Elmer Lee Henderson was born at Garnettsville, Kentucky, on March 23, 1885. He entered the medical profession the hard way, for he left his father's farm in 1902 to continue his education, paying his expenses by working in a highly varied series of occupations. In 1909 he graduated in medicine at the University of Louisville, and two years later established himself in surgical practice at Louisville, where he remained until his death, except for the period of his service in the war of 1914-18. His reputation as a surgeon spread far beyond his own medical school at Louisville, and among the honours which came his way were the presidency of the Southern Medical Association and of the South-eastern Surgical Congress. He was an honorary Fellow of the International College of Surgeons. In 1942 he was appointed a special surgical consultant to the Air Surgeon's Office, U.S. Army. Another post he held in the second world war was that of area chairman of the procurement and assignment service for physicians. In the campaign before the Presidential election last year he was chairman of the National Professional Committee which supported Mr. Eisenhower.

For many years Dr. Henderson was one of the prominent figures in the American Medical Association. Elected in 1937 to the House of Delegates, the policy-making body of the A.M.A., he was a member of the Board of Trustees from 1939 to 1947, and chairman from 1947 to 1949. When, in 1948, the association decided to launch a national campaign against "socialized" medicine he was appointed chairman of the co-ordinating committee, a task he undertook with vigour. Two years later he was elected President of the American Medical Association, and he had a most successful term of office. In the same year he followed Dr. Charles Hill as President of the World Medical Association, to the council of which he had been elected in 1948. In recent years he had travelled widely all over the world.

VICTOR BONNEY, M.D., M.S., F.R.C.S., F.R.C.O.G.

The obituary notice of Mr. Victor Bonney was printed in the *Journal* of July 11 (p. 99). We are indebted to Dr. GEORGE W. KOSMAK, advisory editor of the *American Journal of Obstetrics and Gynecology*, for

the following appreciation: The sad news of the passing away of Victor Bonney, as announced in your *Journal* of July 11, will prove a great shock to his many American friends and colleagues. He endeared himself to them on his visits to this country, and will be remembered by his many contributions to the literature of gynaecologic surgery. Victor Bonney was an outstanding physician and a friendly person whom it was a privilege to know personally for many years.

We are indebted to a former partner of Dr. T. B. Sellors, whose obituary notice appeared last week, for the following appreciation: Dr. Sellors's kind and courteous manner, together with a sympathetic understanding, quickly gained the confidence of his patients. His careful examination, thoughtful treatment, and especially his quiet encouragement often restored health more quickly than could normally be expected. Throughout his busy life in practice he found time to keep in touch with the skin department of the Middlesex Hospital, and the knowledge he acquired was much sought after by his colleagues. He was frequently called into consultation by them, not only on skin diseases, but also on other medical problems. Among his outside activities was Freemasonry. He was a keen member of the Crowstone Lodge, of which he was a founder member. He was always fascinated by fishing, and was never happier on his holidays than with his rod and line.

Dr. JOHN COWPER died at his home at Shanklin, Isle of Wight, on June 28, only a week before his 92nd birthday. Born on July 5, 1861, John Cowper received his medical education at Edinburgh University, where he graduated M.B., C.M. in 1887. After postgraduate work in London, he settled in Shanklin in 1889 and did not retire from practice until 1938. During that half-century he was for many years medical officer of health for Shanklin, and he also gave devoted service to Shanklin Hospital. In addition, he was surgeon to the Royal National Hospital for Diseases of the Chest, Ventnor, to the Isle of Wight Mental Hospital, Newport, and, during the war of 1914-18, to the auxiliary hospital at Gatcombe. As long ago as 1914 his colleagues paid tribute to his ability and integrity by electing him president of the Southern Branch of the British Medical Association. With all these activities Dr. Cowper still found time to interest himself in natural history and to indulge in his favourite recreation of shooting.

T. W. M. writes: It is as a surgeon and as a man that John Cowper will be remembered. Always interested in the surgical side of his chosen profession, he practised his art with great skill until 1926, when he handed over his surgical practice to the late Mr. J. A. Gaynor, who predeceased him by a few months. In his time there can have been few more capable surgeons in the provinces, and so much was his ability recognized and valued that his patients subscribed to build two small hospitals in Shanklin in the early years of this century. As one who was fortunate enough to be his partner during the last 12 years he was in active practice I was able to watch his work with the greatest admiration. As a man he was an inspiration to all who knew him, most upright, honourable, and lovable. We who are left behind should be grateful for his example.

One of Birkenhead's oldest and best-known general practitioners, Dr. W. R. FLOYD, died at his home at Oxton on June 29 at the age of 86. He had been in active practice for nearly 60 years. William Robert Floyd was born at Stalybridge, Cheshire, on May 8, 1867, the second son of the late Rev. Thomas Floyd. His father died when he was 10 years of age, and he was educated at St. Edmund's Clergy Orphans School, Canterbury, where he was a distinguished pupil and a formidable cricketer. From school he went on to Clare College, Cambridge, graduating B.A. in 1888, and four years later he qualified in medicine by taking the

diploma of L.S.A. In 1894 he obtained the degrees of M.B., B.Chir. After qualification Dr. Floyd held the appointment of house-surgeon at the Liverpool Royal Infirmary and then went into practice in Birkenhead with his father's cousin, the late Dr. T. S. Floyd. As the years passed Dr. Floyd became a prominent and respected figure in the life of the town, and was appointed to the honorary medical staffs of the Borough and Maternity Hospitals. He was chairman of the Birkenhead and Wirral Division of the British Medical Association in 1940-1; he served on the local medical war committee during the whole of its existence; and he was elected the first chairman of the local medical committee under the National Health Service Act of 1946. A past president of the Birkenhead Medical Society, he was elected a life member of the society in 1950 as a token of the esteem in which he was held by his fellow practitioners. In addition to his extensive practice Dr. Floyd always maintained a great interest in sport, being wicket-keeper for Birkenhead Park Cricket Club for many years, a life member of the Rugby club, and he played tennis and golf regularly in summer until advancing years reduced him to bowls. He was always known as "Dr. Willie" to his many old patients, and the large attendance at the funeral service showed how much he was liked by them all. His family life was overshadowed by much sorrow. His wife, formerly Miss Madge Rhodes, of Huddersfield, died in 1938, his two daughters died in childhood, one from diphtheria and the other from meningitis, and his elder son was killed in 1918 while on his first solo flight in the Royal Flying Corps. He is survived by his other son, Major G. T. Floyd, to whom we offer our sympathy.—H. C. W. B. and D. J.

Mr. F. COURTENAY MASON, who practised as an oto-rhino-laryngologist in London, died suddenly at his home at Hampstead on July 5 at the age of 62. Francis Courtenay Mason began his student life under adverse circumstances, and in consequence he became a very hard worker. After graduating B.A. at London University he won an entrance scholarship to the Middlesex Hospital in 1912, and followed this success by winning a second-year exhibition in 1914 and the Hetley clinical prize and the junior Broderip scholarship in 1916, in which year he took the diplomas of M.R.C.S., L.R.C.P., and the London degrees of M.B., B.S. At the Middlesex Hospital he was successively house-physician, house-surgeon, resident anaesthetist, and surgical registrar. He then entered the R.A.M.C. and served in France as a captain in the war of 1914-18. On returning to civilian life in 1919 he made the higher surgical qualifications his next objective, and in the following year he proceeded to the M.S. and became a Fellow of the Royal College of Surgeons of England. Mason decided to specialize in oto-rhino-laryngology, and he devoted the rest of his life to the subject. His first appointment in the specialty of his choice was as registrar at the Throat Hospital, Golden Square. Later he became ear, nose, and throat surgeon to several hospitals, including the Dreadnought Hospital, Greenwich, King George Hospital, Ilford, and the West Middlesex Hospital, appointments he carried out with great conscientiousness and care. He was popular with patients, nurses, and colleagues for his thoroughness, courtesy, friendliness, and encouragement, and was particularly active in forwarding the interests of his assistants. He was an adept at rose-growing, and his skill at this was well known. He liked travel abroad, and was knowledgeable about ecclesiastical architecture. He is survived by a widow, a daughter, who is a medical student at his old hospital, and a son.—H. D.

We are indebted to F. A. L. for the following appreciation: The withdrawal of a familiar figure from the wards and out-patient department of a hospital always leaves a gap, but when that figure was one universally regarded not only with respect but with affection the sense of sudden loss is acute. It was never long before acquaintance with Courtenay Mason, whether by professional colleague, nurse, patient, or administrator, developed into warm friendship.

It was clear that he had a particular affection for the Dreadnought Seamen's Hospital at Greenwich, where he worked for 30 years among seafarers of every race, creed, and nationality with great devotion and complete immunity from all idea of personal gain. Retiring, and even withdrawn, in manner, he spoke, if he spoke at all in medical council, at the end of a debate, when he contributed his considered judgment in a slow diction and with a dry humour which now evokes endearing memories.

The colleagues and close friends of Dr. JOHN STOKOE, medical officer of health of Scarborough, were totally unprepared for his sudden death on July 11 at the age of 51, for he had had no preliminary illness. He was born at Blyth, Northumberland, on January 25, 1902, the son of Mr. P. L. Stokoe, and was educated at Barnard Castle School and at the Newcastle College of Medicine, graduating M.B., B.S. from Durham University in 1924. He proceeded to the M.D. in 1938, having taken the degree of B.Hyg. and the D.P.H. two years earlier. After graduation he held hospital posts in Newcastle-upon-Tyne and then followed a few years in general practice in North-east England. In 1935 he entered the public health service with an appointment at the City Infectious Diseases Hospital, Newcastle-upon-Tyne. Two years later he was appointed assistant medical officer of health for Derby, and in January, 1939, became medical officer of health for his home town of Blyth. War broke out a few months later, but his services were retained at Blyth until, in 1943, he entered the R.A.M.C. as a general duties officer. Later he was appointed a hygiene specialist, and when released from the Army in 1946 he had attained the rank of lieutenant-colonel. He served in France, Belgium, Holland, and Germany, and there is no doubt that he found his Army experience both challenging and stimulating. Immediately after demobilization Dr. Stokoe obtained the appointment of medical officer of health for Scarborough. He assumed his new duties at a difficult time, for the "appointed day" was less than two years away, and with it he was to see the independent borough which had appointed him becoming for the most part included in a divisional area of the North Riding County Council of Yorkshire. When the change did come Dr. Stokoe was appointed medical officer to the Scarborough Rural District and the Scalby Urban District, and he tackled the work in his new area, with its wide variety of problems, with characteristic energy, deriving much satisfaction from the welding together of diverse units into an administrative whole. Although such duties took up a large part of his time, Dr. Stokoe never wholly lost his clinical interests, and the immunization clinics and the health of the older schoolboys remained in his care. Like many another medical officer of health, however, he deplored the loss of the fever hospital when it passed to the control of the regional hospital board. He was a strong advocate of clean food, and organized educational campaigns among food-handlers. A man of strong personality, he applied himself with great vigour to every task, however small, never sparing himself either at work or at play. For relaxation he played golf, and was an enthusiastic member of the South Cliff Golf Club. To his widow, formerly Miss Winifred Shy, also of Blyth, and his son our sympathy is extended.—E. R. C.

Dr. JOHN PRINGLE died at his home at Gosforth, Cumberland, on July 12 at the age of 83. He was born on December 13, 1869, and studied medicine at Trinity College, Dublin, where he graduated M.B., B.Ch. in 1894. He proceeded to the M.D. in 1896 and took the Cambridge D.P.H. in the following year. Immediately after graduating he came to England to assist the late Dr. Joseph Henry in practice at Rochdale, Lancashire. At the turn of the century he established himself in his own practice at Manchester, where, in the Whalley Range district, he soon gained the confidence and friendship of his patients. When he retired from practice in 1946 he settled at Gosforth, within easy reach of his beloved hills, and there he spent the remainder

of his life happily engaged in the numerous activities in which he was interested. As well as being a greatly loved physician he was an expert philatelist, having a very fine collection. He was particularly interested in the "balloon post," on which he was an expert, being the author of a book on the subject. In 1911 he married Dorothy Beney, of Beckenham, and she, with his four sons, survives him.—G. A. M.

After two years of ill-health, Dr. J. W. ELLIS died at his home at Kimbolton, Huntingdonshire, on July 20 at the age of 64. He had said that he preferred "wearing out" to "rusting out," and he fulfilled the principle behind his own words, for he remained at work until two months before his death. John Weaver Ellis was born on July 31, 1888, and as a child he went with his parents to New Zealand. On the death of his father he carried on the family farm until a younger brother was old enough to take it over. He then qualified as a pharmacist, and before the war of 1914-18 he had his own chemist's business in New Zealand. In 1914 he returned to England and obtained a commission as a member of the New Zealand Expeditionary Force. For conspicuous bravery in the fighting on the Somme in 1918 he was awarded the Military Cross. After the armistice he went back to New Zealand, where he married Miss Alice Timms. Three years later he became a medical student at Guy's Hospital, and qualified M.R.C.S., L.R.C.P. in 1928. In the following year he settled in practice in Kimbolton, where he stayed until death ended his work 24 years later. Dr. Ellis, whose early life made him peculiarly suited to country practice, was a man of abounding energy, with wide interests and an unfailing sympathy and tolerance. It is as a man and a friend that the people of the 32 villages covered by his practice will miss him, although they will feel keenly, too, the loss of a skilled general practitioner. In addition to the work of his practice, Dr. Ellis acted as medical officer to Gaynes Hall Borstal Institution, and he was a member of the committee of management of the local hospital and of the Huntingdon panel committee. In non-medical spheres his interests were centred on Kimbolton School, of which he was a governor from 1937 onwards, and in freemasonry, which was a constant source of pleasure and relaxation. He was a provincial grand senior warden for the Province of Northamptonshire and Huntingdonshire in 1951, a past master of Euston Lodge, St. Neots, and a founder member of the Old Kimboltonians Lodge. No man fulfilled the principles of freemasonry in his daily life better than he, since love and truth were the bases of his dealings with all, whether acquaintances, friends, or patients. He leaves a widow, a son, and five daughters.—A. F. G.

Dr. H. WALMESLEY GREENWOOD died on May 2 at Redcross, Co. Wicklow, aged 52. Henry Walmesley Greenwood was educated at Ampleforth College, York, and at the Middlesex Hospital Medical School, qualifying M.R.C.S., L.R.C.P. in 1925. As a medical student he had a distinguished career, being awarded the Lister Memorial Prize in physics, and several class prizes. After qualification he held a number of house appointments at the Middlesex Hospital, and later became senior resident medical officer at the City of London Maternity Hospital. In 1927 he entered general practice as a partner in an old-established firm of doctors at Southend-on-Sea, where he met with immediate success. With a temperament particularly suitable for general practice and the gift for making lifelong friendships, he soon gained the confidence of his colleagues. He was also chairman of the South Essex Division of the British Medical Association in 1946-7 and first chairman of the local medical committee. A forceful speaker in committee, he was never afraid to voice an opinion or to speak what he thought to be the truth. He was a Roman Catholic, and his religious faith meant much to him. During the last war he was left to manage a large practice single-handed, a responsibility which caused a breakdown in health from which he never fully recovered. Although he entered the

National Health Service at its inception, he did not take kindly to many of its aspects, particularly the form-filling, and two years ago he gave up his practice to turn to farming in Eire. That he had the esteem and affection of his former patients was clearly shown by the wish of many of them to send wreaths to his funeral in Ireland, and by the decision to erect a commemorative plaque on the grave of his little daughter in Sutton Road Cemetery, Southend-on-Sea. He leaves a widow and one son and one daughter.—J. B.

Medico-Legal

HEALTH SERVICE FRAUDS

Dr. John Joseph Flanigan, aged 28, was at Airdrie Sheriff Court on August 3 sentenced to sixty days' imprisonment for defrauding the Lanarkshire Executive Council. An appeal has been lodged.

Dr. Flanigan had originally been charged with three offences: (1) making false claims in respect of thirty-two patients and defrauding the executive council of £56; (2) defrauding the executive council of £5 8s. 6d. in respect of a claim regarding the confinement of a patient; and (3) uttering, as genuine, twenty maternity medical service claim forms on which signatures of patients were forged. When the case was called, Mr. John Wheatley, Q.C., said that his client was adhering to a plea of not guilty in respect of the second and third charges. He also stated that Dr. Flanigan admitted only twenty-five of the instances alleged in the first charge.

The Fiscal, Mr. A. L. Nixon, accepted that plea, and the second and third charges were dropped, charge one was reduced to twenty-five items, and the amount of money involved amended to £43 15s. Continuing, the Fiscal said that Dr. Flanigan had been in partnership in general practice with Dr. Bernard McLaughlin since 1948. "For some time relations between the partners were not happy, and eventually they became rather hostile. Solicitors for Dr. McLaughlin called on me and made certain complaints, which I felt bound to investigate. While so doing, the present charge came to light."

Mr. Nixon told the court that the Department of Health had intimated to executive councils in 1949 that where a second doctor was present at maternity cases to administer an anaesthetic an additional fee of 35s. was payable. On twenty-five occasions Dr. Flanigan had claimed for the services of a second doctor when, actually, none was present, and the charge had come to light because it was felt that these claims were excessive. It was true that in the terms of the partnership Dr. Flanigan paid the £43 15s. into the business and received a one-third share. But it was he who, by false representation, had induced the executive council to pay the full amount.

Mr. Wheatley said Dr. Flanigan's decision to plead guilty to part of the complaint reflected great credit on his courage and his humanity. He had deemed it unfair to expose his patients and other witnesses to the embarrassment, anxiety, and worry of the witness-box, and he felt it better that the dispute with his partner should be aired in the Civil Court rather than in the glare and limelight of the Criminal Court. Mr. Wheatley pleaded with Sheriff A. J. Stevenson to give Dr. Flanigan an absolute discharge. Dr. Flanigan had manifestly not been setting out purposely to defraud the N.H.S. of large sums. What really happened was that through carelessness on his part, for which the only excuse was overwork and personal anxiety, he made claims for which he was not entitled.

Sheriff Stevenson said that he had given full weight to the history of the charge and Dr. Flanigan's personal background, but such an offence was so much more serious than any other case involving a similar amount of money that he could do no other than send him to prison.

Universities and Colleges

UNIVERSITY OF LONDON

The following have been appointed or nominated for appointment or reappointment as representatives of the University on the governing bodies indicated in parentheses: Dr. G. Selby Wilson (Lister Institute of Preventive Medicine); Professor J. Willis (Royal Dental Hospital of London, School of Dental Surgery); Dr. C. E. Newman (West London Hospital Medical School); Mr. S. Gnessen (Mount Pleasant School).

C. B. Allsopp, D.Sc., Reader in Physics at Guy's Hospital Medical School, has been appointed to the Chair of Physics applied to Medicine tenable at that School from October 1.

The Special Advisory Board in Postgraduate Medical Studies has been constituted from October 1, and until further order, as follows: the Dean of the Faculty of Medicine; the Director of the British Postgraduate Medical Federation; the Dean of the London School of Hygiene and Tropical Medicine; three representatives of the Board of the Faculty of Medicine; the two members of the Senate appointed by the General Medical Schools; one representative of the Board of Advanced Medical Studies; two representatives of the Board of Pre-clinical Studies; one representative of the Board of Studies in Pathology; one representative of the Board of Studies in Hygiene and Public Health; one representative of the Board of Studies in Dentistry; and not more than six other persons to be appointed after report from the Special Advisory Board.

The Paul Philip Reitlinger Prize of the value of £30 is offered for the best essay embodying the result of some research work on a medical subject carried out by the candidate. Candidates must be students of the University who, on June 1 preceding the award, were studying in one of the Schools of the University in the Faculty of Medicine, or graduates of the University who, on the same date, were of not more than five years' standing from the date of taking their first degree, and who are, or were, students in such School. Essays must reach the Academic Registrar, Senate House, not later than October 1, 1954, and must be accompanied by a certificate from the candidate's teacher or other responsible person to the effect that the research work forming the subject of the essay is substantially the work of the candidate presenting the essay.

Dr. R. A. Shooter, Senior Lecturer in Bacteriology in St. Bartholomew's Hospital Medical College, has been appointed to the University Readership in Bacteriology tenable at that College.

UNIVERSITY OF SHEFFIELD

At a meeting of the Council held on June 19 Dr. A. J. N. Warrack was appointed Part-time Honorary Lecturer in Pathology.

The resignation of Dr. S. A. Doxiadis, Senior Lecturer in Child Health, was received.

At a Congregation on June 27 the following medical degrees were conferred:

M.D.—J. A. Griffiths (with distinction), D. Dexter, E. A. Johnson.

M.B., Ch.B.—W. K. C. Morgan (with second-class honours), J. O. Newman (with second-class honours), E. M. Bateson, Audrey M. F. Brook, Juliet S. Bryant, A. H. Clarke, Mary W. Dickson, E. R. J. Emery, Avril M. Frampton, P. N. Griffin, P. C. Griffith, G. Haigh, B. F. Hallatt, R. B. Heath, W. Heathcote, Dorothea V. M. Holmquist, W. P. G. Jones, J. Longstaff, C. M. MacCallum, Ann B. Marples, T. W. May, P. B. Moxon, Mary Neville, Eileen M. O'Neill, C. Protheroe, P. A. Ramsey, G. B. Schofield, W. E. Sharnan, N. W. Shepherd, R. E. Smith, C. F. I. Sparling, A. H. Stearns, Enid M. Stephenson, C. K. Sutcliffe, R. Tym, W. G. Waterlow, J. Wilson, B. Winchurch, J. A. Wright.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

At a meeting of the Council of the College held on July 9 Sir Cecil Wakeley was re-elected President for the ensuing year. Sir Reginald Watson-Jones was re-elected and Professor Lambert C. Rogers elected Vice-presidents.

Dr. E. Rohan Williams (St. Mary's) was co-opted to the Council for the year 1953-4, representing radiology.

It was reported that Dr. E. Ashworth Underwood, director of the Wellcome Historical Medical Museum, had been elected a Hunterian Trustee.

The following three deaths were reported with regret: Mr. Victor Bonney (Past Vice-President and Member of Council);

Mr. R. G. Hogarth (Past Member of Council); and Dr. Frank H. Lahey (Honorary Fellow).

Mr. R. S. Johnson-Gilbert was appointed assistant secretary of the College.

Professors and lecturers for the ensuing year were appointed as follows:

Hunterian Professors.—Mr. V. E. Negus, one lecture on the comparative (and human) anatomy of the nose and nasal sinuses; Mr. D. J. Browne, one lecture on the principle of controlled movement in orthopaedics; Professor R. Milnes Walker, one lecture on the place of venous shunts in the treatment of portal hypertension; Mr. F. W. Holdsworth, one lecture on traumatic paraplegia; Mr. H. S. Morton, one lecture on some potentialities of the electrogastragraph; Mr. J. B. Kinmonth, one lecture on the lymphangiography in clinical surgery and particularly in the treatment of lymphoedema; Mr. D. I. Williams, one lecture on the chronically dilated ureter; Mr. D. J. Robertson, one lecture on congenital arteriovenous fistulae of the extremities; Mr. A. B. Nutt, one lecture on the significance and surgical treatment of congenital ocular palsies; Mr. D. M. Morrissey, one lecture on the treatment of obliterative vascular disease; Mr. I. P. Todd, one lecture on the role of elective surgery in the management of diverticulitis of the colon; Mr. R. H. C. Robins, one lecture on primary reconstruction of the injured hand.

Arris and Gale Lecturers.—Mr. H. A. Haxton, one lecture on the sympathetic supply of the upper limb before and after sympathectomy; Mr. G. J. Hadfield, one lecture on the effect of hormones on healing; Professor D. Slome, one lecture.

Erasmus Wilson Demonstrators.—Dr. G. D. Lumb, one demonstration; Dr. J. S. Young, one demonstration; Dr. L. M. Franks, one demonstration; Mr. W. H. W. Jayne, one demonstration.

Arnott Demonstrators.—Professor M. F. Lucas Keene, two demonstrations; Professor G. W. Causey, one demonstration; Dr. F. Stansfield, one demonstration; Professor R. J. Last, one demonstration.

In addition Sir Stanford Cade was awarded a Hunterian Professorship, Dr. D. R. Haynes an Arnott Demonstratorship, and Dr. B. E. Heard an Erasmus Wilson Demonstratorship.

A Diploma of Fellowship was granted to M. Ali.

Diplomas were granted, jointly with the Royal College of Physicians of London, as follows:

DIPLOMA IN ANAESTHETICS.—R. W. Baxter, D. Bigley, May S. Bisset, T. B. Boulton, J. Burgoyne, A. D. Clarke, N. F. Cockett, D. J. Coleman, M. P. Coplans, T. T. Currie, C. H. Devereux, Beatrice A. Earnshaw, Elizabeth F. Everitt, J. G. Fairer, B. L. Finer, H. P. Graham, J. M. Hansen, H. M. Hardy, A. G. Henderson, J. I. M. Lawson, J. Leibovitz, J. W. R. McIntyre, Maria R. Mackay, A. L. MacKenzie, J. Middleton Price, R. E. Molloy, D. K. Morgan, G. N. Mulliner, C. Nikitik, J. F. Nunn, B. S. Perera, W. J. Pryor, Nancy G. S. Roberts, Margaret Rooms, Judith M. Ross, J. D. St. Clair, W. E. B. Scott, K. N. Sen Gupta, Beatrice E. Sleigh, J. R. Spears, M. K. Sykes, Charlotte McE. Taggart, J. A. Thornton, P. H. Venen, Patricia Wilson, V. P. Wordsworth.

DIPLOMA IN LARYNGOLOGY AND OTOLGY.—S. Ahmad, P. A. O. Anyaegbunam, R. W. Bailie, D. P. Belgrave, M. Brookes, P. B. Foxwell, J. H. Grant, R. Hully, G. Immermann, L. P. B. Kiriella, G. W. Leitch, J. F. McAuliffe, A. G. McCallum, K. G. Malcomson, A. Marsland, I. H. Mazer, G. Murray, M. V. Naidu, M. J. J. Rao, H. N. St. John, D. L. Sugrue, S. Sytcha, Caroline M. van Dorp.

DIPLOMA IN MEDICAL RADIODIAGNOSIS.—A. Ansell, G. Ansell, J. St. C. Ballenden, A. Berezowski, M. E. Berk, A. S. Bligh, H. H. Bloch, D. Brink, N. L. Bucky, J. C. Chartres, C. J. Don, A. J. Eley, H. G. Feltham, Eleanor B. Fielding, A. Fotoohi, H. Freilich, J. Friedman, Sarah H. Getz, N. K. Ghose, L. Green, B. C. Hale, M. A. Harris, J. W. Hoe, P. F. Mathias, J. S. Matthews, J. L. Morris, D. McK. K. Muir, E. Price, L. J. Sandell, H. Smith, J. V. Tillet, B. F. Vaughan, L. E. Wolpert, I. Yentis.

DIPLOMA IN MEDICAL RADIOTHERAPY.—T. W. Backhouse, R. F. Burton, Muriel Coates, A. F. Crook, B. Dosoretz, A. M. Jelliffe, H. Lehrner, M. B. McEvedy, R. G. C. MacLaren, K. W. Mead, R. A. R. Taylor, R. P. Varma.

DIPLOMA IN PSYCHOLOGICAL MEDICINE.—H. Bourne, C. P. C. Gore, E. J. E. Jones, Josephine M. Lomax-Simpson, Frances E. Smart, A. Watt, L. Zollman.

DIPLOMA IN PATHOLOGY.—J. D. Heppleston, P. W. Kippax, H. B. Marsden.

DIPLOMA IN CHILD HEALTH.—Lynda C. Proctor.

DIPLOMA IN OPHTHALMOLOGY.—G. A. O'Reilly.

DIPLOMA IN TROPICAL MEDICINE AND HYGIENE.—L. K. Simango.

AUG. 15, 1953

UNIVERSITIES AND COLLEGES

Hospitals were recognized under paragraph 23 of the F.R.C.S. regulations as follows: Royal United Hospital, Bath, ear, nose, and throat registrar for six months. Cumberland Infirmary, Carlisle, redesignation, junior registrar has now been redesignated "senior house officer." Queen Mary's Hospital for Children, Carshalton, two orthopaedic and general surgical registrars, both for six months. Essex County Hospital, Colchester, decennial revision, two surgical registrars; from January, 1954, two casualty officers. Leicester General Infirmary, additional recognition, three senior house officers for twelve months. Connaught Hospital, London, reduction from twelve to six months in period of recognition of existing posts of resident surgical officer and house-surgeon; from January, 1954, casualty officer. East Ham Memorial Hospital, London, resident surgical officer for twelve months; house-surgeon for six months; from January, 1954, casualty officer. Preston Hospital, North Shields, and Victoria Jubilee Infirmary, Tynemouth, three house-surgeons for six months (provided that each post shall be resident for approximately four months at Tynemouth Infirmary and two months at the Preston Hospital). Crumpsall Hospital, Manchester, additional recognition, senior house officer (genito-urinary department) for six months; from January, 1954, senior house officer (orthopaedics) (hitherto recognized for general surgery). Rochford General Hospital, redesignation, house-surgeon, orthopaedics and fractures, has now become "house-surgeon, general and orthopaedic." R.A.F. General Hospital, Ely, from January, 1954, casualty officer. Stockport Infirmary, decennial revision, resident surgical officer (surgical registrar) for twelve months; assistant resident surgical officer for six months; three house-surgeons for six months; from January, 1954, casualty officer. Southend-on-Sea General Hospital, from January, 1954, casualty officer. North Staffordshire Royal Infirmary, Stoke-on-Trent, from January, 1954, casualty and assistant resident surgical officer (hitherto recognized for general surgery). Sutton and Cheam Hospital, from January, 1954, casualty officer. Victoria Jubilee Infirmary, Tynemouth, see under Preston Hospital, North Shields. Hillingdon Hospital, Uxbridge, additional recognition, house-surgeon (general and thoracic); house-surgeon (general and thoracic) both for six months; from January, 1954, one registrar (casualty); three junior hospital medical officers (casualty); reduction from twelve to six months in period of recognition of senior house-surgeon. Whitehaven and West Cumberland Hospital, surgical registrar for six months. Workington Infirmary, surgical registrar for six months. Rowley Town Orthopaedic Hospital, Woking, two senior house officers (dent) both for twelve months.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH

name of R. S. Morton was mis-spelt as R. S. Norton in the of new Members of the College printed in the *Journal* of just 1 (p. 291).

ROYAL COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS

a meeting of the Council of the College on May 16, with the sident, Mr. Arthur A. Gemmell, in the chair, the following e elected to the Council to fill statutory and other vacancies: representatives of the Fellows, A. M. Claye (Leeds), J. F. ningham (Dublin), V. J. F. Lack (London), D. McK. Hart (agow), J. A. Stallworthy (Oxford). As representatives of the mbers, A. L. Deacon (Birmingham), A. S. Duncan (Edin- gh).

he following were admitted to the Fellowship: H. H. uracre Barnes, J. W. D. Buttery, H. C. Callagher, A. B. Con- on, S. E. Craig, Gladys V. S. Cunningham, J. N. I. Emblin, W. Gall, D. S. Greig, U. P. Gupta, T. N. Hart, A. M. rtwell, W. Hawksworth, O. V. Jones, C. W. A. Kimbell, M. Lemmon, J. T. Louw, D. J. MacRae, Mary H. Mayeur, D. Meares, S. Misra, Coralie W. Rendle-Short, Kathleen M. binson, Dorothy M. Satur, L. J. te Groen, R. A. Tennent, W. L. Thompson, H. K. Waller, J. A. Waterman, B. H. atson, S. A. Way, J. L. Wright.

The following were admitted to the Membership: C. H. rman, D. M. Brodie, B. Bruce-Lockhart, K. G. Cockburn, B. Cooper, Janette G. Cowie, H. J. G. de Villiers, H. G. Dixon, Margaret M. Downes, E. M. Edwards, A. H. Foate, G. S. Foster, E. Fyfe, G. H. Garfield, J. M. Gate, L. Goldman, N. G. ourlay, M. Grant, R. W. Grayburn, D. Hay, G. C. S. Hunter, alentine M. Husband, Sarah I. Jacob, R. A. Kenihan, K. hadenga, H. H. Kirk, B. V. Kyle, J. C. McCawley, J. acpherson, J. S. McVeigh, Jean Murray-Jones, T. J. M. Myles, M. Norburn, E. M. O'Dwyer, S. Panchalingam, Evelyn Peters, M. McK. Pratt, M. J. M. Solomons, W. K. Sutton, T. A. ompson, R. S. Wurm.

INFECTIOUS DISEASES AND VITAL STATISTICS

Summary for British Isles for week ending July 25 (No. 29) and corresponding week 1952.

Figures of cases are for the countries shown and London administrative county. Figures of deaths and births are for the 160 great towns in England and Wales (London included), London administrative county, the 17 principal towns in Scotland, the 10 principal towns in Northern Ireland, and the 14 principal towns in Eire.

A blank space denotes disease not notifiable or no return available. The table is based on information supplied by the Registrars-General of England and Wales, Scotland, N. Ireland, and Eire, the Ministry of Health and Local Government of N. Ireland, and the Department of Health of Eire.

CASES in Countries and London	1953					1952				
	Eng. & Wales	Land.	Scot.	N. Ire.	Eire	Eng. & Wales	Land.	Scot.	N. Ire.	Eire

* Measles not notifiable in Scotland, whence returns are approximate.

† Includes primary and influenzal pneumonia.

‡ Includes puerperal pyrexia.

Vital Statistics

Industrial Accidents and Diseases

The number of workpeople (other than seamen) in the United Kingdom whose deaths from accidents in the course of their employment were reported in June was 120, compared with 130 (revised figure) in the previous month and 122 (revised figure) in June, 1952. The number of cases of industrial disease reported was 36, including lead-poisoning 1, epitheliomatous ulceration 13, and chrome ulceration 15. There were no deaths.—*Ministry of Labour Gazette*, July, 1953.

Graphs of Infectious Diseases

The graphs below show the uncorrected numbers of cases of certain diseases notified weekly in England and Wales. Highest and lowest figures reported in each week during the nine years 1944-52 are shown thus -----, the figures for 1953 thus ———. Except for the curves showing notifications in 1953, the graphs were prepared at the Department of Medical Statistics and Epidemiology, London School of Hygiene and Tropical Medicine.

Infectious Diseases

Only small fluctuations occurred in the incidence of infectious diseases during the week ending July 25 in England and Wales. The largest were a decrease of 401 in the number of notifications of measles, from 4,795 to 4,394, and an increase of 139 for whooping-cough, from 4,218 to 4,357.

The largest decrease in the number of notifications of measles was 99 in Yorkshire East Riding, from 307 to 208. Only small variations occurred in the local trends of whooping-cough; the only exception was an increase of 144 in Essex, from 288 to 432. 1,037 cases of scarlet fever were notified during the week, 19 more than in the preceding week, and no variations of any size occurred in the local returns. 17 cases of diphtheria were notified, one fewer than in the previous week. The largest return was 4 in Staffordshire, Coseley U.D.

266 cases of acute poliomyelitis were notified during the week. These were 4 more for paralytic and 39 more for non-paralytic cases than in the preceding week. The epidemic is still mainly confined to the southern section of the country. The largest returns were London 36 (Camberwell 4, Holborn 4, Lewisham 4; the remaining 24 cases were reported from 15 boroughs); Warwickshire 24 (Coventry C.B. 15, Birmingham C.B. 3, Atherstone R.D. 3), Essex 21 (Southend-on-Sea C.B. 8), Kent 15 (Maidstone M.B. 5), Lancashire 15 (Blackpool C.B. 5), Southampton 14 (Southampton C.B. 5), Surrey 14, Middlesex 14, Sussex 11, and Somersetshire 10 (Taunton M.B. 7).

A fall of 71, from 380 to 309, was recorded in the number of notifications of dysentery. The largest returns were Lancashire 52 (Manchester C.B. 10), London 38, Yorkshire West Riding 36 (Wakefield C.B. 11), Durham 28 (Lanchester R.D. 13), Middlesex 23, and Norfolk 20 (Norwich C.B. 12).

The largest outbreak of food-poisoning reported during the week was Durham, Consett U.D. 121.

Deaths in 1952

The quarterly return of the Registrar-General for England and Wales covering the first quarter of this year compares the numbers of deaths from certain causes in 1952 with those in the previous two years. Some of the figures are given in the Table below.

	1950	1951	1952
Respiratory tuberculosis	14,079	12,031	9,335
Meningeal	890	882	511
Other	1,000	893	739
Diphtheria	49	33	32
Cancer of stomach	14,445	14,661	14,410
" lung	12,241	13,247	14,218
Leukaemia	1,832	1,927	2,043
Coronary disease	54,755	58,309	61,429

Week Ending August 1

The notifications of infectious diseases in England and Wales during the week included scarlet fever 950, whooping-cough 4,107, diphtheria 11, measles 3,587, dysentery 334, paratyphoid fever 19, typhoid fever 4, food-poisoning 769.

Poliomyelitis

Poliomyelitis notifications (uncorrected) in the week ending August 1 (30th week of the year) were as follows: paralytic, 167 (151); non-paralytic, 103 (115); total, 270 (266). This is an increase of 4 compared with the previous week, the figures for which are in parentheses. The individual districts which have notified 15 or more cases in the year to August 1, with incidence per 100,000 in parentheses, are as follows: Southend-on-Sea C.B., 34 (22.44); Liverpool C.B., 21 (2.65); Hendon M.B., 15 (9.63); Birmingham C.B., 40 (3.57); Southampton C.B., 16 (9.12); Coventry C.B., 66 (25.29); Croydon C.B., 16 (6.38); Pewsey R.D.C., 16 (87.77); Manchester C.B., 15 (2.13); Leicester C.B., 19 (6.65); Lewisham M.B., 19 (8.37); Bristol C.B., 16 (3.60); Blackpool C.B., 18 (12.22); Camberwell M.B., 18 (9.93); Islington M.B., 16 (6.79); St. Pancras M.B., 17 (12.18); Bournemouth C.B., 22 (15.84).

The insignificant rise in total notifications from 266 to 270 is reassuring, even though there was an increase of 16 paralytic cases. The curve of incidence this year is now rather like that in 1952, although the seasonal rise started earlier and the figures are at a slightly higher level.

Medical News

Control of Isoniazid.—Under regulations which came into force on July 31 isoniazid and preparations containing it may be supplied to the public only on prescription by doctors, dentists, or veterinary surgeons.

Sports Physicians.—An invitation has been extended to members of the British Medical Association to take part in the international congress for sports physicians to be held at Obertraun, Hallstättersee, September 11 to 13. Details may be obtained from the secretariat: Liga für die Vereinten Nationen, Bösendorferstrasse 9, Vienna, 1.

Royal College of Surgeons in Ireland.—Mr. Michael P. Burke and Mr. Ian Fraser have been re-elected President and Vice-President of the College respectively.

COMING EVENTS

Symposium on Butazolidin.—The Empire Rheumatism Council is holding a symposium on butazolidin at the Royal Society of Medicine on November 13. Application for tickets should be made to the general secretary, Empire Rheumatism Council, Tavistock House (North), Tavistock Square, London, W.C.1.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Arnott.—On July 30, 1953, at Central Middlesex Hospital, Acton Lane, Park Royal, N.W., to Dr. Ruth Arnott (formerly Burt), wife of Dr. D. C. Arnott, a daughter.
Benn.—On July 28, 1953, at Musgrave Park Hospital, Taunton, to Patricia Mary (formerly Simpson), wife of J. Benn, M.D., M.R.C.P., a second son.
Edgington.—On July 31, 1953, at Queen Elizabeth Hospital, Birmingham, to Jean, wife of Dr. John Edgington, a son—Mark Jonathan.
Harrington.—On July 11, 1953, at Queen Victoria Nursing Home, Wolverhampton, to Geradine, wife of Dr. J. J. Harrington, of Dudley, a son—Sean Gerard.
Huggill.—On July 18, 1953, to Margaret (formerly Lawton), M.B., Ch.B., wife of J. A. W. Huggill, M.A., D.Phil., of 35, Warwick Road, Heaton Moor, Stockport, a son.
Matthews.—On August 2, 1953, at Lichfield, Staffordshire, to Joyce (formerly Wallis), wife of Dr. Bryan Matthews, a second son.
Stewart Hunter.—On July 18, 1953, at the General Hospital, Rochford, Essex, to Morfydd (formerly Ellis-Williams), wife of G. C. Stewart Hunter, M.R.C.O.G., a son—Christopher David.

MARRIAGES

Clark-Soutar.—On July 30, 1953, at King's College Chapel, Aberdeen, Charles Grant Clark, M.B., Ch.B., of Fraserburgh, Aberdeenshire, to Nita Millar Soutar, of Montrose, Forfarshire.

DEATHS

Blair.—On July 15, 1953, suddenly, at Ambercross, Links Gate, St. Annes-on-Sea, Robert Love Blair, M.B., Ch.B., aged 56.
Dolan.—On July 28, 1953, at Micklethwaite, Wigton, Cumberland, Edmund Michael Dolan, M.R.C.S., L.R.C.P., aged 73.
Lawson.—On July 27, 1953, Wilfrid Ernest Lawson, M.B., Ch.B., D.P.H., of Henry Square, Ashton-under-Lyne, Lancs, aged 78.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Is Rest Beneficial in Primary Tuberculosis?

Q.—Is there any really good evidence that rest is beneficial in the treatment of primary tuberculosis—even if there are very large hilar nodes? Provided children are not fatigued, is it not better to treat them as out-patients rather than admit them to hospital, especially since they get no specific chemotherapy anyhow?

A.—Nowadays the criteria of "really good evidence" are changing. We know of no controlled trial of the effect of rest in primary tuberculosis, or indeed in any other form of the disease. But the necessity for rest in primary tuberculosis, especially if the child is in any way off colour, is widely accepted. In general, unless he is very ill, it is much better for the child's emotional (and perhaps ethical) development that he should be rested in the security of his home.

Finding Antibiotics

Q.—What are the present methods used for screening moulds or bacteria with antibiotic properties from those without?

A.—The methods used for selecting moulds and bacteria which produce antibiotic substances have changed very little from those originally used. A central colony of the organism to be screened is grown on a petri dish containing a suitable agar medium. Test organisms are then streaked radially from this central colony to the edge of the petri dish, and the plate is then incubated for a further period. The production of a diffusible antibiotic substance is demonstrated by zones of inhibition near the central colony.

When moulds are being screened, it is most important that the agar medium be suitably buffered to prevent the development of low pH; this would produce inhibition even in the absence of an antibiotic substance. If the organism being screened will not grow satisfactorily on a medium suitable for the test organisms, then it must be first grown on its own medium, the growth then being cut out and embedded in a medium suitable for the test organisms.

The number of test organisms used in such screening tests depends on what type of antibiotic is being sought, but it is not unusual for as many as forty to be employed. And, if the screening is to be really thorough, the organisms being screened are grown on a number of different media, as the medium employed often affects the antibiotic substances produced.

Carbon Dioxide Snow and Eczema

Q.—Is the treatment of stubborn patches of eczema with carbon dioxide snow still considered an appropriate form of treatment? It was quite commonly used a generation ago.

A.—The treatment of eczema with carbon dioxide snow is a method which tends to be forgotten from time to time, and revived or rediscovered periodically. There is no doubt that it is occasionally a very effective method, particularly in chronic lichenified areas, when either solid carbon dioxide snow or carbon dioxide slush may be used. It is somewhat out of favour at the present time because other methods are more convenient and perhaps give better results. At the same time, there are always cases of eczema which fail to respond to the more usual methods, and treatment with carbon dioxide is always worth bearing in mind in stubborn cases.

Word-blindness

Q.—The ordinary textbooks on ophthalmology give very little information on the diagnosis of word-blindness. Are there any standardized methods of investigation which might prove useful to the school ophthalmologist, and is there any textbook which gives information about the education of children suffering from word-blindness?

A.—Your correspondent evidently refers to the congenital or developmental form of word-blindness rather than the acquired form. Although a British ophthalmologist, Hinshelwood, published the first complete study of the condition in 1917, the disorder is neurological rather than ophthalmological. Most standard textbooks of neurology give a brief description of the condition, but the subject is more fully considered in S. T. Orton's *Reading, Writing, and Speech Problems in Children* (Chapman & Hall, London). In addition to "word-blindness," the disorder has also been termed alexia, dyslexia, asymbolia, and strephosymbolia. As the disability is rarely total, dyslexia is probably the simplest and most descriptive term. Word-blindness is an unsatisfactory designation, as the child is able to see perfectly letters and words, but continues inadequately to understand their meaning after he has reached an age when other children can read. In most cases the dyslexic child readily learns to recognize single letters and figures, but remains unable to appreciate the significance of words of two, three, or more letters and similar groups of figures. In other cases, simple written or printed words can be understood, but not longer words, and sentences. In all other respects the child may be quite normal.

Investigation is carried out only by patiently testing the child's ability to recognize first of all single letters and figures, then words of two letters, of three letters, and so on. As a preliminary measure, an assessment of the child's intelligence quotient should be made by an educational psychologist to exclude subnormal intelligence. Again, before considering a diagnosis of developmental dyslexia, one should make quite sure, by inquiring into previous methods of education, that the child's inability to read is not merely the result of faulty tuition.

No public facilities exist for treatment, as individual and almost daily tuition is essential if progress is to be made. A few speech therapists with special experience of the condition and some retired schoolmistresses have been known to accept cases for private treatment.

Deafness and Malnutrition

Q.—Having seen some recently repatriated prisoners of war, I would be grateful if you would answer the following questions. (1) What deficiency diseases involve the ear? (2) Could a perceptive deafness, with no other apparent involvement of the nervous system, be due to any nutritional deficiency?

A.—(1) Involvement of the ear with resulting deafness rarely results from deficiency disease. However, there are many scattered reports in the literature which indicate that deafness of perceptive type may occur in pellagra and other associated syndromes which probably result from deficiency of riboflavin and nicotinic acid. Deafness in chronic pellagra is not rare. Beriberi rarely causes nerve deafness.

(2) Experience among repatriated prisoners of war from the Far East in 1945 did, however, demonstrate conclusively that nerve deafness, sometimes of severe degree, occurred when there was gross evidence of malnutrition. It was also seen among German prisoners of war in the Middle East, and was then usually associated with retrobulbar neuritis and spinal ataxia. Occasionally nerve deafness occurred without involvement of the optic disk or spinal cord, but it was rare. These cases do not necessarily suffer from pellagra or beriberi, and the selective nature of the neuropathy constituted a striking feature. For further information on this subject see *Nutritional Diseases of the Nervous System*, by J. D. Spillane (Livingstone, 1946).

Severe Reactions after Vaccination*

Q.—What factors are known to predispose to particularly severe reactions to vaccination? Is x-ray treatment for lymphatic leukaemia likely to do so?

A.—Vaccination is presumed here to refer to vaccinia—or vaccination against smallpox. A living modified virus is used, and in the healthy susceptible individual a considerable local and some systemic reaction follows vaccination, particularly primary vaccination in adult life. The main complications—and they are ordinarily very rare—are generalized vaccinia and post-vaccinal encephalitis; the latter complication is more common after primary vaccination in older children and adults than in infancy or after re-vaccination. Any skin disease like eczema may predispose to secondary vaccinal infection on the affected sites causing one form of Kaposi's varicelliform eruption. Vaccination of a patient suffering from lymphatic leukaemia might carry a greater risk than normal of a generalized vaccinia because of the absence of the granular phagocytes; occasionally a greater risk than normal of a generalized vaccinia because of the lack of any antibody response. X-ray burns might also serve as foci for secondary vaccinal infection.

Does Vasectomy Rejuvenate?

Q.—Does bilateral vasectomy have a rejuvenating effect? Does it lead to the development of prostatic disease later on?

A.—Bilateral vasectomy has no rejuvenating effect, and no influence on the later development of prostatic disease; the testes do not as a rule show any histological change. Vasectomy does prevent epididymitis after prostatectomy in the vast majority of cases.

NOTES AND COMMENTS

Pneumonic Delirium.—Dr. M. ASTON KEY (Southsea) writes: "Your comment on the above subject ('Any Questions?' *Journal*, August 1, p. 296) reminds me that more than 50 years ago I was attending a robust man in middle life with a sharp attack of lobar pneumonia and a high temperature. One afternoon he got up, demanded his clothes, which his wife and her sister were too frightened to refuse him, and left the house with a lady on each arm, walked half a mile to a railway bridge, came home, undressed and got into bed again. They then sent for me and I found the womenfolk had not dared to do so earlier because of his determined attitude. He was none the worse for the escapade and some years later became the landlord of a large inn outside Portsmouth, where he lived for several years."

Correction.—There was an error in our report of the remarks made by Mr. C. Jennings Marshall at the meeting of the Section of Surgery during the Annual Meeting of the B.M.A. in Cardiff (July 25, p. 212). The last sentence should have read as follows: "He warned against the dangers of ligating the cystic duct too far distally and said that he himself was not averse to leaving a long stump."

"Any Questions?" Book.—The second book of selected "Any Questions?" is available, price 7s. 6d. (postage 6d.). Copies may be obtained either direct from the Publishing Manager, B.M.A. House, Tavistock Square, London, W.C.1, or from booksellers.

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 4499. TELEGRAMS: Attitology, Westcent, London. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors overseas should indicate on MSS. if reprints are required, as proofs are not sent abroad. ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. House, Tavistock Square, London, W.C.1 (hours 9 a.m. to 5 p.m.). TELEPHONE: EUSTON 4499. TELEGRAMS: Britmedads, Westcent, London. MEMBERS' SUBSCRIPTIONS should be sent to the SECRETARY of the Association. TELEPHONE: EUSTON 4499. TELEGRAMS: Medisecre, Westcent, London. B.M.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

NULACIN

provides
drip therapy
without a tube

Maintains a continuous

state of gastric anacidity

A maintained continuous state of gastric anacidity has heretofore been impossible without hospitalization and discomfort to the patient.

