger person, the same principles for urgent admission being applied. Old age or infirmity should not, of themselves, prejudice admission to hospital.

94. In many areas there are long lists of old or chronically ill people waiting for admission to institutions. As a means of reducing these lists some doctors suggest the re-establishment of the relieving officer, but the Committee is not in favour of this. It does suggest, however, that an appropriate medical officer should visit and examine every patient proposed for the waiting-list for institutional care, and assess the degree of priority or urgency in consultation with the general practitioner.

95. The Committee believes that the most pressing need in this field is for Eventide Homes rather than for hospitals for the aged and infirm. The very care which the old people receive in Eventide Homes prevents them from reaching the stage where hospital admission is essential. Thus the demand for hospital accommodation can be kept within bounds. A number of these Eventide Homes have been opened in various parts of the country and are performing a great service. Those in the homes are under the care of a general practitioner, who can at least feel that what he is called upon to do for his patients is the more worthwhile on account of their more satisfactory environment.

96. The ideal in many cases is that the old person should be kept going under satisfactory conditions in his or her own home. In order to effect this there is a great need for an expansion of the home-help service. The service of a home help should be interpreted broadly, to include more than the usual domestic work. The good home help will bring a degree of companionship to the aged person or chronic invalid, help him to move about the house as much as possible, and stimulate his interest in various ways. Such service may require a certain amount of training, and efforts should be made to enlist the help of more women of the right type.

97. Another advantage of a more adequate home-help service is that it would enable the earlier return home of many elderly hospital patients who at present tend to occupy beds, badly needed for other purposes, simply because they have no one to look after them on discharge. A complete home-help service would include night attendance. The mere presence of a companion during the night is a great comfort to the old person. Perhaps appropriate voluntary organizations could incorporate the provision of such "night-sitters" in their activities.

Advances in Medical Knowledge

98. The range and methods of general practice are necessarily influenced by the general advance of medical knowledge and by progress or change in other fields of medical practice. Both the field survey and the postal inquiry show that the majority of general practitioners are conscious that they now have in their hands more effective means than their predecessors of diagnosing and treating illness, and that they can cure in the home conditions which could formerly be dealt with only in the hospital.

99. The advances in medical science bring to the general practitioner responsibility as well as power, for they increase the need for vigilance and acumen in making an early diagnosis. They should also raise the relative importance and prestige of general practice in the profession. It is important that this broadening field of the general practitioner should be recognized both by practitioners in other branches of medicine and by the public. Patients might become less "hospital-minded" if they were more aware of the capacity of their own doctors to treat, successfully and quickly, most of the common illnesses.

Changes in the Profession

100. The advance of medical knowledge must necessarily bring with it some changes in the organization of the medical profession. The most noticeable result of the widening horizon of medicine and the greater depth of knowledge is the increasing fragmentation of medicine into specialties. The Committee inquired whether this had any adverse effect on general practice. Many general practitioners are not conscious of any handicap from this cause, but the replies of those who are indicate that some attention should be given to this repercussion.

101. The two particular adverse effects which seem to cause most trouble are the breaking up of hospital accommodation into specialist sections and the difficulty of obtaining general consultant opinions. This latter results in the transfer of the patient from one consultant to another, and a tendency for all of them to overlook the general practitioner's interest in his patient. Increasing specialization in so wide a field as medicine now covers must be accepted, but it emphasizes the necessity for closer liaison between the general practitioner and the hospital.

102. There is, further, the danger that the most able young practitioners may be attracted to specialization at the expense of general practice if the range and interest of the latter are sacrificed. General practice must be allowed to retain its appeal for those young doctors who enter upon their career with the idea of working and living among the people. The view that general practice is a branch of medicine with its own special outlook and special problems should receive wider recognition.

Effect of the Operation of the National Health Service

103. In both the field survey and the postal inquiry about a quarter of the general practitioners concerned felt that the operation of the N.H.S. had had no effect on the scope of their practice. In the field survey 45% considered that their scope had been increased, because they could now do more for their patients without taking finance into account. In the postal inquiry the emphasis of the replies was on the increased attendances, which allowed the doctor less time to undertake services which he formerly gave his patients, thereby diminishing his scope.

104. The changes in hospital organization and the public health service brought about by the introduction of the N.H.S. have had their effect on general practice. This effect is felt rather in the matter of relationships and contacts than in the range of service given by the doctor to his patient, and is therefore reserved for discussion in later sections of the report.

Public Education in Health

105. A feature of modern life which affects the service of the general practitioner is the new knowledge, or perhaps half-knowledge, on medical matters acquired by the public. The effect of the instruction given through the radio, television, the Press, various organizations, and other means may depend upon the personality of the individual patient, and may be good or bad, but it is certain that it has introduced a new complication into general practice in recent years. Often this consists in counteracting the effects of the instructions given by others. Illustrations of how the doctor has to cope with his patients' "little learning" are given in the reports of the field survey and the postal inquiry.

106. There is some divergence of opinion on whether public instruction, even of the highest standard, in the working of the human body and the causation of disease is good or bad for the public health and patients' peace of mind.

V. THE GENERAL PRACTITIONER AND HIS PRACTICE

107. The Cohen Report contains the following sentences in para. 53: "At least part of the secret lies in efficient organization, and this will depend to a considerable extent on the practitioner's having a sense and understanding of business method, the keenness of his interest in his work, and his ability to delegate non-medical duties to competent ancillary staff. Efficient organization enables work to be done with greater ease, more speed, and less distraction from the truly medical work of practice."

108. The investigator in the field survey estimated that in 66% of the practices he visited the organization was "adequate," that in 84% the administration was "adequate," that 49% of the consulting-rooms were adequate for the maintenance of a reasonably high clinical standard, and that 91% of the practitioners had a full range of essential equipment. In record-keeping 53% see the cards of most patients in the surgery, while a further 21% take them out on their rounds as well. The introduction of the N.H.S. does not seem to have caused any radical change in methods of organization.

Non-medical Help

109. The employment of clerical help in the practice relieves the practitioner of much of the burden of administrative detail, and gives him greater freedom for clinical work. In both surveys a number of practitioners reported that they were handicapped in the conduct of their practices by the lack of such help. The Committee believes that, in addition, many doctors who say they do not want clerical help would appreciate its value when once they had it. It recommends that practitioners should be aided and encouraged to employ non-medical help. It is not always necessary to engage for this work a trained shorthand-typist; an intelligent general clerk or receptionist can give valuable help at less cost. The Committee believes in some areas

men or women of a suitable type could be found who would be willing to work at hours to suit the practice, though in others the irregular hours and split working day may cause difficulty.

Nursing Help

110. A small proportion of practitioners have a trained nurse helping them in their work. A substantial number stated that a trained nurse would prove of great value to them in the conduct of their practice. The advantage would be that they could delegate to the nurse the many time-consuming procedures such as dressings and injections, thus allowing more time for the study and diagnosis of the patients' complaints.

111. There are doctors who have no desire for any such assistance, preferring to do themselves for their patients everything that is required. The obstacle of expense is plain to all, but the Committee considers that a trained nurse can be of tremendous advantage to a practitioner. At present the cost must restrict the employment of trained nursing help almost entirely to the larger partnerships.

112. Some have solved the problem satisfactorily by employing a trained nurse for clerical and clinical duties.

The Doctor's Wife

113. A general practice pervades the general practitioner's whole household, and the part played by his wife is of the highest importance to the smooth conduct of the practice. The employment of non-medical help would relieve her to some extent of her unceasing responsibility to the practice, faced as she is with a diminution or a disappearance of domestic help. Among the married doctors 84% in the field survey and 97% in the postal inquiry were helped to at least a moderate extent by their wives. The proportion, however, of those wives who took a considerable part in the administration of the practice was much higher in the postal inquiry (39%) than in the field survey (19%). The difference in figures is accounted for by the more precise classification possible in the field survey.

114. In some places it has proved possible to ease the burden, at least partially, and thus to overcome the problems created by the virtual disappearance of domestic help. Where manual exchanges exist temporary transference of telephone calls to the house of a partner or colleague during off-duty times is a fairly simple matter. In the increasing number of areas served by automatic telephone exchanges the problem is more difficult. It is understood that notice is required in order that the machinery may be adjusted for the purpose. Doctors have adopted the device of installing an extension to their own telephone in the house of their partner, and vice versa, so that if one partner is off duty his calls are automatically received in the house of the other. Some members of the Committee reported on the usefulness of including an alternative number in the telephone directory.

Appointments System

115. Few practitioners in the N.H.S. adopt an appointments system for all consultations—the field survey and the postal inquiry showing 2% each. Appointments are arranged, however, by 65% in the field survey and 76% in the postal inquiry for special examinations and private patients.

116. The former includes, for example, examinations for life assurance and instances where the practitioner feels that he would rather devote a special time to a case calling for detailed or exhaustive examination than undertake it in the rush of a busy surgery. There can be no objection to a system of appointments for private patients only, provided that it does not interfere with the arrangements for N.H.S. patients.

117. The Committee is aware that, over and above these special appointments, many practitioners make appointments less precise as to time, either to meet the clinical needs of the case or to suit the convenience of the patients. For

example, they will ask patients to come at a certain surgery when they expect to be less busy, or they will arrange to see patients attending for routine injections in the half-hour before their surgery officially begins.

Health Centres

118. A Committee of the Association has already reported its views on the general subject of health centres. The present review has given an opportunity of ascertaining the opinions of individual general practitioners on whether the health centre is desired as a basis of general practice. The result was as follows:

	Field Survey		Postal Inquiry	
	No.	%	No.	%
In favour	90	48	139	38
Not in favour	88	47	192	53
No definite opinion ..	10	5	31	9
Total	188	100	362	100

The views for and against the establishment of health centres are varied. One of the main arguments in favour of them is that they would give the doctor and his family more privacy in the home and ease the domestic burden. One of the main arguments against them is that they would disturb the doctor-patient relationship.

119. The Committee would draw the attention of those concerned with the development of general-practice organization to the fact that many who favour the setting up of health centres of the kind on which most argument is at present based do so for the personal reasons mentioned above. The survey has not revealed any considerable body of feeling that health centres are essential to the improvement of the standard of general practice. The Committee believes that further experiment is desirable, including the development of health centres, in stages, from communal surgeries. It is preferable for the development to come from within the profession rather than from some health-centre organization superimposed from outside. There are signs that general practitioners are discovering the advantages of mutual association among neighbours, and they may find through this experience the ideal character of co-operative practice. It is of the utmost importance that general practitioners should be consulted on the subject and not be regarded as so much technical labour.

120. At this juncture it is useful to quote the following paragraph from the Report of the Nuffield Provincial Hospitals Trust for 1948-51. The Committee has no desire to condemn or disparage health centres merely because of a lack of enthusiasm at present prevalent, which, as indicated in the following, cannot be based on experience:

"This declining enthusiasm may be due in part to the differing opinions on what health centres should be, and in part to the general practitioners' individual preference for courteous competition; but not a little of the atmosphere or disillusion may be due to the absence of working examples by which the benefits and defects of different forms of health centre can be judged. The financial limitations which have prevented [...] health centres [...] from being put into operation are to be regretted, not because they have prevented the wide realization of an ideal, but because the general ban has to some extent hindered local experimentation with a few prototypes of different kinds of health centre."

121. Many matters affecting ownership and finance would arise in the consideration of any scheme of health centres. Although some doctors would wish them to be owned, financed, and administered by the profession, many others would expect relief from their present heavy overhead expenses and the provision of non-medical staff at no cost to themselves. Health centres of the latter type are likely, in the Committee's view, to open the door to lay administration and so create new problems for the profession.

Although the doctor may expect to receive assistance in obtaining the necessary services, it must be expected that a substantial proportion of the cost would be borne by the N.H.S. or the doctors themselves.

122. While it is undesirable that local authorities should seek to initiate health centres conceived primarily from the point of view of administration, they should be prepared to support and encourage any co-operative schemes proposed by the local doctors. It would be an advantage to the discussion of the subject if more general practitioners were members of health committees of local authorities.

The Committee's Views on Organization

123. It is not possible to lay down any ideal organization for a general practice, for so much depends upon individual temperament. Some practitioners prefer to work alone, others prefer a partnership. Among the practitioners included in this review between 40% and 45% are in single-handed practice and between 55% and 60% are in partnership. There are disadvantages at each extreme. The rural single-handed doctor may be so completely isolated from his colleagues and from hospitals that he is denied the benefit of new knowledge and methods, while in a large partnership the work may be so subdivided that the individuality of the doctor-patient relationship is obscured.

124. One of the advantages of a partnership practice is the opportunity it gives to each partner to develop some special interest, whether by obtaining hospital appointments or by undertaking all the work of the practice in a particular field. Alternatively, many practitioners prefer to maintain their separate practices but to associate themselves with others in order to enable them to develop a special interest in a similar way. The Committee recommends the encouragement of such group practice. The continuous contact of the group provides a valuable stimulus to all its members, and also permits the easy working of a rota arrangement.

125. In visualizing the general practice of the future, the Committee would include, as essential elements wherever practicable, personal contacts with consultants and public health medical officers, and ready access to diagnostic aids.

VI. THE GENERAL PRACTITIONER AND HIS COLLEAGUES

126. The Cohen Report emphasized the importance to general practice of full co-operation between all branches of medicine. The general practitioner must maintain a series of personal relations which enable him to obtain, when necessary, the best possible advice and treatment for his patient. The Committee accordingly devoted part of its inquiry to this subject.

127. The results of the field survey and the postal inquiry agree fairly well in showing that, on the whole, there is an absence of discord among the general practitioners of a district, though active cordiality is not always evident. The introduction of the N.H.S. has not had any very noticeable effect. Where professional relations were good before, they remain so, but there is a certain amount of mutual suspicion.

Off-duty Arrangements

128. Most practitioners make some arrangement with their partners or assistants or with neighbouring doctors to enable them to have occasional week-ends free of duty, or freedom from night calls or emergencies, and to provide a substitute for periods of illness or holiday. The Committee endorses the remarks of the investigator on the value of such co-operative arrangements where they are practicable. As he puts it, many a rota "has turned the sourness of professional rivalry into the sweetness of co-operation." The number of doctors participating in any one rota should not be too large, or the scheme will become unwieldy and impersonal. A small friendly group, where each practitioner is well known to all the others, is to be preferred. Some doctors

like an unwritten mutual understanding better than a fixed rota. Whatever the detail of the method, the Committee recommends the formation of local rota schemes as a method of providing relief for individual practitioners and of increasing the efficiency of practice. It tends to heighten the ethical tone and neighbourliness of local practice. It enables a practitioner to leave his practice for a short time without fearing that he may lose patients to a rival or that his patients will be neglected. The Committee observes, however, that there can be too much emphasis on "time-off" in general practice. A rota system should be small in extent, lest it warrant the description "organized absenteeism."

Opportunities in the National Health Service

129. One of the dangers of an official medical service is that administrative considerations may stifle freedom and opportunity for the practitioners who provide the medical care.

130. There are widespread reports and complaints about the difficulties confronting the young man in his entry into practice. Not so loudly heard are the voices of those practitioners in middle life who wish to change their practices.

Changing of Practices

131. To consider the latter first, the abolition of the buying and selling of practices in the N.H.S. has affected the freedom of all practitioners. It is not the desire of the Committee to enter into the pros and cons of the sale of practices. The Committee feels, however, that in a survey of general practice it must point out how the freedom of general practitioners has been affected.

132. A certain proportion of practitioners settle in practices as young men and remain by their own desire in the same practices until they retire. Probably the majority do not stay in the same practices but make at least one change in the course of their professional career. Changes in family circumstances, increasing years, and a natural wish of children as they attain adulthood, and a natural wish for a change to more salubrious surroundings, albeit with less financial reward, are some of the common reasons for a change.

133. In the past a general practitioner could sell his practice and search, with his money in his pocket, for what he wanted. It was by no means always easy, but so far as opportunities presented he was the master of his choice. Now a further factor has been introduced which may, at any rate in some cases, make a suitable change more difficult to effect. He now has to apply for what is virtually a public appointment, in the competition for which he has been found to be at a disadvantage, possibly for the very reason for which he is seeking a change, that he is over 45 years of age. He cannot sell and he cannot buy, and his future must be decided by others. Many practitioners feel, as one of them put it, that they are in bondage. There are men who have worked hard in their earlier years in unattractive industrial areas and have covered their children's education and now wish to change to less well remunerated and more pleasantly situated practices. There are also men in small country practices who, in order to provide for growing families and/or larger income to provide for growing families, feel compelled to change to large urban practices. Investigations should be encouraged in the means by which such men may be put into touch with one another. There are facilities, through the Medical Practices Advisory Bureau, for the exchange of practices. In theory such exchanges should be easy to arrange, but experience shows that, in spite of the number of applicants, they are surprisingly difficult.

Assistantships and Partnerships

134. To turn to the young man entering practice, the Committee believes that any measure which leads towards the permanent establishment of practitioners in practice is to the good. Every encouragement should be given to men

and women to practise in the area and type of practice to which they are suited, and in which they can practise good medicine. Some young men like to try two or three types of practice before settling down, but the general rule should be that a man is received into a practice with a view to remaining there. There are, of course, a very small number of doctors who do not wish to become principals at any time and prefer to remain permanent assistants.

135. The Committee believes that assistantship for a reasonable period remains the best introduction to the work of general practice, following the usual resident hospital posts.

136. Assistantship with a view to partnership is the commonest mode of entry to general practice, and probably the best. The ideal period would seem to be from six months to two years. Despite all that has been said over the years it still seems necessary to say that no young doctor should take an assistantship without taking proper advice and seeking the elementary safeguards for his future. So much has been heard of the "view" that turned into a mirage that the Committee reminds all those entering practice of the necessity for safeguards and of the services available through the Association and the Medical Practices Advisory Bureau. The *Medical Practitioners' Handbook* and the model forms of agreement prepared by the Bureau should be carefully studied.

137. Abuses by principals of assistantships occur from time to time. "Farming out" a practice with multiple assistants has died out since 1948. Only occasionally is a practice heard of in which the assistant is required to do the bulk of the work. Assistantship with view may come to an end owing to an incompatibility between the doctors concerned which becomes apparent. On the other hand, it may have been a bait to a series of assistants to attract them to the practice for a limited time, only to change when the question of implementing the promise of partnership is raised by the assistant.

138. Some more senior practitioners are understood to be reluctant to take their assistants into partnership, partly because the remuneration of their practice will not allow of it and partly because such action on their part would have an immediate adverse effect upon their superannuation prospects. Fears on these grounds are understood to be ill founded in many instances, because superannuation is based upon net income—that is, after the deduction of the assistant's salary. The Committee believes, however, that in some circumstances reduction of pension may ensue as a result of taking an assistant into partnership.

139. Applications for practices are reported to be exceedingly uneven; often there are fifty or more applicants for a practice, or a doctor may apply for many practices before he is even short-listed. Nevertheless it is known that a few vacancies in certain areas of the country have received no applications at all, and many receive only a small number. Undoubtedly, there would be more offers of partnership to assistants if a portion of practice compensation could be realized by the principal at the time of taking an assistant into partnership. Whereas the Committee believes in the value of assistantships, it firmly supports any measures which will encourage principals to have partners rather than assistants, the post of assistant being preferably regarded as a temporary measure in any one practice.

Postgraduate Study

140. Opportunity for a high standard of clinical work implies freedom to develop special clinical interests and time for postgraduate study in various forms. Postgraduate study, especially when arranged locally, is also of value in helping the general practitioner to maintain contact with his general-practitioner colleagues and with practitioners in other branches of medicine. There is a discrepancy between the answers in the field survey and the postal inquiry to the question whether practitioners desire more facilities for postgraduate study. In the former only 27% desired more facilities

ties, while the corresponding figure in the postal inquiry was 62%. Probably the objective field survey gives a truer answer. Nevertheless, the Committee believes that, with more time and less pressure of work, practitioners would feel more interested in keeping themselves up to date and participating in local postgraduate activities, and it recommends that the various suggestions made in the Cohen Report should be put into operation wherever possible.

141. It will be remembered that the Cohen Report recommended that the responsibility for all the arrangements in an area should rest with a Postgraduate Committee and the Dean. The needs of the general practitioner in the matter of postgraduate courses were considered to include: (i) the refreshment of basic knowledge and procedures, including the clinical methods; (ii) information on new methods of diagnosis and treatment; (iii) the relation of new knowledge to his own approach to medicine and to his patient; (iv) a periodical restatement of the contribution of other sciences to medicine. The report recommended that programmes of local postgraduate education, which should be arranged in consultation with local general practitioners and for times to suit their convenience, should include: (i) lectures, with or without clinical demonstrations, time being allowed at the end for questions; (ii) various types of courses at local teaching and non-teaching hospitals; (iii) discussion groups and conferences; (iv) clinico-pathological and clinico-therapeutic conferences; (v) medical films; (vi) "brains trusts"; (vii) meetings with members of other professions.

142. Wherever possible, combined clinical meetings between general practitioners and consultants should be held at local hospitals, and the academic interest should be given a social background. This might well be arranged by the hospital's providing for light refreshments to be served: it would appear to be a proper way of using "free moneys" in the provision of educational facilities and staff amenities. It has been shown that this type of meeting is usually better attended than the ordinary lecture or demonstration, and goes further to establish cordial relations between the general practitioner and the hospital staffs.

Trainee Practitioners

143. The trainee practitioner scheme has now been in existence for four years, and it would be inappropriate if a survey of general practice failed to make some comment upon it.

144. To deny the soundness of the theory of an apprentice system for general practice would be difficult. But has the system in practice fulfilled theoretical expectations? Does the trainee practitioner subsequently become a better practitioner than he would have done had he entered practice by the traditional route? The answer to these questions is important for the good of general practice, and for the good of the public purse.

145. The success or otherwise of any education system is difficult to appraise. Examinations are an imperfect yardstick, but the best that can be applied. They are inapplicable to the trainee scheme. Nor can we appeal to comparison as a measure for guidance, since the trainee system is too young. Also the practice of medicine itself changes too much. We must therefore rely for our judgment upon our own experience of the scheme and the impressions we have gained.

146. Clearly the potential benefit to be gained by a willing pupil from the individual instruction of a tutor who has the requisite knowledge and the ability to impart it to others is enormous. No doubt this ideal situation has obtained in many of the doctor-trainee relationships. Equally clearly it cannot have done so in others.

147. Although certain guiding instructions have been laid down which aim at weeding out from the list of trainers these general practitioners who are too busy to teach or whose practices are too small to provide the necessary teaching material, a perfect method of selecting teachers is difficult to devise. The present scheme is fundamentally good,

though there have been criticisms of the way in which trainers have been selected, and also of the way in which trainers have carried out their obligations. It is, however, too early to reach any definite conclusion on its efficiency. Any alternative mode of selection by a central committee would not be an improvement, because lack of local knowledge would obviously be an impediment. Perhaps the best answer to the problem is that intending trainees will naturally select those teachers who have built up a good reputation.

148. It is inevitable from the nature of the financial arrangements of the trainee practitioner scheme that there should be a tendency to regard the trainee as a cheap form of help rather than as one who should be helped. No doubt most principals are conscious of their obligations, but because of lack of time some are unable to carry them out to their satisfaction. They find that they cannot do their own job and teach a trainee at the same time. Others feel that the best way for an assistant to learn general practice is by finding out for himself, and they treat the trainee as they would an ordinary assistant. Many will agree with this opinion, but nevertheless it is not in accord with the intention of the scheme or the purpose of its financial subsidy.

149. It is probable that future generations of general practitioners will benefit from some preliminary training in the practical aspects of their future work. It is open to question whether the present scheme is the best or the most economical means of attaining the object in view.

150. At least one big teaching hospital runs its own "general practice" in which students are working under general practitioners. It would seem well worth while to explore the idea of associating senior medical students with general practitioners, more especially in the neighbourhood of teaching hospitals. This may indicate a means of teaching the ways of general practice to all medical undergraduates, whatever their future work may be, and of bringing a whiff of general practice into the rather rarefied atmosphere of the teaching hospital.

VII. THE GENERAL PRACTITIONER AND THE PUBLIC HEALTH SERVICE

151. The same proportion (79%) of practitioners visited and those replying to the postal inquiry expressed the view that the introduction of the N.H.S. had had no effect on their professional relationships with public health medical officers. Some weakening of the personal contact has occurred through the transfer of certain functions from non-county boroughs to county councils, and by the use of bed bureaux for the admission to hospital of cases of infectious disease, while in London a similar weakening has occurred through the transfer of functions from the Metropolitan Borough Councils to the London County Council. The replacement of the tuberculosis officer by the chest physician and the result of the transfer of responsibility for the treatment of tuberculosis to the regional boards has already been mentioned.

152. In spite of these transfers there is still much of mutual interest to general practitioners and public health medical officers. There is no need for the atmosphere of competition between the two branches to persist. When difficulties arise they are sometimes found to be due to the separate approach to patients by members of the public health staff without communicating with the general practitioner concerned, with the result that conflicting advice is given.

153. The remedy seems to the Committee to be to some extent with the initiative of medical officers of health, who are appreciating more fully this need for personal contact. The M.O.H. should make himself known and accessible to the general practitioners of his area, ascertain their views and their problems in relation to his own service, and ensure that his staff co-operate, in their various spheres, with the patient's family doctor. The Committee heard with pleasure

of a newly appointed M.O.H. who made it one of his first duties to make himself known by telephone to each general practitioner in his area and to offer his help whenever it might be needed. Against this must be set the statements made to the Committee by several general practitioners that they scarcely knew, or never met, their M.O.H.

154. Another suggestion that the Committee would like to make is that the M.O.H. should arrange some system of liaison between the different groups of workers who are each contributing in their own fields to the welfare of the patient—general practitioners, midwives, district nurses, and health visitors. Only good can come from personal contact and knowledge of each other's work.

155. At the same time the Committee wishes to call the attention of general practitioners to the need for reciprocal action in this matter. They are urged to make themselves acquainted with the services and co-operation offered by the public health medical officers, and to respond to their initiative.

156. The Committee has also found that in areas where the M.O.H. is a member of the local medical committee the relationship between him and the general practitioner is improved. This means of contact, if generally adopted, might well resolve many difficulties.

School Medical Officers

157. The complaint of a doctor in the postal inquiry that he had received in five years only two notes from school medical officers about children in his care serves to draw attention to the following policy agreed between the Association and the Society of Medical Officers of Health:

(i) Where, in the opinion of a medical officer employed by a local authority, a child needs special investigation (other than an ophthalmic examination) or treatment, he should send the child to a specialist only after prior consultation with the child's own doctor, upon whom rests the responsibility for general medical care.

(ii) In consulting the general practitioner, the medical officer should give him the opportunity to make the arrangements for a reply consultation or to agree—by replying or in the absence of a reply—that the arrangements should be made by the medical officer.

(iii) A copy of any special report on the child received by the medical officer should be sent to the child's own doctor.

158. The Committee particularly stresses the need for close liaison between school medical officers and general practitioners regarding the treatment (among other things) of all children whose tonsils appear to be enlarged. In its opinion the decision whether a child should be sent to a consultant should rest with the general practitioner. He knows the family history and can relate the child's condition to the environment, and he can best decide whether tonsils, which may be large, are injurious to the child's health. It is important that the school medical officer should refer children to their own doctors and not to the hospital or a specialist.

District Nurses

159. There is less criticism of district nurses than of midwives. Indeed, many practitioners are full of praise for them. They are indispensable to efficient general practice, and can relieve the doctor of many routine duties, such as the changing of dressings or the giving of certain injections. A minority of doctors feel that they are losing place to new. The local district nurse as old methods give place to new. Formerly she worked for a particular district, where she was known to the doctors and patients and was a familiar figure going her rounds on her bicycle. Now she is less visible in her motor-car. She works with limited hours. Despite the obvious and often necessary advantage to the nurse, these new conditions may result in some loss of the personal touch. For example, one patient may be visited by several district nurses in the course of an illness. The doctor is thereby placed at a disadvantage, for there is often no particular district nurse to whom he can give instructions.

160. Wherever this loss of contact has occurred the local doctors should make a positive effort to counteract it. They are in a position to make strong proposals, for, although the district nurse is employed by the local health authority, she works under the clinical direction of the individual doctor whose patient she is attending. A suggestion which appealed to the Committee and seems well worth consideration by the appropriate authorities is that each general practitioner in an area should have a particular district nurse attached to his practice. Both the doctor and the district nurse would gain by the personal contact and common interest in the patient, and the patient would be happier with a district nurse whom he could identify with his doctor's practice. The Committee is, of course, aware that under present circumstances the number of areas in which such an arrangement would be introduced is limited.

161. It was reported to the Committee that some doctors are inclined to leave a great deal to the district nurse without proper supervision, and thus to take up so much of her time that the patients of other doctors are deprived of her services. Doctors should be considerate in this matter. While the giving of certain injections may safely be delegated to a district nurse, the general practitioner must himself supervise her work and visit the patient frequently.

Health Visitors

162. Although the number of practitioners in the field survey and the postal inquiry who made complaints about the activities of health visitors were in a minority, the character of their criticism suggests that in some areas there is serious cause for a review of the functions and activities of this group of public health officers. Hitherto health visitors have been mainly concerned with maternity and child welfare, but now they are rather general social workers visiting the home for a variety of purposes. Some reorientation of training and attitude is required to meet the new type of duty, and in the present transitional stage a number of health visitors, failing to appreciate the change, are causing difficulty between patients and doctors. The Committee agrees with the view that the future training of health visitors should consist of a basic training in nursing, and a general training in social work specially related to the total environment of the patient.

163. Such a training should produce a suitable type of health visitor. The Committee would emphasize the particular need of training her to work in co-operation with the patient's doctor. At present health visitors usually visit the patient's home without the doctor's knowledge and give independent and sometimes different advice. Patients are bewildered and doctors irritated.

164. It is most important that the health visitor should always get into touch with the patient's own doctor so that she may work in close co-operation with him in every case. The administrative arrangements should be such as to give effect to and recognize this relationship. It is understood, of course, that she would also report to the M.O.H. This would tend to increase and improve liaison. The Committee has heard of Joint Committees of the General Practitioners, Midwives, and Health Visitors, which have resulted in improved relations and a better service for the patients.

Liaison with General Practice

165. The Committee has little doubt that medical officers and others working in the public health service are on the whole perfectly ready to work in close liaison with the general practitioner in the interest of the patient. It seems tolerably certain that many general practitioners have hardly considered the possibilities, or, alternatively, look upon the public health service with suspicion.

166. The Committee believes that until there is at least a closer and more general administrative liaison between these two branches of the Service some difficulties and misunderstandings will persist.

VIII. THE GENERAL PRACTITIONER AND CONSULTANTS

167. The personal relationship between general practitioners and consultants is closely bound up with the impact on general practice of the reorganization of the hospital services under the N.H.S. The personal contact remains of the utmost importance, yet there is evidence that it has become weakened during the last few years. The Committee has tried to find out the nature and the cause of the threatened cleavage, and to suggest how it might be averted. In order to avoid a one-sided view it invited a number of consultants in different branches to answer certain questions, and it is most grateful for their willing co-operation.

168. The results of the various questions put to the general practitioners in the field survey and the postal inquiry show that, to the majority, their degree of personal contact with consultants is satisfactory. Out of 32 consultants who were approached 23 (72%) felt that no alteration had occurred in their relations with general practitioners since July, 1948. Yet the Committee does not feel that all is well in this respect. It believes that some general practitioners tend, without much reflection, to accept isolation from hospitals and an impersonal relationship with consultants as an unavoidable result of the N.H.S. This is not in the interests of good medical practice, and the Committee attaches importance to the minority expressions of opinion to the effect that certain features of the consultant services tend to weaken the relationship between the general practitioner and the consultant. If the patient and the general practitioner are to obtain the full value of the consultation there must be personal contact or communication.

169. A complaint which was made in connexion with this and several other aspects of the Committee's inquiry was that a patient referred by a general practitioner to a particular consultant was often seen only by a registrar or junior. The Committee understands that registrars and junior consultants must be given opportunities of acquiring experience, and that the overcrowded out-patient departments require their assistance. Nevertheless, if a general practitioner takes the trouble to select his consultant and to address a letter to him personally, he is justified in expecting that his letter will be seen by that consultant personally, who will take full responsibility for the patient. There is here an insidious alteration of relationship which should not be allowed to develop. Hitherto the consultant was responsible to the general practitioner who sought his opinion, and, indeed, he depended upon the good will of the general practitioner for his livelihood. Now the consultant is becoming a remote impersonal hospital officer who delegates some of his work to registrars. He thus tends to become a consultant, not to the general practitioner sending the case, but to a registrar needing help. This appearance of an intermediate relationship is not in the interests of the patient or of general practice.

170. In drawing attention to practices of this kind the Committee is looking ahead to the attitude of future generations of consultants. The young consultant with only hospital experience of medical practice who absorbs this view of the consultant's function will be unaware of the proper relations between the consultant and the general practitioner and, indeed, of the purpose of the general practitioner's reference.

171. The Committee heard with interest of the success of informal teatime meetings arranged at one or two hospitals in the country where general practitioners are welcomed to demonstrations and discussions of cases. The Committee believes that the widespread development of such meetings will bring decided advantages to patients, consultants, and general practitioners. The Committee looks to all consultants to show more interest in professional gatherings, clinical and otherwise. The opportunities that arise at these meetings for getting to know one another and hearing one another's views are of undoubted importance.

172. There is also much that the general practitioner himself can do to help the development of good neighbourliness between consultant and general practitioner. The Committee knows that social contacts are common in some areas, and believes that the more general they become the better co-operation will there be between these two branches of the profession.

Information to Consultants

173. The Committee understands from its inquiries that most consultants, when a case is referred to them, prefer a letter of medium length summarizing the case history.

174. Of 983 patients referred to 34 consultants, 69% took with them letters from the general practitioners which were considered by the consultants to be satisfactory; 26% took letters of little or no value; and 5% took none at all.

175. The Committee recommends that, where appropriate, hospital authorities should consider the introduction of suitable forms acceptable to both the general practitioner and the consultant for the use of general practitioners who desire them when referring patients to hospital.

176. Whether or not a form is used, hospital procedure should ensure that a letter or form addressed to a consultant is seen only by the consultant, and is not available for scrutiny by the patient or by lay staff other than the confidential clerk concerned. A satisfactory arrangement is mentioned in the report of the field survey—namely, a letter-card addressed to the hospital appointments clerk which contains on the outside all the information required by the clerk, and a sealed inner letter to be opened by the consultant to whom it is addressed.

Domiciliary Consultations

177. The great majority of general practitioners attend to meet the consultant at domiciliary consultations; in fact, the number shows a slight increase since the introduction of the N.H.S. There are, however, some general practitioners who do not feel that it is necessary to be present, and a number of consultants who do not hesitate to see a patient without the general practitioner. The Committee was informed that some consultants arrange domiciliary visits at times to suit themselves, regardless of the convenience of the general practitioner.

178. The Annual Representative Meeting and the Joint Subcommittee of the Central Consultants and the General Medical Services Committees have expressed the view that a domiciliary consultation should be a consultation with both the general practitioner and the consultant present, and that only in exceptional circumstances should a consultant conduct such a consultation in the absence of the general practitioner. The value of the personal consultation cannot be too strongly emphasized. It is, indeed, the essence of the domiciliary consultation, and in the Committee's view no consultation in the proper sense takes place if the general practitioner is not present.

Causes of Diminishing Contact

179. The Committee questioned practitioners on possible specific causes of any diminishing contact or understanding between general practitioners and consultants. There is a distinct feeling (41% in the field survey, and 55% in the postal inquiry) that the tendency of prospective consultants to begin specialist training immediately after qualification frequently places an obstacle to their appreciation of the general practitioner's work and problems. Unless this understanding is present, it is difficult for the consultant to know exactly the kind of help the general practitioner needs when he refers a patient for an opinion.

180. While it is not within the competence of the Committee to make recommendations concerning the training of the consultant, it will not be exceeding its function if it puts forward for the consideration of those concerned some

observations on the repercussion of specialist training on general practice. The general practitioner when referring a patient is justified in expecting that the consultant will appreciate his needs and advise measures that are practical. Unless the consultant has had some actual experience of general practice he is likely to lack a realization of the background and environment of the patients he sees. Several general practitioners in the inquiry stated that the consultants who had had some experience of general practice gave more valuable advice than those who had not, and even that the two groups could be distinguished by their general approach to patients. Further, the consultant who has received his entire training in hospital tends to develop the technical aspects of his work at the expense of the personal touch. This has led to the appearance of what some doctors called the "technician type" of consultant, who is not the type to attract the confidence of the general practitioner. A short period of experience in general practice could do much to counteract this tendency. Although it may involve some modification of the accepted scheme of training of consultants in the N.H.S., the Committee puts forward for consideration the view that such basic clinical grounding, over and above the experience gained prior to registration, is particularly important in view of the high degree of specialization now existing in medicine. Unless those practising a special branch have been so grounded, there is a grave danger that the work and development of that specialty will become warped. After all, the *raison d'être* of the consultant is to advise the general practitioner needing specialist help, and, unless he can in imagination place himself in the general practitioner's position and appreciate the patient's outlook and background, he cannot advise to the most valuable degree.

Administrative Separation

181. Practitioners on the whole do not seem to be conscious of any adverse effect on their practices of the administrative separation of the consultant section of the profession under the regional hospital boards and the general-practitioner section under the local executive councils. They are perhaps not sufficiently interested in administration to give the matter much thought. To the Committee, however, this separation, together with the separation of the public health medical service, is one of the greatest defects of the N.H.S., and one of the most important causes of the lack of contact between the three main branches of the profession. Possibly the divergence of interests had begun before July, 1948, but it has certainly been intensified since that date by a rigid administrative scheme which makes no provision for collaboration between practitioners giving different, though complementary, service in the same profession. The effects permeate general practice, as is shown in various parts of this report, and, while the Committee is not directly concerned with administration, it would recommend that the feasibility of co-ordinating the administration of the N.H.S. should be studied by the authorities concerned as a matter of urgency.

IX. THE GENERAL PRACTITIONER AND THE HOSPITAL: HOSPITAL FACILITIES

182. It was put to the Committee that, just as every patient has his own doctor, so every general practitioner should have his own hospital. Although the two parts of the proposition are perhaps not strictly comparable, there is much to be said for it. It is already the policy of the Representative Body of the Association that the general practitioner should constantly and closely associated with the hospital, and both the field survey and the postal inquiry attempted to ascertain whether this association existed in practice. The result found is that there is insufficient liaison, and there is less now than before July, 1948. At present occupied in adjusting themselves to increased demands, many general practi-

tioners do not appear to feel any serious adverse effect on their practices of the absence of hospital facilities. Some complain that they still do not enjoy direct access to pathological and radiological departments.

183. Interpreting the idea that "every general practitioner should have his own hospital," the administrative arrangements would include direct access to the special departments, the allocation to general practitioners of beds where they could treat their own patients for "general-practitioner conditions," and the appointment of general practitioners to part-time appointments or clinical assistantships. All these facilities will give the practitioner added interest and more incentive to good work, and they will also bring with them the more intangible effect of mingling with consultants on their own ground and of becoming known in the hospital. It is often because he is so little known that the general practitioner receives such scant respect from the hospital staff. A further advantage is that association with a hospital will raise the status of the general practitioner in the eyes of the public. In order to achieve a positive association of the general practitioner with the hospital it will be necessary for hospitals to take steps to encourage contacts.

General-practitioner Beds

184. In the opinion of the Committee general-practitioner beds are a desirable part of the doctor's equipment on both clinical and social grounds. There is often no need for a patient who requires treatment in an institutional bed to enter an ordinary hospital ward under the care of a consultant. Such cases are to-day augmented by social conditions, and many patients who could be treated at home must enter hospital simply because home nursing and attention are not available.

185. Both the field survey and the postal inquiry showed that the great majority of general practitioners (89% in the former and 72% in the latter) have no access to beds. Although some are conscious of the effect of this on their practices, many feel no adverse effect. The Committee feels that general practitioners should be taught to appreciate the value to them of hospital beds where they may treat their own patients for "general-practitioner" conditions.

186. The Committee believes that great benefit will accrue to general practice if hospital authorities provide, whenever possible, a small number of beds specifically allocated to general practitioners for their own cases. These need not necessarily be in a separate hospital, though the modern type of cottage hospital would serve the purpose well. In modern conditions it may be found more convenient to allocate a ward in a general hospital for this purpose rather than to create new units with, possibly, a lower standard of nursing and accommodation. Such an arrangement would be on the understanding that, if a general-practitioner bed were unoccupied, it could be utilized by a consultant rather than allowed to remain empty until the general practitioner next happens to need it.

187. In the view of the Committee it is of particular importance to town practitioners that they should be allowed close association with and access to hospitals. It is doubtful whether industrial practice can ever be run on lines similar to the family practice in the country. The country practitioner, by virtue of distance alone, is bound to perform a wider variety of services for his

patients. In the town it is more convenient, and sometimes even more proper, for the practitioner to pass the patient on to the nearby hospital for such services.

Clinical Assistantships

188. The Committee agrees with the suggestion that there should be general-practitioner clinical assistantships in hospitals. The Cohen Report, in recommending these, emphasizes more particularly that the appointments should not be used to dilute the staff of the hospital, nor should general practitioners be employed primarily to share in the burden of the routine work. They are there, the report says, essentially for educational purposes. The present Committee was interested to note, from the field survey, that 81% of general practitioners were in favour of some type of clinical assistantship. It is a useful means of associating the practitioners with the hospital, and to this the Committee attaches much importance.

189. The Committee favours the suggestions made in the Association's Report on the Association of the General Practitioner with Hospital Work, that there should be three types of clinical assistantship available to general practitioners. The first is the honorary clinical assistant, for practitioners to be attached to a department or departments for their own education. The second type, the established clinical assistant, would be for a longer period and would enable the practitioner to have responsibility in the department, to gain very considerable experience, and to qualify to sit for a diploma. The third type, the senior clinical assistant, would be a post for general practitioners with adequate experience in a specialty.

190. The Committee endorses the warning in the Cohen Report that clinical assistantships must not be used to encourage the appearance of an inferior grade of specialist.

Access to Special Departments

191. The Committee's inquiries show that over half of the general practitioners have access to pathological facilities and about half to radiological facilities, and that the absence of such access causes difficulty to about half of those without it. In the postal inquiry, however, many practitioners, when replying to other questions, mentioned the difficulty and delay caused by having to send cases through a consultant. Other evidence before the Committee suggests that the question of allowing access to these departments to all general practitioners should be considered as a matter of urgency by the authorities concerned.

192. In order that it should see both sides of the subject, the Committee invited a few consulting pathologists and radiologists attached to hospitals or laboratories where direct access was allowed to comment on their experience of the use of their departments by general practitioners. Most of them are satisfied with the arrangements and can cope with work sent by general practitioners. The degree to which practitioners use the departments depends much upon whether the facilities offered are made known to them and upon the standard of interest and knowledge of the practitioner.

193. For example, a consulting pathologist told the Committee: "We have two Dr. F.s using this laboratory; the contrast in what they ask us to do has constantly made us wonder what the difference is in their practices. Dr. F. 1 finds the most exciting cases, uses

the laboratory wisely and constantly, appreciates every figure and result sent to him, and has repeatedly praised the service. Dr. F. 2 sends occasional specimens without any definite indication of what he wants done, seldom appears to recognize the disease he is dealing with even when he has sent the case to us for investigation, has to have even normal figures interpreted to him, and rejects every suggestion we make as to treatment—for example, in pernicious anaemia."

194. A radiologist who states that nearly all the local general practitioners use his department to varying degrees writes: "The privilege does lead to some appreciation of the department. One town general practitioner frequently calls to discuss a case before making any request, and invariably appears later to see the films. This practice is more prevalent among the better-quality general practitioners, and for them is worthy of encouragement."

195. The Committee believes that advantages to both sides would result from the opening of pathological and radiological departments to general practitioners. It would encourage closer relations between the consultant and the practitioner, and it would relieve the strain on out-patient departments. The Committee puts forward the following series of recommendations:

- (i) It is desirable that general practitioners should have direct access to pathological and radiological facilities.
- (ii) It is desirable that general practitioners should have direct access to pathological departments at least for the taking of blood counts and simple chemical investigations, in addition to the bacteriological and serological facilities provided by the public health laboratories.
- (iii) The use of the facilities should be regarded as a consultation between the general practitioner and the pathologist or radiologist.
- (iv) The general practitioner should be encouraged to discuss the results of the investigation with the pathologist or radiologist when such a discussion seems desirable.

Physiotherapy Services

196. The ancillary treatment which general practitioners find it most difficult to obtain for their patients is physiotherapy. This is caused partly by the lack of sufficient physiotherapists and partly by the necessity, in the N.H.S., for sending every patient to a consultant before treatment can be ordered. The patient has to wait a long time for an appointment, the domiciliary service is inadequate, and the long journey that may have to be undertaken to attend the physiotherapy centre sometimes undoes the benefit obtained by the treatment.

197. The Committee was also informed that some consultants who prescribe the treatment may have no experience of general practice or knowledge of the home conditions of patients, that they may prescribe in unsuitable cases, and that they may allow the treatment to be continued longer than is necessary or desirable. In the view of the Committee the advice of a competent general practitioner would help to ensure that the facilities for physiotherapy were used to the best advantage and in those cases where it is likely to prove most beneficial. The number of consultants in physical medicine is likely to remain small for some time to come, and the Committee considers that a physiotherapy department which has no consultant in physical medicine might well be placed under the direction of a suitably trained general practitioner, acting in the capacity of a member of the hospital staff.

X. THE GENERAL PRACTITIONER AND THE HOSPITAL: RELATIONS WITH HOSPITALS

198. The Committee has already considered the general practitioner's personal relations with consultants in hospital and his opportunities, or absence of opportunities, for taking part in hospital work. It now turns to the effect on general practice of the inadequacy of hospital provision and of certain aspects of hospital procedure. About half the practitioners in the field survey and nearly two-thirds in the postal inquiry state that their practice is obstructed in various ways. Replies to other more specific inquiries show that the greatest difficulties arise from the insufficiency of beds, long waits for consultations, and delays in sending notifications and reports to the general practitioner.

199. There is little complaint of actual encroachment on general practice by hospitals. Indeed, as the investigator in the field survey found, many general practitioners are only too glad to let the hospitals relieve them of some of their burden. Patients are rarely accepted in the out-patient department without a letter from the general practitioner, but one-third of practitioners complain that patients sent for consultations are retained for treatment unnecessarily. There was, however, a substantial amount of dissatisfaction that, after the initial treatment or after discharge from the wards, patients are required to return to the hospital at frequent intervals for inspection or aftercare which the practitioner could provide just as well in his surgery.

Out-patient Waiting-lists

200. Both the field survey and the postal inquiry indicate that the period of delay for making an appointment with a consultant in the out-patient department is most frequently two or three weeks, and that the department in which the longest delays occur is the orthopaedic department. Some practitioners in the postal inquiry added that, after the first consultation, further delay occurred before specialist treatment or investigation was carried out.

201. The majority of hospitals operate an appointments system, and the majority of general practitioners who were questioned on this matter found that it worked satisfactorily. The Committee agrees that appointments systems in out-patient departments are desirable. It heard also, however, a certain amount of criticism, and there seems to be room for improvement. For example, it was informed that at some hospitals all patients are instructed to attend at the same time, and then wait their turn, perhaps for two or three hours. In the view of the Committee this does not constitute an appointments system.

202. One cause of delay which was often mentioned in the inquiry and which appears to be a source of irritation to busy general practitioners was the fact that consultants saw only a limited number of patients at each session, and any excess numbers have to be given an appointment at a later date. There may be a good reason for this, as in the case of a surgeon who must restrict the number of consultations he gives in order to keep his operation list within practicable limits, or a consultant who is pressed to keep his other commitments, but some general practitioners have the feeling that consultants who are now salaried, are disinclined to work beyond the limits of their "notional half-day." This is contrasted with the lot of the general practitioner, who must con-

tinue his surgery until the last patient has been seen, no matter how late the hour.

203. The Committee suggested that the difficulty might be eased if separate sessions were held for new patients and "old" patients, appointments being made only for the "old" patients.

204. Both the general practitioner and his patient would undoubtedly feel more satisfied and have more confidence in the consultation if they were assured that all the letters were opened in the first instance by the consultant himself and that only he would delegate cases to a first assistant. The consultant would then be freer to see the more difficult cases himself and still remain available to advise the assistant when necessary. The Committee is informed that this system works efficiently in at least one out-patient department.

Minor Operations in Out-patient Departments

205. Long waits occur also for minor operations to be performed in the out-patient department. One cause of this is that many general practitioners send to hospital cases which, before the introduction of the N.H.S., they would have undertaken themselves. The Committee has already made recommendations on this matter.

206. The greatest delay occurs in the ear, nose, and throat departments; children may wait one or two years for the removal of tonsils. One unavoidable cause of this is the fact that, owing to the danger of subsequent poliomyelitis, operations on tonsils and adenoids are now performed only during the six months from November to April.

Admission to Beds

207. A large majority of the general practitioners in the postal inquiry stated that their patients had to wait for beds, and in the field survey 58% found their practice obstructed by this delay. The waiting period may be as much as a year for some non-urgent cases.

208. Where difficulties arise with emergency admissions they are usually great and frustrating. A feeling which found expression to a considerable extent was that increasing specialization brought with it so much sectionalization of the beds in a hospital as to remove flexibility. This has the effect of reducing the number of beds that can be made available for the admission of cases, particularly in emergency. The Committee does not dispute the necessity for increased sectionalization of hospital beds. It does, however, plead for the abolition of the administrative rigidity associated with such sectionalization.

209. If a general practitioner is associated with any particular hospital, to which he normally sends his cases, that hospital should share with him the responsibility of finding a bed for his patient in an emergency.

210. Another obstruction to the speedy turnover of beds is their occupation by patients who are waiting to see the consultant either before or after treatment. A new patient may occupy a bed for two or three days before he is seen by a consultant, and if it is necessary for two or more consultants in different branches of medicine to see him several days may elapse before a decision on procedure is taken. The Committee recommends that every effort be made to arrange for new patients to be seen on the day of admission by a member of the staff who is competent to make a decision on the disposal of the case.

Reports and Notifications to Practitioner

211. Complaints were received in both the field survey and the postal inquiry of the delay in receiving reports and notifications concerning their patients in hospital. The failure of the hospital staff to inform the general practitioner of the result of an out-patient consultation or of the discharge or death of an in-patient is not only discourteous but it also frequently places the doctor in a difficult or embarrassing position—for example, when the discharged patient comes to him for further treatment or when he hears of the death of his patient from the relatives. It also lowers the status of the practitioner in the eyes of his patients if they find that the hospital does not trouble to give him information.

212. In order to have evidence from both sides the Committee asked a group of consultants whether they sent an immediate report to the general practitioner concerned on the discharge of a patient from hospital. Of 44 consultants 23 replied "Yes" and 21 replied "No." The delay, which was in most cases up to one week, was usually explained as arising in the clerical or records department. Three stated that letters were written only on certain days.

213. There is a natural tendency on the part of the general practitioners to lay the blame for these shortcomings squarely on the shoulders of the medical staff, especially those of more junior status. The Committee urges that every effort be made to solve this problem, which is of very great importance to the practitioner in his treatment of and personal relations with his patient. It realizes that there are difficulties, especially where sufficient clerks conversant with medical terms are not made available to ease the burden borne by many a depleted house staff.

214. A suggestion which was made by a general practitioner and is already adopted by at least one consultant is that on discharge the patient be given a brief letter to present to his doctor. The Committee suggests that this procedure could well be more widely adopted. It also recommends, most emphatically, that when a patient dies in hospital the general practitioner should be notified immediately.

215. The Committee considered, without reaching a definite conclusion, whether it was desirable for a practitioner to be notified when a patient sent for consultation was transferred to another department or required some investigation. Some members thought that he should be informed before any decision was taken, because it was the responsibility of the general practitioner to decide whether the suggested further action should be taken and to select the consultant to be approached for the further opinion. Others thought that the reference back at every stage might cause needless delay, and they would be content for the consultant simply to inform the doctor of the action taken.

216. These difficulties would be minimized if the general practitioner were better known at the hospital and were able to take some part in the work, in accordance with the Committee's earlier suggestions. The result of closer contact between the general practitioner and the hospital would reduce formality in all sorts of ways, and would supplement formal notification with friendly discussion. The almoner is in a position to contribute another link between the general practitioner and the hospital. Whenever a patient is discharged from hospital there should be close liaison between his doctor, the almoner, and the health visitor.

XI. THE GENERAL PRACTITIONER AND THE STATE

217. Since 1911 the majority of general practitioners have combined State practice with private practice, their income being composed in part of capitation fees from the State for State patients and in part of fees assessed by themselves as the value of services rendered to private patients. One of the fundamental changes brought about by the N.H.S. was the severe curtailment of the field for private practice. Most general practitioners now receive all, or nearly all, their income from the State for the treatment of N.H.S. patients. While in theory this fact should make no difference to the quality of medical care, the change has brought with it many new problems. Some of these are concerned with finance and the practitioner's dependence upon a national capitation fee rather than upon his own assessment of fees. Some of them are of a more subtle nature and concern the practitioner's attitude towards his work.

218. The Committee's purpose in this section of its inquiry has been to ascertain whether the N.H.S. has had any adverse effect on the standard of general practice. Some of its questions, for example, attempted to find out whether there was any justification in the complaints frequently heard that general practitioners work much harder now than before July, 1948, and that much of their time is spent in dealing with trivial ailments which would previously have been treated by the patient at home.

Excessive Demands

219. Rather more than half the practitioners in the field survey and 80% in the postal inquiry feel that they are working harder now than before 1948, and 30% and 53% respectively feel that excessive numbers of unnecessary demands on their time are being made by patients. The tendency of some doctors to complain that a certain proportion of their time is spent in the treatment of "trivial" ailments needs scrutiny. There can, of course, be no firm definition of a trivial ailment, either from the patient's point of view or from the doctor's. A request for treatment which to one doctor is merely an annoyance may present to another material of real clinical interest or even a basis for research in the study of so-called trivialities. Moreover, who shall say without examining the patient whether a condition is "trivial"? If patients are encouraged by the profession itself to seek medical advice in the early stages of illness they cannot wholly be blamed if some of them approach the doctor unnecessarily. What seems trivial to the doctor may not be so to the patient, who may have no one else to turn to for help in his problem. Some doctors, especially the younger ones without long experience, may not be aware how helpless the patient may feel in his small troubles and what relief a sympathetic hearing can give him.

220. The Committee is of course aware that in most practices there are a few patients who make unreasonable demands and cause the doctor irritation out of all proportion to their number. It is also aware of the existence of the patient with the "shopping list." Its view is that, while it is important that patients should be encouraged to seek medical advice in the early stages of disease, it is reasonable to expect that the public might be educated to be more self-reliant and to become acquainted with the elements of first-aid and home nursing. Similarly the Committee feels that there is

room for some education of the public in the proper code of conduct in the doctor-patient relationship.

221. The investigator in the field survey had the opportunity of noting that this difficulty of unnecessary demands for service was not met in colliery practices which were formerly conducted as "club practices." These practices had already passed through the change which tends to occur in the attitude of the patient when the financial barrier to the doctor's service is removed, and the coming of the N.H.S. has had little effect on them. Other practices are now passing through a similar phase. Some doctors think that the peak has been reached and the demand is settling down to what is likely to be the normal in the new conditions. Others say that the demand remains at the peak. The Committee believes that the average number of services likely to be required of a practitioner in the future will remain higher than in the pre-N.H.S. years.

Prescribing

222. Overprescribing includes the prescribing of expensive equivalents instead of comparatively inexpensive medicaments, and the use of more popular, more complicated, and more expensive remedies in the place of simple inexpensive drugs which are therapeutically as effective. Some of these inexpensive drugs were proved remedies before the introduction of newer discoveries which have tended to be taken into wholesale, and sometimes indiscriminate, use.

223. The Committee believes that overprescribing plays at least some part in the magnitude of the nation's drug bill. But it does not believe that this is entirely the fault of general practitioners. A potent factor is the demand by patients for expensive preparations which have been recommended by hospitals or have been selected by the patients themselves in response to hearsay.

224. While the Committee recognizes that the General Medical Services Committee has the subject constantly under consideration, it would resist most strongly any attempt to restrict the liberty of any doctor to prescribe what is necessary for the patient. Nevertheless, it believes that many might with advantage review their prescribing habits, including a study of the *National Formulary, 1952*. The Committee believes that the *Formulary* forms an excellent basis for the self-education of the doctor in the art of prescribing at once economically and efficiently. It is of the opinion that all members of hospital staffs, especially house officers, should also be supplied with copies of the *Formulary*.

225. There is, here and there, a tendency to use a steam-hammer where nutcrackers will do. In past years the absence of remedies that now exist and are regarded by some almost as panaceas made it more easy to realize that nature has a part to play in the resolution of illness. Now there is danger, for example, of "sulpha" drugs taking the place of diagnosis.

226. The Committee feels that the nation's drug bill will continue to increase. At present it is difficult for the local medical committees to act in this matter as they are acted under the National Health Insurance because of the backlog which at present obtains in the pricing bureaux.

227. The profession is therefore urged to exercise the greatest care in prescribing in order to counteract the

inevitable rise in the drug bill. Discrimination in prescribing should be more widely taught in the schools, and it should be realized by all that economical prescribing is usually good prescribing.

Size of Lists

228. The reports in the field survey and the postal inquiry show that in 1951-2 the number of patients cared for by a practitioner lay most frequently within the range 2,000-3,500. There were undoubtedly some practitioners who found no great difficulty in properly looking after a full list of patients (4,000). There were others who felt compelled by economic necessity to care for more patients than they could, in their view, properly manage, although their lists were under 4,000. Yet others were finding difficulty in building up a list of patients large enough to give them a reasonable livelihood and sufficient clinical experience.

229. The Committee offers no solution to this problem, but it stresses its view that the mere size of list is by no means the only criterion of a good practice. The financial advantage of a large list has played too great a part in general practice under the N.H.S. It has been sometimes all-important, which is undesirable. It now remains to be seen whether the new financial arrangements will effect the necessary adjustments of these difficulties.

The General Attitude

230. One of the best tests of the efficiency of a medical service is whether the doctors operating it are reasonably happy and contented. The field survey and the postal inquiry agree in showing that about 55% of general practitioners are reasonably happy and contented in the N.H.S., excluding from consideration any question of finance. Obviously there is considerable room for improvement, but the proportion suggests that there is less downright opposition to the N.H.S. than is sometimes supposed. Practitioners are critical and feel restricted in the service they can render to their patients under the scheme, but, as the field investigator has found, they are in a receptive state of mind and are ready to make the scheme a better service if they are allowed the opportunities to do so.

XII. CONCLUSION

231. The ultimate question to which the Committee has sought an answer is whether the general practitioner of to-day is able to practise good medicine. It believes, on the evidence it has collected, that an unqualified affirmative answer cannot be given. If the scope and conditions of general practice are conducive to good work the right type of men and women will enter it and provide a high standard of service for their patients. If the scope and conditions fall short of a satisfactory basis for a career, general practice will either fail to attract the best type of medical practitioner or it will be pursued in a spirit of anxiety and frustration, to the detriment of the medical profession and of the community as a whole.

232. The results of the surveys suggest that about half the general practitioners in the N.H.S. are reasonably happy and contented in their work, and that a similar proportion may be described as "good" doctors. It is significant that in the field survey the youngest age group has the highest proportion of doctors in the category "good"; in the other two age groups the highest pro-

portions are classed as "adequate." If the young entrant to general practice is indeed of a high quality, it is all the more incumbent upon those responsible for the organization of the N.H.S. to ensure that he has the "tools" to do his job.

233. Two obstacles to the improvement of general practice to-day lie in the insufficiency of personal contact between general practitioners and practitioners in other branches of practice and in the separation, in both practice and administration, of the three main branches of medicine—namely, general practice, hospital practice, and public health practice. From these two defects flow most of the general practitioner's difficulties. The tendencies to disunity are not new; they have been creeping on the profession for at least thirty years. They are due, historically, to the continuous broadening of the field of medicine, the consequent specialization, and the different rates of development of the different sections of medical practice. The progress of general practice has been overshadowed by the rapidity of the growth of other branches, and the general practitioner has not shared in the limelight of his specialist colleagues or in the local publicity of the public health services.

234. The practice of good medicine is also endangered when clinical activity has to be subordinated to administrative duties in the N.H.S. and when excessive demands for service curtail the time available for the adequate knowledge and treatment of individual patients. The doctor consequently loses interest and feels frustrated; one young doctor replied to the postal inquiry, "Only rarely do I feel I am really practising medicine." This barrier to good medicine is intensified by the fact that insufficient remuneration leads many doctors to accept larger lists of patients than they can efficiently serve—some may even be selective and refuse to accept the chronic sick or those who are likely to require much attention. The general public, too, must share some of the responsibility for the failure to allow general practice to achieve its fullest scope. The growing emphasis in the public mind on hospitals and specialists at the expense of the general practitioner reached its climax at the introduction of the N.H.S., when, having been promised a complete and "free" medical service, a large proportion of patients demonstrated their opinion of general practitioners as suppliers, on demand, of prescriptions and certificates. Although, as Lord Dawson said, "Man sick is individualistic," and in real illness turns, as always, to his own doctor for help, the time and skill of the general practitioner are too often abused by patients who have no true need of his services or who regard him as only an intermediary to the hospital service. The proper discipline of his patients is, of course, in the hands of the general practitioner himself, but some of the effort which is given to public instruction in the wonders of scientific medicine and the marvels of the modern hospital service might with advantage be devoted to informing the public of the functions of the general practitioner and of the way in which his services should be sought.

235. That there is something wrong seems to be shown by the fact that, although there is a substantial annual increase in the number of principals in general practice, there are still young practitioners who cannot find the kind of practice they want. It is said that they all seek the easier practices in the more favoured parts of the country. The Committee cannot help feeling that some young men expect to get on rather too early and too

quickly. They want the cream before they milk the cow. On the other hand, there are young practitioners who say they cannot find the type of practice where they can "really practise medicine" and not be merely finger-posts. The Committee believes it to be the case that at present there are more opportunities for finger-posts and financial advantages for the practitioner who is inclined to be superficial and who is easy with prescriptions but reluctant to sign on the chronic sick. There are too few openings and inducements for the careful, keen practitioner who likes to be thorough in his examinations and treatment and to have time for study and reflection.

236. The general trends of practice and the dangers threatening general practitioners were recognized by the Association in its *General Medical Service for the Nation* in 1929, by the Medical Planning Commission in 1942, by the profession's negotiators in the years following the issue of the Beveridge Report, and by many of the more thoughtful members of the profession. All this work did not stem the tide, and the practicalities of the N.H.S., with its deliberate tripartite administration, only exacerbated already existing tendencies, with the result that many general practitioners now feel that they are entirely separated and isolated from their colleagues in other branches and left with a contracted scope of practice.

237. One of the greatest services which the present generation of practitioners and administrators could render to the profession would be the reversal of these disintegrating tendencies and the restoration in the professional and the public mind of the sense of the oneness of Medicine. There must be more understanding that, on a long view, the interests of all branches of the profession are the same and that no one section can continue to prosper at the expense of the others. All categories and individuals are interdependent, so that if one group is injured or depreciated the whole balance of medical practice is upset and the standard of service to the community is lowered. General practice is being injured at the present time by disunity and lack of co-ordination. There is urgent need for a sense of professional unity and for deliberate and early action to give the general practitioner his proper place in a united profession, opportunities and freedom to exercise his skill, personality, and initiative to the fullest extent, and an environment of practice in which he may fulfil his sense of vocation as family doctor and personal medical adviser.

SUMMARY

The General Practitioner

1. Those responsible for the selection and training of medical students should have regard to the broad general education and the "all-round" knowledge and skill required for general practice. (Paras. 15-24.)

The Doctor-Patient Relationship

2. The conditions of general practice should be such as will encourage the maintenance of the highest possible standard of the doctor-patient relationship. (Paras. 25-40.)

The General Practitioner's Range of Service

3. In order to permit continuity of care and general responsibility it should be an accepted principle in all hospitals that reasonable opportunities are provided for

general practitioners to visit their patients from time to time and to discuss their progress with members of the hospital staff. (Paras. 42-5.)

4. Arrangements for a division of work in a multiple practice should be such as will encourage the principle of continuous responsibility. (Para. 47.)

5. There should be close and active co-operation in the field of health education and preventive medicine between the general practitioner and the public health department. (Para. 50.)

6. So far as is practicable, occupational health schemes should employ general practitioners in a part-time capacity. (Paras. 51-2.)

7. The conditions of general practice should be such as will give the practitioner the time he needs for each patient. (Para. 53.)

8. The general practitioner should undertake for National Health Service patients those minor operations which, before the Service was introduced, he performed as part of clinical treatment in the ordinary course of general practice. (Paras. 58-61.)

9. Consideration should be given to the possible advantages of granting general practitioners facilities in local hospitals for performing minor surgical procedures for their patients and give immediate aftercare. (Para. 62.)

10. General practitioners and members of hospital staffs should discuss and decide upon their respective ranges of activity in minor surgery and other fields. (Para. 62.)

11. Account should be taken of the difficult position in which the pressure of events has placed the general practitioner with regard to certification. (Paras. 63-4.)

12. General practitioners in an area should meet from time to time to determine and agree upon a "common certification front." (Para. 64.)

13. A general practitioner who wishes to develop a specialty, either within his own practice or with a view to becoming a consultant, should be given opportunities to do so, with a minimum of interference with the management of his practice. (Paras. 66-8.)

14. Midwifery should be regarded as an integral part of general practice, and every possible encouragement should be given to general practitioners to undertake it. (Paras. 69-87.)

15. General-practitioner maternity units should be established for confinements which, but for social circumstances, would have taken place at home. (Paras. 74-5.)

16. The general practitioner and the midwife should work together as a team from the first antenatal examination. (Paras. 76-83.)

17. The use of the term "maternity nurse" should be discontinued when the midwife is working with the doctor. (Para. 83.)

18. The present obstetric lists maintained in England and Wales should be replaced by the Scottish procedure—that is, that every registered medical practitioner who indicates his willingness to practise obstetrics regularly should automatically be eligible to have his name included, if he so desires, in a list of practitioners undertaking to provide midwifery services, and should receive the full fee. (Para. 84.)

19. The maternity services of the local health authority and the general practitioner should be complementary and not alternative, and, in order to preserve continuity of care of the patient, it should be an accepted principle

that the proper person to conduct antenatal examinations is the doctor who will be responsible for the confinement. (Paras. 85-7.)

20. In order to co-ordinate the various sections of the service dealing with the prevention and care of tuberculosis, there should be the closest possible co-operation between the general practitioner, the chest physician, and the tuberculosis visitor. (Paras. 88-91.)

21. In each area beds should be available at reasonably short notice for cases of tuberculosis requiring early admission and for any acute emergencies. (Para. 91.)

22. Old persons who are acutely ill should be treated in a general hospital in the same way as a younger person, the same principles for urgent admission being applied. (Para. 93.)

23. An appropriate medical officer should visit and examine every aged, infirm, or chronic sick patient proposed for the waiting-list for institutional care, and assess the degree of priority or urgency in consultation with the family doctor. (Para. 94.)

24. More Eventide Homes should be provided. (Para. 95.)

25. There should be a substantial expansion of the home help service, including night attendance, for the aged and chronic sick. (Paras. 96-7.)

The Organization of General Practice

26. The attention of general practitioners should be drawn to the advantages of non-medical help for clerical and allied duties. (Para. 109.)

27. The attention of the telephone authorities be drawn anew to the pressing requirements of the profession for easily arranged transfer of messages. (Para. 114.)

28. Any system of health centres should come after further experiment, including the development of communal surgeries set up by general practitioners themselves, rather than be imposed from outside the profession. (Paras. 118-22.)

The General Practitioner and his Colleagues

29. Properly devised local rota schemes are valuable as a method of providing relief for individual practitioners. (Para. 128.)

30. Principals should be encouraged in all possible ways, including the payment of compensation for the part of the practice concerned, to enter into partnership rather than employ permanent assistants. (Paras. 135-9.)

31. The various suggestions for postgraduate education made in the Cohen Report should be put into operation wherever possible. (Para. 141.)

32. Wherever possible, combined clinical meetings between general practitioners and consultants should be held at local hospitals, the academic interest being given a social background. (Para. 142.)

33. The idea of senior medical students being associated with general practitioners, especially in the neighbourhood of teaching hospitals, should be explored. (Para. 150.)

The General Practitioner and the Public Health Service

34. Endeavours should be made by both medical officers of health and general practitioners to improve the contact and understanding between the two branches of practice. (Paras. 152-5, 165-6.)

35. The medical officer of health and the general practitioners in the area should together arrange some

system of liaison between the different groups of workers who are each contributing in their own fields to the welfare of the patients—namely, general practitioners, midwives, district nurses, and health visitors. (Para. 154.)

36. Just as there is provision in the model scheme for the M.O.H. to be a member of the local medical committee, so there should be statutory provision for general practitioners nominated by the local medical committee to be included in the membership of the health committee of the local health authority. (Paras. 156, 122.)

37. All concerned should take active steps to implement the agreement between the Association and the Society of Medical Officers of Health on the reference of school-children to consultants. (Paras. 157-8.)

38. General practitioners should make every effort to maintain personal contact with district nurses, the clinical details of whose work should be arranged in consultation with the patient's doctor. (Paras. 159-60.)

39. Every effort should be made to secure an adequate number of district nurses. (Para. 159.)

40. The health visitor should always get into touch with the patient's doctor so that she may work in close co-operation with him in every case. (Para. 164.)

The General Practitioner and Consultants

41. General practitioners and consultants should be urged to take positive steps to achieve the closest possible co-operation. Opportunities for both professional and social contact should be actively pursued. (Paras. 167-72.)

42. Where appropriate, hospital authorities should consider the introduction of suitable forms, acceptable to both the general practitioner and the consultant, for the use of general practitioners who desire them when referring patients to hospital. (Para. 175.)

43. Administrative arrangements in hospitals should be such that letters addressed to consultants are not seen by the patient or by lay staff other than the confidential clerks concerned. (Para. 176.)

44. A domiciliary consultation should be a consultation with both the general practitioner and the consultant present, and only in exceptional circumstances should a consultant conduct such a consultation in the absence of the general practitioner. (Para. 178.)

45. Every prospective consultant should consider the advantages, both to medical practice and to himself, of including in his training a period in general practice, and it is desirable that he should be afforded opportunities of gaining such experience. (Paras. 179-80.)

Hospital Facilities for the General Practitioner

46. Ideally, every general practitioner should be positively associated with a hospital. In order to achieve this it will be necessary for hospitals to take active steps to encourage closer contact. (Paras. 182-3.)

47. The widest possible application should be accorded to the principle that general-practitioner beds should be available to all practitioners. (Paras. 184-7.)

48. Clinical assistantships should be available to general practitioners on the lines suggested in the Association's Report on *The Association of the General Practitioner with Hospital Work*. (Paras. 188-90.)

49. General practitioners should have direct access to pathological and radiological facilities. (Paras. 191-5.)

50. The use of the facilities of the special departments should be regarded as a consultation between the general practitioner and the pathologist or radiologist. (Para. 195.)

51. The general practitioner should be encouraged to discuss the results of investigations with the pathologist or radiologist when such a discussion seems desirable. (Para. 195.)

52. In order that physiotherapy services may be used to the best advantage, the advice of a suitably trained general practitioner should be available to the physiotherapy department. (Paras. 196-7.)

The General Practitioner's Relations with Hospitals

53. A searching examination of the appointments system in hospital out-patient departments is desirable with a view to eliminating the long waits, special consideration being given to the possible advantages of new cases being seen without appointment. (Paras. 200-3.)

54. A patient referred to a particular consultant should be seen by an assistant only after an express delegation by the consultant in the individual case. (Para. 204.)

55. The availability of beds for admissions should be improved by substituting flexibility for administrative rigidity. (Paras. 207-8.)

56. The hospital to which the general practitioner normally sends his cases should share with him the responsibility of finding a bed for his patient in an emergency. (Para. 209.)

57. Steps should be taken to reduce the time-lag between admission to hospital and the initiation of treatment and between the cessation of treatment and discharge. (Para. 210.)

58. Immediate notification, with the relevant information, be given to the general practitioner on the discharge of a patient from hospital, after attendance as an out-patient, and on reference to another consultant. (Paras. 211-16.)

59. The general practitioner should be notified immediately when a patient of his dies in hospital. (Para. 214.)

The General Practitioner and the State

60. Consideration should be given to educating the public to be more self-reliant and to become acquainted with the elements of first-aid and home nursing. (Para. 220.)

61. General practitioners should review their prescribing habits, including a study of the *National Formulary* 1952. (Paras. 222-7.)

62. All members of hospital staffs, especially house officers, should be supplied with copies of the *National Formulary*. (Para. 224.)

Unity of the Profession

63. General practitioners should take active steps, even at some slight personal sacrifice, to establish friendly relations between them and their general-practitioner colleagues.

There are differences that can be composed and gaps that must be closed between the three branches of the Service. The Committee does not believe that multiplication of liaison committees alone will have the desired effect, and feels that in order to achieve this it

Questions Answered

On Retirement

Q.—On the assumption that my net remuneration as a general practitioner under the N.H.S., has been £1,500 per annum since July, 1948: (1) What would be the lump sum that I would be entitled to if I had retired at the end of the first five years? (2) What would be my pension after ten years' service from July, 1948, if my net remuneration remained the same up to that time?

A.—(1) After five years' service the practitioner would be entitled to a lump sum retiring allowance equal to the greater of (a) $4\frac{1}{2}\%$ of total superannuable remuneration = £337, or (b) a sum equal to the amount of his contributions with interest = £450+compound interest at $2\frac{1}{2}\%$. But, as both these amounts are less than his average remuneration over the last three years' service (£1,500), he could apply to the Superannuation Division of the Ministry of Health for his retiring allowance to be increased by the capital value (surrender value) of the death gratuity that would normally become payable, and then in such a case no death gratuity would become payable later.

(2) After ten years' service the practitioner would be entitled to a pension of $1\frac{1}{2}\%$ of total net remuneration = £225, plus a lump sum retiring allowance of £675 if unmarried and £225 if married.

Sickness Benefits

Our answer to the question, "Are sickness-benefit payments liable for income tax?" (*Supplement*, August 29, p. 91) was to the effect that tax was not payable. This answer was incomplete, for, as our expert writes, "if the sickness benefit continues for the whole of any one financial year—that is, the year ending on April 5—the payments are then regarded as income assessable to income tax on the recipient."

Correspondence

Because of the present high cost of producing the Journal, and the great pressure on our space, correspondents are asked to keep their letters short.

Cost of Prescribing

SIR.—The small amount of comment in your correspondence about the recently distributed classification of proprietary medicines and the accompanying letter of exhortation from Sir John Charles suggests that our passive profession willingly sits on the increasing spikes in the N.H.S. fence. If indeed preparations in categories 5 and 6 are in the opinion of the Ministry of Health not of proved therapeutic value, it is surely its responsibility and bounden duty, strongly supported by the Treasury, to forbid the use of these "worthless" drugs under the N.H.S. Unfortunately neither the Ministry nor its advisers have the courage so to do, and no Government has cared to take the step after the inauguration of the "free" health service which was to supply all remedies to everyone in the country free of charge, regardless of nationality. True, such a ban might embarrass some doctors, but I doubt if either doctors or patients would really suffer unduly by this intrusion upon our freedom.

Paragraph 4 of Sir John Charles's letter, perhaps unwittingly, is a veritable sword of Damocles poised over the profession's head, for, though our prescribing of these preparations will be judged by our colleagues on local medical committees, theirs is not always the final word. There is also the possibility of genuine variance in the opinions of local medical committees, resulting in patients

will be necessary for all individuals concerned in all branches to concentrate their attention rather less on their own individual problems and to bring it to bear on the problems of the N.H.S. as a whole. The Committee recommends that the most urgent consideration be given at all levels to the vast problem of how to achieve the closest possible integration in the Service.

APPENDIX

SOME OTHER INQUIRIES INTO GENERAL PRACTICE

The present condition of general practice is engaging the attention of other bodies both within and outside the British Medical Association. Some of these are concerned with the whole field, others with particular aspects. The Committee thinks it may be useful to list below the various inquiries which it knows to be in progress. Such material as is already available from these inquiries has been taken into consideration.

Central Health Services Council.—A committee was appointed early in 1951, under the chairmanship of Sir Henry Cohen, to study general practice under the National Health Service.

Medical Practices Committee.—Annual Reports of the Medical Practices Committee for England and Wales and of the Scottish Medical Practices Committee on the distribution of the profession.

British Medical Association.—The British Medical Association and the General Medical Services Committee are continuously occupied with matters affecting the general practitioner. Among recent special reports are: "General Practice and the Training of the General Practitioner," 1950. "Report on Health Centres," 1949. The Committee acknowledged the help received from the many Divisions and Branches which set up study groups or special subcommittees to consider the Cohen Report on "General Practice and the Training of the General Practitioner."

Medical Research Council.—An intensive study is being made, under the auspices of the Council, of the work of a single ordinary general practice in London, and of the "needs" of the people in it, by the Social Medicine Research Unit at the Central Middlesex Hospital, Willesden, London, N.W.10.

Scottish Health Services Council.—The Committee welcomes the report of a special committee on the "General Practitioner and the Hospital Service," which was published in December, 1951, and endorses the many valuable suggestions made.

Nuffield Provincial Hospitals Trust.—On behalf of the Trust Dr. Stephen Taylor is making a detailed study of a number of well-organized practices where doctors have already grouped themselves together, adapted their premises, and availed themselves of appropriate ancillary help. The purpose is "to examine the best—to see how good it is and how far it deserves to be set up as a model for others to follow." The Trust is also conducting experiments "to test and demonstrate various conceptions of a health centre. Three are at present in progress: (i) a teaching health centre attached to the medical school of the University of Manchester; (ii) a diagnostic health centre for the new town of Corby, in Northamptonshire; and (iii) a simple type of health centre for the new town of Harlow, in Essex. Another experiment which the Trust has initiated is concerned with the improved co-ordination of medical care. A preliminary survey is being carried out in the area of the East Anglian Regional Hospital Board of (a) arrangements for specialist services; (b) maternity services, urban and rural; (c) the treatment and care of the chronic sick of all ages; and (d) mental health services, with particular reference to co-ordination between the various authorities.

receiving their category 5 or 6 medicine in one area without cost to the doctor, and either being refused it or supplied with it at the doctors' expense in another. And quite a considerable bill could be run up in this manner before the unfortunate doctor is called to account for his action.

Why should it be the doctor's responsibility to refuse to prescribe, or at least endeavour to dissuade his patient on behalf of the Ministry? In some areas such action is believed to be due to the doctor trying to economize in his personal expenditure, and this arouses ill feeling. Why should the doctor have to justify the use of drugs in which some patients at least appear to have so much confidence, and from which they thereby derive some therapeutic benefit, if only psychological? What about the cough bottles in the N.F. which are revered by so many despite the scorn poured upon them in our medical schools?

Surely the onus of deciding whether or not a drug is of proved therapeutic value in any individual patient must rest on the doctor alone and without threats of investigation, even by his colleagues. If, on the other hand, the Ministry is anxious about costs and has no faith in our discrimination, as appears to be the case, let it assume full responsibility by investigating all new drugs and issuing certificates of merit for manufacturers to include in their advertisements in the medical press.

Let us get off our fence, remove the sword of Damocles, and be free to practise medicine knowing precisely where we do stand in relation to our patients and the Ministry. A definite ruling in this matter would help us in our dealings with the general public, who would then happily blame the Ministry of Health and not us for refusing the supply of some of their favourite remedies.—I am, etc.,

Crook, Co. Durham.

G. H. PEARSON.

Investigation of Prescribing

SIR,—We find that the implementation of the regulations governing the investigation into the prescribing of preparations which may or may not have been prescribed as drugs is rather cumbersome and confusing. At the same time matters of principle are involved.

The article on this matter in the *Supplement* of August 1 (p. 68) does little to simplify the procedure, nor does it clarify the doctor's position in

(a) obtaining a patient's consent to disclosure of diagnosis (i.e., whether this is the responsibility of the doctor or the executive council);

(b) the case where the patient refuses consent to disclose clinical details either to lay officials or to a doctor secretary or chairman of a local medical committee.

In our opinion the fact that the procedure involves a matter of principle is of paramount importance. The principle involved—that of disclosure of a patient's diagnosis in a matter which is of no direct concern to the patient himself—is so fundamental that we feel there should not be the slightest confusion in the procedure to be adopted. We therefore feel that, before any details are requested of the doctor, written consent to the disclosure of diagnosis should first be obtained from the patient. The patient should be asked if he is willing that details be disclosed to

(a) lay member(s) of executive council; or

(b) doctor member of local medical committee; or

(c) neither.

We feel that the onus of obtaining this consent should be on the body initiating the inquiry—i.e., the executive council. With this written consent of the patient the clerk of the executive council may then approach the doctor, who can furnish clinical details to either the executive council or the local medical committee.

Should the patient's consent be absolutely withheld, then we feel the investigation could not proceed unless taken to law.—We are, etc.,

B. TAYLOR.
J. G. WATT.

West Smethwick, Staffs.

Association Notices

GROUP COMMITTEE ELECTIONS

The following have been elected to Group Committees to fill vacancies caused by the annual retirement of one-third of the members:

Anaesthetists Group Committee.—A. H. Galley, T. C. Gray, R. P. Harbord, R. Jarman.

Consulting Pathologists Group Committee.—D. Cappell, Cuthbert Dukes, J. D. Allan Gray.

Dermatologists Group Committee.—G. W. Bamber, I. H. McCaw.

Full-time Non-professional Medical Teachers and Research Workers Group Committee.—B. N. Brooke, M. M. Bull, G. I. C. Ingram, J. Joseph, R. C. Nairn, A. H. T. Robb-Smith, H. B. Stoner, Thomas Symington, Ronald Woolmer, K. S. Zinnemann.

Orthopaedic Group Committee.—R. Guy Pulvertaft, R. J. W. Withers. One vacancy.

Otolaryngologists Group Committee.—J. H. Otty, R. D. Owen. A. Russell, Gavin Young.

Ophthalmic Group Committee.—N. P. R. Galloway, A. F. Gilbert, R. Affleck Greeves, J. J. Healy, O. Gayer Morgan, J. R. Wheeler.

Physical Medicine Group Committee.—I. H. M. Curwen, William Dunham, J. B. Stewart.

Psychological Medicine Group Committee.—Doris Odium, J. D. W. Pearce, J. Valentine.

Radiologists Group Committee.—F. H. Kemp, J. G. McWhirter, D. C. Porter, C. Wroth. One vacancy.

Tuberculosis and Diseases of the Chest Group Committee.—T. W. Davies, H. Ramsay, F. Ridehalgh.

Venereologists Group Committee.—D. J. Campbell, W. N. Mascall, I. N. Orpwood Price, Mary M. Shaw.

A. MACRAE,
Secretary.

GENERAL MEDICAL SERVICES COMMITTEE

A meeting of the General Medical Services Committee was held on September 17, with Dr. A. TALBOT ROGERS in the chair.

Dr. H. C. Faulkner, of London, who had been appointed to represent the Medical Practitioners Union in place of Dr. J. E. Outhwaite, was introduced and welcomed.

Dr. M. Sorsby was appointed a member of the Rural Practices Committee in place of Dr. F. Gray, and Dr. F. M. Rose and Dr. I. G. Innes were nominated to the panel from which the professional member of the Tribunal is appointed.

The date of the Annual Conference of Representatives of Local Medical Committees was fixed for June 3, 1954.

The "National Formulary"

The adequacy of general-practitioner representation on the Joint Formulary Committee of the British Medical Association and the Pharmaceutical Society gave rise to discussion. Dr. A. B. DAVIES, a general-practitioner member of the Joint Committee, said that, when it came to voting, yet the general practitioners were outnumbered every time, yet the *National Formulary* was predominantly a general-practitioner matter.

Dr. H. G. DAIN said that the constitution of the Committee "appalled" him. He had no idea it had developed in the way it had done.¹ It included a number of people whose direct interest in the subject was slight, and the pharmaceutical representation was disproportionately large. Yet the object of the *National Formulary* was to provide general practitioners with an easy method of prescribing, using a shortened formula. General practitioners should be in control.

It was agreed to invite the Council to review the constitution of the Joint Committee and to recommend that it should include a substantially higher number of G.P.s. It was understood that any reorganization could not take place for a year.

General Practitioners on Regional Hospital Boards

Tables were furnished to the Committee showing the present state of general-practitioner representation on regional hospital boards. At present each board included a general practitioner.

Dr. A. BEAUCHAMP said that nobody seemed to know on what principles the Ministry appointed general practitioners to these boards.

¹ There are 36 members of the Joint Committee, four of whom are appointed by the General Medical Services Committee and the remainder by some nine other bodies.

The CHAIRMAN said that those chosen were not regarded as representatives of any particular body, but as people able to give sound advice about the hospital service. The Ministry should be told that not only should there be at least one general practitioner on each board, but that there should be one general practitioner who was in regular touch with his colleagues in different parts of the region who could inform the board of such problems as arose, and that the Committee could furnish nominations. If the Ministry thought that, in addition, other general practitioners would be useful in that region and deserved a place on the board there would, of course, be no objection.

Discussion also took place on general-practitioner representation on hospital group medical committees. This matter was deferred until the next meeting, and in the meantime it was suggested, and agreed, that in view of the complexity of administrative set-up a kind of "genealogical tree" showing the derivation and functions of the various hospital committees should be included in the documents for the next meeting.

General Practitioners Working in Hospitals

The CHAIRMAN said that negotiations had been taking place in Committee "B" of the Medical Whitley Council on the terms upon which general practitioners should be employed in hospitals. The view expressed in the General Medical Services Committee had been that no practitioner working as a clinical assistant under supervision should be paid less than the rate laid down in the terms and conditions of service—namely, £175 per annum per weekly half-day. The Ministry, however, considered that this rate should apply only to practitioners in independent charge of a hospital unit who were not directly responsible to a consultant or S.H.M.O. in a specialty, and that a suitable rate for general practitioners working under supervision should be negotiated through Whitley machinery. The Management Side of Whitley Committee "B" had supported a rate of £125 per weekly session and based this rate on the remuneration of hospital registrars. The CHAIRMAN went on to point out that general practitioners were not coming to hospitals to train themselves for some future consultant post but to help in the work of the hospital; often they had had some years of postgraduate training. The figure of £125 was based on comparison with the earnings of a registrar, and also on the idea that the people concerned would be those not fully extended in general practice, to whose income an additional £125 a year might be welcome. He reminded the Committee that any extra money that came to these practitioners would come indirectly out of the general practitioners' pool.

Dr. D. F. HUTCHINSON pointed out that hospital boards were restricted in the amount of money they could spend, and were having a job to make ends meet. Any reserve was put towards increase in consultant staff, and there could be no additional allocation to the boards for general-practitioner service.

Dr. J. C. ARTHUR discussed the matter from the trade-union angle—"the rate for the job." If they accepted £125 as the remuneration for a general practitioner doing a weekly session which might well last three hours, the rate for the job was being cut. He felt that the figure should not be less than £175.

Dr. WAND said that their long-term policy was to establish the general practitioner as part of the hospital life of the country. The average net remuneration of the established general practitioner in this country was now £2,000 net. If the rate for hospital work was accepted as suggested by the Ministry in the region of £1,300 or £1,400, the general practitioner who was doing good work in his own practice was, when he went into hospital, being remunerated at a lower rate for his job. Their purpose was to build up a better general-practitioner and hospital service in this country, and this should not be diverted by the argument that the cheaper rate would assist hospital finance. Even the figure of £175 was too low and should be regarded as minimal. The experienced general practitioner who had been through the mill of general practice for some years was not to be classified with the comparatively young registrar who was earning £1,300 a year.

The CHAIRMAN said that he thought the view of the Committee was in favour of a consolidated method of employment of general practitioners in hospitals in all posts other than those of S.H.M.O.s and consultants, and, having established that principle, the appropriate payment should be negotiated on the understanding that the figure must bear relationship to the payment in other parts of the Service.

This view was generally accepted, and a group of members were nominated to discuss the matter with the Joint Committee (representing the Central Consultants and Specialists Committee and the Royal Colleges) and its Working Party. The members nominated were Drs. Talbot Rogers, A. Beauchamp, D. F. Hutchinson, M. Parkes, F. M. Rose, and S. Wand.

Accommodation in Surgeries and Waiting-rooms

The Committee considered paragraph by paragraph a draft letter which it is proposed to send to individual practitioners on the standard of accommodation in surgeries and waiting-rooms. The letter stated that it was considered neither practicable nor desirable to lay down minimum standards. Any necessary improvements should come about spontaneously from the desire of the doctors concerned to see that their premises were compatible with the prestige and status of general practice in the Service.

Dr. BEAUCHAMP said that there were instances in his own city of Birmingham where surgery and waiting-room accommodation was not satisfactory, and in which the doctor concerned had been approached by the local medical committee. He was sure that the local medical committee was the right body to intervene if intervention was necessary.

Dr. WAND said that it must be made clear that it was the doctor's job to keep his premises in decent order. But the maintenance of practice premises was a legitimate expense, and the cost of any improvements might be a matter for discussion between the accountant on behalf of the practitioner and the income-tax inspector.

It was agreed that the letter, after revision, should have the widest publicity amongst general practitioners. It was also suggested that advice should be given to local medical committees on the way in which they could help.

Another draft letter to local medical committees, which was approved, concerned the need for taking the greatest possible care in issuing certificates, and repeated a practi-

tioner's ethical obligations and the rules for the issue of certificates which are required for National Insurance purposes.

Hospital Reports to the Patient's Doctor

It was reported that the Central Consultants and Specialists Committee had considered a resolution of the Representative Body calling for the Ministry to instruct hospitals that on a patient's discharge a preliminary note containing diagnosis and treatment should be sent to the patient's doctor, followed by a complete report, but that after some discussion the committee had decided that action on the lines suggested was not necessary in view of the fact that it was already an instruction to hospital staff to notify general practitioners of the discharge of their patients.

Several members of the General Medical Services Committee declared from their experience that such an instruction was very necessary. Dr. M. SORSBY said that it was not uncommon for a patient to come to the surgery three or four times after his discharge and still no hospital report was available. Sometimes the practitioner had to telephone or write for it, and it was he who always got the back-wash—"Why haven't you got the report?" The patient was inclined to blame, not the hospital officer, but the general practitioner if the report was not forthcoming. It was high time to tell the hospitals that something should be done in this matter. It was not enough to plead changes of staff or shortage of staff.

Dr. HOWIE WOOD said that in his area there was a rule to this effect for house-officers, and as a result G.P.s had had no difficulties. It was of no use making a request; it should be inserted in the terms of service and then it could be enforced.

Dr. WAND said that the Committee should associate itself with the resolution of the Annual Representative Meeting and indicate to the Consultants and Specialists Committee that if they declined to take action the matter would have to be referred to Council as it was a Representative Body decision.

The Committee indicated its accord.

It was agreed that the Consultants and Specialists Committee should be informed to this effect.

Assistants and Young Practitioners

Comment was made on the lack of nominations for the Assistants and Young Practitioners Subcommittee. Communications had been sent to all members on the electoral roll in the five regions, but only two nominations of assistants (one of them received long after the closing date) and three nominations of unestablished principals had been received, leaving five places unfilled.

Some members urged that a letter be sent to assistants and young practitioners pointing out the importance of this committee; others suggested that it looked as though these people were satisfied with their lot.

The CHAIRMAN said that since the subcommittee had been set up it had played a useful part, and it would be regrettable to see it pass out of existence. But unless it was a real subcommittee it would have to be considered at the end of the session whether it should be continued. Before allowing this to happen, however, he suggested that a further letter be sent out, explaining what had happened, and asking again for nominations. This was agreed to.

A.R.M. Resolutions

The Committee then studied the many resolutions of the Annual Representative Meeting which bore upon its work and decided upon appropriate action where such action was required. On the resolution that ways and means be explored to make it easier for general practitioners to change practice it was agreed to set up a small subcommittee to go into the matter. The following were nominated: Drs. Talbot Rogers, Dain, Cardew, Swanson, and Williams.

Other Business

Questions were raised on a communication from the Ministry enclosing a proposed preface to the price lists of proprietaries and corresponding *National Formulary* preparations which was expected to be ready for issue about October 1. Dr. CARDEW pointed out that it was the right of the doctor to prescribe what drugs he thought best for his patient; if a committee were allowed to take these decisions it would form an unfortunate precedent. The CHAIRMAN explained that there was no veto about it. If a doctor could justify excessive or extravagant prescribing, well and good. The Public Relations Officer said that two Members of Parliament with whom he had spoken were under the impression that these lists of preparations had something mandatory about them, and were not aware that a practitioner could justify his use of a "blacklisted" preparation if he needed it.

The Committee agreed to suggest some changes in the wording of the proposed preface, and to keep the matter on the agenda.

The CHAIRMAN mentioned the position of doctors on the Isle of Man. The Secretary of the Association and himself had gone over there to give evidence to a commission examining the income of public servants on the island. If the commission now sitting decided to lower the salaries of the doctors there because of the lower income tax obtaining, it might mean that the British Medical Guild would come to the Trustees of the N.I.D.T. for a proposal for the fullest support of the doctors in resisting such a project.

The Committee considered a letter from the Medical Insurance Agency, together with counsel's opinion, on the setting up of a pension scheme for medical and dental employees, and the manager of the Agency (Mr. Dixon) attended to explain certain points and to give examples of benefit at different salaries. The Committee considered the scheme to be satisfactory and recommended it to Council, but, of course, left to Council the decision as to appointment of trustees.

A subcommittee of ten, with a separate subcommittee for Scotland, was set up to bring forward suggestions in connexion with the evidence to be tendered to the Guillebaud Committee.

The Committee, which assembled at 10.30 a.m., concluded its business at 5.45 p.m.

The B.M.A. in Committee

AMENDING THE ACTS

A measure so revolutionary, and in some respects so unacceptable to the medical profession, which had to work it, as the National Health Service Act obviously presented many points at which, in the light even of a short experience, amendment was desirable, and some of these points in the view of the British Medical Association were fundamental.

A Standing Committee

Quite early the Council set up a committee whose task was to gather together various proposals for reform which could be presented to the Government when an Amending Bill came to be introduced. This, however, was not a policy-forming committee; it took as the basis of its work Association decisions already formulated. Then, in 1950, after the Act had been in operation for two years, the Representative Body, on the motion of Harrow, supported by Marylebone and other Divisions, resolved that the committee in charge of this amending work should have the status of a standing committee. Since then the Amending Acts Committee, as it is called, has done an amount of good solid work.

The Committee consists of six members appointed by the Representative Body and six by the Council. The chairmen of the General Medical Services Committee, the Central Consultants and Specialists Committee, and the Public Health Committee are members *ex officio*, as are the principal officers of the Association.

The Committee's Field

Amending Acts—in the plural. It is customary to speak only of the National Health Service Act, 1946, but there are also the National Health Service (Scotland) Act, 1947, the Health Services Act (Northern Ireland), 1948, and the National Health Service (Amendment) Act, 1949, all of which figure in the Committee's terms of reference. But these Acts are not all; the Committee is also bidden to consider any other amending or replacing Acts, and—a formidable task—all the regulations, directions, and orders made under these Acts.