Now, NULACIN achieves this desirable state simply, effectively and without attendant disadvantages. A NULACIN tablet placed in the mouth between the cheek and the gum dissolves slowly and releases its contained medicaments at a rate which gives continuous neutralization of the acid gastric juice. NULACIN accomplishes this with considerably less antacid than is required by any other method of oral administration. The results are comparable with those of intragastric milk-alkali drip therapy.

INDICATIONS

NULACIN tablets are indicated whenever neutralization of the acid gastric contents is required: in active and quiescent peptic ulcer, gastritis, gastric hyperacidity.

Dosage: Beginning half-an-hour after food a NULACIN tablet should be placed in the mouth between the cheek and the gum and allowed to dissolve.

Superimposed gastric analysis curves of five cases of duodenal ulcer.

Same patients as in Fig. 1, two days later, showing the striking neutralizing effect of sucking Nulacin tablets (3 an hour). Note the return of acidity when Nulacin is discontinued.

During the stage of ulcer activity up to three tablets an hour may be required. During quiescent periods, for prophylaxis in peptic ulcer and for the relief of discomfort due to gastric hyperacidity, the dose of NULACIN is one or two tablets between meals.

NULACIN tablets are not advertised to the public and have no B.P. equivalent. May be prescribed on E.C.10. The dispensing unit of 25 tablets is free of purchase tax. (Price to pharmacists ... 2/-). Also available in tubes of 12.

HEALTH AND CLEANLINESS

Im-Hotep, the Egyptian god of healing, became known as Asklepios by the Greeks and as Aesculapius by the Romans. The symbol of the healing serpent and knotted staff may be seen at the Roman Baths, at Bath in Somerset. It was here that the warm sulphurous water was used by the Romans for its healing and cleansing effects. These waters are now known to be radio-active, and are still taken for their health-giving properties.

Today, in modern medicine, far more potent radio-active substances are known, and these play a vitally important part in both the diagnosis and treatment of disease.

THE HUNTERIAN ERA: ITS INFLUENCE ON THE ART AND SCIENCE OF SURGERY*

BY

LIONEL E. C. NORBURY, O.B.E., M.B., B.S., F.R.C.S.

Consulting Surgeon, Royal Free Hospital, St. Mark's Hospital, and Belgrave Hospital for Children

In 1813 Dr. Matthew Baillie, a nephew of John Hunter, a distinguished physician and pioneer in the study of morbid anatomy, and Sir Everard Home (Hunter's brother-in-law), comparative anatomist and surgeon, executors, being desirous of showing a lasting mark of respect to the memory of the late John Hunter, inaugurated an oration to be called the Hunterian Oration, to be delivered in the theatre of the College on February 14, the birthday of John Hunter, or as near that date as possible, by the Master or one of the Governors for the time being, or a member of the Court of Assistants; such oration to be expressive of the merits in comparative anatomy, physiology, and surgery, not only of John Hunter but also of all such persons as should be from time to time deceased, whose labours have contributed to the improvement or extension of surgical science.

It will be agreed that the terms of reference, as enunciated by the founders of the Hunterian Oration, are wide, and the scope available to the orator considerable. Yet a study of John Hunter's writings and those of his contemporaries makes one realize the universality of this great man and his teaching—how much has been left unsaid and what inferences still remain to be drawn from his scientific researches. This is especially brought home to one after a study of various Hunterian Orations from the time of their inception in 1814, when the oration was delivered by Sir Everard Home, up to the present. The orator is thus enabled to glean inspiration from the researches of those who have previously held this post of honour. One is, however, left with a sense of frustration as to what unexplored fields of activity remain, and what further influence on the science and art of surgery can be brought to light, having its roots in the life and work of the great master, John Hunter.

John Hunter's Early Training and Character

It is a debatable point whether John Hunter was born on February 13 or 14, 1728. We in this College commemorate his birthday on the 14th.

Stephen Paget records that as a boy John Hunter was deficient in self-control—idle and ignorant; but he showed great neatness of hands and quickness of perception in anything mechanical, though he remained obstinately impenetrable to book-learning. The cultivation of the powers of observation was a great asset to Hunter. The seed was undoubtedly implanted in his mind during early childhood when he lived in the

family house of Long Calderwood, in Lanarkshire, with its farm and beautiful countryside. Instead of attending school he would play truant and spend time in the country imbibing the knowledge that Nature had to teach. To quote from an article on "Long Calderwood," written by Sir Arthur Porritt and published in the *Annals of the College*: "The interest of Long Calderwood to us of the Royal College of Surgeons of England lies in the fact that it provided the background for the first sixteen or seventeen years of John Hunter's life, and must have had a great formative effect on the future development of the genius of our patron saint." It is indeed good news to hear that, under the auspices of a Scottish Corporation, the property of Long Calderwood has been acquired for the purpose of its protection and maintenance as a "National Memorial."

Hunter the Man

As a man, John Hunter has been described as short, red-haired, pugnacious, but very kind; a natural philosopher seeking a clue to human ills by studying the comparative anatomy of animals, birds, and fishes. He was easily provoked and hated deceit. He was a craftsman of no mean order, having in his early days worked in a carpenter's shop under the direction of his sister's husband, Mr. Buchanan.

His work came first, much to the detriment of his wife and family, both socially and financially. Dr. Joseph Adams, in his *Life of John Hunter*, published in 1817, says: "John Hunter's countenance was open, and, though strongly impressed with thought, was by no means habitually severe, but softened into tenderness or sparkled with brilliancy, according to the impression on his mind."

Rudolf, in his address on "Hunteriana" delivered before the Hunterian Society in April, 1951, when referring to the character of John Hunter, said: "At home he was a model husband adored by his pupils and intimates, but to the outside world, a changed being, quarrelsome and disputatious."

His home in Leicester Square, where he spent his last days, was, it is supposed, the *mise en scène* for Robert Louis Stevenson's story *Dr. Jekyll and Mr. Hyde*. A suggestion of this dual personality is discernible in Hunter's character. Paget states that John Hunter was "emotional and impetuous—quickly moved to tears of sympathy, quickly ablaze with anger and fierce word."

One may compare the temporary anger of Hunter on occasions with his friend and pupil Edward Jenner,

*Shortened version of the Hunterian Oration delivered at the Royal College of Surgeons of England on February 13, 1953.

which was soon followed by a letter of apology and a reconciliation, or, again, "Hunter's violent anger just before he died at St. George's Hospital."

In spite of his temperamental nature, Hunter retained an abundant sense of humour, as instanced by some of the letters to his brother William. The following are abstracts of a few of these. One, written before 1780:

Dear brother,

The bearer is very desirous of having your opinion. I do not know his case. He has no money, and you don't want any, so that you are well met.

Ever yours,

John Hunter.

In a letter written to William dated September 28, 1761, when on active service, he says: "My fellow creatures of the hospital are a damn'd disagreeable set." In another, dated May 28, 1762, when on active service, he says: "I am obliged to be physician and everything else, and I think I do as well as the best of them." Another letter to Jenner dated January 29, 1789, in reply to one from Jenner asking Hunter to be a godfather to his child: "I wish you joy—it never rains but it pours. Sooner than the brat should not be a Christian, I will stand as godfather, for I should be unhappy if the poor little thing should go to the devil because I would not stand as godfather. I hope that Mrs. Jenner is well and that you begin to look grave now you are a father."

FIG. 1.—Sir Everard Home.

The Royal College of Surgeons is fortunate in possessing many of John Hunter's original letters. They are written in a clear and legible hand, so different from the handwriting of the majority of medical men of the present era.

In studying the character of John Hunter, one is struck with the comprehensiveness of the man. With him, medicine was the same as all science connected with life. One discovers an earnestness, and a grasp of understanding of natural objects which is phenomenal. He had no time for any study of men's devices. With all his roughness of manner, John Hunter carried an honest independence. He never truckled for advancement nor sought favours, but was at all times more ready to give than to receive.

He had to wait a long time before practice came to him, but in due course his income reached a figure of six thousand guineas a year. A goodly income, but one which in his case went to the advancement of science—to the development of medicine and to the foundation of the incomparable treasures which now are in the possession of the College.

It is recorded that when Hunter's portrait was placed before Lavater, the physiognomist, after deep study he exclaimed: "That man thinks for himself."

Cline, in a Hunterian Oration, says: "Much as Hunter *did*, he thought still more. He often told Mrs. Cline that his delight was to think."

Abernethy, in his Hunterian Oration of 1819, says that Hunter was "profoundly contemplative, his mind had not been taught to act in imitation of others; he disliked to read as much as he liked to think."

Travers wrote: "He was capable of large and comprehensive views of natural phenomena, and endowed with a microscopical faculty of seizing and analysing constituent parts and bearings."

We cannot be reminded too often that the really great men are not the great experimenters, nor the great observers, nor the great readers, nor the great scholars, but the great thinkers. Thought is the creator of all human affairs. Actions, facts, and external manifestations of every kind may triumph for a while, but it is the progress of ideas which ultimately determines the progress of the world.

The Influence of Mrs. Hunter on Her Husband's Work and Social Status

It is axiomatic that a wife may either make or mar her husband's career. Many of our most eminent medical men owe advancement in the science and art of their profession to a co-operative and understanding wife. In 1771 John Hunter married Anne Home, the daughter of an Army surgeon. She was 29 and he was 43 years old. She was a very accomplished and charming lady intellectually, and a great social asset. The marriage was not quite in accord with his bachelor brother William's views. For William, a wife who had no dowry was to his mind a pure mistake for a poor man, however great might be her beauty and her ability to lead and shine in society. But John Hunter had good taste. He was by nature an artist and loved pictures above everything; how then could he fail to desire that the choicest picture in his house should be the most lovely?

She was a good wife—devoted to her husband and fond of gay society, a taste which occasionally interfered with her husband's more philosophical pursuits. He was so wrapped up in his work that she must have had a lonely time, and must have been thrown much on her own resources. They lived first in Jermyn Street, in a house which his brother William had recently vacated. Later on they moved to a house at the north-east side of Leicester Square, where the Odeon Theatre now stands. Here Mrs. Hunter held her parties, which included many celebrities of the day.

Hogarth was a neighbour; Sir Joshua Reynolds lived in the precincts, as also Haydn during his first visit to London in 1782. Mrs. Hunter had many friends, among whom were Mrs. Thrale; Elizabeth Montagu, who was one of the original "blue-stockings"; and Fanny Burney, the novelist and authoress. Fanny Burney's first and best novel was *Evelina*, published in 1778. Samuel Johnson was her friend and admirer. It is said that Burke sat up all night to read *Evelina*, and that Reynolds would not touch his food until he had reached the end.

The management of the house in Jermyn Street must have often taxed the patience of Mrs. Hunter. Her husband invaded the rooms with his specimens, and the place became a veritable natural history museum. On one occasion Hunter was given a giraffe, and as he could find no room to contain it he cut off its legs and fixed it in the passage. Anne Hunter must have had an anxious time with a young family and husband who would not take care of himself—with patients coming and going, rooms filled with specimens and artists drawing them; also resident pupils. Holidays were spent in the country at Earl's Court. Hunter's "country" box, as he called it, at Earl's Court was a pleasant hour's drive from his home in Leicester Fields. The house stood in its own grounds with a meadow behind it.

Mrs. Hunter made the house beautiful, decorating it partly in the Egyptian style, then a prevailing fashion. The ceiling of the drawing-room was richly ornamented with strange birds, which her husband must have laughed at but never dared to classify. For Hunter the gardens were "zoological gardens" containing both wild and tame beasts: gardens in which he rambled at night studying the ways and manners of the varied forms of life in every detail. In spite of the temperamental nature of her husband, the marriage was a happy one, largely due to the patience and good temper of Anne. Dr. Joseph Adams, in his *Life of John Hunter* published in 1817, says: "Hunter had the highest of all human gratifications in the wife of his choice, suited to be his companion, and admirably fitted for, because always accustomed to the elevated rank which her husband had attained."

During his visit to London Haydn composed "The Six Canzonettas for the Voice," for which Mrs. Hunter wrote the libretto, and dedicated them to her. Among her verses is the charming song, "My Mother Bids me Bind my Hair," which lives for ever in the setting Haydn gave it. She also wrote the words of Haydn's *Creation*.

FIG. 2.—Mrs. Hunter.

In a letter to James Baillie, his brother-in-law, dated November 25, 1775, Hunter says: "As to myself, with respect to my family, I can only say that I am happy in a Wife, but my children are too young to form any judgment of them. I am not anxious about my children, but in their doing well in the world. I would rather make them feel one moral virtue than read Libraries of all the dead and living languages. You know I am no scholar, therefore do not feel the beauty of language."

John Hunter died in 1793, in poverty, having spent all his income in the development of his museum. His wife lived in penury until the museum was purchased by the Government in 1799, six years after his death. Mrs. Hunter was a widow for 29 years and died in 1821 at the age of 79. She kept her wit and beauty to the end of her days.

The Hunterian Orator of 1821 paid this compliment to her memory: "She had sustained an honourable widowhood, estimable for talents of her own and venerable as the relict of an illustrious husband."

The Hunterian Era

John Hunter lived and practised his art at a remarkable period in the history of England. He came to London in 1748. William Pitt was guiding the destinies of England. Burke came to London soon after Hunter, to study law, but subsequently turned his attention to politics and literature.

This was also the age of the Arts: Gainsborough, Reynolds, and the portrait painters; of Garrick and the stage. It was also an age which included Chippendale and the Adam brothers. It laid the foundations of modern science and modern medicine, in which John Hunter played a notable part.

The eighteenth century marked an era of religious and social reform, due in part to the influence of such men as John Wesley, William Wilberforce, renowned for his great

work in the abolition of slavery, and the philanthropist John Howard, especially famous for his labours to secure prison reform.

John Hunter must have been acquainted with all sections of the population of London, both fashionable and otherwise. The body-snatchers sold him bodies for dissection, and the poor thronged the newly founded hospitals. Consumption and fevers of all kinds were rife, especially gaol fever. The Hunterian era marked a period of much-needed improvement in London's sanitation.

At the beginning of the eighteenth century there were only four important hospitals in London: St. Bartholomew's, St. Thomas's, Bethlem, and the Chelsea Hospital for invalid soldiers. By the time Hunter arrived in London five more general hospitals had been founded: Westminster, Guy's, St. George's, the London, and the Middlesex—all within a few years of each other.

The eighteenth century was an age of indifference to infant life. Children often died abandoned in garrets and in the street. Those left to the care of the Poor Law and parish did not long survive the exigencies of treatment. Thanks to the prolonged agitation of a certain Captain Coram for an institution for the care of these unfortunate children, a Charter was obtained from George II. With the help of Handel, Hogarth, and others, Coram witnessed the fruition of his labours, and in 1745 the Foundling Hospital came into being.

The Influence of John Hunter's Associates and Friends

Sampson Handley in his Oration of 1939 showed how "Hunter's mind, in spite of a very superficial education, was developed by his association with great men of his period, such as his brother William, Cheselden, etc." But other factors were at work in addition to those especially related to the science of medicine. I refer to his contemporary associates in other fields, such as art, music, literature, and drama, all of which must have acted as a stimulus to general knowledge and mental alertness. Time will only permit reference to a few of those whose names are household words:

David Garrick, a famous actor and playwright—friend and pupil of Samuel Johnson. Garrick came to London with Dr. Johnson about 1737. He studied at Lincoln's Inn and also set up in the "wine trade" with his brother for a time, but soon gave up both these activities for the stage. It is worthy of note that in 1769 the Town Hall at Stratford-on-Avon was dedicated by Garrick to the memory of Shakespeare.

Samuel Johnson, author, who acquired a position in literary and artistic circles that has rewarded the efforts of no other man. He was the acknowledged dictator of the Literary Club, founded in 1763 by himself and Sir Joshua Reynolds, and numbering among its limited membership Burke, Boswell, Garrick, Gibbon, Fox, Sheridan, Goldsmith, and others. Boswell's *Life of Johnson*, long accepted as the greatest portrait ever written, was published in 1791.

Richard Brinsley Sheridan, dramatist and politician. He was considered a dunce by his mother at the age of 7. He had an indifferent record at Harrow and cared nothing for scholastic honours. In this respect the background is similar to that of John Hunter in his early days.

Handel, who numbered Pope, Fielding, and Hogarth among his closest friends. The year 1742 witnessed the production in Dublin of that great oratorio the *Messiah*.

All these men and many others were friends and acquaintances of John Hunter and must have had a salutary influence on his line of thought and intellectual make-up, and indirectly in the development of the science and art of surgery.

Hogarth was a neighbour of John Hunter when he resided in Leicester Square. From 1749 to 1764 Hogarth lived at Chiswick, and a mulberry tree grew in his garden. It was his custom to gather local children around him under the tree and feed them with his fruit. The house and tree were badly damaged by enemy action in 1940. The tree had recently fruited for the first time after a number of years. At the reopening of the former house of this great painter at the

beginning of 1952, a small pie, made from the fruit of Hogarth's mulberry tree, now 300 to 400 years old, was given to each guest.

Hunter as Writer and Lecturer

Hunter has been portrayed as "extremely industrious but a poor lecturer, and never had many pupils." As a lecturer, he stressed the advantages derived by a man of putting his thoughts in writing. He resembles, he said, "a tradesman taking stock, without which he never knows either what he possesses or in what he is deficient." A consciousness of the difficulty in making himself understood might have been among the motives for writing his lectures. Convinced of this difficulty in making others understand what appeared simple to himself, he encouraged conversations with his hearers after each lecture, in order to ascertain that his remarks had been clearly expressed. Hunter always professed his lectures to be on "Practical Surgery, with so much physiology as was necessary to render them perspicuous."

Hunter was not a prolific writer. His first appearance as the author of a comprehensive work was comparatively late in life, in 1771, when he was 43 years of age. In this year he published a "Treatise on the Teeth"—a treatise, it has been said, that was forced out of him in order to defray from its sale the expense of his impending marriage. He wrote a number of medical essays. His "Treatise on the Blood, Inflammation, and Gun-shot Wounds," a work dedicated to the King, was his last, and considered by some the greatest of all the Hunterian works.

In a study of Hunter's writings it is often difficult to grasp his line of thought completely. He observed so many things, held such breadth of view, and tried to compress so much into so little, that even had he possessed the necessary skill in exposition he would have been hard to follow. It is, I think, honest to say that, easily as he acquired knowledge from nature, he was according to ordinary ideas an illiterate man. He read from nature and took no time to read from any other source. The principal monument of Hunter's life was his Museum, so aptly described by Professor Wood Jones as "John Hunter's Unwritten Book." He sought truth fearlessly and the search cost him his life. He taught it as he saw it—earnestly, simply, and directly. His influence on medicine and natural science was far-reaching. Ottley, in his *Life of Hunter*, says: "In his writings we occasionally find an obscurity in the expression of his thought, a want of logical accuracy in his reasonings, and an incorrectness in his language, resulting from a deficient education." John Hunter was a poor lecturer and a man of few words. His power of imparting knowledge was chiefly by means of dissections and specimens, but also by sketches. He maintained a resident artist, who was kept busy making drawings of specimens. William Bell was the artist for fourteen years, and William Clift followed him and remained with Hunter to the end.

Hunter as Observer

As an original investigator, Hunter was one of the most laborious and comprehensive of his period. With regard to experimental work, it must be admitted that many of his experiments were rough, and some inconclusive ones led to incorrect inferences, as, for example, in his argument that the "veins do not absorb." But when he came to anatomy, to the broad outlines of natural history, or to the comprehensive grasp of vital phenomena, he had few equals.

As an instance of John Hunter's powers of observation I would mention the Hunterian specimen, in the Museum, of the "head of a chick at the close of incubation," showing the "shell-breaking knob on the top of the upper mandible." To be accurate, the specimen is that of a gosling. After fulfilling its function of breaking the shell of the egg the knob disappears.

A most interesting account of this "Hunterian Specimen and its Problem" was written by Sir Arthur Keith and published in the *Annals* of the College. He drew attention

to the fact that John Hunter was the first English observer to take notice of the horny knob of the chick. Nowhere does John Hunter himself claim this priority.

Hunter was in the habit of enunciating "general principles" and then making his facts fit into the framework. Coming to England he passed 40 years in the heart of the most empirical nation in Europe; a nation abhorring all general principles and proclaiming the superiority of facts and ideas. During his long residence in England he was acted on by two conflicting forces: The country of his birth made him "deductive"; the country of his adoption made him "inductive."

As a Scot, he preferred reasoning from general principles to particular facts; as an inhabitant of England, he became inured to the opposite plan of reasoning from particular facts to general principles. No doubt one of the reasons why Hunter in investigating a subject is often obscure is that on occasion his mind was divided between these two hostile methods. The conflict darkened his understanding.

Hunter as Surgeon

In *Buckle's History of Civilization*, 1878, it is recorded that Hunter introduced what is probably the most capital improvement in surgery ever effected by a single man—namely, the practice in aneurysm of tying the artery at a distance from the seat of disease—thus saving numerous lives. Before the time of Hunter the operation was performed by cutting into the sac of the aneurysm and tying the vessel above and below. So formidable was this proceeding in its consequences that amputation of the limb was frequently performed as a less dangerous and fatal measure.

As a surgeon, Hunter was a careful if not a brilliant operator; a surgeon who looked upon an operation as the opprobrium of surgery but who did his work well when called upon by necessity. His diagnosis was good for its day, and his observation of phenomena of disease acute. His practical skill was extolled by his former pupil, Astley Cooper. In Brock's recent masterly publication *The Life and Work of Astley Cooper* one realizes the similarity of outlook of master and pupil.

Hunter and the Hunterian tradition were the great inspirations of Astley Cooper's life and work. Hunter, like Astley Cooper, realized the importance of a proper relation between medicine and surgery. Before Hunter's time surgery was held to have but little connexion with medicine.

John Hunter's influence on the development of the science and art of surgery was in the main the natural sequence of his study of the basic sciences of anatomy and physiology, both in health and in disease. His meticulous researches in the realm of morbid anatomy constituted the foundation stone on which he established his *Surgical Principles*. Although the name of John Hunter may not be immortalized as that of a great surgeon, nevertheless he was a great exponent of the art of acquiring knowledge by observation, experiment, and research, without which any advance in surgical procedure is stultified.

Sir Henry Souttar, in his fascinating review of the recently published German book, *Masters of Surgery*, by Professor H. Killian and G. Krämer, lays stress on the brilliant description given of John Hunter as "one whose genius lay in observation and in the elimination of the immature and unscientific; who never wandered in speculation, and whose

FIG. 3.—Drawing of a specimen prepared by Hunter to show the shell-breaking horny knob on the beak of a newly hatched gosling. By Professor F. Wood Jones. (Hunter's specimen 3456, No. 5, "Young Gosling.")

whole train of thought was built upon experience." If John Hunter was not a great surgeon he nevertheless was a talented exponent of those sciences which are essential to a sound knowledge of surgical principles and to the making of a surgeon.

Hunter as Pathologist and Museum Builder

Pathology was the science to which Hunter was most devoted. For him pathology was the basis of diagnosis and treatment. His experiments on the healing of wounds are well illustrated in the Hunterian Collection in the Museum of this College. He was a pioneer of the science and art of grafting and transplantation of tissues. His classical and successful experiment of grafting a cock's spur on to its comb is well known. This specimen is preserved in that Collection. He was also interested, and up to a point successful, in the transplantation of human teeth. He wished to study the comparative "growth powers" of different structures and of different situations, since he believed that this had a bearing on disease processes.

Professor Wood Jones, in an address delivered at St. George's Hospital with the title of "John Hunter's Unwritten Book," says: "The collection of specimens constituting the Hunterian Museum is one of the most remarkable monuments that any man has ever raised to perpetuate his memory. His Museum was the medium by which Hunter sought to express those great principles of life which he so profoundly understood, but which neither by speech nor by writing could he make clear to his contemporaries."

Wood Jones emphasizes the fact that John Hunter recognized that, in order to make satisfactory progress in the study of biology, function and structure must be integral parts of such study, and not divorced from each other. This was also in accord with the precepts enunciated and practised by Leonardo, who was designated by William Hunter as the first anatomist of his time.

The Museum

At the time of Hunter's death Clift was custodian of his Museum. The Government offered the executors £15,000 for the whole collection. This was voted by the

House in 1799 and was accepted. At this time the collection was still housed at Hunter's residence in Castle Street. The lease of this house came to an end in 1806, when the collection was placed in the custody of the Incorporation of Surgeons—soon to become the Royal College of Surgeons of London and later of England—and was moved to a house in Lincoln's Inn Fields belonging to the College.

It was largely due to the good offices of William Eden,

FIG. 4.—Samuel George Shattock.

later to become the first Baron Auckland, a distinguished politician and friend of the Hunters, that after many disappointments the purchase of the Hunterian Collection for the nation was successfully negotiated. He also obtained a government grant for Mrs. Hunter during the first two years of her widowhood. Clift was the first to be appointed Conservator of the Hunterian Collection. He was suc-

ceeded by his son-in-law, Richard Owen. Great advances were made under Owen's direction and subsequently. It remained for Sir Arthur Keith, anthropologist and comparative anatomist, to bring the augmented Hunterian Collection to its zenith as the most important of its kind in existence. Trustees were appointed to guard the Hunterian Collection. These have in succession carried on the good work and have co-operated with the Council of the College in the care of the specimens.

Amongst the events which have shaped the design and destiny of the Museum of the College, one of the most important was the engagement of James Paget, in the beginning of 1842, to prepare a catalogue of its pathological collection. An event of equal if not greater moment was the appointment of Samuel George Shattock to the office of Pathological Curator in 1897. The office was then comparatively new. In 1881, while Sir James Paget, assisted by Sir James Goodhart and Mr. Alban Doran, was preparing a second edition of the Pathological Catalogue, the Council decided to appoint a special officer to take charge of the pathological collection. The first occupant of the post was Sir Frederick Eve, then a young surgeon with a special knowledge of tumours. He was succeeded in 1890 by Mr. James Targett, a young gynaecological surgeon with a knowledge of pathological processes. To this office Mr. Shattock was appointed in 1897 as a successor to Targett. He was then 45 years of age, and in the plenitude of his powers.

Hunterian Pictures in the Museum Collection of the College

Certain pictures in the Museum of the College were part of the original Hunterian Collection and illustrate subjects in which Hunter was especially interested. William Bell and John André were accomplished artists, and most of the original drawings in the Hunterian Collection are by them. Several were painted for John Hunter by Zoffany, William Hodges, Stubbs, Robert Home (Hunter's brother-in-law), and William Cheselden. Amongst the collection is a drawing of William Hunter's dissecting-room by Rowlandson.

A number of the pictures have been reconditioned, thanks to the good offices of Geoffrey Keynes, who is "Curator of Portraits and Works of Art" of the College. The beneficial effect of such restorative processes is well shown in some of the famous paintings by Stubbs in the possession of the College, and which were exhibited in the Stubbs Collection at Liverpool in 1951.

The contemporary science of art in Hunter's time, of which he was no mean exponent, must have influenced his surgery and surgical technique. John Hunter showed his artistic temperament by making beautiful dissections.

Medical Societies

John Hunter was a source of inspiration in connexion with metropolitan medical societies. In 1783, together with Dr. George Fordyce, he founded the Society for the Improvement of Medical and Chirurgical Knowledge. The membership was originally nine, with provision for expansion to twelve. It soon became a dining-club, and was dissolved in 1818.

In 1785 the Lyceum Medicum Londinense was started under the patronage of John Hunter and George Fordyce. It met in Hunter's lecture-room in Castle Street, Leicester Square. There were 350 members. In 1809 its members were transferred to the Westminster Medical Society.

Fordyce wrote a *Treatise on the Digestion of Food*, and was remarkable for his practice of having one meal only in the day, at 4 p.m., but this was gargantuan, and went on for an hour and a half. It included a pound and a half of rump steak, a bonne-bouche such as half a boiled chicken or a plate of fish, a tankard of strong ale, a quarter of a pint of brandy, and a bottle of port. It is hardly surprising that he suffered from gout. Fond of society, he would dispense with sleep, and sometimes lectured for three consecutive hours without having undressed on the previous night.

In the latter part of the eighteenth century it was customary for medical consultants to visit coffee houses, such as the famous "Saracen's Head," in order to write prescriptions, at half a guinea or a guinea a time, for apothecaries who described the symptoms of their patients—a somewhat dubious and risky business, but a common and profitable practice among the more noted consultants of the faculty.

Activities of the College

Many of the activities of this College have their roots in the soil prepared by John Hunter and are products of the Hunterian era. First the Museum, the history and functions of which were so clearly enunciated by Professor Grey Turner in his Hunterian Oration of 1945, in which he showed the steps by which the Hunterian Collection grew into the Museum of the College. The name of George Grey Turner is held in esteem and affection by our College. Surely the mantle of Hunter fell on the shoulders of Grey Turner, who was a true disciple of that great man and a worthy exponent of the Hunterian tradition and all that it stands for.

With the growth and rehabilitation of our Museum after its war injuries, it is hoped that the underlying principles of Hunter's teaching will be fostered and the Hunterian tradition of experiment and research maintained.

This is an age of "ideology," but the practical application is not always easy to attain. The "Graphic Museum" in Khartoum is a modern concept of John Hunter's principles of imparting knowledge by a study of all aspects of disease—anatomical, physiological, and pathological. This is achieved by an orderly series of photographs, drawings, and specimens grouped together. It is possible, by spending an hour or so in a small division or alcove of the Graphic Museum, to obtain a shrewd insight into the aetiology, clinical manifestations, complications, morbid anatomy, and treatment of the particular disease in question. After a visit to that Museum one is struck with the possibilities, in any Museum, of such a comprehensive method of instruction.

Research

In 1931 Sir Buckston Browne, one of the greatest benefactors in the history of the College, presented the College with an "Institution of Surgical Biological Research" in a building adjoining the grounds of Downe House, Kent. In a letter to the Council of the College Sir Buckston said: "We all know that John Hunter had a farm at Earl's Court, where, from close observation of living animals, he was able to make his most important additions to surgical knowledge. It is such a farm that I wish the Royal College of Surgeons to accept." The farm is under the able directorship of Sir Arthur Keith, who has been Master of the Research Farm since its inception. The Hunterian tradition of experiment and research has thus been rendered a practical proposition, with notable advances in physiology, technique, and elaboration of surgical principles. It is of historical interest to recall that in 1928 Sir Buckston (then Mr. Buckston Browne) purchased Darwin's home at Downe, and conveyed the entire property to the British Association for the Advancement of Science, to be maintained for all time as a memorial to Darwin.

Hunter had wide vision as regards scientific problems. He could foresee a study of the basic sciences of anatomy, comparative anatomy, and physiology, and their practical application, taken in conjunction with that of morbid anatomy or pathology, culminating in a sound knowledge of the art and science of surgery.

This College has proved its adherence to the Hunterian precept of education in the basic sciences by the inauguration of an Institute of Basic Medical Sciences. By this means co-ordination with the University of London has been effected. Thus the Institute is at the same time both a Faculty of the College and an Institute of the British Postgraduate Medical Federation. The Institute of Basic

Medical Sciences is responsible for the teaching of anatomy, applied physiology, and pathology in the College under the able guidance of the Dean, Professor Geoffrey Hadfield. Arrangements are being made to form a department of pharmacology, which will also be administered by the Institute.

One of the more recent activities of the College is the institution of a Clinico-Pathological Research Unit in connexion with the Imperial Cancer Research Fund. The Fund, which is a worthy exponent of the Hunterian tradition of experiment and research, celebrated its jubilee last year.

In 1951 the Council of the College, in their wisdom, initiated a Clinico-Pathological Research Unit, with a view to correlating both the clinical and pathological aspects of research. The new department, established in the precincts of the College, is working in conjunction with experimental research carried out at the Fund's laboratories at Mill Hill. The institution of the Clinico-Pathological Unit is in accordance with Hunterian precepts, and marks a milestone in scientific procedure.

An Academy of Medicine

Sir Max Page, in his Hunterian Oration of 1951, envisaged the formation of an "Academy of Medicine." Previous Orators, notably Victor Bonney, have laid stress on the advantages which might accrue from the integration in one corporate body of the various specialties into which medicine of to-day is breaking up. Such an ideality is ever present in the minds of men of vision. There may be difficulties in bringing this Utopian project to fruition, but the formation of an Academy of Medicine or Mecca of Medical Science in London, by cohesion of the three Royal Colleges, together with their Associated Faculties, and under one roof, is an ideal worth striving for. To my mind such a scientific combination would be for the benefit of each and all concerned, as also of medicine in general. Some members of the profession may be sceptical and inquire, "How do you know that such a symbiosis of the Royal Colleges would advance the science and art of medicine?" I feel sure that if John Hunter were living at the present time he would have a ready answer to this query—namely, "Why not try the experiment?"

Hunter's Death and Commemoration Service

John Hunter at the time of his death was in his 65th year, the same age at which his brother William died. Such was the end of two brothers who, in their own Museums, erected their own monuments. Both arrived in London with no capital but genius, industry, and integrity. Each arrived nearly at the same age, finished his career in the same time, and each in the arena of his own labours: William struck with approaches of death in his own theatre, and in his expiring moments anxious to return that he might communicate a physiological fact he never could ascertain till then—namely, "How pleasant a thing it is to die"; John expiring on the spot. To set the time of John Hunter's death by the course of history Cliff wrote this title on his account-book:

John Hunter, Esq., F.R.S.,
Surgeon-General to the Army and
Inspector-General of Hospitals.
Surgeon to St. George's Hospital.
Surgeon-Extraordinary to the King.
etc. etc. etc.
Died October 16th 1793.

On the same day, and perhaps hour, the unfortunate Marie Antoinette, Queen of France, was beheaded in Paris.

John Hunter was buried in St. Martin-in-the-Fields Church. In 1859, when the coffins in the vaults of St. Martin's were moved for reinterment, Frank Buckland, a Member of this College, undertook the task of finding Hunter's body. He began on January 26, and searched for 16 days, by which time he had viewed 3,060 coffins; then he found it, when only three still remained for him to examine.

On March 28, 1859—that is 66 years after Hunter's death—his remains were reinterred in the north aisle of Westminster Abbey. A brass tablet in the stone floor of the nave of the Abbey, placed there by the Royal College of Surgeons of England, records the admiration of the College for:

"His genius as a gifted interpreter of the Divine Power and Wisdom at work in the laws of Organic Life, and their grateful veneration for his services to mankind as the Founder of Scientific Surgery."

The statue of John Hunter in the Museum of the College was erected by subscription on the occasion when John Hunter's remains were transferred to Westminster Abbey, in 1859. The statue is the work of Weeks, and is a copy in marble of the celebrated picture of John Hunter by Sir Joshua Reynolds in the Council Room of the College.

On February 14, 1952, Hunter's birthday, a service was held at St. Martin-in-the-Fields to commemorate the fact that John Hunter was buried in the church until 1859, when his remains were removed to Westminster Abbey. The service was conducted by the Dean of Westminster; the lesson read by the President of the Royal College of Surgeons, Sir Cecil Wakeley; and an address given by Sir Gordon Gordon-Taylor. A plaque was set up in the crypt, and was unveiled by Sir Henry Dale, a Hunterian Trustee. The plaque, besides recording the facts of Hunter's interment and reinterment, commemorates the name of Frank Buckland, the discoverer of the Hunter coffin. As Sir Gordon Gordon-Taylor remarked in his address: "It was owing to the zeal and enthusiasm of the late George Grey Turner that the project to place the plaque in the church had come to fruition."

On the front page of a brochure which deals with the restoration and development of the Royal College of Surgeons of England, the following lines appear: "All through the ages a golden truth is blazoned; the path of Progress is by Experiment, Research, and Trial." Surely here is the essence of the Hunterian tradition, of which the Royal College of Surgeons of England is the custodian.

TREATMENT OF PATIENTS WITH MYELOSCLEROSIS

BY

R. A. HICKLING, M.D., F.R.C.P.
Physician, Charing Cross Hospital

Unless new bone formation in the marrow spaces has occurred (osteosclerosis), which can be detected by x-ray examination, the presence of fibrosis of the bone marrow can be proved in life only by biopsy of a bone in which red marrow is normally present. Needle puncture of the sternum and other bones is not a reliable method of detecting the presence of fibrosis. Bone-marrow cells are usually present among the fibrous tissue or in spaces lined by endothelium in the fibrous tissue, and the fibrosis may be patchy, and an active portion of bone marrow may be encountered. When the fibrosis is very dense, however, few bone-marrow cells may be present.

The object of this paper is to draw attention to the good results which may be obtained by x-ray treatment in certain cases, results comparable to those obtained in treating typical cases of chronic myeloid leukaemia (chronic leukaemic myelosis). Some recent writers, assuming that the enlargement of the spleen is a compensatory process to replace the fibrous bone marrow, have stated that x-ray treatment is harmful (Levinson and Limarzi, 1947; Paolino, 1949; Wyatt and Sommers, 1950).

Rarely patients with myelosclerosis may have the changes in the circulating blood of polycythaemia (Hirsch, 1935; Vaughan and Harrison, 1939; Sussman, 1947; Marson and Meynell, 1949, 1952) or of myeloid leukaemia (Heuck, 1879; Rosenthal and Erf, 1943; Sussman, 1947), but more commonly the changes are those of anaemia. Rarely the patient may die, within a few months from the first symptoms, of severe anaemia, with haemorrhages into the skin and from mucous membranes, presenting a clinical picture like that of acute or subacute leukaemia (Assmann, 1907; Mozer, 1927; Wood and Andrews, 1949). But most patients with myelosclerosis have splenomegaly, slight or no anaemia, with an increase in circulating leucocytes of varying degree and varying proportions of immature leucocytes and nucleated red cells. The enlargement of the spleen is due to myeloid metaplasia, usually involving granulocytes, nucleated red cells, and megakaryocytes. The megakaryocytes are often the most prominent cells in the myeloid metaplasia, partly because of their size and the ease with which they are recognized ("megakaryocytic myelosis").

When severe anaemia is present blood transfusion is the best treatment, and some patients have been kept alive for many years by repeated transfusions (Collins, Sanger, Allen, and Race, 1950). Some patients, however, do not respond to blood transfusions, and these may die of severe anaemia after a short illness. The anaemia does not respond to iron by mouth, or to liver extract by mouth or by injection. But most patients with myelosclerosis live a long time, and in these spontaneous remissions from anaemia may occur, and even polycythaemia may develop (Windholz and Foster, 1947; Hutt and Richardson, 1950).

The patients with myelosclerosis who have either no anaemia or only slight anaemia usually seek advice because of symptoms due to the large spleen. They may, however, have severe gastro-intestinal haemorrhages and large haemorrhages into the tissues, usually have cramps in the legs at night, and may have attacks of gout. Many of these patients ultimately die of severe anaemia, after a long period, but some never develop anaemia throughout and die of weakness and wasting or heart failure.

It is those patients with a high leucocytosis and a high proportion of immature cells in the circulating blood who respond well to x-ray treatment, regardless of the degree of myelosclerosis.

In many of these patients the main trouble is abdominal discomfort due to the large spleen; the general health of the patient may be unaffected, and he may be able to lead an active life consistent with his age. In such cases no treatment should be given except for encouragement to bear with the abdominal symptoms, some relief from which may be given by an abdominal supporting belt. Later on symptoms of general ill-health may occur, such as tiredness, weakness, and, later still, wasting. The first course of x-ray treatment produces the best result, and should be postponed until either severe abdominal symptoms or general symptoms of ill-health occur. This may produce a very good result, the abdominal symptoms diminishing or disappearing as the spleen decreases in size—weakness, tiredness, and cramps in the legs disappearing, and the patient being enabled to lead an active life again. This result is accompanied by a decrease in the numbers of the circulating leucocytes and of the immature leucocytes and nucleated red cells, and a decrease in numbers

of basophils and eosinophils if these were previously abnormally high. The improvement in the patient's condition lasts varying periods of time, as in typical cases of chronic myeloid leukaemia. Courses subsequent to the first usually produce diminishingly good effects.

Present Series

These observations are based upon four patients with osteosclerosis, and five patients with myelosclerosis without demonstrable x-ray changes in the skeleton, who have been under my care. One patient with osteosclerosis is still living. Of the eight who have died, full post-mortem examinations were made upon seven. In the other case, one of advanced osteosclerosis that was under observation from 1923 to 1938, only the spleen and liver were examined at necropsy.

Of these nine patients, seven had x-ray treatment, either to the spleen alone or to the spleen and long bones. One patient had severe anaemia when first seen; there was no increase in circulating leucocytes, though immature leucocytes, nucleated red cells, and megakaryocytes were present (the last up to 21% of the circulating leucocytes). Her response to blood transfusions was poor. Two injections of nitrogen mustard did no good, and she died four months after she was first seen. The remaining patient appeared as a case of acute leukaemia, with severe purpura, severe anaemia, slight leucopenia, immature leucocytes, and nucleated red cells in the circulating blood; he showed poor response to blood transfusions, and died two weeks after he was first seen and five months after the first symptoms of ill-health.

Of the seven patients who had x-ray treatment, two got no benefit. Neither of these had an increase in circulating leucocytes. One died of severe anaemia after five years' observation, during most of which time she had been able to work. Severe anaemia was present only during the last year. The other died of severe anaemia after 16 months' observation. Neither of these two patients responded well to blood transfusions; that is to say, this treatment improved the patient's health only slightly and temporarily.

But the remaining five patients got great benefit from x-ray treatment. They all had a large increase in circulating leucocytes, 20,000 to 70,000 per c.mm. before x-ray treatment. One, a patient with advanced osteosclerosis, was under observation from 1923 to 1938, and died of heart failure, never having severe anaemia throughout. He had a short course of x-ray treatment to the spleen in 1936, which decreased the discomfort due to the large spleen. Another patient, with early osteosclerosis, is still living. He has been under observation from early 1949 until the time of writing. A course of x-ray treatment to the large spleen in July, 1952, greatly improved his feeling of well-being, relieved the severe abdominal symptoms, and stopped the cramp in the legs.

The remaining three patients had more than one course of treatment. One, a patient with advanced osteosclerosis, x-ray pictures of whose bones have been published (Hickling, 1937), had x-ray treatment in 1938, 1939, and 1941. The first two courses produced very good effects upon her general health and upon the abdominal symptoms. The last course produced much less effect, and she died of severe anaemia in 1942, after five and a half years' observation. Severe anaemia was present only during the last year of her life, and did not respond well to blood transfusions. A series of x-ray pictures of this patient's bones was made, and the degree of osteosclerosis appeared to diminish after the first course of x-ray treatment.

Another patient, with myelosclerosis, without x-ray changes in the bones, had three courses of x-ray treatment, in 1948, 1949, and 1950. This man's chief trouble was repeated severe gastro-intestinal haemorrhages. He died after four years and four months' observation. The first two courses of x-ray treatment improved his feeling of

well-being and diminished the abdominal discomfort, but did not seem to diminish his tendency to gastro-intestinal haemorrhages.

The other patient had seven courses of x-ray treatment, to the first four of which his response was very good, though each course brought on an attack of gout, which started eight years before the first course of x-ray treatment. He died in 1945, of weakness, wasting, and chronic gout, after six and a half years' observation.

Discussion

A course of x-ray treatment should be planned so that just enough is given to relieve abdominal symptoms due to the large spleen. This also has the effect of relieving such general symptoms as tiredness, weakness, and cramps in the legs. If more than this is given, anaemia and leucopenia may occur. Two patients developed leucopenia as a result of too much x-ray treatment—one after the first and only course, and the other after the third course. In neither case did the leucopenia do any apparent harm. One patient developed anaemia after a course of x-ray treatment, which otherwise produced a good result, and slow recovery from the anaemia occurred.

Though many writers state that x-ray treatment of patients with myelosclerosis is harmful, some have reported good results (Reiche, 1927; Dameshek, 1945; Marson and Meynell, 1952; Nelson, 1952).

Most writers have taken the view that the myeloid metaplasia of the spleen and other organs is secondary to the fibrous or bony replacement of the bone marrow. Some believe that most cases of osteosclerosis or myelosclerosis are atypical forms of chronic granulocytic leukaemia (Custer, 1949). Others have suggested that myelosclerosis and osteosclerosis may be due to alterations in the undifferentiated cells of the bone marrow, of unknown origin, comparable to the alterations which cause increase in leucoblasts and erythroblasts (Vaughan and Harrison, 1939; Merskey, 1949; Moeschlin, 1951; Robson, 1952). The reduction in the degree of osteosclerosis of one of my patients under x-ray treatment supports this view, if it can be confirmed in other cases.

Splenectomy was not performed on any of the nine patients. Some authorities believe that occasionally this operation might do good (Bodley Scott, 1952; Richardson, 1952). References have been found to 14 patients with osteosclerosis or myelosclerosis who had splenectomy (Nauwerck and Moritz, 1905; Hirschfeld, 1914; Mettler and Rusk, 1937; Carpenter and Flory, 1941; Reich and Rumsey, 1942; Hittmair, 1944; Crail, 1946; Heller, Lewisohn, and Palin, 1947; Dustin, 1947; Crail, Alt, and Nadler, 1948; Wyatt and Sommers, 1950; Franks and Richardson, 1952). Of these 14 patients, four died within three months and four between ten months and six and a half years after splenectomy. Of the six recorded as having survived splenectomy, two survived a short time and four survived between one and five years. No striking improvement was produced in the condition of any of the patients, except one (Franks and Richardson, 1952). This patient was living several months after splenectomy and did not need the very frequent blood transfusions previously required.

Case Reports

Case 1.—A man aged 71. Presenting symptom, hardness of abdomen, and large spleen found February, 1949. No anaemia, no polycythaemia. Leucocytes 26,000 per c.mm., 10% immature cells. Cramps in legs since 1947. General health good for his age. X-ray pictures of skeleton show early osteosclerosis, mainly of humeri. Sternal marrow active, all elements involved, many whole and fragmented megakaryocytes. X-ray treatment to spleen, July and August, 1952; spleen reduced in size, cramps in legs disappeared. Slight anaemia resulted, which gradually disappeared. In good health for his age, February, 1953.

Case 2.—A woman aged 65 died in December, 1951, of weakness, wasting, and heart failure, after five years' obser-

vation. Presenting symptom, thrombosis of ventral vein of retina, December, 1946; enlarged spleen found. Slight anaemia, leucocytes 4,600 per c.mm., 19% immature cells. Spleen gradually increased in size, cramps in legs started in 1950, but she worked until April, 1951, when she became weak and ill. Sternal puncture failed to produce marrow cells. Trephine biopsy of sternum showed advanced myelosclerosis. No x-ray changes in bones. After April, 1951, blood transfusions, liver by mouth and by injection, cortisone and x-ray treatment to spleen were all ineffective. **Necropsy:** Intense myeloid metaplasia of spleen, Malpighian bodies little affected, many megakaryocytes; slight myeloid metaplasia of liver; intense myeloid metaplasia of some lymph nodes; intense fibrosis of marrow of sternum, humerus, femur, ribs, and vertebral bodies.

Case 3.—A man aged 51 died of weakness and wasting, July, 1950, after four years and four months' observation. Presenting symptom, severe intestinal haemorrhage, March, 1946, when a large spleen was first found. These haemorrhages occurred at intervals from 1942 to 1949. Spleen gradually increased in size until 1948, when it reached beyond the midline. No polycythaemia. No anaemia, except after haemorrhages. Leucocytes 15,000 to 24,000 per c.mm., immature cells 8 to 12%, megakaryocytes 1.5 to 2.2%. X-ray treatment December, 1948, caused shrinkage of spleen, decrease in total leucocytes, and percentage of immature cells. Second course in June and July, 1949, again produced improvement. Sternal marrow puncture produced a fluid poor in cells, in which megakaryocytic nuclei and other marrow cells can be seen. A third course of treatment in June, 1950, did no good. **Necropsy:** Intense fibrosis of marrow in sternum, humerus, and femur, but marrow cells recognizable among the fibrous tissue. Myeloid metaplasia of spleen, very few and small Malpighian bodies; very slight myeloid metaplasia of liver; four ulcers, recent in origin, in jejunum.

Case 4.—A man aged 49 died of weakness, wasting, and anaemia in June, 1945, after six and a half years' observation. Presenting symptom, abdominal discomfort, and large spleen found, January, 1939. Attacks of gout since 1931. Cramps in legs since 1938. Bone x-ray pictures normal. No anaemia. Leucocytes 38,400 per c.mm., immature cells 13%, nucleated red cells 3% of total nucleated cells in circulating blood. Sternal marrow active, May, 1943. X-ray treatment 1939, 1940, 1941, 1942. The first three courses produced very good results, the spleen shrinking, leucocytes diminishing, general health improving, and cramps in the legs disappearing. In 1943 weakness and wasting occurred, and anaemia, which did not respond well to blood transfusions. **Necropsy:** Fine fibrosis of marrow of sternum, ribs, and humerus, with spaces lined by endothelium packed with marrow cells, including large numbers of megakaryocytes. Myeloid metaplasia of spleen, with megakaryocytes; intense myeloid metaplasia of liver; few scattered areas of myeloid metaplasia in kidneys.

Case 5.—A woman aged 67 died of anaemia and heart failure in January, 1949, after five months' observation. Presenting symptoms, weakness and abdominal pains, September, 1948; anaemia and a large spleen found. Circulating leucocytes 8,000 per c.mm., of which 12% were immature cells; 5% of nucleated cells were erythroblasts, and 4% megakaryocytes. Bone x-ray pictures normal. Sternal marrow puncture produced a fluid poor in cells, among which megakaryocytic nuclei were prominent. Poor response to blood transfusions. Megakaryocytes in circulating blood later rose to 21%. Two injections of nitrogen mustard did not help. **Necropsy:** Dense fibrosis of marrow of humerus and sternum, no myeloid metaplasia of liver, intense myeloid metaplasia of spleen, megakaryocytes not conspicuous.