Under its chairman, Dr. H. H. D. Sutherland, a London general practitioner, the Committee completed within a year its first report on the reform of the Service, and a special meeting of Council was called to examine it. A couple of months later, in December, 1951, a Special Representative Meeting was summoned for the same purpose. It is a testimony to the interpretative powers of the Committee that its long and detailed and fundamental recommendations should have been, with only slight modifications, cordially approved. Thus encouraged, the Committee turned to the second and perhaps more contentious part of its labours, armed with the instruction of the Representative Body to formulate a detailed programme of the reforms which the profession desired to see adopted.

Pattern for Improvement

The Committee, of course, did not begin its labours with a blank sheet of paper. Various committees of the Association had already been concerned with the operation of the Act in different fields of practice and the need for improvement as they saw it. The new Amending Acts Committee collected those views, moulded them into a pattern, and initiated new suggestions for consideration. From the start it was made clear that the Committee did not undertake its work in any spirit of antagonism to a National Health Service Act. Quite the contrary. Its purpose has been to make the Service one in which all sections of the profession can co-operate with the utmost good will. "Improvement," said Froude, "is from within outwards." A body of people who are actually working the Act themselves, and closely in

INVESTIGATION BY DARTFORD DIVISION

The Dartford Division of the B.M.A., concerned about the possible ill effects of cement-dust-laden atmosphere, sent questionnaires to 400 members in its own and other Divisions neighbouring Thames-side cement works. Doctors were asked if they were aware of any evidence of direct or indirect injury to health from heavy deposits of cement dust.

Ninety-four replies were received. Of these, 5% considered that the dust aggravated asthma. Indirect hazard to health, however, was mentioned in 40% of the replies, the mental and physical irritation caused by the dust being instanced. With few exceptions, opinion was that greater effort should be made to control the nuisance.

Ministry Report

The problem of dust emission from cement works in England and Wales is referred to in the annual report of the Chief Alkali Inspector of the Ministry of Housing and Local Government and the Chief Inspector for Scotland published recently (H.M.S.O., price 2s. 6d.). The failure of electrical precipitators for the de-dusting of kiln gases has been a matter for grave concern, but experience gained in the causes of failure should result in better operation. Progress in dealing with low-level dust emissions is reasonably satisfactory.

touch with the feeling of the entire profession, are well fitted to suggest the improvements which will make the Service a success.

The first recommendation put forward at the Special Representative Meeting was for the establishment of a National Health Service Court of Arbitration. This is still a matter of debate with the Government, and the strong views expressed on the subject at the Cardiff meeting will be fresh in the memory. Other recommendations were made for limiting the powers of the Minister, and for putting the hospital administrative service on a more democratic basis. The debate continues, but the Association, with the help of this Committee, has taken the initiative, and the work it has done and will do should shape the permanent National Health Service of the future.

Example from the Past

A parallel may perhaps be found in the earlier history of the Association as a reply to those who may think that when the time comes for an overhaul of the Act it will be dictated by the political circumstances of the moment. Five years after it was founded the Association set up a Medical Reform Committee to watch from the legislative point of view the interests of the profession at large, the reform of medical education, and the status of the practitioner. The committee drafted a Medical Bill, which was not passed into law, and after many negotiations and memorials and frustrations and defeats the Medical Act of 1858 (which set up the General Medical Council) was passed. That Act was in fact almost entirely the work of the Association. It was the first official recognition of the existence of the great body of medical practitioners and their importance to the State, but again it was only an instalment. The Committee was immediately reconstituted, this time as a Committee on Medical Legislation, and it began the Sisyphean task of modifying the Act of 1858. How trying to the patience are these efforts to amend legislation is shown by the fact that in the period of 11 years as many as 20 amending Bills were brought before Parliament, including three which were sponsored by the Government itself. Twenty-eight years had to pass before the Act of 1858 was amended by the Medical Act of 1886.

It may be hoped that the slow motion of the nineteenth century may not be projected into this age of speed, and that the Committee will not have to wait until the mid-seventies for the fruit of its labours.

REMOVED FROM N.H.S. LISTS

TWO TRIBUNAL CASES

The case of Dr. W. F. Cruickshank, of Brechin, was on June 15 brought before the Scottish National Health Service Tribunal on the complaint of the Angus County Executive Council. Dr. Cruickshank conducted his own case.

The findings of the Tribunal were that Dr. Cruickshank, who had been in practice in Brechin for many years and had been on the medical list of the Angus, Aberdeen, and Kincardine County Executive Councils since the beginning of the National Health Service, had not carried on his practice in person since about the end of March, 1953, but had had his patients looked after by various doctors acting as locumtenents. Before that date, during December, 1952, and January and February, 1953, he had often failed without reasonable cause to attend his surgery during consulting hours without any other intimation to his patients than "Doctor gone—No surgery" on a notice on the door or a similar statement by a member of his household. He made no arrangement on these occasions for his patients to be looked after by anyone else.

The Tribunal further found complaints of neglect of four individual patients were proved, though it was satisfied with Dr. Cruickshank's explanation regarding a fifth.

The instances of neglect found proved were that on December 31, 1952, Dr. Cruickshank was told that while he had been

out of the house there had been a telephone call and a personal message asking him to call on a woman patient because she was seriously ill. He neither went to see her nor tried to find out if she was better or had been seen by another doctor, and as a result another doctor had to attend her. A similar message two days later was similarly ignored.

In January, 1953, a patient whom Dr. Cruickshank had seen in the third and sixth months of pregnancy, whom he was to arrange to be confined at home, and whom he knew to be in her ninth month, had a fall. During the month she sent frequent messages to him to go to see her, but he did not tell her what arrangements had been made for her confinement nor did he visit her until after the baby was born on January 28.

On February 21, 1953, Dr. Cruickshank got a telephone message from a nurse who had been called in that a patient of his who was, as he knew, pregnant had had a haemorrhage at her home, and asking him to come and attend her. Both this message and a similar message later in the day he ignored. As a result another doctor was called in and had her x-rayed and admitted to hospital.

On December 26, 1952, Dr. Cruickshank was called to see a patient suffering from cancer who had been discharged from Dundee Royal Infirmary the day before and had to attend hospital daily as an out-patient until January 16, 1953. Both he and his wife repeatedly asked Dr. Cruickshank to come to see him during that time and later because he was in considerable pain, but he did not do so until early February, 1953. The patient subsequently died.

In all these instances the Tribunal found that there was no reasonable excuse for Dr. Cruickshank's behaviour. It regarded the case as serious, and the evidence as disclosing on the part of Dr. Cruickshank a gross neglect over a considerable period of his duties as a medical practitioner under the National Health Service and a wide disregard of the needs of his patients. It believed him to be a potentially capable doctor who, if he applied his mind wholeheartedly to his duties, could be a useful member of the medical profession, but it was satisfied that his continuance on the list was prejudicial to the efficiency of the Service. It accordingly directed his name to be removed, and ordered him to pay the costs incurred by the executive council before the Tribunal.

Alleged Irregular Dispensing

On April 14-15 the English National Health Service Tribunal heard at Carlisle a complaint by the Cumberland Executive Council against Dr. H. A. K. Rowland.

Dr. Rowland, aged 31, qualified in 1945, when he became a house-surgeon at the Radcliffe Infirmary, Oxford. From 1946 to December 21, 1948, he served as a medical officer in the Royal Air Force, attaining the rank of squadron leader. On December 22, 1948, he started practice at Workington in succession to two doctors whose premises there he had already bought, and his name was included in the Cumberland Executive Council lists. He never had any private patients.

In August, 1949, he informed the Cumberland Executive Council that he wanted to open a surgery for his patients in Distington and that he wished to dispense for them. At the request of the council he sent by his wife a list of 244 patients in Distington, and he elected to be paid for dispensing for them on the basis of the Drug Tariff rather than on the basis of a capitation fee. The council duly allowed him to do so.

The complaint against Dr. Rowland was that he had dispensed or submitted to the pricing bureau prescriptions for people who were on his list but for whom he had no authority to dispense, for people who were not on his list and could not be traced, for people who were dead at the date of the prescription, and for people whose names and addresses he had entered illegibly; that he had submitted for payment prescriptions and duplicates divided into more than one script instead of including the whole prescription on one script; that he had submitted for payment prescriptions which he had not actually dispensed; and that he had failed to maintain and render medical records as required by the regulations.

On the evidence before it the Tribunal could not avoid the conclusion that Dr. Rowland had either not dispensed

all the prescriptions he claimed to have dispensed or had prescribed and dispensed recklessly and with no regard to the needs of his patients or his duty as a medical practitioner under the Health Service. It was satisfied that he had deliberately sought to enrich himself improperly and that a large part of the money claimed and received by him had been deliberately claimed and received dishonestly with intent to defraud the council. It also found that he had failed to render at the proper time certain medical returns.

Being of the unanimous opinion that the continued inclusion of Dr. Rowland on the council's list would be prejudicial to the Service, the Tribunal directed the removal of his name, and that it should not be included on the list of any other council under the Act, and ordered him to pay the costs of the inquiry.

Correspondence

Quality in General Practice

SIR,—Sir Lionel Whitby's "pen picture of the ideal medical student" (*Journal*, August 29, p. 451) has received wide publicity in both the medical and the lay press. Perhaps it is not therefore irrelevant to examine the fate under the National Health Service of some of those who closely approach his requirements.

It will be remembered that he envisages one who is "cultured, broadly educated in the humanities, intelligent and intellectual, of transparent integrity, humane, and sympathetic, and above all one who will love his fellow men with [the *B.M.J.* has "and," but I feel this is probably a misprint] all their weaknesses, their joys, and their sorrows." Let me review briefly the careers of three men, who in my opinion and the opinions of others, when measured by this yardstick, can with truth be described as good examples of the type of person Sir Lionel would like to see in the medical profession.

No. 1 had a brilliant career in another faculty before proceeding to the M.B., which he completed at a British university, gaining first or second place in every major subject in the medical curriculum and graduating with honours. No one who knows him would hesitate to describe him as "cultured, intelligent, and intellectual," and I am sure his colleagues and associates would unanimously concede his "transparent integrity." In addition to "sympathy" I feel they would also allow him one quality which Sir Lionel did not mention, but, I venture to suggest, might have included—humility.

Qualifying early in the war, he was commissioned in H.M. Forces, in which he served for five years, and on his return to civilian life he quickly obtained the diploma of the M.R.C.P. (Lond.) at his first attempt. Though well liked and admired by his superiors, he is to-day a "supernumerary senior registrar," and since his appointment is not at one of the main teaching hospitals of the region his professional prognosis is admittedly poor. He has applied for consultant posts in his own and other regions, and, although he is easily the most able man of his specialty and grading known personally to me, he has been uniformly unsuccessful, failing in the great majority of cases even to reach the short-list. Turning his eyes to the alternative of general practice, he has discovered, as have many other senior registrars, that general practitioners do not care to appoint as assistants men with higher qualifications. Thirteen years after graduation he therefore earns about half the salary of the average general practitioner in Great Britain, but lacks his security.

No. 2 I met three years ago when he was a medical registrar. He held the medical degree of one or other (I forget which) of what I believe are known as "the older universities." He also held the M.R.C.P. (Lond.) and had served during the war with H.M. Forces. Broadly educated in the humanities, he possessed sufficient intelligence and intellect to gain a competitive entrance scholarship to his university. Like No. 1, he was both sympathetic and modest, but his appointment was not to a teaching hospital, and, realizing that his prospects in consultant medicine were flimsy, he completed six months as a house-surgeon in a maternity hospital, having already spent six months in a surgical unit, in the hope that he might obtain a post as an assistant in general practice. My last information concerning him was to the effect that he had attained just that.

No. 3 was yet another ex-Serviceman and the holder of the F.R.C.S. (Eng.). I cannot accurately assess the extent of his "education in the humanities," but he was well above the medical average in intelligence and a competent and kindly practitioner of his art. He also held an appointment in a non-teaching hospital, and, realizing the hopelessness of his chances of attaining specialist status, made unsuccessful attempts to enter general practice in a congenial area. A few months ago I learned that he had permanently abandoned the practice of medicine.

If medical students are drawn from "the upper one-third stratum of the normal distribution of intelligence," senior registrars may be said to be drawn from not the least intelligent of medical practitioners in general. Moreover, their "love of their profession" is well attested by their refusal to enter the relatively lucrative field of general practice immediately after the war when vacancies were numerous, preferring to accept ill-paid resident posts in hospital at considerable material sacrifice to themselves, their wives, and families, so that they might become more proficient in a selected field of medical practice.

To-day those labelled "supernumerary" are the inarticulate expendables of the National Health Service. They are the holders of blind-alley jobs from which promotion to higher rank has a rarity that is proverbial. Their attempts to enter general practice are ludicrously pathetic. Not only will few executive councils seriously consider their applications, but "assistantships with view" are almost closed to them unless providence in the shape of a relative or friend lends them the necessary help. Even applications for ordinary assistantships are in the overwhelming majority of cases unsuccessful.

When I was a medical student a senior member of the staff was wont to urge us not to enter general practice too hastily after qualification. He advocated a rotation of hospital resident posts so that one might, as he put it, "learn sound methods which would last one a lifetime." He may have been right, but one thing is clear. Tenure of a rotation of hospital posts will make no impression upon the average executive council, nor will higher qualifications, education in the humanities, culture, intelligence, or intellect. Short-lists are sometimes drawn up without even the assistance of a referee's opinion of the candidate. What is really important is something not taught in medical schools. It is surrounded by an aura of mystery and is shortly to have its own temple and high priests. It is called "general practice" and is apparently something for which the holders of higher qualifications are deemed to be inherently incapacitated.

It was a layman in a medical bureau who told an applicant for a general practice vacancy that possession of a car was more important than possession of an M.R.C.O.G., which he told him significantly would do him more harm than an F.R.C.S., but (consolation!) not so much harm as an M.R.C.P.

Some of us are less alarmed at the admitted need for intellect, intelligence, and broader education among medical students than the overwhelming need for a sense of ordinary justice and decency among certain of our medical colleagues.

—I am, etc.,

Dunfermline.

R. G. WHITELAW.

Sweated Doctors

SIR,—To the letter from Dr. F. L. P. Heber (*Supplement*, September 12, p. 99) I feel that I must voice a reply. In my young days I did three house appointments without any remuneration beyond being boarded and fed free of charge. We worked longer hours and quite as hard as the present house-officers. I do not remember any serious complaints, and many of us went out of our way to do extra work to gain experience. Those who did the latter benefited in after-life indirectly.

The present house-officers are conspicuous by their lack of enthusiasm to do anything outside their contract. This may be the result of the pay which they get, which I think is very high for their ability when first qualified. It has fallen to my lot to select house-officers for many years now.

A few are good, but many are full of theoretical knowledge with little ability to apply this. The recent alteration to the laws has recognized some of this point of view by the pre-registration period.

It seems clear to me from observation that at the end of one year from qualifying the doctor will be really fit to earn a living salary, but before this he should realize that he is only a postgraduate student. It is deplorable to me that any house-officer should start comparing his salary with other hospital employees.—I am, etc.,

Harrow

HAROLD E. THORN.

Justice for the Sassenach

SIR.—It is high time a campaign was launched to allow doctors practising south of the Border some of the privileges granted to doctors in Scotland, in particular the use of Form E.C.10A.

There seems little to justify this unfair treatment of the southerner, which almost amounts to racial discrimination. One can only assume that our legislators were influenced by the never-ending flood of stories of Scottish providence emanating from north of the Tweed.

It would be a gracious act, and one calculated to improve relations between the two countries, if a Minister of Health bearing the name of Macleod would remedy this particular injustice.—I am, etc.,

Calne, Wilts.

ALASTAIR KER JAMES.

Association Notices

SIR CHARLES HASTINGS CLINICAL PRIZE ESSAY COMPETITION

The Sir Charles Hastings Clinical Prize Essay Competition was established by the Association for the Promotion of systematic observation, research, and record in general practice. The Competition has been extended by the addition of a second prize, known as the Charles Oliver Hawthorne Clinical Prize. The following are the regulations governing the awards:

- (1) The Sir Charles Hastings Clinical Prize, consisting of a certificate and 50 guineas, will be awarded for the best essay submitted.
- (2) The Charles Oliver Hawthorne Clinical Prize, consisting of a certificate and 40 guineas, will be awarded for the second best essay submitted.
- (3) Any member of the Association who is engaged in general practice is eligible to compete for these Prizes.
- (4) The work submitted must include personal observations and experiences collected by the candidate in general practice, and a high order of excellence will be required. If no essay entered is of sufficient merit no award will be made. Candidates in their entries should confine their attention to their own observations in practice rather than to comments on previously published work on the subject, though reference to current literature should not be omitted when it bears directly on their results, their interpretations, and their conclusions. It is suggested that essays should consist of from 3,000 to 10,000 words.
- (5) Essays, or whatever form the candidate desires his work to take, must be sent to the Secretary, British Medical Association, B.M.A. House, Tavistock Square, London, W.C.1, not later than December 31, 1953.
- (6) A prizewinner in any year is eligible for an award of either of the prizes in any subsequent year. A study or essay that has been published in the medical press or elsewhere will not be considered eligible for a prize, and a contribution offered in one year cannot be accepted in any subsequent year unless it includes evidence of further work.
- (7) If any question arises in reference to the eligibility of the candidate or the admissibility of his or her essay the decision of the Council on any such point shall be final.
- (8) Preliminary notice of entry for this competition is required, on a form of application to be obtained from the Secretary.
- (9) Each essay, which should be unsigned, must be typewritten or printed and accompanied by a note of the candidate's name and address.
- (10) Inquiries relative to the prizes should be addressed to the Secretary.

Diary of Central Meetings

OCTOBER

- 1 Thurs. Central Consultants and Specialists Committee, 12.30 p.m.
- 2 Fri. Alcohol and Road Accidents Committee, 10.30 a.m.
- 2 Fri. Joint Committee of B.M.A. and the Magistrates' Association, 11 a.m.
- 2 Fri. Registrars Group Council, 2 p.m.
- 6 Tues. Organization Committee, 2 p.m.
- 7 Wed. Committee on the Rehabilitation of Disabled Persons, 10.15 a.m.
- 7 Wed. Private Practice Committee, 11.30 a.m.
- 8 Thurs. Amending Acts Committee, 2 p.m.
- 8 Thurs. Scientific Exhibition Subcommittee, Arrangements Committee (Glasgow, 1954), 8.30 p.m. (at B.M.A. Regional Office, 234, St. Vincent Street, Glasgow).
- 9 Fri. Ophthalmic Qualifications Committee, 1.45 p.m.
- 9 Fri. Ophthalmic Group Committee, 2 p.m.
- 13 Tues. Central Ethical Committee, 2 p.m.
- 13 Tues. Joint Formulary Committee, 2 p.m.
- 14 Wed. Journal Committee, 10.30 a.m.
- 14 Wed. Public Relations Committee, 2 p.m.
- 14 Wed. Staff Side, Committee "C", 2 p.m.
- 14 Wed. Transport Medical Standards Subcommittee, Occupational Health Committee, 2.30 p.m.
- 14 Wed. Arbitration Machinery Committee, 4 p.m.
- 15 Thurs. Dermatologists Group Committee, 2 p.m.

Branch and Division Meetings to be Held

- BRADFORD DIVISION.**—At Royal Infirmary, Bradford, Wednesday, October 7, 8.15 p.m., meeting. Inaugural address by Dr. A. Bigham: "The Early Days."
- COVENTRY DIVISION.**—At Chace Hotel, London Road, Willenhall, Tuesday, October 6, 7.30 for 8 p.m., dinner; first ordinary general meeting. Inaugural address by Dr. J. F. Galpine: "Poliomyelitis, 1953."
- DARTFORD DIVISION.**—At Livingstone Hospital, Dartford, Thursday, October 8, 8.45 p.m., meeting. Lecture by Dr. A. E. Jones: "Radioactive Isotopes in Medical Treatment." To be illustrated by lantern slides.
- DONCASTER DIVISION.**—At Parkinson's Café, High Street, Doncaster, Tuesday, October 6, 7.30 p.m., joint meeting with Doncaster Medical Society. Address by Mr. W. McC. Scott: "Bladder-neck Obstruction."
- EAST HERTS DIVISION.**—At Hertford County Hospital, Thursday, October 8, 8.30 p.m., meeting. Films.
- EAST KENT DIVISION.**—At Chez Laurie Restaurant, Thaxted Way, Herne Bay, Thursday, October 8, 7.30 p.m., dinner; 8.45 p.m., Dr. G. B. Forbes: "Diseases Transmissible from Household Pets to Man."
- KENSINGTON AND HAMMERSMITH DIVISION.**—At Hammersmith Hospital, Ducane Road, W., Wednesday, October 7, 2 p.m., ward visit for general practitioners.
- LAMBETH AND SOUTHWARK DIVISION.**—At Lambeth Hospital, Brook Drive, S.E., Sunday, October 4, 11 a.m., clinical meeting.
- MIDLAND BRANCH.**—At 154, Great Charles Street, Birmingham, Thursday, October 8, 2.30 p.m., meeting.
- NUNEATON AND TAMWORTH DIVISION.**—At Red Lion Hotel, Atherstone, Tuesday, October 6, 8 p.m., supper; 8.45 p.m., meeting.
- ST. PANCRAZ DIVISION.**—At B.M.A. House, Tavistock Square, London, W.C., Tuesday, October 6, 8.30 p.m., meeting. Lecture and demonstration by Dr. Alan Stoddard: "Osteopathic Technique."
- SCARBOROUGH DIVISION.**—At Scarborough Hospital, Thursday, October 8, 8.30 p.m., meeting. Dr. J. D. Dow: "The Evaluation of Radiological Findings in the Alimentary Tract."
- SCUNTHORPE DIVISION.**—At Scunthorpe and District War Memorial Hospital, Friday, October 9, 8.30 p.m., meeting. Address by Dr. F. S. Cooksey: "The Social Adjustment of the Physically Handicapped." Illustrated by photographs of gadgets, kitchen adaptations, etc.
- SOUTH ESSEX DIVISION.**—At Oldchurch Hospital, Romford, Friday, October 9, 9 p.m., clinical meeting.
- TOWER HAMLETS DIVISION.**—At Poplar Hospital, East India Dock Road, E., Friday, October 2, 8 p.m., meeting. Dr. D. Morris: "Some Recent Advances in Paediatrics."
- TUNBRIDGE WELLS DIVISION.**—At Kent and Sussex Hospital, Tunbridge Wells, refresher course. Saturday, October 10, 2.30 p.m., Mr. A. C. H. Bell: "Care of the Pregnant Woman"; 4.30 p.m., Mr. J. H. Peel: "Unexpected Difficulties in Labour"; 9 p.m., "Brains Trust." Sunday, October 11, 10 a.m., Mr. A. J. Wrigley: "The Care of Mother and Child"; 11.15 a.m., Mr. D. H. Macleod: "Common Gynaecological Complaints, Their Diagnosis and Treatment."
- WEST BROMWICH AND SMETHWICK DIVISION.**—At Recreation Hall, Hallam Hospital, West Bromwich, Tuesday, October 6, 8.30 p.m., meeting. Lecture by Dr. H. W. Everley Jones: "Some Recent Paediatric Developments."
- WOOLWICH DIVISION.**—At St. Nicholas' Hospital, Plumstead, S.E., Tuesday, October 6, 8 p.m., meeting. Members of the Greenwich and Deptford Division are welcomed.

CENTRAL CONSULTANTS AND SPECIALISTS COMMITTEE

FIRST MEETING OF NEW SESSION

The first meeting of the new session of the Central Consultants and Specialists Committee was held at B.M.A. House, London, on October 1. Dr. T. ROWLAND HILL and Mr. T. HOLMES SELLORS were re-elected Chairman and Deputy Chairman respectively.

The death was announced of Mr. V. H. Ellis, who had been a member of the Committee since its formation, and the members stood in silence as a token of respect. Mr. C. E. Kindersley and Mr. H. J. McCurich were co-opted to the Committee.

The CHAIRMAN said that Dr. E. E. Claxton, Assistant Secretary, had given up the secretaryship of the Committee. He paid a high tribute, which was endorsed by all the members, to Dr. Claxton's services. His work in helping to build up the organization had been invaluable. The Chairman welcomed in his place Dr. S. J. Hadfield, Assistant Secretary, and complimented him on his recent survey and report on general practice.

The Committee proceeded to appoint its representatives on the Joint Consultants Committee. The following were appointed: Dr. T. Rowland Hill, Mr. T. Holmes Sellors, Mr. H. H. Langston, Mr. D. W. C. Northfield, and Mr. S. F. R. Whittaker, together with one Scottish member to be nominated later. These six became automatically members of the Executive, and as a result of a ballot the following further members were appointed to the Executive: Mr. A. Lawrence Abel, Professor S. J. Hartfall, Mr. J. R. Dr. P. W. Edwards, Professor G. I. Strachan.

The Committee endorsed the reappointment of its sub-committees concerned with junior hospital staff, public and professional relations, and organization. Mr. B. N. Brooke, Dr. R. D. Lawrence, and Professor Strachan, together with a Scottish representative, were appointed representatives on a subcommittee set up by the General Medical Services Committee to carry out an inquiry into the number of students admitted to medical schools in relation to the probable future need for doctors. Dr. D. F. Hutchinson, on behalf of the General Medical Services Committee, said that it was intended that the subcommittee should cover every possible aspect of the situation.

It was decided, in view of the pressure of business, that the Committee should hold all-day meetings in future, beginning at 10.30 in the forenoon.

Senior Registrars

The CHAIRMAN, in reporting on the work of the Joint Committee, said that the view had again been placed before the Ministry that many senior registrars were engaged in the work of a consultant nature, and that, unless additional consultant posts were created, an acute staffing problem would arise when the transitional posts recently approved by the Ministry came to an end in two years' time. The

Committee had therefore suggested that hospital boards should be advised of the necessity of reviewing their staffing arrangements before there was any further reduction in senior registrar posts. The Ministry had replied that there was no need for special action, as the boards would do this as a matter of course.

Mr. H. H. LANGSTON suggested that the Committee might be in a position to help in this respect by pointing out to the Ministry exactly where additional posts were necessary. The information could be collected from the regions, and the need for increasing the establishment in a particular region and in a particular branch of medicine could be pointed out.

A representative of the registrars mentioned one specialty—namely, serology—in which the number of consultants' posts was very small indeed, and the whole pattern of registrar appointments needed examination. The CHAIRMAN promised that all these considerations would be brought before the Joint Committee.

On the question of the medical staffing of casualty departments in the light of the increasing risk of litigation affecting hospital officers, it was stated that the Joint Committee did not oppose the suggested appointment of senior casualty officers with a tenure of up to four years at a salary within the S.H.M.O. range, but would be guided by the work of the subcommittee which had just been set up to study junior staffing problems.

Whole-time and Part-time Service

Some figures were laid before the Committee concerning the number of whole-time and part-time consultants. At the end of last year the number of whole-time consultants was 1,780 and of part-time 4,467. These figures compared with 1,310 and 3,879 respectively at the end of 1949. The percentage of consultants who were whole-time had risen during the last four years from 25.2 to 28.5, the chief increase being in the ancillary departments.

Reference was made in the discussion to the difficulty of the whole-timer becoming a part-timer.

It was stated that the Ministry had again been urged to advise the boards, wherever practicable, to offer candidates for consultant appointments an option for whole-time or part-time service, and that, where such an option was offered, candidates should not be asked for their preference at the time of the interview, as this might appear to be prejudicial to those who had expressed a preference for part-time service.

Domiciliary Consultations

A question arose concerning the statement giving the diagnosis on the domiciliary consultation certificate. There were instances, it was stated, where this information had been abused. The Ministry, while agreeing to look into the matter, had stated that its impression was that the diagnosis was of considerable value to the boards for the purpose of regional planning, and it required further evidence before the certificate was judged to be undesirable.

Mr. STAVELEY GOUGH pointed out that a precise diagnosis on the certificate was not essential. No information which it was undesirable to give need be given.

Mr. LANGSTON said that in his region the strongest objection was taken to putting down the diagnosis, both by consultants and, even more strongly, by general practitioners. It was not regarded as a minor point at all. There had been cases where the forms had been sent back for more exact diagnosis.

Reports to General Practitioners on Discharge of Hospital Patients

Dr. J. D. R. MURRAY, representing the General Medical Services Committee, brought forward the question of reports from hospitals to general practitioners. The Representative Body had urged that hospitals should be instructed that on the day of discharge of a patient a preliminary note concerning diagnosis and treatment should be sent to the patient's doctor, to be followed later by a complete report. The Central Consultants and Specialists Committee, however, had expressed the view that any action on these lines was unnecessary in view of existing instructions, but this was a view the General Medical Services Committee could not accept. In its opinion the Ministry should be asked to impose an obligation upon junior hospital medical staff to issue a report to the general practitioner on the day of discharge or death. Dr. Murray said that there was ample evidence from all over the country of the great difficulty which was being experienced at the present time by general practitioners in getting information about their patients.

In discussion a member suggested that a representative from the local medical committee should have a seat on the medical advisory committee with a view to working out a satisfactory local arrangement. Mr. LANGSTON said that they were well aware that there had been lapses, but he objected to the Ministry being asked to give a directive to hospital medical staffs. Other members said that the trouble was solely due to the shortage of clerical staff. Mr. J. R. NICHOLSON-LAILEY suggested that regional committees should be asked to consider the matter and determine whether local arrangements were satisfactory. Mr. STAVELEY GOUGH said that there was no disagreement on the principle of early notification, but clerical assistance was not always available.

The CHAIRMAN said that he felt that general practitioners, very much aware of their own difficulties, sometimes failed to comprehend the difficulties of hospital medical staffs. The pressure both on consultants and on house officers was very great—infinitely greater than it had been in the past. To increase the difficulties of the doctor in hospital was not the right way to meet the situation. He agreed that the general practitioner must be helped in every way possible by early notification on discharge, but he was not in sympathy with the idea that hospitals should be directed on the subject. He was sure that general practitioners, for their part, would not take kindly to directives given to them by the Ministry of Health. The Committee was sympathetic and would do all in its power to meet the difficulty in a spirit of understanding.

The Guillebaud Committee

The Committee considered a memorandum of guidance to the standing committees of the Association which were invited to prepare evidence for submission to the Guillebaud Committee. A steering committee had been set up under the chairmanship of the Chairman of Council, with the chairmen of the main committees as members, among them the Chairman of the Central Consultants and Specialists Committee. It was agreed to authorize the executive to go into this matter as one of urgency and to report to the next meeting. The Chairman commented on the extremely wide terms of reference of the Guillebaud Committee.

Legal Actions Involving Hospital Staff

A request from the Council to consider the desirability, in view of the increasing litigiousness of the public so far

as doctors were concerned, of establishing a panel of experienced consultants who would be prepared to give their time to the assistance of their younger colleagues in such matters as threatened actions for alleged negligence, was before the Committee.

Dr. S. COCHRANE SHANKS pointed out that in the medical defence and protection societies they had a distinguished group of medical men—consultants, general practitioners, and public health officers—who were well versed in the handling of medico-legal problems, and each of these societies had a medical secretariat of wide experience. These were by far the best people to handle the situation.

Other members expressed themselves to the same effect, and the Committee appeared to be in general agreement.

The Committee proceeded to discuss some twenty other resolutions of the Representative Body, and decided on the appropriate further action in each case. Among the resolutions of the Representative Body which were endorsed by the Committee was one urging that, when dependants of Service personnel who are on hospital waiting-lists remove from one area to another, the length of time that the patient has already been on a waiting-list should be taken into account at the new hospital.

Proposals from the Treasury concerning fees for part-time employment in Government departments were laid before the Committee and referred to the Executive for detailed study and report.

CERTIFICATION

GENERAL PRACTITIONERS' INCREASING DIFFICULTIES

The following announcement has been sent by the B.M.A. to local medical committees:

From time to time isolated instances have arisen where the accuracy of medical certificates given by general practitioners has been called to question, and indeed the validity of the certificates themselves challenged by regional medical officers of the Ministry of Health.

The General Medical Services Committee is in no doubt about the high standards which the vast majority of general practitioners have set themselves in issuing certificates, nor does it dispute the necessity for the Ministry to have a check upon the disbursement of public money, but undoubtedly the increased call for certificates resulting from the National Insurance scheme and the increasing tendency of employers to demand certificates for even short periods of absence has increased the difficulties of general practitioners in this respect.

The Committee feels, therefore, that this is an appropriate occasion upon which to draw the attention of general practitioners to the need for taking the greatest possible care in issuing medical certificates.

First, every general practitioner must conform to certain well-defined ethical obligations when issuing medical certificates, and indeed, in the words of the warning notice issued by the General Medical Council, a certificate must not be untrue, misleading, or improper. In addition, however, lax certification may well lead to investigations by regional medical officers, and the general practitioner is expected to observe certain rules for the issue of certificates which are required for National Insurance purposes. These rules require primarily that every certificate must be in writing in ink or other indelible substance and contain the following particulars:

- (a) the claimant's name;
- (b) the date of the examination on which the certificate is based;
- (c) a concise statement of the disease or disablement by which the claimant is, in the practitioner's opinion, at the time rendered incapable of work;
- (d) the date on which the certificate is given;
- (e) the address of the practitioner.

They also lay down that the certificate shall specify the cause of incapacity as precisely as possible, and that every

certificate must be given on a date not more than a day later than the examination upon which it is based.

It is, in the Committee's view, of the greatest importance that the public should have a proper respect for the value of certificates which are issued by general practitioners, and it is hoped that local medical committees will, in their areas, from time to time draw the attention of practitioners to their statutory and ethical obligations in this matter, and take up on their behalf any cases where it would appear that unreasonable demands have been made.

PRACTICE PREMISES

CALL FOR HIGHEST POSSIBLE STANDARDS

The following letter from the Chairman of the General Medical Services Committee has been sent to every general practitioner in the National Health Service:

When the Minister of Health addressed the Annual Conference of Local Medical Committees in June this year, he paid tribute to the unique position of the general practitioner as the leader of the clinical team in the health field.

The General Medical Services Committee has expressed considerable satisfaction at this public recognition of the general practitioner's work, and it feels that everything possible should be done to maintain and enhance the status of this section of the profession.

One important factor which in the mind of the public reflects directly on the status of the individual doctor is his surgery and waiting-room accommodation, and, although in spite of post-war difficulties the general standard is of a high order, a number of general practitioners have, by reason of building restrictions and the high cost of repairs and maintenance, been prevented from doing all that they would have wished in this respect.

Under his terms of service a practitioner at his own expense "is required to provide proper and sufficient surgery and waiting-room accommodation for his patients having regard to the circumstances of his practice." Any member or officer of the executive council or the local medical committee can, under the regulations, be authorized to inspect the accommodation provided and to report upon it.

It is clear from recent questions and answers in Parliament that attention is likely to be focused upon isolated cases where the standard of accommodation falls short of what is desirable, and the General Medical Services Committee is anxious to forestall any criticism which might arise.

A doctor's remuneration in the National Health Service takes into account his obligation to provide suitable premises, and it remains his personal responsibility to provide them at his own expense.

For a number of reasons the Committee now feels that it should invite individual doctors to review the surgery and waiting-room accommodation in their practices.

First, there has been some general relaxation in building restrictions. No licence is now required for building work up to £500, and all development charges under the Town and Country Planning Act have been abolished.

Secondly, the widespread establishment of health centres no longer seems likely, at any rate for some considerable time to come.

Thirdly, as a result of the Danckwerts award, general practitioners may now feel themselves to be in a better position to embark upon expenditure of this nature.

Fourthly, the practice expenses ratio established by the Danckwerts award includes a substantial element in respect of the cost of maintaining surgery premises. In this way the amounts allowed as legitimate practice expenses by the Inland Revenue authorities by way of depreciation, repairs, and renewals, etc., are reflected in the net amount of the Central Pool. Thus a practitioner who continues to maintain practice premises of a substantially lower standard than that of his colleagues derives an unfair financial advantage.

The Committee is convinced that it would be neither practicable nor desirable to attempt to lay down any minimum standards, since conditions of practice must vary widely in different parts of the country. It believes that any necessary improvements in the standard of accommodation provided should develop spontaneously from a wish by the individual doctors concerned to ensure that their practice premises are compatible with the prestige and status of general practice in the Service, and as such will enable them to give of their best to their patients.

This is the concern of all doctors wherever they practise, whether in partnership or alone. It is separate from, and should not be confused with, certain arrangements now under discussion which are intended, in approved cases, to encourage group practices.

The Committee earnestly hopes that every general practitioner will do his utmost to provide the highest possible standard of surgery and waiting-room accommodation for his patients. Local medical committees, local executive councils, and local housing authorities are always ready to offer advice and guidance in any way possible, and, in any particularly difficult cases where the aid of the Ministry or the Department of Health for Scotland would be useful, the Committee has been assured that it will be readily forthcoming.

Correspondence

General Practice

SIR,—Dr. Stephen J. Hadfield is to be congratulated on his fine service to the purposes for which he undertook "A Field Survey of General Practice, 1951-2" (*Journal*, September 26, p. 683). Yet most general practitioners who read his remarkable document will surely feel that, whatever purposes inspired him, Dr. Hadfield has, like the compiler of Domesday Book, painted a lively and penetrating picture from the life of his time. In years to come those for whom history is not merely photographic or statistical will here light upon a composite drawing of medical life in the early days of the National Health Service—a composition which for all its wealth of picturesque detail never for a moment creates any doubt as to its author's sincere devotion to fact-finding research.

No ordinary professional contacts can give such insight or afford the general practitioner this wonderful view of himself and his colleagues. In assembling a wealth of character and circumstance under appropriate headings Dr. Hadfield is all the time introducing us to individual doctors. One may not exactly recognize oneself amongst these, and yet may marvel at how much one has in common with the lot. For as you travel round with Dr. Hadfield he inevitably fits you into his picture.—I am, etc.,

Eye, Suffolk.

J. SHACKLETON BAILEY.

SIR,—Your "General Practice" number (September 26) contains comprehensive, if restrained, comments on the whole field of G.P. work and provides material for many long letters, some of which you will no doubt receive. Meanwhile, may one be permitted three comments?

First, Dr. Stephen J. Hadfield, in his admirable article (p. 683), suggests that 92% of general practitioners are "adequate or better than adequate." Faint praise. The tone of his article suggests to me that his standard of adequacy could justifiably be set rather higher. When one remembers that the doctors interviewed knew they were the subject of a critical survey, and therefore likely to be on their best behaviour, his figure of 92% becomes a trifle optimistic.

Secondly, practice is exactly what the doctor makes of it, and patients behave just as their family doctor has trained them to. The man whose patients come to him only for a letter to hospital is only reaping the lack of trust engendered by years of poor medicines, for patients naturally

rely on their doctor, while he who refuses to do minor surgery, etc., unless he is paid for every stroke has only himself to blame if practice becomes a wearisome unvarying grind.

Finally, the phrase "lack of time" recurs again and again to explain the G.P.s' failure to attend postgraduate classes, keep records, co-operate with each other, etc. Surely this is not an acceptable excuse. It must be realized that to take advantage of recent advances more time must be given to each patient even than 10 years ago. Of all members of the profession the general practitioner is best able to adjust the amount of work he does to a reasonable level. There is no need for any G.P. to be overworked, least of all for financial reasons. I believe that the desire to keep on increasing income accounts for many of the evils of practice to-day, and is entirely responsible for the difficulty in entering general practice.—I am, etc.,

Petts Wood, Kent.

H. P. HILDITCH.

SIR,—Presumably Dr. Stephen J. Hadfield's "Field Survey" (*Journal*, September 26, p. 683) and the postal inquiry (*Supplement*, September 26, p. 105) were meant to give a picture of general practice in Britain to-day. If so, the picture is incomplete. Why was no attempt made to find out what the all-too-many assistants think of the Health Service?

No one asked them about their fears or frustrations, their anxieties or their hopes for the future. Dr. Hadfield must surely have met them in his travels, even though it may have been in the presence of their principals; in such a situation they might, wisely, have had little to say, for assistantships are not easy to come by these days, even in the Welsh mining valleys or industrial Lanarkshire.

I suggest that a postal inquiry among assistants might reveal the seamier side of practice in this country. It could start by asking how many jobs the assistant has had since he began in practice, and how many assistants had had his job before him. From there it could easily lead on to broken promises about partnerships and such minor abuses. Assistants would not like to see their names in print, but by post they could remain anonymous. There should be no difficulty in getting in touch with them, as every executive council holds a list of their names. I am sure their answers to a properly chosen set of questions would alter some of the conclusions reached in your issue of September 26.—I am, etc.,

Wellington, Salop.

W. J. REILLY.

Branch and Division Meetings to be Held

ALDERSHOT AND FARNHAM DIVISION.—At Aldershot Civil Infectious Diseases Hospital, Redan Road, Aldershot, Tuesday, October 13, 8.30 p.m., annual general meeting.

BLACKPOOL AND FYLDE DIVISION.—At Savoy Hotel, Blackpool, Wednesday, October 14, 7.15 p.m., dinner; 8.30 p.m., Mr. W. Lamont: "The Arthritic Knee Joint."

CITY DIVISION.—At Woodberry Down Health Centre, Green Lane, N., Tuesday, October 13, 7.30 p.m., Centre open for inspection; 8.30 p.m., meeting.

CROYDON DIVISION.—At 43, Wellesley Road, West Croydon, Tuesday, October 13, 8.30 p.m., general meeting. Address by Mr. A. M. Macarthur: "A Review of Cardiac Surgery."

DEWSBURY DIVISION.—At General Infirmary, Dewsbury, Friday, October 16, 8.30 p.m., meeting. Dr. W. Yeoman: "The Home Treatment of the Rheumatic Patient."

GUILDFORD DIVISION.—At Royal Surrey County Hospital, Guildford, Thursday, October 15, 8.30 p.m., meeting. Dr. W. J. O'Donovan: "Drug Eruptions New and Old."

HAMPSTEAD DIVISION.—At Hampstead General and North-West London Hospital, Haverstock Hill, N.W., Wednesday, October 14, 8.30 p.m., meeting. Mr. J. C. R. Hindenach: "The Orthopaedic Disabilities of the Lower Limb in Childhood."

HASTINGS DIVISION.—At Royal East Sussex Hospital, Tuesday, October 13, 8.15 p.m., meeting. Address by Dr. W. E. Davidson: "Origin, Progress, and Future of General Practice."

HENDON DIVISION.—At Hendon Hall Hotel, London, N.W., Tuesday, October 13, 8.45 p.m., meeting. Sir Gordon Gordon-Taylor: "In Retrospect." Illustrated by lantern slides.

KENSINGTON AND HAMMERSMITH DIVISION.—At Hammersmith Hospital, Duane Road, W., Wednesday, October 14, 2 p.m., ward visit for general practitioners.

KINGSTON-ON-THAMES DIVISION.—At Kingston Hospital, Wolverson Avenue, Kingston-on-Thames, Tuesday, October 13, 8 for 8.30 p.m., meeting. Dr. Robert Forbes: "Recent Developments in Medical Litigation."

NORTH OF ENGLAND BRANCH.—At New Lecture Theatre, Royal Victoria Infirmary, Newcastle-upon-Tyne, Thursday, October 15, scientific meeting—7.15 p.m., Clinical demonstration by Mr. F. Denis Hindmarsh: "Problems of Varicose Ulceration"; 8.45 p.m., address by Dr. R. Bodley Scott: "Enlargement of the Lymph Nodes."

NORTH MIDDLESEX DIVISION.—At North Middlesex Hospital, Silver Street, Edmonton, N., Tuesday, October 13, 8.30 p.m., local conference on tuberculosis. All members of the Liaison Subcommittee are invited.

NORTH-WEST WALES DIVISION.—At Royal Hotel, Capel Cerrig, North Wales, Saturday, October 17, 7.30 for 8 p.m., informal dinner followed by two films: (1) Senile Obliterative Arteritis of the Legs; (2) Management of Normal Labour.

ROCHDALE DIVISION.—At Kingsway Hotel, Rochdale, Monday, October 12, 8.30 p.m., meeting. Dr. Basil Wolman: "Problems of the Newborn."

SOUTH MIDDLESEX DIVISION.—At Red Lion Hotel, Hounslow, Wednesday, October 14, 7.30 for 8 p.m. Informal supper with pharmacists, followed by a discussion to be opened by Mr. Harold Moss, president of the Thames Valley Pharmaceutical Association.

SOUTH-WEST ESSEX DIVISION.—At Connaught Hospital, Orford Road, Walthamstow, E., Tuesday, October 13, 8.30 p.m., meeting. B.M.A. lecture by Mr. J. Bentley: "Recent Advances in Vascular Surgery."

SUNDERLAND DIVISION.—At Royal Infirmary, Sunderland, Friday, October 16, 8 p.m., meeting. Address by Dr. Robert Forbes: "Medical Litigation."

SWANSEA DIVISION.—At Morriston Hospital, Swansea, Thursday, October 15, clinical meeting.

WANDSWORTH DIVISION.—At St. James' Hospital, Balham, Wednesday, October 14, 8 p.m. Cocktail party.

WEST HERTS DIVISION.—At The Avenue Clinic, Watford, Tuesday, Wednesday, and Thursday, October 13, 14, and 15, 4.30 to 5.30 p.m., periods for general practitioners to meet health visitors in area.

Meetings of Branches and Divisions

NORTH STAFFS DIVISION

The North Staffordshire Division celebrated its Golden Jubilee on September 24. A most successful and well-attended B.M.A. lecture was given by Mr. T. Holmes Sellors entitled "The Diagnosis and Treatment of Cancer of the Lung."

In the evening a Jubilee Dinner took place at the North Stafford Hotel. It was attended by 147 members and friends. The toast of the B.M.A. was proposed by Mr. P. T. Bowcock, president of the North Staffordshire Law Society, and responded to by Mr. J. W. Tudor Thomas, President of the B.M.A. The health of the Division was proposed by Dr. S. Wand, Chairman of the Representative Body, and the response was from Dr. Peter Edwards, chairman of the North Staffordshire Division. The toast of the guests was proposed by Dr. H. J. Browne, vice-chairman of the North Staffordshire Division, and Dr. A. B. Davies responded. Dr. A. Macrae, Secretary of the B.M.A., and Dr. E. E. Claxton, Assistant Secretary, also spoke on behalf of the guests.

GRADING OF S.H.M.O.s MINISTRY REFUSES TO ALLOW FURTHER REVIEW OF CASES

At the Annual Representative Meeting in July, 1952, considerable disquiet was expressed about alleged injustices following the review of S.H.M.O.s which had taken place some months earlier, and a plea was put forward that there should be a right of appeal to some central body against decisions of the review committees. As a right of appeal had previously been refused by the Government the Central Consultants and Specialists Committee did not feel that any useful purpose would be served by pursuing the matter, but the Committee gave an undertaking that it would raise individual cases of apparent injustice with the Ministry.

The Committee subsequently examined the claims of those S.H.M.O.s who had expressed dissatisfaction with their grading, and sought advice from independent sources. As a result the Committee was satisfied that there was prima facie evidence for suggesting that in certain cases injustice had been done, and these cases were brought to the notice of the Ministry. The Ministry replied that the status of all of the doctors originally graded as S.H.M.O.s had been thoroughly reviewed on more than one occasion, and that it was clearly understood that the review at the end of 1951—the machinery for which had been agreed with the Joint Committee—would be the final approach to the problem. The Ministry stated that it was always ready to satisfy itself that in any particular case the proper arrangements had been made for the review of grading, and it had ascertained that in each case to which its attention had been directed the fullest consideration had been given by a committee which was expert, locally informed, and constituted in the agreed manner. The Ministry thought that no central appeal committee could enjoy all these advantages, and it saw no reason, therefore, for reopening the question.

The matter was thereupon taken up by the Joint Committee, which informed the Ministry that, while it did not doubt that the review committees had been properly constituted, it did not feel that the possibility of error should be ruled out. The Joint Committee stated that in its view the cases to which the Central Consultants and Specialists Committee had drawn attention provided evidence of mistakes in grading sufficient to justify further investigation, and it urged that they should be examined again.