Case 6.—A man aged 71 died of weakness, wasting, and heart failure in March, 1938, after fifteen years' observation. Presenting symptom, abdominal pains, 1923, and large spleen found. No anaemia, no polycythaemia. Leucocytes 16,000 per c.mm.; 31% immature cells, and 4% erythroblasts. No bone x-ray pictures until 1936, when extensive advanced osteosclerosis was found. Cramps in legs 1936 onwards. No

treatment until 1936, when spleen extended nearly to the right anterior superior iliac spine. X-ray treatment caused some shrinkage of spleen. Leucocytes rose greatly at end, being between 40,000 and 90,000 per c.mm., from 1936 to 1938, with monocytes 12 to 25%. **Necropsy:** No other disease found, but only spleen and liver available for section. Intense myeloid metaplasia of spleen, mainly composed of one type of cell, Malpighian bodies absent; intense myeloid metaplasia of liver.

Case 7.—A woman aged 66 died of weakness, wasting, and anaemia in February, 1942, after six and a half years' observation. Presenting symptom, abdominal pains, 1935, and a mass felt in abdomen. At operation, performed on incorrect diagnosis, the mass was found to be a large spleen; a spleniculus was removed for histology. Leucocytes 30,000 per c.mm., 18% immature cells. Cramps in legs 1939–42. Bone x-ray pictures, 1936, showed advanced osteosclerosis. X-ray treatment to spleen and long bones 1938, 1939, 1941. The first course produced excellent results, spleen shrinking, general health improving, and serial x-ray pictures of bones showed diminution in intensity of osteosclerosis, especially after the first course. The second course also did good, the last was ineffective. **Necropsy:** Dense osteosclerosis of sternum, humerus, femur, ribs. Intense myeloid metaplasia of spleen, no visible Malpighian bodies. The spleniculus removed in 1935 showed myeloid metaplasia of pulp, with unaffected Malpighian bodies. Moderate myeloid metaplasia of liver. Intense myeloid metaplasia of lymph nodes from different areas and of lymph tissue in appendix.

Case 8.—A man aged 61 died of wasting, weakness, and anaemia, November, 1940, after one year and four months' observation. Presenting symptoms, tiredness, and irritability of legs, but rarely cramps. Moderate anaemia, total leucocytes normal, constant presence of immature cells and erythroblasts. Bone x-ray pictures normal. Iron and liver extract by mouth were no help. X-ray treatment produced very slight improvement in his health, spleen shrank considerably. Later, blood transfusions produced transient improvement only. **Necropsy:** Fine fibrosis of marrow of sternum and humerus, with endothelium-lined spaces packed with marrow cells; megakaryocytes plentiful. Myeloid metaplasia of spleen; Malpighian bodies not affected. Slight myeloid metaplasia of liver.

Case 9.—A man died of severe anaemia, June, 1952, after two weeks' observation. Presenting symptom, severe arthritis of hands, May, 1952. Moderate enlargement of spleen, purpura of legs and mucous membrane of mouth, severe anaemia, slight leucopenia, immature leucocytes 8%, nucleated red cells 36%. Serum uric acid 8.3 mg. per 100 ml. Sternal marrow puncture produced very few marrow cells. Poor response to large blood transfusion. **Necropsy:** Dense osteosclerosis of sternum and humerus, with practically no marrow cells visible; myeloid metaplasia of liver, spleen, and spleniculus; Malpighian bodies present but small; megakaryocytes not conspicuous.

Summary

A brief account is given of the chief clinical features of patients who have sclerosis of the bone marrow.

Those patients who have large numbers of leucocytes in the circulating blood, with immature cells among them, respond well to x-ray treatment, regardless of the degree of marrow sclerosis.

Serial x-ray photographs of the bones of one patient, before, during, and after x-ray treatment, were taken by Dr. W. H. Coldwell. Sir Alun Rowlands and Professor Clifford Wilson allowed me to see patients with myelosclerosis under their care. I am grateful to these gentlemen for their help.

Medicine

Reduction or obliteration of the bone marrow by connective-tissue proliferation or increased formation of bone occurs in the hereditary childhood condition of osteopetrosis, or marble bone disease of Albers-Schönberg, and also in a non-hereditary adult condition. This latter is probably best known as myelosclerosis, in which myelofibrosis or ossification of the marrow, sometimes called osteosclerosis, may be the predominant feature. The blood picture characteristically accompanying this condition shows leuco-erythroblastosis—defined by Vaughan (1936a) as “an anaemia characterized by the presence in the peripheral blood of unusually immature red cells and a few immature white cells of the myeloid series. The anaemia is not necessarily severe, nor is there usually a marked leucocytosis.” Previous polycythaemia in cases which eventually showed leuco-erythroblastosis and myelosclerosis has been described by Lehndorff and Zak (1907), Hirsch (1935), Vogel, Erf, and Rosenthal (1937), Stone and Woodman (1938), Rosenthal and Bassen (1938), Markoff (1939), Vaughan and Harrison (1939), Thompson and Illyne (1940), Jackson, Lemon, and Parker (1940), Rosenthal and Erf (1943), Stealy and Sumerlin (1944), Windholz and Foster (1947), Marson and Meynell (1949), Merskey (1949), Wyatt and Sommers (1950), and H. N. Robson (personal communication, 1952).

We are here reporting three further cases presenting as polycythaemia and terminating as leuco-erythroblastic anaemia and myelosclerosis.

Case 1

A 69-year-old woman, first seen in May, 1946, complained of pain in the lumbar region and in the hips and calves for one year and an aching mass in the left side of the abdomen for five months. Examination revealed a malar flush with slight cyanosis, a moderately enlarged heart, splenomegaly extending down to the symphysis pubis and across to the right side of the abdomen, and slight hepatomegaly. A blood count showed: red cells, 5,920,000 per c.mm.; Hb, 113%; white cells, 11,600 per c.mm. (premyelocytes 1%, myelocytes 8%, metamyelocytes 4%, neutrophils 68%, eosinophils 3%, basophils 2%, lymphocytes 11%, monocytes 3%); 2 nucleated red cells per 100 white cells; and some polychromasia. Achlorhydria was present, serum calcium was 9.6 mg. per 100 ml., and the Wassermann reaction was negative.

Nearly four years later, in February, 1950, readmission was necessary for pain and weakness of the left leg, frequency and urgency of micturition, and weakness, lassitude, and loss of weight. Ankle oedema with pigmentation and ecchymoses over both legs was present. All other physical signs were unchanged. Liver-function tests and radiographs of the long bones were normal. A blood count showed: red cells, 3,100,000; Hb, 66%; white cells 7,000 (myeloblasts 4.5%, premyelocytes 0.5%, myelocytes 6%, metamyelocytes 0.5%, neutrophils 56%, eosinophils 0.5%, basophils 5%, lymphocytes 16.5%, monocytes 8.5%, atypical monocytes 1.5%, mitotic figures 0.5%); 14 nucleated red cells per 100 white cells; and some macrocytosis. A biopsy of sternal marrow showed myelofibrosis; the haemopoietic tissue was almost entirely replaced by fibrous tissue; of the cellular elements megakaryocytes were present in increased numbers; polymorphonuclear cells with a small number of normoblasts could be seen scattered amongst the fibrous tissue; no haemosiderin could be detected by Perles's stain.

Case 2

A 48-year-old farmer's wife, when first seen in June, 1937, complained of morning hunger pains and three recent attacks of epigastric pain, backache, and vomiting. Examination showed a plethoric facies, slight sclerotic icterus, and splenomegaly extending 8 cm. below the costal margin. A blood count showed: red cells 8,500,000; Hb, 122%; white cells, 9,100 (neutrophils 92%, eosinophils 2.5%, basophils 1.5%, lymphocytes 2%, monocytes 2%); reticulocytes, 0.5–1%; some macrocytosis and moderate anisocytosis. Barium-meal examination showed only displacement of the stomach to the right. The presumptive diagnosis being polycythaemia vera, the spleen was irradiated, with considerable improvement.

Irradiation of the humeri and femora with reduction in the blood count—which had again risen to red cells, 7,500,000; Hb, 128%; white cells, 7,400—was carried out in February and March 1942. She remained fairly well for over three years, apart from several severe epistaxes in January, 1944, and on July 19, 1945. In January, 1946, treatment was necessary for the anaemia, then present—red cells, 3,200,000; Hb, 60%; white cells, 3,000; subsequently her condition remained stationary for over three years. Further treatment for the anaemia was necessary in August, 1949. The blood count showed red cells, 2,500,000; Hb, 48%; white cells, 4,200 (myelocytes 2%, metamyelocytes 6%, neutrophils 55%, eosinophils 4%, basophils 2%, lymphocytes 29%, monocytes 2%); 12 nucleated red cells per 100 white cells; and 3% reticulocytes. The spleen extended almost into the left iliac fossa and the liver to 9 cm. below the costal margin. Radiographs of the skull, pelvis, and long bones showed no abnormality. The red-cell fragility test showed commencing haemolysis in 0.5%

Sternal Marrow Counts

Cells	Case 1	Case 2	Case 3
Blasts	4.0	3.0	2.4
Premyelocytes	1.0	—	0.4
Myelocytes	22.0	15.0	10.0
Metamyelocytes	11.0	13.0	7.2
Neutrophils	41.0	34.0	39.6
Eosinophils	—	2.0	2.8
Basophils	—	—	2.4
Lymphocytes	1.0	21.0	23.6
Monocytes	4.0	—	3.2
Normoblasts	A	—	6.0
“	B	5.0	1.6
“	C	7.0	0.4
Mitoses	1.0	—	0.4
Megakaryocytes	—	—	—
Unclassified	3.0	—	—
Nucleated Cell Count per c.mm.	—	—	6,300
Leuco-Erythroid Ratio	—	—	1.6 : 1
Comment	—	A very poor cellular marrow.	Marrow easily obtained, bone not unduly resistant.

saline and completion in 0.35% solution. Sternal puncture revealed a very poor cellular marrow (see Table).

A biopsy was taken from the eighth rib. On section, the outer compact bone formed a thin layer no more than 2 mm. in thickness; the marrow cavity appeared greyish in the preserved specimen; transverse sections showed a notable fibrosis of the marrow spaces in the peripheral zones and a loose-constructed fibrosis, together with adipose tissue in the centre of the medullary cavity; there was no increase in the bony trabeculation of the rib, and, in fact, in many areas giant-cell osteoclasts was active; there was a marked reduction in haemopoietic tissue, which was mainly confined to one or two islets near the rib cortex; the predominant cells seemed to be eosinophil myelocytes; and there were also many eosinophil polymorphonuclears.

Subsequently she was admitted frequently in 1949, 1950, and 1951 for blood transfusion.

Case 3

A foreman engineer aged 51 was seen in March, 1944, complaining of occasional attacks of gout, recent slight loss of weight, and a left subcostal mass present for two years but only recently causing intermittent pain.

Examination showed only moderate enlargement of the spleen. A blood count showed: red cells, 5,600,000, Hb, 120%; white cells, 13,600 (myelocytes 9%, metamyelocytes 3%, neutrophils 45%, eosinophils 1%, lymphocytes 36%, monocytes 6%); 3 nucleated red cells per 100 white cells; and slight anisocytosis. Achlorhydria was present. Radiographs of the chest, lumbar spine, and pelvis revealed no bony abnormalities.

In September, 1945, the spleen extended into the left iliac fossa and the liver was slightly enlarged; few petechiae were scattered over the body. Irradiation of the spleen was carried out then, and in January, 1947, and in March, 1948, his general condition remaining fair. In March, 1949, he had severe perisplenic pain, general weakness, and acute gout. A blood count showed: red cells, 3,400,000; Hb, 64%; white cells, 9,200 (myelocytes 6%, metamyelocytes 15%, neutrophils 66%, lymphocytes 13%); 9 nucleated red cells per 100 white cells; reticulocytes, 3%; bleeding time, 3½ minutes; and clotting time, 5 minutes. The ribs showed an alteration in the bony texture radiologically, but no destructive process was visible. A sternal marrow biopsy showed myelofibrosis; the bony trabeculae were coarse and compactly arranged; the intervening marrow spaces were filled in some areas by adipose tissue, in others by vascular fibrous tissue; islets of haemopoietic cells were few, small, and widely scattered, and in most places were represented by the presence of a few megakaryocytes.

On his last admission, on September 27, 1949, five and a half years after his first appearance, examination showed

anaemia, gross splenomegaly, moderate hepatomegaly, ascites, basal pulmonary oedema, and gross oedema of the ankles. Death occurred on October 12, 1949.

Necropsy Findings

The lungs showed oedema with congestion of the lower lobes. The heart was dilated, with a pale greasy myocardium. The spleen weighed 2,330 g. Its capsule showed several large and small white opaque patches. On slicing, no Malpighian corpuscles could be seen. The surface showed a pale brick-red appearance with several irregular haemorrhagic zones of varying size. The liver weighed 4,020 g. Its capsule also showed opaque white patches. On slicing, the surface was paler and the consistency firmer than normal. There was an irregular fine whitish mottling, in parts simulating the nutmeg effect. Both kidneys on section were paler than normal. The gastric mucosa showed haemorrhagic patches. Some haemorrhages were also visible in the bladder.

Histology

Rib.—A section of rib showed pronounced osteosclerosis. Thick bony trabeculae were present. In some parts the trabeculae were very wide and the marrow space very small. The marrow was fatty towards the centre of the bone, but showed prominent fibrous areas with spindle-shaped cells, apparently fibroblasts, and groups of red- and white-cell precursors. The precursors were scanty and patchily distributed. Giant cells of the megakaryocytic type were prominent in some of the fibrous areas.

Vertebral Body.—The most striking changes were the presence of loose fibrous marrow and the sparseness of red- and white-cell precursors. Occasional multinucleated giant cells were visible. In some areas the bony trabeculae were wider than normal, but osteosclerosis was less pronounced than in the rib.

Spleen.—The normal splenic architecture was destroyed. Some increase in fibrosis was present. Malpighian bodies were absent. Numerous precursors of the red and white cells were present. Large cells with convoluted nuclei, some polychromatic and vesicular and others hyperchromic, were prominent in some parts, as many as eleven being in one high-power field. Numerous cells with indented nuclei and an eosinophilic slightly granular cytoplasm were also present.

Liver.—This showed scattered foci of leucopoiesis and erythropoiesis, situated mainly around the central vein. Amongst the cells of the granular and erythrocyte series there were large multinucleated cells similar to those found in the bone marrow and spleen.

Kidney.—Small foci of erythropoiesis and leucopoiesis were present.

Discussion

These cases presented the characteristic symptomatology, splenomegaly, and other physical signs and haematological features of polycythaemia vera, and resembled others described in that the polycythaemic blood-count figures were not very high.

The development of anaemia in the later stages of polycythaemia has often been noted. Minot and Buckman (1923) described a “secondary” anaemia, but the report of immature red and white cells in the blood suggests that this may have been leuco-erythroblastic anaemia. Several other authors have described the development of a typical leuco-erythroblastic anaemia. It is possible that the leuco-erythroblastic state has often been missed, for McMichael and Mc-Nee (1936) considered that repeated examination of the blood might be required to detect primitive red and white cells owing to the variations and fluctuations in the haematological features. In Case 2, unlike the others, immature red and white cells were not observed until the anaemic phase. As in the other cases mentioned above, myelosclerosis was found during the period of leuco-erythroblastosis. Recently, however, Hutt (1950) and Marson and Meynell (1952) in two cases discovered fibrosis of the sternal

marrow during actual polycythaemia. Cases of myelosclerosis with leuco-erythroblastic anaemia, but without previously recorded polycythaemia, have been reported by several authors, including Stephens and Bredeck (1933) and Rosenthal and Erf (1943).

A common feature of these cases, both with and without previous polycythaemia, has been the presence of myeloid metaplasia in the spleen. Numerous authors have commented on this—for example, Chapman (1933) found extramedullary hyperplasia of myeloid tissue described in 11 out of 14 reported cases. Askanazy (1904) apparently was among the first to indicate that reticulo-endothelial cells could become blood-forming cells in adults, while Hirschfeld (1905) recognized the importance of this myeloid metaplasia as a unifying feature of the cases. In the metaplasia Carpenter and Flory (1941) pointed out that, "in addition to leucoblastic cells, erythroblasts are constantly prominent and giant cells (megakaryocytes) are numerous." Most accounts, with the notable exception of that of Heller, Lewisohn, and Palin (1947), are in agreement with the view that all haemopoietic tissues are involved.

Vaughan (1936b) summarized 17 cases of myelosclerosis: in only one of the 14 cases in which necropsy or biopsy was performed was no myeloid metaplasia found in the spleen. Stephens and Bredeck (1933) collected 24 cases from the literature—19 of which were complete enough to be tabulated—and found that these latter showed splenomegaly, myelosclerosis, and myelaemia, and all but one showed normoblastaemia.

Despite the frequency of the occurrence together of myelosclerosis, leuco-erythroblastosis, myeloid metaplasia in the spleen, and megakaryocytic prominence in the spleen and marrow, which perusal of the literature reveals, the establishment of the syndrome comprising them has been rendered difficult by different authors emphasizing in their titles various characteristic features in these essentially similar cases.

The Syndrome

The morphological, haematological, and clinical features of this polymorphic leukaemia-like syndrome have been discussed by Heller *et al.* (1947). The condition, they say, is characterized clinically by a slowly progressive splenomegaly occurring in persons of either sex, usually within or beyond the fifth decade of life. There may be little impairment in the general health for many years, following which generalized weakness, anorexia, weight loss, ill-defined aches and pains, and discomfort occasioned by the greatly enlarged spleen frequently occur. The liver may enlarge. As a rule there is no significant involvement of the lymph nodes. The blood picture, according to Carpenter and Flory (1941), displays widely varying conditions from a rare initial polycythaemia to varying grades of anaemia, usually normochromic, but occasionally hypochromic; nucleated red cells have been prominent in all but a few cases. Immature red cells have not been seen in the peripheral blood in some cases—for example, Tudhope (1937) and Heller *et al.* (1947). Macrocytosis has occurred in the cases of Carpenter and Flory (1941), Heller *et al.* (1947), Robson (personal communication, 1952), and our Cases 1 and 2. Lindeboom (1938) thought that polychromasia, poikilocytosis, and anisocytosis were more pronounced in these cases than would be expected for the degree of anaemia.

The total white-cell count, according to Thompson and Illyne (1940), is rarely very high and is almost always well below the levels seen in untreated leukaemia. Myelocytes in the peripheral blood are rarely numerous. Occasionally, immature white cells have been absent from the blood as in the cases of Hewer (1937), Tudhope (1937), and Heller *et al.* (1947). Bleeding has occurred in several cases both with and without reported decreases in platelets (Hickling, 1937; Thompson and Illyne, 1940; Carpenter and Flory, 1941; and Heller *et al.*, 1947). Abnormal platelets, megakaryocytic fragments, and megakaryoblasts were observed by Hickling (1937), Carpenter and Flory (1941), Rosenthal and Erf (1943), and Heller *et al.* (1947). Other inconstant

features such as increased fragility of the red cells, slight reticulocytosis, positive indirect van den Bergh reaction, and high blood uric acid levels have been occasionally reported.

In several cases the liver as well as the spleen has been the seat of a myeloid change—for example, McMichael and McNee (1936), Hickling (1937), and Stone and Woodman (1938). This has been found commonly in the dilated sinusoids, but also in the periportal areas or peripherally between adjacent lobules. Less frequently the lymph nodes have been involved as well, as reported by Stone and Woodman (1938), Vaughan and Harrison (1939), and Rosenthal and Erf (1943). Fibrosis of the spleen has also been described by Stone and Woodman (1938) and Jackson *et al.* (1940). Our Case 3 showed some fibrosis in the myeloid metaplasia of the spleen; the liver showed the metaplastic reaction mainly around the central vein.

The bone marrow has not been reported as myelosclerotic in all cases showing leuco-erythroblastic anaemia, splenomegaly, myeloid metaplasia, and symptoms of long duration. How far this may have been due to incomplete examination of the bones cannot now be decided. In nine cases of this syndrome called by them "agnogenic myeloid metaplasia" Jackson *et al.* (1940) described the bone marrow as myelosclerotic in six and hyperplastic, aplastic, and normal in the others. Similar variation is found in the literature, but most frequently the marrow is hypoplastic. Sometimes "hyperplastic foci of haematopoiesis" have been scattered through the fibrotic elements; in a few cases hyperplastic myeloid tissue and fibrosis have been recognized together.

In regard to the sequence of events in the marrow, Wyatt and Sommers (1950), analysing 30 cases, regarded the fundamental lesion as necrosis of partly matured erythroid and myeloid cells with hyperplasia of surviving, usually more immature, cells and marrow reticulum cells. Subsequently, foci of atrophy appear. Eventually "the marrow is relatively acellular, made up of scattered reticulum cells, between which is a pink fibrillar or granular matrix and with numerous dilated empty vessels surrounded by small groups of bizarre megakaryocytes or nondescript haematopoietic cells." The end stage in certain cases involves a distinct type of new bone formation with "focal granular deposits of calcium in the eosinophilic matrix" and later deposition of bone in a layer about part or all of the old trabecular surfaces. The bony radiographic appearances of myelosclerosis have been described by Sussman (1947) as initially widening and increased density of the trabeculae followed by deposition of bone in an irregular fashion throughout the marrow cavity without thickening of the cortices or periosteal reaction.

Nature and Pathogenesis

Most authors, with the notable exception of Heller *et al.* (1947), believe this syndrome to be a separate entity and not merely a variant of leukaemia. Carpenter and Flory (1941) listed the principal features which have been held to differentiate this syndrome from leukaemic myelosis (myelogenous leukaemia) as (1) the diversity of cell types in metaplastic zones in organs and in the bone marrow; (2) the commonly low white-cell count with the low proportion of circulating primitive cells; (3) the almost constant presence of nucleated red cells; (4) the frequency with which osteosclerosis and myelofibrosis are encountered; and (5) the absence of characteristic leukaemic infiltrations. Further differentiation from leukaemia has been made by Erf and Herbut (1944), who pointed out that "extramedullary haematopoiesis is a focus of normal bone marrow situated elsewhere than within bone and attempting to produce normal circulating red and white cells," whereas "leukaemic infiltration is a focus of infiltrating immature white blood cells which because of their inherent reproducing capacities produce more immature white cells." They have also drawn attention to the large numbers of giant cells in the metaplastic myeloid tissue in the organs. In view of its asso-

ciation at times with tuberculosis of the spleen (Swirski-shewskaja, 1926), generalized infections (Brannan, 1927), and malignant metastatic deposits in the bone marrow (Hickling, 1937), it would appear that extramedullary haematopoiesis cannot be regarded simply as compensatory to the marrow sclerosis. Indeed, as Heller *et al.* (1947) have pointed out, more severe and persistent anaemias of other types do not occasion the massive extramedullary haematopoiesis found in myelosclerosis.

The myelosclerosis has been thought to result from an unknown toxin (Donhauser, 1908), the irritative effect of hyperplastic myeloid tissue (Hewer, 1937), or atrophy of the marrow (Wolf, 1932); it has been found in association with haemolytic anaemia (Wyatt and Sommers, 1950), metastatic carcinomatous deposits (Thompson and Illyne, 1940; Erf and Herbut, 1944), and tuberculosis (Hewer, 1937; Stone and Woodman, 1938). Windholz and Foster (1947) suggested the importance of Rh factor serological studies.

We agree with Vaughan and Harrison (1939) that the sclerosis of the marrow follows the same stimulus as produces extramedullary haematopoiesis. In other words the myelosclerosis is a dynamic process resulting from a definite stimulus rather than a sequel to atrophy of haematopoietic elements. The stimulus might be a deficiency in some nutritional factor, either direct or conditioned by other disease, or an abnormal metabolite. As pointed out by Vaughan and Harrison (1939) all the cell types involved in the hyperplasia are derived from a common source—the primitive reticulum-cell of Maximow. A common stimulus might therefore affect in degrees, varying from patient to patient, the osteoblasts, fibroblasts, the several series of haematopoietic cells, and megakaryocytes.

From this basic pathological process with diverse morphological possibilities a complex clinical and haematological syndrome results, not every case of which, as might be expected, will show all the various features recognized as characteristic. In this respect, Robson's case (personal communication, 1952) is of interest. Initially a sternal trephine was obtained showing marked osteosclerosis and megakaryocytosis with fibrosis, the blood picture being leuco-erythroblastic anaemia, and the spleen and liver showing myeloid metaplasia. Subsequently the blood count reached polycythaemic levels. Finally, at necropsy, three years after the onset, the marrow was seen to have reverted to a hyperplastic state with megakaryocytes still numerous, and some fibrosis still remaining but with little sign of the previous osteosclerosis, while the spleen and liver still showed metaplasia. In another case subsequent polycythaemia was described by McMichael and McNee (1936) 17 months after splenectomy had been undertaken for splenomegaly, myeloid metaplasia, and leuco-erythroblastic anaemia.

An indication of this diagnosis may be obtained during the investigation of obscure anaemia by the finding of difficulty in obtaining marrow from a sternal puncture and the absence of the characteristic "give" which occurs normally when the needle has penetrated to the marrow cavity. Most important, however, is the performance of marrow biopsy in cases showing features suggestive of the syndrome, or where sternal puncture fails.

Summary

Three cases of polycythaemia in two women aged 69 and 48 and a man aged 51, are described. Leuco-erythroblastic anaemia and myelosclerosis subsequently developed after 4, 12, and 5 years respectively.

Previous reports of leuco-erythroblastosis with myeloid metaplasia and myelosclerosis following polycythaemia vera are reviewed.

The syndrome, comprising leuco-erythroblastosis, myeloid metaplasia, and myelosclerosis, as revealed in the literature, has a varied clinical picture. It is thought to be distinct from myeloid leukaemia.

Vaughan and Harrison's view of the concomitant development from a common source—the primitive reticulum-cell of Maximow—of extramedullary haematopoieses and of myelosclerosis following some, as yet unknown, stimulus offers a reasonable explanation of the events.

We wish to thank Dr. L. Howells, Professor S. J. Hartfall, and Dr. J. R. H. Towers for permission to publish these cases, and Professor J. Gough and Dr. D. H. Collins for advice and criticism. We are grateful to Dr. D. H. Collins and Dr. T. W. Sutherland for haematological and pathological data in Cases 2 and 3.

New regulations enable penicillin and aureomycin (the latter in a restricted form) to be used in the food of pigs and poultry, subject to certain safeguards. Both these preparations are controlled under the Penicillin Act, 1947, so that their retail distribution is otherwise limited to supplies given by, or under the direction of, doctors, dentists, and veterinary surgeons, or dispensed on their authority by pharmacists. The regulations have been made after consultation with the Medical Research Council and Agricultural Research Council, and come into operation on September 1. The antibiotics may be used either in the form of a supplement to be added to existing food or ready mixed with the food by the manufacturers of pig and poultry food. Safeguards to health are provided for in that (a) only minute quantities are needed and a maximum concentration is specified for both the supplement and the feeding-stuffs, and (b) the appropriate Health Minister must approve the composition of the diluent of the supplement. It will not be practicable to extract the antibiotic for use as medicine. These arrangements will not affect medical supplies. There is plenty of penicillin, and aureomycin will be used in the form of the residue from the process of extraction or in any other approved dilute preparation. The regulations also require certain information relating to the supplement and the antibiotic included to be given on the labels of the containers in such manner as the appropriate Agriculture Minister may require; they also empower him to require additional information to be given about the storage and use of supplement. The regulations apply to England and Wales, Scotland, and Northern Ireland, and are entitled the Therapeutic Substances (Supply of Antibiotics for Agricultural Purposes) Regulations, 1953.

SOME COMPLICATIONS OF TEMPORAL ARTERITIS

BY

DAVID KENDALL, D.M., M.R.C.P.

Neurologist, Royal Surrey County Hospital

The first clear description of the condition known as temporal arteritis appeared in the article on intracranial aneurysm by Schmidt (1930); he did not, however, recognize the condition present. The disease was first fully described by Horton, Magath, and Brown (1932). Since that time many cases have been recorded, and it has become clear that the term temporal arteritis is an inadequate one, for the disease consists of a widespread arteritis affecting predominantly the branches of the external and internal carotid vessels (Bénard, Rambert, and Pestel, 1949), but in addition there has been evidence of arteritis elsewhere (Cooke, Cloake, Govan, and Colbeck, 1946; Cardell and Hanley, 1951).

Nothing is known of the fundamental aetiology of the disease; that it is allied to polyarteritis nodosa seems likely, but the changes in the affected vessels are not identical: the condition runs a more benign course and tends to affect very much older subjects than the latter condition.

The general course of the illness follows a fairly constant pattern. The subjects are usually elderly—average age 65 (Harrison, 1948)—and men and women are affected in approximately equal numbers. The onset is often insidious, with increasing malaise, mild fever, and pain in the head of variable intensity. When this pain is severe the slightest contact with the scalp at the site of pain may be unbearable, brushing or combing the hair may be very painful, and there may be pain on moving the jaw (Hoyt, Perera, and Kauvar, 1941; Bénard *et al.*, 1949).

In an uncomplicated case the pain and tenderness gradually subside, usually over a period of many weeks, and the general constitutional disturbance likewise resolves. In a high proportion of cases, however, other manifestations appear, and it is often these complications that cause the patient first to seek medical advice. Ocular complications are common. Wagener (1946) found visual disturbance in 18 of 37 patients; Bruce (1950) reported ocular involvement in 34 of 84 patients. Unilateral or bilateral blindness is common and is usually of sudden onset. Isolated sector defects may appear in the field of vision of one eye; there may be ocular palsy. Vertigo has been reported (Cooke *et al.*, 1946), there may be affection of the skin along the course of the temporal vessels, and small multiple ulcerative lesions of the nasal and buccal mucous membranes have been observed by Schweitzer and de Yong (1949).

Laboratory tests give variable results: there is a fairly constant rise in the erythrocyte sedimentation rate, there may be a slight polymorphonuclear leucocytosis, and an eosinophilia has been found by Hoyt *et al.* (1941).

Biopsy of a section of thrombosed temporal artery confirms the diagnosis. The affected vessel shows marked intimal thickening; infiltration of the media with lymphocytes, plasma cells, and at times giant cells; fragmentation of the elastic lamina of the media; and a thrombus in the lumen of the vessel in a varying state of organization and recanalization.

A description is here given of nine patients who suffered from temporal arteritis. It is of interest that all were country dwellers—an observation also made by Horton *et al.* (1932) and by Cohen and Harrison (1948).

Case 1

A woman aged 78, while recovering from a severe exacerbation of arthritis of the hips, wrists, and fingers in January, 1951, had intense temporal headache associated with intermittent fever to 102° F. (38.9° C.), a constant tachycardia of 100–120, anorexia, and loss of weight. The intensity of the pain increased, and the mere contact of any part of the head with the pillow became unbearable. Brushing the hair was impossible. She was at times mildly confused and delirious. Four weeks after the onset she awoke to find that vision was misty in each eye and within 48 hours all sight was lost. Examination at this time showed a considerable degree of emaciation. The whole scalp was acutely tender, and in all areas of the scalp thrombosed vessels could be felt. Both facial arteries were tender and non-pulsatile. Vision was lost in each eye; the pupils were of medium size and inactive to light. The optic disks were pale and the retinal arteries narrow and very tortuous. The peripheral vessels were sclerotic and the blood pressure was 150/70. There was widespread osteoarthritis, affecting the hands in particular.

One month later the pain and constitutional symptoms were subsiding. She had, however, developed an extensive area of necrosis of the scalp in the right parietal region near the vertex (see illustration). There was necrosis of the nasal septum, with a large perforation of the cartilage and offensive discharge.

The scalp healed very slowly over a period of four months, and the nasal discharge ceased. Nine months from the onset the patient was well although quite blind.

Photograph of Case 1 showing area of necrosis of scalp.

Comment.—The extent of the involvement of the scalp vessels seems to have been of a quite unusual severity—sufficient for a time to deprive one area of the scalp of an adequate blood supply.

Case 2

A woman aged 72 complained in July, 1948, of severe right-sided headaches and tenderness of the temporal region. Her past health had been good apart from severe arthritis of the spine and fingers. The onset of symptoms was gradual, with mild fever to 100° F. (37.8° C.) at times, and a tachycardia of about 120. When seen by me seven weeks from the onset she was pale, ill, and wasted. There was moderate tenderness of the right side of the scalp, the temporal vessels being hard, tender, tortuous, and non-pulsatile. The blood pressure was 220/120.

Salicylates gave some relief of pain, and the tenderness subsided in about one month. Three months later, while doing housework, she suddenly found that sight had failed

in the left eye. When seen one week later the left optic disk was pale, there was no perception of light, and the pupil did not react to direct illumination. The eye has since remained blind.

Comment.—The long interval between the onset of symptoms and the occurrence of blindness is by no means unusual. The part played by temporal arteritis may not at first be apparent if the symptoms have been slight.

Case 3

A man aged 66 was seen in August, 1949, complaining of intense left- and right-sided head pain of two weeks' duration, and giddiness and nausea of two days' duration. The onset of the latter symptoms had been sudden on rising in the morning. The giddiness was almost constant, with a feeling of being pulled to the left side, and was associated with a ringing tinnitus in the left ear.

Examination showed extensive thrombosis of the temporal vessels, mainly on the left side, with great tenderness. There was a coarse nystagmus to the left, and a moderate degree of nerve deafness on that side. The whole of the left side of the face did not move as well as the right. A blood count showed 26% of eosinophils in a total of 11,000 white corpuscles. The E.S.R. was 60 mm. in the first hour. A segment of the left temporal artery was removed under local analgesia with considerable resultant relief of pain. Section of the vessel showed typical changes of temporal arteritis.

The vertigo lasted about two weeks, at the end of which time there was considerable improvement. When he was seen six months later there was a mild degree of nerve deafness on the left side. There were no other symptoms.

Case 4

A man aged 78 was first seen in May, 1950, complaining of bitemporal pain and pain in the neck for two weeks, and loss of vision in the right eye for one week and in the left eye for two days. The onset had been gradual, with soreness in the temporal and occipital regions. After one week he noticed a dark patch in front of the right eye, and on waking next morning the eye was completely blind. Five days later he awoke to find the left eye blind. There had been no constitutional disturbance.

On examination the temporal and occipital vessels were tender and tortuous, but pulsatile. There was no perception of light in either eye, and the pupils were inactive. The right optic disk was pale. The blood pressure was 170/100. No other symptoms or signs developed, and he was well but blind five months later.

Case 5

A woman aged 69 started to complain in February, 1952, of severe pain on the right side of the head, pain on moving the jaw, and a recurrence of arthritis of the fingers, hips, and knees. Her symptoms gradually increased, and after four weeks she complained of double vision; this was followed by complete closure of the right eyelid.

On examination there was extensive bilateral thrombosis of the temporal vessels, the skin overlying the vessels was red and shiny, and the vessels were extremely tender. Tenderness was present over both temporo-mandibular joints. The temperature was 101° F. (38.3° C.) and pulse 110. There was much sweating. On the right side was a complete paralysis of the third cranial nerve. A blood count was normal, but the E.S.R. was raised to 40 mm. in the first hour.

Salicylates relieved the pain a little, and this subsided during the next six weeks. When seen in May, 1952, there was a partial right third-nerve paralysis, with dilated fixed pupil, incomplete ptosis, and defective adduction of the globe.

Case 6

A man aged 82 complained in March, 1952, of headache and soreness of the scalp which interfered with his sleep

owing to the pressure of the pillow. There was, however, no major constitutional upset and he continued to lead an active life. Six weeks later, while weeding his garden, he noticed that the left eye was blurred, and very shortly afterwards the right eye was likewise affected. Within 24 hours all vision had been lost. When seen one week later there was bilateral optic atrophy with no perception of light. The pupils were large and inactive. The temporal vessels on both sides were thrombosed and tortuous, but were not tender. The blood pressure was 190/100. A blood film was normal. Two months later the patient was well but blind.

Case 7

A woman aged 73 was seen in May, 1952. Three months earlier she started to complain of "fibrositis" all over her head. After a week or two she noticed numerous tender "knobs" in the temporal regions and at the back of her head. The pain and tenderness persisted for about six weeks. Three weeks before attending hospital she noticed an appearance as if a spider's web were before the left eye; one week later, on waking, she could only see downwards and to the left with the left eye.

Examination showed numerous nodular thromboses in the temporal and occipital vessels, some of which were still somewhat tender. The left optic disk was pale. There was perception of hand movements with the left eye in the lower temporal field only. The left pupil reacted sluggishly to direct illumination. A blood count showed a mild normocytic anaemia with a leucocytosis of 11,500 per c.mm. The differential count was normal. The E.S.R. was 99 mm. in the first hour.

One month later her vision had improved to 6/60 with the left eye, and the density of the visual field disturbance was diminished.

Comment.—The incompleteness of the visual loss and its tendency to recover suggests, in the absence of obvious retinal change, that there was an incomplete or transitory occlusion of the central retinal artery.

Case 8

A man aged 72 developed in September, 1951, pain in the head of diffuse nature with malaise, anorexia, and slight fever. The pain increased in severity, and after two weeks he awoke to find that he was blind.

Examination showed tender thrombosed temporal vessels with some reddening of the overlying skin. There was no perception of light in either eye, and the pupils were dilated and fixed. The optic disks were normal. The blood pressure was 200/110. The constitutional and local symptoms subsided rapidly, leaving the patient permanently blind.

Case 9

This patient, a woman aged 78, was one of nine further patients suffering from temporal arteritis, in none of whom was there any central nervous complication. The history and findings in her case were typical of this group. She first complained of headache in the occipital and left temporal region in November, 1951. This symptom increased, and after 8 to 10 weeks there was complete loss of appetite. The pain was now severe and prevented sleep. A moderate bilateral conjunctivitis had developed. Her temperature was 100° F. (37.8° C.) and pulse 110. There was tenderness over the left temporal vessels, which were thrombosed and tortuous. Any contact or draught on the left side of the head was resented. The blood pressure was 220/120. A blood count showed: haemoglobin, 80%; white cells, 15,800 per c.mm. (87% polymorphs); E.S.R., 54 mm. in the first hour.

There was a quite rapid symptomatic and clinical improvement following the administration of mist. sod. salicyl. (N.F.). After four weeks the scalp tenderness was barely perceptible and appetite was returning. There was no fever.

Six weeks later her weight was increasing and pulsation could be felt in the previously occluded vessels.

Summary

The clinical course of nine patients suffering from temporal arteritis is described. The following points emerge: the patients are without exception elderly, often of arthritic disposition, and arteriosclerotic; the disease runs a protracted though benign course but may leave permanent damage to vision; temporal arteritis is a not uncommon cause of sudden visual failure in the elderly, and the underlying disease may be overlooked if the symptoms have not been severe or if they have occurred some weeks or months before; salicylates are of value, at least in the relief of symptoms. The ischaemia of the scalp may be sufficient to result in necrosis.

DIETARY "FIBRE" AND PREGNANCY TOXAEMIA†

BY

EBEN H. HIPSLEY, M.B., B.S.

(From the Australian Institute of Anatomy, Commonwealth Department of Health, Canberra, Australia)

Amongst the numerous hypotheses which have been put forward from time to time to account for the cause of pregnancy toxæmia is the "dietary" hypothesis. The most consistent advocates of this have been Theobald in the United Kingdom and Dieckmann in the United States.

Despite the fact that a consideration of the possible dietary factors has so far been unproductive of conclusions on the role of any one factor in the cause of the disease, the evidence indicates that a relationship of diet with toxæmia exists. The problem is to examine all the facts where the relationship seems to exist and try to fit them into a unified pattern.

A study of the literature reveals observations which apparently cannot be reconciled. For example, Ebbs, Tisdall, and Scott (1941) found that toxæmia and the incidence of stillbirth and neonatal deaths are more common in women with "poor" diets than in those with "good" diets or in those with poor diets supplemented throughout pregnancy with oranges, tomato pulp, wheat germ, milk, and vitamin D. How are these findings to be reconciled with the observation that toxæmia is very rare in some native populations living on so-called poor diets, and also with the findings that

the incidence of eclampsia fell in Germany during the last two years of the 1914-18 war, and in the Netherlands during the 1939-45 war—that is, in periods of relative famine?

Diet and Toxaemia in Sydney

In a review of the monthly incidence of eclampsia in two hospitals in Sydney during the period 1938-45 I showed that eclampsia was more common from May to September (winter), when fruit and vegetables were scarce, than it was from November to March (summer) (Hipsley, 1949). In 1942, when there was a severe shortage of vegetables, the incidence of eclampsia was comparatively high, and the combined stillbirth and neonatal deaths reached record heights. The notion that this shortage may have contributed to the increased morbidity was strengthened by experience in New Guinea, where it was noted that native diets are predominantly vegetarian and that toxæmia is very rare. These observations suggested that there may have been a dietary factor which operated in the diet of peasant vegetarian communities and in the good diets of civilized communities but was apparently absent from poor diets of civilized communities.

Eclampsia in the Fiji Islands

In 1950 Bell and Wills noted a pronounced racial difference in the incidence of eclampsia between the indigenous Fijians and the Indians living in Fiji. In the three years 1947-9 there were 18 cases of eclampsia in 1,106 Indian confinements, while there were no cases in the same period in 717 confinements of Fijians. In 1949 there were 27 cases of pre-eclampsia in 416 Indian confinements, but no cases in 266 Fijian confinements.

The indigenous Fijians and the Indians living in the Fiji Islands are each a well-defined racial group differing widely in social, religious, and dietary habits. Such a situation seemed to offer a unique opportunity for the study of the dietary background of the disease. The staple food of the Fijian is a starchy fruit vegetable of which relatively large quantities are eaten, together with bananas, coconut, papaw, leafy greens, and small quantities of meat, fish, and crabs. The important foodstuffs in the Indian diet are flour (sharps), white rice, coconut oil, ghee, sugar, with small quantities of dhal, meat, milk, vegetables, and fruit. The bulk of this diet consists of the refined foodstuffs, white rice and flour (sharps).

A comparison of the diets of the two races shows that they differ greatly in "fibre" content (see Table I). This observation, together with the Sydney observations previ-

TABLE I.—Fibre Content of Diets of Indians Living in Fiji Compared with New Guinea Diets

Indian*				New Guinea†			
Foodstuff	g./Day/Head	Fibre† g./Day	Calories	Foodstuff	g./Day/Head	Fibre† g./Day	Calories
Bread	7.8	V.L.		Taro	106	1.80

		>0.9	1,000			8.2	1,000

* Bell and Wills, 1950.

† No quantitative assessment of Fijian diets is available. Quantitative data for Kaviaria (a village in the Trobriand Islands) have been used (see Report on the New Guinea Nutrition Survey Expedition, 1947. Department of Territories, Commonwealth of Australia, 1950.)

‡ The calculations for the fibre content of diets have been made using tables published by Nicholls (1951).

V.L.=Very little.

ously mentioned, suggested that further evidence be sought on whether a deficiency of dietary fibre could be concerned in the causation of toxæmia.

It was of interest to find out whether the incidence of eclampsia was high in the areas from which the Indians living in Fiji had emigrated—that is, Southern India—and whether the diets were similar. Mudaliar (1938) states that there were 148 cases of eclampsia in two years at his hospital in Madras; and Indian obstetricians who have worked in Southern India are unanimous in stating that eclampsia is very common there, and much more common in the cities than in the rural areas. Dr. Sunanda Bai (1952), an obstetrician who has worked in both the southern and the northern provinces of India, states that eclampsia is much less common in the northern provinces, especially in the Punjab, "where the diet is much better balanced and contains home-pounded wheat (instead of flour), more vegetables, more fruit, and more milk." Theobald (1946) has drawn attention to the very high incidence of eclampsia in the native population of Colombo (Ceylon), where the diet pattern is very similar to that of Southern India.

On the other hand, the diet pattern of the Fijians resembles closely that of the natives of New Guinea, amongst whom toxæmia is a rare disease.

Eclampsia and the Diet of Other Native Communities

Among the natives of the Transkei eclampsia is rare. The diet consists of meal porridge, milk, eggs, and a very small amount of meat (Crichton, 1947).

From reliable authorities, all of whom have had considerable experience in medical work in various native communities, information has been collected concerning the incidence of eclampsia and the diet pattern. Professor J. H. de Haas (1952), of Leyden, said that pregnancy toxæmia was very rare in Java. There the diet consisted of crudely milled and pounded rice, starchy root vegetables, some maize, and some leafy greens. Where fish was available this was eaten. Pregnancy toxæmia was very uncommon in the Celebes according to Dr. de Wijn (1952), of Leyden. The diet consisted mainly of home-pounded rice, leafy greens, coconut, and only a small quantity of starchy root vegetables, melons, and fruit. On the coast some fish was eaten. It is noteworthy that in these communities, where toxæmia was uncommon, the diet was comparatively rich in fibre.

Trends in Eclampsia in War-stricken Countries

One of the most notable features of eclampsia is that the incidence has been observed to vary in the same geographical area, apparently as a result of a marked change in the environment. Thus a change in eclampsia incidence has been particularly noticeable in war-stricken countries. The effect of war has been by no means consistent: apparently it has sometimes been adverse and at other times beneficial.

Hong Kong.—King and Ride (1945) reported that in Hong Kong in 1940-1 there was a striking increase in the incidence of eclampsia, reaching almost epidemic proportions. This coincided with a serious outbreak of beriberi. Eclampsia

TABLE II.—Showing Correlation of Fibre Content of Diet with Incidence of Eclampsia or Pregnancy Toxaemia

Group	Description of Diet	Dietary Fibre Grading*	Eclampsia† or Toxaemia	Authority
New Guinea natives	Starchy roots, green leaves, nuts, fruit, plus small amounts of fish and meat	++++	0	Hipsley (1949); Bell and Wills (1950)
Fijians	Home-pounded wheat, starchy roots, pumpkin, fruit, plus a little milk	++++	+	Bai (1952)
Transkei (South Africa)	Meal porridge, milk, eggs, and small amount of meat	++++	0	Crichton (1947)
Java	Home-pounded rice, green leaves, maize, starchy roots, little fish	++++	+	de Haas (1952)
Celebes	Home-pounded rice, greens, coconut. Small amounts of vegetables, melons, and fruit	+	++++	de Wijn (1952)
Indians (Fiji)	Polished rice, flour (sharps), ghee, coconut oil, dhal. Small amounts sugar, meat, and vegetables	+	++++	Bell and Wills (1950)
Indians (South India)	Ditto	+	++++	Mudaliar (1938); Bai (1952)
Colombo	Ditto	+	++++	Theobald (1946)
Europeans (Toronto) "poor" diet group	Inexpensive high-energy-yielding foods. Minimum of "protective" fruit and vegetables which are more costly	Increased	Reduced	Ebbs, Tisdall, and Scott (1941)
Europeans (Toronto) "good" diet group	Increased consumption of fruit and vegetables			

TABLE III.—Showing the Apparent Effect of a Change in Fibre Content of the Diet on the Incidence of Eclampsia or Toxaemia

Group	Period of Change	Dietary Change	Dietary Fibre Grading*	Eclampsia† or Toxaemia	Authority
Hong Kong	1939	Mixed diet	+++	++	King and Ride (1945)
	1940-1	To polished rice	+	+++	
	1945	To mixed diet	+++	++	
Netherlands	1940	Mixed diet (70% extra bread)	+	Reduced	Holmer (1947)
	1944	To food shortage (90% extra bread) and starchy roots and vegetables	+	Increased	
		To relief of famine, refined high-calorie foods (70% extra bread)	+	Reduced	
Scotland	1939	Mixed diet containing 70% extra bread	+++	+	Baird (1952)
	1942 et seq.	To 85% extraction bread and more vegetables	+++	+	
			+++	+	
Sydney	1939	Mixed diet	+++	+	Hipsley (1949)
	1942	To acute shortage of vegetables	+++	+	
	1943	To normal mixed diet	+++	+	
"	Summer	Mixed diet containing moderate fruit and vegetables	+++	Increased	Hamlin (1952)
	Winter	To reduced consumption of fruit and vegetables	++	+	
	Control of weight gain in pregnancy	Restriction of concentrated high-energy foods with increased consumption of fruit and vegetables	++	0	

* Fibre grading (approximate): ++++ Very high=above 4 g./1,000 cal. +++ High=2-4 g./1,000 cal. ++ Moderate=1-2 g./1,000 cal. + Low=below 1 g./1,000 cal.

† Incidence of eclampsia (approximate): ++++ Very high=8 eclampsias/1,000 deliveries. +++ High=2-8 eclampsias/1,000 deliveries. ++ Moderate=1-2 eclampsias/1,000 deliveries. + Low=below 1 eclampsia/1,000 deliveries. 0 Absent or very low.

*The term "fibre" as used in this paper includes lignin, cellulose, and the hemicelluloses.

†Some of this work was carried out during the tenure of a World Health Organization Fellowship in 1952, but the statements made and the opinions expressed are not necessarily those of the Organization.

was particularly common in the beriberi cases, and Browne (1944) has commented that the data of King and Ride show that eclampsia was 50 times more common in women with beriberi than in those without it. On the other hand, vitamin B₁ has proved valueless either in the prevention or in the treatment of the disease. It is of interest to examine the changes in diet which resulted in this increase of beriberi. King and Ride state that there was a change from a relatively mixed diet to one of polished rice, owing to an influx of refugees from war areas, with consequent poverty and overcrowding of the city. After the war the eclampsia had declined to the original 1938 level, and the beriberi incidence had declined also (King, 1947). Burgess (1952) has pointed out that since the war less white rice has been available in Hong Kong. The change in the fibre content of the diets of Hong Kong would seem to run parallel with the change in the incidence of eclampsia.