The following reply has now been received from the Chief Medical Officer of the Ministry of Health:

"I promised to consider further your suggestion of an informal meeting, with documents, to discuss the grading of certain senior hospital medical officers. I have now done so in the light of what was said at that meeting, and on previous occasions when we have discussed these matters of grading."

"I must say, after the fullest consideration, that we are unable to accept the suggestion of a further review of these gradings. The review in 1951 was entrusted, with the agreement of both sides, to specially constituted professional committees and was accepted by both sides as final. I cannot see how we could justify questioning the decisions of these committees which were made on that understanding, and have now been put into practice. It seems to me it would greatly increase the difficulty of ever making any settled arrangements, if matters so definitely and finally decided could be reopened."

OCCUPATIONAL HEALTH SERVICES

The first meeting of the new session of the Occupational Health Committee was held at B.M.A. Headquarters on September 30. Dr. J. A. L. VAUGHAN JONES, on taking the chair, to which he had been re-elected, said that during last year the Committee had experienced difficulties and had not accomplished as much as was hoped. He trusted that this year they would achieve a considerable degree of unanimity and move forward. He welcomed the following new members of the Committee: Dr. J. J. O'Dwyer (nominated by the Association of Industrial Medical Officers), Dr. M. E. M. Herford (nominated by the Association of Certifying Factory Surgeons), Dr. J. M. Campbell, Dr. A. P. Robertson, Dr. F. Lishman, and Dr. Llywelyn Roberts (appointed by the Representative Body, the Council, the General Medical Services Committee, and the Public Health Committee, respectively).

The Planning, Remuneration, Occupational Dermatitis, Transport Medical Standards, and the D.I.H./D.P.H. Subcommittees were reappointed.

Ethical Rules for Industrial Medical Officers

The Committee proceeded to consider the decisions taken at the Annual Representative Meeting relating to industrial health. One of these decisions was that the ethical rules for industrial medical officers should be specifically brought to the notice of all such officers, whether members of the Association or not, and that the Representative Body hoped that such rules would be scrupulously observed.

It was suggested that, to give effect to this, an approach might be made through the honorary secretaries of Divisions, or that it would be sufficient to republish the rules in the *British Medical Journal*. It was pointed out that the majority of the people affected by these rules would be general practitioners engaged part-time in industrial medicine, and the difficulty of compiling any complete list was stressed. The compilation of a register of all those engaged in industrial medicine was urged. It was felt that, while information might be obtained from the Ministry of Labour about Appointed Factory Doctors, information about other sections in this branch of medicine must necessarily be incomplete.

It was agreed to recommend to Council that the rules should be brought to the attention of those concerned by publication in the *Journal*.

Private Certificates for Fitness

Another motion of the Representative Body which led to some discussion was that medical certificates required for fitness to undertake employment should be obtained from the independent medical referee at the expense of the prospective employers. It was pointed out in the Committee that, theoretically, the cost should be borne by the person applying for the job. Only if the man was already employed and the employer wanted a certificate in connexion with superannuation or some other matter should the cost of the certificate properly fall on the employer.

It was decided to ask the General Medical Services Committee for its interpretation of the precise meaning of the resolution.

A similar matter arose on a report from the Consultants and General Practitioners Liaison Committee, which stated *inter alia* that members of hospital medical staffs are not entitled to charge fees for examining and reporting upon prospective employees referred to them at hospital by general practitioners.

It was decided that this was not a question for the Occupational Health Committee, but one for the consultants, if they thought it desirable, to take up with the appropriate authorities. It was the general view of the Committee after discussion that no improvement in the position could be achieved without a new regulation.

Advisory Councils on Occupational Health

Attention was drawn to a letter from the Burton and District Advisory Council on Occupational Health which stated that nine councils would support the convening of a joint conference of advisory councils, and it was desired that such a conference should be sponsored by the British Medical Association. The holding of a conference had been considered by the Occupational Health Committee and the Council in 1951 and again in 1952, but had been withdrawn owing to financial considerations. The CHAIRMAN said that unless something was done the movement might collapse. It was agreed to recommend to the Council that such a conference, sponsored by the British Medical Association, should take place in the early part of next year.

Future of Occupational Health Services

The Committee then entered upon a long consideration of the already debated document—the memorandum on the future of occupational health services—on which some differences had arisen between the Committee and in particular the Public Health Committee. The comments of the latter and of other committees of the Association were brought forward. The CHAIRMAN said that he did not propose to allow discussion on the question of continued treatment at the factory. They were bound by the resolution of the Annual Representative Meeting: "That the Representative Body cannot agree that industrial medical officers should be permitted to undertake continued treatment of workpeople, and instructs the Council not to depart from the rules at present in operation."

If continued treatment went on in the factory it must do so only in consultation with the general practitioner.

In further discussion it was suggested that in any working population at least 10% were unaware of the name of their general practitioner; one member said that at one large works known to him he would be surprised if 80% of the workpeople had their cards in order. The CHAIRMAN, however, maintained that as 97% of the people of the country were registered with a doctor it was inconceivable that more than a small proportion did not know who their family doctor was.

Eventually it was agreed that the relevant passage in the memorandum describing the functions of an occupational health service should read: "treatment for minor conditions, in agreement with the general practitioner, in order that the worker may be enabled to continue at work." There were two dissentients.

Development of the Service

On the question of the development of the service, the general feeling of the Committee—each member being asked individually for his opinion—was that this should be encouraged independently of the National Health Service, but co-ordinated with it. One member pointed out that industry comprised so many varying factors, including the varying size and character of firms, that it would be very difficult to get a service going on what might be called a political basis.

The CHAIRMAN said that there had been active discussions in which some had expressed themselves in favour of development in conjunction with the National Health Service, but the general opinion was in favour of independent development, because it was feared that if occupational health became part of the larger service it would be a very minor part.

After some further discussion and consideration of amendments the revised document was generally agreed and will be submitted to Council.

It was agreed to set up a committee to consider the evidence to be given on behalf of the Association to the Departmental Committee which has recently been appointed by the Minister of National Insurance to review the provisions of the Industrial Injuries Act under which benefit is paid for diseases and for personal injuries not caused by accident.

SCOTTISH COMMITTEE JUBILEE

To celebrate the fiftieth anniversary of the founding of the Scottish Committee at Swansea in 1903 the Scottish Committee held a dinner at B.M.A. Scottish House, Edinburgh, on October 9. Advantage was taken of the occasion to entertain a number of prominent representatives of public life in Scotland, the guest of honour being the Secretary of State for Scotland, the Rt. Hon. James Stuart. The Committee was also glad to have the opportunity to do honour to the President of the Association, Mr. Tudor Thomas, and the Secretary, Dr. A. Macrae, whom they had not previously had a chance of welcoming since his appointment to the office. Other medical guests included Sir David Campbell, president of the General Medical Council, Dr. Mary Esslemont, president of the Medical Women's Federation, Dr. E. A. Gregg, Chairman of Council, and Dr. S. Wand, Chairman of the Representative Body.

The Very Rev. Dr. Charles L. Warr, Dean of the Thistle and Chapel Royal, proposed the toast of "The British Medical Association." The National Health Service, he said, would demand much of doctors in the coming years. It would require vision and patience and adaptability. He thought it must be accepted that the Health Service was an inevitable concept of modern society, and it was here to stay. It was up to everyone to make it the best health service in the world, staffed by the best general practitioners, consultants, and specialists. Dr. E. A. Gregg, Chairman of Council, replied to the toast and said it was

the Association's determined intention to see that the quality of the Health Service was of the highest.

The health of "The Guests" was proposed by Dr. J. B. Miller, Vice-President of the Association and an ex-chairman of the Committee. Mr. James Stuart replied on behalf of the lay guests and Dr. Macrae on behalf of the doctors. Mr. Stuart was one of several speakers who referred to the good relations existing between the Department of Health for Scotland and the Scottish Committee. He thanked the B.M.A. for these friendly and helpful relations, and he trusted they would continue. He assured the medical profession that he would do everything to maintain and foster these friendly relations.

Dr. S. Wand, Chairman of the Representative Body, proposed the health of "The Scottish Committee," and Dr. J. G. M. Hamilton, chairman of the Committee, replied. He said that the premises of Scottish House were now stretched to the limit, but plans for reconstruction had been made. They had been postponed, but the Scottish Committee hoped it would not be necessary to carry the postponement much further.

PARTNERSHIP CHANGES AND INCOME TAX

A CHANGED OPTION

Since income tax on profits is payable for one year on the basis of the amount of the profits of the previous year, a rule is needed on the liability for the year in which the person ceases to be entitled to the income—for example, when a business or practice changes hands. The normal rule is that the assessment for the last financial year—or part of that year—is made on the amount of the profits of that period, and that the assessment for the penultimate financial year can also, at the option of the Revenue, be adjusted to the amount of the profits of that year. There is a special rule applicable to the case where the change in proprietorship is not a simple transfer of the business or practice from A to B, but results from a change of personnel by the addition or withdrawal of a partner. As many medical practices are carried on in partnership, this rule is of some importance to doctors, and a change effected by Section 19 of the Finance Act of this year is explained here.

The special feature is that, in the case of a change in proprietorship arising from the entry or departure of a partner, the Income Tax Acts give an option to the group concerned: the choice is whether the practice is to be regarded (a) as having ceased and been recommenced at the date of change, or (b) as a continuing practice. This option still applies, but, whereas up to the present year non-exercise of the option resulted in the practice being treated as continuing, the reverse now applies. Thus, unless the option is exercised, the practice will now be regarded as having ceased and been recommenced. The choice may affect materially the amount of tax payable for two or three consecutive years, and there might be a conflict of interest between the individuals concerned. It may help to make the matter clear if one or two types of case are explained in some detail.

Two Cases

The simplest case is perhaps that of a sole proprietor of a practice who takes his assistant into partnership. Then the assistant's remuneration—including his car allowance if any—prior to his entry into partnership will have been treated as an expense of the practice, and the assessment for the following year will, to a greater or less extent according to the relevant dates, be based on the earnings of one practitioner only, though it will cover the liability of both practitioners. In such a case the continuing procedure is preferable, and failure to exercise the option will now affect adversely both partners.

Again, if the profits of the practice are rising, it will be to the advantage of all concerned to adhere to the previous

year's basis of assessment and therefore to exercise the option for the continuing basis. If, on the other hand, the profits have been falling in the recent past but may be expected to rise in the near future, there may well be a conflict of interest. An outgoing partner would gain by the cessation alternative—involving *ex hypothesi* a reduction of his liability for the final year—whereas the new firm's choice might be for the continuing basis. The option must be a unanimous one exercised by all the individuals concerned, outgoing as well as incoming partners, and such cases will obviously have to be dealt with by mutual arrangement between them.

The option, when exercised, is to be given by notice signed by all the persons concerned and sent to the inspector of taxes at any time within 12 months after the date of the change in proprietorship.

FAR TOO MANY REGULATIONS

SENSIBLE USE OF N.H.S.

Far too many regulations govern the work of the executive councils, said Mr. Macleod, Minister of Health, last week. He was speaking at the annual meeting of the Executive Councils Association (England), and added, "I hope we may one day reach a state when the Department issues general guidance that executive councils interpret and adapt to local conditions in the light of common sense."

The cost of prescribing at £46,300,000 a year, he continued, was prejudicing many other most urgent developments in the National Health Service. Executive councils might explain to the public the importance of using the Health Service sensibly and point out that patients must not expect doctors to prescribe for them whatever they thought they ought to have. In particular, household remedies for self-medication were things patients were expected to buy for themselves.

Growing Co-operation

Special reports from local health authorities had shown growing co-operation between general practitioners and these authorities. The build-up of clinical teams which would give the general practitioner the same kind of ancillary help as was available to doctors in hospitals necessarily took time, but he thought it was developing satisfactorily. In evidence he gave a number of examples:

At York three general practitioners asked for midwives to be allocated to attend antenatal clinics run for their own patients in their own surgeries, and this has been arranged.

At Wolverhampton a co-ordinated scheme of antenatal care based on a somewhat similar procedure had been agreed between the local health authority and the local general practitioners.

At Gloucester a special nursing service had been provided to relieve general practitioners of night visiting in order, for example, to give subcutaneous injections.

In Staffordshire a scheme was now in operation whereby the general practitioner referred any chronic-sick case which he considered could not be nursed at home to the area medical officer, who then tried to arrange for the patient to stay at home through the provision of home nurses and home helps. This had resulted in many patients being nursed at home who would otherwise be removed to hospital.

The Minister said he would like to see social workers as members of the general practitioner's clinical team—particularly valuable in helping him to care for unmarried mothers, handicapped persons, and old people.

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

Metropolitan Borough Councils.—Fulham, Southwark.
Non-County Borough Councils.—Crewe.
Urban District Councils.—Houghton-le-Spring.

CHEMICALS THAT CAN BE PRESCRIBED

The Minister of Health has decided that the following diagnostic reagents are chemicals that may be prescribed by general practitioners: Dick test, protein sensitization test solutions. Schick test, tuberculin tests (Koch test, Mantoux test, patch test, diagnostic jelly).

The chemical reagents that may already be provided are the following: Benedict's solution (qualitative), diagnostic solution (tablets of copper), Fehling's solution, Gerhardt's reagent, indicators required for measurement of pH of urine, litmus papers, Rothera's reagent, and strong solution of ammonia.

Notes and News

Exchange of Hospitality.—A Swiss dentist would like his daughter, aged 19, to live with an English family for a time in order to learn the language, and in return offers hospitality to an English girl in his home at Vevey. Would anyone interested please communicate with Dr. H. A. Sandiford, International Medical Visitors' Bureau, B.M.A. House, Tavistock Square, London, W.C.1?

Hospitality Wanted.—A French doctor's daughter, aged 20, would like to live *au pair* with a doctor's family in this country for a year, and in return for hospitality would teach Italian, or Italian and French, but not French alone, as she wishes to keep up her knowledge of Italian as well as perfecting her English. Would anyone interested please write to Dr. H. A. Sandiford, International Medical Visitors' Bureau, B.M.A. House, Tavistock Square, London, W.C.1?

Correspondence

Because of the present high cost of producing the Journal, and the great pressure on our space, correspondents are asked to keep their letters short.

Senior Registrar Problem

SIR,—May I be allowed to correct an error which appears in your report of the meeting (October 1) of the Central Consultants and Specialists Committee (*Supplement*, October 10, p. 163)? During the discussion on the senior registrar problem I pointed out that the recent establishment of "transitional" senior registrar posts has given a breathing space of two years, during which a final solution to the problem must be found. As we have stressed in the past, this can only be achieved satisfactorily by expansion of the consultant establishment so that those senior registrars who are doing consultant work can be replaced by consultants. If steps in this direction are not taken within the near future there will be yet another crisis in eighteen months' time. At the same time I expressed the view that the agreed senior registrar establishment of 960 does not appear to be closely related to future consultant vacancies, particularly in certain specialties, and needs to be reviewed. Serology, as mentioned in your columns, was not among the specialties I quoted; but in such branches as cardiology, neurology, and others there appear to be far too many registrars in training, very few of whom can hope to succeed to the very limited consultant vacancies which seem likely to occur in these subjects.

Now is no time for complacency. The Ministry's recent action has averted a serious crisis, but further steps must be taken soon if the problem is finally to be solved.—I am, etc.,

JOHN N. WALTON,
Late Chairman, Registrars' Group, B.M.A.

The General Practitioner and the Hospital Service

SIR,—The articles in your issue of September 26, on general practitioners and the hospital services, by Sir Heneage Ogilvie (p. 707) and Dr. J. G. M. Hamilton (p. 711), and your editorial comments thereon (p. 719), gave great satisfaction here. The fact that three-quarters of the practitioners in the country are obliged to do their work without any hospital beds under their care is an anachronism that must be remedied if we are to have a first-class service in the future. The point is well made by both contributors that further beds in a large hospital present almost insuperable administrative difficulties, and the alternative method of setting up a large number of small local or "neighbourhood" hospitals, staffed by the local doctors, with visiting consultants, would seem the ideal and indeed the only solution.

How satisfactory that arrangement is can be testified to by all those—alas, only a minority of our profession—who have had the happiness to work in such an institution. The ability to discuss a difficult medical case at the bedside with the consultant, and personally to carry out the treatment he recommends; to assist at operations, and see for oneself the condition found; to treat some of one's patients as one did as a house-officer, with a consultant's guidance; to have x-ray and laboratory facilities, skilled nursing, and all the resources of a modern hospital at one's command—these are an inestimable refreshment, and cannot but result in an enhanced interest and efficiency in one's work. Such an arrangement furnishes a happier professional life for the doctor, and consequently a better standard of service to the patients he attends in his practice outside.

These things we in this district lost three years ago, but hope soon to have them back by means of a new local hospital set up by voluntary effort. What encourages us greatly now is the belief, borne out by your contributors and your leading article, that the importance of the small local practitioner hospital is really becoming recognized, and, instead of being gradually, by one pretext or another, shut down or converted to other use, as was their probable fate a very short time ago, it now seems possible that existing ones may be cherished and new ones set up as part of a healthier Health Service everywhere.—I am, etc.,

Kingston-on-Thames.

F. B. LAKE,
Chairman, Kingston and Malden Victoria
Medical Foundation.

SIR,—As one of those concerned in the fight three years ago to retain the Kingston Victoria as a general-practitioner hospital, I read your issue of September 26 with considerable interest.

It seemed to us at that time that the general-practitioner hospital, with consultant staff in regular attendance, was the only practical way in which to avoid that divergence of the great branches of our profession which is now causing so much concern, and to prevent each branch from working in splendid isolation to the detriment of our patients and ourselves.

I was therefore very encouraged to find our views upheld by two eminent writers—Sir Heneage Ogilvie (p. 707) and Dr. J. G. M. Hamilton (p. 711), who advocate the setting up of hospitals throughout the country of a type similar to the Kingston Victoria. There, local patients were attended throughout by their own doctors in close association with the consultant staff. This was very greatly appreciated by the patients and was a source of considerable pride in the neighbourhood.

The passing of this hospital was bitterly regretted, and energetic endeavours are being made to replace it by a new voluntary hospital on the same lines. Much as we wish these endeavours to succeed, however, we should find even greater satisfaction if professional and public interest in this very important matter could persuade the powers that be to reverse their policy by making general-practitioner hospitals an essential part of the hospital service of the country.—I am, etc.,

South Croydon, Surrey.

B. J. SKENTELBERRY.

The Care of the Tuberculous

SIR,—I am writing to congratulate the General Practice Review Committee on its report (*Supplement*, September 26, p. 131) in so far as the section on "The Care of Tuberculosis" is concerned.

Most chest physicians will agree that they do far too little domiciliary visiting, though they have a fair knowledge at second hand of the domestic problems confronting their patients. In the majority of cases, this is not due to a lack of sympathy with this aspect of their work, nor to the competing attraction of the purely clinical side. The cause is indeed not hard to find: simply lack of time. Many of us are in contract to give a fraction of our time (usually three-eighths) to the local authority for work in connexion with prevention and aftercare. The management of tuberculosis cannot of course be split into neat administrative compartments, but it seems clear that this portion of our time is not enough. The solution would appear to be more medical staff, but the need for an increase in domiciliary work may not be regarded by regional hospital boards as a strong argument for more adequate staffing.

One cannot conclude without a tribute to the general practitioners. If it were not for their sympathetic understanding of our difficulties, the domiciliary treatment of tuberculosis would have ended long ago in utter failure.—I am, etc.,

Wrexham.

E. CLIFFORD-JONES.

General Practice

SIR,—I wish to comment on some points made by Dr. Stephen J. Hadfield in "A Field Survey of General Practice, 1951-2" (*Journal*, September 26, p. 683), from the viewpoint of the junior hospital doctor.

Some practitioners complained that hospitals are encroaching on general practice by seeing patients without a doctor's letter. In many hospitals the lay clerks, whom the patients first encounter, are instructed not to refuse any patient asking to see a doctor for fear of turning away a serious case. The patients are sent to the casualty department. Here, when asked why they have not been to their own doctor, their answers—in approximate order of frequency—are: "The doctor is not at home"; "There is no surgery"; "until this evening and I didn't think I ought to wait"; "It's my doctor's half-day off"; "If I saw my doctor, he'd only send me here anyway"; "My doctor is on (often years ago for another complaint); "My doctor is on holiday"; "I'm not satisfied with my own doctor's advice"; "I haven't got a doctor."

In some districts in North London it is recognized that Thursday evening is the most hectic in casualty because so many doctors have Thursday as their half-day. Once a patient has been documented, has perhaps queued, and has eventually ensconced himself in casualty, it is kinder, quicker, and more pleasant to treat him rather than turn him away.

The reasons for retaining the attendance of patients longer than the general practitioner thinks necessary are a desire to finish a job one has started and to see its results, and a fear of patients complaining of incomplete and inadequate treatment if there is a relapse or complication. Some treatments are more easily performed by hospital doctors—materials are ordered, and instruments sterilized, prepared, and cleaned for us, whereas the general practitioner has to spend time doing all this himself.—I am, etc.,

Beckenham, Kent.

D. GOLDMAN.

The Cost of Drugs

SIR,—I have been grossly disappointed in the booklet "Costs of National Formulary and Proprietary Preparations." If we follow its guidance we will reduce the costs to the N.H.S. for drugs, but in a manner which the profession can hardly approve.

The booklet shows a large number of proprietaries which cost the Service less than do the official equivalents, and

E.C.N.129 says that in these cases the proprietary "should be prescribed." The booklet fails to remind us that the dispensing fee for proprietaries is less than is the dispensing fee for non-proprietaries (*vide* Drug Tariff, Part II, paras. 1 and 2, pp. 9 and 10). I am assured by pharmacists that, in every case where the list shows the cost of a proprietary to the Service as being less than the cost of the official equivalent, in fact the cost to the pharmacist at current market prices is more. The saving shown in the booklet arises only because a lower dispensing fee is paid. The list encourages us to use the products of the manufacturer of the more expensive form, and saves by paying the dispensing chemist a lower fee. Why, taking 24 tablets from a 500 bottle of "benerva" tablets, boxing, labelling, and wrapping them, should be worth only eight-pennyworth of the chemist's time, while doing the same thing from a bottle of tab. aneurin. hydrochlor. B.P. should be worth a shilling, is not clear to me.

If dispensing fees are too high the Ministry should open negotiations with the pharmacists with a view to reducing them. We are being asked to save costs by enabling it to pay a lower dispensing fee, even though it means prescribing a more expensive drug. It would be more honest and more effective, if the chemist is overpaid, to pay the lower dispensing fee for all drugs. We could then use a cheaper form in all cases, and effect an even greater saving.

E.C.N.129 tells us that in 47 instances we should prescribe a proprietary in preference to the standard preparation. This is tantamount to saying that we should not prescribe these standard preparations. Yet 29 of them bear in the Drug Tariff the double asterisk which signifies that the chemist "as far as is practicable shall stock them." One wonders who is to pay for this dead stock—the retail pharmacist again?

The idea of a list comparing the cost of proprietary and non-proprietary drugs is an excellent one, but it would seem that its preparation calls for more thoughtful co-operation between the concerned parties than the present booklet suggests. The illogical differential dispensing fee appears only to introduce confusion. It leads to a position in which savings are effected only by discouraging the manufacture of certain moderately priced standard preparations and reducing the pharmacist's dispensing fee in a covert, and therefore unpleasant, manner.—I am, etc.,

West Bromwich.

D. SAKLATVALA.

Proprietary Medicines

SIR,—I have recently received from the Ministry of Health, along with all general practitioners, a list of proprietary preparations which the committee set up to consider them states "have not been proved of therapeutic value."

While there may be a few preparations on this list over which some doubt may reasonably be expressed, the majority are ones which most of us practitioners have long considered, and in many cases proved to our own satisfaction by trial, to be nothing more than money-making adventures on the part of the firms responsible for them. When we have prescribed them for our patients it has only been when, by pressure, our line of least resistance has given way. With each prescription has sunk lower, in our own estimation, our status as physicians.

I continue to receive advertisements of these useless preparations; in fact my advertisement mail has increased since the publication of the committee's report. Until the advertising of this rubbish to the profession is stopped, waste of money on its purchase will continue, be it out of the patients' own pockets or the national purse.

My own method of dealing with the advertisers is to write to the firms as follows:

With reference to advertisement for ——— received to-day, I notice that the Ministry of Health list this preparation as one which has not been proved of therapeutic value.

I am surprised that you continue, in the face of reliable medical opinion, to advertise it. It causes one to lose faith in any preparation that you now or in future may advertise. Until you

cease the production and advertisement of — I shall avoid the use of your other preparations.

I am of the opinion that, by adopting this course, we could quickly stamp out the racket in many proprietary drugs, to the good of the general public and the betterment of the status of the general practitioner.—I am, etc.,

Manchester.

RAYMOND M. PEARCE.

Private Practice

SIR,—Time after time I have had applications from patients for acceptance on my N.H.S. list who freely state that they would prefer to be treated as private patients, but who imagine that by accepting private treatment they would automatically be debarred from the numerous hospital and other forms of medical treatment otherwise available to them.

This misconception is not only widespread, but general. So far as I am aware, neither the B.M.A. nor the Ministry of Health has taken any effective step to impress upon the public the fact that everyone, whether on a doctor's list or not, is entitled to all hospital and other medical services. This culpable policy of silence on such a vital matter is one of the direct causes of the lamentable state of private practice to-day, and is robbing general practitioners of an important potential source of income.—I am, etc.,

London, S.W.3.

VICTOR CONSTAD.

Sources of Income

SIR,—In company with other doctors whose list of N.H.S. patients is under 1,200, I have received a questionnaire as to other sources of earned income. I would make three comments:

(1) Why are we asked about "remunerative work of a non-medical character"? Surely the use of leisure is our private concern.

(2) Why are not also those with lists of over 1,200 questioned as to the industrial appointments, medical boards, insurance examinations, etc., they are able to undertake in addition to the extra hours spent in general practice?

(3) Those who can state correctly how many hours per week were spent in various types of work during the year ending last March must have a phenomenal memory.—I am, etc.,

Clifton, Bristol.

H. K. V. SOLTAE.

Association Notices

PRIZE ESSAY COMPETITION FOR MEDICAL STUDENTS, 1954

The Council of the British Medical Association is prepared to consider the award, in 1954, of prizes to medical students for essays submitted in open competition. The subject of the essay will be: "Is the Medical Curriculum too Heavily Loaded?"

The purpose of this competition is to promote systematic observation among medical students. In awarding the prizes due regard will be given to evidence of personal observation. No study or essay that has previously appeared in the medical press or elsewhere will be considered eligible for a prize. Previous prizewinners are eligible for a second award of a prize.

Any medical student who is a registered member of a medical school in the United Kingdom or the Colonial Empire at the time of submission of the essay is eligible to compete for a prize. If any question arises in reference to the eligibility of a candidate or the admissibility of his or her essay, the decision of the Council of the British Medical Association will be final. Should the Council decide that no essay entered is of sufficient merit, no award will be made. In determining the number and amount of prizes to be awarded, the Council will take into consideration the number and standard of essays received.

It is suggested that essays should consist of from 2,000 to 5,000 words. Essays must be typewritten or legibly written in the English language on foolscap paper, on one side only, must be unsigned, and must be accompanied by a note of the name

and the medical school of the entrant. Notice of entry for this competition is necessary and a form of application can be obtained from the undersigned.

Essays must be forwarded so as to reach the Secretary of the British Medical Association not later than December 31, 1953. Inquiries relative to the Competition should be addressed to the Secretary, British Medical Association, B.M.A. House, Tavistock Square, London, W.C.1.

A. MACRAE,
Secretary.

Diary of Central Meetings

OCTOBER

- | | |
|-----------|---|
| 19 Mon. | Armed Forces Committee, 2 p.m. |
| 20 Tues. | Guillebaud Evidence Subcommittee, G.M.S. Committee, 11 a.m. |
| 20 Tues. | G.M.S. Subcommittee to Consider Maternity Medical Services, 2 p.m. |
| 20 Tues. | Industrial Injuries Evidence Subcommittee, Occupational Health Committee, 2 p.m. |
| 22 Thurs. | Full-time Non-professional Medical Teachers and Research Workers Group Committee, 2 p.m. |
| 22 Thurs. | International Relations Committee, 2 p.m. |
| 23 Fri. | Library Subcommittee, Science Committee, 11.30 a.m. (postponed from September 25). |
| 23 Fri. | Science Committee, 2 p.m. (postponed from September 25). |
| 23 Fri. | G.M.S. Subcommittee on Service Committee and Tribunal Regulations, 2 p.m. |
| 27 Tues. | Executive Subcommittee, Joint Formulary Committee (at Pharmaceutical Society, 17, Bloomsbury Square, London, W.C.2), 2 p.m. |
| 28 Wed. | Compensation and Superannuation Committee, 2 p.m. |
| 28 Wed. | Welsh Committee (at Raven Hotel, Shrewsbury), 2.15 p.m. |
| 29 Thurs. | Anaesthetists Group Committee, 2 p.m. |

Branch and Division Meetings to be Held

BIRMINGHAM DIVISION.—At 154, Great Charles Street, Birmingham, Tuesday, October 20, 8.30 p.m., film evening: (1) "Some Aspects of Accessible Cancers—Cervix and Uterus"; (2) "The Nose Has It"; (3) "Senile Obliterative Arteritis of the Legs."

CHELSEA AND FULHAM DIVISION.—At Fulham Town Hall, S.W., Friday, October 23, 9 p.m., general meeting.

COVENTRY DIVISION.—At St. Anne's Church, Acacia Avenue, Coventry, Sunday, October 18, 6.30 p.m., annual church service.

EAST NORFOLK AND NORWICH DIVISIONS.—At St. Peter Mancroft, Sunday, October 18, 3 p.m., annual service for doctors, nurses, and members of the allied professions. Address by Dr. George H. Day.

GRIMSBY DIVISION.—At Field House, Grimsby, Thursday, October 22, 6.30 p.m., annual meeting; election of officers, etc. Followed by dinner, at which the principal guest will be Sir Ernest Finch.

HYDE DIVISION.—At Pack Horse Inn, Mottram, Wednesday, October 21, 8.45 p.m., meeting. Colour film: "Infections of the Hand." Discussion to be opened by Mr. R. T. Grime.

ISLE OF WIGHT DIVISION.—At St. Mary's Hospital, Newport, Sunday, October 18, 3 p.m., meeting. Lecture by Dr. Ernest White: "Differential Diagnosis of Anxiety and Depressive States."

KENSINGTON AND HAMMERSMITH DIVISION.—At Hammersmith Hospital, Duane Road, W., Wednesday, October 21, 2 p.m., ward visits for general practitioners.

LEWISHAM DIVISION.—At Lewisham General Hospital, High Street, S.E., Friday, October 16, 8.30 p.m., extra meeting of Division.

NORTH BEDFORDSHIRE DIVISION.—At Bedford General Hospital, Wednesday, October 21, 8.30 p.m., joint clinical meeting with Bedford Medical Society.

NORTH MIDDLESEX DIVISION.—At North Middlesex Hospital, Silver Street, Edmonton, N., Tuesday, October 20, 2.30 p.m., Practitioners' Round; 8.30 p.m., meeting, programme arranged by Mr. J. H. Dobree.

NUNEATON AND TAMWORTH DIVISION.—At Chadwick Manor Hotel, Knowle, Saturday, October 24, 8.15 p.m., annual dinner and dance.

OLDHAM DIVISION.—At Oldham Hotel, Rhodes Bank, Oldham, Monday, October 19, 9 p.m., meeting. Dr. Oscar Janus: "Arthritis in General Practice."

STRATFORD DIVISION.—At Queen Mary's Hospital, Stratford, E., Tuesday, October 20, 9 p.m., annual general meeting.

SWINDON DIVISION.—At Goddard Arms Hotel, Swindon, Friday, October 16, 9 p.m., annual general meeting. Election of officers, etc., and consideration of revised ethical rules.

WEST DENBIGH AND FLINT DIVISION.—At Sanatorium, Llan-gwyfan, near Denbigh, Friday, October 23, 3 p.m., clinical meeting. Symposium: "The Necessity for Regarding Tuberculosis as a General Disease Therapeutically."

SOME HEALTH SERVICE DEVELOPMENTS

BY

ARTHUR BEAUCHAMP, M.B., Ch.B.

It has been obvious that integration of the services included in the National Health Service must be brought about if the patient and the doctor are to get the full benefit of that Service. In Birmingham we have believed that the right way is to experiment locally, and then if it is successful to spread the experiment further, not only in area but in content.

Direct Access to Special Services

The first effort was to ask for direct access for general practitioners to pathological and x-ray services. The sound reasons behind these requests were immediately appreciated by the regional hospital board and board of governors, and free access to pathological services was given; the principle of free access to radiological facilities was admitted and of free access to radiological facilities was implemented. The promised when it was possible to implement the idea. The pathologists worked out the details with representatives of the local medical committee. The scheme has been economical in cost, is not abused, and extends the knowledge of the general practitioner.

A Glimpse for Students

The next step to be taken was to show final-year students the attractiveness of general practice. This had to be a joint effort between the dean of the medical school and the local medical committee. We are fortunate in having as dean Professor A. P. Thomson, who welcomed the idea with great enthusiasm. The scheme was that general-practitioner teachers, selected by the dean, should have a final-year student for a fortnight. The students were asked to select from the list the general practitioner to whom they would like to go, and in spite of the fact that it was entirely voluntary over 80% of them agreed to spend a precious fortnight of their final year learning something of general practice.

Hospitals Welcome G.P.s

A further step has now been taken. The dean, who is also an active clinical teacher, has invited the general practitioners to visit their patients in hospital. It may be said with truth that it has always been possible to visit our patients while they are in hospital, but in many cases the general practitioner was tolerated and often unwelcome by

reason of the fact that he arrived at a time which was awkward for the nursing staff. Indeed, on one occasion, when asking if I might see a child in whose condition I was interested, I was asked by a student nurse if I was the father of the child. Once in the ward, the next problem was to find a house-man who could tell the general practitioner something about the case and explain what was being done; this might take anything up to 20 minutes.

The scheme suggested by Professor Thomson gets rid of all these difficulties. Registrars and house-officers will be on duty in their wards from 2.30 to 3.30 p.m. on two days a week. They will welcome the general practitioner, and will not only discuss his patient with him but will be able to guide him gently through the morass of unintelligible findings of weird and wonderful investigations. How badly many of us need this guide. And how happy we shall be to tell the registrar of the patient's family history, his home environment, his fears and his hopes. Together we can discuss the treatment to be given when the patient returns home, and with our full knowledge of home conditions be able to advise on whether to send him out early or not.

Comfort to Patient

Many of us feel that this scheme will not only be a valuable form of postgraduate education but will engender the feeling that the general practitioner plays not a separate but an integral part in the medical services which the patient receives. Perhaps the most important fact of all is the comfort it will give to the patient. He will feel no longer that his doctor has sent him away from his home to live in a strange, sterile place, in the care of women he has never seen before, treated by a group of doctors about whom he knows nothing, but that his treatment is a continual process, with the stay in hospital an interlude, and his friend his own doctor is part of the team responsible for his health.

The scheme will cater for some 500 general practitioners in Birmingham and is confined at present to the general hospital, but if it is successful there is little doubt that more hospitals, both teaching and non-teaching, will be included, and that practitioners from the surrounding counties of Staffordshire, Worcestershire, and Warwickshire will avail themselves of this generous offer. When this is working well there are many logical steps along the same road which can be easily taken. With the welfare of the patient and the improvement of the Service (which are really one and the same thing) as the guiding principle for all concerned, it is felt that progress towards the end which we all desire can be achieved.

Scottish News

GENERAL MEDICAL SERVICES SUBCOMMITTEE (SCOTLAND)

The first meeting of the session was held at the Scottish Office, Edinburgh, on October 1, when Dr. J. T. BALDWIN (Milton Bridge) and Dr. C. J. SWANSON (Aberfeldy) were reappointed chairman and vice-chairman respectively. The Subcommittee appointed various subcommittees and nominated representatives to serve on other bodies.

Dr. A. F. WILKIE MILLAR, chairman of the Scottish Medical Practices Committee, commented on a few of the matters which had recently been occupying the attention of his committee. In view of his comments it was decided that representatives of the Subcommittee should seek a meeting with representatives of the Scottish Medical Practices Committee and the Department of Health for Scotland to discuss two points—namely: (1) the admission to the executive council list of a whole-time assistant as a principal in the same area; (2) the hearing of an appeal against the appointment of a successor in a practice vacancy.

The Subcommittee was not in favour of a whole-time assistant being admitted as a principal in the same area, and felt that the present arrangement for an appeal against the appointment of a successor in a practice vacancy should be examined. At the present time, when an appeal is made, only the case of the appellant is reconsidered. It was felt that consideration might be given to a provision which would require that all the unsuccessful candidates' cases should be examined when an appeal was made.

The Subcommittee also considered certain anomalies which had arisen from the provision in the distribution scheme whereby "restricted lists" carry no loaded capitation fees and a percentage reduction in ordinary capitation fees. As a result of this discussion it was decided that representatives of the Subcommittee should meet the Department of Health to discuss certain proposals to overcome any difficulties in this connexion.

Increasing Use of Ambulances

It was reported that representatives of the Subcommittee had had discussions with the Department on the continued increase in use of the ambulance service. The representatives had agreed that local medical committees should be asked to interview any general practitioners who appeared to be using this service excessively or improperly. It was explained that local medical committees, while being asked to interview practitioners, would have no power to impose any penalties. It was hoped, however, that by such interviews general practitioners might become aware of the difficulties of the situation. The Department had undertaken that the attention of the hospital service would be drawn to the serious situation which had arisen in connexion with the number of services provided by ambulances, and that hospitals too would be required to take steps to bring about a reduction.

The Subcommittee also received from the Department some amendments to the Medical and Pharmaceutical Services Committee and Tribunal Regulations for their consideration. The Subcommittee decided not to consider the proposals at this stage but to await the final report from the special subcommittee of the General Medical Services Committee which was considering the general question of service committees.

Registrars Group.—The annual general meeting of the South-west Metropolitan (Eastern Area) Regional Registrars Group will be held at B.M.A. House, Tavistock Square, London, W.C.1, on Tuesday, November 10, at 7.30 p.m. All senior registrars and registrars in the area are invited to attend. Dr. E. E. Claxton, Assistant Secretary of the B.M.A., will speak on "Current Problems in the Registrars' Field."

DOCTORS AND PHARMACISTS

SOUTH MIDDLESEX DIVISION MEETING

A combined meeting of doctors and pharmacists was held at Hounslow on October 14 at the invitation of the chairman of the South Middlesex Division of the B.M.A. An informal dinner was followed by a general discussion, the object being to allow members of both professions to get to know each other. Dr. Henry Bergh, chairman of the South Middlesex Division of the B.M.A., presided over a company of 60.

Mr. Harold Moss, chairman of the Thames Valley branch of the Pharmaceutical Society, said that a new problem was that concerned with the result of the Cohen Committee Report. Although it was obvious to both professions that the Service was costing too much, the problem now facing pharmacists was: What were they going to be left with? Doctors, on the other hand, had the trouble of going through the lists, and at least one doctor he knew had said: "N.F. for me in the future," so the good tended to be thrown out with the bad. This attitude would not help doctors, pharmacists, or the public. The report also posed a very real problem for the manufacturers: Were they going to spend thousands of pounds a year on research when the product might be placed in category 5 or 6?

Mr. Moss next mentioned the new regulations for supplying trusses and elastic hosiery, and pointed out that, if a pharmacist accepted a prescription which did not conform, it would not be paid. The patient had then to be sent back to the doctor.

Question Time

The chairman then invited questions. In reply to questions put by several doctors, pharmacists explained the difficulties connected with ambiguous prescriptions which would cause complications in the Pricing Bureau if they did not comply with tariff requirements. The marking of "urgent" prescriptions was mentioned, with a request for such marking if the doctor considered that the patient required the medicine after 7 p.m. One doctor complained of difficulty in remembering doses of new preparations and asked whether, no dose being given on the prescription, the pharmacist could dispense an intermediate dose. He was told that this could be done, but not with Schedule 4 preparations. Pharmacists agreed that they would be willing to advise doctors if they prescribed products in categories 5 and 6.

With regard to the prescribing of oxygen, one doctor suggested that the present position was unsatisfactory and that oxygen should be delivered by ambulance. Divergent views were expressed on this point by two pharmacists, one agreeing that the responsibility should be taken over by the local authority, while another emphatically stated that the proper source of supply was the pharmacist. He explained that requests to the Ministry had been made unsuccessfully for a delivery fee and asked for the doctors' support in their application.

When pharmacists were asked their opinion on the charge for bottles under the N.H.S., it was explained that the deposit system which operated under the N.H.I. was unsatisfactory, but that payment by the patient for the bottle would be acceptable.

One pharmacist emphasized the dangers of prescribing for two patients on one form, particularly when one was a child and the other an adult. The meeting was reminded that this practice was directly against the terms of service, and that most doctors were aware of its dangers. Prescriptions for double-strength mixtures, often received by another speaker, sometimes had the incorrect dosage, and he suggested that such prescriptions be endorsed accordingly.

In proposing a vote of thanks, Dr. W. A. Shearman expressed his gratitude to Mr. Moss for his work in making the evening such a success. Mr. K. W. Richardson thanked the chairman, Dr. Bergh, and Dr. G. C. L. Woodroffe (secretary to the South Middlesex Division), who first had the idea of holding the meeting. Dr. Woodroffe in reply said he hoped to have an attendance of 100 next year.

PUBLIC HEALTH MEDICAL OFFICERS

MOTOR-CAR ALLOWANCES

The following M.D.C. circular No. 18, on motor-car allowances for public health officers in England and Wales, has been issued by Whitley Committee "C."

With reference to the scheme of motor-car allowances appended to M.D.C. Circular No. 13, dated October 15, 1951, we have to advise you that Committee "C" of the Medical Whitley Council has now agreed that the following two paragraphs should be added to that enclosure. The effect of these paragraphs is to ensure that when an officer is entitled to an allowance for only part of a year the mileage in respect of which he is entitled to receive a higher allowance (cf. paragraph 4 of Enclosure to M.D.C. Circular No. 13) during that part of a year should be reduced to a suitable fraction of 7,200 miles.

1. The period over which the car allowances are paid should be from April 1 in any year to the succeeding March 31.
2. In the case of an officer who takes up an appointment with a local authority after April 1 in any year, or leaves a local authority to take up an appointment with another local authority, or alternatively leaves the local government service altogether, the allowance should be so calculated that the amount payable bears the same proportion to a full year's allowance as the number of months in the year during which the officer uses his car bears to twelve.

The calculation of the mileage allowances would thus be made on a proportionate basis in accord with the following procedure:

- (a) The mileage allowance to be paid at the higher rate would, at 7,200 miles per annum, be equivalent to 600 miles per month of service.
- (b) The excess over 600 miles per month of service would be paid at the reduced rate—for example, where the total service in the financial year is five months, then up to 3,000 miles would be paid at the higher rate, and the excess over 3,000 miles would be paid at the lower rate.

Similarly the lump sum payment should be divided into 12 monthly payments. Where an authority pays the allowance quarterly, the appropriate calculation should be made on the basis of dividing by four instead of twelve.

When an officer leaves the service of an authority, a calculation shall be made in respect of his entitlement for the portion of the year served with the authority and any necessary adjustment made thereafter.

EXECUTIVE COUNCILS ASSOCIATION

ANNUAL MEETING

The annual meeting of the Executive Councils Association (England) took place at Torquay on Thursday and Friday, October 8 and 9, presided over by Captain S. H. HAMPSON, the president of the association.*

Dr. F. E. GOULD (Birmingham) moved to request the Minister of Health to remove the restrictions on patients changing doctors. Circumstances had altered since 1950, when the restriction was made; the Health Service had become stabilized, people had settled down, they had their doctors, and they knew what they wanted. The number of changes was considerably less, and the time had come when patients should have the right to immediate transfer.

The motion was opposed by most speakers and was lost. Dr. J. T. DALY (Worcestershire) proposed a motion asking the Minister to reconsider the view that, where a woman was to be confined in hospital, the hospital should normally assume responsibility for all antenatal and post-natal care, and that the Executive Councils Association consider that the provision of such care by a general practitioner was complementary to the service provided by the hospital and essential for the welfare of the patient.

*The Minister of Health's address was reported in the Supplement of October 17, p. 169.

Dr. J. KERR (Cheshire) moved an amendment to the effect that it was of the utmost importance that such services should be given against the background of the patient's home circumstances and manner of life and that arrangements for the whole of the antenatal and post-natal care to be given in a hospital should be the exception rather than the rule, and the motion was carried in that form.

Access to Pathology Services

Mr. N. BAYLISS (Staffordshire) brought forward a resolution urging the Minister to press hospital management committees to implement his expressed wish that x-ray and pathological services should be made available to general practitioners at an early date.

Alderman Mrs. CHAMBERS (Bradford), seconding, said that consultants should welcome general practitioners as colleagues and realize the help that they could give.

Dr. H. P. FAY (Stockport) said that in his area no difficulty was put in the way of a general practitioner who wished to make use of hospital x-ray and pathological services; on the contrary, he was helped in every possible way.

Brigadier W. LESLIE, for the management committee, said that what was wanted was direct access by the general practitioner to these departments in order to save time; the committee supported the resolution, which was carried.

It was noted in the committee's report that the Minister's medical advisers had informed the Queen's Institute of District Nursing that, where a home nurse found surplus drugs in a house, in the interests of safety and with the consent of the householder she should destroy them. Dr. R. W. McCONNEL (Bucks) thought this advice led to great wastage, and asked that the management committee should reconsider the matter with a view to a doctor or nurse removing such things for use with other patients. Alderman H. C. BROWN (past president) said that the committee felt that, although there might be some wastage, in the interests of safety it was very much better to adopt the recommendation of the Minister. A motion from Essex that the present position under which responsibility for the collection of oxygen cylinders for the treatment of patients rested with the patient's personal representatives was entirely unsatisfactory and that arrangement should be made for the delivery of the cylinders at the cost of the Service was carried.

Charges for Drugs

Alderman A. BUXTON (Rotherham) moved to urge the Minister to repeal the charges for drugs and appliances in view of the discouragement to economy in prescribing and the hardship and inconvenience to old-age pensioners and others by its imposition. The introduction of the charge, he said, had not achieved its object. Doctors' surgeries were as full as ever; in his area more prescriptions had been issued than there were two years ago in the same period. One had to bear in mind the effect of the 1s. charge on the lower wage-earning group: one family with two children paid out 12s. for prescriptions when they were ill with measles. The fear of such expense deterred mothers from taking their children to the doctor at an early stage.

Dr. R. W. McCONNEL (Bucks) opposed the resolution. He said that the object of the regulation was to make money, and it was making money. At the present time the Ministry, the doctors, and the chemists were trying to find the way to economy. If the 1s. was taken away the Government would drop the revenue and would put it on something else or limit the range of drugs.

Mr. H. A. SWEET (Southampton) supported the resolution on the words "old age and hardship." He would prefer to see the management committee instructed to make representations to the Minister on behalf of old-age pensioners and members of the community suffering from hardship. Many preferred to pay the 1s. rather than approach the National Assistance Board and reveal their means before that august body.

Alderman BUXTON said that what was happening was that Health Service costs were being diverted to another Government department. According to the report of the National

H.M. Forces Appointments

ROYAL ARMY MEDICAL CORPS

Lieutenant-Colonel R. W. Scott, O.B.E., has retired on retired pay, and has been granted the honorary rank of Colonel.
Major T. McEvel to be Lieutenant-Colonel.
Major H. R. Hartnell, M.B.E., has retired with a gratuity, and has been granted the honorary rank of Lieutenant-Colonel. (Substituted for the notification in a *Supplement to the London Gazette* dated April 21.)
Major G. M. Homan has retired on account of disability.
Captain R. Houston has resigned his commission and has been granted the honorary rank of Major.
Captain D. H. Provan to be Major.
Short Service Commissions.—Captains J. W. Weston, M. S. C. Rooney, and J. S. Webster, O.B.E., to be Majors. Major J. W. Weston has retired with a gratuity. (Substituted for the notification in a *Supplement to the London Gazette* dated August 7.)