Netherlands.—Contrary to experience in Hong Kong, the impact of war apparently had a beneficial effect on the incidence of eclampsia. Holmer (1947) and Duncan, Baird, and Thomson (1952), the latter using data supplied by Posthuma and others, have reported that the incidence of toxæmia fell in the Netherlands from 1940 to 1945, but rose again after the war to almost its pre-war level. Holmer states that in Holland during the food shortages pregnant women did remarkably well. There were few cases of eclampsia, but immediately after the relief of the famine he saw seven cases, three of which were fatal. The first food distributed to the starved population had a high caloric value, and consisted mainly of fats, protein, and sugar; it was also very salty. During the war the diet pattern in the Netherlands altered as food became scarcer. Bread, which before the war was made from 70% extraction flour, was made from flour which at times was 90–95% extraction; turnips and potatoes became much more prominent in the diet; and in 1944, during the worst period of famine, even linseed meal, tulip bulbs, and sugar beets were eaten. There is no doubt that the fibre content of the diet increased from 1940 to 1944 and has decreased again since that date.

Scotland.—Duncan, Baird, and Thomson (1952) have shown that in Scotland from 1943 onwards a steady and considerable fall occurred in the stillbirth rates resulting from toxæmia. This fall they attributed to "improvement from 1941 onwards in the efficiency of the physiological mechanisms which govern the growth and vitality of the foetus." They thought the improvement was unlikely to have been due to better antenatal care, but was probably due to improved economic conditions, assisted by the effects of scientific rationing. An important widespread change in the diet was the change from 72% extraction bread to 85% early in 1942. The fibre content of 70% extraction flour is negligible, while that of 85% extraction is 1%. This single change in bread, a staple foodstuff, would have brought about a widespread increase in the fibre content of the diet from approximately 1.2 g. per 1,000 calories to 2.4 g.

Effect of Control of Weight Gain in Pregnancy

Hamlin (1952) published the results of a three-year attack on eclampsia at the Crown Street Women's Hospital in Sydney. He claims that eclampsia has virtually been eliminated by changing the diet from a "high-carbohydrate, low-protein diet to a low-carbohydrate, high-protein, high-vitamin diet before mid-pregnancy." These measures were coupled with increased antenatal supervision and control of excessive weight gain in mid-pregnancy by dieting. The dietary changes advocated by Hamlin would have the effect of increasing the intake of fibre. Especially is this so in the case of diets designed to limit weight gain in pregnancy, where the restriction of the concentrated high-calorie foods such as flour, sugar, and fats is countered by an increased intake of the more bulky but less fattening fruits and vegetables.

In assessing Hamlin's results it should be noted that eclampsia—that is, the actual occurrence of fits—can often be prevented by careful supervision and treatment of tox-

aemia patients. In other words, the incidence of eclampsia is susceptible to antenatal care, and does not always bear a true relationship to the incidence of toxæmia, especially where there is a high standard of obstetric service. Baird (1952) is of the opinion that the combined stillbirth and neonatal death rate has a much closer relationship with the true toxæmia incidence, because these morbid conditions are so often the result of toxæmia. Unfortunately Hamlin does not give evidence on the incidence of toxæmia (without eclampsia) or on the combined stillbirth and neonatal death rates.

Toxaemia in Poor and Good Diets of Urban Communities

One of the characteristic features of poor urban diets is that people tend to satisfy hunger with concentrated energy-producing foods which are cheap, whilst neglecting the more costly "protective" foods, such as fruit and vegetables. These foods, in addition to being rich in minerals and vitamins, also contain fibre. Ebbs, Tisdall, and Scott (1941) demonstrated that good diets and poor diets, supplemented with a number of fruits and vegetables (see above), apparently had a beneficial effect on the incidence of toxæmia. These diets undoubtedly had a higher fibre content than the poor diets.

In review, most of the above observations relating diet to the incidence of pregnancy show that toxæmia is more common where the fibre content of the diet is low. The evidence for this is summarized in Tables II and III.

Summary

The incidence of pregnancy toxæmia in various groups of people consuming widely different diets, together with observations of trends in the incidence of this disease in the same group of people but at different periods (such as during wartime), has been discussed.

The suggestion is made that some factor or factors associated with the "fibre" content of the diet tend to inhibit the occurrence of toxæmia.

From the *Gentlemen's Magazine*, August, 1853: "The Royal Family has been suffering from measles. It first appeared on H.R.H. the Prince of Wales, who in consequence was absent from his brother's [Prince Leopold's] christening. On July 8 it was announced that Prince Albert [Prince Consort] was attacked, and on the 19th that Her Majesty also had the complaint. Meanwhile all the royal children except the first have successively taken the infection. The whole Royal Family have passed through the disease very favourably. On July 6 the foundation stone of the Medical Benevolent College was laid in Epsom . . . H.R.H. Prince Albert, who had promised to lay the stone, was absent from illness."

PROSTATIC DYSPEPSIA

BY

B. E. CRAWFORD STANLEY, M.S., F.R.C.S.

Late Assistant to the Surgical Unit, St. Mary's Hospital, Paddington; Consulting Surgeon, St. Bartholomew's Hospital, Rochester

Although "silent prostatism" is a well-recognized clinical condition, it is surprising how few references to it occur in the current literature, and, with one or two possible exceptions, mention of the condition is conspicuous by its absence from the standard undergraduate and postgraduate textbooks of surgery and urology. Ewert and Summons (1951) have drawn attention to the not uncommon insidious onset of prostatic obstruction. They have emphasized that this condition may present itself with symptoms unrelated to the genito-urinary tract, and state that these symptoms are due to varying degrees of renal insufficiency.

Silent prostatism is more common than is generally realized and may present as a gastro-intestinal disturbance, with a history suggestive of carcinoma of the stomach or early hepatic cirrhosis in the absence of urinary symptoms and before there is biochemical evidence of renal insufficiency or azotaemia. Eighteen cases of this type were encountered during the last five years in a series of just over 200 patients who had undergone prostatectomy.

The presenting symptoms of this syndrome, which may well be called "prostatic dyspepsia," are upper abdominal discomfort or pain, nausea, and anorexia. Urinary symptoms are absent, but the residual urine is invariably much increased and the cystoscopic appearances confirm the diagnosis. The following case histories are typical.

Three Case Reports

Case 1.—A man aged 73 was admitted to a medical ward for investigation. He had a four-months history of dyspepsia, anorexia, and vomiting with loss of weight. Barium meal examination and fractional test meal and liver-function tests showed nothing abnormal. Blood urea was 27 mg. per 100 ml. An intravenous pyelogram showed normal function of both kidneys, but a large filling defect at the base of the bladder and considerable vesical retention in the post-micturition film. Cystoscopy was attempted, but the instrument was not long enough to get through the prostate, which could be felt above the symphysis pubis when the bladder was empty. A one-stage prostatectomy was carried out and a gland weighing 340 g. was removed. Three months after operation the patient declared himself to be in perfect health with complete restoration of his digestive powers.

Case 2.—This patient, aged 65, was referred by his general practitioner with a history of four months' anorexia, pain, and nausea. He had lost 2 stone (12.7 kg.) in weight. He would admit to no urinary symptoms. Barium meal, test meal, and liver-function tests revealed no abnormality. Blood urea was 34 mg. per 100 ml.; haemoglobin, 76%. The history was so typical of gastric carcinoma that laparotomy was advised. This was performed, but no lesion of the stomach or intestines was detected. When the hand was palpating the pelvis the bladder was felt to contain several ounces of urine. Subsequent investigations showed a residual urine of 8 oz. (230 ml.), a normal intravenous pyelogram, and a moderately trabeculated bladder. The man did not rise at night to pass his water and had complete control with no delay or urgency. Removal of a small prostate (24 g.) cured his digestive symptoms, and his weight was back to normal three months after operation.

Case 3.—A man aged 68 attended his doctor complaining of feeling out of sorts with loss of appetite and constipation. He had no urinary symptoms, sometimes rose once at night to micturate, but passed urine with a good stream. On examination he had a bladder palpable 3 in. (7.5 cm.) above the symphysis pubis. The prostate was moderately enlarged but benign. The blood urea was 36 mg. per 100 ml., and the urine was uninfected. An intravenous pyelogram showed normal concentration in the kidneys with no hydronephrosis. The bladder shadow was enlarged. Cystoscopy showed moderate intravesical projection of the prostate and trabeculation of the bladder, with 30 oz. (850 ml.) residual urine. This examination precipitated an acute retention of urine, so a closed transvesical prostatectomy was performed 24 hours later. Convalescence was delayed by a femoral thrombosis, but when seen three months after operation, although he still had a little swelling of the leg, he said he was feeling fitter than for some time.

Remainder of Series

Fifteen other cases of the condition have been seen, a summary of whose clinical histories are tabulated below.

Details of Cases

Age	Predominant Symptom	Initial Provisional Diagnosis	Blood Urea mg./100 ml.	Urine	Residual Urine	
					oz.	ml.

Comment

It is a well-recognized fact that patients who have had a prostatectomy frequently volunteer the information after the operation that they feel fitter than they have felt for some time. The observation is not limited to those in whom there has been some degree of uraemia.

Several of the patients in this series were submitted to detailed investigations, including urea concentration and clearance tests, blood alkali reserve, etc., and in none has there been evidence of renal impairment.

The cause of the syndrome of dyspepsia, nausea, and anorexia, associated with prostatic obstruction which has not gone on to the stage of renal impairment, is not clear, but is in my submission a definite entity which is not generally recognized until uraemic symptoms supervene. It would seem that the importance of these cases, which in my experience account for a little over 5% of all patients requiring prostatectomy, lies in the fact that, unless the clinician concerned, usually not a surgeon or urologist, is alive to the possibilities of prostatic obstruction being the underlying cause, the patient may be sent away after a negative gastro-enterological examination or submitted to an unnecessary laparotomy, when the catheter to measure the residual urine or the cystoscope will make the diagnosis clear.

Summary

A syndrome of epigastric pain, nausea, and anorexia is a not uncommon initial complaint in patients with prostatic obstruction without urinary symptoms.

A series of eighteen patients are described with this syndrome in whom there was no real evidence of renal impairment.

The importance of the condition lies in the fact that after a negative gastro-enterological investigation it can be, and often is, overlooked until uraemic symptoms supervene.

HYPERPARATHYROIDISM WITH NORMAL SERUM CALCIUM

BY

H. GORDON MATHER, M.B., M.R.C.P.

Medical Registrar, King's College Hospital, London

Osteitis fibrosa cystica was first described by von Recklinghausen in 1891, but the first clear demonstration that a parathyroid adenoma was the cause came in 1925, when Mandl cured a man crippled with the disease by the removal of such a tumour. Since then our knowledge of the disease, its clinical, radiographic, and biochemical features, has steadily increased, though as recently as 1950 Rienhoff estimated that there were only 597 proved cases in the world's literature or known to him personally. Thus the disease is rare enough to warrant a record of every case, especially when there are any unusual findings, and since treatment is so effective.

Case Report

A spinster tea-packer aged 33 first consulted her doctor in February, 1951, because of "rheumatism" in the legs and back for five months. Before this her health had been good; she had lived an active life and had played tennis during the previous summer. The aching pain had started in her right thigh rather suddenly in September, 1950, and had spread in several weeks to involve the lower back, thighs, and knees. The pain was made worse by movement, but did not prevent sleep. She noticed increasing weakness in the legs, so that walking, especially starting off, became difficult: a waddling gait developed. These disabilities caused her to stop her work at Christmas, 1950. The symptoms became increasingly severe; some aching and weakness developed in the right shoulder, and a painful lump appeared below the manubrium sterni. She had noticed some frequency of micturition, which disturbed her twice each night.

She was referred to the medical out-patient department, where the most striking abnormality was her gait as she entered the room. It resembled the waddling of a duck, and was thought to be due to muscular weakness, especially of the hip abductors. She was of stocky build, and had a marked thoracic kyphosis, which, though present since childhood, she thought had become more pronounced. The bones were not tender, and passive movement of the limbs was full and pain-free. There was definite muscular weakness of the abductors, flexors, and extensors of the hip-joints, but no wasting and no reflex or sensory changes. Examination of the neck, lungs, heart, and abdomen was normal. The blood pressure was 130/90 and weight 8 st. 9 lb. (54.9 kg.). There was a tender bony lump in the sternum between the third

costal cartilages. X-ray examination of the pelvis revealed a generalized osteoporosis, so she was admitted for investigation with a tentative diagnosis of hyperparathyroidism.

Investigations.—In order to confirm the clinical diagnosis and to exclude in particular multiple myelomatosis and polyostotic fibrous dysplasia (Albright's disease) extensive investigations were made. Skeletal x-ray films revealed generalized osteoporosis, with a "moth-eaten" appearance in the skull (Fig. 1), and early fibrocystic areas, especially in the pelvis and right upper humerus. There was a fracture of the body of the sternum, and a loss of the lamina dura of the teeth. No calcification was seen in the renal tract. Four pre-operative serum calcium estimations (10.8, 10.32, 9.8, and 9.7 mg. per 100 ml.) during three months were within the normal range: the method used was that described by Trevan and Bainbridge (1926). Two out of the three plasma phosphorus estimations (1.7, 2.2, and 1.8 mg. per 100 ml.) were, however, below normal limits. The serum alkaline phosphatase was 92.4, 94.4, and 98.0 King-Armstrong units per 100 ml. at monthly intervals. The blood urea (34 mg. per 100 ml.) and urea clearance were normal, as were the serum proteins (total, 6.7 g.; albumin, 4.16 g. per 100 ml.). An eight-day calcium balance showed that on an intake of 97 mg. daily her average urinary excretion was 322 mg. and faecal excretion 162 mg., a daily negative balance of 387 mg. The combination of low plasma phosphorus and a negative calcium balance, even in the presence of normal serum calcium, made the diagnosis almost certain.

A sternal bone biopsy showed osteoclastic destruction of bone trabeculae associated with proliferation of fibrous tissue. There was very little evidence of new bone formation and there was no mosaic pattern in the islets. The appearances were those of osteitis fibrosa cystica.

A blood count showed: red cells, 4,300,000 per c.mm.; Hb, 11.9 g. (80%); colour index, 0.9; E.S.R. 4 mm. (Wintrobe corrected); white-cell count, normal. There were no casts, cells, or albumin in the urine.

Operation.—On June 11, 1951, Mr. E. G. Muir explored the neck through the usual collar incision. A normal parathyroid gland was identified on the left side, but a small parathyroid adenoma was found attached to the right lower pole of the thyroid. It was removed by dividing the short pedicle. The adenoma was deep red in colour with a smooth surface; it measured 1.8 by 1 by 0.8 cm. and weighed 0.9 g. Microscopical examination showed parathyroid tissue composed almost entirely of "wasserhelle" cells.

Subsequent Course.—The patient was given 2 pints (1,140 ml.) of milk, 60 gr. (4 g.) of calcium lactate, and 10,000 units of calciferol daily from three days before operation until six months afterwards. The bone pain vanished immediately after operation, and muscle strength returned within a few weeks. Five days after operation latent tetany was detected by a positive Chvostek's sign; at that time the serum calcium was 7.9 mg. per 100 ml. The dose of calcium lactate was increased to 240 gr.

FIG. 1

FIG. 2

FIG. 1.—Skull. Moth-eaten osteoporosis. FIG. 2.—Skull. Six months after operation.

(16 g.) daily. The sign disappeared after two days, and thereafter convalescence was uneventful. Subsequent biochemical tests are recorded in Fig. 3. On the sixteenth day the daily urinary excretion of calcium had fallen to 40 mg. despite an intake of more than 3,900 mg. of calcium ion. Three months after operation radiographs of the bones showed much recalcification; the gait was normal and the patient symptom-free. Six months after operation radiographs were almost normal (Fig. 2), and the phosphatase had fallen to 14.7 units per 100 ml. All treatment was then stopped.

FIG. 3.—Serial estimations of serum alkaline phosphatase, serum calcium, and plasma phosphorus. Normal ranges are shown thus ———.

Discussion

This case is of special interest because of the very short duration of symptoms, the normal serum calcium, and the rapid and complete response to treatment. Most reported cases have had symptoms for more than two years before the diagnosis has been made (Norris, 1947). The importance of early diagnosis is seen in Rienhoff's own 27 patients, who were followed for several years: within a few years of operation 10 died from uraemia or hypertension following nephrocalcinosis. In general, the fatalities were among those with the longest histories before operation and those with renal damage.

Since the prognosis is so much improved by early diagnosis, the early symptoms of hyperparathyroidism merit emphasis. They are usually described as: (1) due to decalcification of the skeleton—aching bones, deformities, spontaneous fractures; (2) due to hypercalcaemia—polyuria, thirst, renal pain; or (3) due to hypercalcaemia—anorexia, nausea, constipation, muscular weakness, increasing muscular fatigue, waddling gait.

Although this patient had the symptoms usually ascribed to hypercalcaemia, her serum calcium was in fact within normal limits. Four estimations were made in three months, by an experienced technician, at a time when the patient had marked symptoms from the disease. It is obvious that these symptoms may be caused by factors other than hypercalcaemia.

Gutman and his colleagues (1936), reviewing the serum calcium levels of 114 cases of hyperparathyroidism, found values below 11 mg. in five only and below 12 mg. in 23

only. They thought that normal serum calcium values could be explained in one of four different ways.

1. **Renal Failure.**—This commonly occurs in cases of long duration. It causes phosphate retention with secondary depression of the serum calcium level. This is well illustrated by Case 2 of Gutman *et al.*, in which renal failure occurred while the patient was in hospital, with a fall in calcium from 12.4 to 10.5 mg. along with a rise in phosphorus from 3.9 to 6.1 mg.

2. **Hypoproteinaemia.**—Normally about 50% of the total serum calcium is bound to protein; the remainder is ionic calcium, and it is this fraction which is raised in hyperparathyroidism. Coincidental hypoproteinaemia, with a low protein-bound fraction, may thus mask a pathologically high ionized calcium when the total serum calcium is normal.

3. **Insufficient Testing.**—Sometimes a normal value is found in an isolated test, but repeated estimations show the typical elevation. For instance, the initial estimation of Case 2 of Albright *et al.* (1934) showed a level of 10.4 mg.; on subsequent testing it was 12.3 mg.

4. **Short Duration of Symptoms, with Normal Kidneys.**—Under these circumstances the excess calcium mobilized from the bones can be excreted without accumulation in the blood: such is the explanation in the present case. The kidney-function tests were normal, as were the serum proteins; the disease was active as judged by the bone pain and negative calcium balance, yet the serum calcium was normal on four occasions during three months.

Summary

An example of hyperparathyroidism is described in which the duration of bone pain and weakness was only five months and the serum calcium was normal. The early symptoms of the disease are reviewed and emphasized. The normal serum calcium was thought to be due to effective excretion of calcium by the kidneys. A parathyroid adenoma was removed successfully and the patient's health restored.

I wish to thank Dr. Clifford Hoyle, under whose care the patient was admitted, for help with this paper; Mr. E. G. Muir, who did the operation; Dr. A. M. Rackow for the radiographs; Professor C. H. Gray for the biochemical investigations; and Dr. B. S. Cardell for the histology.

The outstanding social problem of our age, particularly in northern towns, is unsatisfactory housing, says Dr. C. Metcalfe Brown, medical officer of health to the city of Manchester, in his annual report. "Notwithstanding the strenuous efforts of the housing department in providing new houses," he writes, "the housing position in the city is bad. Hundreds of cases annually seek the help of the health department for the alleviation of hardship caused by wretched housing conditions. The department takes all action within its power, but this action is severely limited by the controlling factor—namely, the grave shortage of new houses. Enormous distress is being caused to thousands of Manchester people because of the inadequacy of housing accommodation. The health, happiness, and integrity of family life cannot be achieved and maintained to the full unless housing is good."

TREATMENT OF LIME BURNS OF THE EYE WITH CORVASYMTON AND UNDERMINING OF CONJUNCTIVA

BY

F. J. DAMATO, M.D., F.R.C.S., D.O., D.O.M.S.

Senior Ophthalmic Surgeon, Medical and Health Department, Malta

The satisfactory results of the treatment of chemical burns of the eye with "corvasymton" as reported by Fischer, Hodgson, and Wagenaar (1950) and Wagenaar (1952) drew my attention to this new preparation. Its use started quite accidentally when in a carbide burn of the eye it was instilled by mistake instead of vitamin A oil. The cornea was clear and transparent after instillation every 15 minutes for three hours. A generous supply of corvasymton enabled me to carry out an intensive treatment of several cases of lime burns of the eye. Here is a record of some of them.

Case 1

On June 24, 1952, a 23-year-old man was hit on the right eye by a handful of quicklime thrown at him by a fellow workman. When at last the eye was cleansed of all particles of lime, by means of copious irrigations with saline solutions and by pledgets of cotton-wool carried on a conjunctival forceps, the lower third of the cornea presented a porcelain-white appearance. The remaining part of the cornea was so hazy that the iris could scarcely be seen. The conjunctiva of the entire lower fornix was greyish white in colour, and showed such a severe degree of chemosis that no blood vessels could be seen. Vision was reduced down to vague hand movements.

The eye was immediately operated upon. The "necrotic" conjunctiva was loosened up by means of a straight keratome along the limbus corneae in a sector between 5 and 7 o'clock and extensively undermined in a peripheral direction down to the fornix. The conjunctiva was cut at the limits of the undermined area so that a trapdoor flap with the hinge at the fornix was formed. A portion of the sclera was laid bare. No part of the conjunctiva or subconjunctival tissue was removed. There was no loss of blood. This fact suggests that there was occlusion of the blood vessels. The eye was irrigated with corvasymton 10% and instillation continued every hour.

The chemosis soon started to subside and the conjunctiva regained very gradually its normal pink colour. The cornea took a longer time to acquire its bright healthy appearance. The cloudiness of the upper part of the cornea was the first to disappear, and, except for one tiny spot at 6 o'clock near the limbus, the porcelain-white patch cleared off completely. There remained, however, a small narrow symblepharon deep down in the lower fornix in the same line as the spot on the cornea; it never showed any sign of increasing in extent, and no further intervention was necessary.

Vision in both eyes was 6/12 unaided and 6/6 with glasses. There was never any sign of a rise of intraocular tension and there were no corneal vascular changes. Atropine was never used. The patient was discharged three weeks after admission. I think that, had I loosened up the conjunctiva at the limbus along a wider section, both the corneal opacity and symblepharon would have been prevented.

Case 2

On July 17, 1952, a 17-year-old youth was admitted into hospital for a lime burn of the right eye. On examination the cornea and conjunctiva presented much the same degree of injury as Case 1. No blood vessels were to be seen on the chemotic conjunctiva of the lower fornix. There was a

porcelain-white patch on the lower part of the cornea. Diffuse cloudiness of the cornea was very marked. Vision was limited to hand movements.

As there was a considerable degree of blepharospasm, the patient was operated on under general anaesthesia. All residual particles of lime were removed. The same procedure was followed as in Case 1. However, in an attempt to prevent all possible complications, I loosened up the ocular conjunctiva on a much wider section—that is, between 3 and 9 o'clock (see Fig.). The eye was then irrigated with corvasymton solution and instillation continued hourly.

The chemosis gradually disappeared and the conjunctiva soon began to show its normal appearance. The conjunctival flap was noticed to gain reattachment to its scleral bed. The cloudiness of the cornea gradually disappeared. After one week the patient started to complain of pain in the eye. Instillation of fluorescein solution revealed a fairly large staining spot in the cornea near the limbus at 6 o'clock. The eye was kept bandaged between the instillations. After five days there was no sign of corneal staining.

When discharged after three weeks the cornea was clear and the lower fornix was completely free. No corneal vascularization was present. One month after being discharged the vision in both eyes was 6/6.

Case 3

A boy aged 8 was struck in the left eye by a piece of quicklime. The injury was localized mainly to the upper fornix region. The cornea was diffusely hazy and he could count fingers at one metre. Instillation of corvasymton every hour was immediately started. As the chemosis was not pronounced, no undermining of conjunctiva was performed. Three days later it was noticed that the conjunctiva in the inner angle of the upper fornix was very swollen. The patient was examined under general anaesthesia. A piece of lime had burnt its way deep into the conjunctiva, which was loosened up throughout the upper half of the limbus and deeply undermined peripherally. The piece of lime along with the conjunctiva was excised.

Recovery was quick and complete. When the patient was discharged two weeks later there was a small adhesion deep into the inner angle of the superior fornix corresponding to the excised parties of the conjunctiva. The cornea was completely free from opacities. Vision was 6/6.

Case 4

A man aged 35 was injured in both eyes by a splash of quicklime. The burn was mainly limited to the corneae, which were very hazy. There was a moderate degree of swelling of the ocular conjunctiva. Vision was reduced to counting fingers at one metre. Corvasymton was instilled every hour. No undermining was done. The corneae gradually acquired their normal brightness and the patient was discharged after 10 days.

Case 5

On September 8, 1952, a man aged 70 was admitted to hospital for a lime burn of the right eye. On examination the cornea was very hazy and vision was reduced to hand movements. The ocular conjunctiva was moderately swollen. The haziness of the cornea disappeared after two weeks. But there was a tiny persistent staining spot at 7 o'clock just within the limbus. When the patient was discharged after six weeks the cornea was clear except for a small dense opacity corresponding to the staining spot. The fornix was free.

Discussion

Corvasymton is an oxyphenyl-methylaminoethanol tartrate solution. It is related to "sympatol," which is closely allied to adrenaline: dioxyphenylmethylaminethanol. When corvasymton solution 10% is instilled into the eye, constriction of the vessels follows, but the permeability is not altered. The intraocular tension does not show any change and there is no evidence of any toxic action.

The curative effect of corvasymton cannot be attributed to its vasoconstrictory action. Burns treated with adrenaline in any concentration do not show any improvement. On the contrary, if adrenaline is instilled in a concentration higher than 1:1,000 the condition of the eye is made worse.

It is thought that the beneficial effect of corvasymton is due to the adrenalone which it contains. Adrenalone is dioxyphenyloxymethylaminoethanol

which is a keto form of adrenaline. It has been found (Loewi and Meyer, 1905; Dale, 1909) that adrenalone is much less toxic and has much less vasoconstrictory action than adrenaline. In solution of the latter the keto form of adrenalone is absent.

Besides the restoration of corneal transparency, the treatment of chemical burns of the eye has in view the prevention of adhesions between the conjunctiva and the ocular globe. As early as 1912 Denig removed the necrotic conjunctiva and replaced it by mucous membrane from the mouth. Thies (1928) again drew attention to the favourable effect of this treatment. However, in 1939, Passow noted that an oral mucosa graft was unnecessary, as the same results could be obtained by loosening up and undermining of the injured conjunctiva at the limbus corneae. In spite of its "necrotic" appearance, the conjunctiva is still capable of remarkable recovery.

In a chemical burn of the eye a deposit of the corroding agent is retained beneath the conjunctiva. Its gradual absorption, by impairing the nutrition of the sclera, cornea, and conjunctiva, gives rise to the well-known sequelae of chemical burns. By loosening up and undermining the conjunctiva at the limbus, the formation of a deposit is prevented and the subconjunctival tissue is laid open to the direct action of corvasymton.

I used to treat conjunctival and corneal chemical burns in the usual way—that is, by copious irrigation of saline solution or ammonium tartrate 10% solution; removal of all particles of the injurious material; frequent instillation of cod-liver oil, and insertion of a plastic contact glass to prevent formation of adhesions between raw surfaces. The most favourable cases took a long time to recover, and a completely clear cornea was an unusual result. In severe cases corneal opacities and wide adhesions were inevitable sequelae of the use of the contact glass.

I never had the opportunity to use tolazoline hydrochloride, which is a hyperaemia-inducing preparation recommended by Nagy (1951), nor transplantation of the oral mucosa (Denig-Thies operation).

The quick disappearance of the chemosis and the complete clarification of the corneal cloudiness and opacities which follow upon the frequent instillation of corvasymton, coupled with free loosening and undermining of the conjunctiva, are

so impressive that this preparation may be regarded as a very important asset in the treatment of lime burns of the eye.

POLIOMYELITIS IN CHILDREN UNDER 6 MONTHS IN ENGLAND AND WALES DURING 1950

BY

D. H. GEFFEN, M.D., D.P.H.

Medical Officer of Health, Metropolitan Boroughs of St. Pancras and Hampstead

AND

SUSAN TRACY, M.R.C.S., D.P.H.

Deputy Medical Officer of Health, Metropolitan Borough of St. Pancras

Logan (1952) in his report on the distribution of poliomyelitis in England and Wales in 1950 stated that 82 cases of poliomyelitis were notified in children under the age of 6 months.

In correspondence with the medical officers of the districts in which these 82 cases occurred we found that in fact 5 were over 6 months old. Of these 2 were non-paralytic and 3 were paralytic. On the other hand, we were given information of 5 children who developed poliomyelitis during 1950 and were under the age of 6 months, but who were not included in Logan's figures. These 5 children had a paralytic attack. We have excluded the 5 children who were over 6 months of age and included the 5 referred to above. It is on this revised list of 82 cases that we are reporting the results of our investigation.

Logan's figures show that of the 82 cases that were notified in children under 6 months 72 were paralytic and 10 were non-paralytic. Our follow-up of the revised list of cases shows that 77 were paralytic (including the fatal cases) and 5 non-paralytic.

Our primary object was to consider: (1) the incidence of poliomyelitis in children under the age of 6 months; (2) its fatality, severity, and the extent of recovery; and (3) whether breast-feeding had any effect in preventing poliomyelitis.

Incidence

The incidence of poliomyelitis in children under 6 months of age was of particular interest to us in connexion with immunization against diphtheria, either alone or combined with a vaccine against whooping-cough; for Bousfield (1951) had suggested in 1951 that if children received their immunization earlier in infancy they would run less risk of contracting that type of paralytic poliomyelitis which is associated with immunization. It was assumed that this suggestion was based on the supposed infrequency of poliomyelitis in children under this age.

In children under 15 the total number of notifications of paralytic poliomyelitis in 1950 was 3,799. The number of children under 6 months per 1,000 children under 15 in 1950 was 35.8. The expected number of notifications in children under 6 months would therefore have been $35.8 \times 3,799 = 136$. There were in fact 77 cases according to our investigations.

In the same age group there were notified 1,525 cases of non-paralytic poliomyelitis. On the same basis the expected number in children under 6 months would have been 54.5. There were in fact, according to our investigations, 5.

It would appear, therefore, that the incidence of paralytic poliomyelitis in infants under 6 months was approximately 56.6% of what it would have been had it been evenly distributed in six-monthly age groups in children under the age of 15, and for non-paralytic poliomyelitis 9%.

In our opinion: (1) These facts, together with the severity of the disease in this age group (see later) would not have warranted the continuation of immunization in 1950 in children under 6 months in a district where there was an outbreak of poliomyelitis, solely on the grounds that the children were under 6 months old. (2) Non-paralytic poliomyelitis is not frequently notified in children under 6 months. This may be due to (a) the difficulty of diagnosis of non-paralytic poliomyelitis in children under 6 months; and (b) the possibility that lowered resistance to the poliomyelitis virus in this age group results in almost all cases developing paralysis.

Mortality

Of the 82 patients we investigated 19 died, giving a mortality rate of 23%. We have compared this with the mortality rate of poliomyelitis in 1950 in persons over the age of 6 months. During that year there were 7,668 notifications in this age group, and of these patients 715 died, giving a death rate of 9.3%. It is therefore apparent that in 1950 the mortality rate of poliomyelitis in children under 6 months was more than double that of persons over this age.

Table I shows the mortality rate in three separate age groups for children under 6 months of age. It also indicates that for poliomyelitis in 1950 the younger the children the greater was the mortality rate. Table II gives the age of onset and death of the 19 fatal cases.

TABLE I.—Fatality

	M	F	Total	Died	Survived	Mortality
0-9 weeks ..	14	10	24	9 (F 4, M 5)	15	37.5%
10-18 " ..	13	16	29	6 (F 3, M 3)	23	20.7%
19-26 " ..	19	7	26	4 (F 0, M 4)	22	15.4%

We have had to exclude three children whose exact age we were unable to ascertain.

TABLE II

	Age at Onset of Poliomyelitis	Age at Death
J. F. T. ..	8 days	10 days
L. E. G. ..	13 "	20 "
S. H. ..	2 weeks	18 "
B. O. ..	4 "	46 "
A. R. ..	5 "	6 weeks
P. H. ..	6 "	6 1/2 "
M. J. G. ..	7 "	9 "
C. G. B. ..	7 "	20 "
E. R. ..	8 "	8 "
U. J. ..	12 "	13 "
A. A. ..	12 "	12 "
J. S. ..	16 "	16 "
D. R. ..	16 "	16 "
J. P. ..	17 "	17 "
K. B. ..	18 "	18 1/2 "
T. G. ..	19 "	19 "
R. D. A. ..	22 "	22 1/2 "
K. G. C. ..	23 "	23 1/2 "
S. S. ..	23 "	23 "

These figures are an additional indication of the severity of paralytic poliomyelitis in the early weeks of life. It will be seen that in most cases death ensued within a question of days from the onset of the disease.

The mortality of poliomyelitis in young babies has been reported upon by Smallpeice and Ounsted (1952). They describe an outbreak of poliomyelitis in a nursing-home. The patients were infants aged 7, 3, and 2 weeks respectively. Two died and one is an epileptic idiot with palsies and athetosis. It is interesting to note that these authors

state that all forms of poliomyelitis are uncommon in early infancy, quoting Mouton, Smillie, and Bower (1950). This statement was not borne out in the 1950 epidemic in England. We have also information of an outbreak in a maternity home in 1952. Three newborn babies contracted poliomyelitis and two died.

We would refer to the report of an outbreak of poliomyelitis in Israel in 1951 (Health Services of Israel, 1952). Of 1,602 cases notified 30% were in children under 1 year of age. We have not yet received information concerning the actual ages of the children, nor the death rate in monthly or quarterly age groups.

Severity and Recovery

For the purposes of this review we have classified our cases as fatal, paralytic, and non-paralytic. Of the 82 cases, 19 were fatal, 58 paralytic, and 5 non-paralytic. We have classified the extent of paralysis in the paralytic cases as follows: A, three or more limbs or two limbs and one other part of the body affected. B, two limbs or one limb and one other part of the body affected. C, one limb affected. R, complete recovery.

Table III sets out the extent of paralysis in 55 of the 58 paralytic cases. In three cases we did not succeed in obtaining information about the initial extent of paralysis and the condition three years later.

TABLE III

Initial Paralysis		Condition 3 Years Later			
		A	B	C	R
A	18	8	6	3	1
B	12	—	4	7	1
C	25	—	—	16	9
Not known	3	—	—	—	—
Total	58	8	10	26	11

We have not been able to make a scientific comparison between the severity of the disease in children under 6 months and the severity at all ages in 1950, for we have no comparable figures. We can only draw attention to the fact that 19 children died and that 18 were very severely paralysed. On the other hand, dealing with the question of recovery, we would confirm our opinion, previously expressed, that in poliomyelitis recovery is to some extent proportionate to the initial severity of the paralysis of the affected limbs (Geffen, Paterson, and Tracy, 1953).

Breast-feeding

Dr. S. K. Sanders, in a personal communication, gave us some information concerning mouse encephalomyelitis virus, which behaves in some ways in the same manner as the poliomyelitis virus. Female mice which have a high degree of circulating antibody as a result of active immunization transfer this immunity to their offspring via the colostrum and milk. Suckling mice of such mothers are correspondingly more resistant to peripheral challenge with active virus than the offspring of mothers who have not been so immunized. This is also true of the Coxsackie virus.

It was with this in mind that we determined to inquire into (1) the history of the mothers of the 82 children, with a view to ascertaining if they had had any recent attack of poliomyelitis; and (2) the extent to which the 82 children were breast-fed.

(1) In 76 of the 82 cases we could obtain no history that the mother had at any time suffered a diagnosed attack of poliomyelitis. In the remaining six cases the mother and the child both developed poliomyelitis either simultaneously or within a few days of each other. Further details of these six cases are given below.

(2) Of the 19 children who died, 4 were being entirely breast-fed at the time of death; 8 had been breast-fed for varying periods; 4 had never been breast-fed; and in the

remaining 3 cases we could obtain no information. Of the children who survived, 15 were entirely breast-fed; 32 had been breast-fed for varying periods; 10 had never been breast-fed; of 6 we could get no history.

Thirteen children developed poliomyelitis under the age of 6 weeks—6 died and 7 survived. Of the 7 survivors, 5 were entirely breast-fed, and, of these, 3 had a mild attack (category C).

In the absence of a history of poliomyelitis in the mother, or knowledge of whether she had had an undiagnosed attack, we are unable to make any deductions of value from these figures.

The following are the details of the six cases in which the mother also had poliomyelitis.

Case 1. J. F. T.—The mother died of poliomyelitis six days after the baby was born. This baby died of poliomyelitis at the age of 10 days.

Case 2. R. H. H.—The mother died of poliomyelitis on the fifth day of the puerperium. The child developed poliomyelitis at the age of 10 days and had a very severe attack (category A).

Case 21. A. D. T.—The mother contracted an abortive attack of poliomyelitis at the same time as the child. The child—aged 9 weeks—contracted a serious attack of poliomyelitis (category A).

Case 33. O. H. G.—The mother contracted an abortive attack of poliomyelitis at the same time as the child. The child contracted poliomyelitis at the age of 13 weeks and had a serious attack.

Case 39. S. F.—The mother had a severe attack of poliomyelitis seven days before the child. The child contracted poliomyelitis at the age of 15 weeks and had a mild attack.

Case 51. A. B.—The mother had poliomyelitis two days before the baby. The child developed poliomyelitis at the age of 17 weeks and had a mild attack (category C).

History of Immunization or any Operative Procedure

We inquired in every case whether the child had been immunized or subjected to any operation. In view of the fact that all the children were under 6 months it is not surprising to find that only one of them had been immunized, and this was against whooping-cough. The injection was in the right arm, and took place six to eight weeks before admission to hospital. Paralysis was limited to the left leg.

Only one child had been vaccinated against smallpox. Vaccination took place at the age of 4 weeks, and the child contracted poliomyelitis at the age of 22 weeks. This case (R. D. A.) was fatal.

One child (B. O.) had an operation for pyloric stenosis on August 4. On August 14 the mother noticed that the child had difficulty in breathing. He was readmitted to hospital on the 17th and died on the 18th.

Pre-paralytic Symptoms

In view of the difficulty of diagnosis of poliomyelitis in infants, we have attempted to assess the importance of the pre-paralytic symptoms which have been recorded. Table IV sets out the position.

TABLE IV.—Pre-Paralytic Symptoms

Nil	11
Not known	9
Drowsiness alone or associated with other symptoms	15
Pyrexia, either alone or associated with other symptoms	21
Irritability	4
Abdominal symptoms such as loss of appetite, pain, diarrhoea, and vomiting	8
Other symptoms	11

We are of the opinion, judging from the above Table and from the reading of individual case sheets, that in this series there were no definite pre-paralytic symptoms diagnostic of poliomyelitis; they were rather symptoms of any acute infection in the first six months of life.

Summary

A report is presented of 82 cases of poliomyelitis in children under 6 months which occurred in England and Wales during 1950. Of the 82 cases, 77 were paralytic and 5 non-paralytic.

The incidence of paralytic poliomyelitis in infants under 6 months was 56.6% of what it would have been if such incidence had been equally distributed in six-monthly age groups in children under 15 years.

Non-paralytic poliomyelitis is infrequently diagnosed in children under 6 months.

The overall mortality rate was 23%, and this mortality increased as age diminished. In children under 9 weeks the mortality rate was 37.5%.

Of the 58 paralytic cases who survived, 30 were either very severely or severely paralysed, and of these only 2 made a complete recovery.

We have discussed the influence of breast feeding on the incidence and course of the disease.

The pre-paralytic symptoms were not diagnostic except of an acute infection in a child under 6 months.

Medical Memoranda

Acute Strychnine Poisoning after a Massive Dose

Deaths from strychnine poisoning are not uncommon and have been exhaustively dealt with in the literature. The interest of the present case lies in (a) the enormous dose which must have been taken and the rapidity with which death occurred; (b) the little evidence of any of the classical symptoms of strychnine poisoning; and (c) the further evidence of the extreme rapidity of absorption of the drug from the alimentary canal.

CASE REPORT

The deceased was a pharmacist aged 56. At 10 o'clock one morning, having dispatched all but one of his assistants on various errands, he retired to a room over the shop. Eighteen minutes later he was found in this room by an assistant, lying on a couch with his head on the seat and his legs dangling over the raised end. Examination by a doctor five minutes later proved life to be extinct, and it seems probable that he was already dead at 10.18, when found by the assistant. There is good evidence, therefore, that death ensued at the most 15 minutes after swallowing the poison, and probably rather less. When the body was examined by the doctor there was no trace of any muscular rigidity. It is probable that if there had been any violent convulsions before death the man would not have remained on the couch but would have rolled off on the floor. Beside the body was found a partly filled bottle of solution of strychnine hydrochloride, and crystals of what later proved to be strychnine hydrochloride were found in the deceased's mouth, down the front of his pullover, and on the floor surrounding the body.

The necropsy findings were largely negative apart from rather meagre evidence of asphyxia.

The viscera were subjected to the classical Stas-Otto extraction. The residues from the chloroform-caustic-soda extraction were heated on a water bath for 30 minutes with concentrated sulphuric acid, diluted with water, filtered, made alkaline, and re-extracted with chloroform. Removal of the chloroform yielded a white, crystalline, weighable residue which was proved to be practically pure strychnine by melting-point determination and titration. This last was effected by dissolving the residue in 0.01N sulphuric acid and back-titrating with 0.01N caustic soda, using methyl orange as an indicator. From the titration figures the fol-

lowing amounts of strychnine hydrochloride were calculated to be in each organ: liver, 125 mg.; kidneys, 30 mg.; bowel, 4,608 mg.; stomach and contents, 653 mg.; blood, 4 mg. per 100 ml.; urine, trace.

If we assume a circulation volume of 5 litres the total amount of strychnine in this would be 200 mg. There is, therefore, a total recovery of about 5.6 g. (84 gr.) of strychnine from the main viscera. It was estimated that the deceased had consumed 12 fl. oz. (340 ml.) of solution of strychnine hydrochloride (containing about 53 gr. (3.4 g.) of strychnine hydrochloride), but the amount of crystalline strychnine hydrochloride taken was not known.

Primary Carcinoma Simulating Empyema of the Gall-bladder

Primary carcinoma of the gall-bladder is the fifth or sixth in order of frequency of cancers of the alimentary system. It is found in from 1 to 2.6% of all gall-bladder operations, in 0.42% of all necropsies, and in 2.8% of all cases of malignant disease. These figures are given by Illingworth (1935), who studied 50 cases. Judd and Gray (1932), Lichtenstein and Tannenbaum (1940), Kirshbaum and Kozoll (1941), Vadheim, Gray, and Dockerty (1944), Benjamin (1948), and Sainburg and Garlock (1948), and other American surgeons have all reported numerous examples. The following two cases, however, seem remarkable enough to warrant publication.

CASE 1

A compositor aged 78 was admitted on July 5, 1949. He had been well until a fortnight before, when he noticed a dull aching pain between the shoulder-blades. This persisted for a week, when he visited his doctor, who found he was jaundiced. He then admitted that his urine had been dark in colour for about 10 days. On examination the liver was palpable two fingerbreadths below the costal margin and the gall-bladder was felt below it.

On July 14 the serum bilirubin was 22.4 mg. per 100 ml.; blood cholesterol, 380 mg. per 100 ml.; blood urea, 25 mg. per 100 ml.; thymol turbidity, 1 unit; colloidal gold, 0; alkaline phosphatase, 64 units; serum protein, 6.4% (albumin 2.9%, globulin 3.5%). On July 29 the abdomen was opened through a right paramedian incision. Several pints of ascitic fluid escaped. The liver was cirrhotic and the gall-bladder large and tense with a sugar-icing surface. The gall-bladder was opened and cheese-like material removed with a spoon. It was excised with difficulty and a T-tube was placed in the common bile-duct. The patient became drowsy after the operation, gradually weakened, and died on July 31, 26 days after admission. Biliary cirrhosis, thrombosis of the hepatic vessels with patchy necrosis, and some metastases in the liver were found at necropsy.

Pathology.—The gall-bladder was 9 cm. long and 5.5 cm. in diameter. It was completely filled with yellow cheese-like material. Microscopically, no normal mucosa was seen. The wall was infiltrated by an ill-differentiated adenocarcinoma, which was forming acini in some places and not in others. The nuclei were large and vesicular with prominent nucleoli. There was very little mucin production. The material in the lumen had the structure of necrotic tumour and contained some pyknotic nuclei.

CASE 2

A secretary aged 52 first attended as an out-patient on December 11, 1950, complaining of bouts of pain between the shoulder-blades and on the right side of the abdomen, with occasional pain on the left side. She had always had to be careful what food she ate, but had never been jaundiced. On examination she was seen to be of sallow

complexion. A swelling was felt below the ribs on the right side, and on January 3, 1951, a cholecystogram showed no filling of the gall-bladder. On February 5 the abdomen was opened by a right paramedian incision and a greatly enlarged gall-bladder presented. It was slightly inflamed, and the many adhesions were divided. Because of the size of the gall-bladder, a retrograde cholecystectomy was performed and the abdomen was closed with a drain. On February 20 the patient was discharged from hospital, having made an uneventful recovery. She was seen last on September 5 of that year, when she complained of occasional attacks of pain, but on examination nothing abnormal was found.

Pathology.—The gall-bladder weighed 460 g. and was 17.5 cm. long and 7 cm. in diameter. The surface in contact with the liver was 8.5 by 6 cm. Large veins coursed over its surface. It was filled with grey cheese-like material, which when washed away from the wall left a shaggy lining. There were 20 mixed faceted calculi; the largest, 1.5 cm. in diameter, was impacted in Hartmann's pouch. There was a thickening up to 0.5 cm. of the wall of the organ on the ventral surface 5 cm. from the fundus. Microscopically, the contents of the gall-bladder could be demonstrated as masses of necrotic cancer. A section of the thickened wall showed a columnar-cell papillary adenocarcinoma growing in long trabeculae in a fine stroma. The cells were producing a little mucus and had large dark-staining nuclei with frequent mitoses. The wall of the gall-bladder did not appear to be completely penetrated by tumour at any point, and a section of the cystic duct showed no neoplastic tissue.

DISCUSSION

In both these cases, following a short history of symptoms referable to the biliary tract, a laparotomy was performed, and a grossly enlarged gall-bladder filled with cheese-like material was removed. In neither case was a diagnosis made until microscopical examination revealed an adenocarcinoma growing into the lumen of the organ. The cheese-like material was necrotic cancer, and there was no evidence of infection. Illingworth (1935) observed that the papillary type of carcinoma might reach a considerable size, partly filling the gall-bladder. It was prone to haemorrhage and necrosis, and might be so soft as to be mistaken for inspissated pus. In the series of 48 cases examined by Cooper (1937) 12% had papillary tumours, and some of these distended the gall-bladder. Rhodes and Greenblatt (1937) describe obstruction of the cystic duct by tumour as a cause of distension of the gall-bladder, which may simulate an empyema, but they make no mention of the organ being filled with necrotic tumour. Vadheim, Gray, and Dockerty (1944) found that 26 of their 77 cases had gall-bladders distended to four times the normal size, but the largest carcinoma they encountered measured only 7 by 6 by 5 cm. It is interesting to note that in 17 of their cases the carcinoma was limited to the mucosa and submucosa without penetration of the muscularis.

It therefore appears that the two tumours described are very large examples of a type recorded by some authors, but by no means universally recognized. A grave error would be made if cholecystostomy were performed in such a case.

My thanks are due to Mr. Ralph Shackman and Mr. Rodney Smith for permission to publish the cases and to Professor T. Crawford for his assistance in preparing the paper.

Reviews

A PHILOSOPHY OF LIFE

The Natural History of Infectious Disease. By Sir Macfarlane Burnet, M.D., F.R.S. Second edition. (Pp. 356. 22s. 6d.) Cambridge: The University Press. 1953.

In 1940 Sir Macfarlane Burnet gave us a work entitled *Biological Aspects of Infectious Diseases*. This volume is described as its second edition, yet since the original work was written so many advances have been made in attacking the problems of infectious disease that the book has not only been given a new title but has been practically rewritten. It is not too high praise to term Sir Macfarlane's excellent book a philosophy of life, for it is written as Aristotle himself might have described the discoveries of modern science, and it is impossible to improve upon the Greek approach to the study of natural phenomena.

Under biological considerations the ecological aspect of infectious diseases, so important in epidemiology, and the evolution of infection and disease are examined. The aggressors—bacteria, protozoa, and viruses—are described. The chapter on viruses crystallizes modern research on the subject. How real these formerly hypothetical organisms have become is demonstrated by the frontispiece to the book, which shows the brick-shaped granular forms of the vaccinia virus as revealed by the electron microscope. Discussing the origin of these foes of men, animals, and plants, the author says that most research workers prefer the theory that animal viruses are the diminished descendants of pathogenic bacteria or protozoa.

Next come the processes of defence. After recounting the normal defences against bacterial infections and the development of immunity after disease, its chemical basis, antibodies, and its wider significance, the author examines "what makes bacteria dangerous," and reminds us that, even to-day, probably more than half of all human deaths are due essentially to micro-organismal invasion. Except for certain abnormally fatal epidemics, the state of the host is more important in determining the outcome than is the virulence of the micro-organism. Hence the importance of healthy living and adequate nutrition. He then describes the natural history of infectious disease—how infections spread, the transfer of infection from one species to another—animal reservoirs, the general character of epidemics, the prevalence of infectious disease, endemic epidemics, age-incidence of infectious disease, immunity as an epidemiological factor, the general principles of controlling infectious disease, together with an account of the antibacterial drugs, which within the short space of a decade have shorn many deadly diseases of their terrors and paved the way for the eradication of others.

A section of the book is devoted to the study of certain important diseases—diphtheria, influenza, plague, cholera, malaria, and yellow fever. Finally, the grave problem of atomic warfare and the use of micro-biological weapons are discussed. The outlook is indeed gloomy if mankind is destined to destroy civilization through its scientific discoveries.

This is a book which should be read by doctors, men of science, health administrators, and politicians. It emphasizes the recent warning of Professor A. V. Hill that every scientific and medical discovery brings with it human problems to solve—moral, social, political, or aesthetic. Scientific and technical progress cannot alone solve the problems of humanity. "That belief is magic and magic of the unattractive sort that denies a place to the human spirit."

ARTHUR S. MACNALT, Y.

*Address delivered at the annual assembly of faculties of University College, London, on July 2, 1953.

FOUNDER OF THE RED CROSS

Man Born to Live: Life and Work of Henry Dunant, Founder of the Red Cross. By Ellen Hart. With preface by H.R.H. the Princess Royal, and an introduction by Paul Ruegger, President of the International Committee of the Red Cross. (Pp. 371. £1 2s. 6d.) London: Victor Gollancz. 1953.

Many, perhaps most, people do not know that Henry Dunant was the man chiefly responsible for the Red Cross movement and the Geneva Convention. The reason for this is that he was really not a strong or very admirable character. The story of his life is well and faithfully told in this book, which will attract many readers.

Henry Dunant was born in 1828 in Geneva and was a "mother's boy" to such an extent that the maternal influence "set him back and for the rest of his life he was lacking maturity in some of its aspects." In his youth he was an earnest evangelical Christian. He entered the service of a bank and willingly went to Algeria, where he thought he might combine business with evangelism. There he started a private business venture, left the bank, and tried to obtain influential support for his enterprise. He was a good talker and had a most persuasive manner. In attempting to obtain support from the Emperor Napoleon III he followed the latter to the battlefield of Solferino, where he was so moved by the horrible sights he saw that for a time he did good work in succouring the wounded. In 1862, under the influence of strong emotion, he wrote *Un Souvenir de Solferino*, in which he included views which were to lead to the formation of the Red Cross organization. He sent copies of this work to many influential people, including the crowned heads of Europe. The ideals set forth therein were supported by a committee formed in Geneva, and Dunant's personal and sometimes irresponsible efforts spread its influence, but his financial ruin, which involved many of his relatives and friends, compelled him to leave his native city. For many years he lived in comparative obscurity, but in later life his pioneer work was recognized and he obtained a Nobel award. He died at the age of 82.

There is no doubt that Dunant was a man inspired by high ideals and able to move others along humanitarian lines, but he worked "by instinct and emotion," and some of his projects were impractical if not hare-brained. He was an individualist who described himself as "the dupe of a burning imagination, of an over-impressionable temperament," and he seems to have been a poor man of business. Nevertheless he impressed a great humanitarian idea on those who held the reins of authority in Europe, and for this we must hold him in honour.

ZACHARY COPE.

DIABETES

Die Zuckerkrankheit: Diagnose, Klinik, Pathologie, und Therapie. By Professor Ernst Wiechmann. (Pp. 318. M. 28.50.) Munich: J. F. Lehmanns Verlag. 1953.

After a silence of many years three large books on diabetes have appeared in the German language in the last three years. This one by Professor Wiechmann is voluminous and comprehensive. His foreword states that he started to write it in 1929 and has been absorbed in the subject ever since. The effect of this is obvious, and he has not criticized and excluded sufficiently the older references he gives. He lists some 2,000 references, arranges them well in an addendum, but gives the reader no critical evaluation of their contents. Much of the later work he quotes disproves the validity of the earlier. Great historical thoroughness, but too much of it is out-dated and useless. And, as an author quoted, I am a little sad to find that the last edition of my book was produced in 1927 and not, as in fact, in 1951.

The author addresses his book to all students and doctors, and makes a true point in his preface. He points out that diabetes affects all branches of medicine and surgery in a

special way of its own—from eyes, liver, nervous system, to feet—and so it behoves all general doctors and specialists to know its widespread effects. This is so true that all should ponder it.

The book covers all these aspects very well. But it gives insufficient help in practice to any doctor who wants to know how to use insulin and its different types or how to treat diabetic coma. The recommendation to give glucose, fructose, and saline by rectum requires changing.

R. D. LAWRENCE.

NERVE-ROOT CYSTS

Sacral Nerve-Root Cysts: Another Cause of the Sciatic or Cauda Equina Syndrome. By Professor I. M. Tarlov, M.D. (Pp. 134; 65 figures. £2 7s. 6d.) Springfield, Illinois: Charles C. Thomas. Oxford: Blackwell Scientific Publications. 1953.

This short monograph by the professor of neurology and neurosurgery at the New York Medical College is of considerable interest. Some years ago he made a study of the histology of the filum terminale, and in the course of dissecting 30 cases he found perineural cysts of the posterior-sacral nerve roots and ganglia in five. These cysts, which arise at the junction of the dorsal root and ganglion, vary in size up to 3 cm. in diameter and may be multiple. They do not communicate with the subarachnoid space, and are disclosed only when the posterior sacral arch is removed. At first the author regarded these cysts as pathological curiosities without clinical importance, but in 1947, when operating on a patient with sciatica, the suspected protrusion of an intervertebral disk was not found. On removing part of the posterior arch of the sacrum a cyst was seen on the second sacral root, and after the cyst had been removed the patient was relieved of sciatic pain. Professor Tarlov has subsequently operated on three further patients in whom similar cysts were causing symptoms either of sciatic pain or of disturbance of function of the lower sacral roots, and he mentions in detail three patients treated by other surgeons.

The author gives an excellent illustrated account of the naked-eye and histological appearances of these perineural cysts and discusses their possible aetiology. As a clinical account and a guide to the best method of treatment, it must be regarded as a preliminary report owing to the small number of cases so far recognized. But the author has probably drawn attention to a condition of clinical importance, and the monograph is well worth the attention of anyone interested in sciatica and in disturbances of the cauda equina.

J. W. ALDREN TURNER.

THE MIND MADE EASY

Psychology Without Tears. By William O'Connor, L.M.S.S.A.(Lond.), D.P.M.(Lond.). (Pp. 220. 12s. 6d.) London: Rider and Co. 1953.

The lay public has in these days a great appetite for popular psychology in plays, lectures, and books. It delights in being made aware of how people think and how reassuringly commonplace are its own secret thoughts. Interest in the subject is no longer confined to the lunatic fringe of society and to those with pretensions to intellectualism. The conscious application of psychological knowledge and theory is considered a legitimate part of the conduct of life by the diplomat, the salesman, the seducer, or the schoolboy who wishes to extract a tip from a rich uncle. A good deal of sharp practice can, in fact, be rationalized in the name of psychology. One of its most important applications, on the other hand, is that a knowledge of mind can turn mere good will into informed kindness, and nowhere is this more important than at the bedside.

If psychology is to be learned without tears—and tears are here a symbol for the painful effort of concentrated thought—there can be no atmosphere more congenial than that of the dinner-table, and Dr. Connor's style has the easy flow of the man who has, by general consent, monopolized the conversation. A sententious opening and

evidence here and there of a moralizing tendency detract very little from a survey of those parts of the subject which are likely to be of interest to the mentally healthy and inquiring layman.

The approach is singularly free from the bias of any particular school of thought, and gives little encouragement to morbid introspection, and the patient who asks for a "book on psychology" will come to no harm if he reads this one. Other popular writers in this field might have chosen different aspects of the subject, might have been more profound, but would probably have been far less readable.

ALEXANDER KENNEDY.

THE OESOPHAGUS

The Esophagus and its Diseases. By Eddy D. Palmer. (Pp. 553; illustrations by Phyllis Anderson. £4 13s.) London: Cassell and Co. 1953.

This book of 553 pages describes first the anatomy and clinical physiology of the oesophagus, and then in the twenty-five following chapters covers all the common and uncommon groups of disorders or diseases of the oesophagus. Each chapter is followed by a lavish bibliography.

The book has a useful collection of references, but even so it is curiously incomplete. No one in Britain writing about hiatus hernia would omit Harrington's contributions from the U.S.A., and yet Allison's work, of similar scale and importance in this country, is not mentioned in the book. Similarly, in writing about atresia of the oesophagus, British writers would properly refer to Sweet and Swenson, yet corresponding work by Franklin in Britain has been overlooked.

It is difficult to believe that this book is representative of American views. Operations for anastomosing the stomach and oesophagus for achalasia have ceased to be done in Britain but are advocated in this book. Heller's operation is scarcely mentioned. Many patients with hiatus hernia derive much relief from raising their shoulders on pillows at night or by raising the head of the bed on blocks, but in this book we are merely told that "certain simple postural measures would be helpful if they did not interfere to an excessive extent with normal living." Throughout the book the reader is lost in a forest of references and his therapeutic route is dimly marked. It is curious that there should be no section on the investigation of oesophageal diseases by oesophagoscopy or radiology. The book will be of interest to those whose work brings them particularly into contact with this branch of medicine or surgery, but for the general physician or surgeon it is dangerously misleading and is not recommended.

F. AVERY JONES.

CONTACT LENSES

Contact Lens Routine Practice. By Norman Bier, F.B.O.A. (Hons.), F.A.A.O., D.Orth. Foreword by F. A. Williamson-Noble, F.R.C.S. (Pp. 188; 105 figures. £2 2s.) London: Butterworth Scientific Publications. 1953.

This is a short practical book on the theory and practice of contact lenses. This comparatively new form of optical correction is rapidly becoming popular, and, although it is probably true that the day of basic discoveries has now ended, new improvements in technique are constantly being suggested. Among these full-clearance perforated (or vented) lenses, sealed minimum-clearance lenses, and corneal lenses without the usual supporting rim resting on the sclera are fully discussed, and their advantages and disadvantages assessed in the light of the author's considerable experience. He unhesitatingly prefers perforated contact lenses in preference to the sealed types in all but exceptional cases, as, for example, marked conical cornea. He presents clearly the technicalities of the subject and gives much detailed and sound practical advice on fitting the lenses and on their wear and aftercare by patients. The illustrations are unusually clear and informative.

STEWART DUKE-ELDER.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY AUGUST 22 1953

BACKWARD READERS

Illiteracy is a much more complicated subject than might be thought from the many confident statements made about it nowadays. Some figures particularly liable to misinterpretation have recently been issued by the Director of Army Education. They were in a survey of the numbers of "illiterate" and "sub-illiterate or backward" recruits among some 45,000 National Servicemen. The percentage of backward recruits is given as 23, though it ranges from 6% to 45% in different counties.

In the interpretation of such figures much depends on the criterion or test used to measure reading ability. Here the tests were arithmetical and verbal. The illiterates, who totalled 1.2%, were those who could not fill in the answers to a set of simple questions about personal particulars. If we defined illiteracy as inability to read aloud or as a person's inability to understand what he is reading, the results might differ. Again, people do not fall into distinct classes; rather there is a continuous gradation from superior to minimal educational attainment. Hence the proportions of backward or illiterate persons will depend on where an arbitrary line is drawn, and the Army's figure of 23% is meaningless without precise definition of the degree of backwardness to which it refers. The corresponding number below this borderline early in the war was about 15%, and it must be admitted that there has been a decline in educational standards over the war years which has not yet been made up. The figure of 1.2% illiterate also needs interpretation, though for a different reason. In general, Army recruits constitute a fairly representative sample of the young adult male population, but at the bottom an unspecified number are rejected at recruiting centres on medical or psychological grounds, and if these were included the proportion of illiterates would certainly be higher. Even so the results tend to confirm the careful survey published in 1950 by the Ministry of Education,¹ where it was shown that illiterate school-leavers and young

adults amounted to about 1% of their group. Illiteracy was, there defined as reading comprehension poorer than that of average 7-year-old children in 1938. The survey also showed that the proportions of backward readers (with a "reading age" less than 12 years by 1938 standards) were 30% among 15-year-olds and 17% among adults.

Many of the figures that the Army gave for different counties must be treated with great caution because the numbers are small, but at least some of the differences between larger groupings are significant. Thus Welsh counties show 32½% of "backwardness," Scottish ones only 19½%. The latter figure probably reflects the greater emphasis on mechanical drill in arithmetic at Scottish schools, while the former is obviously affected by the difficulties of Welsh-speaking recruits with an English-language test. There is apparently more backwardness in rural than in urban areas, for the most populous counties usually, though not always, get the best percentages. There are other difficulties, seldom recognized, in the interpretation of the figures which many education authorities are collecting in response to the present public outcry about illiteracy among school-leavers. Some, for example, use tests which are based either on 1918 or on 1948 standards, and these naturally give a more gratifying picture than tests based on 1938 standards. Again, the business man who complains of the illiteracy of his office-boys and typists has overlooked the change in occupational distributions during the past 30 to 40 years. Far more of the brightest and best-educated adolescents nowadays enter skilled engineering or administrative and professional services, and employers often have to go much further down the scale of intelligence than they used to do.

Though the question how much illiteracy there is in the population is impossible to answer, the serious fact is that the proportion of backward individuals in Britain (on any criterion) is greater than before the war. In other words, average educational standards have fallen. Explanations of this are highly controversial and difficult to prove or disprove. That there has been a general decline in national intelligence, as forecast by eugenic writers, is not borne out by the Scottish Council for Research in Education's investigations. Often the blame is cast on modern educational methods. Here, too, the only available scientific evidence is negative; children educated in good "progressive" schools reach as high attainments as those taught in more "orthodox" schools. But it may still be true that some so-called progressive methods are slipshod and ineffective. Even so,

¹ *Reading Ability*, Pamphlet No. 18.

Sir Cyril Burt has found that much the most frequent causes of educational backwardness are, first, lack of intelligence, secondly, unfavourable home circumstances, and, thirdly, emotional maladjustment, anxiety, and lack of confidence. Poor teaching methods or school organization are only occasionally prominent. It would seem that the main reasons for the decline were wartime upsets such as bombing and evacuation, large classes, frequent changes of staff, and unsettled home conditions. Several of these still exist. For example, because of the high birth rate just after the war, the schools must for another ten years take more pupils than they are fitted for. No one knows whether certain home factors may not be more important—for instance, a decline in parental responsibility or increases in cinema-going and radio-listening or viewing. There is still much ground to be regained before achieving even pre-war standards.

TRAUMATIC EPILEPSY

When the Military Hospital for Head Injuries at Oxford was started in the early part of the war one of its purposes was the collection of well-documented case histories for research purposes, and since the end of the war a Head Injury Advice Bureau has kept in touch with many of the patients. Ritchie Russell and Whitty have made use of this material in a study of traumatic epilepsy, of which the first two papers have been published.^{1,2}

Here they have considered only penetrating wounds of the brain. The occurrence of a single epileptic fit or focal attack put the case into the category of traumatic epilepsy, though some patients who had attacks about which too little was known were not classified as epileptic. Of 820 survivors of penetrating brain wounds, 43% have developed epilepsy within five years of the wound. Among the 464 patients who have not developed epilepsy, 61 have been followed up for less than five years, and the probability is that some of these men may also become epileptic in the future. It is well recognized that epilepsy may start later than five years after an injury. In Ashcroft's³ first war series fits started at a later date in 10% of the cases, and therefore the eventual incidence of post-traumatic epilepsy in the series is likely to be higher than 43%. However, in over half the cases fits are

infrequent and are not in themselves causing serious disability. Figures from the first war are similar. Ashcroft, using Ministry of Pensions records, found a 45% incidence in 129 cases, and in other series the figures have been 44% of 562 cases⁴ and 49.5% of 1,234 cases.⁵ It is disappointing to find much the same incidence in the two wars, for it was hoped that the earlier surgery practised in the last war, the better wound debridement, and the reduction of infection with less scarring as a consequence would diminish the incidence of this complication. But some severely wounded patients may have survived who might have died of their wounds in the first war. This comparable incidence of traumatic epilepsy is some evidence against the idea that an important cause of the epilepsy is progressive scarring in the brain. As the authors point out, the incidence is very similar to that of epilepsy occurring after a brain abscess (50%).⁶ Referring to what they call this one-to-one ratio between patients who do and do not develop epilepsy, they consider that it points to "a balance of two equally important factors which may swing towards or against epilepsy developing, according to which of the two factors is most damaged."

As in previous reports^{3,7} there is a higher incidence of epilepsy with wounds in the central part of the brain than with wounds towards the poles, but the authors have made the new observation that wounds within 5 cm. of the sagittal line have a statistically much lower incidence of traumatic epilepsy than wounds elsewhere in the brain.

The second paper is devoted to a study of focal motor and somatic sensory fits, including fits which start focally and become generalized later. These form by far the largest group of focal epilepsies in the series, and the observations are based on 85 cases. A number of interesting points have been brought out here. A fit starting with a sensory aura and then showing clonic movements is common, but it is very rare for the reverse spread from motor to sensory phenomena to occur. In only one patient were focal clonic movements followed by numbness, and in a few others by the uncommon epileptic phenomena of sensations of heat or of pain. It is also rare for one type of sensory aura to change to a different sensory aura.

From these two observations the authors suggest that the cortical cells concerned with sensation have easier anatomical access to the motor cortex than to post-central cells concerned with other types of sensation. Inhibitory epileptic attacks—and the authors suggest that numbness is the sensory counterpart of an inhibitory motor fit—tend to affect large

areas of the body than clonic motor or positive sensory attacks. This agrees with the experimental findings in monkeys that stimulation of suppressor areas tends to cause widespread rather than local motor inhibition. But there seems to be little evidence for the authors' suggestion that post-epileptic paralysis is due to involvement or release of some inhibitory mechanism rather than the more usually accepted view that it is an exhaustion phenomenon. One other observation is of importance. It is that clonic focal attacks are more frequent with small Rolandic wounds with a slight permanent sensory-motor deficit than with extensive wounds causing a severe hemiplegia. This undoubtedly supports the view that the cortex is specifically concerned with clonic movements.

These detailed clinical studies of the course of the epileptic fit in a series of cases where the extent of brain damage is fairly accurately known are of great value, especially when considered in relation to the results of electrical stimulation of the exposed human brain.⁸ Further reports on the more complicated fits with auras relating to the special senses, to speech, and to the body image will be awaited with interest, and of special importance will be the authors' final conclusions on the cause of traumatic epilepsy.

WORLD CONFERENCE ON EDUCATION

The First World Conference on Medical Education takes place in London next week. The British Medical Association is acting as host organization and will welcome to its Headquarters the many hundreds of visitors, from overseas as well as from Great Britain, who are meeting to exchange their diverse ideas and experience on undergraduate medical education—the main theme of the Conference. It is being held under the auspices of the World Medical Association, and the World Health Organization has lent a helping hand from an early stage; much support has also been received from the Council for International Organizations of the Medical Sciences and the International Association of Universities. Sir Lionel Whitby, the President, will be supported by Professor W. Melville Arnott as Deputy President, and, as Vice-Presidents, Professor A. Hurtado (Peru), Dr. Victor Johnson (U.S.A.), Sir Arcot L. Mudaliar (India), and Dr. A. Stampar (Yugoslavia), the last-named having taken the place of Professor René Sand, whose enforced absence through illness is much regretted.

The great variety of topics to be discussed at the Conference will make it of wide appeal to doctors, and it is hoped that as many as possible in this country will be able to take some time off, even if only

a day or so, to make their contribution to discussing what Sir Lionel Whitby describes as "the dominant problem facing the medical profession in the second half of the twentieth century"—the problem of medical education. He asks how, in an age of ever-increasing scientific advance and ever-increasing specialization of knowledge, we can best teach the young men and women who will be the doctors of the future. This is the challenge before the Conference. While no final answer can be expected, the great range of subjects to be debated and the participation of distinguished men from all over the world give promise that the first large-scale attack on the problem will carry far.

Registration takes place in the Registration Bureau of the Conference, Great Hall, B.M.A. House. The Bureau will be open between the following hours: Saturday, August 22, 11 a.m. to 4 p.m.; Sunday, August 23, 10 a.m. to 4 p.m.; Monday, August 24 onwards, 9 a.m. to 6 p.m. The registration fee will be £4 sterling, and concessionary fees are charged to those who take part for less than the full week.

METHYLPENTYNOL

A good many years have passed since a new kind of hypnotic has been discovered, and we have grown accustomed to the almost exclusive use of the barbiturates in one form or another. About two years ago Margolin and his colleagues¹ described the hypnotic properties of 3-methyl-pentyne-ol-3. The structure of this substance can be regarded as derived from that of methyl alcohol, CH_3OH , by substituting for the three hydrogen atoms (1) $-\text{C}_2\text{H}_5$, (2) $-\text{CH}_3$, and (3) $-\text{C}_2\text{H}_5$, respectively, the last substituent being the group remaining when one hydrogen atom is removed from acetylene, so that it can be written $-\text{C}\equiv\text{CH}$. Methylpentynol, as it is called (or methylparafynol), is unlike methyl alcohol in that it does not cause intoxication, but when administered to animals or man it sends them to sleep. It can be given by mouth. In addition it has the very important advantage that it is broken down in the body with fair speed. The safety of a hypnotic depends on the rate of its removal or breakdown, and when methylpentynol was given to dogs in amounts of 200 mg./kg. less than 5% was excreted during 24 hours, and none could be detected in the blood after two hours.

Hirsh and Orsinger² have studied the hypnotic action in 276 patients of ages from 20 to 83 suffering from various diseases, and found that when 500 mg. was given 93% fell asleep in one hour and slept for five hours or more. Only 5 out of the 276 noticed any after-effects.

Several other clinical reports have been published^{3,4,5} in which similar results have been described. In all the clinical trials sleep was induced in a very high percentage of subjects, with no hangover on awakening and no nausea or other reactions. In one case the drug was taken daily for six months. Dogs and rats have been given amounts equivalent to 70 times the therapeutic dose, and no gross pathological changes were found and no abnormalities of the blood, of renal function, or of blood sugar. There appear to be no contraindications to the use of methylpentynol. It has been given safely to patients with hypertension, arteriosclerosis, portal cirrhosis, and diabetes. Children in hospital who experienced long periods of wakefulness and restlessness before sleep were able to sleep more quickly when given 150 mg. of methylpentynol, and were not drowsy when they awoke. In some cases sleep was permanently improved when the drug was given for a month and then stopped.

An overdose of methylpentynol causes deep sleep from which the subject can be roused by the injection of caffeine. The drug is said to have no depressant action on heart and respiration and no anaesthetic or analgesic action. For this reason it is less effective when sleeplessness is due to pain.

All the published accounts suggest that a useful new means of dealing with insomnia has been discovered. But a cautious attitude about the safety of methylpentynol must be maintained until it has been more widely used, for most new drugs pass through a phase in which they are esteemed too highly. A substance of this kind, related to alcohol, will almost certainly have depressant effects on the liver, on the heart, and on the respiration, even if these are slight, and no responsible person should suggest at this stage that it is completely harmless.

BIOLOGICAL SYNTHESIS OF VITAMIN C

An important advance in our knowledge of how plants make vitamin C has recently been achieved at Cambridge by Mapson and his colleagues. Vitamin C, or ascorbic acid, is closely related to the hexose sugars, of which glucose is the most familiar. But whereas glucose has a D configuration according to a scheme based on the structural formula rather than on the actual optical rotation, the natural form of ascorbic acid has an L configuration. In the manufacture of synthetic vitamin C, therefore, glucose cannot be used as the starting point. The chemist has to turn to sorbose, a less readily available hexose having an L configuration.

But twenty years ago Ray¹ showed clearly that the plant is less particular in its choice of starting material for synthesizing the vitamin. When excised pea embryos were nourished on media containing various sugars, glucose was found to be highly effective in increasing synthesis. Since ascorbic acid is formed by all plant

tissues, and not only in those rare instances in which L sugars predominate, Ray's observations were perhaps only to be expected. The subtle mechanisms of the plant cell can obviously induce structural changes in the hexose molecule in ways which cannot yet be imitated by the organic chemist.

Until recently we were not only unable to imitate the plant's mechanism, but had no reasonable theory about the sequence of the reactions leading to the production of the vitamin from glucose. Thus it was thought possible at one time that D-hexoses, such as glucose or galactose, might be split up into trioses, which could then be recombined in an L configuration. But experiments with the rat, an animal which resembles the plant in being able to synthesize ascorbic acid, failed to support this view. When glucose uniformly labelled with radioactive carbon atoms was administered, the ascorbic acid which was produced from it was also found to be uniformly labelled. This would be an improbable finding if the glucose molecule had been split in half, since most of the radioactive triose would presumably have recombined with non-radioactive trioses formed in the normal course of metabolism.

The evolution by Isherwood, Chen, and Mapson² of an alternative theory which seems completely to fit the facts must therefore be counted an outstanding scientific advance. These workers took their clue from the well-known observation that when animals are dosed with hypnotic drugs, such as chlorbutanol, the production of glucuronic acid, which is used for detoxication, is accompanied by a large increase in the production of ascorbic acid. Might this not mean that glucuronic acid is an intermediate step in the production of ascorbic acid from D-hexoses?

Intensive chemical studies in which various hexoses and derivatives of glucuronic acid were tested as sources of L-ascorbic acid confirmed this hypothesis, and gave an ingenious explanation of the reversal between the D and L configurations. Let us picture the glucose molecule as having a hydroxyl (reduced) group at one end and an aldehyde (oxidized) group at the other. Further oxidation of the aldehyde group to form the carboxyl group of glucuronic acid would leave the configuration in the D form, and attempts to synthesize ascorbic acid would inevitably end with the D isomer, which has very little biological activity. But if the oxidation to carboxyl occurs at the alcohol end of the molecule, and the aldehyde group is later reduced, the configuration of the molecule is effectively turned upside down. Processes directed towards the formation of the ascorbic acid must now produce the natural L variety.

According to Isherwood, Chen, and Mapson the steps along the route of synthesis in the plant or animal are D-glucose, D-glucurono-γ-lactone, L-gulonono-γ-lactone and L-ascorbic acid. With galactose the corresponding steps are D-galactose, D-galacturonic methyl ester, L-galactono-γ-lactone, and L-ascorbic acid. L-Galactono-γ-lactone is more efficient than L-gulonono-γ-lactone in promoting the synthesis of ascorbic acid in plants, but both are equally effective in animals. Experiments of

the synthesis of vitamin C by enzyme systems *in vitro* are proceeding, and successful preliminary experiments are, we understand, soon to be published.³ The enzyme necessary for the conversion of the γ-lactone to ascorbic acid is present in the mitochondria of plant cells.

MORPHINE AND ALCOHOL

A few weeks ago we discussed the synergistic action of alcohol and barbiturates taken together, and suggested that drivers of cars would be very unwise to mix their drugs in this way.¹ Two recent papers from Professor K. O. Moeller,^{2,3} of Copenhagen, contain some details about the effects of morphine on patients who had fairly high concentrations of alcohol in their blood, and he reports seven deaths. The alcohol concentration in the blood of these patients was from 0.18 to 0.27%, far lower than the amount usually regarded as lethal (0.4 to 0.5%). One patient was a woman with cholelithiasis. She was strongly addicted to alcohol, and had already consumed a large quantity when she went to her doctor for an injection to relieve her pain. As he was not at home at the time she persuaded the doctor's wife to give her an injection of 20 mg. (½ gr.) of morphine. Two hours later the patient was found unconscious at home and she died shortly afterwards. At necropsy gall-stones were found in the gall-bladder, morphine in the liver and urine, and alcohol in the blood in a concentration of 0.2%. In a second fatal case morphine was given for biliary colic and in a third for renal colic (stones were present in both). In the remaining four cases morphine or morphine and scopolamine was given to quieten restless or violent alcoholics—the dose of morphine varying from 15 mg. (¼ gr.) to 26 mg. (½ gr.)—and in addition two of the patients were also given an intravenous injection of a barbiturate compound. All died from one and a half to five hours after the administration of morphine. In healthy individuals the lethal dose of morphine is as high as 100 mg. (1½ gr.) by subcutaneous injection, and, since the concentration of alcohol in the blood of all these patients did not approach the lethal amount, Moeller concludes that morphine acts synergistically with alcohol. Thus the administration of morphine to patients under the influence of alcohol may have serious consequences.

CARE OF AGED IN SCOTLAND

The study of how best to care for old people is in no danger of becoming one of the neglected backwaters of medicine. Now a new report⁴ from Scotland adds some sound and kindly advice on what is already a considerable problem. Between 1921 and 1947 the number of people of pensionable age in Scotland rose from 377,000 to 629,000. By 1969 they are expected to number 858,000, or 15.5% of the population, as compared with 7.7% in 1921. The proportion of elderly people varies in different areas, in 1947 ranging from 25% in the north to 10% in the Lanarkshire burghs. This is no doubt one of the consequences of industrialization, for the young

men are tempted to seek their living near the city lights. The old people are left behind, and families are neither large enough nowadays to care for the elderly members easily nor so dutiful as to make the often considerable sacrifice that was expected in former times.

The ideal that this report advocates is "to have healthy people living their own lives in their own homes, and to postpone senescence as long as possible." Much can be done, the report adds, and perhaps the most pressing of the needs whose fulfilment it advocates is the provision of suitable houses and, where necessary, domestic help. In the long run this is probably of much more importance to the wellbeing of the old than anything the health services can offer, and it is a matter for regret that the authors of the report found a "great lack of information and knowledge" here. They were right to point out also—though without the emphasis it deserves—that a happy old age is something that must be prepared for. It is not so much a question of cheap tobacco and Windsor chairs and T.V. sets as the consequence of a youth ill or well spent. Whether the Welfare State, in partly relieving many people of the need to save up for old age, will also diminish their capacity to prepare mentally for it is a matter for speculation. But at any rate the report does make the point that old people's interests must be kept up, hobbies encouraged, and loneliness dispelled.

For people who cannot, even with help, manage their own lives, some kind of hostel care is necessary—and much more of it than exists at present. The committee finds that about 10,000 places are available but that at least 17,000 are needed. Nor is their provision a matter only of affording the most suitable accommodation: the scarcity of hostel places is uneconomic, for 35 old people in a hostel can be looked after by a staff of 7 or 8, in a general hospital by about 20, in a long-stay annexe by 13 or 14, and in their own homes by about 12 full-time home helps. There are clearly strong arguments here for including more hostels in the current building programmes.

The report is rightly emphatic about the need to restrict hospital admissions of elderly people to those who require investigations or treatment best undertaken in hospital. And the corollary is no less important—namely, that the patient should be discharged when the investigation or treatment comes to an end. Unfortunately many circumstances compel hospitals to depart from these ideals, one of the commonest being that there is no home to which the patient can be discharged. While this again is a problem that is perhaps more social than strictly medical, the report has some valuable suggestions on the part that efficient aftercare services could play in helping the old person get back to health outside hospital. But until long-term measures get going the elderly are bound to make considerable demands on hospital beds, and all who have the care of them will especially welcome the committee's plea for more field research into the best means of helping them.

REFRESHER COURSE FOR GENERAL PRACTITIONERS

SUBACUTE BACTERIAL ENDOCARDITIS

BY

RONALD V. CHRISTIE, M.D., F.R.C.P.

Professor of Medicine, University of London; Physician, St. Bartholomew's Hospital

The effective use of antibiotics has not only changed the prognosis and clinical course of subacute bacterial endocarditis but has entirely altered the emphasis on early diagnosis. Ten years ago the diagnosis was seldom made until the disease was well established, while today any patient with a heart murmur and unexplained fever should be suspect. In my own wards patients suffering from rheumatic fever, cystitis, glandular fever, virus pneumonia, carcinoma of the stomach, periarteritis nodosa, haemolytic anaemia, and perianal abscess have been admitted with the diagnosis of subacute bacterial endocarditis, and in each case, although the initial diagnosis was shown to be wrong, the admission of the patient to hospital should be taken as evidence of good judgment and efficiency on the part of the general practitioner involved. Early diagnosis is of great importance to the patient, therefore a full investigation is indicated when subacute bacterial endocarditis is first suspected.

Early Diagnosis

It is unfortunate that the early clinical manifestations are not only variable but often vague and ill defined. Fever is probably the most reliable early sign, but the degree of malaise with which it is associated is often so slight that it may pass unnoticed. The first complaint is usually of fatigue, loss of appetite, and sometimes pains in the joints. The patient may feel chilly and slightly feverish, and the temperature is found to be raised. If the patient is examined at this stage some of the physical signs of the disease such as splenic enlargement, petechiae, or embolic phenomena may be found, but often these are absent and the diagnosis can be established only by blood culture. Less frequently the disease remains unsuspected until the sudden onset of rigors and fever or of embolism and infarction.

Early diagnosis is now important, since delay in treatment undoubtedly diminishes the chances of survival, not because the infection is less readily controlled but because damage to the heart is both progressive and dangerous. Any patient with valvular or congenital heart disease who has unexplained fever should be suspect, and it follows that in the differential diagnosis all conditions which give rise to prolonged fever have to be considered, particularly those associated with splenic enlargement. Urinary infection is a common source of error, and tuberculosis and typhoid, glandular, and other fevers may have to be excluded.

The most difficult disease to distinguish from subacute bacterial endocarditis is rheumatic fever, a difficulty which was emphasized by Horder over 40 years ago. "It is probable that all the symptoms and signs of infective endocarditis may be met with in rheumatic fever, save the isolation of micro-organisms from the blood. Recurring attacks of subacute rheumatism in patients who have previously developed valvular disease often give rise to considerable anxiety on account of the similarity which they bear to the symptoms of infection of the endocardium." It is now much more important than it was to distinguish between these two diseases, but unfortunately there has been no corresponding improvement in diagnostic methods during the past 40 years. Even if blood cultures are repeatedly negative the diagnosis may remain in doubt, and therapeutic tests, first with salicylates and then with penicillin, may

have to be resorted to. The response to cortisone should never be used as a guide, since this may be disastrous in patients with subacute bacterial endocarditis.

Treatment

A unique feature of this disease is its resistance to treatment, although the infecting organism, which is usually a streptococcus viridans, may be sensitive to penicillin and to a variety of other chemotherapeutic agents. Large doses of penicillin are now recommended, and, although accurate figures are not yet available, it seems probable that the infection can be controlled in 95% or more of the cases. When the organism is not more than twice as resistant to penicillin as the standard Oxford staphylococcus, 2,000,000 units a day for four to six weeks will almost always be effective. In about 10% of cases the resistance of the organism is approximately four times that of the Oxford staphylococcus, and in these the daily dose should be increased to about 4,000,000 units. In about 5% of cases the resistance of the organism is more than eight times that of the Oxford staphylococcus, and under these circumstances the system of dosage to be adopted should be decided only after careful consideration of each individual case.

It is with this group of patients that disappointing results have been obtained. Information is as yet inadequate on the system of dosage which should be adopted in the treatment of these resistant cases, but in general it is true that the best results are obtained when the daily dose, if given by continuous infusion, would maintain a concentration in the blood which is about 50 or 100 times as great as the concentration required to kill cultures of the organism. In some patients very large amounts of penicillin may be sufficient, either when given alone or when given with some substance such as probenidol which delays the excretion of penicillin. As much as 40,000,000 units a day may be required, but when this degree of resistance is encountered the use of other antibiotics should always be considered, and it is in making this selection that mistakes are often made.

When antibiotics other than penicillin are used it should be borne in mind that bacteriostatic agents such as aureomycin and terramycin are seldom effective even when laboratory investigations indicate that the organism is highly sensitive. The practice of giving aureomycin because the laboratory report seems favourable and because the patient does not appear to be responding to penicillin should be condemned, since it seldom succeeds and usually only leads to delay in effective treatment. A more profitable line of approach is a combination of penicillin with streptomycin, which is also bactericidal, but it should be emphasized that combined antibiotics should be used only under close laboratory supervision. The interaction of antibiotics is a matter of great complexity, and the laboratory supervision of cases which are resistant to treatment with penicillin demands a high degree of skill and specialized knowledge.

For obvious reasons the patient should be confined to bed and the general principles involved in the treatment of any prolonged febrile illness should be applied. Anaemia should be given treatment appropriate to its severity, and it is important that an adequate state of nutrition should be maintained. Foci of infection should be searched for, and dental sepsis should if possible be eradicated while the patient is being treated with penicillin.

Response to Treatment.—The blood culture usually becomes sterile within a few days of the beginning of

treatment, but not infrequently fever persists longer, although it usually falls within a week. The danger of infarction and other embolic phenomena remains throughout treatment and convalescence, but in lessening degree. The spleen diminishes in size, often quite rapidly. In contrast, haematuria may persist long into convalescence. The erythrocyte sedimentation rate may remain high during treatment, but falls slowly during convalescence. In the absence of complications such as heart failure or major emboli it is usual to allow patients to sit in a chair for a week after the cessation of treatment, and then to encourage an increase in activity according to the patient's capacity.

Relapses, Prophylaxis, and Prognosis

Relapses.—These seldom occur more than a month after treatment, but a slight risk, amounting to about 2% of patients per annum, of relapse or reinfection remains. The treatment of patients who fail to respond to the usual dosage presents a special and difficult problem. A larger dose should be given, probably at least 5,000,000 units a day for a period of six to eight weeks, but, as already emphasized, the system of dosage should be carefully regulated according to the sensitivity of the infecting organism.

Prophylaxis.—Dental extraction and removal of other foci of infection have long been regarded as precipitating factors in this disease. In patients with rheumatic endocarditis or congenital heart disease a prophylactic course of penicillin for these minor operations should be insisted upon. A dosage of 500,000 units daily for three days is usually recommended, the first dose being given an hour or two before the operation. It is perhaps not generally realized that this system of dosage, which is the one generally used in prophylaxis, is based not on clinical trials but on an intelligent guess made many years ago when penicillin was in short supply.

Prognosis.—Death from heart failure is now a much greater hazard to the patient than the risk of failure to respond to penicillin. About a third of the patients who are apparently cured die in heart failure within two years of treatment with penicillin, and the outlook is particularly gloomy in those who have evidence of heart failure when treatment is started. If heart failure is severe the patient rarely survives more than a few months, and even if it is slight the chances against survival for more than two years are about four to one. Other adverse factors in prognosis are delay in treatment and relative insensitivity of the infecting organism to penicillin.

Refresher Course Book.—The first collection of articles of this series (fully revised) are available as a book containing 55 chapters, price 25s. Copies can be obtained either direct from the Publishing Manager, B.M.A. House, Tavistock Square, London, W.C.1, or from booksellers.

Nova et Vetera

THE DISCOVERY OF INSULIN

The Nobel Prize was awarded in 1923 to Banting and Macleod "for the discovery of insulin." Macleod's contribution to this dramatic discovery has been for long disputed. It is widely thought to have been both considerable and direct, and nearly 20 years later, in 1941, the *British Medical Journal* obituary notice on Sir Frederick Banting referred to "experiments in collaboration with the late Professor J. J. R. Macleod and Dr. C. H. Best which led to the discovery of insulin." Macleod's close participation in the research would not have been surprising, for the absorbing interest of his academic life was the metabolism of carbohydrates. His first papers on experimental glycosuria were published in 1905, and a series of 12 papers under the general title of "Studies in Experimental Glycosuria" was published in the *American Journal of Physiology* between

1907 and 1917 in addition to a series of 18 papers between 1908 and 1921 dealing with other aspects of carbohydrate metabolism.

Yet his inclusion in the Nobel Prize award led to bitter criticism of the prize-jury's decision. It was alleged that Macleod had been away from Toronto when the decisive experiment was made, and that, although he had put the facilities of his laboratory at Banting's disposal, he had had no part either in the formulation of the hypothesis on which the discovery was based or in any of the experimental investigations by which insulin was isolated and evaluated as a therapeutic agent. Best, who was Banting's close and acknowledged collaborator, was not given a share in the honour. According to Göran Liljestrand (1951), Banting expressed his dissatisfaction by sharing his half of the prize with Best, whereupon Macleod gave a corresponding part of his to J. B. Collip, who had participated with him in the purification and standardization of insulin.

Some Simple Facts

Nearly 30 years after the event we can now read Best's version (1952) of the early days, given as his corrective to "a few interesting statements about the early development of insulin which I completely fail to recognize." In the Banting Memorial Lecture for 1952 he writes:

"The facts are simple and straightforward. The young surgeon formulated an hypothesis which was vital to his initiation of the work and it thus completely fulfilled its function. He obtained permission to explore this hypothesis in the Physiological Laboratory of his Alma Mater and he received some excellent general advice from the Head of the Department. The second working hypothesis was that an internal secretion of the pancreas existed and that it could be captured. This one Banting and I shared, and in its exploration we invested our time and energy. We formed a partnership which was based on the new knowledge and experience which we gained together. We had no stipends, but the facilities of Professor Macleod's deserted department were at our disposal. We worked completely alone during the four summer months of 1921 without any verbal or written advice from any senior investigator and until well after the salient facts, consistent dramatic lowering of blood and urinary sugars and complete recovery of our moribund depancreatized dogs, had been repeatedly demonstrated." (There are no italics in the original.)

"Banting and I presented our work to the Medical Faculty at a departmental seminar in the autumn of 1921, and our findings were later published in two papers under our names in the *Journal of Laboratory and Clinical Medicine*. These papers give the first detailed account of our isolation of insulin. We were given an impression that a member's name was necessary for the acceptance of a paper to be read at the meeting of the American Physiological Society, and for this reason Professor Macleod's was added to the preliminary paper presented in December, 1921. Banting and I always hoped that our article on 'The Internal Secretion of the Pancreas,' which appeared in the February, 1922, issue of the *Journal of Laboratory and Clinical Medicine* and which we wrote for and presented to our Medical Faculty on November 14, 1921, would be universally accepted for what it in fact was, the original record of our work. The paper which bore, in addition, the name of the Head of the Department was a summary of the longer one. We prepared it later, but it appeared in print first."

Another commonly held misconception is also dispelled by Best—namely, that he was a medical student when he volunteered to work with Banting. He was, in fact, after five years of university study (and a year in the Canadian Army) a very recent graduate in the arts course of physiology and biochemistry. For family reasons he was particularly interested in diabetes and had been a part-time research worker on this subject and a demonstrator in physiology to medical students during 1920–1. He registered for an M.A. in physiology during the year that he and Banting worked together and was admitted to the degree in June, 1922. It was not until September, 1922, 16 months after the joint work on insulin had begun, that he decided to proceed to an M.D. and registered as a medical student in the University of Toronto.

The Pain of Transurethral Manipulations

SIR,—As a general practitioner I cannot listen unmoved to my patients' accounts of how they have suffered during their in-patient treatment for genito-urinary complaints. During the past few years one after the other has told me of the agony he has suffered during cystoscopy and urethral catheterization, and particularly during such transurethral manipulations as are required to treat the complications of prostatectomy whichever route is employed. It appears that some attempt is made at anaesthetizing the urethral mucosa with a surface anaesthetic, but the pre-operative injections do little to support them during the ensuing ordeal.

These men tell me that they have endured as much as they can bear, and in two cases, where repeated manipulations were required for treatment of neoplasm, the patients discharged themselves because they were not brave enough to endure any more. These patients were not neurotics, and I hear no complaints from those who have undergone other forms of surgical treatment. Nor have all these patients attended the same hospital, but four different centres, so I assume that the technique differs little from place to place.

Are anaesthetists so few that none can be spared for "minor" genito-urinary sessions? Or do surgeons hesitate to employ them for "minor" procedures because the complexity of modern anaesthetics tends to reduce the operations to a mere incident in the induction of the anaesthesia? At all events it seems that the demon pain has been evicted from nearly every corner of surgery except from the cystoscopy and other things which are pushed up the male urethra. I am aware that genito-urinary surgeons are not by nature callous, but by long practice they have come to countenance the patients' reactions to urethral instrumentation as routine. The consolation that "it will soon be over" and "it has got to be done" does little to dull the pain of a large-size operating cystoscope turning through 360 degrees in the urethra—likewise the bladder washout via the urethra to control post-operative haemorrhage—for by then the spark of human vitality has grown very dim and the patient has literally reached the limit of endurance.—I am, etc.,

Sheffield.

E. C. ATKINSON.

Comfort in Callipers

SIR,—Dr. H. L. Rogerson (*Journal*, August 8, p. 337) has, I am afraid, done nothing to improve the design of the walking-calliper. What he has produced is not a calliper but a walking-splint for the lower extremity, the design of which is rooted in greater antiquity than the "antiquated calliper" about which he complains. This is not to say that his appliance is not an excellent one for his own particular case and illustrates the virtues of what one may call bespoke craftsmanship. The appliance is an expensive one to make, and, though it may stand up to Dr. Rogerson's personal needs, would not be suitable for everyday use by the majority of patients. For nine out of ten cases of poliomyelitis with the amount of paresis which he described (especially those who are young, active, and often heavy) it would be mechanically unsound.

The principle of the long outside iron fitted to a pelvic band was in use in the early nineteenth century. It was discussed and discarded by H. O. Thomas for the purposes for which he designed the calliper. The self-locking and quick-release knee hinge, the posteriorly placed knee hinge, and the eccentric articulation are all well known to surgical appliance makers; there is nothing new in that. The use of "duralumin" is of dubious advantage, for it has not, size

for size, the strength of steel, it cannot readily be forged, and in jointed parts the friction surfaces must be faced with steel. A well-forged steel appliance is little, if any, heavier than duralumin and is stronger. Certainly at the hip the need for strength is very great.

From hard experience one must say that in splint design "there is nothing new under the sun." Dr. Rogerson has, however, emphasized the need to provide long-term appliances for poliomyelitis which are made by individual craftsmanship for the particular problem. Mass production cannot solve this problem.—I am, etc.,

Exeter.

NORMAN CAPENER.

Fog Control in the Home

SIR,—In view of the great increase in sickness and deaths from pulmonary disorders attributable to the poisonous composition and long duration of the London fog of December 5-9, 1952, and the possible recurrence of that disaster, it is essential that any valuable lessons to be learnt from that experience should not be lost sight of.

In this connexion I beg to draw attention to certain ready and practicable measures which the householder can take to prevent the gross penetration of fog into living-rooms and bedrooms, as illustrated by the case of a lady aged about 75 living in London, who invariably suffers from bronchitis during the winter. Some years ago she had the open fireplace in her bedroom sealed off and used an electric radiator for heating the room. Normally she keeps the windows open, but during the intense fog of December, 1952, they were closed and the room, in which she was confined to bed, was practically free from fog during the worst period. I think she owes her survival to this fact.

Based on this experience, I do feel that in the event of a recurrence of dense fog the following action should be taken in houses supplied with electricity. No open fires or gas fires should be lit in living-rooms or bedrooms, as the room air passing up the chimney causes fog-laden air to be drawn into the room from outside. Windows should be kept closed and fireplaces or chimney flues sealed off, as an open flue causes a good deal of ventilation even though the fire is not lit. Electric radiators should be used if heating is required in the room, but less heat will be needed, as the ventilation is reduced. Provided flueless gas heaters are not used in small rooms, it might be desirable for air-bricks to be sealed up during the fog and to reopen them and unseal the fireplaces in other rooms as soon as the fog has abated.

If prompt action is taken to carry out the above recommendations, not only will the gross penetration of fog into rooms be prevented but its entry into the house as a whole will be lessened. These measures are calculated to be of particular benefit to persons with respiratory disabilities whose distress is aggravated by breathing fog-laden air.

Finally, Sir, it may be worth while recalling that the A.R.P. sealing of rooms to prevent the entry of poisonous gas was carried out by countless householders in the early days of the war. It would be gratifying if that experience finds application in ordinary times pending the hoped-for solution of the difficult problem of atmospheric pollution.—I am, etc.,

London, W.C.1.

GUY P. CROWDEN.

Chronic Bronchitis

SIR,—The annotation under the above heading (*Journal*, August 1, p. 268) is very timely. It points out the extreme gravity of the condition and draws attention to the economic loss we suffer from a too facile attitude to coughing. I believe we shall not progress in prevention of this and other chest diseases until we regard a persistent cough as seriously as persistent vomiting. The two symptoms have similar causes, infection and local irritation being the most prominent. In 1950, the last year for which figures are available, 16,500,000 working days were lost in England and Wales from bronchitis. Your contributors are too pessimistic when they conclude that a logically planned attack is not yet possible. Most of the factors are known—they are: (a) recurrent infection related particularly to overcrowding at home, at school, and at work; (b) atmospheric

pollution; (c) inhalation of dust and fumes at work; and (d) smoking, especially cigarettes.

As a profession we can do much more about each of these problems than we do at present. Our views on the lives of people in overcrowded areas have not been expressed sufficiently forcibly. In the Gorbals district of Glasgow 296 people live on each acre of ground. Cattle could not exist in such numbers. The incidence of tuberculosis and respiratory disease is closely related to this factor. The conditions in many urban and rural schools prevent children remaining well. Those responsible for the health of school-children should press for more healthy provision for scholars. Early and continued attention should be given to each attack of respiratory infection, and more seaside and country convalescent homes should be available for use by the general practitioner. It is absurd that a patient must be referred to hospital before convalescence can be arranged.

The overwhelming importance of atmospheric pollution in relation to respiratory disease was demonstrated by the great London fog of December, 1952. 6,000 people died as the direct result of this, while hundreds of thousands had their bronchitis exacerbated and their lives shortened. At the same time some of the finest cattle from the countryside were unable to live in our vitiated air and died of bronchitis and acute emphysema during a cattle show. No more scientifically controlled experiment could have been devised and yet it seems that little will be done. Eight months after the event a committee is set up by the Government to study the problem. In the past this has so frequently been a device for ensuring no action was taken that one fears this may be intended again. As a profession I think we should be active in smoke abatement both at home and nationally. Life could be much more pleasant and healthier, despite our damp climate. The conditions in factory, foundry, and mine leave much to be desired in most areas. Chronic pulmonary cripples are being produced each year by needless dust and fumes. The workers of the country must breathe pure air.