ARMY EMERGENCY RESERVE OF OFFICERS

ROYAL ARMY MEDICAL CORPS

Major (Honorary Colonel) A. D. Bourne, R.A.R.O., to be Major.
Major O. Walker, from R.A.R.O., to be Major.
Captain (Honorary Major) H. K. Meller, M.B.E., from T.A.R.O., to be Captain, and has been granted the acting rank of Lieutenant-Colonel.
Captain A. W. Weller has been granted the acting rank of Major.
Lieutenant (War Substantive Captain) E. H. J. Smyth, from Emergency Commission, to be Captain, and has been granted the acting rank of Lieutenant-Colonel.

COLONIAL MEDICAL SERVICE

The following appointments have been announced: A. G. Farr, M.B.E., M.B., B.Ch., D.T.M.&H., D.P.H., D.I.H., and D. E. Thompson, M.B., B.Ch., D.T.M.&H., Senior Medical Officers, Tanganyika; J. Carnegie, M.B., J. F. Grech, M.D., and F. A. Viapree, M.B., Medical Officers, Nigeria; R. Noble, F.R.C.S., M.R.C.O.G., Medical Specialist (Obstetrics and Gynaecology), Jamaica; W. A. Dos Santos, M.B., Ch.B., D.Bact., Pathologist, Grade A, Trinidad and Tobago; E. V. Strisiver, M.D., F.R.C.S., Specialist, Sierra Leone; P. Grech, M.D., and J. H. Jackson, M.B., B.S., Medical Officers, Tanganyika; K. S. Alstad, M.D., M.R.C.P., D.P.H., Physician Specialist, Federation of Malaya; C. A. Brand, M.D., Medical Officer, Gold Coast; M. Stilton De Piro, M.D., and J. Gatt, M.D., House Physicians and Surgeons (Temporary), Nigeria; I. M. Dingwall, M.B., Ch.B., Medical Officer, Barbados; J. T. C. Glover, M.B., B.S., Medical Officer, Local Civil Service, Gold Coast; A. K. Mitra, M.B., B.S., D.P.H., D.T.M.&H., Assistant Medical Officer of Health, Aden; H. J. Penkala, M.B., Ch.B., Assistant Medical Officer (Inspec.), Bahamas. The appointment of B. V. Earle, M.D., M.R.C.P., D.P.M., should read Medical Superintendent, Mental Hospital, British Guiana and not Barbados as stated in the *Supplement to the Journal* (July 4, p. 10).

Branch and Division Meetings to be Held

COVENTRY DIVISION.—At Gymnasium, Coventry and Warwickshire Hospital, Tuesday, November 3, 8.30 p.m., annual B.M.A. Lecture by Mr. A. Lawrence Abel: "Some Common Diseases of the Rectum and Anal Canal." Followed by film: "Modern Operation for Carcinoma of the Rectum."

DARTFORD DIVISION.—At Joyce Green Hospital, Dartford, Thursday, November 5, 2.30 p.m., clinical meeting. All medical practitioners in the area of the Division are invited.

ISLE OF WIGHT DIVISION.—At St. Mary's Hospital, Newport, Saturday, November 7, 2 to 5 p.m., and Sunday, November 8, 10 a.m. to 4 p.m., refresher course.

KENSINGTON AND HAMMERSMITH DIVISION.—At Hammersmith Hospital, Duane Road, W., Wednesday, November 4, 2 p.m., ward visits for general practitioners.

LAMBETH AND SOUTHWARK DIVISION.—At Lambeth Hospital, Brook Drive, Kennington Road, S.E., Sunday, November 1, 11 a.m., clinical meeting.

LEWISHAM DIVISION.—At Lewisham General Hospital, High Street, S.E., Friday, November 6, 8.30 p.m., meeting. Dr. T. M. L. Price: "The Early Signs of Cancer."

MIDLAND BRANCH.—(1) At Lecture Theatre, Nuffield House, Queen Elizabeth Hospital, Birmingham, Friday, October 30, 8 p.m., meeting of Clinical and Pathological Section. (2) At 154, Great Charles Street, Birmingham, Thursday, November 5, 3 p.m., 92nd annual meeting. Address by retiring President: "Mechanics with Tears."

MONMOUTHSHIRE DIVISION.—At Tredegar Arms Hotel, Newport, Tuesday, November 3, 8.15 p.m., dinner followed by a clinical discussion on "Headache." Special speakers, Mr. L. J. Horne, Dr. Aneurin Hughes, Dr. J. C. H. Bird, and Dr. J. D. Spillane.

NORTH MIDDLESEX DIVISION.—At North Middlesex Hospital, Silver Street, Edmonton, N., Tuesday, November 3, 2.30 p.m., practitioners' round.

NORTH WALES BRANCH.—At Royal Hotel, Capel Curig, Thursday, November 5, 3 p.m., autumn meeting. B.M.A. Lecture by Mr. Emlyn E. Lewis.

NORWICH DIVISION.—At Assembly House, Norwich, Tuesday, November 3, 7.30 p.m., invitation by Norwich and District Branch of Pharmaceutical Society to B.M.A. Lecture by Mr. A. R. Channings: "New Drugs and the B.P. 1953."

NUNEATON AND TAMWORTH DIVISION.—At Red Lion Hotel, Atherton, Tuesday, November 3, 8 p.m., informal supper; 8.45 p.m., meeting. Symposium to be opened by Dr. P. A. V. Barford: "Hypertension."

REIGATE DIVISION.—At Burford Bridge Hotel, Dorking, Wednesday, November 4, 7.30 for 8 p.m., 51th annual dinner and dance.

ST. PANCRAS DIVISION.—At B.M.A. House, Tavistock Square, London, W.C., Tuesday, November 3, 8.30 p.m., meeting. Dr. Dorothy F. Egan: "The Functions of Health Visitors and the Possibility of Co-operation Between Them and General Practitioners."

SCUNTHORPE DIVISION.—At Scunthorpe and District War Memorial Hospital, Wednesday, November 4, 8.30 p.m., meeting. Mr. M. R. Ewing: "The Clinical History and Diagnosis of Cancer of the Large Bowel."

SHROPSHIRE AND MID-WALES BRANCH.—At Royal Salop Infirmary, Shrewsbury, Tuesday, November 3, 8.30 p.m., meeting.

SOUTH-EAST ESSEX DIVISION.—At Southend General Hospital, Tuesday, November 3, 8.30 p.m., meeting. Address by Mr. W. A. Law: "The Place of Surgery in the Treatment of Arthritis."

SOUTH ESSEX DIVISION.—At Oldchurch Hospital, Romford, Friday, November 6, 9 p.m., meeting. Dr. Andrew Topping: "The Medical Profession—A House Divided."

WEST SUFFOLK DIVISION.—At Everard's Hotel, Bury St. Edmund's, Saturday, November 7, 7.30 for 8 p.m., 27th "Doctors' Armistice" Dinner.

Meetings of Branches and Divisions

BOLTON DIVISION

The annual general meeting was held at the Victoria Hotel on July 30, 1953. There were 11 members present. The following officers were elected for 1953:

Chairman.—Dr. L. F. Evans.
Vice-chairman.—Dr. E. P. Johnson.
Joint Honorary Secretaries.—Dr. R. A. Cranna and Dr. M. S. Rowley.

WINCHESTER DIVISION

The annual meeting of the Winchester Division was held at the Royal Hotel, Winchester, on October 3. Dr. Ronald Gibson was in the chair, and 51 members were present. The following officers were elected for 1953-4:

Chairman.—Dr. C. F. Cope.
Vice-chairman.—Dr. H. L. Cronk.
Hon. Secretary and Treasurer.—Dr. G. Swift.
Public Relations Secretary.—Dr. Ronald Gibson.
Representatives to the A.R.M.—Mr. H. H. Langston and Dr. G. Swift.

The meeting was followed by a dinner, after which Dr. O. C. Carter addressed the meeting in response to the toast of "The B.M.A."

HEALTH SERVICES CONFERENCE
MAKING THE MOST OF PRESENT RESOURCES

The Institute of Public Administration arranged a Health Services Conference at Church House, Westminster, on October 28-30. A large attendance of representatives of hospital boards, executive councils, local health authorities, and local medical committees from most parts of the British Isles assembled under the chairmanship of Mr. HENRY LESSER for discussions on the general theme of "Making the Most of Present Resources."

Domiciliary and Out-patient Services

In discussing the question, "Should domiciliary and out-patient services be extended?" Professor A. LESLIE BANKS (Cambridge) pointed out that a great deal of work formerly done in the ward was now done in the out-patient department, and more could be done but for cramped accommodation. In studying the working of a large provincial group of hospitals as seen by the consulting staff, no great tendency had been noted on the part of general practitioners to unload "rubbish" on to the hospital. In considering domiciliary care three social factors had to be taken into account: (1) the changes in age structure of the population, with an increased number of elderly patients with prolonged or recurrent maladies; (2) inadequate housing; (3) the preference of the public for hospital care, particularly expectant mothers for maternity accommodation. We had not reached the American standard of "99% of confinements in hospital and the remaining 1% in taxis," but in some parts of this country 80% were hospital deliveries.

Professor Banks said that Kipling might have written his story "The Ship that Found Herself" around the present state of medical care. The objective was known, the highly skilled organization was available, but time and effort were wasted in trying to run the service in three different sections, each of which, like the components of Kipling's ship, groaned against the others. A corporate spirit was lacking. There ought to be in the National Health Service a trained corps of administrators, lay and medical, trained not only in their own departments but in the others, who appreciated the need for an integrated service, interpreted the regulations liberally, and themselves formed a team undivided by administrative boundaries.

Dr. H. K. COWAN (M.O.H., Essex) considered that the resources immediately available were not used to capacity. One of the pressing problems was the care of the chronic sick, but there were special hospitals and wings of general hospitals for the chronic sick, geriatric homes, health visitors, home helps, public assistance officers, voluntary workers, and a host of other agencies concerned with the problem. Under experienced geriatricians it was now possible to rehabilitate chronically sick people who had been confined to bed for a long period, to mobilize the apparently immobile, and to return people to their homes to live in reasonable comfort. It was remarkable that so little had been done to provide a domiciliary geriatric service at all comparable with the modern geriatric units in hospital. The time was overdue for the chronic sick to receive domiciliary service, with home nursing, physiotherapy, chiropody, and so on. In many areas there were numbers of women who were not only State-registered nurses but had undertaken a considerable amount of post-certificate training to enable them to take the techniques learned at hospital into the more difficult life of the home. There was no reason why these women should not deal, if home conditions were suitable, with cases in the early stages of recovery so that they could be discharged from hospital at an earlier date.

The General Practitioner and the Home

Dr. A. BEAUCHAMP (Chairman, Birmingham Local Medical Committee) said that if patients were sent home under skilled nursing care it would alleviate the problem. But the general practitioner was the only person who knew to what kind of home the patient would return, and in thirty years' practice he had never been asked by a hospital officer whether the home was suitable for earlier return. Domiciliary nursing presupposed an adequate nursing service, and home helps as well as district nurses were in short supply. "In general practice I want a nurse who can go into a home and nurse a 14-stone patient in a double bed in a single room."

Many out-patient departments, Dr. Beauchamp continued, were "a bit like Paddington station." Much could be done by reorganization without rebuilding. Medical staff did not keep their appointments at the proper time. Patients were called *en bloc* for 9 a.m., and some of them not seen until 11. The out-patient hall was an anachronism.

Women should not be encouraged to go into hospital for normal confinement. They were just as safe or safer in their own homes. Hospital midwifery in America in no way compared with domiciliary midwifery here. In teaching hospitals it cost £20 a week for a woman to have her baby in hospital. The answer to the question before the Conference was: "Use properly the resources already available."

Dr. J. GREENWOOD WILSON (M.O.H., Cardiff) said that after Dr. Beauchamp's speech he would never say again that the general practitioner had not got a preventive outlook. Professor Banks wanted to have a trained corps of administrators, but until 1946, when a dynamic personality said that the Service, like Gaul, must be divided into three parts, the administrators had not been conscious of any such division.

Mr. WILLIS (clerk to the Rotherham Executive Council) suggested that medical officers of health, secretaries of hospital management committees, and clerks of executive councils in each locality should meet together on a principle of co-option to each other's councils; also that doctors staffing out-patient and casualty departments should get together with the general practitioners. Dr. J. O. F. DAVIES (Oxford) said that the dismal (and rather overdrawn) picture of geriatric patients would be greatly ameliorated if hospitals shared the responsibility with the home and the general practitioner. Dr. HOWIE WOOD (Isle of Wight Local Medical Committee) said that executive councils had the full confidence of general practitioners and had proper medical representation, which did not obtain in other branches of the Service. He had yet to hear of an executive council which complained of being "bossed around" by its medical members, but in regional hospital boards there were murmurs of an undue degree of medical representation. Mr. JOHN DODD (Secretary, Bristol Local Medical Committee) gave some glaring examples of delay in informing the patient's doctor of his discharge from hospital or of his death. Dr. A. TALBOT ROGERS urged that out-patient departments should be consultative only. When doctors sent patients to a consultant they did so for his opinion and advice; the same should obtain in the out-patient department.

The Economics of Prescribing

Another session was devoted to the possible contribution of the medical profession to economy in prescription and treatment. Dr. A. M. G. CAMPBELL, whose paper was read for him by Dr. Glyn Hughes, said that at Bristol Royal Hospital an economy committee consisting of five members of the staff had set itself to cut down the increasing drug bill, especially for antibiotics. The chief dispenser outlined to them each month the individual items and their cost, and after discussion, if any expenditure was thought excessive, steps were taken to curtail it. As a result there had been a saving of about £1,000 a year. The pharmacists had been told wherever possible to dispense B.P. drugs as opposed to any proprietary compound, unless the latter was specifically ordered by the consultant. Economy in general practice, however, was a much more difficult matter. The general practitioner was more likely to prescribe a drug that could be given by mouth rather than injected. One general practitioner of his acquaintance tended to prescribe proprietary compounds because he could remember their names more easily, and in a busy practice it was a consideration to be able to write one word instead of three. The College of General Practitioners should interest itself in economy and correct use of drugs.

The Question of Proprieties

Mr. JOHN HANBURY (Allen and Hanburys Ltd.) said that antibiotics accounted for about 40% of the expenditure on drugs and dressings in hospitals to-day. But if the rational use of antibiotics shortened the patient's stay in hospital by a few days or weeks (the average weekly cost of a patient in a hospital bed being £15) it was well justified economically. It was assumed that proprietary drugs were more costly than their non-proprietary equivalents, but in a representative cross-section of commonly prescribed substances it was found that, while 48% of the proprietaries were dearer, 35% were cheaper. Some would like an absolute embargo on proprietaries. This would lead to the rise of imitators, who would make their products as cheaply as possible and be unable or unwilling to accept adequate pharmacological or other control.

Mr. Hanbury added that by far the greater number of drugs introduced to the medical profession during the last 30 years had been worked out in the research laboratories of pharmaceutical chemists. The pharmaceutical industry had rendered good service to the profession and to national health, and the discouragement of proprietary products would bring the imitator right into his own. At the same

time, he was no believer in *laissez-faire*. Some degree of guidance and restraint to discourage excessive prescription was imperative.

Dr. STANLEY THOMAS (Vice-chairman, East Ham Executive Council) agreed that in the case of antibiotics there was something to be set on the credit side. These preparations had enabled the family doctor to treat many patients in their own homes at a fraction of the cost of hospitalization. There was an appalling waste in out-patient departments in some hospitals. In assessing the general practitioner's liability, one might bear in mind the consultant who ordered various substances of nutrient value which were not prescribable by the general practitioner, who, however, might have to face an inquiry and possible surcharge, when it would be no excuse for him to say that they were ordered by the consultant. The increase in the price of dressings was not always borne in mind when people exclaimed at these costs; cotton-wool to-day was three times the price it was in 1941.

Substitution of Equivalents

Many pharmacists and clerks to executive councils made suggestions for economies in drugs and dressings. It was stated that in London during the last complete year over 20 million prescriptions were dispensed at an average cost of about 4s. During the five years since the Act came into operation no doctors in London had been brought before the executive council and fined for excessive prescribing. Mr. A. G. SHORT (President of the Guild of Public Pharmacists) urged that some method be adopted for stopping the continuing use of antibiotics in cases in which they were no longer effective. The pharmaceutical department in hospitals should be given authority to substitute official drugs when they were equivalent to the proprietaries named. Much economy could be effected in dressings. Gauze, dear and difficult to obtain, need not be used when small swabs would do the job just as efficiently.

Dr. TALBOT ROGERS said that the doctor in general practice never knew whether in his endeavour to give good service to his patients he was keeping in step with his colleagues. It was not fair to compare prescribing in different parts of the country—the prescribing of a doctor in a Lancashire town, for example, with that of a doctor in a Hampshire village—but it was a good thing to compare the prescribing of doctors in adjacent streets, as was done under National Health Insurance. Dr. A. BEAUCHAMP urged that the student should be taught not only pharmacology but also prescribing, which was not at all the same thing.

Mr. HANBURY, in reply, took exception to the suggestion that the pharmacist should take authority unto himself to substitute a non-proprietary for a proprietary. Many equivalents were only reputedly so. The tone of the discussion, he added, had been all in favour of intelligent co-operation between doctors and pharmacists. The latter were nowadays very well informed and trained people. He protested against a suggestion that the wireless could help in removing mistaken ideas about drugs; it was more likely to encourage hypochondriacs.

Use of Medical Manpower

One session was devoted to the question whether manpower was used to the best advantage. The discussion turned largely on nursing and domestic service in hospitals. Sir ZACHARY COPE spoke of medical manpower—a difficult problem, he said, because of the strongly individualistic character of the profession. Under the old voluntary hospital system consultants were not paid and it was necessary for them to get a fair connexion often at hospitals separated by considerable distances. That system had been inherited by the N.H.S., but it was not essential, and manpower would be saved if in future, when appointments were made to various hospitals, there was close scrutiny of where in relation to the hospital the physician or surgeon proposed to live. Another suggestion was that in various

parts of the country where there were clinics close together covering the same field such clinics should in future be combined.

On the question of whole-time service, Sir Zachary Cope said that they all recognized that some posts were well fitted for whole-time occupancy and some men were well adapted for that form of work. Each regional board should be prepared to sanction, in consultation with the medical committee, whole-time employment in particular cases. Finally, the new service involved a good deal of committee work, which consumed valuable time. Men in consultant practice should be released from this for their clinical duties so far as possible.

Medical Planning in the Regions

Sir FREDERICK MESSER (Chairman, Central Health Services Council) pleaded for a National Health and Welfare Board, somewhat on the lines of his own council, to have overall responsibility for the administration of the service instead of the Ministry of Health. Hospital regions should be reduced in size, and regions should conform to the boundaries of groups of local authorities.

Dr. T. LLOYD HUGHES (Liverpool Regional Hospital Board) said that the regional plan had enabled rationalization and an effective redistribution of specialist and consultant services to take place, so that each area had its proportion of specialist services, though certain essential developments had been prevented by the restriction on allocation of capital. The problem of junior hospital medical staff called for much thought. Advances in technique required more junior staff to carry out the various procedures, but with the pre-registration year and the two years' National Service the young medical officers were not as ready to go back to hospital as in the past.

Dr. T. A. MORRISON (Chairman, Brighton Executive Council) said that, although the general practitioner had been called the first line of defence, this was only lip-service, and in fact he had become more and more a purveyor of prescriptions and certificates and less and less a clinician and adviser. Out of this ruck the doctor must be raised, and the Ministry, the regional board, and the local health authority must be prepared to help him. The general practitioner should have a bigger stake in the hospital service. Clinical assistantships were not the complete answer; they did not furnish the line of continuity from home through hospital and back home again. Interchangeability between registrars and general practitioners merited consideration. This would admit the general practitioner to the hospital service and ensure that the specialist had early experience of general medicine.

Sir ALLEN DALEY (late Chief Medical Officer, L.C.C.) said that regional boards were too few and too big, and there were too many executive councils and local health authorities in each region. The fact that there were only 14 regional boards was due to the supposed necessity of having a teaching hospital within each region. But there could be association between non-teaching hospitals and regional boards without a teaching hospital within the boundary. The original White Paper and the Willink proposals presumed 40 regional boards, and this would make it possible, except in Greater London, to ensure non-interference with county boundaries.

THE "NATIONAL FORMULARY"

The Joint Formulary Committee has considered criticisms of the arrangement of the *National Formulary*, 1952, received from medical and pharmaceutical organizations and from individual members of both professions, and has decided to revert, in the next edition, to the arrangement used in the *National Formulary*, 1949. Abbreviated Latin titles will be used as the main titles for individual preparations; full Latin titles will not be included. The Committee is investigating a proposal that a limited edition should be published using a pharmacological and therapeutic arrangement.

DOMICILIARY PHYSIOTHERAPY

The Physical Medicine Group Committee at a recent meeting discussed domiciliary physiotherapy and had the benefit of representatives from the General Medical Services Committee to express the point of view of the general practitioner.

Domiciliary physiotherapy presents several difficulties, and the cost appears to be one of the most serious; there is also a scarcity of physiotherapists available for the work. Because of the time spent in travelling when a physiotherapist visits the patient's home, it is more economical and convenient to bring the patient to a centre where all equipment is available. There are certain conditions, however, which prevent patients from attending at a hospital clinic, and for these treatment in the home may be essential. Another factor mentioned was the inability of mothers to leave young children while they attended at a hospital for perhaps several hours twice or three times a week.

Again the early treatment of conditions such as "lumbago" may shorten the illness considerably, whereas the arrangements for attendance at hospital necessarily impose some delay before treatment can be started. The general practitioner, too, is anxious to supervise his own cases, and by sending a patient to a hospital he may lose touch with the case.

It was thought that domiciliary physiotherapy would help to relieve overworked physical medicine departments, and a domiciliary van or vans might be equipped instead of extending such departments. Cost would have to be considered, though this would offset in some measure the number of ambulances or cars required for taking patients to hospital for physiotherapy. It was mentioned that in many towns there are private physiotherapists who could be employed by hospitals for domiciliary work, and also that voluntary effort and the assistance of bodies such as the Red Cross would supplement official arrangements.

It was agreed that the supervision of cases would have to be considered so that treatment should not go on indefinitely. To prevent this the domiciliary service could be linked to a physiotherapy department and the consultant in charge see all cases at intervals.

Another point raised was that some patients are unable to attend physiotherapy departments at the stated times, and for them, if evening clinics could not be provided, a domiciliary service might be possible.

It was generally agreed that general practitioners should have access to physical medicine departments, and if this were the custom the general practitioner could make the necessary arrangements for the domiciliary service of his patients in need.

The position was summarized by the conclusion that domiciliary physiotherapy was highly desirable and in many places appeared to be absolutely necessary, though it was recognized that the provision of such a service was not practical at the present time. Meanwhile the following lines could well be explored in various localities:

The use of private physiotherapists, perhaps with some subsidy from private and voluntary organizations.

Wherever possible, particularly in rural areas, there should be an extension of the present arrangements whereby vans equipped with necessary apparatus are provided.

The possibility of evening clinics should be explored, and also access by general practitioners to physical medicine departments.

In conclusion, it was emphasized that the number of cases for which domiciliary physiotherapy is essential is relatively small. Unless this is appreciated, the opportunity of making progress in this connexion might be lost for fear of the expense.

Registrars' Group, Scottish Western Region.—An extraordinary general meeting will be held on Friday, November 13, at 7.30 p.m. in the Lister Lecture Theatre, Glasgow Royal Infirmary.

BROMLEY DIVISION DINNER

MR. MACMILLAN ON DEBT TO DOCTORS

We all owed a debt to the profession, not only as doctors but as family friends, said Mr. HAROLD MACMILLAN, Minister of Housing and Local Government, at a dinner of the Bromley Division on October 28. Proposing the toast of the B.M.A., he said that, as an amateur, he had probably a greater knowledge of doctoring than most men. From his experience in hospitals since the first world war he could compare old methods with new, and it was quite a pleasure to have an operation these days. The doctors' work was more than a profession, it was a service, he said, and we had come to rely on their great tradition. The politicians were still mucking about with them, but the doctors carried on with the highest standards of professional conduct without worrying about it.

The chairman, Dr. H. J. PARISH, welcomed the Minister and his wife, and the secretary, Dr. J. W. EWART PURVES, replied to the toast of the Association. The Association at Bromley, he said, was made up of all political ideals, but they all welcomed the man who had the gift of understanding his constituents.

Notes and News

Hospital Costing.—The Minister of Health has set up a working party to devise a system of hospital costing based on departments and services. The system could be used to supplement the existing subjective accounts system of dividing expenditure under such headings as salaries and wages, drugs and dressings, and provisions. His decision follows consideration of comments received from hospital bodies on the "Reports on Hospital Costing" prepared by the King Edward's Hospital Fund for London, the Nuffield Provincial Hospitals Trust, and a subcommittee appointed by the committee of regional hospital board treasurers. The Minister considers that, while it is not practicable at present to replace the present subjective accounts system by one based on the departments and services of a hospital, a system of departmental and unit costing (supplementary to the subjective analysis of expenditure in the accounts), in at any rate the larger hospitals, would be of value to hospital administration and would facilitate efficient and economical spending. The working party includes representatives of the Ministry, the administrative and financial officers of the various types of hospital authorities, the King's Fund, and the Nuffield Trust. It will suggest to what types and sizes of hospital the system it recommends should apply and will be free to suggest different systems for different types and sizes.

Exchange of Hospitality.—A French surgeon's son, aged 16, at present at school in London, would like to receive occasional hospitality at week-ends, and possibly during the Christmas or Easter holidays, from a medical, preferably Catholic, family in London, and in return an English boy or girl could stay during the summer holiday either at the French surgeon's home in the Vendée or at his summer house on the Brittany coast.

A French doctor's daughter, aged 20, would like to receive hospitality from a British medical family and in return could teach French and help look after children. She has had some experience with children, for she is one of a large family and has been a cub mistress for the past three years.

Anyone interested should communicate with Dr. H. A. Sandiford, International Medical Visitors' Bureau, B.M.A. House, Tavistock Square, London, W.C.1.

Correspondence

Care of the Tuberculous

SIR,—The above section of the report of the General Practice Review Committee (*Supplement*, September 26, p. 103), even though collected in July, 1951, appears to show a lack of information among principals of the present-day set-up of chest diseases in the N.H.S. The "tuberculosis officer" as such has in most regional hospital board areas been replaced by the chest physician. This is not a mere change of name, but implies a widening of the latter's work to include all types of chest diseases. Chest physicians are of various grades, from part-time and full-time chest consultants, S.H.M.O.s, and assistant chest physicians. At least two regional boards still appoint "tuberculosis physicians" of S.H.M.O. status to work under chest consultants.

All these grades are appointed and remunerated by the regional boards, and not the borough or county councils, although they undertake care and prevention work which is still in the N.H.S. the responsibility of the local authorities, in the same way that these authorities are responsible for the aftercare work of any patient once they leave hospital, whatever the disease.

The chest physician is available for domiciliary consultations in the same manner as any other specialist, on request, but the care of the patient in the home is primarily the responsibility of the family doctor. The criticism that "the tuberculosis officer rarely visits the patients" is a relic of the pre-1948 days, when some practitioners appeared to pass all responsibility to the now defunct tuberculosis officer.

For those patients who are unfit to attend the chest clinic, it is the practitioner's responsibility to request a domiciliary consultation if he wishes to have further guidance. There is no division of responsibility: the primary care of the tuberculous in the home lies with the practitioner. That practitioner who declared that "far too many cases clutter up the visiting list" is not carrying out his terms of service under the N.H.S.

As to the bed position, the position has improved out of all recognition within the past two years. In my hospital area, whereas the waiting-list was nine months in 1951, it is now two to three weeks. The treatment of patients in huts is now obsolete because of the better rehousing programme.

The criticism of the "dilatory easy-going attitude" to the problem by the public health department, etc., and the "great time lag" in putting into effect treatment is a misstatement, as the public health department has no longer any concern with treatment, which is the responsibility of the regional hospital boards.

Many R.H.B.s have now completed their rearrangements of their chest services, although in isolated instances these are not yet complete. Their chest physicians run out-patient clinics either in hospitals or in isolated clinics, which in time will be removed to within the structure of the hospitals—at least that is the modern tendency. Health visitors or tuberculosis visitors are still employed by the local authorities and attend the various chest clinics so that they can have a link-up with their work in the homes.

Most chest clinics, especially those within hospitals, are no longer "tuberculosis dispensaries" but deal with all types of chest diseases, and many chest consultants have their own beds in general hospitals for the treatment of non-tuberculous chest diseases.

I hope this will clear up some of the erroneous statements expressed in this section of the report.—I am, etc.,

Worthing.

E. W. THOMPSON EVANS.

Service Recruitment

SIR,—There are three problems in the recruitment of medical officers. First is the recruitment of the long-service medical officer, whose prime duty must be to maintain the administrative and training establishment. The second is to ensure that wherever he may be serving the Serviceman can have readily available the professional care and skill at least equal to that obtainable in civil life. The third is the military training of National Service medical officers, not

merely in military medicine, but also in the practice of command and training of troops.

Potential recruits for long-service commissions are basically of two types: the soldier with a medical qualification and the doctor who is also interested in the Services. Provided the remuneration is reasonable the former will always serve. The latter will never do so unless they have failed to make the grade in civil life.

Dealing as it does almost entirely with the young, fit, adult male, the scope of general and specialist practice is severely restricted. Even in civil life a population of about 75,000 is the minimum upon which a worthwhile consultant practice can be based, and in the peacetime Services even a community of 250,000 would hardly produce work of a corresponding professional interest. Military considerations would never allow concentrations of that order. Only in a few specialties such as tropical medicine, hygiene, and bacteriology can the Services hope to offer a career of absorbing interest. Too many National Service medical officers fail to realize why Parliament has put them into uniform. It is not so that they can engage in medical practice but so that they can become properly trained officers and subsequently competent members of the reserve Army. The kernel of the problem is that of providing medical care for the Serviceman in peace. At present training and administration is suffering from the fact that far too high a proportion of regular officers are being trained as specialists and the military training of National Service medical officers is suffering.

There is only one solution, and even though it is unpleasant it is a fact which I think must be faced. To-day we have largely a citizen as opposed to a professional army and a National Health Service. It is logical, therefore, to make the responsibility for medical care of the Serviceman in peacetime the responsibility of the Ministry of Health, and this must apply to troops based both at home and overseas. The ordinary National Service of the medical officer could then be cut down to a year's military training immediately after registration, and thereafter any registered medical practitioner working in the Health Service would be liable for further professional duties with the armed Forces. This would probably work out at something like a further year's service between the ages of 40 and 45. In this way the ordinary medical care of troops would not only be looked after by experienced general practitioners but the Services would have the valuable skill of the established consultant.—I am, etc.,

GUY RIGBY-JONES.

London, W.1.

SIR,—I have read Dr. L. C. Kreeger's letter (*Supplement*, October 24, p. 178). The attitude to Army life expressed in it shocks me.

Surely the highest form of service we can give our country is membership of her armed Forces. Not for nothing did the old Romans, who kept the peace—peace, mark you, Sir—in the world for five hundred years use the word *miles* as either "soldier" or "man."

Dr. Kreeger complains of "lack of professional status" and of doing non-medical work. Can he not see that a soldier's duty is to serve, not to get? An M.O. in the Army is privileged to do his National Service as a commissioned officer from the start. How can he complain if he is paid the compliment of being given work to do to which other officers have but painfully acquired the right after service in the ranks? This is a matter for self-compliment, not for complaint.

Too many M.O.s think that National Service, or regular service, are means to their own personal ends alone, that the Army is lucky to have these demi-gods in it. Service in a Service means subordination of one's self to the good of that Service, and, as Jacob found after wrestling with a disguised angel, in the end one is blest. An M.O. must be a better doctor, first and a doctor second. He will then be a better doctor because his one aim will be the good of his men because they are his men, and he will know how to achieve this and combine it with the advancements of that Service of which he and they are alike members.—I am, etc.,

C. LIFFE.

Richmond, Yorks.

Quality in General Practice

SIR,—After reading some of the recent correspondence in the *British Medical Journal* under the titles "Quality in General Practice" and "Sweated Doctors," I realize how fortunate I was to qualify in 1930 and not in 1950. As a house-surgeon in 1930-1, I was better off financially than the house-officer of to-day, allowing for the great difference in the cost of living and income tax, and the fact that my job was "all found" and that there were legitimate extras to supplement my salary.

It surely must be admitted that more knowledge is required of the young doctor to-day. The medical course is longer and more extensive, and he must have a practical knowledge of techniques little used, or as yet undiscovered, when I qualified. There are, of course, good and bad among the house-officers of to-day as there always have been, but I must admit that I have been favourably impressed by the knowledge and ability of some of the recent and relatively recent graduates with whom I have worked, and I have been glad to learn many things from them.

I feel a very real sympathy for the young doctor to-day. If he aspires to the specialties or general medicine or surgery, examinations which are virtually competitive and of increasing complexity and difficulty await him. Then if, despite having acquired the necessary higher qualifications, there are not sufficient vacancies available, he turns to general practice, he is liable to be rejected by committees, not because he is too poorly but because he is too highly qualified. Is this why we are exporting so many of our promising young doctors? If so, can we afford to lose them?

When I qualified I am grateful to remember that these committees had not yet been invented and one could go into practice where one chose and stand or fall on one's own merits. Britain was then free.

Dr. C. J. Gordon Taylor (*Supplement*, October 24, p. 179) particularly mentions the M.R.C.P. This extremely difficult examination requires a very sound and detailed knowledge of medicine and allied subjects, and, though the G.P. also has to practise the other branches of his profession, surely a profound knowledge of medicine should still be considered a good practitioner's most essential asset. A doctor possessing sufficient intelligence and perseverance to pass this examination—and these are qualities much needed in practice—should have little difficulty in bringing his knowledge of the other branches of his profession up to the not too exacting standards necessary to-day when specialist and hospital assistance are so ready to hand. And in any case an intelligent and keen man will not be content to remain inadequate in any branch of practice. Has a sound knowledge of medicine ceased to be considered the hallmark of good practice? I hope not.

It is surely a shortsighted policy to refuse admission to general practice to men with higher qualifications. The standards of general practice can hardly be said to have risen since 1948 and one doubts if the new College of General Practitioners will save the day—the suggested requirements for membership of this college give one little reason to hope.—I am, etc.,

London, W.1.

DONALD J. C. DAWSON.

SIR,—I disagree entirely with Dr. C. J. Gordon Taylor (*Supplement*, October 24, p. 179). First and foremost, it is essential in any branch of medicine to be a good diagnostician. It is equally important for the physician to diagnose an acute appendicitis or a perforated peptic ulcer or a ruptured ectopic as it is for a surgeon to diagnose or to suspect a lobar pneumonia, coronary thrombosis, or impending diabetic coma. Moreover, some of us have had to take the M.R.C.P. from general practice while doing obstetrics and minor surgery.

No, Sir, the reason why M.R.C.P.s cannot enter general practice is because there are not sufficient practices available. It is high time that there was more co-operation among us all in all branches of medicine. There should be more consultant posts, a better future for the registrar, and a lowering of the maximum lists, with a corresponding

crease in the capitation fee, so as to allow more doctors to enter general practice. Then and only then will you get an efficient National Health Service.

I feel the consultants are underpaid for their sessions considering their experience, qualifications, and number of patients to see or operate upon, but the position of the senior registrar is scandalous.

I have no axe to grind, but it is time we G.P.s thought a little about our other colleagues.—I am, etc.,

W. Harrow, Middlesex.

D. V. MORGAN-JONES.

Association Notices

CHANGE OF NAME OF BRIGHTON DIVISION

Notice is hereby given by the Council of the Association that the name of the Brighton Division of the Sussex Branch has been changed to Brighton and Mid-Sussex.

A. MACRAE,
Secretary.

NORTHERN RHODESIA BRANCH

Notice is hereby given by the Council to all concerned that it is proposed to reconstitute the existing Northern Rhodesia Branch, which has no Divisions, into one with two Divisions with the following titles and areas:

(a) Northern Division, comprising the Western Province with the districts of Kawambwa and Fort Rosebery.

(b) Southern Division, comprising the Northern Province (excluding the districts of Kawambwa and Fort Rosebery), and the Eastern, Central, Southern, and Barotse Provinces.

Any member affected by this proposal and objecting thereto should write to the Secretary of the Association by Monday, December 14, 1953.

A. MACRAE,
Secretary.

Diary of Central Meetings

NOVEMBER

9 Mon.	Registrars Executive Committee, 2 p.m.
10 Tues.	Distribution Subcommittee, Medical War Relief Fund Committee, 11.30 a.m.
10 Tues.	Building Committee, 2 p.m.
11 Wed.	Joint Subcommittee of General Medical Services and Public Health Committees on Health Visitors, 10.30 a.m.
11 Wed.	Psychological Medicine Group Committee, 2 p.m.
11 Wed.	Consultants and General Practitioners Liaison Committee, 2 p.m.
12 Thurs.	Amending Acts Committee, 2 p.m.
13 Fri.	Public Health Committee, Special Meeting, 10.30 a.m.
13 Fri.	Staff Side Medical Whitley Council, 3.45 p.m.
17 Tues.	Arrangements Committee (Toronto, 1955), 11 a.m.
17 Tues.	Medical War Relief Fund Committee, 12.30 p.m.
17 Tues.	Subcommittee on Admission of Students to Medical Schools, 2 p.m.
18 Wed.	Transport Medical Standards Subcommittee, Occupational Health Committee, 2.30 p.m.

Branch and Division Meetings to be Held

BLACKPOOL AND FYLDE DIVISION.—At Savoy Hotel, Queens Drive, Blackpool, Wednesday, November 11, 7.15 p.m., dinner; 8.30 p.m., Dr. S. F. Gilbert: "Hypnosis in Medicine."

BOLTON DIVISION.—At Gymnasium, Bolton Royal Infirmary, Tuesday, November 10, 8.30 p.m., film show. Sound and colour films: (1) "Special Problems in Peptic Ulcer"; (2) "Radiography of the Vertebrae."

BROMLEY DIVISION.—At the Bell Hotel, Bromley, Thursday, November 12, address by Dr. W. Hedgcock (Assistant Secretary, B.M.A.).

BURTON-ON-TRENT DIVISION.—At Bretby Golf Club, Ashby Road, Burton-on-Trent, Tuesday, November 10, 7.45 p.m., dinner; lecture by Dr. F. E. Camps: "Death in Rillington Place."

CHESTERFIELD DIVISION.—At Walton Sanatorium, Chesterfield, Friday, November 13, 8.45 p.m., meeting. Presidential Address by Dr. R. B. Knowles: "Some Illustrations of Contact Dermatitis."

CITY DIVISION.—At Finsbury Health Centre, Pine Street, E.C., Tuesday, November 10, 8.30 p.m., meeting. Mr. J. Vincent O'Sullivan: "Dysmenorrhoea."

CROYDON DIVISION.—At 43, Wellesley Road, Croydon, Tuesday, November 10, 8.30 p.m., general meeting. Address by Mr. A. York Mason: "Some Aspects of the Surgical Treatment of Peptic Ulceration."

DONCASTER DIVISION.—At Messrs. Parkinsons' Café, High Street, Doncaster, Tuesday, November 10, 7.30 p.m., joint meeting with Doncaster Medical Society. Dinner, followed by Address by Dr. H. L. Settle: "The Work of a Health Department."

DUDLEY DIVISION.—At Education Offices, St. James' Road, Dudley, Tuesday, November 10, 9 p.m., annual general meeting.

EAST HERTS DIVISION.—At Hertford County Hospital, Thursday, November 12, 8.30 p.m., clinical meeting. Members of Hertford Medical Society are invited.

EAST KENT DIVISION.—At Chez Laurie Restaurant, Thanet Way, Herne Bay, Thursday, November 12, 7.30 p.m., dinner; 8.45 p.m., Dr. A. R. French: "Medico-Legal Problems."

EAST YORKSHIRE BRANCH.—At Quern House, Hull, Wednesday, November 11, 8.30 p.m., meeting. Dr. A. W. D. Leishman: "Treatment of the Cardiac Case in General Practice."

ENFIELD AND POTTERS BAR DIVISION.—At Chase Farm Hospital, The Ridgeway, Enfield, Friday, November 13, 8.30 p.m., meeting. Debate.

GRIMSBY DIVISION.—At Scartho Road Infirmary, Grimsby, Thursday, November 12, 8.30 p.m., clinical meeting. Professor W. H. McMenemey: "The Laboratory and the G.P." All members of the profession are invited.

GUILDFORD DIVISION.—At Royal Surrey County Hospital, Guildford, Thursday, November 12, 8.30 p.m., Dr. C. C. Chesterman: "Tropical Diseases to be Expected in Troops from Korea" (with film).

HASTINGS DIVISION.—At Royal East Sussex Hospital, Hastings, Tuesday, November 10, 8.15 p.m., meeting. Address by Dr. K. Shirley Smith: "Practical Problems of Cardiac Infarction with Special Reference to the Treatment of Shock" (illustrated by slides).

HENDON DIVISION.—At Hendon Hall Hotel, London, N.W., Tuesday, November 10, 8.45 p.m., meeting; Dr. W. S. C. Cope: "Modern Treatment of Rheumatism."

KENSINGTON AND HAMMERSMITH DIVISION.—At Hammersmith Hospital, Duane Road, W., Wednesday, November 11, 2 p.m., ward visits for general practitioners.

KESTEVEN DIVISION.—At White Hart Hotel, Sleaford, Thursday, November 12, 7 for 7.30 p.m., dinner; 8.30 p.m., Address by Dr. E. Grey Turner (Assistant Secretary, B.M.A.): "Quacks and Quackery."

KINGSTON-ON-THAMES DIVISION.—At Kingston Hospital, Wolverton Avenue, Kingston-on-Thames, Tuesday, November 10, 7.30 p.m., clinical meeting.

LEIGH DIVISION.—At Courts Hotel, Church Street, Leigh, Tuesday, November 10, 8.30 p.m., annual general meeting. Address by Dr. A. McNair Aitken: "Some Medical Aspects of Atomic Bombs."

NORTH BEDFORDSHIRE DIVISION.—At Bedford General Hospital, Bedford, Wednesday, November 11, 8.30 p.m., joint clinical meeting with Bedford Medical Society.

NORTH MIDDLESEX DIVISION.—At Highlands Hospital, Winchmore Hill, N., Tuesday, November 10, 2.30 p.m., clinical meeting.

READING DIVISION.—At Royal Berkshire Hospital, Reading, Wednesday, November 11, 8.30 p.m., meeting. Discussion on the personal and professional relationships between doctors—"Bridging The Gulf." Introductory speakers, Dr. J. J. Kempton, Dr. W. G. Tait, Dr. E. Hughes, and Mr. G. T. W. Cashell.

ROCHDALE DIVISION.—At Kingsway Hotel, Rochdale, Monday, November 9, 8.30 p.m., clinical meeting. Dr. N. J. de Ville Mather: "Present Views on Schizophrenia."

SCARBOROUGH DIVISION.—At Scarborough Hospital, Thursday, November 12, 8.30 p.m., joint meeting with Scarborough Law Society. Professor C. J. Polson: "Poisons and Homicidal Poisoning."

SOUTH ESSEX DIVISION.—(1) At Oldchurch Hospital, Romford, Friday, November 6, 9 p.m., meeting. Dr. A. Topping: "Medical Profession—A House Divided." (2) At Hyde Park Hotel, London, S.W., Thursday, November 12, 7.30 p.m. to 1 a.m., dinner dance.

SUNDERLAND DIVISION.—(1) At Royal Infirmary, Sunderland, Thursday, November 12, 3 p.m., meeting. Annual address by Professor Charles F. W. Illingworth: "The Peptic Ulcer." (2) At Seaburn Hotel, Sunderland, 7.30 p.m., annual dinner.

TOWER HAMLETS DIVISION.—At Mile End Hospital, Bancroft Road, E., Friday, November 13, 3 p.m., clinical meeting.

TUNBRIDGE WELLS DIVISION.—At Kent and Sussex Hospital, Tunbridge Wells, Tuesday, November 10, 8.30 p.m., clinical meeting. Dr. MacDonald Critchley: "Nervous Disorders."

WEST HERTS DIVISION.—At Leavesden Hospital, Abbots Langley, Sunday, November 15, 10.30 a.m., clinical demonstration. All medical practitioners in the area of the Division will be welcome.

WEST MIDDLESEX DIVISION.—At Bryon Hotel, Ruislip Road, Greenford, Saturday, November 14, 8 to 12 p.m., Divisional dance.

WOOLWICH DIVISION.—At Woolwich Memorial Hospital, Shooters Hill, London, S.E., Tuesday, November 10, 8.30 p.m., meeting. Dr. P. H. Addison: "Medico-Legal Problems in Private and Consultant Practice." Members of the Greenwich and Deptford Division and other local medical practitioners are invited.

British Medical Association

PROCEEDINGS OF COUNCIL

Wednesday, November 4

A meeting of the Council of the Association was held at B.M.A. House, London, on November 4, with Dr. E. A. GREGG in the chair.

Preliminary Business

The CHAIRMAN referred with regret to the death of two former Presidents, Sir Ewen Maclean, of Cardiff, and Mr. R. G. Hogarth, of Nottingham, as well as other former members of Council. He said that it was invidious to make a distinction between one person and another; they all in their own places, and according to their gifts and talents, contributed to the well-being of the Association.

The members present stood in silent tribute, and the Chairman was authorized to send a letter of condolence to the relatives.

The Chairman said that the whole Council would agree with him in extending their congratulations to Dr. Guy Dain, who was present in his accustomed place, on his 83rd birthday on the morrow. He was the recipient of their appreciation and most affectionate regard.

A handsome Chinese vase was on view before the Council. The gift of Dr. J. A. Ireland, of Shrewsbury. The thanks of the Council were extended to the donor.

The Chairman said that they were indebted to the President (Mr. Tudor Thomas) for representing them at the annual meeting of the Danish Medical Association and furnishing them with an admirable report; also to Dr. Talbot Rogers, who had produced a very interesting report about the meeting of the West German Medical Association, at which he had represented the Association.

It was reported that several letters had been received in appreciation of the organization of the First World Conference on Medical Education. The Chairman said that this was certainly a memorable event. There had come into his hands a letter from the Director of the Mayo Foundation: "I have never attended a meeting so beautifully organized and where every possible eventuality was anticipated."

Dr. R. P. LISTON reported on the cricket match which had taken place between the B.M.A. and the Law Society in July last and said that the Law Society had challenged the Association to a return match, which would be played on May 30 next year.

Representatives of the Association on nine outside bodies were appointed or reappointed.

A letter was read from the Bishop of Coventry, stating that it was desired to enlarge the representation (at present two members) of the British Medical Association on the Churches' Council of Healing. The Council decided to invite six members of the Association to serve in this way.

Annual Meeting Arrangements

A resolution passed by the Physical Medicine Group Committee expressing disappointment at the absence of a section in physical medicine in the programme of the Annual Meeting came before the Council. The Council decided that such a section should be arranged.

With regard to the Joint Annual Meeting at Toronto in 1955, a letter was read from Dr. T. C. Routley accepting with deep appreciation his election to the Presidency.

It was reported that the Canadian Medical Association at its Annual Session assembled in Winnipeg had accepted the invitation to a meeting jointly with the British Medical Association in England in 1959, and had invited the British Medical Association to nominate one of its members as president of the Canadian Medical Association for that year.

It was reported that the three plenary sessions at the Annual Meeting at Glasgow would be devoted to "The Problem of Sleep," "Food and Disease," and "The Problem of Pulmonary Tuberculosis To-day." The appointment of officers to the scientific sections was now complete.