Finally, the harm done by smoking must be appreciated. No person who has smoked cigarettes for 20 years or more fails to cough—and many cough persistently each morning. Few will admit this because of a desire to continue the addiction. In practice more than 80% of bronchitics are heavy smokers. We should set them an example by not smoking ourselves and then assure them that unless they give up smoking no adequate relief from coughing can be expected.

The air we breathe is as important as the water we drink. It must be uninfected and unpolluted. A sanitary revolution commencing 100 years ago has done much to eliminate water-borne disease. We should work for the elimination of bronchitis and other air-borne diseases.—I am, etc.,

London, N.W.10.

H. JOULES.

Breast-feeding in Oxford

SIR,—I was very interested in the paper by Drs. Alice Stewart and Celia Westropp on breast-feeding (*Journal*, August 8, p. 305). I feel, however, although I am in no sense a statistician, that the conclusions are fallacious. The following are some of the criticisms which seem to me to invalidate the conclusions.

The children studied were selected. The writers state that "the enrolment procedure effectively excluded babies who were seriously ill at or before this age (2 months)." What proportion of the babies excluded were breast-fed at 2 months? It is very likely that a large proportion were bottle-fed. In that case an unduly large proportion of babies who had been ill would be excluded from the artificially fed group, and so the entire results would be invalidated.

There is no mention as to how and by whom the various observations were made. Were all the babies examined by the same person, and did that person know to which group the babies belonged? If she did, the element of bias was not eliminated. This might well be important, for several of the features studied were matters of opinion and interpretation. How, for instance, was the "closure of the fontanelle" assessed? If it was assessed by palpation, then it was a matter of opinion whether it was closed or not. Bias might well affect that opinion.

The writers say that "at the age of 1 year the babies who were bottle-fed from the beginning . . . showed signs of being slightly more mature." I can find no evidence for that statement. It is not clear what is meant by "more mature," but, if it refers to the radiological data, the "closure of the fontanelle," and the "crawling and walking," then I cannot see how that conclusion was reached. They give figures for the appearance of the distal radial epiphysis: unless my deductions from their

Table are incorrect, 61% of those weaned at or after the fourth month had the distal radial epiphysis, as compared with exactly the same proportion, 61%, of those weaned earlier. Their Table shows that there were exactly the same number of carpal bones (2.24) per radiograph per child in the two feeding groups, group 1 (babies weaned in the first month) and group 4 (weaned after the fifth month). As for the closure of the fontanelle, the differences between the various groups are not statistically significant (unless my mathematics are wrong), neither is there even a constant trend in the Table: for 41.7% of those in group 2 (babies weaned in the second or third months) and 31.1% in group 3 had a "closed fontanelle" at 12 months as compared with 30.3% in group 1 (those weaned in the first month).

As for the "milestones," walking and crawling, unfortunately these are not defined. Does "walking" mean walking with two hands held, one hand held, or without support? And was it assessed by the mother or doctor? However, taking the figures as they are given, once more there is no evidence to support the statements made: 63% of the babies in groups 3 and 4 were crawling at 10 months, as compared with 64% in groups 1 and 2; 71.7% of those in group 3 were crawling at 10 months, as compared with 61.8% of those in group 1. As for "walking," the difference between groups 1 and 4 is not of statistical significance. I do not think that many will accept the statement that "at 14 months the babies who were breast-fed longest were very slightly 'less mobile' than the others." It is interesting to note that the average number of teeth in group 4 at 12 months was 6.04, as compared with 6.82 in group 1. But in what way does it matter?

In the section on the incidence of infection, I am not able to follow all the statistical arguments. But what is the meaning of the statement: "In the case of head colds it was often impossible to identify the precise mode of feeding at the time of the illness"? Do the data on the method of feeding depend on the mother's memory of what she did some months back? Having shown that the incidence of colds is greater, as is well known, in households in which there are schoolchildren, the writers do not say whether the incidence of households with schoolchildren is the same in the four feeding groups. If it were different, it would alter the incidence of infections in the various groups.

The writers discuss the fact that the bottle-fed babies weighed slightly more at 12 months than the breast-fed babies, and say: "We are therefore driven to the conclusion that, in spite of continuous medical supervision, minor degrees of underfeeding among the breast-fed babies had occurred and had been overlooked." Surely that argument is fallacious. Because one child weighs less than another at the same age it does not mean that he is underfed. Babies who are weaned early might well be given rather a lot of starchy foods, which would increase the weight. But surely there is no evidence to suggest that such babies are better because they are bigger.

There are other points in the paper which cast doubt on the validity of the results, but space will not permit of their consideration here.—I am, etc.,

Sheffield.

R. S. ILLINGWORTH.

SIR,—I found the Oxford breast-feeding survey by Drs. Alice Stewart and Celia Westropp (*Journal*, August 8, p. 305) very interesting, particularly as the findings were in rather striking contrast to a small survey I did in Bristol in 1942-3. In this survey, for which statistical details are, unfortunately, not available, 1,000 consecutive cases were studied. They were studied in four groups: (1) 1-6 months, subdivided into 1-3 months; (2) 6 months-1 year; (3) 1 year-18 months; (4) 18 months-2 years. They were investigated for colds, tonsillitis, otitis media, gastro-enteritis, broncho-pneumonia, and skin infections.

My figures showed that upper respiratory infections were definitely more common in the bottle-fed children in group 1. Gastro-enteritis was slightly more common and more severe in the bottle-feds up to 18 months. The incidence of bronchopneumonia in groups 3 and 4 was about equal, but was more severe in the bottle-fed babies. Skin infections, particularly eczema, were not frequent in bottle-feds in each age group.

The bottle-fed infants weighed more than the breast-fed, but maturity was not assessed, except in regard to crawling and walking. The breast-fed babies were, in this series, the more mobile—possibly, I thought, owing to being lighter in weight.—I am, etc.,

Farnham Royal, Bucks.

MARY HERFORD.

Clinical Research in the N.H.S.

SIR,—I would like to support the letter from Dr. G. I. Watson (*Journal*, August 1, p. 286).

"Systematic investigations undertaken deliberately and often over long periods" are just the sort of investigations which general practitioners, either singly or in groups, would be most likely to undertake successfully. The more intensive type of investigation is particularly difficult for them, except as members of a team led by whole-time research workers.

I am glad that Dr. Watson has pointed out this unfortunate misconception in the *White Paper*.—I am, etc.,

Cirencester.

R. E. HOPE SIMPSON.

SIR,—I have had some experience of clinical research supplemented by experimental research. I have come to the conclusion that clinicians, which includes general practitioners, should be given an opportunity of doing part-time research of not less than two sessions per week with generous remuneration. Clinical research should not be restricted to those of registrar status, and the staff of hospitals should be encouraged to do this part-time work.

A niche in a research laboratory, with the services of a trained technician, should be provided, preferably at a research institute attached to a teaching hospital or to a university, where the advice and help of the departments of anatomy, physiology, pathology, radiology, and physics, etc., are available. The co-operation and support of one's colleagues and a supply of clinical material are essential.

Animal experiments require a team of an experienced experimenter with a licence, a trained technician, and an observer (a clinician or research worker), and in some experiments a physicist is desirable. Animal experiments may last five or more hours.

A clinician who has retired from his hospital appointment is well able to do clinical research in his spare time. He will find it interesting and he will be able to contribute something useful to medicine.

I could enlarge on this theme and give more details, but space will not permit.—I am, etc.,

London, W.1.

E. D. D. DAVIS.

Indigestion in Childhood

SIR,—As a general practitioner I have read Professor Norman B. Capon's Refresher Course article on indigestion in childhood (*Journal*, July 25, p. 197) with special interest, for there are few patients who cause more trouble to parents and G.P.s than the child with indigestion or who "won't eat." In some ways the G.P. who follows these cases from babyhood to maturity, and sometimes from generation to generation, is more fortunately placed to observe them even than the paediatrician; so continuous practice in a small town for some 30 years must be my defence for making some contentious observations on the paper of an expert that I have read with pleasure, particularly his remarks on the general management of these cases.

The first comment I would make, which will doubtless be met with the criticism that I have a one-track mind, is that I am sorry Professor Capon only mentioned appendicitis in connexion with acute indigestion. In my experience it is a common cause of the chronic variety also. I know this is often disputed, but as I was, I believe, the first person in this country to postulate from clinical examination the existence of "measles appendix," which was shortly afterwards described by a German pathologist. I have at least some claim to be able to recognize a pathological appendix when I meet one. Incidentally, the histological features of the measles appendix are so characteristic that some years later a surgeon in America removed an appendix, sent it down to the pathologist, and received the diagnosis of measles before the rash appeared, which it duly did.

In these childish cases the children seldom complain of abdominal pain unless the appendix is lying just below the abdominal wall. A more common complaint is a "stitch" in the right leg presumably due to irritation of the ileo-psoas, on or near which the inflamed appendix is lying, on active movement. This in turn often leads the child to avoid strenuous games and so to keep away from other children and cling to its mother's

apron strings. Subconsciously it feels that it is not quite as other children are and all sorts of behaviour disturbances may arise. It is often good-looking and usually nervy and excitable, for the mildly inflamed appendix seems to act as a nervous irritant. On examination the most constant and characteristic feature is the presence of Ligat's reflex over the appendicular spot, but examination for this must be very gentle or the child's confidence will be lost and any replies untrustworthy. Often it is best to ask no questions at all, for if the hyperaesthesia is at all marked the little patient's whole frame will be felt to stiffen as the spot is gently pinched, or next time it is examined it may cry instead. Usually there is tenderness on deep but gentle palpation, and some degree of muscle rigidity or guarding can be appreciated. The reality of this rigidity can be demonstrated by looking at the child with its shoulders bare, for the right shoulder will often be found an inch or so lower than the left owing to the constant excessive tone of the right abdominal muscles. (There are of course other causes of this crooked stance, but in my experience a chronic mild appendicitis is the commonest, and it is not normally present in a true acute appendicular flare-up, for relatively few of these cases ever progress to the common acute appendix.)

More might usefully be said about this condition, but I will only add that in these cases one can often wait months or years before deciding whether or when operation is desirable. It is, I think, commoner in girls than in boys, and, while the latter show some tendency to overgrow the condition, girls, I think, never do. If an operation is performed it must be done in such a way as not to terrify the child, and then the results for child, parents, and doctor are almost invariably gratifying.

The other point I would raise is that I am disappointed Professor Capon said so little about medical treatment. I know that it is fashionable to decry medicines, and especially glycerophosphates, but the fact remains that over 30 years I have found one preparation which does stimulate the appetite of these children in a remarkable way. I have seen it do it many times with my own children, and hundreds of mothers in Winsford have seen it with theirs. It is a long, complicated prescription known as Dr. Robin's formula for syrup, glycerophos. co. As it seems to vary according to the maker, I should say that for 25 years I have used that supplied by James Woolley & Co., of Manchester. I know of nothing else to touch it for stimulating appetite, though there may be others. I fancy that the most active principle may be the kola, but, as Lord Horder wrote of a much simpler mixture: "How much of the good which this preparation has done to humanity since some genius first invented it is due to any one of its ingredients none can say . . . nor at which part of the gastro-intestinal tract."

Of course there is a lot to be said against treating a symptom such as loss of appetite, but experience proves that if a child begins to eat well it usually begins to improve, and, though many of the conditions mentioned by Professor Capon may be pending or actually present, a healthy appetite goes a long way to make a healthy child, and these underlying or accompanying disorders tend to disappear.—I am, etc.,

Winsford, Cheshire.

Eczema and Reticulosis

SIR,—The description of a case of Sézary's reticulosis with exfoliative dermatitis by Drs. Harold T. H. Wilson and J. Fielding (*Journal*, May 16, p. 1087) has drawn attention to an important association which is more common than published evidence would indicate. It is customary to regard the reticuloses as a single pathological process which can adopt a number of histological and clinical appearances, either pure or mixed.¹ The frequency of the eczema-reticulosis association is evident from my series of approximately 60 malignant reticuloses, of whom eight patients have suffered from eczema (four with Hodgkin's disease and four with lymphosarcoma). All eight patients are living, with a relatively benign form of reticulosis. In seven patients the eczema developed either at the time of the appearance of the reticulosis or within the preceding year, while in one patient eczema antedated her lymphosarcoma by 10 years. Six patients have had a recurrence of eczema following the diagnosis of reticulosis. With one exception, the eczema was localized and controllable by superficial x-ray therapy

or skin lotions. Mycosis fungoides has been excluded in every instance. As a reticulosis usually has a subclinical onset several months before palpable lymphadenopathy, it may be assumed that the two pathological processes have had a concurrent onset in seven patients. Further evidence of the association of allergy with reticulosis is afforded by one patient aged 48 years who developed lymphosarcoma in 1947 and in each succeeding summer has had severe hay-fever. She had been well before 1947. This does not apply to the three cases of asthma in my series, one of whom lost his asthma five months before the onset of the reticulosis, while in two an existing asthma became less severe with the onset of reticulosis. These 12 cases would appear to offer evidence of a powerful antigenic factor in the early stages of the malignancy. An initial attack of eczema, hay-fever, or asthma may precede the appearance of a carcinoma.²

May I conclude with a plea to radiotherapists to investigate the incidence of allergic disorders in their patients with malignant lymphomas as a possible key to the riddle of cancer?—I am, etc.,

Wellington, New Zealand.

Genetics and Clinical Research

SIR,—It was interesting to see your leading article on this subject (*Journal*, August 8, p. 326). I was sorry, however, to miss in it the name of one of the pioneers in this field, Professor Julius Bauer. This omission appears the more regrettable as he is well known to you, and you devoted a first leading article to his work in the past (*Journal*, April 24, 1943, p. 510).

Several of the problems mentioned in your present article have been studied intensively by J. Bauer and reported in original papers. I would like to mention—among many others—his studies on genetic factors in cancer and ulceration of the stomach; but, of course, in 1943 you yourself referred to the importance of his book *Constitution and Disease*.¹—I am, etc.,

London, S.W.3.

Dr. Samuel Gee

SIR,—May I point out that, being misled by Sir Philip Manson-Bahr (*Journal*, August 1, p. 284), you have given Dr. Samuel Gee a title in your leading article (p. 266)? The story which was current in St. Bartholomew's Hospital 50 years ago was that one of his colleagues saw Dr. Samuel Gee in the Square, wearing a fine fur coat, and expressed the hope that he might receive some recognition for looking after a royal personage. Gee replied: "They asked me if I would like to be made a baronet, but I said I would much rather have a fur coat, and this," fingering the lapel, "is it."—I am, etc.,

GEORGE GRAHAM.

Upside Down

SIR,—Dr. Wilfred Harris (*Journal*, August 8, p. 297) provokes us by saying: "We know from the optics of the eye that the image of any object seen is inverted on the retina. Why then do we see objects in their correct position and not upside down?" To see everything, including ourselves, as "upside down" would merely mean "upside down" in relation to perceptions derived from the other sense organs, and the position in space of the representation on the retina or visual cortex will have nothing to do with this relationship.

The young children he reports as seeing "all test letters upside down" are perhaps more mysterious than he makes out. If they simply saw everything upside down then they would be expected to draw the right way up, so that when

they looked at their drawing and saw it inverted it would match the object they were attempting to portray. Perhaps they are drawing from memory.—I am, etc.,

H. ASHER.

Physiology Dept., Birmingham University.

Myocardial Infarction

SIR,—The article by Dr. H. E. S. Pearson (*Journal*, July 4, p. 4) once again demonstrates the reduction in mortality and complications achieved by the use of anticoagulant therapy. Cardiac failure and its effects are important early complications which might be included when considering this subject. I have recently had under my care a man doing well under anticoagulant therapy with complicating congestive failure. Although the latter was treated, at the end of the third week he developed a sudden passive pleural effusion which proved fatal before medical aid could reach him.

Dr. R. A. Murray Scott (*Journal*, July 18, p. 151) quotes three references in support of his claim that prothrombin depression need not be taken below 60% of normal. I think these deserve some comment. Wright *et al.* achieved a 6% incidence of thrombo-embolism, with prothrombin levels of 20% and less. However, they went on to analyse their failures, and found that out of 38 such cases only four were actually in their desired therapeutic range of prothrombin depression, the others having escaped from control. Furthermore, they concluded that a considerable proportion of these failures were in fact due to inadequate prolongation of the prothrombin time. Burt *et al.*¹ described a series of cases of thrombo-embolism occurring in peripheral blood vessels, and did not describe any cases of coronary thrombosis. Their results are not therefore really comparable to the subject under discussion. Peters *et al.*² record the surprisingly optimistic figure of only 2% of thrombo-embolic complications in their series of 50 cases, rather than the 6% credited to them by Dr. Murray Scott. Their mortality rate of only 4% is also well below that of other writers, who usually put it at about 13.8%.³ However, their patients were selected ones in whom they claimed to have demonstrated an increased coagulability of the blood. They do not give details of the proportion of severe cases, or many clinical details. In view of these circumstances I feel that their results should be interpreted with reserve.

Finally, I would like to quote Gulchrist's opinion⁴ that adequate anticoagulant therapy has a favourable influence on shock in support of my plea for the prompt use of this treatment by the general practitioner.—I am, etc.,

Twickenham.

The Egg Maligned

SIR,—My morning bacon and egg is being impugned by Dr. H. W. Fullerton *et al.* (*Journal*, August 1, p. 250). It is literally blood-curdling, and, despite the cautious wording of the authors, already many a casual reader of the daily press may be switching to a Continental breakfast. It is hard to relate our restricted consumption of fats during the last years to the rising incidence of coronary thrombosis. For my own part I shall continue to take an English breakfast, and shall comfort myself with the reflection that coagulation has its virtues and that not every clot is clumsy.

As a surgeon I see arteriosclerosis and secondary thrombosis mainly in the lower limbs of patients complaining of intermittent claudication. In the last few years I have advised over 300 such patients, and, though I know nothing of their breakfast habits, I cannot recall a single one who was not an inveterate cigarette smoker. The link between cigarettes and arteriosclerosis in the lower limbs appears to me to be almost invariable and quite inescapable. I can recall only one patient who was able to give up smoking for even a few weeks, and he, poor fellow, died of coronary

thrombosis shortly after an operation. About coronary thrombosis itself I must write with more caution, because this is a disease which, in general, I have not studied. In claudication, however, the coronary accident is so common, and so frequent a cause of death, that the two do appear to be related—at least to each other if not to tobacco.

Your authors say that "the pathogenesis of arteriosclerosis remains obscure." Without any reference to tobacco, they indict, albeit tentatively, the egg. This seems so unfair that it has stung me into writing this letter and saying something I have been wanting to say for a long time.—I am, etc.,

Liverpool, 7.

CHARLES WELLS.

The Role of the Pathologist

SIR,—Drs. M. Goldman and D. H. Miller (*Journal*, July 25, p. 227) accuse pathologists of being "self-appointed judge and jury of their clinical colleagues." May I remind them that they appear in court as witnesses on oath and answer the interrogation of judge, counsel, or coroner to the best of their ability? They are not permitted to give a spontaneous expression of their views. They are in fact already "confined to a statement of facts and, at the most, an expression of opinion as to the cause of death."—I am, etc.,

Keighley.

IAN STEWART.

Malaria in Ex-Servicemen

SIR,—I was very interested to read the letter by Drs. A. F. Knyvett and F. D. Schofield (*Journal*, August 8, p. 339) on malaria in ex-Servicemen. I thought the following two cases might be of interest.

Case 1.—A Territorial soldier, aged 22, admitted with pyrexia and generalized muscular aches of 24 hours' duration. No diagnosis was made at this time because of the bizarre and seemingly unrelated nature of the symptoms, which included vague abdominal pains and headaches. A peripheral blood smear taken during a rigor 96 hours after admission revealed the schizonts of *Plasmodium vivax*.

Case 2.—A regular soldier, aged 24, also admitted with a very similar history of malaise and pyrexia, but he had carried on for six days without reporting sick. This case also had many of the features of an "influenzal" illness, but here again a peripheral blood smear examined at 24 hours demonstrated the schizonts of *Plasmodium vivax*.

Both these patients were seen within six weeks of each other and had served in Korea last summer. One had returned eight months ago and the other six months ago. No previous history of malaria was obtained, although the first patient had had a mild pyrexial illness with one rigor shortly after returning to this country. Both men had taken the issue of proguanil whilst overseas.

First impressions in both—namely, that they were cases of influenza—tended to obscure the diagnosis, which in the first was not made until the periodicity of the rigors was recognized after 96 hours. There were no other signs in either case, such as splenomegaly, to assist in arriving at the diagnosis.—I am, etc.,

Holt, Norfolk.

W. A. CRABBE.

Polyarthritis in Rubella

SIR,—I was most interested to see that Dr. K. H. Pickworth (*Journal*, August 8, p. 339) and Dr. G. W. Lewis (*Journal*, July 18, p. 149) found, as I did (*Journal*, June 20, p. 1388), that the complication of polyarthritis in rubella seemed to be confined to adult women. I can think of no other infectious illness affecting both children and adults which behaves so differently in the group of adult women only, and in this curious fact there may be hidden some clue to the aetiology of the arthritis. Dr. Pickworth suggests that the polyarthritis of rubella is allied to the aches and pains that occur at the beginning of the majority of infections, and he goes further and suggests that all these phenomena are allergic and allied to serum sickness.

I cannot agree, for the following reasons: (1) The polyarthritis continued in my experience long after any slight fever associated with the rash, and in 5 out of my 16 cases

first appeared on or after the second day of the illness. (2) The severity of the pains in the joints was out of all proportion to the mildness of the illness itself. (3) If the polyarthritis were in the nature of an allergic response it would be reasonable to suppose that there might be an accompanying eosinophilia and that the joint symptoms would subside if antihistamine drugs were given.

In two of my cases blood films were examined for eosinophilia and there was none. Four of my cases received diphenhydramine, 50 mg. three times a day, without any alteration of joint symptoms.

Four cases is, admittedly, a small number, but soon after plans were laid for investigating the possibility of the allergic nature of the arthritis the epidemic died out.—I am, etc.,

Wantage.

I. S. L. LOUDON.

Intravenous Picrotoxin for Barbiturate Poisoning

SIR,—Intravenous picrotoxin, as advocated by Dr. R. S. Saxton (*Journal*, July 25, p. 227), is not without hazard. I have seen a patient on more than one occasion in coma from barbiturate poisoning having convulsions as a result of picrotoxin therapy, while in no way coming out of the coma. In serious cases, which nowadays occur not infrequently in the course of a routine "take in," gastric lavage is always indicated, and hospital treatment should not be denied to these patients. One sees cases surviving after three or more days in coma, and psychiatric aftercare may be instituted speedily under in-patient conditions.

All cases recently reviewed in a Scandinavian paper¹ were treated with amphetamine, as picrotoxin was considered too toxic for routine use.—I am, etc.,

Collingbourne Ducis,
Wilts.

Please Wash Your Hands

SIR,—All G.P.s, not to mention the general public, must by now be heartily tired of the gastro-enteritis which has become endemic in this country in the last few years. Public health activities seem confined to looking for carriers after major outbreaks, but the number of carriers must be legion and this seems a hopeless task. There seems to be some agreement that nine-tenths of the trouble would stop if the public were educated to wash their hands after visiting the lavatory, but no one educates them.

I should like to suggest a simple solution. If every public lavatory abolished the charge for a wash, and exhibited a notice saying, "Please wash your hands before leaving. No charge," the result would probably be as effective as in the two precedents of "Please do not spit" and "Please adjust your dress before leaving." Once it became a habit in public lavatories it would soon become a habit elsewhere.

If the Ministry of Health offered to pay local authorities the cost, it would soon make a profit from the reduced number of prescriptions for sulphonamides and antibiotics. Is it possible for our public health colleagues to use their influence in bringing about this reform?—I am, etc.,

Ashted, Surrey.

W. EDWARDS.

Brain of Kernicteric Infants: An Appeal

SIR,—I would be very grateful for specimens of the brain of kernicteric infants. I am investigating the pigments occurring in the blood and tissues of infants affected with haemolytic disease of the newborn, and there is at present an extreme shortage of post-mortem material from infants dying of kernicterus. The specimens should preferably be unfixed, as formalin and alcohol seem to affect the pigments.

If any specimens occur I can arrange for them to be collected within a radius of 100 miles of Manchester if a telegram or 'phone call is made to URMston 4022 or SALE 3111.—I am, etc.,

Park Hospital, Davyhulme,
Urmston, nr. Manchester.

D. C. A. BEVIS.

Obituary

Dr. S. M. VASSALLO, formerly a senior specialist officer in surgery in the Colonial Medical Service, died suddenly at his home at Epsom, Surrey, on July 23, at the age of 62. Salvatore Michael Vassallo was born in Malta on January 28, 1891, and received his medical training at the University of Malta, where he graduated M.D. in 1913, gaining a Government exhibition for first place. He then came to England as a postgraduate student, and in 1914 entered the Colonial Medical Service, being posted to the Leeward Islands as a medical officer. From 1917 to 1919 he served as a captain in the R.A.M.C., and was mentioned in dispatches. On demobilization he resumed his work in the Colonial Medical Service, this time in Uganda, returning to England to take the D.T.M.&H. in 1922. In 1925 he was appointed resident surgical officer in Zanzibar, the title of his post being changed to that of senior specialist officer ten years later. In 1928 he was admitted F.R.C.S. Ed. While in Zanzibar Dr. Vassallo was medical adviser to the Sultan from 1925 to 1939, and he was President of the Zanzibar Branch of the British Medical Association in 1929–30, and again in 1934–5. In 1936 the insignia of the third class of the Order of the Brilliant Star of Zanzibar was conferred upon him; he also received the King's Silver Jubilee Medal in 1935 and the Coronation Medal in 1937. When war broke out again in 1939 Dr. Vassallo immediately re-entered the R.A.M.C. as a lieutenant, being promoted to major in three months, and served first as a surgical specialist and then, from 1942, as the officer in charge of a surgical division. He remained in the Army until November, 1948, by which time he had attained the rank of lieutenant-colonel. He was mentioned in dispatches in 1941. On his return to civilian life he became senior surgical specialist at the Royal Herbert Hospital, Woolwich, a position he held until his retirement last year. Dr. Vassallo leaves a widow and one daughter.

Dr. B. Spearman, late Director of Medical Services, Zanzibar, sends the following appreciation: For 10 years I was in constant touch with Dr. Vassallo and saw that with diverse nationalities—European, Arab, Indian, and African—he proved a boon and a blessing. A surgeon of outstanding abilities, he never spared himself and worked long hours in the tropical heat, and one sometimes wondered at his staying capacity. While on leave he continued his studies and took the Edinburgh F.R.C.S. He was also a capable and wise physician and thoroughly experienced in tropical diseases. Everyone, whatever his faith or creed, put his faith in Michael, and his patients came from India and all parts of East Africa. He retired in 1939, only to rejoin the R.A.M.C. In his spare time he served as honorary secretary to the East African Pensioners' Association, and all those who received benefits through this organization owe him a big debt of gratitude. Knowing seven languages, he did much abstracting work for *Abstracts of World Medicine* and *World Surgery*, and for the *Journal of Urology*. The sympathy of all who knew him, of whatever creed or colour, whether in the United Kingdom or scattered throughout the British Empire, goes out to his wife and daughter in their irreparable loss.

Lieutenant-Colonel A. B. Dempsey, R.A.M.C., writes: Michael Vassallo, after a distinguished surgical career in Zanzibar for 25 years, brought to the Army Medical Services a wealth of clinical wisdom and practical surgical experience when he left a well-earned retirement to volunteer at the outbreak of the last war. He served with distinction in the Middle East for some years, but it is for his work at the Royal Herbert Hospital, Woolwich, from 1944 to 1952 that he will best be remembered. During this period many regular surgeons passed through his hands when he was in charge of the surgical division. They were working, in every case successfully, for higher surgical

qualifications, and their successes were in no small part due to his kindly advice, teaching, and encouragement, and to the fact that at considerable personal inconvenience he carried a very heavy load himself in order to allow them more time for study. "Vass," as he was known to his many friends in the Royal Army Medical Corps, will be greatly missed. His quiet smile, often hiding an almost impish sense of humour, endeared him to all his juniors. He will be remembered with affection and gratitude by surgeons now serving in many parts of the world, who owe him much.

By the sudden death of Dr. SAMUEL ROSE at his home on July 1 at the age of 55, Wimbeldon has lost a popular and skilful general practitioner. Samuel Rose was born in New York on October 5, 1897, and was educated at University College School, London, and at Guy's Hospital, where he qualified in 1919. Two years later he took the London degrees of M.B., B.S. After a house-surgeoncy at Guy's he became senior assistant medical officer at Fulham Infirmary. In 1924 Dr. Rose settled at Wimbeldon, in partnership with three other doctors, and soon developed a large practice. His professional skill, his kindly manner, and his sympathetic approach to other people's problems made him a popular member of the local community. For many years he was a member of the honorary staff of Wimbeldon Hospital, and he acted also as deputy police surgeon and Treasury medical officer for West Wimbeldon. In the last war he served as a medical officer in the Home Guard, a heart affection preventing him from giving full-time service in the Forces. Despite this disability, which ultimately caused his death, he continued his work throughout the war, and many local residents, including those injured in air raids, owe much to his ability as a surgeon. Dr. Rose had wide interests, and his genial manner and great vitality brought him many friends. Interested in all kinds of sport, he was an enthusiastic member of the Royal Wimbeldon Golf Club. He leaves a widow and two daughters.

Dr. J. R. HALL died at Wingate, Co. Durham, on July 10 at the age of 70. Born on December 6, 1882, the son of the late Mr. W. T. Hall, J.P.—the first chairman of the Bellingham Rural District Council—John Robertson Hall was educated at Dollar and Edinburgh Academies and at Edinburgh University, where he graduated M.B., Ch.B. in 1907. Soon after graduation he joined his brother, the late Dr. W. T. Hall, in practice at Newcastle-upon-Tyne. In 1911 he set up his plate on his own account at Fence Houses, Co. Durham, and there he remained until 1938, when he moved to Wingate, except for a period of service in the R.A.M.C. in the war of 1914–18. He was invalided out of the Army after receiving wounds in the Battle of the Somme. Always attracted to the work of the St. John Ambulance Association, to which he had been an examiner since 1914, Dr. Hall was a popular lecturer to first-aid classes. He was appointed a Serving Brother of the Order of St. John of Jerusalem in 1937. The outbreak of the last war in 1939 saw an increase in his activities on behalf of the Association, but he found time to lecture also on air-raid precautions and to serve on medical boards. In addition he was a captain in the Home Guard. Outside his profession Dr. Hall derived much satisfaction from the study of Border history, and, having a good memory, he could be relied upon to provide many an interesting reminiscence. He leaves a widow.

The untimely death of Dr. LOUIS SHELDON at the early age of 49 has deprived the practice of medicine in Willesden and Wembley of one of its outstanding figures; for Louis Sheldon was one of that breed of men who shed lustre on their profession, and to whom hard work did not spell hardship. Born in South Africa on October 30, 1903, Sheldon came to England at the age of 21, and qualified L.M.S.S.A. from the London Hospital in 1926. He took over an old-established practice in Willesden soon afterwards, and there

for 25 fruitful years he was guide, philosopher, and friend to an ever-increasing circle of patients. He allied clinical acumen of a high order with boundless energy, and inevitably acquired a splendid reputation as a practitioner in the best family-doctor tradition. He did not spare himself, and on many an occasion Sheldon would excuse himself to his guests—there was nothing he liked better than to play the host—to go and visit a patient in response to an urgent message. This spirit was apparent even during his last illness, when he was to be seen, driven by his son, for he was no longer able to drive his car himself, doing his round of visits, an ill man and obviously suffering. During his busy life he found time for broader interests and served on the executive committee of the Willesden Division of the British Medical Association, where his unobtrusive good sense made him a valued member. He was well known at the Willesden General Hospital, where he worked for some time as clinical assistant, and at the West End Hospital for Nervous Diseases. His local interests were many. He served as medical officer to the local Red Cross detachment, St. John Ambulance Brigade, and the Willesden Air Training Cadets, and, in another field, as medical officer to the Hendon Football Club, a reflection of his youthful enthusiasm for soccer and his days in the London Hospital first eleven. During the last war he was one of those whose work at the Stonebridge first-aid post during the worst days is still remembered. All in all he left his mark on Willesden, and his death leaves a gap which will not easily be filled. His patients' sorrow can best be epitomized in the inscription on a wreath sent by one of them—"To our dear doctor and friend." His colleagues in Willesden will not soon forget him. To his widow, who bore the great strain of his last illness with wonderful courage, and to his son, who carries on the medical tradition of his father, his colleagues and friends offer their heartfelt sympathy.—M. M.

Medico-Legal

FATAL PENICILLIN INJECTION

At an inquest held in Kingston-upon-Hull on July 14 the coroner recorded a verdict of misadventure on a woman aged 41 who had died from anaphylaxis following an injection of penicillin administered for pyrexia during delivery.

After a normal pregnancy the patient was admitted to hospital at 10.30 a.m. on June 30. The same evening she was still in early labour and was given morphine $\frac{1}{2}$ gr. (16 mg.). On the evening of July 1 she developed a temperature of 101° F. (38.3° C.). No cause for the pyrexia was apparent, but she was given 400,000 units of procaine penicillin intramuscularly at 6.30 p.m. At 7.30 p.m. the patient vomited; two minutes later she had a labour pain, and while at the height of this pain she suddenly collapsed. She immediately became unconscious, and her breathing was stertorous as in cerebral haemorrhage. Despite all attempts at resuscitation she died within a few minutes. The patient had had previous injections of penicillin, though she had no history of previous reactions to it. Other patients had received injections from the same batch of penicillin without ill effect.

Dr. James Ross McKenzie, senior registrar, Kingston General Hospital, Hull, who did the post-mortem examination, said there were signs of asphyxia, with many petechial haemorrhages over the surfaces of the lungs. He gave the cause of death as anaphylaxis following the injection of penicillin. He was able to find only two such cases reported in this country out of the millions of penicillin injections which had been given. Only one such case had been reported in the American literature.

The coroner, in summing up, suggested that it would be a wise precaution for any patient who had had a previous reaction from penicillin to tell a new doctor about it before penicillin was administered.

Universities and Colleges

UNIVERSITY OF OXFORD

The following medical degrees were conferred on June 25:

D.M.—W. D. M. Paton, R. Seidelin, G. Loewi.

B.M.—R. B. Roe.

On July 1, in connexion with the centenary of Cecil Rhodes and the jubilee of the Rhodes scholarships, the honorary degree of D.C.L. was conferred on W. G. Penfield, O.M., Honorary Fellow of Merton College, Director of the Montreal Neurological Institute, and Professor of Neurosurgery in the University of McGill.

In Congregation on July 18 the following medical degrees were conferred:

D.M.—R. M. Mason, J. T. Wright.

B.M.—B. C. Davies, B. J. Drake, W. A. F. Macdonald, H. Merskey, P. S. Mitchell, G. L. Feinstein, G. C. Fisk, M. R. C. Heffernan, M. P. Carter, J. G. Ross, J. H. Fairley, P. D. P. McGrath, C. J. Good, I. E. Hughes, V. Parsons, R. W. G. P. Best, J. B. L. Gee, J. A. Kay, G. A. Rose, Christian A. K. Carritt, Diana J. Collins, Rosalind M. Rewcastle, *C. E. Elliott, *N. R. Garden, *R. E. Gillson, *F. I. Caird, *J. I. McFeeters, *Priscilla A. Clark-Maxwell.

The Theodore Williams Scholarship in Human Anatomy for 1953 has been awarded to Oliver Wolf Sacks, Scholar of Queen's College.

The Radcliffe Scholarship in Pharmacology has been awarded to Antony Babington Herring (Brasenose College) and John Verrier Jones (University College).

Dr. R. S. Creed has been elected a member of the Board of Studies for Psychology for two years from October 1, 1953.

*In absence.

UNIVERSITY OF GLASGOW

The following medical degrees were conferred on July 4:

M.D.—P. A. Duke, *G. M. Edington, *C. R. Forrest, *J. MacGillivray, *A. F. McLean, W. W. McNeish, D. G. Scott.

M.B., Ch.B.—J. Allan, J. M. Atkinson, J. T. B. Bain, Muriel M. E. Barr, *J. S. Beck, Sheila J. D. Black, M. Blair, D. A. P. Brown, D. D. Bryson, T. H. L. Bryson, R. T. Cameron, J. S. Cant, R. L. K. Colville, I. J. Coulthart, J. L. C. Dall, A. Davidson, J. S. H. Davidson, J. A. S. Dickson, H. P. Dinwoodie, A. Donnelly, J. A. Duncan, I. E. Farrington, H. C. Ferguson, A. H. Findlay, Margaret E. Finlayson, T. Forrest, J. Frame, W. Gallacher, H. H. Gebbie, Lilian M. Gibson, Biruta R. Giedraitis, I. E. Gillespie, S. S. Graham, J. H. Graham-Marr, M. Haase, W. A. McL. Hall, L. Harris, D. D. Hart, Grace J. K. Harvey, J. C. Henderson, Martha C. Howat, R. McN. Howie, R. M. Humble, R. Hume, Isobel H. Hunter, A. G. Hutchison, Margaret W. Irwin, G. H. Johnson, J. A. Johnston, Margaret N. S. Johnston, C. C. Keay, J. D. Kinloch, J. W. S. Knox, K. A. Kwarko, T. J. Lees, H. C. Leslie, J. G. Lindsay, L. E. Loneragan, E. C. McCracken, Morag C. McCulloch, J. C. H. McDonald, C. G. McEwen, A. McGowan, Berthea J. MacGregor, W. L. MacIndoe, Eleanor M. MacIver, T. M. McKendrick, Catriona Mackenzie, A. C. MacLachlan, K. M. McLaren, J. C. MacLaurin, Lindsay McLeman, P. B. McMain, J. P. McMillan, G. W. Macnab, Christine McNair, *M. W. McNicol, W. A. Maley, T. S. Mann, F. Mariotti, J. J. F. Merry, H. McL. Morgan, Elizabeth A. Mowat, I. S. Murray, J. W. Myles, G. F. Nabi, E. G. Oram, J. R. Paterson, P. M. Peacock, J. G. Provan, Maria A. Ratzer, C. B. Rennick, C. J. C. Renton, J. A. Riddell, A. Robertson, K. M. Robertson, A. J. Rosin, Margaret C. Russell, R. C. I. Russell, R. J. Scott, R. Shields, A. M. Short, *J. D. Sleight, V. B. Slorach, Margaret B. Smith, M. G. H. Smith, N. M. Smith, V. Smith, Kathleen A. R. Smith, W. T. Sommerville, C. Sorbie, Isobel Speirs, J. M. Stark, Norah E. Stewart, J. R. Styles, V. Sweeney, Lilian M. G. Tait, T. E. Torbet, J. J. Treanor, R. D. Unkles, D. H. Urquhart, J. M. T. Warnock, J. McL. Williamson, A. Wilson, D. W. Wylie.

*In absentia. *With high commendation. *With commendation. *With honours.

UNIVERSITY OF LONDON

Dr. J. D. N. Nabarro and Dr. Howard Nicholson have been recognized as teachers of medicine in the University at University College Hospital Medical School.

The Sir William Dunn Scholarship for 1953-4 has been awarded to Barbara Joan Boucher (London Hospital Medical College).

Vital Statistics

Poliomyelitis

Poliomyelitis notifications (uncorrected) in the week ending August 8 (31st week of the year) were as follows: paralytic, 181 (167); non-paralytic, 116 (103); total, 297 (270). This is an increase of 27 compared with the previous week, the figures for which are in parentheses. The individual districts which have notified 20 or more cases in the year to August 8, with incidences per 100,000 in parentheses, are as follows: Southend-on-Sea C.B., 37 (24.42); Liverpool C.B., 25 (3.16); Birmingham C.B., 46 (4.11); Coventry C.B., 76 (29.12); Leicester C.B., 22 (7.69); Lewisham M.B., 22 (9.69); Blackpool C.B., 21 (14.26); Camberwell M.B., 20 (11.04); Islington M.B., 21 (8.92); Bournemouth C.B., 25 (18.00).

The seasonal rise in the notifications of poliomyelitis is not gaining momentum. The increase in paralytic cases was two less than in the previous week (14 compared with 16), and there is still hope that the curve will be like that for 1952. Although the seasonal rise is expected to continue, the outlook is somewhat more favourable than it appeared to be a month ago. Epidemic proportions are not being approached in any of the greater centres of population.

Graphs of Infectious Diseases

The graphs below show the uncorrected numbers of cases of certain diseases notified weekly in England and Wales. Highest and lowest figures reported in each week during the nine years 1944-52 are shown thus ————, the figures for 1953 thus ————. Except for the curves showing notifications in 1953, the graphs were prepared at the Department of Medical Statistics and Epidemiology, London School of Hygiene and Tropical Medicine.

UNIVERSITY OF LEEDS

Dr. Geoffrey Watkinson, lecturer in the Department of Medicine, has been granted leave of absence for the session 1953-4 to enable him to take up a Rockefeller Travelling Fellowship.

The Services

Major-General F. Kingsley Norris, C.B.E., D.S.O., E.D., R.A.A.M.C., has been appointed Honorary Physician to the Queen, and Colonel K. B. Fraser, E.D., R.A.A.M.C., Honorary Surgeon to the Queen.

Major-General F. C. Hilton-Sergeant, Q.H.P., late R.A.M.C., has been appointed Commandant and Director of Studies, Royal Army Medical College, in succession to Major-General F. R. H. Mollan, C.B., O.B.E., M.C., Q.H.S., late R.A.M.C., who is retiring.

Colonel A. Swindale, C.B.E., T.D., has been appointed Honorary Colonel of a T.A. Unit in succession to Colonel A. H. Whyte, D.S.O., T.D., whose tenure has expired.

A Supplement to the London Gazette has announced the following appointments in recognition of gallant and distinguished services in Korea:

C.B.E. (Military Division).—Colonel G. L. M. Smith, O.B.E., C.D., R.C.A.M.C.

M.B.E. (Military Division).—Lieutenant-Colonel (Acting) R. A. Smillie, R.C.A.M.C.

A Supplement to the London Gazette has announced the following awards:

First Clasp to the Territorial Efficiency Decoration.—Major R. Barraclough, M.B.E., T.D., and Captain (Honorary Major) H. R. Vernon, R.A.M.C.

Territorial Efficiency Decoration.—Major (Honorary Lieutenant-Colonel) J. B. McEwen, M.C., and Captain (Honorary Major) H. R. Vernon, R.A.M.C.

Infectious Diseases

Infectious diseases were less prevalent in England and Wales during the week ending August 1. The largest falls in the number of notifications were 807 for measles, from 4,394 to 3,587, 250 for whooping-cough, from 4,357 to 4,107, and 87 for scarlet fever, from 1,037 to 950.

The largest falls in the number of notifications of measles were 133 in Lancashire, from 804 to 671, and 71 in Somersetshire, from 162 to 91. A small decline in the incidence of scarlet fever was recorded in every region except the north-western, where the notifications were 42 more than in the previous week. The largest decline in the number of notifications of whooping-cough was 42 in London, from 389 to 347. 11 cases of diphtheria were notified, 6 fewer than in the previous week.

270 cases of acute poliomyelitis were notified during the week. These cases were 16 more for paralytic and 12 fewer for non-paralytic than in the preceding week. The chief centres of infection were still in the southern section of the country and were London 34 (Camberwell 5, Islington 5, St. Pancras 5, Lambeth 4), Essex 22 (Chelmsford M.B. 4), Middlesex 21 (Finchley M.B. 3, Heston and Isleworth M.B. 3), Southampton 19 (Bournemouth C.B. 8), Surrey 16 (Croydon C.B. 3, Reigate M.B. 3), Warwickshire 16 (Coventry C.B. 13), Kent 15 (Maidstone M.B. 4), Lancashire 14 (Liverpool C.B. 3), and Cheshire 10 (Nantwich R.D. 4).

334 cases of dysentery, 25 more than in the preceding week, were notified. The largest returns were Lancashire 67 (Blackburn C.B. 24, Manchester C.B. 15), London 35, Yorkshire West Riding 27, Durham 26, Middlesex 21, and Essex 18.

The largest outbreaks of food-poisoning notified during the week were 131 cases in Camberwell, London, 119 cases in Prestatyn, Flintshire, 100 cases in Wakefield C.B., Yorkshire West Riding, 69 cases in Consett U.D., Durham, and 54 cases in Lancaster M.B., Lancashire.

Week Ending August 8

The notifications of infectious diseases in England and Wales during the week included scarlet fever 690, whooping-cough 3,864, diphtheria 22, measles 2,730, dysentery 217, paratyphoid fever 12, typhoid fever 3, and food-poisoning 415.

INFECTIOUS DISEASES AND VITAL STATISTICS

Summary for British Isles for week ending August 1 (No. 30) and corresponding week 1952.

Figures of cases are for the countries shown and London administrative county. Figures of deaths and births are for the 160 great towns in England and Wales (London included), London administrative county, the 17 principal towns in Scotland, the 10 principal towns in Northern Ireland, and the 14 principal towns in Eire.

A blank space denotes disease not notifiable or no return available. The table is based on information supplied by the Registrars-General of England and Wales, Scotland, N. Ireland, and Eire, the Ministry of Health and Local Government of N. Ireland, and the Department of Health of Eire.

* Measles not notifiable in Scotland, whence returns are approximate.
† Includes primary and influenza pneumonia.
‡ Includes puerperal pyrexia.

Medical News

Family Rehabilitation.—The Elizabeth Fry Memorial Trust has just issued an account of the establishment of the Spofforth Hall Recuperative Centre, to which mothers (and their children) are sent who fail to provide a satisfactory home for themselves and their families. The majority of the mothers have simply failed to cope with domestic problems and difficulties, and have reached a point when they have accepted defeat and allowed the home conditions to deteriorate. A small proportion of the families are those in which the parents have already been charged in the courts with neglecting their children. Instead of sending the mother to prison, often the prelude to the permanent collapse of the home, she can be put on probation and, with the consent of the Home Office, may be required to accept at least four months' residence at Spofforth Hall, which is near Harrogate. "In more human terms the results of homes which have failed are seen in the dispirited mothers and pathetic babies and children who come to Spofforth Hall." The home was established under the auspices of the Society of Friends, and the first families arrived last November. The demand for accommodation has grown rapidly since then, and the trustees have decided to adapt an extra wing of Spofforth Hall in order that three more families may be received. Although the cost of maintaining most of the families is met by statutory authorities, there is still need for generous public support of this worthy project.

Society of Apothecaries.—On August 18 the Society elected as Master Dr. H. Seaward Morley, as Senior Warden Sir Cecil Wakeley, P.R.C.S., and as Junior Warden Dr. N. S. Finzi.

NEW ISSUES

Journal of Neurology, Neurosurgery, and Psychiatry.—The next issue (Vol. 16, No. 3) will be available in a week's time.

Journal of Clinical Pathology.—The next issue (Vol. 6, No. 3) will be available in a week's time.

Issued quarterly; annual subscription £2 2s., single copy 12s. 6d. These journals are obtainable from the Publishing Manager, B.M.A. House, Tavistock Square, London, W.C.1.

SOCIETIES AND LECTURES

A fee is charged or a ticket is required for attending lectures marked ●. Applications should be made first to the institution concerned.

Tuesday, August 25

INSTITUTE OF NEUROLOGY, National Hospital, Queen Square, W.C.—5 p.m.,

Professor John Fulton (U.S.A.), Harvey Cushing: A Biographical Appreciation.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Hales.—On July 1, 1953, at the London Hospital, London, E., to Mary (formerly Notley), wife of John Hales, M.B., B.S., a daughter—Kathryn Mary.

Scott.—On August 11, 1953, at the General Hospital, Neath, Glamorgan, to Dorothy, M.B., Ch.B. (formerly Wood), wife of Dr. B. K. Scott, a daughter.

Walsh.—On August 5, 1953, at Saint John, New Brunswick, Canada, to Ruth (formerly Broughton), wife of Peter Walsh, M.R.C.P., of 260, Germain Street, Saint John, New Brunswick, Canada, a son—Robert Edward.

DEATHS

Jhangiani.—On July 5, 1953, Parmanand Harumal Jhangiani, M.B., B.S., D.M.R.E., of Canonbury, London, N.

Legat.—On July 23, 1953, at his home, 8, Hughenden Road, Clifton, Bristol, Robert Eddowes Legat, M.B., C.M., aged 83.

McMichael.—On July 28, 1953, Arthur William McMichael, M.R.C.S., L.R.C.P., of 27, Frenchay Road, Weston-super-Mare, late of Vowchurch, Herefordshire, aged 85.

Rafferty.—On July 28, 1953, suddenly, at Clayton Hospital, Wakefield, Patrick Joseph Rafferty, L.R.C.P.S.I. & L.M., of Westgate End House, Wakefield, Yorks, aged 54.

Raw.—On July 25, 1953, at Arday (Bonar Bridge), Ross-shire, Mary Raw, M.B., B.S., of Ravenswood, Low Fell, Gateshead, late of the Baptist Missionary Society's Dholpur Station, India.

Talbot.—On July 28, 1953, at his home, Coed-y-Castell, Deganwy, Caern., N. Wales, Philip Talbot, M.B., Ch.B., F.R.C.S., aged 72.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Sensitivity to Oil of Bergamot

Q.—Is a skin reaction to oil of bergamot found only in certain sensitive individuals, or will it occur in anyone under appropriate conditions? What is meant by the term "photosensitivity," which is often used in describing bergamot reactions?

A.—The skin reaction to oil of bergamot is found only in certain people. In these subjects the application of oil of bergamot to the skin results in a temporary increase in light sensitivity on that particular area of skin. The mechanism by which this occurs is not known, but the substances most often involved are of vegetable origin, and for this type of reaction the term "phyto-photo dermatitis" was coined by Klaber,¹ whose original work should be consulted.

REFERENCE

¹ Klaber, R., and Wittkower, E. (1939). *Brit. J. Derm.*, 51, 501.

Vaginitis in Girls

Q.—What is the modern treatment of non-gonococcal vaginitis in small girls?

A.—The organisms responsible for the vaginitis should first be determined by examination (direct smear and culture) of the discharge obtained from the vagina by a swab or fine pipette gently inserted through the hymeneal opening. The possibility of a foreign body in the vagina should be considered and excluded, especially if the discharge is blood-stained as well as purulent.

The treatment of the vaginitis depends to a large extent on the organisms present and on their sensitivity to chemotherapeutic and antibiotic agents. The appropriate agent should be administered systemically, and at the same time it is an advantage to administer oestrone, 0.3 mg. twice daily by mouth, for three to four weeks. This latter increases the resistance of the vagina, but can have undesirable temporary side-effects such as enlargement of the breasts and uterine bleeding.

Intravaginal therapy is best avoided because of possible psychological reactions. However, under certain circumstances—trichomonal vaginitis, for example—it may be necessary to administer appropriate antiseptics by means of a small-sized vaginal pessary. Thrice-weekly instillations of a 0.5% aqueous solution of mercurochrome by means of a funnel and fine soft rubber catheter are useful in some cases.

Many other considerations arise, and these include measures to reduce the risk of transfer of the infection to other children, and the general management of the child and its mother to avoid introspective tendencies and over-anxiety.

Congenital Deformities of Fingers and Toes

Q.—What can be done surgically to correct congenital absence or fusion of the fingers or toes? When is the best time to start treatment?

A.—Little surgically can be done to correct congenital absence of fingers and toes. Later in life, provided some thumb metacarpal function remains, it may be possible to construct a gripping mechanism, but this will always depend upon the individual case.

Fusion of the fingers or toes is much more amenable to surgical treatment, and the excellence of the result depends upon the degree of webbing of the fingers. Where a simple skin web exists it can, under the best circumstances, be effectively separated to produce a good result without

deformity of the fingers. Where there is insufficient skin to make flaps to cover the fingers, a free graft may be introduced. Where the bones are fused the matter is much more difficult: although the fingers can be separated, mobile interphalangeal joints are not often obtained. The real difficulty lies in constructing an interdigital web which does not recur. The treatment of this condition is normally carried out by plastic surgeons. The best time to operate is between 3 and 5 years, when the child is fairly co-operative.

Aspirin Intoxication

Q.—What adverse effects are known to result from prolonged daily use of aspirin and allied preparations? Is the drug habit-forming?

A.—There is considerable individual variation in tolerance to the salicylates; but sweating, thirst, headache, dizziness, tinnitus, and nausea are signs of mild intoxication with these drugs. A more severe degree of intoxication is shown by fever, vomiting, diarrhoea, hyperpnoea, and severe excitation which may later change to coma. Aspirin has a particularly irritating effect on the gastric mucosa; in susceptible subjects it may produce gastric erosion with haematemesis if given as relatively insoluble tablets on an empty stomach. A few cases have been reported in which red striations of the skin, similar to those seen in Cushing's syndrome, have developed after very prolonged treatment.

Intolerance to the salicylates occurs occasionally and is shown by the development of a macular rash associated in the more severe cases with pyrexia and gastro-intestinal disturbance. The salicylates are not drugs of addiction.

Total Hysterectomy after the Menopause

Q.—It was recently stated that even at an advanced age the ovaries are seldom inert. In view of this, what physical and psychological symptoms would be likely to follow total hysterectomy in a woman aged 60?

A.—Although there is a good deal of evidence to suggest that the climacteric often occurs a few years after the menopause, and that meanwhile the ovaries are to some extent functional, few authorities would confidently assert that the ovaries produce significant amounts of oestrogen for very long after the menopause. Indeed, when oestrogen is found in circulation after the menopause it is often suggested that it has its origin in some other organ such as the adrenal cortex.

If a woman 60 years of age had the menopause at the usual time, and especially if it was accompanied by menopausal (or more strictly climacteric) symptoms, and if she shows the usual atrophic changes in the vagina and vulva, total hysterectomy with removal of both ovaries should not have any physical effects other than those directly related to the operation, nor is it likely to result in any psychological disturbance.

Wedding-ring Sensitivity

Q.—A young woman is unable to wear her 9 carat gold wedding-ring because it causes an itchy rash to appear under it. What is the cause, and what treatment is advised?

A.—Although occasionally psychological factors seem to be responsible for a localized eruption in this site, it seems more probable that in the case quoted the patient has become sensitized to the metal of her wedding-ring. Sensitivity to jewellery made of gold is not very common, but undoubtedly does occur. Such sensitivity usually lasts indefinitely, and the only solution is for the patient to avoid contact with the particular metal. In the case quoted, sensitivity may well be not to gold itself but to one of the metals used in the alloy. If this is so, different varieties of gold articles may not elicit the reaction. It might therefore be worth this patient trying a different gold ring to see its effect. Alternatively she will probably be able to wear a platinum ring without trouble.

NOTES AND COMMENTS

Syringes in General Practice.—Dr. DONALD MCGREGOR (Sutherland) writes: With regard to the question on this subject ("Any Questions?" July 25, p. 235) I would like to make the following comment. If syringes are carried in spirit, the needles must either be rinsed in boiled water in the patient's house before use (a tiresome procedure where water has to be sub-carried and there is only a peat fire) or the patient must be submitted to the irritation of 95% alcohol subcutaneously. This can be guaranteed to lose patients. I suggest that the proper routine is to carry the syringes in spirit-proof cases without the spirit in them. The cases are sterilized in boiling water at the same time as their contents, and simply and quickly drained of water. Pasteur's experiments with retorts and turned-up mouths, suggest that the syringes would, once housed in an empty, sterile, spirit-proof case, stay sterile indefinitely. Personally I re-sterilize any syringes I have not used each month to be on the safe side.

OUR EXPERT writes: Most of the spirit in the needle and in the barrel of a syringe which has been carried in a case containing 75% spirit can be removed by withdrawing the plunger several times and squirting. The last of the spirit can be removed by drawing up through the needle some sterile pyrogen-free water, or normal saline, carried in a rubber-capped bottle. Some of the solution that is to be injected may be used for this purpose if the makers of ampoules provide enough, as they often do, or if the injection is supplied in a rubber-capped bottle. If the syringe is to be used once only it can safely be carried, as your correspondent suggests, in an airtight case without spirit. But if the case contains six needles, and the barrel of the syringe is to be handled and used again with a different needle, it is safer to keep the syringe in 75% spirit.

Height and Weight Tables.—Mr. W. F. F. KEMSLEY (London, W.1) writes: On looking through the *Journal* of July 25 (p. 236) I have noticed in "Any Questions?" a reference to height and weight tables. In the reply it is stated that there are no up-to-date tables for heights and weights of British adults. This is not the case. Some time ago I compiled tables based on measurements made in 1943 on 27,000 men and 33,000 women. These tables will be found in the *Annals of Eugenics*, vol. 16, pp. 316-334, 1952, the paper being entitled "Body Weight at Different Ages and Heights." The paper explains how the tables were derived and gives comparisons between these new tables and earlier tables.

Dr. G. I. M. SWYER (London, W.C.1) writes: In the answer to the question on "height and weight tables" I am surprised to read: "Unfortunately, there are no up-to-date tables for the heights and weights of British children." There is an excellent book by A. Sutcliffe and J. W. Canham, *The Heights and Weights of Boys and Girls*, John Murray, London, 1950. This book includes data on some 17,000 English boys and girls, very carefully selected from all parts of the country and from different school groups, so as to avoid any possible bias. The tables give figures for 5 to 17 years inclusive, and I think would certainly supply your questioner's requirements so far as children are concerned. Perhaps the most valuable feature of this book is the inclusion of tables of height and weight indices calculated in an analogous fashion to intelligence quotients. These enable one to decide, when either height or weight is considerably different from the average, whether the two are proportionate or not. Moreover, they enable one, when following the growth of a child, to decide whether the increments are occurring at the expected rate. I find this book to be quite invaluable in my dealings with growing children.

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 4499. TELEGRAMS: *Attology, Westcent, London.* ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors overseas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

First World Conference on Medical Education

President's Address

THE CHALLENGE TO MEDICAL EDUCATION IN THE SECOND HALF OF THE TWENTIETH CENTURY

BY

Sir LIONEL WHITBY, C.V.O., M.D., F.R.C.P.

Regius Professor of Physic, University of Cambridge

The title of my address has not been framed as a question, since there can be no doubt that the second half of the twentieth century offers a challenge to medical education, as indeed it offers a challenge to every variety of medical experience, to every aspect of medicine, and to the practice of medicine in every part of the world.

It is for me to examine the nature of the challenge and for you to listen in the coming week to speakers from all over the world who will make their contributions to our discussions, and who, though having in mind the general issue, will nevertheless instruct us in some of the particular difficulties of their own countries and conditions. For perhaps the first abiding value of this conference may be that we shall know more of each other and each other's conditions. There can be little doubt that when we individually think of medical education we think only of our own countries.

The world, however, has now become so shrunken, because of modern communications, that we can no longer take a parochial view of our problems, whether they be economical, political, social, or, above all, medical, since medicine mercifully knows no international boundaries and happily has the same ideals in all countries. Even when countries are at war their medical professions can co-operate and be at peace one with another in a common task. Fortunately, there is a growing world-wide awareness of the common bonds of medicine and the contributions which these can make to world peace.

The World Health Organization of the United Nations and the medical offshoot of Unesco, C.I.O.M.S., both intergovernmental in constitution, are a formal international recognition that medicine, health, science, and education present common world problems which can, in part, be faced and partially solved by men and women from different countries meeting together and expressing their views. Medical men themselves have realized the challenge by founding the World Medical Association, and I am proud to know that in this the British Medical Association has played a prominent part. The World Medical Association represents the field workers, those who have to do the job.

It would indeed be unusual, if not an indication of inertia and ill-health, if the practising doctors did not have their disagreements with intergovernmental planners. We regard the scene from different standpoints.

and I can understand at least this much of Einstein's theory of relativity, that what is observed depends upon the position of the observer.

It is perhaps significant that the first great project of the World Medical Association is the holding of the First World Conference on Medical Education, and it is also significant that it has secured the willing collaboration of the World Health Organization, whilst the support and interest of the International Association of Universities can only mean that the sure foundation of medical studies is the university and the university ideal.

The Challenge to Education

The first challenge which has come to the fore in the second half of the twentieth century is not confined to medical education, but is levelled at education itself, whatever calling or profession a man or a woman is to take up. The basic trouble is the same as with medicine, that the accumulation of knowledge is such as to demand early specialization and to make it impossible for a student to be comprehensive in his approach to his subject.

Abraham Flexner said that medical education was not so much a matter of medicine as of education. It is fortunate, therefore, that Sir Richard Livingstone, who has probed deeper than any of us into the meaning and purpose of education, has paid us the great compliment of coming to address a gathering of doctors and to give us the benefit of his wisdom.

It is also fitting that Professor Fulton, who has made the physiology of the brain his special study, should follow Sir Richard Livingstone and speak on his other special interest, that of medical history, telling us of the background of the theme of the conference under the title of "The History of Medical Education."

And then, several thousands of miles from New England, Colonel Mallick comes from Pakistan to speak on the parting of the ways between the medicine of this century and before that time. Is medicine a technology or a profession? And if the answer is clear, as I think it is, then how must we educate youth to respond to the challenge implicit in this conception of our common faith?

In preparing for any calling there are challenges from three directions. These are directed at the teachers, at those they teach, and at what they teach. These aspects therefore form the basis of three of the main sections for

the Conference, whilst the fourth, preventive and social medicine, reflects our enhanced consciousness of its importance and of its potentialities both in the medical profession and among the general public, including their elected representatives in the governments of the world.

Social medicine, not to be confused with socialist medicine, is indeed our main contact with the laity, since it covers a part of medicine which they can readily understand, and the execution of it, particularly from the financial angle, lies in their hands. In this field of medicine, too, the fundamental principles are the same in all parts of the world, whether the conditions be civilized or primitive.

Challenge to the Student

What is the challenge to the student? There are certain qualities essential to all students, from whatever part of the world they may derive. It is not difficult to draw a brief pen-picture of the ideal medical student; cultured, broadly educated in the humanities, intelligent and intellectual, of transparent integrity, humane and sympathetic, and, above all, one who will love his profession as well as his fellow men and all their weaknesses, their joys, and their sorrows.

It would be impossible for all students to attain such an ideal, but all should have some at least of these qualities, either inherent or capable of development, for I personally believe that unless this is so the man will never make a doctor, however well he is taught. Selection therefore becomes of importance, and will be a part of our discussion.

It is reasonable to suggest that the profession of medicine, being recruited from the upper one-third stratum of the normal distribution of intelligence, should be composed of something better than a high average. This view must necessarily be related to the demands of other professions and occupations, which likewise need to be recruited from the same stratum. Indeed, it may be necessary to survey the man-power available in relation to the number of doctors required by the various peoples, some countries being prosperous and urbanized, others prosperous and rural, many poor and underdeveloped.

In all countries it is important that the medical profession, while being technically competent, should also have such intellectual and social prestige and such unquestionable integrity as to command respect in the councils of the nation, the province, and the community. Medical students must be recruited on individual qualities and ability, quite independent of family, of personal fortune, of class or family distinction, save that a cultured philanthropic family tends to foster desirable qualities.

There can indeed be little doubt that the first challenge to medical education at this time is the challenge to education itself. Has the government of a particular country so ordered its educational system that a proportion of its youth will be fit to take up the most exacting profession in the world? If this is not the case, then the omission may need to be rectified at adult phase, perhaps in another country, otherwise there is little point in making fine or even coarse adjustments in the medical curriculum if the soil is not fit to receive the seed.

The Medical Teacher

Just as we think of the ideal medical student (though we ought really to think of the average, for this is the type with which our educational methods have to contend), so also we can picture the ideal medical teacher, whether he be teaching at the bedside, in the out-patient department, in the operating theatre, in the laboratory, in the lecture-room, or in the field.

Not all can attain the ideal, and it is not necessarily true, in fact often not so, that an expert in his subject can readily hand on his knowledge to others. Yet the expert and the artist can usually impart something which the professional

teacher cannot convey. There is, however, much to be said for the wide use of some form of tutorial system in the teaching of medicine. By this I do not mean what is generally implied by a medical tutorial—namely, question and answer in preparation for an examination. I think, instead, of the relatively young, experienced, keen member of a hospital staff to whom a small group of students can be permanently attached during the whole time of their hospital learning. The group could gather with the tutor, once or twice a week, from their several and different duties and discuss with him the doings and experiences of the week. Such a tutor, who might well be a general practitioner, could direct studies, review the work of the week, integrate and co-ordinate the various experiences, and give point and emphasis in such a review to all the aspects of medicine, social, hygienic, psychological, ecological, historical, and so on, which various advocates would especially wish to have inserted into an already overloaded medical curriculum. Such a tutor would indeed help to correct the departmental attitude which tends to over-emphasize a narrow subject. Good tutors are difficult to find, and they should not be overloaded with too many students, otherwise the personal atmosphere, that of a family rather than a tutorial class, would be destroyed.

Presentation is in many ways as important as what is presented. The classics, thought by many to be the ideal form of education, are worse than useless if presented to the student in a way which repels him.

The selection and appointment of future teachers might well be more deliberate than hitherto, in order that some may be chosen for their teaching capabilities; and such appointments in some grades might be for limited terms instead of for life.

What is to be Taught?

So much, then, for the medical student himself and his teacher. I must now take up the third challenge—namely, what is the student to be taught. From the narrow point of view one can argue endlessly whether this or that subject should be included in the curriculum and how many hours a week or a term should be devoted to it. With such an approach this conference would probably make little progress even if it were to confine its attention to the problems of the various medical schools and faculties in Britain.

Obviously the content of the curriculum is important, and during this week we shall learn a lot from each other with regard to it. Medical education, however, in any one area must to some extent be related to the medical needs of the population of that area. For example, the doctor practising in Britain will not need to be an expert in tropical medicine. Yet Britain's world-wide responsibilities in the Commonwealth have been reflected in the fundamental contribution made to the subject of tropical medicine by British workers. I need mention no more than Manson, Ross, Bruce, Leishman, and Leonard Rogers. This illustrates at least the fact that medical education can never be parochial.

The approach I have made with my programme committee has been to determine four principal sections and to select topics within these which will bring out and illuminate principles and methods. Let us just look for a moment at a few of the many things in which a medical student might be profitably instructed or of which he at least ought to have some knowledge. The complexity and variety of the subject arise from the enormous accumulation of knowledge during the past 50 years, and especially the last 25 years.

Nuclear physics, colloid science, and enzyme chemistry have provided us with new instruments of thought and practice. The bacteriologist has come to govern the surgeon in the operating theatre, the nurse in the ward, the cook in the kitchen, the practising doctor who uses antibiotics, and the public health worker who is concerned with community infections. The problems of blood transfusion, at one time seemingly simple, are now an affair of genetics,

specialized serology, and statistical analysis. Even clinical experience and a flair for diagnosis can no longer be regarded as infallible guides to ultimate clinical truth: the opinion needs to be checked by means of which the clinician may be profoundly ignorant. The clinician may indeed be momentarily embarrassed when asked for a quantitative expression of his observations and deductions. Medicine is coming to draw even more heavily on the more exact basic sciences and to become more precise and scientific in the formulation and execution of its tasks. It has been said that "science is measurement," and the medical statistician is now an indispensable member of the team which assesses the results of new remedies in a clinical trial or the efficacy of a new immunizing agent.

The challenge to our universities and medical schools is a simple one. Are we preparing our students at least to grasp the principles behind all this scientific work? Does the student leave the university with an understanding of the methods of science and with some knowledge of its history? The doctor of the future will have to be grounded more firmly in the basic sciences than was the student of 20 or 30 years ago, otherwise he will not be prepared to meet the challenge of advancing knowledge which is making medicine a more complete science. And here at once we come up against a difficulty. Because of the length and the ever-increasing complexity of medical studies university authorities ask that the boy at school shall have passed his first medical examination in the basic sciences of chemistry, physics, and biology before he enters the medical faculty. Parents, too, approve of this requirement because of the cost of medical education. The schoolmaster has had to bow the knee to this necessity. But there is evidence that there is now some poverty of mind in the finished medical and science graduates because of lack of general education in the humanities, literature, language, history, philosophy, and the arts. There is little doubt that the medical student who is to be a practising doctor should understand the world in which his patients live, and should be able to approach them as human beings with a depth of understanding that can come only from an appreciation of civilized values. We are indeed aware of the obvious dangers of too early specialization in science among those who are going to graduate in science and medicine. Perhaps the discussion between schoolmasters and doctors at the Conference will help to find an answer to this problem. Here, however, I would say that it is not advisable to extend the graduate period of education if it can be avoided.

It is also desirable, wherever possible, to preserve the continuity of education in school, university, and, indeed, in postgraduate studies. For example, the inorganic and organic chemistry at school should lead to extension of these subjects in the first medical examination and so to the biochemistry and physiological chemistry of the second medical examination, and thence to the application of these to the clinical work of the bedside in the form of chemical pathology. I shall listen with interest to hear whether speakers will state at which point in a student's education at school and university a medical orientation should be given, for example, to the teaching of chemistry.

From the undergraduate standpoint the depth to which the subject should be taught also presents a problem. How much chemistry? How much physics? How much anatomy? Does the intending and practising doctor need to memorize in detail, and then forget, the three-dimensional relations of the posterior triangle of the neck? Does he need to learn the dosage in Röntgen units of the radiation treatment of carcinoma of the cervix? Does he learn anything, as a student, when spending hours in an operating theatre watching the surgeon remove a tumour of the brain? Could he not spend his time more profitably in the out-patient department, the casualty reception, the polyclinic, or even in an art gallery or on the football field?

Sometimes a subject may become a burden in a particular medical school because of a struggle to maintain a department in a prominent position. I myself believe that a student

should receive continuous and lengthy instruction only in the common and basic and useful and everyday clinical problems, but he should content himself with a single experience in rare or specialized procedures. The brain operation which I have quoted will serve as an example, and likewise with the highly specialist work of the ophthalmic and other departments. On the other hand, more experience in such special departments as dermatology would be repaid in the field of actual practice.

Only by discussing such views and exchanging ideas shall we eventually find out how to unload the medical curriculum to make room for new subjects and how to give more attention to parts of training that have been neglected or should receive a fresh emphasis.

I should like once again to emphasize the need for continuity of teaching and how important it is to avoid presenting the student with separate blocks of instruction, the one block being unrelated to the other except in terms of successive examinations which have to be passed. The student must never think of the various phases of his education as a vista of obstacles between him and his final qualification, to be overcome as soon as possible and, once overcome, to be forgotten.

Integration of Medicine

Some of the themes for discussion this week remind me of one of my most distinguished predecessors at Cambridge, Sir Clifford Allbutt, who protested eloquently and with learning against the separation of medicine and surgery, a separation for which physicians are much to blame. Likewise many now hold the view that physiology and anatomy should be integrated as a single basic subject in the curriculum. We do not now need to train the nineteenth-century prosector. He can train himself after he has qualified.

Integration is indeed a fundamental requirement in the curriculum. Teaching has grown up piecemeal. Some aspects are mere survivals which have long lost their relative importance; others, of modern conception, have not been fully appreciated or orientated. Someone might well attempt to write a reasonably short textbook giving the principles governing the integration of all the many facets of medicine. If all the bees could be collected in one bonnet we should indeed have made progress. Happily the clinician in the wards is now accustomed to welcome to the bedside the physiologist, the pathologist, the radiologist, and, especially, the general practitioner.

I feel sure myself that the properly chosen medical tutor could contribute so very much to real integration and do away with both piecemeal instruction as well as the danger of disproportionate departmental and sectional emphasis.

Preventive and Social Medicine

This country's experiment with a National Health Service is one manifestation of the view that medicine is also a social science. The illness of one person is not an isolated event having no effect on others. Tuberculosis is not caused only by the tubercle bacillus. Housing, nutrition, conditions of life and work, all play their part, whilst in the chain of recovery the physician, the surgeon, the pathologist, the radiologist, the sanatorium, the public health officer, and the social worker in the home and in industry are all involved.

The study of man in relation to his environment, human ecology, is the fundamental basis of what is now called social medicine. The challenge to medical education to meet this growing consciousness of the importance of social medicine comes from within as well as from without the medical profession.

A complete section of this conference is concerned with the teaching of preventive and social medicine, a subject in which the World Health Organization takes a special interest. Thus, there will be opportunities for educationists from all parts of the world to exchange ideas and experiences. And it is to be hoped that what is said will help those responsible for medical education in countries where facilities are less

highly developed, especially, perhaps, in the fields of social and preventive medicine.

The Objective of Medical Education

Whatever be taught to the student, it is as well at some phase to ask ourselves coldly and critically, What is the object of undergraduate medical education? The short and incomplete answer is to turn out someone fundamentally equipped to be a practising doctor. The period of training should not be specifically directed towards the training of a general practitioner or a specialist or a public health official or an administrator, but should provide the student with a foundation for his after-career in any branch of medicine. It is his postgraduation apprenticeship and narrower studies which finally complete his early education in the branch of medicine he elects to follow, whether this be general practice or a specialized field.

The undergraduate teacher should aim at producing an educated person grounded in principle and method, able to see what the whole of medicine stands for and means, trained to observe with his hands and his senses, encouraged to think logically and critically, instructed in the use of the instruments of measurement, and equipped with a basic knowledge upon which he will continue to build for the rest of his professional life.

Are we as medical teachers doing this? Or is teaching just a by-product of our professional life? Do we positively examine ourselves from time to time with a critical eye, or do we complacently content ourselves with no more than getting the student over an examination hurdle?

Are we also satisfied with the means by which a student's competence to be qualified is assessed? Has the examination a hampering effect on what is taught and learned, and, if so, can we suggest any alternatives? Always we have to bear in mind that in many countries the manner of assessing competence and the standard are governed by law. There is, however, little doubt that experiment would show some ways in which the perpetual orthodox examinations could be advantageously modified.

Those of us who had the task of devising the programme for this Conference had to pack a great deal into the short space of a week. Many themes I should like to have heard discussed have had to be omitted. Many here might have made different choices. All of you will, I hope, by the end of this week conclude that we have made a useful beginning in tackling this most fundamental of all medical questions—education. And if that is the conclusion, I hope that, individually and collectively, you may decide that the organizations which you represent might be asked to repeat the Conference in four or five years if it is felt that that would carry the matter further.

In the meanwhile what likelihood is there that something will be done? That those in control of medical education will really have the humility and courage to admit that all is not at its best in the best of all possible worlds, their worlds? That those who hold the shaping of the future in their hands will fashion it with vision and imagination so as to inspire the young man and woman to pursue the tasks of our great profession with a feeling of dedication to something greater than themselves? There is indeed a likelihood, otherwise so many of us would not have met here in London in the month of August. But the possibilities must be turned into probabilities and certainties, and until this happens we must possess our souls with that discontent that has so aptly been called divine.

We may aim higher than we can reach. But if we aim high we shall at least reach somewhere. Our individual and collective responsibility as a profession grows, and will grow. We cannot escape it. Medicine to-day demands much from character, intellect, and practical ability, and medicine also provides a wide variety of opportunity for all kinds of talent. But talents will be wasted or misused if the structure and content of medical education are faulty, and if medical educationists remain complacently satisfied with themselves and their methods.

WHAT IS EDUCATION?*

BY

Sir RICHARD LIVINGSTONE, M.A., Hon.D.Litt.,
Hon.LL.D.

We have—most of us—to earn a livelihood. We find ourselves on an immense stage called the universe, occupied by strange creatures called men, and we must have enough knowledge of this scene and of its inhabitants to play our parts intelligently. And we are human beings, with a body, a mind, and also something elusive and indescribable but very real, which we call a soul or spirit—three elements which combine in our personality and which interact on each other; and we wish to make the best of all of them, so far as our natural endowments allow. For even if there were no Great Assize before which at the end we shall be summoned to say what we have done with ourselves and our talents, the world will judge us; and, what is more disquieting, in moments of insight and reflection we shall judge ourselves.

These three needs determine the aims of education. It should prepare us, either by a general or a vocational training, to earn our bread; it should give us some understanding of the universe and of men; and it should help us to become fully developed human beings. Of these three aims the vocational one which concerns us as breadwinners is least likely to be overlooked; and I shall therefore say nothing about it, but concentrate on the other two aims—the making of intelligent citizens of the world and of good human beings—*homines maxime homines*. These two are the most important to us as men, but, since they are the less obvious and the more difficult, they may be neglected, and especially the last of them. Yet the human being is a work of art, capable of a quality and beauty of its own, quite apart from any practical purposes to which its powers are put.

Science an Essential Part of Education

We have to live in a material universe inhabited by men, and to live intelligently we must know something of both. The keys to a knowledge of the material world are commonly called (not very happily) science, and so some knowledge of it is an essential part of education. But in planning our curriculum we should distinguish between scientists, doctors, engineers, and others, who require exact knowledge of science in their occupation, and those who do not. For the needs of these two classes are not the same. The former class must have specialist knowledge of the sciences which they require for their life's work. The need of the others is different. It is less important to teach them chemistry or physics or biology than to give them an idea of the meaning of the changes that came in human affairs about 600 B.C., when some Greeks realized that there was more in the universe than the senses could perceive, and began looking beneath the surface of phenomena to underlying realities and laws, and science was born: and, again, when in a later day other men conceived that through such knowledge nature could be controlled as well as understood, and science gave birth to her child, technology.

To realize the meaning of science, her powers and procedures, the instruments of observation and experiment by which she works—that is more important than teaching individual sciences to pupils who are not going to specialize in science—it is, of course, only of them that I am speaking. By all means add to this essential core as much as

*An address given in the plenary session of the First World Conference on Medical Education on August 24.

time permits. But I can see no use in being taught, as I was, the elements of chemistry and physics without ever having an idea of their meaning and use, or any conception of the fascinating truth that you can transform things by analysing them into their constituent elements. The teaching I had did not make me less of a stranger in the material universe than I was before. It only gave me a transitory knowledge of some isolated facts in which I saw no meaning.

Science, then, though in different forms, must have a place in all education, for the material universe is the stage on which the human drama is played. We say, no doubt, that man is not the centre of the universe, but, however true that may be, everyone continues to act much as if he was; if we did not think our activities of great importance we should cease to take them seriously. But the drama is human and the actors are men, and the actor is more important and interesting than the stage. His fortunes are, in practice if not in theory, the fortunes of our world, and apart from them it would have lost any meaning. Man is the source of ideas and ideals, the deviser of progress and its instrument, the maker of that rich and ingenious structure which we call civilization. As Shakespeare put it, "What a piece of work is a man. How noble in reason! how infinite in faculty! . . . in action how like an angel! in apprehension how like a god! the beauty of the world! the paragon of animals!" That is man in his better moments; he has other moments too. Anyhow, in himself he is a fascinating study, and without some study of him we shall not live our lives with intelligence, interest, or, in any but the narrowest sense, success. That is why Dr. Conant, himself a distinguished chemist, said that "in terms of general education, poetry and philosophy are of vastly more importance than science"; so history and literature must enter into any education; for they are our chief records of man and his ways.

Place of History and Literature

In history we see his slow ascent from savagery to a complicated civilization, his experiments, mistakes, failures and successes in the climb, the states he has founded, static or progressive, transitory or stable, the forces that have brought him on or kept him back, the virtues that have sustained his efforts, the vices that have brought them to nothing. History is a clinical study of man in society. Literature is more personal. Here we meet man in his intimate moments, talking to the world, but really to himself, so that in literature are recorded all the thoughts, feelings, passions, visions, and dreams that have ever passed through the human mind; and some of the visions play a great part in human progress. In one way literature is less instructive than history, because history has to do with facts, and poetry with visions; in another way more so, just because it is more intimate, more personal. We meet human nature in undress, we meet ourselves, but also we are taken beyond ourselves to an exceeding high mountain and shown all the kingdom of man and the glory of it. Religion first, but close after it poetry, reveal powers and qualities in man which otherwise we should not know. Lifted on the shoulders of genius, we catch a glimpse of undivined worlds which are within the reach of the human spirit.

The Right Aim

But, you may reasonably ask, is this the way in which literature and history are taught in schools, or even in universities; is this the light in which they are presented to the pupil; and do not many people study them without any clear idea what they are about? I will not answer these delicate questions, but they remind us of an important fact. It has been said that it does not matter what subject you teach a pupil, if you teach it well. I would add (though neither of these epigrams is quite true) that it is

¹ Education in a Divided World, p. 126.

no use teaching anything if you teach it badly. And not only must a subject be taught well it must be taught appropriately. I argued earlier that it is a mistake to teach science to an arts specialist in exactly the same way as you would teach it to someone whose main study it is. I do not think that this mistake is now often made in teaching science to those who will never specialize in it. But it is, I fancy, sometimes made in teaching literature and history to scientists. The right aim in teaching these subjects to those whose work and interests are in science is less to instruct them than to awake the mind, to make the pupil feel the interest of literature and history, even though his detailed knowledge of them may be small. I would rather that a boy had read one dialogue of Plato, one canto of Dante, one play of Shakespeare or Racine with real enjoyment, and with a keen sense of its greatness, than that he should be hurried through masses of literature which he neither understands nor enjoys nor absorbs. If he is interested, he is likely to pursue the study further in his leisure; and he will at least have become aware that there are more things in heaven and earth than are dreamt of in his specialism. By all means add to this stimulus as much knowledge, as wide a survey, of history and literature as you have time for: but without the stimulus these are vain. General culture is designed, as Whitehead said, "to foster an activity of mind."

Four Points

So far I have been talking about the introduction to the kingdoms of nature and of man—a preparation to feeling at home and living intelligently on the stage where we find ourselves. But we also need some instruction about how to behave there, and I shall mention briefly four points of good behaviour. One point is to learn how to express ourselves intelligibly to others. A second point is to know how to read a book, noting exactly what it says. A third point is to think clearly and logically. John Morley said that an educated man knew when a thing was proved and that an uneducated man did not know; and this saying, though not an exhaustive account of education, calls attention to an essential element in it.

Logical thinking is one way to truth, but it is not the only road, nor is it a complete one, and so I should add to my proposed code of behaviour a fourth item—the insight that comes from sensitiveness—to supplement and correct the knowledge which comes from hard thinking. This is often neglected in our education. The sensitive person with an undisciplined mind is a danger; so, less obviously, is the mere intellectual. He is not likely to be good at what has been described as the sacred duty of getting under other people's skins—especially the skins of people unlike himself. Some human beings are born with the sensitiveness that makes this easy and habitual. But it is a gift that can be trained, and the best training in it is given by two subjects that find a place in any curriculum—history and literature, especially literature, where the reader enters into the mood of the writer, the atmosphere of the poem, the temperament of the character described. Take for instance Shakespeare's *Othello*. Except for the pleasure which the rich language gives, one might just as well not read it if one does not for the moment creep under the skin of the Moor, of Desdemona—yes, and of Iago—and feel as they feel in the play. Of course literature has the power of absorbing us in bad, as well as good, moods and atmospheres; that is the reason why Plato thought it dangerous. But a training in sensibility and the insights which sensibility gives is essential. For knowledge is not merely the collection of facts; it depends on imagination as well as on reason.

An Overruling Principle

So far I have suggested that the aim of education is at least to introduce us to the worlds of Nature and of Man, and to train the powers of reason and imagination and the art of expression needed for effective behaviour in them.

But that is not enough. It would be possible to have all these and yet be without that overruling principle which we call a philosophy of life; a force to steady the purpose and give it direction, to concentrate the abilities and bring them to bear, to recall and revive the flagging energies; a force which is

Victory and law
When empty terrors overawe;
From vain temptations doth set free
And calm the weary strife of frail humanity.

An education is incomplete unless it leaves people with what I have called a philosophy of life, and never was this more needed than in our age of uncertainty. But the very conditions which make it desirable make it difficult. Order is not easily visible in chaos, nor a clear voice audible in a confusion of tongues. The Christian no doubt has firm beliefs and clear standards, and my own conviction is that Christianity will become again the philosophy of the Western world; but that day is not yet. Meanwhile can we find an interim philosophy which can be imparted through education and which is sufficiently powerful to dominate men's minds and hearts, sufficiently convincing to win a general assent? It is not easy to see one. What philosophy of life—to take an obvious instance—can the Western and the Russian blocs share? There is only one creed which men in every continent agree to repeat: "I believe in Science and in its child Technology." That is a starting-point; it is something. But it only covers a limited area of conduct, and it does not profess to answer the most important questions about life and human nature. You cannot call it a philosophy. A principle of wider range is needed.

Philosophy of the First-rate

There is a philosophy which gives standards of value and judgment that apply to all spheres and activities of human life. It is a very simple one, and no one would reject it. I would call it the Philosophy of the First-rate. Ask a doctor or a surgeon if he is ignorant of or indifferent to the best methods in his profession. Would he answer yes? Or would he consider that there are no differences of quality in art, literature, music, architecture, and that it does not matter whether a picture or a sonata or a play or a building is first-rate or third-rate? Or, taking the inquiry into a still more important province, do we think that when we apply the words good or bad to human character and conduct we are drawing meaningless and unimportant distinctions? In all fields of life all people, whatever their creed or race, admit what I called the philosophy of the first-rate. I have already quoted John Morley's saying that an educated man knew when a thing was proved and that an uneducated man did not know. I would prefer to say that an educated man knows, and an uneducated man does not know, what is first-rate, and that the best-educated man is he who knows the first-rate in the most important human activities.

The supremacy of the first-rate is a self-evident axiom. But it is sometimes an unrealized axiom. We are like the slave in the *Meno*, who had the principles of geometry latent in his mind, but never recognized them till Socrates played the midwife and brought his subconscious knowledge to the birth. For our purpose education must be the midwife—the metaphor suggests one of the most fruitful and fundamental conceptions in that field—and bring to birth this philosophy of the first-rate, which is so fruitful and which no human being would disown.

But how do you know the first-rate? How do you recognize it in practice? There is only one way of getting to know it—by seeing it; and that is the way in which it can be taught. I imagine that the medical student will learn more by seeing a great surgeon at work or by going round the wards with a great doctor than all the textbooks in the world can teach him. It is the same in anything. People learn what is first-rate by contact with it. You learn what is great music by hearing it, what is great architecture

by seeing it. You learn first-rate business methods by working in a first-rate business firm. It is the same everywhere. You acquire a good taste in wine by drinking good wine, in good cigars by smoking them.

In cigars and wine, if we have the money, in art and music, even if we have not, it is easy to come across the first-rate. But where do we find it in character and life? It is at hand; in the great religions, and the great moral systems, but also in literature and history, though here the pure gold runs in veins amid much worthless matter. Make, for instance, a list of the good men and women in Shakespeare's plays, and what a company of noble characters you will assemble. Here, and throughout the literatures and the history of every country, archetypes of excellence are present for the looking. These are the great sources on which we can draw, and here is one reason why an education which ignores the humanities is disastrously incomplete. I do not of course suggest that the study of history and literature is only the study of human ideals, conduct, and character. Obviously these subjects have many other aspects. But it is with this aspect of them that we are concerned at the moment. Therefore, for our particular purpose, history and literature must be read from this angle and with this aim in view. Unfortunately this is often ignored in the teaching of history and even of literature. Their teachers have usually been trained as experts by experts, and are interested in those other aspects of the subject with which universities concern themselves, but which, necessary and important as they are, are of no use for our particular purpose. For that, history and literature must be treated as mirrors of human character, and indeed as moral philosophy in the concrete.

But, you may ask, how do you know what is first-rate in literature and art, and still more in human character? As Browning puts it,

Ten men love what I hate,
Shun what I follow, slight what I receive,
Ten, who in ears and eyes
Match me: we all surmise
They this thing, and I that: whom shall my soul believe?

That is a plausible question, but more embarrassing in dialectic than in fact. There is no real doubt that Homer and Shakespeare are great poets, Bach and Beethoven great musicians, Plato and Kant great thinkers, Newton and Faraday great men of science. Even in the more uncertain field of character and conduct no one is likely to doubt that in St. Francis or the Buddha, in Lincoln and Masaryk, we see the first-rate. We are safe in accepting the judgment of time; it is rarely reversed on appeal.

To repeat, an education which leaves us without a philosophy of life is as incomplete as one which leaves us unable to think or to express our thoughts. And never was a philosophy as necessary as in an age of divided purposes and paralysing doubts about ultimate ends. Our civilization is fluid, its future form still to seek and make. At present it is a curate's egg civilization—some of it excellent, some of it fourth-rate. If you question this criticism, look at our cheap daily papers. Yet ours is an age of great vitality, of unlimited powers and possibilities, too often frittered away or misused. We have the materials of a great civilization: all that is needed is to stamp it with the print of excellence. The more reason that our education should train our youth to desire, recognize, and pursue the first-rate.

According to a press report, a public opinion poll organized by the psychology department of Victoria University College, Wellington, New Zealand, showed that the social status of doctors was put higher than that of the other professions and occupations. After the doctors came lawyers, company directors, business managers, nonconformist clergy, accountants, chiefs of Civil Service departments, works managers, farmers, and teachers, in that order.

HISTORY OF MEDICAL EDUCATION*

BY

JOHN F. FULTON, O.B.E., M.D., F.R.C.P.

Sterling Professor of the History of Medicine, Yale University, New Haven, Connecticut, U.S.A.

"From the earliest times, medicine has been a curious blend of superstition, empiricism, and that kind of sagacious observation which is the stuff out of which ultimately science is made. Of these three strands—superstition, empiricism, and observation—medicine was constituted in the days of the priest-physicians of Egypt and Babylonia; of the same three strands it is still composed. The proportions have, however, varied significantly; an increasingly alert and determined effort, running through the ages, has endeavoured to expel superstition, to narrow the range of empiricism, and to enlarge, refine, and systematize the scope of observation. . . . The general trend of medicine has been away from magic and empiricism and in the direction of rationality. . . ." (Flexner, 1925).

The quotation above is from Abraham Flexner's well-known monograph on medical education, and I repeat it here because it expresses so succinctly the broad sweep of medicine from its beginnings to the present day, when the teaching of the art is of sufficient import to bring together at this World Conference men who are concerned with all its phases and implications. From the days of the early priest-physicians the teaching of medicine has had a highly personal flavour, and this close physician-pupil relationship has persisted until modern times, varying in degree as times have changed, but never altogether disappearing. There are many in this era who lament the fact that the personal tie between teacher and pupil no longer plays so vital a part in medical education, and they would urge a return to the earlier mode of teaching.

Ancient Precepts

In early Sanskrit medical literature there emerges through the mists of Hindu legend an eminent physician named Charaka, who, like Hippocrates, was a great teacher and an indefatigable writer (Puschmann,† 1889; Jelliffe, 1906). In his commentaries on the *Ayurveda* (c. 500 B.C.) he admonishes young men who propose to study medicine to find a good teacher—one "whose precepts are sound, whose practical skill is widely approved, who is clever, dextrous, upright, and blameless; one who knows also how to use his hands, has the requisite instruments and all his senses about him, is confident with simple cases and sure of his treatment in those which are difficult; of genuine learning, unaffected, not morose or passionate, and who is likewise patient and kind to his pupils" (Lakshmi Pathi, 1944). This is one of the earliest statements of the pupil-teacher relationship in the literature of medicine, but no doubt there were many other great teacher-physicians in China, Egypt, and among the Jews whose views about the training of students have not survived.

The medical literature of Greece and Rome, however, gives detailed insight into both the principles and the practice of student education; here the source materials become

*An address given in the plenary session of the First World Conference on Medical Education on August 24.

†In tracing the early history of medical education one inevitably turns to Theodor Puschmann's scholarly treatise, published at Leipzig in 1889, *Geschichte des medizinischen Unterrichts von den ältesten Zeiten bis zur Gegenwart*. In 1891 Evan H. Hare, F.R.C.S., gave an admirable English rendering under the title, *A History of Medical Education from the Most Remote to the Most Recent Times*.

vast (Drabkin, 1944),‡ for the Greeks were much concerned with education and wrote of it at length. In the period before Hippocrates, Greek traditions had begun to spread westward. Thus in the fifth century B.C. a medical school was already established at Croton, in southernmost Italy (on the instep of the Italian boot facing North Africa). Here flourished another figure, Alcmaeon, who, like Charaka, is known nebulously through the writings of others. From Theophrastus it is learned that Alcmaeon was a neurophysiologist—the first of whom there is record. Theophrastus states that he carried out experiments on the brain and spinal cord of living animals and that he distinguished between sensory and motor nerves; indeed, some believe that he had even grasped the concept of the reflex. Alcmaeon is said to have attracted many students and to have carried out anatomical dissection and demonstration (Stella, 1939).

Throughout the Greek world, medical education was based more on experience than on book learning, practical training generally being acquired from a physician-father, or by an aspiring student apprenticing himself to a practitioner for a period of years. Books were used, but only as adjuncts, and they never replaced practical experience. There is an interesting passage in the *Laws* of Plato in which distinction is made between the training of free doctors and those who are merely to become their assistants. "All bear the name [of physicians]," he wrote, "whether freemen, or slaves who gain their professional knowledge by watching their masters and obeying their directions in empiric fashion, not in the scientific way in which freemen learn their art and teach it to their pupil" (Taylor, 1934; *Laws*, 720).

The spirit of the student-teacher relationship is also well exemplified in the Hippocratic Oath: "To hold him who has taught me this art as equal to my parents and to live my life in partnership with him, and if he is in need of money to give him a share of mine, and to regard his offspring as equal to my brothers in male lineage and to teach them this art—if they desire to learn it—without fee and covenant. . . ." The Oath also distinguishes between general precepts and practical instruction, such as that derived from attending a physician on his rounds and observing and helping in the temple where he sees his patients.§

The apprenticeship system spread to Rome and persisted there long after formal schools of medicine with regular course work had been established. According to Galen, anatomical dissections were sometimes carried out by students in early childhood under the direction of a father-physician. Galen adds significantly that when childhood dissection was given up it became necessary to have written manuals of instruction (Drabkin, 1944), which led to a gradual standardization of medical instruction throughout the Roman world and the establishment of medical schools offering lectures and obligatory dissections (usually on animals), sometimes carried out by the student himself, but more usually by a teacher or demonstrator. During this time there was a gradual separation of medical theory and practice, and little by little instruction in surgery became divorced from that of medicine.

Both in Greek and in Roman medicine great emphasis came to be placed on the scientific approaches. As Sir Richard Livingstone (1944) has said so eloquently, "Science

‡Drabkin (p. 350) points out that, while more in the way of medical writings have come down to us than in that of any other field of ancient literature, the greatest part of medical literature as such has failed to survive. No attempt can be made to estimate how many thousands of books have been lost, but Drabkin cites one instance of an unnamed doctor who wrote 256 books and not a fragment of any one of them survives. All of which points to caution in any type of historical reconstruction such as that of early medical education.

§The age of the Oath has been disputed, some having maintained that it probably antedates Hippocrates himself—i.e., sixth century B.C. (Puschmann, 1889)—but Edelstein (1943) believes that it comes from the fourth or fifth century B.C.

profoundly affected Greek thought but did not alter the conditions of Greek life, and we have the spectacle, so strange to us, of men profoundly interested in it but almost unaware of its practical uses. To the Athenian thinker—a fact curiously overlooked in much classical English education—scientific study was essential to the educated life. . . . Half of Aristotle's writings are on the same subject (science); and every Greek philosophic system, except Cynicism, has its physics as well as its ethics."

Mediaeval Times

The first school of medicine of mediaeval times came into existence, probably in the ninth century, on the shores of the Tyrrhenian Sea, in the town of Salerno. Tradition has it that the school was founded by representatives of the four cultural forces which had persisted through the Middle Ages—a Greek, a Latin, a Jew, and an Arab. Few traces now remain of this once flourishing centre of medical thought; however, its published texts, such as the *Regimen of Health (Regimen Sanitatis Salernitanum)*, bear eloquent testimony to the virility of a great school of learning. Prominent patients, as well as innumerable students, came to Salerno from far and wide, even from as far north as Germany and Denmark. One student, Gilles de Corbier, from Paris (c. 1200), returned to become private physician to King Philippe Auguste, and it was Gilles among others who proclaimed with tongue and pen the fame of Salernian medicine.

Some details are known about the mode of teaching at Salerno. In anatomy, for example, students dissected various animals, including pigs and monkeys, and they likewise attended formal demonstrations. Although much disputed, tradition holds that Salerno was the first school to admit women for medical training, and there are still those who believe that the author of the celebrated mediaeval treatise on diseases of women, *Trotula*,* was one of its graduates. "Mythoclasts" of the Sudhoff school—as Osler called them—have ungallantly tried to deprive Trotula both of her sex and of her position in history, but the late H. P. Bayon (1940) has found evidence in extant Trotula manuscripts that a thirteenth-century author bearing the name of "Trotula" clearly existed and that almost certainly she was a woman; but Dr. Bayon was not prepared to proclaim her the first female professor in a modern university.

While Salerno was developing its traditions of medical teaching, in far-away China, during the Sung dynasty (960–1280 A.D.), when Korea was first invaded, the position of court physician became stabilized, and to him was given the task of instructing students in the canonical books of medicine. During the Mongol dynasty (1280–1368), the Emperor Khublai introduced medical examinations and a system of licensure based on examinations, while in the Ming dynasty (1368–1644)—when Korea was again invaded—the Medical College of Peiping was founded, the first medical school in China (Castiglioni, 1947, p. 106).

By the twelfth century, in Europe, men trained at Salerno began to found schools elsewhere—in France, Spain, Portugal, and England; the earliest were those of Paris and Montpellier. The exact time of founding of these schools is in no case clear, but we know that Adalbert of Mayence studied medicine at Montpellier in 1137.†

There were three outstanding teachers connected with Montpellier—Arnold of Villanova, Henri de Mondeville, and Guy de Chauliac. Since Montpellier was situated near the Spanish border the receding tide of the eighth-century

**Curandarum Aegritudinum muliebrium ante, in et post partum liber unicus*; known also by its subtitle, *Passionibus mulierum curandarum*. The text was first printed in 1544 by Schottus of Strassburg, but the later text, published by the Aldines in 1547, is the one usually followed. An English translation by Elizabeth Mason-Hohl was published in 1940 under the title, *The Diseases of Women by Trotula of Salerno* (Ward Ritchie Press, California).

†In addition to following the example of Salerno in the teaching of anatomy and surgery, Paris and Montpellier also stressed medical botany; thus the French physician Odo Merndon (c. 1130) probably wrote the famous poem *De viribus herbarum* in two thousand Latin hexameters (generally attributed to Macer Floridus), and there were many other writings in the field of medical botany dating from this period.

Arab invasion had left its mark in this part of France, and it was inevitable that the teachings of these physicians would show a strong Arabic influence. Arnold of Villanova was well travelled and widely read, and he was one of the most prolific writers of the Middle Ages. Henry de Mondeville, also dominated by Arabic influence, was an excellent practical surgeon whose success was in no small part due to the fact that he was a keen observer. The most influential of the Montpellier trio was undoubtedly Guy de Chauliac, whose textbook of surgery, one of the most important of the late Middle Ages, was reprinted far into the seventeenth century and often in vernacular tongues. Both Mondeville and Guy de Chauliac were practical men who appreciated the value of training their hands both for diagnosis and for the operations of surgery, but too little is known about their actual teaching methods to warrant more detailed consideration here.