The CHAIRMAN raised the question of the Annual Dinner in connexion with the Annual Meeting. He said that this had been an unsatisfactory event, alike from the point of view of attendance and the number and length of speeches. He suggested that it be considered whether the Annual Dinner should not be held earlier in the week so as to make it possible for more of the representatives who would otherwise be returning home to attend. The toast list should also be ruthlessly cut and the proceedings limited to two toasts, that of the "British Medical Association" and "Our Guests." The Council accepted the Chairman's suggestions for consideration by the Arrangements Committee.

A question arose as to the date of the Annual Representative Meeting, 1955, in which year the Annual Scientific Meeting will begin in Toronto on June 20. The Council agreed that the Annual Representative Meeting should be held in London from July 20 to 23. The alternative arrange-

On this point, Dr. TALBOT ROGERS, on behalf of the General Medical Services Committee, called attention to the membership of the Joint Formulary Committee. The primary purpose of the Committee, which was set up by the British Medical Association and the Pharmaceutical Society, was to assist general practitioners, but by reason of co-optation the membership of the Committee had become heavily overweighted on the scientific and pharmaceutical side, so that now out of its 37 members only 7 were general practitioners. The Committee had a different pattern now from what it had originally.

Professor WAYNE said that the Committee had to think of other requirements in addition to those of general practice, as the *National Formulary* was used in other branches of practice and also by pharmacists. While it might not be opportune to upset the balance on a joint committee representing many interests, he thought that a larger proportion of general practitioners might with advantage be included in the Executive Subcommittee, which was at present engaged in the work of revision.

The SECRETARY said that the appropriate course might be to ask the General Medical Services Committee to draft a revised constitution for the Joint Formulary Committee, and, if this were approved by the Council, to submit it to the Pharmaceutical Society for their comments.

Dr. W. WOOLLEY drew attention to a decision of the Joint Formulary Committee in relation to a resolution of the last Annual Representative Meeting, and, on the motion of Dr. DAIN, this was referred back for further consideration. The report was otherwise approved, and Dr. TALBOT ROGERS, on behalf of the General Medical Services Committee, accepted the Secretary's suggestion that his Committee should draft a revised constitution for the Joint Formulary Committee.

Appointment of Constitution Committee

The Council turned to the question of setting up, on the instructions of the Representative Body, an *ad hoc* Constitution Committee to take evidence, consider, and report on a reorganization of the Representative Body, and such other constitutional matters as the Council may decide. It had been also resolved at the Representative Meeting that while the Council should appoint the committee, not more than 50% of its members should be members of Council.

Dr. J. A. PRIDHAM, chairman of the Organization Committee, said that his Committee considered that a committee of 25 members, 12 from the Council and 13 others, with power to co-opt, would be reasonable. When the Council had appointed its quota, the remaining places could be filled from a panel drawn up on a regional basis. There should be not fewer than three representatives from Scotland, one from Wales, and one from Northern Ireland, whilst overseas members would be represented by the chairman of the Overseas Committee or his nominee. The four chief officers of the Association should be on the Committee *ex officio*, as well as the chairman or other representative of the Organization Committee, certain members of the Representative Body, including those who had taken an active part in the discussion on this question, honorary secretaries of Branches and Divisions, and members selected for their individual experience.

A ballot was then taken for seven members of Council, who, with the members *ex officio*, including the chairman of the Organization Committee, would make up the Council's twelve. Eleven names were suggested and the following were elected: Dr. R. G. Gibson, Dr. I. D. Grant, Dr. Frank Gray, Dr. R. Hale-White, Dr. J. G. M. Hamilton, Mr. H. H. Langston, Dr. A. Talbot Rogers.

Dr. S. WAND pointed out that the Committee was charged with the consideration not only of a reorganization of the Representative Body but of "such other constitutional matters as Council may decide." He thought the Council should decide what it wanted to refer to this committee, and this might have a bearing on the choice of the thirteen members and the manner in which they were chosen. Dr.

R. HALE-WHITE said that his impression of the discussion of this matter at the Annual Representative Meeting was that there was not felt to be any dramatic urgency about it. Indeed, the idea was that it would be a long business.

The CHAIRMAN said that at the Council meeting in January the Council would have before it a wide selection of names from which to appoint the thirteen non-Council members, and it would then be time to determine what matters should be referred to the Committee.

Consultants and Specialists

Dr. T. ROWLAND HILL, chairman of the Central Consultants and Specialists Committee, presented a report which covered the two meetings of that committee on July 30 and October 1, both of which were fully reported in the ensuing *Supplements*.

On the question of senior registrars and additional consultant posts—a matter which had exercised the Annual Representative Meeting—Dr. Hill said that the view of his Committee was that the paucity of consultant vacancies in general medicine and surgery was largely due to the fact that many senior registrars in these specialties were engaged in work of a consultant nature. The Ministry had been urged to impress upon hospital boards the necessity of reviewing their medical staffing arrangements in order to offset the reduction of senior registrar posts where necessary by the creation of additional consultant posts.

He also drew attention to the circular regarding the constitution and functions of medical advisory committees lately issued by the Ministry. The circular, which applied to boards of governors and hospital management committees, though not, unfortunately, to regional hospital boards, made it clear that the constitution of these committees rested with hospital medical staffs themselves and laid down the principle that hospital authorities should regularly seek the advice of these committees on all matters within their sphere.

Other questions which figured in the recent agenda of his Committee concerned the increase in the number of whole-time consultants, the qualifications of medical auxiliaries, the preparation of evidence for the Guillebaud Committee, the review of the gradings of S.H.M.O.s, hospital junior staffing difficulties, and comments on several resolutions of the recent Annual Representative Meeting. The Committee had included a whole-time consultant among the six representatives whom it appointed to the Joint Committee.

A number of questions were asked on the report, particularly concerning the registrar position and also the review of S.H.M.O. grading. With regard to this latter, Dr. L. A. GIBBONS called attention to anomalies of grading. In the north-west region all those who had come up for further review were upgraded, and in the north-east none were upgraded. What were the criteria whereby these people were made consultants? Dr. T. W. DAVIES said that if senior registrars were doing the work of consultants they should be paid as such.

Dr. HILL said that continuous pressure had been exercised by the Joint Committee upon the Ministry of Health with a view to stimulating the boards to expand their consultant services. Much of the trouble, he thought, was due to local circumstances, not to central policy. As regards the correction of faulty S.H.M.O. grading, the Ministry's "No" would not be taken for an answer, and the pressure would be kept up. One suggestion which the Joint Committee had been asked to pursue was that the senior registrar establishment of 960 posts, agreed in 1951, and the distribution of senior registrars among the different specialties within the agreed establishment, should be reviewed again to ensure that the senior registrar consultant ratio was satisfactory. The Joint Committee had accepted an invitation from the Ministry to nominate two physicians and two surgeons to serve on a small committee to consider applications from boards for permission to appoint additional consultants. Sir Harold Boldero, Mr. D. W. C. Northfield, Sir Arthur Porritt, and himself had been nominated, and the

committee, under the chairmanship of Dr. Godber, of the Ministry, had begun its work. If there was a good case for an increased establishment permission would be given.

Dr. GRAY called attention to a comment by the Consultants and Specialists Committee on the Representative Body resolution concerning the filling of general-practitioner vacancies. The resolution read that equal consideration should be given to practitioners who had spent several years in hospital "provided they have adequate experience in general practice." The Committee said it welcomed the resolution though it felt that the proviso detracted greatly from its value, and that the handicap at all. The handicap was that a considerable number of people from time to time went straight out of hospital into single-handed practice—large practice—with no experience of general practice whatever. Surely if, as an analogy, a man applied for a post in a psychiatric department and said he knew nothing about psychiatry but a great deal about orthopaedic surgery he would not get the post.

After some further discussion the report was approved.

Occupational Health Services

Dr. J. A. L. VAUGHAN JONES brought forward the revised memorandum on the future of occupational health services, which had been amended as a result of comments by other committees of the Association. The observations of the Society of Medical Officers of Health were also reported to the Council. The Society strongly urged that any comprehensive occupational health service should be part of the National Health Service, whereas the Committee had felt that, while there should be an administrative link with the N.H.S., full provision to meet special health needs of occupational groups was not made under the existing N.H.S. administration, and that additional arrangements, closely integrated, were necessary.

Dr. K. COWAN, chairman of the Public Health Committee, said that he was not quite clear why the Occupational Health Committee felt that the occupational health service should be part of the N.H.S. There would appear to be every advantage in such an arrangement. The occupational health service had its ramifications in industry and its relation to the health of the worker, and it seemed most desirable that all the questions relating to sickness benefit and other matters which really formed part and parcel of the N.H.S. should be not only closely integrated but in the same system of administration, particularly central. Unless there was a very substantial reason why the occupational health service should be outside, he could see every advantage in its functioning as part of the N.H.S. There might be some highly specialized parts of industry—such as industries where pneumoconiosis was prevalent—which might offer ground for special treatment, but he would have thought that even here there was no more reason why they should be outside the service than that brain surgery or thoracic surgery should be outside.

Dr. GRAY said that the proposals of the Society of Medical Officers of Health meant that the industrial medical officer should be under the M.O.H. That would take them into party politics. It would be, in effect, nationalizing a part of party politics. It would mean, "You cannot have your own doctor, you have got to take the doctor of the local health authority."

Dr. H. D. CHALKE said that there was no suggestion of party politics. The whole idea of having the service within the N.H.S. would be free choice of doctor, because most of the work would be done not by the medical officer of health but by the general practitioner.

Dr. VAUGHAN JONES said that his Committee felt that the occupational health service was not expanding as it should. No action had been taken by the Ministry of Labour to set up the standing joint advisory committee recommended in the report of the Dale Committee on Industrial Health Services. It had been learned, however, that the Ministry of Labour would be willing to receive suggestions from the

Association, and that was the reason why the document was going in the first instance to that Ministry. Whatever Dr. Cowan or Dr. Chalke might say, the position had not yet arrived at which they wanted the industrial health service taken over by the public health authority. That was his Committee's view and his own. At this stage it was unwise, having in mind the political issue, that the service should become part of the N.H.S. It was also impracticable to have free choice of doctor in industry. Apart from that, the occupational health service had not grown on a voluntary basis; a certain amount of statutory basis was necessary for its development, but that basis should not be the National Health Service, in which it might be completely submerged.

A certain amount of discussion on detailed matters in the memorandum took place. Dr. WAND called attention to a certain lack of clarity at one point in the proposals for general health services to workers. Exception was taken to the proposal under "certain general health services" to have diagnostic or periodic general health examinations in addition to the examination of individual workers with a view to advising management as to their conditions of employment, and a proposal by Dr. W. E. DORNAN to add to the title, after "certain general health services to workers," the words "subject always to strict observance of the ethical rules of the profession," was rejected. Objection was also taken to another paragraph which was concerned with the method of appointing industrial medical officers.

After further discussion it was agreed on the motion of Dr. GRANT, seconded by Dr. HUTCHINSON, to leave it to Dr. Vaughan Jones, in consultation with Dr. Wand and others, to make such alterations in the wording as might seem necessary in accordance with the discussion which had taken place, and, subject to this, the report was approved.

Other Committee Reports

Dr. TALBOT ROGERS presented the report of the General Medical Services Committee, which covered matters discussed at three meetings reported in the *Supplements* of August 1 (p. 69), October 3 (p. 157), and October 24 (p. 176). The report was approved without discussion.

Dr. K. COWAN presented the report of the Public Health Committee, the proceedings of which were recorded in the *Supplement* of September 19 (p. 101). This report also was approved without discussion.

Dr. H. H. D. SUTHERLAND said that the last meeting of the Amending Acts Committee was devoted almost entirely to the consideration of the memorandum of evidence to be given to the Guillebaud Committee. The Committee had still to consider some matters of long-term policy.

The Science Committee report, which was adopted, was concerned with storage space for the library, and with recommendations for the award of the Association prizes. It was agreed that the Science Committee be asked for its observations on a programme which had been sent to the Association for the celebration of the Columbia University bicentenary.

Dr. I. D. GRANT presented the report of the Private Practice Committee. This covered matters set out in the report of the Committee in the *Supplement* of October 24 (p. 175). A recommendation that an improved car badge be produced for sale to members at 10s. each, including postage and packing, was adopted.

Dr. G. DAIN presented the report of the Public Relations Committee, which dealt with formal business; also the report of the War Memorial Committee, which proposed that the £330 donated up to the present specifically for charitable purposes should be transferred to the Medical War Relief Fund, with a request that it be used to assist in the education of children of medical practitioners, victims of the second world war who were in need of such assistance.

Reports of the Journal Committee and the Family Doctor Committee were adopted without discussion. In presenting the Scottish Committee report Dr. J. G. M. HAMILTON

referred to the highly successful jubilee dinner of the Scottish Committee, and said how gratified they had been by the presence of the President, the Chairmen of Council and of the Representative Body, and the Secretary.

Other committee reports received were from the Rehabilitation of Disabled Persons Committee, which is preparing evidence for submission to the Departmental Committee; the Joint Committee with the Magistrates' Association, which is preparing a report on the whole subject of cruelty to and neglect of children; the Building Committee, which concerned exterior and interior decorations at B.M.A. House and renewal of tenants' leases, and the Office Committee, which dealt with staff matters. Dr. L. W. JONES, in presenting the report of the Welsh Committee, said that it had decided to recommend to the Amending Acts Committee that a Medical Practices Committee for Wales should be established. They were not satisfied with having only one representative accorded to Wales.

Dr. R. FORBES, for the Central Ethical Committee, said that it had been decided to send a further communication to the few Divisions and Branches which had not yet adopted the revised ethical rules approved by the Representative Body in 1950. Another matter which was before the Committee was the compilation, in conjunction with the Public Relations Committee, of a list of the various matters which might be discussed with the new Press Council. This arose out of the resolution of the Annual Representative Meeting deploring the paragraphs which sometimes appeared in the gossip columns of the Press concerning estimated incomes of prominent medical men.

The International Relations Committee report dealt, *inter alia*, with the question of subscriptions to the World Medical Association. The question of aid for South Korean doctors was brought forward, and it was left to the International Relations Committee to make some proposal to the Council. Dr. H. M. GOLDING reported for the Charities Committee.

Other Business

Dr. S. WAND brought forward a proposal that the Council should consider the desirability of setting up as soon as might be practicable a Committee on Medical Education, particularly with reference to postgraduate teaching and to the suggestions made at the recent Hague Assembly of the World Medical Association. The Council deferred its decision on this proposal.

The memoranda of evidence submitted on behalf of the Council to the Tynwald Commission on salaries and emoluments in the Isle of Man were before the Council. It was stated that as yet no conclusions could be reported, but the CHAIRMAN OF COUNCIL said how much they and their colleagues in the Isle of Man were indebted to the Secretary of the Association for his prompt action in the matter, and also to Dr. Talbot Rogers for accompanying the deputation at very short notice.

Dr. Hale-White was appointed fraternal delegate to the meeting of the Canadian Medical Association next year, and two public health service members on the Council (Drs. Chalke and Cowan) were appointed delegates to the Congress of the Royal Sanitary Institute at Scarborough next year.

The Council elected 165 new members of the Association. The proceedings terminated at 6.45 p.m.

CHEMICALS THAT CAN BE PRESCRIBED

Diagnostic reagents which the Minister of Health has decided are chemicals that may be prescribed were listed in the *Supplement* of October 17 (p. 170). The method of the prescription is for a Form E.C.10, together with the receipted bill from the chemist supplying the reagent, to be sent by the doctor concerned direct to the executive council of the area, which will then refund to the doctor the cost of the reagent.

MEDICAL PRACTICES COMMITTEE

AMENDMENT OF CLASSIFICATION OF AREAS

The following amendments to the classification of areas have been issued by the Medical Practices Committee (August 2 to October 16, 1953).

ENGLAND: COUNTIES

Bedfordshire.—Woburn, Toddington, Amphill and Cranfield District, Intermediate from *Designated.

Buckinghamshire.—High Wycombe, Intermediate from *Designated.

Essex.—Borough of Chingford, Borough of Leyton, Rural District of Rochford, Intermediate from *Designated; Urban District of Frinton and Walton, Restricted from Intermediate.

Gloucester County and City.—Hanham, Kingswood and Warmley, Intermediate from *Designated.

Lancashire.—Middleton, Stretford, Intermediate from *Designated.

Lincolnshire (Lindsey).—Caistor Area: Urban District of Market Rasen, Restricted from Intermediate.

London.—Borough of Hampstead: West End Ward, Restricted from Intermediate. Borough of Westminster: Victoria Ward, Intermediate from *Designated.

Middlesex.—Borough of Hendon: West Hendon Ward, Intermediate from *Designated.

Northumberland.—Urban District of Bedlingtonshire, Intermediate from *Designated.

Notts County and City.—Arnold District, Beeston District, Intermediate from *Designated.

Salop.—Shrewsbury, Intermediate from *Designated.

Surrey.—Borough of Sutton and Cheam, *Designated from Intermediate.

Yorks (West Riding).—Urban District of Featherstone, Intermediate from *Designated.

COUNTY BOROUGHES

Halifax.—Whole of County Borough, Intermediate from *Designated.

Liverpool.—District No. 8, Intermediate from *Designated.

Southend-on-Sea.—Southend-on-Sea and Thorpe Bay District, Intermediate from *Designated.

Stoke-on-Trent.—Smallthorne and Norton, Intermediate from *Designated.

Wakefield.—Whole of the County Borough, Intermediate from *Designated.

West Hartlepool.—Whole of County Borough, Intermediate from *Designated.

WALES

Caernarvonshire.—Borough of Conway and Llandudno Junction, Restricted from Intermediate.

Merionethshire.—Corwen, Intermediate from Restricted.

OPHTHALMIC GROUP COMMITTEE

The Ophthalmic Group Committee held its first meeting of the new session on October 9 and reappointed Mr. O. GAYER MORGAN to the chair. Mr. Morgan was also reappointed the Group Committee's representative on the Central Consultants and Specialists Committee.

Three new members were welcomed to the Committee—namely, Mr. H. V. Ingram and Mr. E. F. King, appointed by the Faculty of Ophthalmologists, and Dr. A. F. Gilbert, elected by the non-members of the Group who are on the central ophthalmic list.

"Reminders"

The Committee considered the use of reminders in the supplementary ophthalmic service—that is, written communications sent to patients for the purpose of arranging a further sight test. In the Committee's view such communications are most undesirable and result in unnecessary frequency of sight-testing and expenditure of public funds. Representations have from time to time been made to the Ministry that such reminders should be prohibited, and the

*Areas in which the position is finely balanced and the admission of only one or two doctors may result in reclassification.

matter is now under consideration by the Standing Ophthalmic Advisory Committee of the Central Health Services Council.

Bifocals

Difficulty has sometimes been caused by the Ministry's requirement that bifocals shall be prescribed only when "clinically necessary." In the Committee's view this expression is not an appropriate one, since more often than not patients need bifocals for other than strictly clinical reasons. The Ministry has been requested to introduce some phrase which will leave it to the prescriber to decide whether bifocals are essential for the patient.

Sight-testing in Sanatoria

The Committee considered the position of an ophthalmic surgeon who had been asked to test the sight of patients in sanatoria under a clause in his contract which required him to undertake occasional visits to other hospitals without additional remuneration. In the Committee's opinion it is important to maintain the principle of a medical sight-test, and if an ophthalmic surgeon who receives a request of this kind finds difficulty in meeting it he should ask for an additional session to be included in his contract. Alternatively, he might explore the possibility of delegating the work to a clinical assistant.

Clinical Instruction of Opticians

From time to time inquiries are received from ophthalmologists on the Committee's attitude to the subject of instructing opticians and student opticians. The Committee has always held the view that it is most undesirable for ophthalmologists personally to undertake this work except in the case of opticians who are employed whole-time in the hospital service.

Salaries of Dispensing Opticians

Recently the Group Committee drew the Ministry's attention to the difficulty of securing dispensing opticians in the hospital service owing to inadequate salary scales. The Ministry has replied that the Management Side of the Optical Whitley Council has made it clear that it is unable to agree to any increase in the current scale itself, unless an investigation is undertaken and evidence can be shown that the present scale is out of line with remuneration now being earned by opticians outside the Health Service or by comparable kinds of staff inside and outside the Service.

Contact Lens Centres

In view of the widening scope of contact lens centres the Central Ethical Committee has sought the Group Committee's views on the running of these centres, and a representative of the Group Committee will attend a meeting of the Central Ethical Committee to discuss the matter.

The Group Committee has decided to seek the views of the Ministry on the question of the provision of ophthalmic services at health centres, and has also appointed a sub-committee to consider the matter. Other questions which the Committee intends to raise with the Ministry include the attendance of observers from ophthalmic services committees at executive council meetings, and the prescription of glasses in the case of persons referred to the hospital service.

The Committee wishes to call the attention of general practitioners and local medical committees respectively to the two matters dealt with in the following paragraphs:

OPHTHALMIC REPRESENTATION ON LOCAL MEDICAL COMMITTEES

The Minister of Health has made regulations (S.I. No. 1177, 1953) which provide for the removal of the name of an ophthalmic medical practitioner or ophthalmic optician from a local ophthalmic list in certain circum-

stances—for example, where the person concerned has ceased to provide supplementary ophthalmic services in the area.

Before an ophthalmic services committee takes such action it is required to consult the local medical committee, and the Ophthalmic Group Committee of the Association feels that the local medical committee may wish to co-opt an ophthalmic representative when considering a proposal for the removal of an ophthalmic medical practitioner from the list.

It is therefore suggested that a local medical committee in these circumstances should communicate with the Secretary of the Association, who will arrange for a nomination to be forwarded.

"DIRECTION" BY GENERAL PRACTITIONERS OF PATIENTS NEEDING A SIGHT TEST

The criticism is sometimes made that a general practitioner who, when issuing a Form O.S.C.1, gives a patient the name of a particular ophthalmic medical practitioner or ophthalmic optician is directing the patient to that individual for his sight test, thus overriding the principle of freedom of choice. This shows a misunderstanding of the position.

The regulations contain nothing to prevent a general medical practitioner from supplying a patient with the name and address of an ophthalmic medical practitioner or ophthalmic optician, and there is no objection to his doing so, provided nothing is said that might seem to override the clear statement in the note on the back of Form O.S.C.1 that the patient has a free choice in selecting the person who is to test his sight.

As a result of representations made by the Group Committee the Ministry has recently made the position clear to executive councils in an official circular, E.C.L. 66/53.

The Committee wishes to suggest to general practitioners that the patient's Form O.S.C.1 should never be put in a sealed envelope with the form or envelope endorsed with the name of an ophthalmic practitioner or optician, since this could with some justification give rise to a complaint that the patient had been deprived of freedom of choice because he would not be able to read the notes on the form.

Overseas News

Salary Dispute with Cyprus

The Colonial Office has announced that the Secretary of State has agreed to arrange for the visit to Cyprus of an expert to examine the salary structure of the Government service and to advise whether any measure of reorganization is called for, and whether there are any anomalies or inequities which should be removed having regard to the responsibilities borne by Government officers and to the social and economic conditions prevailing in Cyprus at the present time.

The Overseas Committee has welcomed this announcement, but after careful consideration has decided that it makes no material change in the circumstances which obliged the Association to include the Government of Cyprus in the Important Notice in May, 1953. For the present, therefore, Cyprus continues to be included in the Important Notice.

East Africa Salaries Commission

A commission to examine Civil Service salaries and conditions of service in East Africa under the chairmanship of Sir David Lidbury has recently taken evidence in East Africa, including evidence submitted by the Uganda Branch. A further memorandum of evidence will now be submitted to the Commission in London by the Overseas Committee.

Testimonials for Former Colonial Medical Officers

Some time ago the Association represented to the Colonial Office that former members of the Colonial Medical Service

should be permitted to give the names of Directors of Medical Services under whom they had served as personal referees to whom any prospective employer might refer direct for a personal and confidential opinion. Previously, in many Colonies, the Director of Medical Services was permitted to furnish a testimonial for one of his ex-officers only through the Chief Secretary or Colonial Secretary, and this tended to restrict such testimonials to short and formal reports.

The Colonial Office accepted the Association's suggestion and recommended it to Colonial Governments, and it has now been learned that all Colonial Governments have adopted it.

Amendment of Medical Registration Ordinance in Hong Kong

The Hong Kong Government has recently made an amendment to the Medical Registration Ordinance of the Colony. It empowers the Governor to grant permission to doctors holding medical qualifications which do not entitle them to be registered in Hong Kong to practise medicine within a limited field—that is, to examine prospective immigrants to foreign countries on behalf of the governments of those countries. The amendment was drafted without any prior consultation with either the Hong Kong Branch of the B.M.A. or the Colony's Chinese Medical Association, and without consulting the Hong Kong Medical Board, which is the registration authority for the Colony. A strong protest against this arbitrary procedure has been sent to the Colonial Office.

Correspondence

Bureaucratic Hierarchy

SIR,—I have been following with interest your correspondence on "Sweated Doctors" and "Quality in Medical Practice," but feel that your correspondents have overlooked a most important point—namely, that of the status of the doctor under the National Health Service.

I embarked on the study of medicine at the comparatively late age of 28. As well as being then a highly trained and competent shipowner's secretary I had read widely and had broad interests, mainly in the field of adult education, and had no difficulty in passing the University Entrance Board Examination in a very short time, and therefore came somewhere near the requirements for the "ideal" medical student. It meant hard work and considerable financial sacrifice, but I felt that the satisfying vocation and rise in professional status would be ample compensation.

My first house job was in the month of October, 1948, before the machinery of the National Health Service had been properly set in motion. Though house-officers were paid less than the maids who cleaned our rooms, dimness of future prospects was not yet so apparent, and we were quite happy in the job. Two years later, after my fourth house job, and during which time the creaking wheels of the State-controlled Health Service were beginning to turn slowly and the present atmosphere of apathy, anxiety, and frustration was making itself felt in the house-officers' mess, I decided to satisfy another ambition to travel as far and wide as possible to see for myself what other lands were like and how the people lived. I have been singularly fortunate. My travels so far have taken me to Malaya, Indonesia, China, Japan, and Australia. In all these countries, as Dr. Ian D. Grant (*Supplement*, October 24, p. 173) says of New Zealand, "the doctor occupies an honourable and influential position in the life of the community," and "the status of the general practitioner is high."

Now after almost two years' absence I return to find that the wheels of the State-controlled Health Service are in full motion, but unlike New Zealand, which also has a national health service, the Health Service here is under complete

domination of the administrative bureaucracy. The status of the doctor, whether he be junior house-officer, consultant, or general practitioner, has been lowered till he is merely another Civil Servant of comparatively low rank. In hospital I am surrounded by clerks whose work I could do in my spare time and who are better paid in many cases. In reply to Dr. Harold E. Thorn's latest letter (*Supplement*, October 31, p. 185), the time he spent giving intravenous infusions is now taken up in filling up the innumerable forms demanded by the Health Service. It is much more important now that forms, etc., be completed and sent to the office before 10.30 a.m. on the day of a patient's discharge than that necessary clinical work be attended to.

It would seem that this bureaucratic hierarchy with its waste of time and material is an inevitable feature of State control of any industry or profession, but what a pity it had to happen to medicine.—I am, etc.,

Glasgow.

JESSIE M. LINDSAY.

Sweated Doctors

SIR,—Under the old regime doctors and nurses worked very long hours for very little money as a matter of professional religion. The young doctor was free to plan his own life after qualification. Nowadays he must take up house appointments by legal compulsion, having no say whatever in his long hours of highly skilled and responsible work, nor in his pay. This is forced labour, and nothing else, by which the State mans its hospitals. In any decent country the hours should be halved, or, if doctors just do not exist, the present salary doubled as overtime. I am surprised the B.M.A. or Medical Practitioners' Union has not done something to reduce these very long hours of duty. Scattered up and down the country the house-men are not organized, and only the strong representation of the whole profession can help them. It is no good saying, "It's always been a twenty-four-hour-a-day job. This is 1953, when all men expect some leisure."—I am, etc.,

Shrewsbury.

ALBERT E. NICHOLLS.

SIR,—Like Dr. Thorn (*Supplement*, October 3, p. 161) I am under the impression that the present generation in all walks of life are less interested in their work and more concerned with holidays, free time, and pay than we used to be, but it is quite possible that our seniors thought the same about us. I was on the resident staff of three hospitals more than 30 years ago in which the conditions varied very greatly. In my teaching hospital we received our board and lodging and £20 at the end of the quarter, paid with a large Bank-of-England cheque. As there was a large resident staff, the work was not heavy, and personally I remember having a considerable amount of leisure. In the second, this time a non-teaching hospital in the London area, I was paid £150 a year, with board and lodging. The food was abominable, but we were by no means overworked and had most Saturday and Sunday afternoons free. In the third hospital, in Wales, we were paid £200 to £250 a year. In addition, some of us received upwards of £100 a year as medical officer to the V.D. clinic, and about £50 a year on medical reports for patients, and an equal amount for assisting our chiefs with private patients at nursing-homes.

In those days we did not pay income tax on our board and lodging, as present residents have to do. The food was excellent, but the work was extremely hard, including a great deal of casualty work, for which we had no casualty officer. There were, I think, 10 honorary anaesthetists, none of whom ever appeared at the hospital, so we had to share the anaesthetics between us, and we often had to anaesthetize for eight to ten hours in a day. Our chiefs usually left all emergency operations to us, and sometimes we had to deputize for them in the routine operations. I remember calculating that we worked, on an average, 80 to 90 hours a week, and a hard day's work was often followed by almost the entire night spent in the operating theatre. The work was interesting; we had a great deal of experience, but one had an uncomfortable feeling that one would never catch up with one's work.

Nov. 14, 1953

CORRESPONDENCE

SUPPLEMENT TO THE
BRITISH MEDICAL JOURNAL 201

Undoubtedly we were well paid, and the income tax was negligible, and we were able to save much of our pay, especially as we had not time to spend it. Our white coats were provided, and we had a free pass on the local railway and free admission to the local theatre and music hall, but we rarely had time to avail ourselves of these. None of us ever had a free week-end or a day off, and I was 18 months there before two of us thought of applying for a holiday to visit our parents abroad. This was granted after some opposition from some members of the board.

From what I hear, in most hospitals now the residents have a fair share of time off, with frequent free week-ends. I do not grudge them this. It is all to the good that conditions should improve. One of my sons, who is a house-surgeon at the present time, tells me that he finds his work very hard and leisure almost non-existent. It is hard to generalize.—I am, etc.,

Rainham, Kent.

W. U. DESMOND LONGFORD.

Grading of S.H.M.O.s

SIR,—Since the publication of the Minister of Health's decision not to admit the recognition of any cases of hardship to, or unfair grading of, S.H.M.O.s (*Supplement*, October 17, p. 167), I have received a letter from a constituent of mine which I consider justifies the reopening of the whole subject.

To begin with, the very idea of grading should never have been accepted by our negotiators at the inception of the Service. It is both hurtful and harmful to the individuals concerned, and also literally degrading to the whole profession. My constituent is one who has had higher qualifications in a specialty for eight years, and has practised this specialty for fourteen years, and is recognized by hospital colleagues, general practitioners, and the public as a consultant in that special branch of medicine. Further, more this practitioner holds a senior post at a hospital, classified as a consultant post. This is one example of many where there is gross injustice, not only in medical status, but also financially. (And in these days this must not be forgotten when S.H.M.O.s are often working as hard as and bearing the same or similar responsibilities as their colleagues of superior rank.)

It should be made plain to the Minister, the profession, and the public that all medical men and women who are duly qualified and registered, and so recognized by the law of the land, are of the same identical status, and that a few only are more eminent than others. I urge all S.H.M.O.s to take this matter up with their members of Council, with their Representatives, and with the Central Consultants and Specialists Committee. I urge them to promote a series of strong motions from their Divisions to the Representative Body, and to unite and work together.

If all this does not move the Minister to act justly in our affairs through the machinery and prestige of the B.M.A. and the Joint Committee, then Members of Parliament must be instructed to ask, and persist in asking, questions of the Minister on the floor of the House of Commons. (All Ministers hate questions which concern injustice to individuals or possible personal hardship.) This problem of S.H.M.O.s is just one of the many injustices in this Act. All must and will in time be righted by continued and determined effort.—I am, etc.,

Reading, Berks.

S. F. LOGAN DAHNE,
Member of Council for
Berks, Bucks, Oxon, and Northants.

Consultant Appointments

SIR,—You report in the *Supplement* of October 10 (p. 163) that the Ministry has been again urged by the Central Consultants and Specialists Committee to advise boards to offer candidates for consultant appointments an option for whole-time or part-time service, and that where such an option is offered candidates should not be asked for their preference at the time of interview, as this might appear to be prejudicial to those who had expressed a preference for part-time service. The expression of a preference for whole-

time service might also be prejudicial to a candidate. The financial conditions for whole-time service are so inferior to those for part-time service that the selection of whole-time conditions by a candidate might be thought to show indifference to enlightened self-interest to a degree that might be a disadvantage to his social group.

There is another point in connexion with the recommendation of the Consultants Committee that should be carefully considered. Presumably a board willing to appoint a whole-time consultant has a need for service amounting to a nominal eleven sessions, and if someone is appointed for, say, nine sessions there will be a deficiency for which the appointment of another consultant will be required. No doubt the advice given to the Minister seems reasonable to the committee, but will it be thought to make for good administration by an economist who has been appointed "to suggest means, whether by modification in organization or otherwise, of ensuring the most effective control and efficient use of such Exchequer funds as may be made available"?—I am, etc.,

Liverpool.

HENRY H. MACWILLIAM.

Cost of Practice Premises

SIR,—We general practitioners have been asked to improve our surgery premises, but I feel that this problem is not being tackled at the root. Most surgeries are situated in buildings that were never intended for such use. The Inland Revenue allows practice expenses for alterations in the surgery, but if one replaces surgery premises and builds a new surgery this counts as a capital expenditure, and one cannot claim anything for it. Having received the Danckwerts award, must we bear further instructions from the powers-that-be in silence, and abide by this blatant injustice?

I received £860 as my share of the Danckwerts award, and the Inland Revenue claimed £230 as their legitimate portion. The new surgery premises cost me over £1,000. Under these terms the value of the Danckwerts award is completely lost.—I am, etc.,

Whitwell, Derbyshire.

JOSEPH MAIZEL.

£100 Vanished

SIR,—Some months ago (*Supplement*, April 4, p. 133) you kindly published a letter from me in which I pointed out that I and others in a similar position were likely to lose £100 a year owing to the Danckwerts award. I was somewhat severely blamed for this letter, but it has, alas, turned out to have been fully justified. The £100 has now vanished into the pockets of others.—I am, etc.,

Sevenoaks, Kent.

GORDON WARD.

Keeping the Patient

SIR,—The hospital doctor can scarcely be criticized for treating the casual patient who has a reasonable excuse for coming without a doctor's letter, but the question of telling him to continue to attend is a different matter. Dr. D. Goldman (*Supplement*, October 17, p. 171) gives a number of reasons for keeping the patient: might he not have added that it is easier to say, "Come again to-morrow," than to sit down and write a letter?

At hospitals generally little attention seems to be paid to the circumstances of the patient: the mother with her shopping, cooking, and washing to do; the workman, a key man perhaps; the typist, often the only one in her office; the self-employed man whose livelihood depends on his presence at his business: to all of these a day, even half a day, at hospital means more than a little inconvenience. If they are returned to their own doctor they usually have a choice of morning or evening hours, and frequently fewer attendances will be required.

I do not see why hospitals should do the work of the family doctor unless he is known to desire it. If he is in the Health Service surely it is part of his contract; if he is in private practice it is part of his bread-and-butter.—I am, etc.,

Beckenham, Kent.

W. MAXWELL PENNY.

Association Notices

SCHOLARSHIPS IN AID OF SCIENTIFIC RESEARCH

The Council of the British Medical Association is prepared to receive applications for research scholarships as follows:

- An Ernest Hart Memorial Scholarship of the value of £250.
A Walter Dixon Scholarship of the value of £250.

These scholarships will be awarded to candidates whom the Science Committee of the Association recommends as qualified to undertake research in any subject (including State medicine) relating to the causation, prevention, or treatment of disease.

Each scholarship is tenable for one year commencing October 1, 1954. A current scholar may apply to be re-appointed for an additional year. No scholarship may be held for more than three years. A scholar is not necessarily required to devote the whole of his or her time to the work of research, but may be a member of H.M. Forces or may hold a junior appointment at a university, medical school, or hospital, provided the duties of such appointment will not, in the opinion of the Science Committee, interfere with his or her work as a scholar.

Applications for scholarships must be made not later than March 1, 1954, on the prescribed form, a copy of which will be supplied on application to the Secretary, British Medical Association, B.M.A. House, Tavistock Square, London, W.C.1.

Applicants are required to furnish the names of three referees who are competent to speak as to their capacity for the research contemplated.

Diary of Central Meetings

NOVEMBER

- 17 Tues. Arrangements Committee (Toronto, 1955), 11 a.m.
17 Tues. Medical War Relief Fund Committee, 12.30 p.m.
17 Tues. Subcommittee on Admission of Students to Medical Schools, 2 p.m.
18 Wed. Guillebaud Evidence Subcommittee, G.M.S. Committee, 2 p.m.
18 Wed. Transport Medical Standards Subcommittee, Occupational Health Committee, 2.30 p.m.
19 Thurs. Film Committee, 10 a.m.
19 Thurs. G.M.S. Committee, 10.30 a.m.
19 Thurs. Journal Committee, 2 p.m.
19 Thurs. Radiologists Group Committee, 2 p.m.
20 Fri. Tuberculosis and Diseases of the Chest Group Committee, 12 noon.
23 Mon. Hospital Junior Staffing Subcommittee, Central Consultants and Specialists Committee, 11.30 a.m.
23 Mon. Public and Professional Relations Subcommittee, Central Consultants and Specialists Committee, 4 p.m.
25 Wed. Rehabilitation Committee, 10.15 a.m.
26 Thurs. Executive Subcommittee, Joint Formulary Committee (at Pharmaceutical Society, 17, Bloomsbury Square, London, W.C.), 2 p.m.
26 Thurs. Maternity Subcommittee, G.M.S. Committee, 2 p.m.
26 Thurs. Staff Side, Committee "C" Medical Whitley Council (at 14, Russell Square, London, W.C.), 2 p.m.
26 Thurs. Committee "C" Medical Whitley Council (at 14, Russell Square, London, W.C.), 3 p.m.
27 Fri. Joint Committee of B.M.A. and the Magistrates' Association, 10.30 a.m.
27 Fri. Industrial Injuries Evidence Subcommittee, Occupational Health Committee, 2 p.m.
27 Fri. Venereologists Group Committee, 2 p.m.

DECEMBER

- 1 Tues. Staffing Committee, 11 a.m.
2 Wed. Remuneration Subcommittee, Occupational Health Committee, 10 a.m.
2 Wed. Occupational Dermatitis Subcommittee, Occupational Health Committee, 2 p.m.

Branch and Division Meetings to be Held

BIRMINGHAM DIVISION.—At 151, Great Charles Street, Birmingham, Tuesday, November 17, 8.30 p.m., meeting. Debate: "That This House is of the Opinion that the Modern Doctor is in Danger of Losing the Use of His Senses." Proposer, Dr. H. W. Donovan; opposer, Dr. J. M. Malins.

BLACKBURN DIVISION.—At White Bull Hotel, Church Street, Blackburn, Tuesday, November 17, 8.15 p.m., B.M.A. Lecture by Dr. Ffrangcon Roberts: Health and Civilization. All medical practitioners in the area of the Division are invited.

COVENTRY DIVISION.—At Gymnasium, Coventry and Warwickshire Hospital, Tuesday, November 17, 8.30 p.m., special meeting. Sir Claude H. S. Frankau: "Conditions Arising out of a State of Emergency"—(a) A short Description of the Organization of a Civil Defence Division with its Sections; (b) Medical Organization: (i) The Medical Services During a State of Emergency After an Outbreak of War. (ii) After an Attack has been Made.

GOOLE AND SELBY DIVISION.—At The Lodge, Snaith, Thursday, November 19, 7.30 p.m., meeting. Dr. S. T. Anning: "Varicose Ulceration of the Legs."

GREENWICH AND DEPTFORD DIVISION.—At Miller General Hospital, Greenwich High Road, London, S.E., Wednesday, November 18, 8.30 p.m., meeting. Mr. K. L. Wilson: "Earache, Deafness, and Discharge." Visitors are welcomed.

HYDE DIVISION.—At New Inn, Mottram Road, Hyde, Wednesday, November 18, 8.30 p.m., meeting. Dr. H. A. H. Selbourne: "The Adventures of a Medical Bibliophile."

ISLE OF WIGHT DIVISION.—At St. Mary's Hospital, Newport, Saturday, November 21, 2 p.m. to 5 p.m., and Sunday, November 22, 10 a.m. to 4 p.m., refresher course.

KENSINGTON AND HAMMERSMITH DIVISION.—At Hammersmith Hospital, Ducane Road, W., Wednesday, November 18, 2 p.m., ward visits for general practitioners.

MACCLESFIELD AND EAST CHESHIRE DIVISION.—At Macclesfield Arms Hotel, Macclesfield, Wednesday, November 18, 9 p.m., social evening.

NORTH OF ENGLAND BRANCH.—At Royal Victoria Infirmary, Newcastle-upon-Tyne, Thursday, November 19, 7.15 p.m., clinical demonstration by Mr. F. McGuckin: "Some Aspects of Deafness"; 8.45 p.m., Address by Dr. Manuel Anderson: "Beethoven and His Deafness."

NORTH MIDDLESEX DIVISION.—At North Middlesex Hospital, Silver Street, Edmonton, N., Tuesday, November 17, 2.30 p.m., practitioners' round.

OLDHAM DIVISION.—At Oldham Hotel, Rhodes Bank, Oldham, Monday, November 16, 9 p.m., meeting. Professor Victor F. Lambert: "The Significance of Hoarseness."

REIGATE DIVISION.—At Redhill County Hospital, Tuesday, November 17, 8.30 p.m., joint meeting with Reigate, Redhill and District Branch of Pharmaceutical Society of Great Britain. Address by Mr. F. C. Wilson (Secretary of Surrey Pharmaceutical Council): "The National Health Service Problems as they Affect Both Doctors and Chemists."

ROCHDALE DIVISION.—At Turner Hall, Birch Hill Hospital, Rochdale, Thursday, November 19, 8 for 8.30 p.m., annual dinner. Members are invited to bring medical guests.

SOUTH MIDDLESEX DIVISION.—At Jersey Rooms, Red Lion Hotel, Hounslow, Thursday, November 19, 7.15 for 7.45 p.m., annual dinner dance.

SOUTH STAFFS DIVISION.—At Bell Library, Royal Hospital, Wolverhampton, Tuesday, November 17, 8 for 8.30 p.m., meeting. Dr. J. D. Powell David and Mr. E. G. Dolton: "Surgery in the Treatment of Pulmonary Tuberculosis."

SOUTHAMPTON DIVISION.—At Southampton General Hospital, Wednesday, November 18, 8 for 8.30 p.m., general meeting. Discussion to be opened by Miss G. Padfield (Superintendent Health Visitor, The William Budd Health Centre, Bristol): "The Place of the Health Visitor in the National Health Service."

SUTTON COLDFIELD DIVISION.—At Sutton Coldfield Hospital, Thursday, November 19, 9.15 p.m., meeting. Address by Dr. L. S. Potter (Assistant Secretary, B.M.A.): "The General Practitioner and the Hospital in the Future." An open discussion will follow.

SWANSEA DIVISION.—At Osborne Hotel, Swansea, Thursday, November 19, lecture by Dr. J. H. Sheldon.

WEST BROMWICH AND SMETHWICK DIVISION.—At West Bromwich and District General Hospital, Sunday, November 15, 11 a.m., annual general meeting.

WEST DERBYSHIRE DIVISION.—At Smedley's Hydro, Matlock, (1) Wednesday, November 18, 8.30 p.m., meeting. Mr. H. R. M. Richards: "Modern Trends in the Treatment of Venereal Diseases." (2) Saturday, November 21, 7 to 9 p.m., cocktail party.

WEST SOMERSET DIVISION.—At The Empire Hall, County Hotel, Taunton, Thursday, November 19, 7.45 for 8.15 p.m., second annual dinner and dance. Guests, medical and non-medical, will be welcome.

Meetings of Branches and Divisions

MATABELELAND BRANCH

A meeting was held at the hospital, Bulawayo, on July 16, 1953. With Dr. G. A. Jamieson in the chair there were 12 members present.

SOUTH-WEST ESSEX DIVISION

The Annual Dinner and Dance of the South-west Essex Division was held at Epping on October 29. Ninety members and guests attended. Dr. A. R. Fox was in the chair and he proposed the toast of the guests, to which a reply was made by Dr. J. Arthur Moody, President of the Metropolitan Counties Branch. After dinner, dancing went on until 12.30 a.m. The master of ceremonies was Mr. Charles King, of Kingford.

The B.M.A. in Committee

ORGANIZATION

Of the many committees at Headquarters, the Organization Committee is the least spectacular, its work the most pedestrian. It sends no deputations to Ministers. No controversy arises on public policy arise out of its recommendations; it is concerned entirely with matters internal to the Association. Other committees may show up more prominently in the B.M.A. structure, but the Organization Committee is the homely mortar which binds the bricks together. Without it there would be loose straggling heaps but no structure.

The Organization Committee has existed ever since the momentous meeting of July 19, 1832. It may have had other names, but the word from the mediaeval Latin is as good as any. "What is organization," asked Lord Chief Justice Coleridge, "but the connexion of parts in and for the whole so that each part is, at once, both end and means?" He might have been describing the British Medical Association with its Branches and Divisions and all its local and central democratic machinery.

It is quite a small committee, which benefits the detailed job it has to do. Four of its members are elected by the Representative Body and four by the Council, with one nominated by the Overseas Committee. The chairman of the Secretaries' Conference is included in the committee for the period of his office. Small as the elected membership is, at present it covers Scotland, Yorkshire, the West and the East of England, Wales, and the southern counties. There is no representative of the Metropolitan Counties, but two of the principal officers of the Association, who are *ex officio* members of the Committee, belong to that Branch.

Safeguarding the Constitution

The Committee is concerned with maintaining the effectiveness of the Association, central, regional, and local, at home and overseas. It must be remembered that the Association did not descend from heaven as a prepared plan to be fitted on the medical profession of the country 120 years ago. It just "grew'd." It arose in different places on the initiative of doctors who had attended the inaugural meeting at Worcester or had been in correspondence with Sir Charles Hastings. Sometimes loosely organized local medical societies became Branches of the new Association. There were eight Branches by 1848, fourteen by 1852, twenty-five by the time of the Association's jubilee thirty

years later. At first they underwent a good deal of change both in name and in area. As the historian of the Association said in the centenary volume, there was "a certain amount of fermentation in the new wine of the Association before it settled down into a stable combination of elements." But gradually a common pattern was evolved. What might have been a loose grouping of medical societies became a federation. The whole of the United Kingdom was covered, and by 1877 there was one Branch overseas (Jamaica). The second overseas Branch was a territory in the news to-day—British Guiana.

With the new constitution of 1902 the Division became the primary unit, and the Branches were groups of such units. But all the units, while having their own administrative procedure and rules, were subject to the limitations deemed necessary for the co-operation of all as laid down in the articles and by-laws of the Association. It can now be said that at what is often called the periphery (as if it were almost on the outside of things, but really meaning only its local structure and functioning) the Association is as uniform as it is healthy for such a body to be.

Organization must be interpreted in the biological rather than the mechanical sense. The Association is a living thing, and its outward framework as well as its inward spirit must be adjusted continually to the changes which occur in the society it serves. To judge from a resolution passed at the last Annual Representative Meeting, it may not be long before some reshaping of the constitution has to take place, but that will not mean that the present constitution which has existed for fifty years has not served its purpose. Indeed, it has done so to a degree which its makers cannot fully have foreseen.

An Eye on the Membership

The Committee keeps a watchful eye on the membership statistics. Membership has been going up now for many years, and the chairman of the Committee has had to report on almost every occasion a new top figure, with the possible exception of a purely temporary setback following an increase in rates of subscription. One subcommittee is concerned with medical students and the newly qualified. This makes the effort to ensure that, so far as possible, along with qualification goes enlistment into the Association. The subcommittee is reinforced by representatives from the teaching centres and also by two representatives of the British Medical Students Association.

The co-ordination of the rules under which the local units work is an important task of the Organization Committee. It must make sure that there is no conflict between local rules and Association by-laws, and, so far as possible, that

there is harmony with the set of model rules. The areas of the units, the creation from time to time of new Divisions or the amalgamation of existing ones, the annual grouping of Divisions for the formation of constituencies in the Representative Body, the maintenance of liaison between Headquarters and the regional and local organization—all these are among the duties assigned to the Committee.

One of its principal subcommittees is concerned with grants to meet Branch and Division expenditure. It is the Committee's job to analyse the annual reports and accounts of Branches and Divisions, and to make any necessary representations on the use of the Association's money in accordance with the Association's constitution. The financial needs of the units have to be ascertained, and the appropriate capitation grants recommended.

One of the Committee's tasks is the supervision of new editions of two of the Association's publications. These are, first, the *Yearbook*, prepared specially for the assistance of workers for the Association both locally and centrally; and, secondly, the *Medical Practitioners' Handbook*—a most useful vade-mecum for every practitioner. Yet another is the consideration of petitions for the formation of special groups in the Association—that is to say, groups representing special branches of medicine whose practitioners are not numerous enough to ensure the representation of their views through the ordinary channels. Again, what must be one of its driest duties, it is concerned with articles and by-laws and standing orders; also, along with the Finance Committee, subscription rates.

The Association Watchdog

One anomaly in the constitution, which the Committee is at present concerned in rectifying, was revealed early in 1953 owing to the action of a number of members of the Association in requisitioning an Extraordinary General Meeting. The question arose whether any resolution of such a meeting, if approved by the Council or by subsequent referendum as required under the Articles, which was at variance with decisions of the Representative Body, could have validity. Counsel's opinion was sought on the matter. The present situation appears to be that, although it is constitutionally in order to call an Extraordinary General Meeting, yet if the object of calling the meeting concerns a matter which encroaches upon the jurisdiction of the Representative Body any resolution passed will be ineffective and will not become the policy of the Association. The Committee is now examining the relevant Articles with a view to removing the anomaly.

The Organization Committee has always been fortunate in enlisting some very able men in its service—men devoted to the interests of the Association and willing to work for it in a way which never attracted the limelight. One recalls Dr. Morton Mackenzie, of Dorking, who was its chairman for twelve years; Dr. J. C. Matthews, of Downton, who was its chairman for thirteen years; Dr. F. A. Roper, who was a member for seventeen years; and in earlier days Mr. Russell Coombe, Dr. J. W. Bone, Dr. E. R. Fothergill, Dr. A. Lyndon, and many others. Its present chairman is Dr. J. A. Pridham, of Weymouth, under whose guidance work of considerable importance to the Association is being undertaken.

PUBLIC HEALTH AND GUILLEBAUD

A meeting of the Public Health Committee of the Association was held on November 13, under the chairmanship of Dr. H. K. Cowan, when the morning and afternoon sessions were given to the consideration of the evidence to be tendered by the Association to the Guillebaud Committee. The views of the Committee will be transmitted to the Steering Committee, which will co-ordinate the conclusions of all the standing committees concerned and, in due course, submit to the Council for its approval an agreed document of evidence.

FELLOWSHIP FOR FREEDOM IN MEDICINE

ANNUAL GENERAL MEETING

The annual general meeting of the Fellowship for Freedom in Medicine was held at Caxton Hall, Westminster, on Saturday afternoon, November 21, with Lord Horder in the chair. It was preceded by meetings of lay associate members and of local secretaries.

A decrease in the membership was reported by the honorary secretary (Dr. E. C. Warner). About one-third of the names in the 1950 register were no longer there. The Fellowship, said Dr. Warner, had always recognized that a number of those who rushed to join it at the beginning gave it only a half-hearted allegiance. But more than 2,000 of the original members continued their support, and 500 new members had joined in the same period as the others had been lost, so that it was felt that they had now a more solid body of membership than before. There were 167 lay associates, and 41 local secretaries in various parts of the country. The Fellowship had shown its strength at the last Annual Representative Meeting of the British Medical Association in furthering a resolution, against opposition, calling for the consideration of some practical scheme for the optional restoration of goodwill. There were eight members of the Fellowship in the Amending Acts Committee of the Association. By meetings, newspaper correspondence, and literature the Fellowship had done much to impress the Government and the public that something better than the present National Health Service was demanded.

Dr. G. I. V. CROSBY introduced a report of the General Practitioner Hospitals Subcommittee, pointing out that the general-practitioner hospital was a much more economic proposition than the health centre, judging from the cost of Woodberry Down, which was £155,000, and out of all proportion to the services it provided. General practitioners in some parts of the country were now being asked to take on some of the work from which they were excluded in 1948.

A report of the Private Practice Subcommittee was submitted by Dr. G. M. GOODWILL, who said that inquiries at the time when the National Health Service was started showed that private practice had diminished considerably, but since then, although there had been a great decrease in private midwifery and a considerable decrease in private work amongst children, the level of private work amongst those over 40 had remained fairly steady. It was remarked that doctors in a purely private practice found it easier to keep their patients than doctors with a mixed practice.

Reform of the Service

Dr. A. C. E. BREACH then brought forward, on behalf of the Amending Acts Subcommittee, a programme of reform of health services. This contained about 24 recommendations, all of which were passed by the meeting unanimously and almost without discussion. They called for the encouragement of private practice; for moderately priced beds in private wings of hospitals and nursing-homes; for provision of facilities for opting out of the N.H.S. scheme; for the examination of the possibility of vesting N.H.S. administration in an independent body of persons of national repute, responsible only to Parliament. Another recommendation called for the repeal of Section 35 of the Acts in order to restore the optional right to buy and sell the goodwill of general practices. A permanent independent court of arbitration under the presidency of someone of the standing of a High Court judge, and accessible to either party in a dispute, was also demanded. A series of recommendations called for a certain pruning of the Minister's powers for as long as the control of the service was vested in him. It was considered also desirable further to investigate the whole question of remuneration so as to relate the doctor's income to the quality of his work. The need for steps to

facilitate and encourage the close and responsible association of general practitioners with hospitals and institutions for the elderly was the subject of another recommendation, and yet another called for the discontinuance of the provision of health centres owned and controlled by local authorities and for encouragement, by the provision of long-term loans, of the formation of group practices. The policy of the British Medical Association for reform of the disciplinary system as approved at the recent Cardiff meeting was supported. The final recommendations concerned the need for freedom of medical teaching and research from political interference.

Dr. Breach, who was warmly congratulated, said that a supplementary report on certain other matters would be forthcoming.

The meeting agreed to the formation of a committee of lay associates, and the first task referred to it was the consideration of the expediency of a campaign in the constituencies intended to bring home to Members of Parliament the need for early legislation to enable patients who made their own private arrangements for medical attendance to obtain their medicines and appliances on the same basis as N.H.S. patients.

The Chairman's Survey

LORD HORDER deferred to the end of the meeting his own brief survey, which began with a comment on what he called the Wolverhampton incident in which practitioners, who formed themselves into a roster, had come to the rescue of the services of the local hospital, and in this connexion he reminded the meeting of the remark of the then Minister of Health on the appointed day that the problem of hospital care was the apotheosis of medicine. Recently, said Lord Horder, he opened a pathological block for a large and extremely active hospital management committee. He found that the G.P.s in this area were once more working in the hospitals.

The Guillebaud Committee gave them a chance of saying again that anything which short-circuited the G.P., the man who knew, the man who had been trained, would cost the country and the patients more money and more time, with a less good result. He recalled the remark of Disraeli: "There can be no economy where there is no efficiency."

They had been dealing that afternoon, Lord Horder continued, with some of the basic principles for which the whole profession stood or used to stand. Those who spoke for the whole profession had always declared themselves against a whole-time service, but we were now told that it would not be long before a whole-time service was a *fait accompli*. Only five or six years ago it was stated from the platform of the British Medical Association, "One thing on which we will never give way is the acceptance of a whole-time salaried service," and now they were told that they were fighting a lost cause. Take such matters as the restoration of the right to buy and sell goodwill or the enablement of private patients to obtain drugs on the same basis as N.H.S. Patients. Some of those who had formerly proclaimed adherence to certain of these vital principles were now rather irritated by these reminders. Mr. John Pringle, the Public Relations Officer of the British Medical Association, writing in the *Sunday Express*, had said, "All the signs are that the public in general is thoroughly satisfied with the [National Health] Service." That was not true. It might be that 97% of the population were on doctors' lists, but how many of them had a private doctor as well, owing to the fear, as someone had expressed it, that "I know my N.H.S. doctor will not have time to look into this"?

Putting Back the Clock

"I am proud," said Lord Horder in conclusion, "to have inspired this Fellowship, but now I look on and say, 'Bless you, my children.' I believe what Sir Earle Page said recently at The Hague, 'If we destroy our medical tradition, we shall not be able to build it up again in this generation—if ever.' We have been called reactionaries.

It was said that we were putting back the clock of medicine, because we would have no part in this conveyor-belt business, but, of course, it is the others who are the reactionaries, it is they who have put back the clock. The doctors are the experts, and anyone who says that the work can be done without the expert is bound to meet failure. Not only must there be an expert, but the expert must have room to move, room to develop. The expert to-day, properly trained and keen on his job, must have room to expand: he will not be the same expert in two years' time. The art of living is the art of learning. Medicine must control itself; it cannot accept control by the State, least of all by party politicians. If the community wants the best that medicine can give the autonomy of medicine must be preserved against all comers." (Applause.)

On the motion of Dr. S. F. LOGAN DAHNE, the Executive was instructed to consider ways and means of recruiting new members from the younger members of the profession—house officers and registrars—in order to safeguard the work of the Fellowship in the future.

A warmly accorded vote of thanks to Lord Horder concluded the proceedings.

ASSAM BRANCH ANNUAL GENERAL MEETING

The annual general meeting of the Assam Branch of the British Medical Association was held at the Indian Tea Association Guest House, Cinnamara, from March 12–15, 1953. The president, Dr. W. J. Savage, was in the chair, and there were 22 members and guests present.

Dr. K. J. Dunlop was elected president for the year 1953–4, and Dr. J. P. Norman was elected hon. secretary and treasurer. In the scientific section the following papers were read: "Effects of Surfaces on Absorption of Insecticides," by Dr. A. B. Gilroy; "Pathology of Tuberculosis," by Dr. O. W. Hasselblad; "Scrub Typhus in Upper Burma," by Dr. J. P. Norman; "Burns," by Dr. G. B. Young; and "Sickle-celled Anaemias in Assam," by Dr. K. J. Dunlop. Dr. M. E. T. Burke showed a film on "Coolie Welfare," and Dr. Mary K. Berry gave a demonstration of clinical cases of leprosy at the Borbha Lepar Colony.

The meeting closed with the annual dinner, at which Mr. Eric Hannay, chairman of the Assam branch of the Indian Tea Association, and Mrs. Hannay were the guests of honour.

WAR MEMORIAL

Members visiting B.M.A. House have suffered minor inconvenience during the last six months through excavating and building operations that have been in progress in the Court of Honour. The Court itself had suffered during the course of years from a certain amount of settlement and wear which was accelerated during the war, particularly when it was used as a car park, and this necessitated its being relaid. At the same time the foundations of the War Memorial were laid in order to save additional work.

These works have now been completed, and the monumental builders are now engaged in the erection of the Memorial itself. This consists of a central fountain around which stand symbolic figures depicting Medicine's historic service to mankind. When the Memorial is complete a detailed description of the figures and their symbolism will be issued.

The sculptor is Mr. James Woodford, O.B.E., R.A., who is well known for this type of work and who recently designed the Queen's Beasts on the Coronation Annexe of Westminster Abbey. It is expected that the Memorial will be completed about the middle of next year.

HOSPITAL ENDOWMENTS

SCOTTISH COMMISSION

Under schemes which are being put forward by the Hospital Endowments Commission every hospital board of management in Scotland is to have funds, amounting to at least £2 per bed a year, to provide amenities for patients and staff, like additional furnishings and wireless sets, and other things which cannot always be charged to the National Health Service. The Commission has to make schemes for the future of the £13m. of voluntary endowments given by private individuals to hospitals in Scotland.

Where a board of management has at present no endowments or insufficient endowments, the Commission says that funds should be transferred to them from other boards in the same general area. This, the Commission holds, would be in keeping with the "spirit of the intention" of the founders of hospital endowments. It points out that the endowments were originally given to provide something which it was not at the time within the scope of a public service to provide. The original purposes of most of these endowments are now met by the Health Service, and new outlets must therefore be provided.

The chairman of the Endowments Commission is Sir Sydney Smith, until recently Regius Professor of Forensic Medicine in the University of Edinburgh and Dean of the Faculty of Medicine.

Questions Answered

Practice Expenses

Q.—Can I claim as expense for the running of my practice, for income-tax purposes, the following: (1) employment of a sitter-in twice weekly who takes all messages and contacts me by phone as necessary; I pay him a sum equivalent to £1 weekly; (2) 5s. weekly towards the upkeep of the garden in front of the house; (3) 15s. weekly towards the cleaning of my residence, where I see patients daily?

A.—(1) If the sitter-in would be provided even if he were not required to pass on telephone and other messages the expense serves both private and professional purposes, and a claim for one-half of the expense is suggested as appropriate. (2) If the patients pass through the garden to reach the consulting-room, a claim for one-half the expense of upkeep seems appropriate. (3) The total payment for cleaning of the residence should be divided in the ratio of the total cleaning to the cleaning of the part used for the practice.

Q.—May I claim income-tax relief on the following: (1) subscriptions for golf club, which I find I must join in order to help my practice; (2) the "Encyclopaedia Britannica," which I find I need for my lecturing; (3) the decoration of my surgery and waiting-room of my new house?

A.—(1) It is, of course, agreed that membership of a golf club may increase the number of patients and the income from a practice, but it is considered that it will not be possible to establish the claim to treat the club subscription—or even any material part of it—as a professional expense. The words "wholly and exclusively" in the statutory Rule do not constitute an absolute bar to the claim, but it is thought that the subscription would fall into that class of personal expenditure, such as that necessary to maintain a certain social standard and suitable personal attire, which the courts have not regarded as allowable for income-tax purposes. (2) The cost of an encyclopaedia would be regarded as capital outlay—that is, as not deductible as an expense of earning the income from lecturing. (3) The cost of decorating the surgery should be allowed unless there are special circumstances—for example, unless the premises

were in such a poor condition that the capital sum paid for them was thereby reduced or unless the cost included some structural alteration.

Car Expenses Not Covered by Allowance

Q.—As an assistant my remuneration for the last year has been £850 plus £150 car allowance. My car expenses are considerably in excess of the allowance. What income-tax rebate can I claim on this account?

A.—If the expenses "wholly, exclusively, and necessarily" incurred in the provision of a means of travelling when engaged on the work of the practice exceed the cash allowance received, the excess can be claimed as an expense for income-tax purposes. It should, however, be borne in mind that the phrase quoted above is strictly applied, so that if, for instance, the car provided is of greater power or superior grade to that required for the work, only a portion of the total expense will be allowable. A similar restriction will apply if the car is used for private as well as for professional purposes. In calculating the total expense there can be included 25% of the written-down value of the car.

Car Purchase and Budget Changes

Q.—I purchased a new car in February this year for £900; my previous car sold for £200. What allowances can I claim? Are they operative on the income-tax year 1952-3, or do they begin after April, 1953, when there were Budget changes in respect of initial allowances?

A.—As the car was purchased before the date specified in the 1953 Finance Act, no "initial allowance" is due, but the allowance for wear and tear can be claimed for 1953-4 at 25% per annum, provided that the yearly practice accounts are not made up to a date prior to the date of purchase of the car. If, for instance, the practice accounts are made up to December 31, the claim in respect of the new car will operate for 1954-5. If the sale of the former car at £200 shows that the aggregate of the given allowances for that car has been insufficient, the deficiency can be claimed as a "balancing allowance"; if the converse is the case, the amount of the excess allowable becomes liable to tax as a "balancing charge."

Notes and News

Holiday Exchanges.—Several holiday exchanges have been arranged during 1953, and if any British doctors would like to arrange such exchanges for their children with children of Continental doctors during the summer, 1954, would they please write to Dr. H. A. Sandiford, International Medical Visitors Bureau, B.M.A. House, Tavistock Square, London, W.C.1.

West Germany.—A doctor in West Germany would like to arrange a holiday exchange for his daughter, aged 12, with a British doctor's daughter, of similar age, for four to five weeks during the summer, 1954. The British child could travel to Germany with the German child. Would anyone interested please communicate with Dr. H. A. Sandiford, International Medical Visitors Bureau, B.M.A. House, Tavistock Square, London, W.C.1.

Questions Answered.—Doctor: "Tell me now, what do you notice wrong?"

Patient: "What, with you, sir?"

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

Metropolitan Borough Councils.—Fulham, Southwark.

Non-County Borough Councils.—Crewe.

Urban District Councils.—Houghton-le-Spring.

Nov. 28, 1953

CORRESPONDENCE

SUPPLEMENT TO THE
BRITISH MEDICAL JOURNAL 213

Correspondence

Because of the present high cost of producing the Journal, and the great pressure on our space, correspondents are asked to keep their letters short.

Grading of S.H.M.O.s

SIR.—Dr. S. F. Logan Dahne's letter (*Supplement*, November 14, p. 201) appeals for justice for S.H.M.O.s doing consultant work. There are many S.H.M.O.s who, while doing consultant work and enjoying the full confidence of their colleagues in general and hospital practice, are yet graded and paid as S.H.M.O.s. Those about whom I am particularly concerned are the men who have achieved consultant status and higher qualification (but not grade and pay) whilst working in general practice. I think all will agree that it is far more difficult to do this than to carry on in hospital to attain the same status. It would appear from cases within my personal knowledge that the one thing that damns a man in the eyes of a grading committee is that he has been in general practice, whereas in the minds of all sensible people he would be regarded as a great attribute to his ability.

Divisions and Branches, with great help from the Secretariat, have tried hard to remove these injustices, but they still persist. What then remains? An appeal to Parliament through the S.H.M.O.'s own M.P.—not just a question in the House but a pursuit until justice is done. However, before this is done the Central Consultants and Specialists Committee should be given until January 1, 1954, to clear up all outstanding cases. I may add that I have no personal axe to grind.—I am, etc.,

ARTHUR BEAUCHAMP.

Birmingham.

SIR.—You publish in the *Supplement* of October 17, page 167, a statement from the Ministry of Health rejecting a request for further consideration of certain S.H.M.O. gradings that the profession considers still to be unjust. This seems to call for some protest from the ground that the rejection appears to be based on the ground that the review committees were properly constituted and locally informed. The fact remains that in this country appeals are allowed from the decision of Her Majesty's judges, whose courts are presumably also properly constituted and not without experience. It seems therefore that the S.H.M.O. doctors who feel that their cases have not been thoroughly understood should have the same elementary right to present the facts for a further impartial review at a higher level. Few as these cases may be, the rights of even the smallest minorities deserve consideration.

It is indeed surprising that this announcement should have been taken with such apparent placidity by the B.M.A. and the profession as a whole: one would have expected a more vigorous reaction. Personally, I should like to see a demand that S.H.M.O. gradings, if not abolished entirely, should be reviewed every five years at least so that these men should not nurse a sense of frustration and grievance that must otherwise embitter them for life.—I am, etc.,

L. HENRY.

Cheltenham

Service Recruitment

SIR.—I, like Dr. L. C. Kreeger (*Supplement*, October 24, p. 178), am interested in the recent proposals for stimulating recruitment for the medical branches of the Services primarily by pay increases, and, again like him, feel that this latest effort will be unsuccessful.

For the last 14 years every newly qualified doctor, if fit, has had to do his service along with most other men in this country, and he has seen for himself only too clearly what Service medicine is like. In the old days a man, imagining the life would suit him, signed on without any first-hand knowledge of the conditions, and when he made his discovery it was too late. That is all changed now. The only

difference which the new rates of pay will make will be, in my opinion, to increase the bad feeling between the medical and other officers which existed under the old scheme, and of which I have personal knowledge. This, of course, is due to the fact that officers of equal seniority in the medical and other branches did not receive the same pay, and now the gap is being widened further. The resentment is perhaps justifiable.

Dr. C. Iliffe (*Supplement*, November 7, p. 191) suggests that the highest form of service we can give our country is with her armed Forces. This is arguable, but, supposing it were true, would he agree that a doctor looking after only 250 men (and in the healthiest age group at that) for four months in a destroyer which was in port nearly every night and never left the English Channel was doing all that he might for his country? My working day during that time was from 9 to 9.30 a.m. And is the training to become, "subsequently, competent members of the reserve Army" (Navy), to which Colonel G. Rigby-Jones refers in (*Supplement*, November 7, p. 191), really furthered by sitting in the wardroom doing the *Daily Telegraph* crossword and looking after the wine accounts? Every National Service medical officer that I have met has had one thought uppermost in his mind—how long is it until I am "outside" and get back to a job of work?

It is not wage increases that are needed to ensure the adequate staffing of the medical branches of the three Services, but a drastic alteration in the whole of the medical organization to enable each medical officer to have a reasonably full and satisfying day from a professional point of view.—I am, etc.,

N.S.M.O.

SIR.—Colonel Guy Rigby-Jones (*Supplement*, November 7, p. 190) has been forthright in what he considers to be the needs of the Army, but overlooks the fact that a medical training is a very valuable thing which should not be frittered away on pay parades and other non-medical duties. Further, at the outbreak of a war there is always, and always will be, a shortage of doctors, for both civilian and military needs, for purely medical purposes. I consider that it is iniquitous to train doctors for administrative duties in the Army. As regimental medical officer or hospital medical officer, not only is a young doctor doing a well worthwhile job, but he is getting an invaluable training in human values. Other duties, such as those of a static field ambulance and in administrative headquarters, are not only an unnecessary and a useless burden on him but would be better performed by non-medical personnel. I have often listened to infantry officers saying that doctors playing at soldiers is farcical. Furthermore, I have frequently found that a soldier has attached quite misplaced confidence in the medical advice and opinion of a senior R.A.M.C. officer whose only claim to seniority was service (in time) in non-medical duties, and who privately would be the first to admit that he had forgotten most of the medical knowledge with which he qualified; and yet the same patient-soldier would prefer his opinion to that of the young, recently well-qualified doctor who had much inferior rank.

The American system of having a medical administrative corps attached to the medical services and consisting entirely of non-medical personnel has much to commend it. I see no value whatever in training young doctors to take pay parades, etc. What essentials in man management are required in daily life are already inculcated in public school. Doctors are required for more important tasks.—I am, etc.,

W. J. ATKINSON.

Shortlands, Kent.

Quality in General Practice

SIR.—With reference to recent correspondence under the heading "Quality in General Practice," I would like to suggest that the reason for the unsatisfactory position of the holder of higher qualifications in general practice is to be found in the fact that such qualifications do not command any higher remunerative prospects.

After all, such qualifications are meant to confirm extra study and knowledge, and if this were recognized by some increase in remuneration—by "merit award" or otherwise

—the surplus M.R.C.P. would be in great demand in partnership practice. The practitioner with higher qualifications and necessary experience could then afford to reduce his numbers, giving a higher standard of service, and so make the entry of the unestablished practitioner less difficult.—I am, etc.,

Dundee.

R. A. B. RORIE.

Fees for Coroners' Necropsies

SIR,—In the *Supplement* of March 28 (p. 83) it was stated that the Home Office had assured the Association that it would be informed as soon as there was any possibility of legislation to amend the Act of 1926 by which the fee for a coroner's necropsy was fixed at the present level—namely, two guineas.

Parliamentary time has been found for a Bill to increase the salaries of H.M. Judges, who, unlike coroners' pathologists, have security of tenure and the right to a pension; and now time is to be found for discussing the pay of Members of Parliament, who gave themselves an increase as recently as 1948.

The B.M.A. can exert a great deal of pressure on any Government; and it appears to be essential, in the interests of fairness to a small group of its members, that this power should be used so that coroners' pathologists can be relieved of the dubious honour of being paid no more than they were receiving a quarter of a century ago.—I am, etc.,

London, W.1.

A. PINLEY.

Unwilling to Pay

SIR,—We would be glad to know if other colleagues of ours in general practice are faced with the problem of settling insurance claims after the death of the assured and how they deal with it.

We are a partnership in an industrial part of London, and it is very common in this area for insurance companies to persuade their client to take out a small policy on the life of a relative. The sum assured and the premium are usually not very large, and it is particularly stressed at the time of taking out the policy that no medical examination of the assured is required. The policy holder is merely asked to sign a statement as to the state of the health of the assured as far as they know it. When death occurs and the money is claimed, in many cases payment is refused pending a medical report upon the state of health of the deceased prior to the date upon which the policy holder signed. The next procedure usually is that a letter comes from the insurance company stating that they understand that the deceased was a patient of ours, and requesting details of medical history prior to the date of the policy. As an inducement to comply meekly with their request, a fee is often enclosed in advance.

In our experience, most of these requests are made without permission of the relatives, and, therefore, under the guise of being helpful, we are being asked to divulge confidential information to a third party, the lever being that if this information is withheld hardship is caused to the policy holder by reason of non-payment of the claim. Some of us react by returning the cheque with a firm refusal to supply any information unless there is written permission from the relatives. Others of us have taken an even stronger line and have refused to give any information at all, feeling that this should have been asked for from the assured himself before the policy was broached. We have spoken to several insurance agents about this, but have never received a satisfactory explanation.

Surely, the insurance companies cannot have it both ways. They should either accept a signed statement of the policy holder with the risk of early unexpected death, or they should insist on some form of previous medical investigation before issuing a policy.—We are, etc.,

W. B. MUMFORD.

GENERAL MEDICAL COUNCIL

187th SESSION

The 187th session of the General Medical Council opened at the Council's offices, 44, Hallam Street, W.1, on November 24, when the chair was taken by Professor Sir David Campbell.

Mr. KEITH PATERSON BROWN, F.R.C.S.Ed., was introduced as representing the Royal College of Surgeons of Edinburgh and took his seat.

On the proposal of Dr. H. GUY DAIN the Council placed on record its special pleasure at the knighthood which Her Majesty had conferred on Sir David Campbell. Dr. Dain, who spoke on behalf of the English Branch Council, was supported by representatives of the Scottish and Irish Branch Councils, a representative of the Dental Board on the Council, one of the lay members, and the Legal Assessor. The resolution was cordially adopted and Sir David Campbell suitably replied.

PRESIDENT'S ADDRESS

Sir DAVID CAMPBELL referred first to the death in August of Norman King, a former registrar of the Council. Entering the service of the Council in 1897, he had proved himself "one of our most distinguished servants for the long period of 36 years." He retired from office in 1933.

Sir David then went on to speak of the removal from the Council as a whole of its responsibility for professional discipline by concentrating that responsibility on the smaller Disciplinary Committee. From now on the Council as a whole, except for cases reported for action by the Dental Board, would be entirely free from disciplinary business and will be able to devote its energies more effectively to the many-sided problems of medical education.

"Nevertheless," said the President, "it appeared to the Council, having regard to the great importance of the disciplinary functions entrusted to it by Parliament, that it was desirable that if at all possible every member of the Council should be afforded an opportunity of serving for a period on the Medical Disciplinary Committee or on the Penal Cases Committee." The Council would therefore be asked to approve a method of election, including a scheme of rotation, which, while preserving a degree of continuity in membership, would give each member of the Council an opportunity to serve.

The Medical Curriculum

Six years have passed since the publication of the current recommendations relating to the medical curriculum, and the President thought that the time was approaching when the Council would have to study the effects of these recommendations and consider how far it may be necessary to revise them in the light of the changing circumstances of medical practice. In making such a review, it was desirable that the Council should have before it the reports

of visitors in the various subjects of the curriculum, and especially the reports of the inspectors of the qualifying examinations. With that end in view, the Council last May had appointed visitors in the subjects of anatomy, physiology, social medicine and public health, and inspectors in the qualifying examinations in medicine, surgery, and midwifery. These same visitors and inspectors had been invited by the Medical Registration Council of Ireland to visit and inspect examinations and medical schools in the Republic. Sir David went on to say that a debate next May on the whole question of medical education, including the impact thereon of the compulsory period of house-officer appointments, would be desirable.

Approved Hospital Posts

In order to assist young graduates and hospital authorities generally the Council published last year a list of the hospitals in Great Britain and Ireland and of the posts therein approved for the time being by licensing bodies for the purpose of house-officer service under the Act of 1950. That list included 634 hospitals and 3,048 posts. Since then the Council has been informed that 53 other hospitals have been approved, while 4 included in the list have ceased to be approved. The number of recognized posts has increased to 3,232. A list setting out in detail the changes in the number of both hospitals and posts has now been issued by the Council for the guidance of all concerned.

Licensing bodies are empowered by the Act to approve for this purpose hospitals not only in this country but also in the Commonwealth and in foreign countries. For the assistance of all persons interested the Council has now issued a list showing the hospitals and institutions in Colonial territories which have been formally approved by one or more licensing bodies for an indefinite period.

Statutory Registration of Opticians

Some months ago the Minister of Health announced in Parliament that in conjunction with the Secretary of State for Scotland he was proposing to discuss with the bodies concerned the findings of the Report submitted last year by the Interdepartmental Committee on the Statutory Registration of Opticians, of which the chairman was Lord Crook. The principal recommendation was that registration of opticians should be in the hands of a General Optical Council, which would contain representatives of the medical profession, ophthalmic opticians, and dispensing opticians, together with an independent chairman and two Privy Council nominees. The medical practitioners were to include three ophthalmologists, one medical practitioner engaged in the preclinical training of students, and one general practitioner. "While it would not be fitting for me," said the President, "to comment on the wider issues involved—and it is to be noted that the Committee was instructed to proceed on the assumption that there should be a system of statutory registration of opticians—the

PADDINGTON DIVISION.—At Paddington Town Hall, London, W., Thursday, December 10, 8.30 p.m., meeting. Film: "Modern Handling of Ankylosing Spondylitis."

SCUNTHORPE DIVISION.—At Blue Bell Hotel, Scunthorpe, Thursday, December 10, 8 for 8.30 p.m., annual dinner.

SHROPSHIRE AND MID-WALES BRANCH.—At Copthorne Hospitals, Shrewsbury, Wednesday, December 9, 8 p.m., meeting of clinical and pathological section. Discussion: "The Place of Tonsillectomy in Present-day Practice."

SOUTH BEDFORDSHIRE DIVISION.—At Luton and Dunstable Hospital, Luton, Friday, December 11, 9 p.m., meeting. Dr. L. Handley Ashken: "The Special Clinic—Its Uses and Usefulness." A film and slides will be shown.

SOUTH MIDDLESEX DIVISION.—At Anchor Hotel, Shepperton, Monday, December 7, 8.45 p.m., annual general meeting.

SOUTH-WEST ESSEX DIVISION.—At Out-patients' Department, Thorpe Coombe Maternity Hospital, Forest Road, Walthamstow, E., Wednesday, December 9, 8.30 p.m., meeting. B.M.A. lecture by Sir Zachary Cope: "The Regional Diagnosis of Acute Abdominal Disease." A discussion will follow.

SWANSEA DIVISION.—At Osborne Hotel, Swansea, Thursday, December 10, lecture by Dr. L. G. C. E. Pugh.

TUNBRIDGE WELLS DIVISION.—At Kent and Sussex Hospital, Tunbridge Wells, Tuesday, December 8, 8.30 p.m., clinical meeting. Mr. G. C. Knight: "Facial Pain."

WEST HERTS DIVISION.—At Crown Hotel, Garston, Wednesday, December 9, 8.30 for 9 p.m., general meeting. Address by Dr. S. J. Hadfield (Assistant Secretary, B.M.A.): "General Practice—a Factual Survey." A discussion will follow.

WEST MIDDLESEX DIVISION.—At Nelson Room, Ealing Town Hall, London, W., Wednesday, December 9, 8.30 p.m., meeting. Address by Dr. R. Forbes: "Litigation and the Profession."

WEST SUSSEX DIVISION.—At The Black Horse Hotel, West Street, Horsham, Thursday, December 10, 6.30 p.m., meeting. Address by Dr. H. L. Marriott: "Some Recent Advances in Diagnosis and Treatment," followed by business meeting and a discussion.

WILLESDEN DIVISION.—At Central Middlesex Hospital, Park Royal, N.W., Tuesday, December 8, 9 p.m., general meeting. Dr. F. Avery Jones will talk on his recent tour of India and Australia, illustrated by colour photographs.

WOOLWICH DIVISION.—At Brook General Hospital, Shooters Hill Road, S.E., Tuesday, December 8, 8 p.m., joint clinical meeting with Greenwich and Deptford Division.

Meetings of Branches and Divisions

BIRKENHEAD AND WIRRAL DIVISION

The annual general meeting was held at the Arrowe Park Hotel on October 31, 1953. With Dr. R. Vaughan Thomas in the chair, there were 12 members present. The following officers were elected for the coming session:

Chairman.—Dr. R. Johnson.
Vice-chairman.—Dr. R. W. L. Pearson.
Honorary Secretary and Treasurer.—Dr. H. C. W. Baker.

NORTH WALES BRANCH

The autumn meeting was held at Capel Curig, on November 5, 1953. With Dr. R. Salter Ellis in the chair, there were 14 members present. Mr. Emyln Lewis gave a lecture on plastic surgery, and a film of the operative procedure and aftercare of a case of brown pigmentation of both eyelids was shown.

The B.M.A. in Committee

ITS PARISH THE WORLD

It is 76 years since the first Overseas Branch of the British Medical Association was formed. Since then the Association has established itself all over that aggregate of territories which owe allegiance to the Crown. The first Branch was formed in Jamaica in 1877 and afterwards there appeared a quick succession of Branches in various parts of what is now called the British Commonwealth. A South Australian Branch was formed in 1879, one in British Guiana in 1883, the first Indian Branch in 1884, Ceylon in 1887, the first African Branches in 1888, the first in the Far East in 1891, and so on. The Branches now range through the alphabet from Aden to Zanzibar. They are to be found in all the continents except North America. There are Branches in the Caribbean, in the Mediterranean, in the Malay archipelago, in Polynesia. Africa has fifteen Branches; Australia has six; New Zealand is one Branch comprising seventeen Divisions.

Originally there were Branches in Canada, the first of them in Halifax, Nova Scotia, in 1887, but since 1926 these have been dissolved on the affiliation of the Canadian Medical Association with the British Medical Association. So close is this affiliation that in 1955 and again in 1959 the two Associations will hold joint Annual Meetings, in Canada under a Canadian president and in Great Britain under a British president. In the Union of South Africa also the South African Medical Association is affiliated with the B.M.A.

The Overseas Committee

At the Annual Meeting every year the overseas representatives attending are limelighted on two or three occasions, but it is not always remembered that there is at Headquarters an Overseas Committee which for many years under one name or another (until recently the Colonies and Dependencies Committee) has zealously looked after the interests of members of the Association abroad. The work of the Committee is mainly concerned with the Colonies and the protectorates. The corporate branches in the Dominions with their own excellent organization make little demand on Headquarters in London.

The Overseas Committee includes members who themselves have seen service overseas and have ties with the countries in which they served. They bring wisdom and experience to its deliberations. It is quite a small committee.

In addition to the four chief officers of the Association, who are members *ex officio*, it consists of seven representatives of overseas constituencies elected by the democratic machinery of the Association and holding office for three years; two members appointed by the Council; two by the Representative Body, and one by the Organization Committee; and there is power to co-opt additional members for areas not otherwise represented. The grouping of overseas constituencies for election of members to the Committee is: Australia (two members); New Zealand and Fiji; South-east Asia; Africa and the Middle East; the Caribbean; and the Irish Republic.

Varied Agenda

The agenda of a typical meeting (to take a recent example) may include consideration of disputes in Cyprus over pensionable salaries of specialists in Government employment; working conditions of the medical profession in Malta; the evidence to be given before the commission which is examining Civil Service salaries and conditions in East Africa; remuneration for medical services in certain African protectorates; the progress towards unification of Government medical services in the Caribbean; a proposal for a visit by a representative of the parent body to Branches in the Far East; a demand for new salary scales in Borneo; an amendment of the Medical Registration Ordinance in Hong Kong; the question of private practice by Government doctors in the Seychelles; security of tenure in the colonial research service, as well as such domestic matters as the method of representation of Overseas Branches in the Representative Body. All that in the programme of business for one meeting.

Occasionally a large general question will arise, such as a proposal for the formation of a Commonwealth Civil Service, but in general the business of the Committee concerns one or other of the many congeries of communities in the British Commonwealth with their various forms of government, social customs, and standards of cultures, demanding knowledge and, if possible, personal experience of the particular community. No sooner is a satisfactory adjustment made in one area than some difficulty arises in another. A question which in different forms is constantly presenting itself is whether, a medical service in some part of the colonial world being unsatisfactory, the Association, acting against its traditions, should condone it and continue to recruit doctors for it, or should blacklist it. The question of unqualified doctors in certain areas and of the sphere of those whom we in this country call medical auxiliaries comes forward in overseas territories much more acutely than it

does at home. The Committee has also to bear in mind the three Branches of the Association which are in foreign countries (Egypt, Sudan, and the Middle East), and those members abroad who are not attached to any Branch.

The chairman of the Committee for some years past has been Mr. J. L. Gilks, and its secretary is Dr. E. Grey-Turner.

International Relations Committee

The British Commonwealth is itself a great experiment in international and inter-racial relations, but in recent years the Association has increasingly developed a world consciousness. Since the war the World Medical Association has come into existence, on the foundation of a much smaller and structurally looser body, the Association Professionnelle Internationale des Médecins, of which Dr. Alfred Cox, then secretary of the Association, was one of the founders. The World Medical Association is a body of great importance to each national medical association. It costs 100,000 dollars a year to run, and has a *Bulletin* which is published four times a year in three languages.

For some years now an International Relations Committee has functioned at Headquarters under the chairmanship of Dr. J. A. Pridham. This constitutes an active link with the World Medical Association, and through it with the World Health Organization of the United Nations, arranging for attendance at assemblies abroad, participating in various international conferences, and entertaining foreign delegates when they come to this country. The International Relations Committee has also done all it can to enlist the interest of Government departments, especially the Foreign Office and the Commonwealth Relations Office, in the promotion of British medical ideas and methods abroad. The Committee, which consists in all of about twenty members, is the growing point of interest in the concerns of the medical profession in other countries where there is a common ethic and ideal, and on both sides there is much to be given and received.

CENTRAL CONSULTANTS AND SPECIALISTS COMMITTEE

GUILLEBAUD EVIDENCE

An all-day meeting of the Central Consultants and Specialists Committee was held on December 3, with Dr. T. Rowland Hill in the chair. A full programme of business awaited the Committee, with as many as 10 lengthy documents to consider, and 32 items on the agenda, some of which were referred for decision by the Executive.

Much time was devoted to the consideration of a draft memorandum of evidence prepared by the Chairman on the authority of the Executive for the Guillebaud Evidence Steering Committee. This was a comprehensive document dealing with the general administration of the hospital service, the medical advisory machinery, medical staffing whole- and part-time, the relation of general practitioners to hospitals, and other matters. After detailed discussion of the document, together with the views expressed by regional committees, it was generally approved.

The Executive also submitted a report on a number of matters which had been the subject of previous discussion. One of these concerned the appointment of medical members of regional hospital boards.

Consultation Fees for Government Services

The Treasury's proposals for fees for part-time services of consultants in various Government departments were considered, and a number of recommendations were made for increases. Notably the fees proposed by the Treasury were in some instances below the three guineas which the Committee considered to be the minimum for a consultant opinion.

S.H.M.O. Grading

The dissatisfaction expressed by a considerable number of S.H.M.O.s with their grading following the last review again came forward. It was the view of the Executive, confirmed by the Committee, that there was evidence to suggest that some of these practitioners had been unfairly treated and should have been given consultant status. The Ministry's attitude was set out in a letter which appeared in the *Supplement* of October 17 (p. 167). Despite the Ministry's obvious unwillingness to interfere with the decisions of the review committees, it was felt that the matter should not be dropped. It was pointed out that to some extent the injustices might have arisen out of different standards adopted by the review committees in the various regions.

Complaints Procedure

Dr. Robert Forbes, in the absence of Dr. Cochrane Shanks, the chairman of the subcommittee concerned, presented a report on complaints procedure. He reminded the Committee that doctors were called upon to provide reports, and in doing so they might well be furnishing something which would prejudice their own interests in the event of further proceedings. An earlier circular from the Ministry stated that if a doctor was responsible for an act or omission which was made the basis of litigation the Ministry or the regional board or management committee should seek to serve a notice of contribution on him, calling upon him to contribute towards any damages or costs that might follow. The Ministry was, so to speak, bringing in the doctor as a third party. In reply to a protest on this point, the Ministry had asked what would be the attitude of the profession if in future it changed its policy and did not seek to obtain such a contribution. This new situation had been discussed with representatives of the Ministry, who had been warned of the possibility that if the current policy were continued doctors might be unwilling to prepare adequate clinical notes, lest by so doing they prejudiced their own interests. It was therefore imperative to devise some machinery enabling medical staff to co-operate with their employing authorities by reporting accidents and other incidents which might lead to complaint without involving them in subsequent disadvantage should the matter go to litigation.

Accordingly he now submitted to the Committee a draft memorandum which was the result of consideration between the Ministry, the subcommittee, and representatives of the defence societies. It set out in detail the course which should be followed if it was decided to settle the action out of court or to defend it in court. If accepted it would mean that all concerned would have to depend on the goodwill of the others. He thought the arrangement would make for a better atmosphere between employers and employed. The draft memorandum was unanimously approved.

Liaison with General Practitioners

Another report presented was from the Consultants and General Practitioners Liaison Committee, of which Dr. Rowland Hill is chairman. One of its recommendations was that a joint subcommittee representative of the different aspects of the subject be appointed to give further study to the establishment of an integrated service for the treatment and rehabilitation of chronic disablement arising from age or illness. Dr. Talbot Rogers said that he was a member of the previous Association committee in 1949 on the care and treatment of the elderly and infirm, but the scheme it drew up was largely theoretical; some of its ideas had been put into practice, but new ideas had emerged, and the subject was ripe for further review.

It was also proposed that steps be taken to draw the attention of members of hospital medical staffs to the importance of ensuring that general practitioners were promptly notified of the death or discharge of their patients. Dr. Talbot Rogers said that it was not necessarily a long report which was required, but a simple immediate notification.

Hospital Junior Staff

A recommendation was submitted by the Hospital Junior Staffing Subcommittee, under the chairmanship of Professor G. I. Strachan, that medical recruitment committees be asked to grant to the greatest extent possible post-registration deferment of call-up for periods of up to one year; that the salary of all posts below the grade of senior registrar be increased for a period of two years where held by a practitioner who had undertaken a period of national service as a medical officer; that every effort be made to persuade hospital authorities of the urgent need to make married quarters available for junior hospital staff, and that facilities be increased and encouragement given to married women practitioners to undertake part-time employment in hospitals as casualty officers and the like.

It was stated that owing to the policy adopted by the medical schools at the request of the Government at the end of the war of admitting a high proportion of ex-Service students a large number of the students who would qualify in the next two years would not be liable for national service. This meant that for the next two years the comparatively small number of young practitioners liable for national service would make it difficult to meet the requirements of the Services and the policy would probably be to grant deferments in exceptional circumstances only.

It was agreed, after some discussion, that the whole report should at once go to the Joint Consultants Committee.

Public and Professional Relations

The Chairman mentioned that the setting up of a Public and Professional Relations Subcommittee had been the subject of a question from the Public Relations Committee of the Association, but he had made it quite clear that the new subcommittee had no executive functions but was charged solely with the task of examining and reporting to its parent committee on matters of personal concern to all members of hospital medical staffs, and that it would consult with the Public Relations Committee before embarking upon any publicity campaign.

A report from this new subcommittee was presented by its chairman, Professor P. C. P. Cloake. It contained many recommendations, including the issue of information leaflets in hospitals to give welcome, comfort, and guidance to the patient; the revival of groups of hospital friends and similar bodies; the appointment of a senior or recently retired consultant to give general supervision to the interests of patients, and certain arrangements to acquaint the press and the public with the hospitals' arrangements and problems. It was also proposed that a pamphlet be prepared and sent to all consultants, S.H.M.O.s, and registrars setting out the present organization for negotiating and conducting the affairs of hospital medical staffs, that in each region an annual meeting open to all members of medical staffs be summoned; that general practitioners be notified that at certain definite times they would be welcomed to the wards to visit their patients and to discuss the cases with members of the hospital staff available, and that social gatherings where medical staff and local general practitioners could meet be stimulated and encouraged.

A further series, not of recommendations, but of suggestions, were that when seeking to arrange out-patient appointments general practitioners should be asked to indicate those cases which they considered for medical reasons to be urgent, and that these should have priority; and that wherever practicable out-patients should be referred back to their general practitioners for intermediate treatment or supervision.

The Committee also received a letter from the Society of Medical Officers of Health referring to the widespread failure to notify cases of tuberculosis. The Committee decided to draw the attention of hospital medical staffs to this matter. Several other matters remained on the agenda, including resolutions from group and regional committees, and various business was referred to the Executive for future report.

LIFE ASSURANCE

FEE FOR "LONG" FORM

For some time information has been received suggesting that the fee for the ordinary form of medical examination report for life assurance is not considered satisfactory by many doctors. As a result of discussion of this problem at the A.R.M. this year it was resolved:

"That the fee for the long form of medical report for life assurance should be increased from £1 11s. 6d. to £2 2s."

Meeting with Life Offices

Recently representatives of the Private Practice Committee met representatives of the Life Offices Association to discuss a number of matters, including the question of this fee. It was explained that the present fee, which had been agreed in 1947, was considered inadequate for a variety of reasons and should be increased to £2 2s.

No Evidence of Dissatisfaction

After a full discussion the Life Offices Association stated that their members were unanimous in the view that a fee of £1 11s. 6d. was adequate for this service. They supported this contention by stating that they had little evidence that doctors were dissatisfied with the fee—in fact, the contrary appeared to be the case. This was reported to the Executive Subcommittee of the Private Practice Committee.

"BONUS SHIFT CERTIFICATES"

In November, 1952, the Five-day Week Agreement between the National Coal Board and the National Union of Mineworkers was extended to permit the payment of a proportionate bonus *inter alia* when a miner is absent from work on account of certified sickness. As a result of this extension the number of medical certificates required by miners from their family doctors increased, and this appeared to be mainly in respect of absence from work due to sickness where the miner had not sought examination or treatment by his doctor. In such a case the doctor is usually asked by a man who is fit for work to issue a certificate stating that he was unfit the day before. In almost all cases the doctor is unable to certify that the man was unfit for work, as there is no clinical evidence of incapacity.

No Certificate on Hearsay Evidence

From information which has reached the B.M.A. it is clear that miners often try to persuade their family doctors to issue a certificate which is only a repetition of the man's own statement. Doctors consider that they should not be asked to issue such *ipse dixit* certificates.

At the A.R.M. this year at Cardiff the matter was fully discussed, and it was resolved:

"That the Representative Body disapproves of the issuing of bonus-shift certificates to a miner, unless he has been actually attended by the doctor during his illness, and that the Council be asked to consider reopening the question with the National Coal Board."

Coal Board's Reply

Representations were made to inquire from the National Coal Board what steps could be taken to resolve these difficulties. The following reply has been received:

"With reference to your letter of November 18, the Board have recently had under consideration the arrangements for payment of proportionate bonus. The attention of the Board has been drawn to the type of certificate to which you have referred—namely, a certificate which says 'A. B. says he was unfit for work yesterday.' Such a certificate is not regarded as a medical certificate but is merely hearsay evidence. These difficulties have been discussed with the National Union of Mineworkers, who are as concerned as the Board that only cases of genuine sickness should be protected, but the Union stated that if there was abuse of the provisions it was for the Board to deal with the matter

administratively and that if they were dissatisfied with a decision of the Board it should be open to them to make representations to the Board.

"Divisions [of the National Coal Board] have been informed that the procedure should be tightened up but not so as to interfere with genuine cases. If a man who is really sick sees or calls in a doctor the following day and is still sick, a proper medical certificate covering the whole period of sickness would not be challenged. It is, in the Board's view, essential if abuse of the new provisions is to be avoided that medical certificates should only be issued where a doctor has actually examined the patient at the time of sickness and should state the nature of the incapacity which renders the man incapable of following his employment."

SOCIAL SECURITY BENEFITS RECIPROCAL ARRANGEMENTS WITH AUSTRALIA

Reciprocal arrangements on social security benefits between Great Britain and Australia will come into force on January 7, 1954. The arrangements will enable people who go from this country to Australia to receive benefits under the Australian scheme to supplement any retirement pension or widows' benefits which they may be receiving from the Ministry of Pensions and National Insurance. People who come from Australia to this country will be treated as if they had been insured under the National Insurance schemes while they were in Australia so as to help them to qualify for National Insurance benefits here.

Family Allowances

A separate agreement with Australia on family allowances will come into effect on the same day under Regulations which are being made by the Minister of Pensions and National Insurance. This will ensure that families going from one country to the other will be able to qualify for family allowances in the new country as soon as they arrive there.

LOANS ON COMPENSATION SPECIAL TERMS FOR MEMBERS

About 18 months ago the Association, with the help of the Medical Insurance Agency, initiated discussions with the Ministry of Health about the possibility of using the compensation standing to the credit of a practitioner, but not ordinarily payable until retirement, as security for a loan under a form of mortgage. Negotiations were eventually successful, agreement being reached on the form of mortgage appropriate to this transaction and the procedure to be adopted. An announcement was published in the *Supplement* to the *Journal* of September 27, 1952 (p. 143).

Hardship Only

Before the appointed day it was possible in certain circumstances to use the goodwill of a general practice as security for a loan, but the effect of Section 35 of the Act was to destroy this possibility. The Minister has power under the Regulations to make, at his discretion, advance payments of compensation if delay until retirement or death would mean hardship. Advances made hitherto amount in the aggregate to a substantial sum and further payments have been very strictly limited to cases of debts outstanding on the appointed day and incurred through the purchase of a practice. Thus it has been impossible to realize the capital represented by goodwill to finance new projects such as the improvement of practice premises. The possibility of borrowing a proportion of the sum due may therefore be of great help to doctors faced with unforeseen commitments, and, by assigning to the lender the whole of the interest which he is receiving, the borrower is able to pay the interest at the higher rate on the proportion borrowed, without facing recurrent charges.

Rate of Commission

It was only to be expected that, once the possibilities of this scheme were known, finance companies, insurance brokers, and other firms would wish to take advantage of a new field of business open to them. Many doctors will have received circular letters offering to lend money in accordance with the accepted procedure. Whatever may be the opinion of the Association on the practice of circularizing G.P.s on matters of this kind, there is no doubt that it is legitimate business. It is not always made clear, however, that a commission varying between 2½ and 5% (in addition to interest and the legal costs involved in a mortgage) may be charged. Doctors should bear in mind, therefore, that the Medical Insurance Agency, a non-profit-seeking body, is in a position to offer special terms for this facility—lately much improved—and any member interested is advised to consult the Agency when considering a loan on compensation. The address of the Agency's chief office is: Medical Insurance Agency, B.M.A. House, Tavistock Square, London, W.C.1.

G.P. OBSTETRIC BEDS IN BLACKBURN THREATENED CLOSURE

The following resolution and addendum were passed without contrary vote by the Blackburn Executive Council at its meeting on December 8:

"That this Council views with grave concern the fact that it was not consulted or asked to voice its opinion at any time by Blackburn and District H.M.C. or regional hospital board with regard to the proposed closing of Springfield, the only remaining general-practitioner maternity hospital in Blackburn, this being contrary to the smooth liaison which should exist between the local administrative bodies of the N.H.S., and it directs that this protest be forwarded to (1) the Minister of Health, (2) regional hospital board, Manchester, (3) the local M.P.s, and (4) the Executive Councils' Association (England)."

"That no action be taken with regard to the closure of Springfield until the matter has been fully discussed by this Council."

G.P.s' Opposition

The Executive Council's resolution is the latest move in the opposition to the decision of the Blackburn Group Hospital Management Committee and the Manchester Regional Hospital Board to close the 20 G.P. obstetric beds in Springfield Maternity Home on the grounds of redundancy, and to reopen them as geriatric beds. When the hospital management committee's intention became known, Blackburn Local Medical Committee and the Blackburn Division of the B.M.A. passed resolutions of protest and were supported by the Lancashire Local Medical Committee and its chairman, Dr. A. Campbell, who has been prominent in organizing the opposition.

Reasons for Opposition

Local reports indicate that the closure of the Springfield Home would reduce the G.P. obstetric beds in the district from 70 to 50, and, furthermore, the beds at Springfield are the only ones conveniently situated for doctors and patients. The general practitioners consider that the closure of these beds would seriously affect their ability to practise obstetrics and would be contrary to the Ministry's and the profession's policy on the matter of G.P. maternity beds. The executive council's resolution is evidence of the feeling that the hospital management committee and the regional hospital board should have consulted the executive council and the local medical committee before making a decision of such importance to Blackburn general practitioners and their patients.

The Local Position

The population of Blackburn alone is over 111,000. There are 71 general practitioners on the executive council list, of whom 66 are on the obstetric list. The district is a

compact industrial one in which a high proportion of female labour is employed. Home conditions are in the main unsuitable for domiciliary midwifery, and the number of general-practitioner obstetric beds has always been relatively higher than in other areas. There are up to about 100 hospital maternity beds which are not open to general practitioners.

So far the Springfield Home has not been closed. The Blackburn press is devoting much space to a whole-hearted ventilation of local opinion about the matter.

PUBLIC HEALTH COMMITTEE A JUBILEE PARTY

Although its functions and responsibilities have grown considerably with the years, the Public Health Committee is the only committee set up under the new constitution of the Association in 1902 that has not changed its name. The Committee has completed 50 years' work, and during that time has had 12 chairmen, including the present one, Dr. K. Cowan. Not always have they been medical officers of health, for two surgeons, one physician, and one general practitioner have held the office. The last of these was Mr. E. J. Domville, a surgeon of Exeter, who retired from the chair in 1920.

Something to Celebrate

These and other details emerged at a small informal party given by the chairman and members of the Committee at the conclusion of the business of its meeting on Friday, December 11. Dr. Cowan, in a short speech, explained that the Committee thought that its Jubilee was a happy occasion on which to gather together some of those who had helped to guide its work in the past, and who were still living and able to come. Of the past chairmen, Professor R. M. F. Picken, who held office for a record period from 1932 to 1945 (there was a short wartime break from 1939-42 when committee work was suspended), and Dr. J. Fenton were present. Dr. C. Metcalfe Brown was unable to be there. Dr. Cowan welcomed that grand old man of the B.M.A., Dr. Alfred Cox, who was a member of the Constitution Committee which gave birth in 1902 to the Public Health Committee, of which he was later to be secretary, and Dr. R. Forbes, another past secretary. Dr. Charles Hill, M.P., was in Rome and regretfully was unable to be at B.M.A. House too. The Committee clerks were represented by Mr. J. Woodcock, now secretary of the Medical School, Cambridge, and Mr. A. H. Towner, still with the B.M.A. Dr. A. Macrae and the Scottish Secretary, Dr. E. R. C. Walker, and Dr. A. V. Kelyack and Mr. J. D. Huish, the present secretary and clerk, were also there.

The Old Days

Professor Picken, thanking the Committee for the party, spoke in reminiscent vein and recalled in particular the work that Dr. Cox did in support of the Public Health Service. Dr. Cox said a few words in a way which showed that his interest in the affairs of the Association is undiminished. Most members of the Committee, including the President, the Chairman of Council, and the Chairman of the Representative Body, were able to be present.

DUNBARTONSHIRE DIVISION PRESENTATION TO SECRETARY

The Dunbartonshire Division held their annual dinner-dance in the Buchanan Arms Hotel, Drymen, on December 2, when Dr. William Scott, Alexandria, presided over a large gathering of members and friends. Among the guests were Dr. J. T. McCutcheon, Assistant Scottish Secretary, and Mrs. McCutcheon.

During the course of the evening, occasion was taken to make a presentation to Dr. William Gibson, Aurora, Old Kilpatrick, who had been secretary of the Division since 1930 and for over 30 years an active member of many committees.

Questions Answered

Secretary-receptionist and P.A.Y.E.

Q.—I have had a friend living with me who has acted as my secretary and receptionist and whom I have paid a salary of £2 18s. per week. She now wishes to live on her own with a higher salary, and so she becomes liable for coding for P.A.Y.E. My accountant tells me, however, that she has already been liable for coding while living with me, as her accommodation and subsistence have been an additional income. Can you give me the ruling on this?

A.—It was decided by the High Court very many years ago that accommodation and board, being inconvertible by the employee into money, are not "income" on which the employee is chargeable to tax, and I do not understand on what grounds the accountant regards that benefit as "additional income." The questioner is entitled to treat as an expense of her practice the cost of her friend's salary, board, and lodging in so far as that cost was borne for assistance in the work of the practice, and equally, of course, she will be entitled to deduct the monetary cost under the proposed new arrangement. (To avoid misunderstanding I may perhaps add that in the case of certain classes of taxpayer—directors of companies—non-monetary benefits are liable, but this case is outside the scope of such liability.)

Sickness Benefits

Q.—For some years prior to February 7, 1952, I drew sickness benefit under an insurance policy. I claimed back the income tax I had paid on the payments during the financial year 1951-2 on the ground that the payments did not continue for the whole of that financial year. The inspector of taxes replied that as the sickness benefit had been paid continuously for a number of years it is still assessable for 1951-2. May I have your expert's observations on this?

A.—The leading case on this question is *Forsyth v. Thompson* (H.M. Inspector of Taxes) reported in [1940] 2 K.B. 366. It involved, *inter alia*, consideration of a contract with the Medical Sickness Annuity and Life Assurance Society, and several objections to the assessment of the benefit were raised by counsel. The material objection for present purposes was that the benefit did not provide "annual" sums, but only sums payable on contracts which determined at the end of each year. The judge declined to accept that contention and held that the benefits were "annual" and were therefore assessable. The appellant had been "permanently disabled" and the question of whether liability would attach to the final payment of benefit did not arise, and was not referred to in the arguments of counsel or in the judgment. The point is not beyond dispute, but in all the circumstances I cannot advise your correspondent to carry his objection to appeal.

Government Pensions

Q.—Are local or central government pensions treated by the income-tax authorities as "earned" or "unearned" income?

A.—Pensions of the kind referred to are regarded as earned income.

SALARIES COMMISSION IN CYPRUS

The Secretary of State for the Colonies has arranged for Sir Rex Surridge to examine the salary structure of the Government service in Cyprus. The Cyprus Branch has submitted a memorandum of evidence to the Commissioner, and a further memorandum is to be submitted by the Overseas Committee of the B.M.A.

Correspondence

Because of the present high cost of producing the Journal, and the great pressure on our space, correspondents are asked to keep their letters short.

Obstetric House Appointments

SIR,—When the more scarce house appointments, such as obstetrics, are being filled may I put in a plea for special consideration for the ex-National Service candidate who has served in a hazardous area—such as Korea or Malaya—in a field unit—that is, as a regimental M.O. or in a field ambulance or the equivalent of these? Others who have served in hospitals or bases deserve consideration for having served at all, but not to the same extent.

I learn from young ex-Service men that if they are fortunate enough to get short-listed they find themselves in competition with men from such places as Eire and South Africa, and with women, and one of these usually gets the post. This group is not liable to two years' National Service and during that period gains extra experience—hospital experience—and so is at an advantage *vis-à-vis* the average ex-Service man under the present system of selection. I was told of one post where the successful candidate, a lady, actually already held the post and was reapplying. Her re-appointment made the third obstetric post she had had, though she disclaimed any intention of specializing. I hope no one will write virtuously that he, or she, always chooses the most experienced candidate. It depends on the definition of "experience." I am not advocating the appointment of a nitwit just because he has served. I am submitting that most men who have experienced the responsibilities, hardships, and hazards of active service in the field mature more rapidly than those who have not had such experience. Further, that that special experience is an asset in a houseman. I urge that special credit be given to ex-Service candidates for such house appointments as obstetrics for serving their country in dangerous areas to offset the purely hospital experience of others who have not served at all.—I am, etc.,

Maldon, Essex.

IVAN PIRRIE.

Service Recruitment

SIR,—It must be accepted that Service life, by its nature, can appeal only to a comparatively small number. The Naval Medical Service now being virtually split into a "specialist" and a "general practitioner" service, this is particularly true of the latter. There is here little or no place for the practitioner whose only professional interests lie in a constant supply of clinical material. A medical officer must be able to take a much wider view of his profession and find interest in all details, many at first sight irrelevant, which affect the well-being of the men in his care. The medical officer of a destroyer who cannot profitably employ himself after 0930 is obviously unsuited for "general practice" in the Navy. This is in no way to disparage "N.S.M.O." (*Supplement*, November 28, p. 213), but, accepting that his interests are deep rather than wide, I cannot believe that any practicable alterations in conditions of service are likely to attract him.

Although I cannot speak for the specialists, it would seem that, at present, the established specialists in the Navy enjoy advantages which make the branch reasonably attractive—specialists' allowances, relative security in the tenure of appointments, few appointments necessitating prolonged separation from their families, and excellent prospects of promotion to the highest ranks. Perhaps any further improvement in their lot might lie in the amalgamation of the hospital and specialist facilities of the three Services. It is that small proportion of the profession who, by virtue of their inclinations, would make efficient and, with suitable conditions, contented general practitioners within the Service who most need attracting. It is of no use that these officers should be frustrated specialists.

The factors which discourage such from joining are many. Among them I would number: (1) Uncertainty as to the duration

of a current appointment and inability to forecast the probable nature or whereabouts of the next; (2) difficulty in finding accommodation for families; (3) poor prospects of promotion to the higher ranks, but, for the great majority, compulsory retirement at the age of 55 at a time when expenses are likely to be heaviest; (4) necessary but tedious paper-work which could well be done by ratings properly trained in clerical duties; (5) absence of adequate facilities to undergo short refresher courses in civilian hospitals; (6) pay not closely enough related to one's civilian counterpart; and (7) a widespread lack of confidence, born of past experience, in the good faith of those responsible for determining pay and conditions. There is a fear that if by various inducements and attractions the medical services were to reach full complement there would follow an arbitrary reduction in pay and deterioration in conditions of service. The steps which might be taken to remedy these defects are, generally, self-evident. The housing shortage is, of course, nation-wide and the medical officer cannot expect special advantages.

How best to deserve and win the full confidence of the profession is a matter with which the powers that be should seriously concern themselves. It is essential that this confidence should exist, for once the medical officer has accepted a permanent commission his future is entirely in their hands. He does not even retain the right to resign. Perhaps this present lack of confidence may, after all, prove the greatest obstacle.—I am, etc.,

G.P., R.N.

The G.M.C.'s Warning

SIR,—The *Concise Oxford Dictionary* defines "council" as an "advisory or deliberative assembly." Accordingly the G.M.C. was strictly correct in its warning, which achieved wide publicity. Whether this warning, which must be repugnant to the vast majority of doctors, was necessary or desirable is a different question. If the majority resent it, their remedy must lie in strenuously opposing the re-election of its sponsors to the Council. One would not continue to play golf or bridge with gentlemen who consider it necessary to warn their colleagues against sharp practice.—I am, etc.,

Harrow.

J. E. S. STEPHENS.

SIR,—Dr. C. H. Ross Carmichael's letter is timely. I seem to remember receiving through the post a few days ago a printed copy of this warning. Unfortunately, I did not keep it, but it was probably sent by the G.M.C. It irritated me and I tore it up. Is it really necessary to bring to the notice of the whole profession that fraud is a crime?—I am, etc.,

Rugby.

W. J. BOLD.

Sweated Doctors

SIR,—I am very glad to see from Dr. H. Kelson Ford's letter (*Supplement*, December 5, p. 221) that there are men holding house appointments who do not consider themselves imposed upon by the need for long hours of work. The resident is seen to be in clover when conditions of service are compared with those of 40 years ago. At that time board residence was the full recompense in teaching hospitals in London and was regarded as ample when coupled with the splendid experience a hard-working young doctor obtained.

I admire the spirit of Dr. Ford's letter and hope that there are still plenty of men of that calibre entering the medical profession.—I am, etc.,

London, W.1.

HUMPHREY NEAME.

SIR,—My previous letter on this subject (*Supplement*, November 14, p. 200) was prompted by my observing the pale, tired appearance of housemen I occasionally encounter. I feel rather concerned over Dr. H. Kelson Ford's patients. He tells us (*Supplement*, December 5, p. 221) that he likes "to see each patient's progress from hour to hour and day to day. . . ." This is certainly doctoring at its very best. Later on in his letter he tells us he has a month's annual leave, occasional week-ends, and frequent free afternoons. How are his patients faring in the meantime? The only really practical suggestion I can offer him is borrowed from African witch-doctors. In their

enforced absence they leave a carved wooden little deputy to keep an eye on their patients. I think this is a capital idea for those of us who would like a free week-end occasionally.—I am, etc.,

Shrewsbury.

ALBERT E. NICHOLLS.

Remuneration of Hospital Medical Staff

SIR,—It is now over a year since negotiations were started in the Medical Whitley Council Committee "B" for the revision of the remuneration of hospital medical staff. It is many months since the Management Side gave an undertaking to reply to the Staff Side's proposals within a month, and since the Minister of Health, in answer to a question in the House, gave the assurance that negotiations would not be unduly protracted.

Our claims are simple and clear-cut. The Government and the profession have both accepted the recommendations of the Spens Committee as a basis for the remuneration of medical staff in the Health Service. The Danckwerts award to general practitioners has fixed a betterment factor to be applied retrospectively to G.P.'s remuneration. It is surely simple justice to demand that the same betterment factor be applied retrospectively to hospital medical staff in the same way. Why, then, if the Government and Management Side are acting in good faith, should there be any delay in meeting our claim?

I suggest that we should meet this problem in the same way that our general-practitioner colleagues have solved theirs—namely, (1) that the Management Side should be asked to reply by a specified date; (2) if they do not reply, or their reply is unsatisfactory, we should ask that our claim be submitted to arbitration; (3) if this is not agreed to, then the Association should organize the threat of mass resignation from the hospital service in the same way as was done for our G.P. colleagues.

Sir, we are over five years in arrears in the receipt of part of our salary. Is it not high time that this appalling state of affairs was remedied?—I am, etc.,

Meols, Cheshire.

E. SNELL.

Fees for Coroners' Necropsies

SIR,—In the *Supplement* of November 28 (p. 214) you published a very timely letter from Dr. A. Piney on the subject of fees for coroners' necropsies. I think the following experience of mine is pertinent to the matter raised.

About a year ago I performed a necropsy and gave evidence at the inquest. A local undertaker conveyed the body from the deceased's house to the mortuary and took it back—in all a total distance of half a mile. To my astonishment I gathered afterwards that the undertaker's fee exceeded mine of 3 guineas by many shillings.

Is it too much to expect the B.M.A. to bestir itself on behalf of those members not recipients of a Danckwerts award or equivalent?—I am, etc.,

Wales.

C. L. HOLLICK.

Unwilling to Pay

SIR,—With reference to the letter by Dr. W. B. Mumford and others (*Supplement*, November 28, p. 214), for many years it has been my practice under such circumstances to say to the relations: "Go to the agent or the head office of the company and say that your doctor has advised you to go to your solicitor and to tell him that he (your doctor) is prepared to go to court and give evidence on your behalf."

I have never known this to fail and payment not to be made on the spot.—I am, etc.,

London, S.E.25.

H. H. A. ELDER.

The Facts on Forms

SIR,—Is it unreasonable to expect the staff of the local Ministry of National Insurance and food offices to know a few of the facts of life? I have to-day had brought back to me by an expectant mother a form for maternity benefit on which I had put the day and month of her expected delivery but not the year. This omission was heavily marked in red pencil. The mother in question therefore had to make a

special journey to wait in a crowded surgery in order that I should insert four figures before she could hope to draw her benefit.

I am likewise frequently asked for continuation "extra ration" certificates by women who are within a week or two of their expected confinements, the dates of which are already known to the food office, and whose state of, as yet, uncompleted pregnancy must surely be apparent to anyone.—I am, etc.,

Wordsley, near Stourbridge.

MARY J. BARTLETT.

Practice Premises

SIR,—Once again the question of the doctor's "workshop" has been raised in the House of Commons, and action is to be suspended until the results of the G.M.S. Committee's letter (*Supplement*, October 10, p. 165) are seen.

I feel, Sir, that this is yet another fault following our relinquishment of the goodwill of our practices. For we must be loath to spend, say, £500 on the improvement of premises that we may never dispose of to another doctor. Of course, if this were not to be considered a capital expense by the income-tax authorities, some relief could be afforded to those public-spirited doctors who were not too much concerned with the impossibility of "seeing their money back."—I am, etc.,

Seven Kings, Essex.

I. M. SEGAL.

Bang goes Saxpence

SIR,—With the differences in dispensing fees between England and Scotland, some of the proprietaries which are cheaper than the official preparations in England turn out to be dearer than the official ones in Scotland—e.g., tab. gardenal, tab. gardenal sod., "physeptone" tablets, "pabestrol" tablets. Others, cheaper in England, are of equal price in Scotland—e.g., "benerva" tablets, "cantan" tablets, "sulphamethazine" tablets. This causes rather a headache to those of us who have practices on the border and have patients in both countries.—I am, etc.,

Newcastle-on.

ARTHUR D. BETHUNE.

Economy in Prescribing

SIR,—We, the undersigned, all experienced and fully occupied in general practice, realize the necessity of economy in prescribing. We are eager to assist the Minister in his efforts to procure this economy, but feel that the means adopted to date by the Ministry have produced little but frustration.

The Cohen Committee's report and several official publications imply that there should be no absolute restriction on the prescribing by a G.P. of any drug which, in his opinion, is necessary for the proper treatment of a patient, but that he might have to justify his doing so before his colleagues on the local medical committee. Such justification, in our view, can be most difficult, as (a) the drug is given in all good faith at the time, and the choice is based on the G.P.'s clinical judgment and experience, and (b) the charge of over-prescribing does not arise until many months have elapsed and when the case history and its attendant subtleties have faded in the memory.

Much has been published, both official and unofficial, entreating the G.P.s to economize in their prescribing, but no positive lead, we submit, has yet been given on how they are to accomplish this. No doctor is likely to expose himself to a charge of over-prescribing unless he believes in the efficacy of the drug he prescribes. He does not prescribe irresponsibly, as the Ministry seems to think. It is a widely held impression among G.P.s, especially those in industrial areas, that those who compile the various categories have little or no knowledge of general practice as it exists in these areas. We feel that the public are not given sufficient direction by propaganda, etc., to ease their demands on the G.P., and told that they too have to take part in the economy drive. To them, apart from paying their shilling, the service is free. We realize that this is fraught with political difficulties. We believe that much of the responsibility for the prescribing of proprietary drugs rests on the

hospital consultants, as their advice, when sought, is usually studded with proprietary preparations. Very often, if the patient has been in hospital, he presents himself at the surgery with a detailed list of things he has to be given. We have yet to hear of a consultant having to justify his prescribing.

Until such a time as the Minister has the courage to tackle the service as a whole—patients, consultants, G.P.s, chemists, and proprietary drug manufacturers—we consider he is unlikely to achieve the reduction in the drug bill we all wish to see.—We are, etc.,

B. MACKENZIE HEGARTY. A. J. MARSHALL.
H. M. MURRAY. J. G. FISHER.

Luton.

POINTS FROM LETTERS

General Practice Vacancies

Dr. HECTOR SMITH (Southall, Middx) writes: It is becoming evident that young doctors are having difficulty in getting practices of their own, and that the better the qualifications they may hold the greater is their difficulty. . . . A very small practice might provide just the opening required by some energetic and capable young doctor, but as he will be hoping to carve a bigger practice from among the patients of other practitioners he is not likely to be given the opportunity under the present arrangement. I would suggest that all appointments to vacancies should be made by the Medical Practices Committee, or some other central body, none of whose members are likely to be interested persons.

H.M. Forces Appointments

ROYAL NAVY

Surgeon Rear-Admiral T. Madill, C.B., O.B.E., Q.H.P., has retired.

Acting Interim Surgeon Lieutenant-Commanders T. C. Barras, F. A. F. MacKenzie, and J. Keeling to be Surgeon Lieutenant-Commanders.

ROYAL NAVAL VOLUNTEER RESERVE

Surgeon Commander J. D. Simpson has retired.

TERRITORIAL ARMY

TERRITORIAL ARMY RESERVE OF OFFICERS: ROYAL ARMY MEDICAL CORPS

Colonel (Honorary Brigadier) F. R. Sandford, C.B.E., M.C., T.D., Q.H.P., from Active List, to be Colonel.

Colonels J. B. Forsyth, T.D., T. F. Briggs, O.B.E., T.D., M. E. M. Herford, D.S.O., M.B.E., M.C., L. Fletcher, O.B.E., and A. T. B. Dickson, O.B.E., T.D., from Active List, to be Colonels.

Lieutenant-Colonel A. A. Eagger, C.B.E., T.D., having attained the age limit of liability to recall, has ceased to belong to the T.A.R.O., and has been granted the honorary rank of Brigadier.

Lieutenant-Colonels (Honorary Colonels) W. A. Lister, T.D., R. P. S. Kelman, T.D., and F. A. R. Stammers, C.B.E., having attained the age limit of liability to recall, have ceased to belong to the T.A.R.O.

Lieutenant-Colonels T. A. S. Samuel, M.C., T.D., W. R. Blunt, T.D., W. J. McIntosh, O.B.E., T.D., C. J. Cellan-Jones, T. T. P. Murphy, O.B.E., T.D., and A. Harrison-Hall, having attained the age limit of liability to recall, have ceased to belong to the T.A.R.O.

Major (Honorary Colonel) E. Parry, from Active List, to be Major.

Major (Honorary Colonel) J. K. Reid, T.D., having attained the age limit of liability to recall, has ceased to belong to the T.A.R.O.

Majors (Honorary Lieutenant-Colonels) J. McKenzie, St. C. E. J. Barrett, and D. Laing, having attained the age limit of liability to recall, have ceased to belong to the T.A.R.O.

Major W. B. Evans, from Active List, to be Major, and has been granted the honorary rank of Lieutenant-Colonel. (Substituted for the notification in a *Supplement* to the *London Gazette* dated June 16.)

Majors S. F. Seelig, J. Gregory, and S. H. Madden, from Active List, to be Majors.

Major R. E. Holme, T.D., having attained the age limit of liability to recall, has ceased to belong to the T.A.R.O.

Captain (Honorary Major) W. H. Stephen, having attained the age limit of liability to recall, has ceased to belong to the T.A.R.O.

ROYAL AIR FORCE

Air Vice-Marshal W. E. Barnes, C.B.E., Q.H.S., has retired at his own request.

Group Captain B. W. Cross has retired at his own request.

Squadron Leader J. N. Agate has relinquished his temporary commission, retaining his rank.

Flight Lieutenants M. F. P. Marshall and A. Stewart have been transferred to the Reserve, retaining the rank of Squadron Leader.

Flight Lieutenants R. A. Armstrong, T. B. Benson, and J. Donnelly have reverted to the Reserve, retaining the rank of Squadron Leader.

Flight Lieutenants P. W. Robertson, C. J. W. Soutar, T. M. Nott-Bower, and W. A. Crawford to be Squadron Leaders.

ROYAL AIR FORCE VOLUNTEER RESERVE

Flight Lieutenants S. Bender and G. A. Mandow to be Squadron Leaders.

Branch and Division Meetings to be Held

TOWER HAMLETS DIVISION.—At Poplar Hospital, East India Dock Road, E., Friday, December 18, 8 p.m., meeting. Mr. J. Suchet: "Uses and Abuses of Hormones in Gynaecological Practice."

Meetings of Branches and Divisions

ENFIELD AND POTTERS BAR DIVISION

A meeting of the Division was held at the Chase Farm Hospital, Enfield, on November 13, 1953. The following motion was debated: "That in the opinion of this meeting there is room for improvement in the relationship and mutual understanding between general practitioners and hospital medical staffs."

The following were some of the points made by speakers: experience of general practice is desirable for specialists; the gap between general practitioners and hospital medical staffs is increasing; let hospital staffs beware of the unguarded word that might be construed by the patient as reflecting criticism of the general practitioner; the general practitioner should avoid any overstatement of the urgency of a case when seeking its admission to hospital; consultative clinics and domiciliary visits provide an invaluable bridge over the gap between consultants and general practitioners; too many minor accidents are referred to hospital in the evening, and too many non-urgent cases are referred to x-ray examination at the week-end; the "hospital letter" should be written and dispatched on the day that the patient leaves hospital.

Arising out of the debate, the following suggestions, among others, were made: that a time should be arranged at which members of the hospital medical staff would be available for consultation with general practitioners concerning their patients undergoing treatment in hospital; and that facilities should be made available to house medical officers to spend a day or series of days with a general practitioner to enable them to gain some knowledge of general practice.

HOLLAND DIVISION

A meeting was held at the Peacock and Royal Hotel, Boston, on November 28, 1953. With Dr. W. Gibson Barrie in the chair, there were 40 members present. Mr. L. G. Cruickshank addressed the meeting on the subject of "Cardiac Surgery—the Present Advances."

Correction.—We regret that a mistake was made in reproducing the letter from Dr. Cyril F. Mayne in last week's *Supplement* (p. 229). The second paragraph should have begun as follows: "Taking the mass of letters as a whole, however, one thing strikes me as outstanding: the unwillingness of the young members of our profession, of all professions, to carry out their duty in the armed Forces of our country."

The B.M.A. in Committee

SPECIAL GROUPS

The setting up of special Groups, with their committees, which the Council first sanctioned some 20 years ago, is not a departure from the democratic constitution of the Association but a reinforcement of it. The aim is to secure that the voice of those members who have special interests, but whose numbers are so few or who are so distributed that they cannot command anywhere a majority, or perhaps not even an influential minority, shall be heard in Association councils. For many years the Association was regarded as being preoccupied with the welfare of general practitioners, although in fact many of its principal officers and active councillors have been and are consultants. It was a pre-eminent surgeon, Sir Victor Horsley, who took the lead in establishing the Representative Body. Sir Henry Butlin, a president of the Royal College of Surgeons, was for six years the Association's treasurer. Andrew Clark, Chairman of Council during the reform period, Lawson Tait, Edmund Owen, J. R. Thomson, Robert Saundby, Bishop Harman, and many others, not to name anyone now living, were consultants and specialists.

Specialist Opinion

Nevertheless, the difficulty of assembling the opinions of specialists and consultants on professional issues was increasingly felt. In many Divisions the number of members who are consultants or specialists is very small; in only a few does it constitute a considerable proportion, and perhaps in only one (Marylebone, which includes the Harley Street sector) is it preponderant. Therefore some 20 years ago it was decided to adopt the machinery of specialist Groups.

The Groups consisted of those whose interests were not adequately represented in the Divisions and Branches either by reason of the fact that their numbers were small or because they were inadequately distributed from the point of view of ensuring representation. There was a good deal of discussion at the time on what constituted a "full" or "pure" consultant, but the proposal went through the Council without dissent. At the same time the then Chairman of the Council, the late Sir Henry Brackenbury, expressed the hope that the Groups would be temporary and would remain only until consultants had been persuaded to pull their weight in the Divisions and Branches, when there would be no further need for the Groups. Other members of Council, among them Dr. Dain, took the view that the Groups would be a permanent feature. In a sense both prognostications have been proved right.

The First Groups

In May, 1934, consultants and specialists Groups were formed for England and Wales, for Scotland, and for Northern Ireland. Other more specialized Groups quickly followed. In 1938, for example, two of the largest Groups were established, the Ophthalmic Group, which reported 353 members, and the Orthopaedic Group, which reported 110 applications at its first meeting. The latter Group set to work at once to investigate and endeavour to improve the teaching of orthopaedic surgery in the universities and schools. A more restricted and immediate matter was to send a pronouncement from the Association on the danger of ill-fitting shoes.

The interests of consultants and specialists in general are now covered by a large autonomous body, the Central Consultants and Specialists Committee, which has 70 members. On that committee each of the special Groups is represented. The 13 Groups now in existence, together with the number of members in each, are as follows:

Dermatologists	185
Ophthalmic	465
Orthopaedic	265
Otolaryngologists	204
Physical Medicine	106
Psychological Medicine	338
Radiologists	366
Tuberculosis and Diseases of the Chest	537
Anaesthetists	784
Consulting Pathologists	260
Full-time non-professional Medical Teachers and Research Workers	312
Spa Practitioners	47
Venereologists	150

Conditions of Membership

Each Group has its own criteria for membership and its own rules. Basically the rules for the Groups are that the member must be predominantly employed in the practice of his specialty. This applies to the first eight Groups in the above list. The Anaesthetists Group consists of members of the Association who are under contract as anaesthetists with a regional hospital board or board of governors on either a whole-time or regular sessional basis, or who are anaesthetists on the staff of recognized hospitals outside the National Health Service. The Consulting Pathologists Group likewise consists of members who hold permanent appointments as pathologists in the National Health Service or who, not being in that service, have devoted at least five years to the postgraduate study and practice of pathology and continue to be engaged predominantly therein. The Group of full-time non-professional Medical Teachers and Research Workers consists of those who are full-time members of a university staff or full-time salaried research workers in university departments or other institutes.

The Spa Practitioners are a small body of those who regularly prescribe the mineral waters or baths of the spas in which they reside or are on the staffs of hospitals or clinics where the use of the local mineral waters is part of the routine treatment. Finally the Venereologists Group consists of members of the Association who have been qualified for at least five years and who are—and have been for at least three years—either engaged principally in the practice of venereology or are in charge of venereal disease clinics, though not engaged predominantly in that specialty.

A Group with a Difference

In addition there is one other Group which is on a different basis—the Registrars Group, which consists of persons who are in a temporary grade. The other Groups comprise individuals engaged in a specialty, but the Registrars Group, which has been in existence for only five years, cannot deal, of course, with specialist problems; its field is the general problems pertaining to registrars in all the specialties. It is a particularly active Group and has put forward a number of ideas which the Central Consultants and Specialists Committee (on which it has two representatives, whereas the other Groups have only one) and the Joint Committee have negotiated with the Ministry. The registrars have taken steps to ensure that the membership of their committee shall include representatives of both registrars and senior registrars from teaching and non-teaching hospitals alike.

This article is not intended to be a record of the achievements of the various Groups, but many of them have been very active. The Tuberculosis and Diseases of the Chest Group has published reports in the *Supplement* which have aroused widespread public attention. The Anaesthetists Group has done some constructive work on anaesthetic equipment. The Consulting Pathologists Group held a recent conference at which methods of blood transfusion were discussed. The Psychological Medicine Group had an interesting discussion a year or two ago on hypnotism in medical practice, and so with the others.

Liaison with Kindred Societies

The Groups are in close liaison by means of cross representation, or sometimes by joint committees, with the corresponding professional associations: for example, the Association of Anaesthetists or the Medical Society for the Study of Venereal Diseases. They are in fact expert bodies, and the Council will always refer to them for the advice which may be sought from time to time of the Association by the Ministry of Health or other outside bodies.

Each of the Groups has a committee, one-third of whose members retire annually. It is elected generally by postal vote or it may be from regional constituencies. There is an annual meeting of each Group, open to all members. In the case of the Registrars Group it would hardly be practicable to summon all the registrars in the country, and in this case the committee is elected from the Regional Associations.

The Groups are formed strictly according to the Association's by-laws. Permission to form a group is given by the Council, subject to appeal to the Representative Body. If the Council is of opinion that the ordinary machinery of the Association is sufficient for the representation of the particular interests concerned the petition for a group will be dismissed. The inclusion of any individual within a group is at the discretion of the Group committee and the candidate must sign a declaration that he comes within the prescribed definition. There is no additional subscription, by the way, for Group membership.

The findings of the Group committees are referred to the Central Consultants and Specialists Committee, which in its turn reports them to the Council, and if the findings come also within the reference of some other standing committee they are referred to it for its views. In this way the policy of the Association in these matters is carefully formulated.

THE ASSOCIATION AND PUBLIC HEALTH

A meeting of the Public Health Committee was held on December 11, with Dr. H. K. Cowan in the chair. The action of the chairman in appointing Dr. H. D. Chalke as representative of the Committee on the Control of Medical Manpower Committee and Dr. H. M. Cohen as one of the Committee's representatives on the Public Relations Committee was approved. The Committee also appointed representatives on the Liaison Committee, which up to now has embraced consultants and general practitioners only, but which it had been felt should be widened to include public health medical officers.

The Committee approved a memorandum for submission to the Steering Committee which is preparing the Association's evidence to the Guillebaud Committee. In this connexion the Committee had before it a note on hospital costs from which it appeared that the cost for domiciliary care and treatment was considerably less than that for treatment in hospital.

General Practitioners and Health Visitors

The report of the joint Subcommittee of the Public Health and General Medical Services Committees regarding co-operation between general practitioners and health visitors was considered.

Arising from a resolution of the Annual Representative Meeting, a statement of guidance had been drawn up. In approving the report, and a statement for submission to Council, it was also agreed to recommend that the document be submitted to the council of the Society of Medical Officers of Health with a view to obtaining agreement for joint publication.

Vaccination

The Committee considered the recent Ministry of Health circular regarding B.C.G. vaccination of schoolchildren. It was pointed out that this circular had been sent to local health authorities and to local education authorities, who had been asked to co-operate. It was reported that the General Medical Services Committee had expressed regret that the Association had not been given an opportunity to see the document. The Public Health Committee concurred with this view.

At a previous meeting the Committee had considered the resolution of the Representative Body urging measures centrally and through the Divisions to secure vaccination of all infants against smallpox. The matter had been the subject of correspondence with the Ministry of Health, which was equally anxious to ensure a high proportion of infant vaccinations. Local health authorities were already aware of the importance of this matter. The Chairman said he felt that medical officers of health were doing everything they could, but he suggested that the Council might reinforce such action by urging every individual general practitioner to do his best with his individual patients to bring about this desired result. It was agreed that this action be recommended to Council.

Superannuation Regulations

Dr. Wand, Acting Chairman of the Compensation and Superannuation Committee, reported on the revised draft of the Local Government Superannuation (Benefits) Regulations. The main point at issue concerned the exclusion of medical and nursing staff of a local authority from the Regulation that "Where, for the efficient discharge of his duties, a contributory employee of an employing authority is required to possess professional or other qualifications not ordinarily to be acquired in the service of the authority, the authority may, if application for the purpose is made in accordance with the regulation, direct that a number of years be added to his contributing service." It has always been the view of the Association that the principle of "added years" should apply to doctors, and great disappointment was expressed at the alteration in the original

draft regulations. It was agreed to make representations to the Ministry on the subject and to request that a deputation be received.

Disclosure of Records to Police

Discussion took place on a letter from a Divisional secretary concerning the propriety of disclosing medical records to the antenatal clinic to the police. The police had asked the public health department for certain records, but access to the records had been refused. Dr. Robert Forbes, who was attending the Committee in connexion with another item on the agenda, pointed out that the records were not the property of any medical officer but of the local health authority. It would, however, be for the medical officer of health to explain to his committee the profession's ethical rules. It was conceivable that the police might report the refusal to their own watch or standing joint committee, which might then ask the Public Health Committee for the records. It appeared that the occasion might arise when the duty of an employee conflicted with the ethical views of the profession. In such a situation it was for the individual doctor to judge what course he should follow, but in the view of the Committee every effort should be made to adhere to the ethical rules.

After discussion the Chairman said that Dr. Forbes as Chairman of the Central Ethical Committee would have gathered the opinion of the Public Health Committee, and the Committee would hope for guidance from the Ethical Committee in due course.

Other Matters

The Committee appointed four of its members to a joint subcommittee appointed to give further study to the question of the establishment of an integrated service for treatment and rehabilitation of the chronically disabled as a result of age or illness.

The Assistant Secretary reported on the four authorities which are still not fully implementing the awards of the Industrial Court and the appeals relating to these cases. An interim report was also given regarding further discussions on the appeals machinery for the medical profession in Northern Ireland.

Notes and News

American Medical Association.—In the report of the secretary to the members of the House of Delegates of the American Medical Association (*Journal of the American Medical Association*, November 7, 1953) the following information about membership is given. The number of paid members increased during the first eight months of 1953 by 7,323, making a total of 117,063, against 109,740 in 1952. The revenue from subscriptions for the first eight months of 1953 was \$2,923,625.25. The comparable figure for 1952 was \$2,739,520.00. The headquarters' personnel now numbers 823 full-time workers in the office and mechanical departments.

Appointment to Board of Governors.—The Minister of Health has approved the appointment of Mr. Norman Roberts to fill an outstanding vacancy on the board of governors of the United Liverpool Hospitals for the period ending March 31, 1956.

Economy with Efficiency.—The following question appeared in a paper on medicine in the Final examination for the degree of M.B. of Manchester University: "By what means could you, as a general practitioner, reduce the cost of prescribing while maintaining or increasing the efficiency of your practice?"

Hospitality Wanted.—The 20-year-old daughter of a professor of surgery in Switzerland would like to receive hospitality from a medical family in London from January, 1954, for some time, either as a paying guest or in return

for hospitality to an English girl in Switzerland. The Swiss girl is coming to London to study handicrafts. Would anyone interested please communicate with Dr. H. A. Sandiford, International Medical Visitors Bureau, B.M.A. House, Tavistock Square, London, W.C.1.

Questions Answered

Colonial Medical Service Income-tax Liabilities

Q.—I am a member of the Colonial Medical Service (permanent and pensionable) serving in the Gold Coast. Before leaving the U.K. last July I applied for repayment of income tax I had paid during the current year. I had been on leave without pay for two years in order to acquire a higher qualification and had been employed in the hospital service during that time. Repayment was refused on the grounds that I was leaving my wife and family in the U.K., and that, as my tours of service would only be 18 months, I was considered as being technically resident in the U.K. I was also told that any moneys I remitted to the U.K. would be liable to taxation if I spent as much as a single day in the year in the U.K. Is this correct?

A.—Two questions are raised: (a) Whether income-tax liability attaches to the earnings in this country; and (b) What is the tax position during absence from the United Kingdom? It should be borne in mind that in law an individual can be "resident" in more than one country in the same financial year. If this results in income-tax liability in both countries there is usually relief provided under the various double-taxation agreements made between the Governments concerned. As regards the Gold Coast, this agreement is embodied in Statutory Rules and Orders, 1947, No. 2868, issued by H.M. Stationery Office in 1948, price 2d.

(a) Assuming that in each of the financial two years concerned the questioner was in the United Kingdom for at least 183 days, he would rank as a British resident for those years and as such would be liable to British income tax. (b) Whether the questioner would rank as a British resident while actually abroad would depend partly on whether he was in the United Kingdom for 183 days of the financial year concerned, and partly on whether there was an abode in the United Kingdom available for his return. If he has to pay tax here for such years he may be able to claim credit for that tax against tax payable by him abroad on his Service earnings, but that is a matter which he can best raise locally when and if he becomes liable to payment of British tax.

Income-tax Relief on Expenses

Q.—Are the following expenses allowable against income tax: (1) graduation fee at university; (2) registration fee with General Medical Council, membership of B.M.A., and membership of a medical defence society; (3) purchase of instruments?

A.—(1) This is not allowable. Objections are (a) that such an expense is not incurred wholly and exclusively for the purposes of the profession, and (b) that such fees are capital outlay for the purpose of acquiring a particular status or qualifications. (2) Fees paid to professional associations are allowable in the case of individuals in practice on their own account or in partnership, provided that they are annual expenses and not of the once-for-all order. In the case of individuals in employment these fees are not allowable unless maintenance of membership is required by the terms of the contract of employment. (3) Expenditure on the purchase of professional instruments is allowable to the extent to which it is incurred to maintain rather than to acquire or improve the professional equipment of the individual concerned. In the case of an employee it is assumed that the maintenance of the private equipment is a condition of the employment.

Correspondence

Lord Horder's Address

SIR,—I observe in the *Supplement* of November 28 (p. 210) that Lord Horder, during an address to the Fellowship for Freedom in Medicine, is reported as saying, "Those who spoke for the whole profession had always declared themselves against a whole-time service, but we were now told that it would not be long before a whole-time service was a *fait accompli*."

In view of the declared policy of the B.M.A., I feel that the identity of Lord Horder's informants should be revealed to the profession, and have been surprised to find no reference to this quotation in either the editorial or the correspondence columns of a subsequent issue of the *Journal*.—I am, etc.,

Chigwell, Essex.

J. D. WIMBS.

Entry into Medicine

SIR,—In the *Journal* of August 29 (p. 490) there appeared a table of statistics on which no adequate comment has been made. This shows, in short, that there were just over 12,000 more doctors on the *Register* in 1952 than in 1943.

It would be good if your actuary could work out what is the probable increase in numbers for, say, the next ten years, and how many practitioners can be absorbed in practice during the same time in the United Kingdom.

Unless I am very much mistaken it will be found that there will be thousands of young doctors who have no prospect of getting established in practice. Nor can I see that anything, short of shutting perhaps half the medical schools, will bring the numbers down to requirements.

I need hardly say, Sir, that this is a matter of the utmost importance to the profession.—I am, etc.,

London, N.16.

D. S. BRYAN-BROWN.

B.M.A. LIBRARY

The following books have been added to the Library:

- Anderson, A. K.: *Essentials of Physiological Chemistry*. Fourth edition. 1953.
 Archer, W. H.: *Manual of Oral Surgery*. 1952.

Association Notices

NORTHERN RHODESIA BRANCH

Notice is hereby given by the Council to all concerned that the existing Northern Rhodesia Branch, which has no Divisions, has been reconstituted as from the date of this notice into a Branch with two Divisions with the following titles and areas:

- (a) Northern Division, comprising the Western Province with districts of Kawambwa and Fort Rosebery.
 (b) Southern Division, comprising the Northern Province (excluding the districts of Kawambwa and Fort Rosebery) and the Eastern, Central, Southern and Barotsse Provinces.

A. MACRAE,
Secretary.

Diary of Central Meetings

DECEMBER

31 Thurs. Guildford Steering Committee, 10.30 a.m.

JANUARY

- 5 Tues. War Memorial Committee, 12 noon.
 7 Thurs. Rural Practices Committee, G.M.S. Committee, 2 p.m.
 7 Thurs. Central Consultants and Specialists Committee Executive, 2.30 p.m.
 8 Fri. Industrial Injuries Evidence Subcommittee, Occupational Health Committee, 2 p.m.
 12 Tues. Central Ethical Committee, 12 noon.
 12 Tues. Amending Acts Committee, 2 p.m.
 13 Wed. Council, 10 a.m.
 14 Thurs. Central Consultants and Specialists Organization Subcommittee, 10 a.m.
 14 Thurs. Staff Side, Committee "C," Medical Whitley Council (at 14, Russell Square, London, W.C.), 2 p.m.
 14 Thurs. Complaints Procedure Subcommittee, Central Consultants and Specialists Committee, 2.30 p.m.
 14 Thurs. Full Committee "C," Medical Whitley Council (at 14, Russell Square, London, W.C.), 3 p.m.
 15 Fri. Joint Committee of B.M.A. and the Magistrates' Association, 10.30 a.m.

Correction.—The year mentioned in connexion with Dr. S. Q. Servanté (*Supplement*, December 12, p. 225) should have been 1950 and not 1940.