A contemporary of these men who was earning an equally distinguished reputation as a writer and teacher was Peter of Abano, who was one of the first of the great physicians of the school of Padua. Sir William Osler (1921) points out that 8 of the 182 medical books printed before 1481 were from his pen, and from this we can judge his influence not only upon his contemporaries but on the history of medicine. Medicine of the Middle Ages was of course closely aligned with theology, and, since the clergy were the most learned men of the time, two of these must be mentioned in passing for the tremendous influence they exerted in turning men's minds towards scientific approaches to the facts of nature. The first was Albertus Magnus, who so magnificently interpreted Aristotle to his generation; the second Roger Bacon. Albertus Magnus was a man of encyclopaedic learning whose paraphrase of the natural history of Aristotle became the basis for all subsequent Aristotelian studies. His medical works were also widely known, and, while he inspired many, his greatest pupil was Thomas Aquinas.

Roger Bacon was one of the first to lay stress on the importance of acquiring knowledge through original research rather than from existing authorities, but his contemporaries had little appreciation of his practical philosophy, and he himself lacked the ability to put his teaching into practice. The result is that readers of to-day find a refreshing modernity in his writing.

The Renaissance and After

The fifteenth century marks the renaissance of the great Italian schools, especially those of Padua, Bologna, Ferrara, and Pisa. In the following century students went over the Alps in great numbers, and in each university formed themselves into "nations"; thus we find Fabricius of Aquapendente dedicating his celebrated treatise on the valves in the veins to the "German nation"—confusing indeed if one did not know that he was addressing himself to a particular group of attentive students who had seen him demonstrate, even as had William Harvey, these important venous structures, which ultimately led Harvey to the discovery of the circulation.

Many of the practising physicians in England during the fourteenth and fifteenth centuries had studied medicine in the good Continental universities—Padua being the most popular until the religious difficulties of the late sixteenth and early seventeenth centuries caused English students to turn to the Protestant schools of Switzerland and Holland, especially Leyden, where Boerhaave's medical clinic had become celebrated. It is true that "physic" was taught at Oxford and Cambridge, but instruction was usually theoretical and success involved gaining a verbatim knowledge of ancient writers, such as Galen and Hippocrates and a number of the Salernian texts. The popularity of the Continental schools was such that Parliament made into a law in 1421 a petition from the English universities that graduates of foreign schools must become "incorporated," with an M.D. either from Oxford or Cambridge before they could practise medicine. This ultimately became a routine procedure (Allen, 1946).

During the next century the need for a system of licensure became increasingly apparent, and in 1518 Thomas Linacre,

who had studied in Italy (for 12 years), founded the Royal College of Physicians under charter from Henry VIII. Recognizing the need also for medical chairs, Linacre established three medical lectureships—two at Oxford, one at Cambridge—and in due time the first two of these lectureships became the Regius Chairs of Medicine at Oxford and Cambridge. Linacre's second lectureship at Oxford bore his own name and still survives (Chaplin, 1919).

Another prominent advocate of a more modern approach to medicine was Linacre's near contemporary, John Caius, who had brought back from Padua the teachings of Vesalius. As Master of Gonville College he endowed three fellowships—two for medicine—and twenty scholarships, and Gonville and Caius College, as it later was to be known, came to be the centre of medical study at Cambridge.

Period of Transition—1600–1800

As the "New Learning" of the sixteenth century transformed scholarship in the western world, so the "Experimental Philosophy" of the seventeenth gave new life both to medicine and to science. Bacon had set the stage in his *Advancement of Learning*, and Harvey, a short time later, became the centre of that stage through his monumental discovery of the circulation; but the full meaning of the Harveyan discovery for medical science and teaching was not fully appreciated until later in the century, after the Royal Society and the other scientific academies in Europe had been founded. Then came two remarkable figures, both Englishmen, who left their distinctive mark on medical education—the one in theory, the other in practice. To quote Sir George Newman (1918, p. 21):

"Locke and Sydenham . . . taught that, over and above the university spirit and a university standard of learning, the medical student requires (i) a training in observation and the inductive method, (ii) exercise and practice in his craft, and (iii) some apprehension of the rationale and laws and limitations of Medicine. His dormant faculty of observation will be awakened in his preliminary study of science, and indeed all through his medical curriculum it can be trained and stimulated to become a talent and a habit of keen, serious, patient, continuous seeking, of honest perceiving and of valid reasoning. The student must also have ample opportunity of everyday practice. Medicine is the art of healing not less than the science of disease. 'Our art,' wrote Sydenham to Dr. Mapletoft, 'is not to be better learned than by its exercise and use'—not an exercise of healing only in the sense of curing a particular patient, but of learning from each patient increased power in the art of healing all similar patients."

In England at the beginning of the eighteenth century a medical education could be secured only in London, Edinburgh, Aberdeen, and Dublin (Chaplin, 1919, p. 17). There were seven of the London hospitals in which a general knowledge of medicine could be obtained, but, except at the London, Guy's, and St. Thomas's Hospitals, formal teaching was much neglected. By far the larger number of students were educated at schools supported by private enterprise. Best known were those maintained by Dr. George Fordyce at his house in Essex Street, Strand, and at Windmill Street, where the two Hunters, Hewson, Cruikshank, Baillie, and Wilson combined forces. Attendance for a period of time at the lectures of men such as these enabled an aspiring surgeon to present himself for examination to the Corporation of Surgeons or the Worshipful Society of Apothecaries and, if successful, to receive a diploma. To prepare as a physician, on the other hand, involved a much longer course of study. The student must have a degree from some university, and, if he wished to practise in London, must pass the licentiate examination of the College of Physicians. This was obligatory for all physicians who wished to practise in the provinces, except graduates of Oxford and Cambridge. To qualify as a licentiate a candidate, according to Chaplin (1919), had not only to prove himself familiar with the principles of medicine but also to exhibit some general "erudition and culture." (See also Chaplin, 1920.)

In the early nineteenth century students began to find their way more often to the French schools, where Corvisart,

Laennec, and Louis were the harbingers of modern medicine. Louis in particular, with his statistical approach to medical problems, exerted a strong influence on many young men from America, who were to return and become the medical educators of that time. Later in the century it was Germany which attracted some of the best of the younger minds, for it was in Germany that practical laboratory teaching was first established within the universities. In these laboratories the sciences of chemistry, physics, pathology, physiology, and eventually bacteriology reached a mature status through the efforts of men such as Liebig, Helmholtz, Virchow, Müller, Cohnheim, and Ludwig (Fulton, 1950).

Developments in North America

Medical education in America was of course strongly influenced by both the French and the German systems of teaching, but the earliest influences stemmed from Edinburgh and London. The apprentice system which obtained in America from the beginning had been brought from England, with all its virtues and shortcomings. The inadequacies of the system were soon recognized by the enlightened physicians of the Colonies, and in the eighteenth century the more ambitious of those wishing to enter the profession of medicine made the hazardous journey to Edinburgh, London, Paris, or Leyden to complete their training. One of these, William Shippen the younger, returned to his native Philadelphia after a sojourn of five years abroad and began a series of lectures in mid-wifery and later in anatomy (Flexner, 1910). When his friend and fellow student, John Morgan, returned from his study abroad, he, Morgan, carried into effect the plans they had made together in Edinburgh—to found a medical school at the College of Philadelphia.

In an address delivered at the graduation exercises of the College in 1765 he proposed the creation of a professorship in the theory and practice of medicine. This celebrated discourse, still pertinent to-day, was entitled: *A discourse upon the institution of medical schools in America; delivered at a public anniversary commencement held in the College of Philadelphia May 30 and 31, 1765*. Morgan himself was appointed to the chair of medicine, William Shippen and Benjamin Rush being appointed at a later date. This school subsequently joined with the school of the University of Pennsylvania, and has continued to the present day (Klickstein, 1953). In 1813 a school of medicine was founded at Yale College, making five schools of medicine in the United States—and at what is now Columbia University, Harvard, and Dartmouth. Unfortunately, however, the sound ideals on which these schools were founded were in large measure lost sight of in the next century. Schools of medicine without university affiliation began springing up everywhere, and, as the numbers increased, the quality of the education they offered sharply decreased.

During the eighteenth century there was still no system of licensure in North American schools, and while some schools granted the M.D. or M.B. degree, usually after a period of two years' study, there were many apprentices, as there were in England during the same period, who announced themselves as practitioners without formal qualifications. The state and country medical societies eventually insisted on licensure, and by 1821 the state of Connecticut, through its medical society, had set up a board of medical examiners, and they forced all unlicensed practitioners to take the state examinations. This movement spread to other states and through the initiative of the New York Medical Society the American Medical Association was founded in 1847 with the end in view of raising standards of medical education on all fronts: requirements for admission to medical schools, examinations for licensure—this and much else, all duly recorded in a historical monograph by the founder of the Association, Nathan Smith Davis (1877).

During these years, despite the deplorable conditions in some of the so-called medical schools, a number of good

physicians were nevertheless practising and teaching in America, and the better students were well educated at their hands. The establishment of the School of Medicine at the Johns Hopkins University in Baltimore on a true university basis, with four years of college required for entrance, exerted a most salutary influence on the medical schools in the United States. The Flexner report (1910) on medical education and moneys from the newly formed Rockefeller and Carnegie Foundations reduced the numbers of schools of medicine and brought higher standards to those which survived. Graduates of the Hopkins went from there to other schools, taking the precepts and ideals of men such as Welch and Osler with them, and thus the influence spread.

One of these men, Milton C. Winternitz, came to the Yale University School of Medicine in 1917, and, building on the foundation of reform already begun by Dr. George E. Blumer, also a Hopkins graduate, he launched a new curriculum of medical education which has come to be known as "the Yale plan." Under this system the student is placed largely on his own; periodic examinations have been dispensed with, and he is allowed an unusual amount of freedom to pursue his particular interests and to explore the literature to which his lectures have directed him. Qualifying examinations are eventually taken through the National Board of Medical Examiners. This system, although it has been under fire by its critics since it was instituted in the 1920's, has seemingly stood the test of time, and the ideas which were thus given expression by Dr. Winternitz have spread widely—even back to Johns Hopkins and to this World Conference.

Recent Developments

Important history is often being made in our midst, passing largely unrecognized, and this is notably true of the British schools at the present time. In this country the cause of medical education has been notably advanced, not only for British schools but for those of the world at large, by a series of important Government-sponsored studies and reports—those little-read documents that so often represent the best thinking of their time.

Among the earliest was Mr. Henry Warburton's celebrated "Report from the Select Committee on Medical Education," in four volumes, prepared and printed by order of the House of Commons in 1834, in which the views on medical education of many men of British medicine of that period were sought and duly recorded. Thus Henry Holland, who had been Physician to Queen Caroline, stressed his conviction that the Royal College of Physicians should maintain a close affiliation with the English universities. He says, "I conceive that this affiliation has tended to place the profession in England, in relation to general society, higher than in any part of the continent of Europe" (vol. 1, p. 193). Holland thus gave voice to the importance of a university education in medicine. The testimony throughout the Warburton report is of challenging interest because it so frequently gives the *confessio fidei* of some of the most eminent medical leaders of the time—source material, incidentally, of the greatest value from the standpoint of biography. Thus Sir Astley Cooper gave 22 pages of testimony, in which he outlines his view of the ideal educational programme for a surgeon; he spoke with great candour on existing shortcomings, and urged that a year on the Continent should be a *sine qua non* of the training of every young British surgeon.

Of like significance was the Earl of Selborne's Commission of 1889 on the "Advancement of higher education in London," in which men such as Joseph Lister, Richard Quain, Norman Moore, James Paget, and many other prominent London physicians gave their views. In passing it is interesting to note that Lister, after relating at some length many of his own experiences as a student, insisted that he was better able to examine his own students than an examiner from the outside, although an outside examiner was always appointed to sit with him; Lister, however, served as the chief examiner.

Sir George Newman's two reports of 1918 and 1923 have already become classics in the historical literature of medical education, for no one in recent years has described the great issues with broader vision and perspective, and I here refer especially to the section of his first report entitled "A

University Education in Medicine," in which he wrote eloquently upon the theme that a medical school without university affiliation ceases to be a medical school in the modern sense.

Within the past decade there have been two other highly significant reports emanating from British sources: that of Sir William Goodenough's "Interdepartmental Committee on Medical Schools," which appeared in 1944, and the five-year report on "University Development" of the University Grants Committee (covering the years 1947 to 1952), which appeared a few weeks ago. The Goodenough Committee had proposed a vast reform and reorganization of medical education in the British schools, involving increased annual expenditures of more than £2,000,000. Perhaps the most remarkable feature of the report was its insistence upon the establishment of full-time clinical chairs of the Hopkins type for all the major departments, with provision for university stipends of such amounts that it would be unnecessary for the holders to supplement them from outside earnings. It also proposed that a suitable number of full-time readers and lecturers be appointed in these departments, with the expectation that it would be from among these lesser full-time posts that the professors of the future would be recruited.

Nearly ten years have now passed since the Goodenough Committee made its sweeping recommendations, and it is heartening to record that in that interval 55 new full-time chairs in clinical subjects have been created in the recognized medical schools of Great Britain, a fact mentioned with justifiable pride by the University Grants Committee. This committee also records progress in other directions in line with the Goodenough recommendations—for example, the strengthening of postgraduate medical education through creation of the British Postgraduate Medical Federation, and the making of clinical material available for teaching purposes in the non-teaching hospitals (Trueman, 1953).

In my opinion, there are two areas which should receive further attention in the immediate future, not only here but in North America, Scandinavia, and, indeed, wherever medicine is taught: first is the problem of the liberalization and lightening of the entire medical curriculum, the elimination of outmoded and unused areas of instruction, with the ultimate end in view of shortening the curriculum so that an able man may, with adequate training, go into practice and become financially independent and scientifically productive in a period of less than the eight or ten years now regarded as essential. Not long ago a well-known dean with many forward-looking ideas, feeling frustrated after a meeting of his reactionary faculty, exclaimed: "It is easier to move a cemetery than to change the curriculum." It is not for me, an historian, to suggest ways of improving the curriculum, but it will be my duty at some later date to record what the members of this Conference have achieved.

The second phase of medical education which urgently requires the consideration of this World Conference is mentioned only in passing by the University Grants Report—namely, the creation of halls of residence and common-rooms, where students of all faculties, including those of medicine, can come together, for there is no more stultifying tendency among young physicians than to be sufficient unto themselves, and thus to lose contact with the broader humanistic interests that make fully educated men and women. As Sir George Newman contended, this can be realized only in the university atmosphere, and I look upon it as one of the solid achievements of the past ten years that now all medical schools in this country are affiliated with the broadening atmosphere of the university community. This would have been especially gratifying to the late Sir Clifford Allbutt, who wrote in 1906: "It appears that the function of university education is not special instruction in the lines of a profession or trade, however these ends may substantively be promoted, but in expanding and enlarging the mind and making it a more and more perfect instrument of knowledge and progress, whatsoever its destination."

MEDICINE—A TECHNOLOGY OR A PROFESSION*

BY

Lieutenant-Colonel S. M. K. MALLICK, M.D.
F.R.C.P., D.P.H.

Dean, Dow Medical College, Karachi, Pakistan

I am gratefully conscious of the signal honour done to me and to my country by the Programme Committee in extending an invitation to me to speak on "Medicine—A Technology or a Profession" at the First World Conference on Medical Education, in its inaugural session. I should like to take this opportunity of conveying to this Conference a message of good will and friendship from the people of Pakistan in general and medical educationists in particular.

The status of medicine as a profession is not only extremely well founded but is a matter of universal acceptance. To those who are not perhaps conversant with modern trends the theme of my talk and the priority accorded to it in such a high-level Conference might appear paradoxical. Keeping in view, however, the changing times, the propensities of the people, the rapid diversification of the profession, and the tendency amongst the politicians and administrators, who have relegated to themselves the responsibility for planning health relief and who are graciously inclined to place us in a class of highly trained technologists and regard

*An address given in the plenary session of the First World Conference on Medical Education on August 24.

our education as purely vocational, no time will be lost in taking stock of the situation and making readjustments, wherever indicated, so as to safeguard the noble heritage of medicine in the precincts as conceived and elaborated by generations of savants and of practitioners of the healing art.

Literally speaking, "profession," according to the Oxford English Dictionary, implies an occupation in which one professes to be skilled and which one adopts as a means of living; it is a specialized knowledge pertaining to an art or a science, being applied to the affairs of others on a basis of recompense. Technically, a body of persons engaged in a particular calling could be said to be occupied in that profession. Thus defined, engineers, teachers, smiths, carpenters, cobblers, etc., could all be designated as professionalists. In practice, however, these vocations are named crafts or technical callings, and not professions. Only three vocations have, however, been granted that status—namely, Divinity, Law, and Medicine. Are there any reasons to restrict the word "profession" to these vocations only? I think there were, and still are, good reasons for doing so, as we shall see hereafter.

Technology may be defined as a systematized or scientific study of the practical or industrial arts, while medicine is a specialized knowledge, and its practice is concerned with the cure, alleviation, and prevention of disease in human beings and with the restoration, preservation, and, lately, with the advancement of health—that is, improvement of future generations of man.

Aspects of the Problem

Naturally the relationship between the practitioners of medicine and the other sections of society is the problem under consideration rather than the intrinsic nature of medicine itself, although the latter cannot be ignored altogether, for the basic nature of the subject has a determinative effect on this relationship.

Science means learning or knowledge. Medicine is not a science in the sense that it is a compendium of factual knowledge about health and disease. The matter is far more comprehensive. It is a systematized knowledge of the human body in health and disease, but it also takes into account the environment and conditions under which man lives. This is only one aspect of the problem; the other is the sociological side of medicine, which is so intricate, so vast and comprehensive, that it actually embraces almost every sphere of human activity.

The vast and imposing structure of modern medicine is perhaps one of the greatest triumphs of the human mind. To comprehend its development, both scientifically and sociologically, the evolutionary history of modern trends should prove useful, inasmuch as it will enable us to appreciate the steady and methodical progress of medicine as an ideology. It must also be appreciated that the evolution of a point of view has always been through a succession of transitions; the ideas of to-day are merely precursors of those of to-morrow. Fundamental ideas undergo a gradual maturation, until we arrive at natural laws. It must be stressed, however, that even these natural laws are not incontrovertible truths. "If a scientific man has not learnt heresy he has learnt nothing," was said by Mian Afzal Husain¹ in his presidential address in the first Science Conference held at Karachi in 1949.

The close and intimate relationship between the advancement of medicine and the advancement of

human civilization needs no comment. All phases of human activity—progress and setbacks, poverty and wealth, trade and crafts, arts and literature, poetry and philosophy, laws and social customs, economic strifes and wars—have been interlinked with the healing art, whether it was in the guise of magical rites or in the garb of religious practices, astronomical juggleries, or supplications to natural phenomena, Hippocratic rationalism or monkish or Brahminical dogmatism, speculative philosophies or scientific discoveries. Psychological maladjustment, major or minor, fixed or ephemeral, obvious or dubious, almost universally affects the human race. Has the world known a higher suggestive agent than medicine for such affections?

Nations have risen and fallen, wars and revolutions have come and gone, civilizations have appeared, matured, decayed, and died; but that noblest expression of human aspirations to deliver men from physical and moral disabilities has maintained its unity of purpose throughout the ages. While fully appreciating the fact that the medicine of to-day is very much different from the medicine of yesterday, it has divided and subdivided into innumerable subsections, each subsection being a colossal thing in itself; but, even as such, each is served by an arterial stem, which, like the human body, draws its nutriment and force from the heart; in the case of medicine this heart being humanitarian considerations, self-effacement, and sacrifice. Such a conception is included in the word "profession." If medicine becomes a technology then it is a machinery, a power without a soul, its sinews being steam and iron, not blood and heart. With this brief introduction let us delve into the wisdoms of the bygone ages and see if we can find something there for our guidance.

Early Needs of Man

Let us for a moment consider the earliest settlement of man on earth, of which naturally there are no records. After human beings had firmly established themselves on the earth as a separate and distinct species, their immediate and urgent requirements would have been food and water. They would have tended to group together, community life offering better chances of survival. As suitable places became available the nomadic life would have gradually tended to take the shape of small settlements. The need for succour in inexplicable afflictions created deities; the need for succour in injuries and illness produced medical men; and need for settlement of disputes established rules of conduct—i.e., law. This, then, was the beginning of the three professions, Divinity, Medicine, and Law.

We are now in a position to study the latter phases of the development of human society, of which meagre records are available. It should be remembered, however, that there has been a lapse of untold centuries between the two epochs.

The word religion here has been used in a collective sense. In ancient times the gods, the demons, magics, astrology, supernatural and subtle forces, good and evil spirits, were all jumbled together, worshipped and invoked whenever a calamity, drought, disease, death, or any other misfortune confronted men. Gradually a group of people took to the art of communicating with the subtle beings and warding off their baneful influences. They were the wise ones—namely, the religious-cum-medical men. To practise their art these people must have needed authority. It was necessary to inspire awe and respect into their charges. To that end they had to adopt peculiar costumes and imposing practices. The life of early settlers on earth was thus enveloped in mysticism and blind faith. But it must not be assumed that it was all valueless jugglery. Unmask the witch doctor and you will find a really intelligent and

clever physician. His methods may be empirical, but enveloped and deeply hidden in his symbolical and mystic practices you will find a kernel, a sizeable kernel of truth, gleaned and nurtured by generations of wise observation and experience. Merger of medicine and religion was inevitable. Medicine aetiologically involved knowledge of malignant and beneficial forces. Treatment, besides exhibition of pills and potions and dressing of wounds, entailed propitiation of those forces. The major portion of religion was propitiation, through ritual incantations and sacrifices. The two practices were so much akin in their objective—the warding off of evil—that their amalgamation was a foregone conclusion. The result was that medicine began to lose contact with the forests and the fields, and along with religion began to enter sanctuaries, and for centuries to come these constituted its abode and its nursery.

So far we have been discussing the probable course of the development of medicine and its practice in prehistoric times. The earliest records of civilization that flourished are to be found around the valley of the Tigris and the Euphrates; the Nile; along the shore of the Mediterranean; the valleys of the Indus and the Ganges; and the Yang-tse-kiang and Hoangho, in China.

Religion and Medicine

The earliest civilizations about which records exist are the Sumerian, the Akkadian, and the Babylonian, the Egyptian, the Greek, the Persian, the Indian, the Chinese, and the Arabic. In this context the impacts of the great religions on medicine have also to be borne in mind. At the height of the Babylonian civilization, medicine definitely began to take a scientific turn, and a dissociation between religion and medicine was largely effected. Egyptians were the first to lay the foundations of socialistic medicine. Laws were extant which covered every aspect of Egyptian life from birth to death, diet, dwellings, sex—in fact, nothing was left out. Just as for other sections of society, the status as well as the practice of medicine was well defined by regulations. As physicians their technical talent was held in high esteem, not only in Egypt but also in the neighbouring countries. Homer² in his *Odyssey* terms them as men "with knowledge beyond all men." Specialization in various branches of medicine was placed on a firm footing. Medical men were paid by the State or the community; private practice was not allowed. Hospitals and sanatoria were annexed to temples but were administered separately. The formulation of laws of public health and their practice were functions of the medical man.

The next era which has an important bearing on the subject under deliberation is the dawn of great religions in Mesopotamia. The new religion did not aim at a federation of the extant deities, in place of that it advocated a single God, conceived in perfection and endowed with supreme power, exercising his authority through his apostles, over the creation below. The system had many advantages, but it had disadvantages also. The advantages were mostly social. It led to a levelling up of society. The world and its good things ceased to be a monopoly of the selected few, particularly when these few had become so vainglorious and self-centred that common folk counted worse than flies. The disadvantage was that it led to the virtual death of the scientific attitude to life. Over hill and dale, in solitude and in company during night and day, people hankered after the truth. Metaphysics became the order of the day.

To the hand of the diver
The gains of the tide,
To the eyes of the bridegroom
The face of his bride,
To the heart of the dreamer
The dreams of his youth,
For me, O my Master,
The rapture of Truth.—SAROJINI NAIDU³

Even whatever progress had been made by the Babylonians, Assyrians, and the Egyptians was destroyed deliberately, and, so far as they could manage, completely—of

course with the proverbial best of intentions. The Jewish medicine was theurgic in nature, God being the source of health as well as disease. The concept of life was teleologic. In spite of the dominance of priesthood the ancient empirical medicine, however, continued to thrive.

Indian Medicine

In ancient India medicine constituted a part of religion. *Sushruta Samhita*⁴ is the most representative book of Ayur Veda, or Hindu Medicine. A study of this work unmistakably reveals the high premium that was placed on the selection of students for entry into the precincts of this sacred knowledge. Ethical standards, laid down both for the teacher and for the taught, constitute gratifying reading. Only a brief presentation of the initiation of a student to the study of medicine can be given here.

Samhita lays down special qualifications for taking up a medical career. It says, "He should be of tender years, born of a good family, possessed of a desire to learn, self-strength, energy of action, contentment, character, self-control, a good retentive memory, intellect, courage, purity of mind and body, and a simple and clear comprehension. . . ."

It lays down rigid ethical standards both for the teacher and for the student. The preceptor addresses the student at the time of the initiation in the following words:

"Thou shalt renounce lust, anger, greed, ignorance, vanity, egoistic feelings, envy, harshness, niggardliness, falsehood, idleness, may all acts that soil the good name of a man. . . . If I, on the other hand, treat thee unjustly even with thy perfect obedience and in full conformity to the terms agreed upon, may I incur equal sin with thee, and may all my knowledge prove futile, and never have any scope of work or display. . . ."

Having read this it hardly leaves any room for comment on the expectations of society from a medical man and of the status of the medical profession in ancient India. Medical man was accorded the status of Devtas, or God-like man.

Greek Medicine

Now we come to a period and a country whose medical development has left a lasting effect on the medical concepts and medical practice of the world. I refer to Greek medicine. In the early Hellenic medicine we still find the priest clinging on to medicine. As time passes, medical development gradually but with certainty takes a scientific turn. There are some new developments also—a philosophy, a system of deductive logic and speculative reflections to explain away natural phenomena associated with medicine. All the practices of ancient medicine prior to this period were purposeful and practical in nature—that is, were designed to get rid of or ward off impending evils. No heed was given to the basic phenomena, particularly in relation to cause and effect. A study of the relationship between the microcosm and the cosmos led to a rich and colourful speculative philosophy. The requisites of scientific development are freedom of thought and freedom of action. In ancient Greece religion was there, but it had not taken the shape of shackles and taboos; political ambition and motivation had not yet learnt to utilize religion or medicine as a means to their ends. Criticism and contradictions of well-established and current notions were tolerated. Human thought and activity were not directed and confined to narrow impervious channels, which later the great religions contrived to inflict on the freedom of human thought, any deviation from which surely and unerringly led to inquisitions and the scaffold. In the days of Homer, medicine had established itself as a noble art. A physician, in the words of the great poet, was "a man who was worth more than many others."⁵

With regard to ethical standards, the Hippocratic Oath cannot only stand repetitions but, in the interests of ethical standards of our own times, its enunciation from time to time should act as a sort of "lest we forget." I feel it will do the profession immense good if it is included in the

curriculum of medical studies. Hippocrates (460–355 B.C.) taught that a physician should be modest and dignified. He should be serene and tranquil. His judgments should be based on knowledge and not on superstitions. A physician's religion was his loyalty to the interests of his patients and his faith, search for truth pertaining to disease. Medicine for the sake of medicine without any magical alloys and religious amalgams, divorced from dogmas and based on observation with a philosophic outlook, and meant for the service of afflicted humanity, as an end in itself, without reference to conceptions of divine intervention, should constitute an article of faith for a physician.

Thus we find the cult of medicine based on foundations as firm as the rocks. Priestly medicine did not die out, and shall survive so long as superstition and weakness balk the spheres of human activity. Hippocrates and his school, however, succeeded in fairly establishing an art which could and did exist as an honourable and revered profession without religious or magical embellishments.

Contribution of Rome

The next great civilization, that of the Romans, although it produced little new, did contribute immensely in another direction—namely, consolidation of the gains made so far.

A perfect system of hygienic legislation was established. The medical profession was accorded a definite status recognized by the law. Physicians constituted an esteemed class; they were recipients of the highest State dignities and held socio-political and administrative posts of a high order. Medical schools were granted official recognition. It was during the Roman Empire that legal medicine came into being.

At this time an event transpired which brought about an upheaval involving almost a major portion of the known world. I refer to the advent of Christianity. For the faithful, Jesus Christ was the physician for both the body and the soul. Medicine thus again became theurgic. The saints or the holy relics began to attract pilgrims, mostly sick people in large numbers. To house and look after them special buildings called Hospitalia were allocated.⁶ Priesthood had succeeded in establishing itself in a very dominating position. This dominance was not confined to the Christian world alone. Usurpation of authority was a universal trait with the priesthood. This state of affairs could not last for ever. There were protests against it in Europe as well as in Asia.

A reorientation of the social structure took the shape of Islam in Asia. According to the Islamic faith, Mohammed was the last of a chain of prophets through whom God had been conveying his messages to the creation below. Islam definitely and clearly discouraged the formation of priestly castes. "There is going to be no monasticism in Islam," declared Mohammed. Thus at one stroke the age-old grip of the priesthood on medicine came to an end. This in my opinion constitutes the greatest contribution of the Arabist period to the development of the medical profession. Ethical standards were raised; registration and conferment of degrees after education in colleges were started. Hygienic measures of a far-reaching nature, regulating the entire life of the people, were introduced and enforced. During the Renaissance and the post-Renaissance period, and even today, the practice of medicine is practically a true copy of the traditions set up by the Arabs. With regard to ethical standards, two examples from the Arabist period should clarify the position. Bu Ali Sina (Avicenna, 980–1037) in his autobiography writes: "At first I treated patients not for fees but for my own instruction. During this period of my studies I never passed the whole night in sleep, nor passed a whole day in any occupation but study. Whenever I met an obscure point, it was my custom to perform a total ablation and then proceed to a mosque, where I prayed to God to grant me comprehension and unlock for me the gates of difficulty." When Hunayn Ibn Ishaq (Johanitus Onan, 807–877) refused to oblige Caliph Al-Mutawakkil by concocting a poisonous draught to free him of one of

his enemies, the physician was interrogated to find out what enabled a humble physician to disdain alike the pleasure and the wrath of the caliph. Hunayn replied, "It is my religion and my profession."

Contributions of the Profession to Society

On the corner-stone of Hoff Hall⁷ of the Medical Field Service School, U.S.A., the words of Jeremy Taylor (1613-67) are engraved: "To preserve a man alive in midst of chances and hostilities is as great a miracle as creation." In the day-to-day life of a medical man there is a definite and continuously operating humanitarian bias. This attitude towards others stands out in marked contrast with some vocations that are organized round utter selfishness and self-aggrandizement. In other walks of life there undeniably have been men and women who have made sacrifices, but such instances have been purely individualistic. In medicine this phenomenon pervades the entire profession. Mostly this characteristic has manifested itself in person-to-person relationship, but in some cases, by nature imbued with a sense of fellow-feeling which vibrates violently and incessantly with every twang of pain in others, it has assumed the shape of social reforms.

Medical men naturally were the first to become cognizant of the social, cultural, and environmental factors responsible for disease. How much the industrial revolution, reforms for the elimination of overcrowding and slums, improvement of factory conditions, drainage and town planning, maternity and child welfare schemes, pure water supplies, control of food and drugs, prevention and control of preventable diseases, owe to the efforts of the medical profession needs no recapitulation. In their selfless endeavours and self-effacing sacrifice for an ideal against heavy odds, who can say they have not shared equal honours with the great apostles? Reduction in various mortality rates and control of epidemics have deeply affected the world both psychologically and economically. Anxiety neuroses and community hysteria associated with epidemics are now matters of historical importance only. Constructive creative work and long-range planning necessitate tranquillity of mind. If organized efforts of the medical profession have succeeded in controlling and in certain cases eliminating epidemic manifestations of disease, the world should look upon them with appreciative gratitude. It should also be mentioned that the basic sciences owe their development to a considerable extent to medical men. Thus Copernicus (1473-1543), Galileo (1564-1642), Gilbert (1544-1603), Galvani (1737-98), and Geber (Sufi Jabir Bin Hayyan, middle of seventh century) were all medical men. Professor Huxley (1825-95) had remarked in 1854: "Medicine was the foster mother of Chemistry." In my humble opinion if one substituted basic sciences for Chemistry it would represent the situation more correctly.

Development of Medical Education

Two outstanding features mark the trends of medical education in ancient times: (1) the critical selection of new entrants to the profession; and (2) the close and intimate relationship between teacher and taught. The pupils lived more or less as members of the family of the preceptor. Not only were they thus provided with ample opportunities for picking up the technical side of the profession, but imperceptibly and with certainty they became conversant with the manners and the morality of the profession also. It is not possible to reproduce atmospheric isobars in intellectual fields, but reasonably good replicas of the great masters were often turned out. The prevalent systems of government definitely influenced the progress of the profession. There was the omnipotent king. It was he who appointed or dismissed the ministers and the administrators; the latter were therefore responsible to him and not to the people. Their weal and well-being were linked with the courts. Courtship of the people therefore did not interest him. As time went on settlements took the shape of kingdoms and kingdoms expanded into empires. The ancient system could no longer cope with the needs of the times.

The Romans were the first to provide institutional treatment for the sick. Their hospitals they called "valetudinaria."⁸ Automatically these institutions also became the centres of medical education. Medical men could now be turned out in larger numbers, but at the same time the selection of the proper type of student and the individual attention of the preceptor had to be relaxed. There were physicians, surgeons, and pharmacists attached to these hospitals; students had to go to all of them. In the Arabist period "bemaristins," and later in Christian Europe hospitals, were established. During the Renaissance in Europe medical practice and education followed exactly the pattern established by the Arabs at Bagdad and Andalusia (Spain). Medical education thus practically became impersonal.

There was a gradual, imperceptible, but sure change in power politics also. Power began to pass more and more from the kings to the people. The politicians and the administrators began to feel the need for courtship of the people. From the press and the pulpit, propaganda for more and more doctors and greater and greater specialization was made. These downward trends were further precipitated by the advent of the two major wars, after a brief spell of peace in between. The last war has been followed by a cold war between two ideologies dividing the world into two potential war camps armed with the atom bomb and the hydrogen bomb.

This state of affairs is giving impetus to a greater and greater production of doctors, and particularly to the mass production of specialists. The absence of sustained emphasis on the classical background of the profession during their undergraduate training has materially altered the outlook of medical students. They have begun to regard their medical education as vocational training, and the impression gathered by the general public seems to be of the same order. For specialization the highest type of general medical education should be the first prerequisite. This should be followed by protracted practice as general physicians or general surgeons over many years. Our mighty rivers, which with the majesty of their flow, the enormity of their expanse, and the dignity of their depth inspire awe in the spectators and infuse life in our lands, were but tiny rivulets to start with. While coursing through hill and dale they annexed a tributary here and a pool there until they assumed the status of great streams. No pumping system that human ingenuity or diligence is capable of inventing could create such phenomena. Specialists should be allowed to develop in the same way. Hippocrates, Galen (129-200), Avicenna, Rhazes, Sushrta, Vesalius (1514-64), Koch (1843-1910), Virchow (1821-1922), Sydenham (1624-72), J. Bright (1789-1858), Jenner (1749-1823), were not rushed through any special courses after obtaining their general medical qualifications. It was their lifelong study and sustained endeavour that brought their specialties to them, and it is this type of specialization that can do, and has done, lasting good to the world and brought honour to the profession. Mass production of immature specialists can have but one ending—conversion of the profession into a technology. To accord the status of a cardiologist, a urologist, and so forth to a freshly qualified postgraduate would be courting disaster. A half-baked specialist is as bad as a half-baked potato—one upsets a poor digestion, the other sets up a poor profession. Socialization of medicine is another step which is leading the profession in the same direction.

There is, however, a question to be answered. Why are our young men heading headlong towards specialization? The answer is very simple. It brings them status as well as money. If we stop this specialization, what are we offering them in exchange? Ethics, morality, and so forth alone cannot cut much ice. A medical man, whatever we might designate him, must have a sound income to enable him to maintain a respectable status and a comfortable standard of living. Neither the official services nor general practice are conducive to high profits or high status. There is nothing intrinsically wrong with the present generation. Society,

administrative machinery, and even ourselves have created conditions by which they can move only in one direction—mass specialization, which is alike detrimental to society as well as to the profession.

After the Renaissance in Europe phenomenal progress in medicine was a direct result of advances in basic sciences. At the present time attention is being paid more and more to a still closer association between medicine and the basic sciences. This infiltration of the medical profession leads to further maturity and appreciation of the width of the foundation on which the edifice of medical research rests. No doubt it is a move in the right direction, and it has certainly heralded great discoveries, but unfortunately, directly or indirectly, it again lays stress on technology. It is not my intention to decry the latter, but this concentrated attention on technique to the exclusion of a stress on discipline is bound to have a harmful effect on the professional concepts in the minds both of society and of the young undergraduates.

It is this aspect of the question which is drawing the attention of more and more educationists to-day. Medical education constitutes a university discipline and not vocational training. That position it has occupied for centuries. With the advancement in other sciences there has not only been enormous expansion in the parent subject but a great many newer branches have sprouted and established themselves in an apparent independent existence. As these sub-branches gain momentum they become more and more technical and highly involved. Ultimately there is a danger that these specialized studies may swamp the basic general education that a university discipline is calculated to impart. Any system which aims at preparing the undergraduate in a subject or group of subjects must have a relevance to life in general. The essential aim of technological training is to impart existing knowledge of a particular subject. It is concerned with the future so far as existing knowledge can be applied to particular situations which for the time being cannot be foreseen. All education, therefore, has its basis in technology. Education, in the higher sense of the development of the power to form judgments, becomes possible only after such techniques have been mastered. Technical knowledge is therefore an indispensable foundation for higher education.

University education as it pertains to medicine has three objectives—learning the technique, learning the art of applying this technique, and learning to give priority to the interests of others. In medical practice the last two constitute the dominant aspects. Such concepts have no place in a technical calling.

Dangerous Trends

In spite of having gathered so much glory around it the medical profession was never in so much danger as to-day. There are several reasons, internal as well as external. Among the internal causes the foremost, paradoxical though it may seem, is the great development in techniques and diversification of medicine into innumerable channels. This has resulted in the formation of cults within cults. This aspect has already been dealt with, but its importance, I feel, justifies a reiteration in some detail. Our undergraduates are becoming more and more vocational in outlook. Under the stress of time and of market demands we have also initiated mass production of medical specialists. If the profession does not make strenuous efforts to formulate a coherent policy by which the younger shoots continue to derive their sap and stamina from the roots and the stem of the parent tree till they are mature enough to maintain an independent existence they may drift away into discord and disaster. Engrossed and enamoured with the study of the individual trees, the concept of the forest is being lost.

As stated above, this overemphasis on technique is adversely affecting the concept of the profession. Consideration of the patient as an individual with a peculiar environment and a particular psychic background is largely ignored. The stethoscope, the x ray, and the electrocardiogram have

come so much into the limelight that the poor patient whose coronary artery or valve is the subject of this instrumentation is lost in the shadows of the umbras and the penumbras. The position of the medical man is above that of a slave of the instruments, and the patient deserves greater consideration than that given to a laboratory analytical specimen. No, he is not just a case. In his social set-up he occupies an important and a complicated position. His illness or death has a bearing on the lives of scores of others, epidemiologically as well as sociologically. The adage that we are treating a human being with a disease and not a disease should never be lost sight of.

The same is true of the specialties. They are not selective. Students pick a specialty rather from expediency and by chance than from their natural inclination. The defect is in our system of education. We allow specialization before a young man has sufficient maturity to decide anything for himself intelligently. This hit-and-run of random specialization without experience as a general practitioner cannot help a medical man properly to decide what his specialty is going to be. Let first things come first. Development of individuality must have precedence over specialization. We must refrain from putting the cart before the horse. Deciding factors naturally are the requirements of the country and its resources. In most underdeveloped countries the crying need is the control of preventable disease. The economic resources of these countries are generally inadequate even partially to cover this fundamental need. Even rich and advanced countries are uncomfortably conscious of the financial burden associated with the maintenance of specialists and the institutions and equipment which are prerequisites for the adequate discharge of their duties.

Let us consider again this specialization in the context of a world problem. In most of the backward countries even basic medical aid is not available, leave alone specialization. More than three-quarters of the world consists of such less fortunate countries. In view of the larger interests of the world, therefore, the maintenance and the revival of the concept of "profession" and what it stands for are of vital importance. There is no other solution. The politician is never slow to turn situations to his own advantage: power is like intoxication, the more you have the more you want to have. The administrator also appreciates that the situation is shaping into a position which can be of considerable advantage to him. That the profession of medicine to-day is a dead letter and a slogan, and a medical man merely a high-class technician, suits both the politician and the administrator. We as medical men have a different background, different traditions, and a different outlook on life. The generality of people are incapable of appreciating collective good. They do not know the difference between the amenities they enjoy to-day and the conditions that prevailed say a century back. A gulf is being created between us and the public which is being widened by interested parties. It is our duty to bridge this gulf. We do not need help from the State or from any other source to accomplish it. It is a domestic affair, and we should be capable of managing it ourselves in spite of every obstacle that is placed in our way. It is neither possible nor proper to offer any detailed proposals on the subject here. I feel that the solution lies in the revival of the general physician and the general surgeon on better-organized lines.

The confusion is worse confounded by ignorance, natural or wilful, on the part of the politicians and administrators who have assumed responsibility for medical programmes, by complacency and a tendency to drift with the stream on the part of the medical educationists, and by the exigencies of the times, which have allowed little opportunity for us to probe into the problem to the depth the situation called for. Instead of facing the situation squarely we have started playing to the gallery. Technology and profession are closely linked with indissoluble links, and yet they are not one and the same thing. Technology is the foundation on which the edifice of the profession has been built. It has its birth in the laboratory, and provides us with concrete, exact, dry

facts. A patient brings a chit from the laboratory, "*Bact. coli* isolated from the urine"; another presents an electrocardiogram. If one were to go over hundreds of such patients no two would present exactly similar systems. The machinery has done its work; it requires a mind to interpret and correlate the facts presented by the laboratory. Profession begins where technology ends. Technology is but an adjunct to profession. Profession existed when there was no technology. Without profession, technology is a sterile endeavour. What use is even a jet plane without a pilot?

Let us leave aside for a while acts of omission and commission by others. Some heart-searching is indicated at home also. How far have we ourselves contributed to the prevalent notions? The crux, the backbone, of an ideology is a study of its history, inculcation of its ethics, and an appreciation of the duties it ordains and the privileges it confers. In our zeal for mass production and in our zest for specialization we have ignored this fundamental formative aspect of the profession. Medical men that we have turned out during the last few decades have no such background. Society judges things by their face value. The word "leader" is becoming a misnomer. Leaders of to-day do not lead, they are led by the people. To their "aye" they say "aye," and to their "nay" they shout "nay." If public opinion fits in with their scheme of things also, their declamations are all the more vociferous. The jury's verdict is also not in our favour: the judges have no reason to go against the jury. We cannot preach one thing and practise another. Our bona fides has to be judged on the anvil of facts. Let us set our house in order and then invite an inspection. In the history of a profession as old as the world itself, decadence for a few generations should be of little moment. From what I have said there can be no gain-saying the fact that the profession of medicine is a profession first and last and not a mere technology, the latter being just one of the basic links in the medical set-up.

The discernment of the difference between a locomotive and the wheels of a locomotive can constitute a problem only for cortical amblyopes.

Light Ahead

I have pondered deep and long over the matter of this discourse. In my endeavour I am but following in the wake of many others who have preceded me. The goal lay high up at dizzy heights, enveloped in bewildering haze. During the last century diverse approaches to it were conceived and executed. The haze is lifting now. With the improved visibility we can now see things in their proper perspective. Our previous efforts were based on an optical illusion; we had been following a false image. The highways we have built lead away from the goal and are strewn with pitfalls and covered with unstable shingle. We have to discard them. The question of paramount importance before us is the education of the undergraduate on proper lines. The conception associated with the word "profession," its scope, its responsibilities, and its privileges should be fully brought home to him. Technical education constitutes the foundation on which the future edifice of medicine is going to rest. This aspect should also be accorded the consideration it rightfully deserves. It should, however, be consistent with and conform to the nature of duties that are going to be assigned to him after his graduation: no more and no less. It should help in making the medical education correct, concise, and yet productive of medical men of a higher order. Those who show promise should be afforded opportunities of acquiring the highest type of general education—that is, general medical or general surgical. I want to lay special emphasis on this point. Postgraduate qualifications, M.D. (Cardiology) or F.R.C.S. (E.N.T.), and so forth, should never be countenanced. After the benefit of this type of medical education the men should enter into the general practice of their art. Many years of such a practice should assist them in expressing themselves. It is not cramming with set courses which makes real specialists. Proficiency is born of pro-

pensity. For a final moulding the trusted and trained hands of accomplished specialists are essential. The time should then be ripe to place the developing specialist under their care, he being allowed an opportunity to work under a man of his own choice. When this final stage has been completed satisfactorily the new specialist could embark on an independent career. Any institutional training after this should be superfluous.

Technology has its place in medicine as a very important, I should say an indispensable, auxiliary, but I do feel it is sheer waste of time and energy to impart medical and advanced technological education as applied to medicine to one and the same person. Let me elucidate my point by a few examples. Anatomy, applied physiology, biochemistry, pharmacy, pharmacology, bacteriology, including protozoology, helminthology, entomology, histology, histopathology, radiology, electrocardiology, and so forth, can all be taught and practised as independent subjects. Technical advancement and proficiency in practice should be much greater if they could be studied as independent sciences, and not as appendages to medicine. As no lures of private practice could be attached to these technologies those practising it could do much more concentrated work. It goes without saying that these studies should be afforded post-graduate educational facilities of the highest type while remaining outside the medical profession proper, but, acting as its auxiliaries, they could be eligible for the highest honours and status open to other sciences. They could also with advantage be associated with medical education proper if, when, and where indicated.

These suggestions deserve the deepest consideration. If they are adopted the controversy, "Medicine—A Technology or a Profession," automatically comes to an end. If undergraduates could be relieved of the unnecessary burden of technique more stress could be laid on the basic aspects of medicine. Both medicine and medical technology could benefit considerably by such a dissociation. We could produce better medical men, fully alive to the fundamental concept of the profession of medicine. Chances of research and consequent advancement in technologies auxiliary to medicine could be much more enhanced. Medicine and technology could develop side by side, each aiding the other but without any chance of trespass.

Conclusion

I have discussed here at some length the historical development of the medical profession. I have shown the intrinsic difference between "profession" and "technology." I have also indicated the part medicine plays and has played in the social and economic development of the world. We have also seen the drift that medicine is taking to-day and the intrinsic and extrinsic dangers to which it is exposed. I have also broadly hinted at the task which lies ahead of medical educationists. The greater the magnitude of the task the greater the responsibility. There is, however, no room for despondency. Our forefathers weathered worse storms and with faith, honesty of purpose, and organized effort won more glory; and the prestige of the profession has been ever rising. I think—nay, I believe—we have material which can rise on any occasion. Ours is a profession built on the rock of humanitarianism, strengthened by self-effacement and self-sacrifice. We have a place of pride and honour in the community we live in. I am sure we shall live up to the traditions of our noble profession.

THE SECTIONS OF THE FIRST WORLD CONFERENCE ON MEDICAL EDUCATION

We invited the Vice-Presidents of the Conference to present brief statements on the subjects of the sections they presided over this week, and these are printed below under the headings of each of the four sections.

REQUIREMENTS FOR ENTRY INTO MEDICAL SCHOOLS

THE SELECTION OF STUDENTS

BY

VICTOR JOHNSON, M.D., Ph.D.

Mayo Foundation for Medical Education and Research,
Rochester, Minnesota, U.S.A.

No greater responsibility devolves upon medical educators than that of determining who are qualified to study medicine and who are not. I am sure that any evaluation of the results of these selective efforts by those who exercise such responsibility would be characterized by extreme modesty, if not humility. All will admit that errors in judgment have excluded from medicine some who are qualified to become physicians and have included some who should not enter medicine.

Section A of the First World Conference on Medical Education addresses itself to this problem to the end that world-wide experience may help achieve a closer approximation to the ideal goal. Certain qualifications of potential medical students are relatively easy to measure, while others are virtually impossible to determine.

It is granted that acceptable candidates must be intelligent and that we can measure that intelligence with a degree of accuracy by various testing devices, examinations, and the academic performance of the applicant. But how may we be satisfied that a candidate couples emotional stability with his intelligence? I believe it remains to be demonstrated that brilliance is more likely than mediocrity to be associated with emotional instability. Yet we have all seen too many examples of intellectually able medical students whose lack of stability unfits them to be medical students and physicians of a high order. May we eventually be able to determine emotional stability as effectively as we can determine intelligence?

Motivation

Again, let us suppose our candidate possesses the aptitude for science and medicine. Although aptitude tests may be less reliable than those of intelligence, we can probably arrive at a reasonable approximation to the truth by appropriate means. But is the aptitude joined with proper motivation? Is our student possessed of a drive toward medicine that cannot be denied? Has he a single-minded devotion to his work as a student, a house officer, and a physician so that the many denials to himself are fully compensated by the gratifications of his chosen tasks? The arduous job of studying medicine leaves no room for less than wholehearted effort.

A misdirected apparent orientation towards medicine, of which the student himself may be unaware, may stubbornly defy detection. I do not refer to the simple case of the intelligent, apt candidate who says, "My father always wanted me to study medicine, but I do not." His case is easy. Also, he is rare. More common is the misfit student who fully believes he is properly motivated. He says, "My father always wanted me to study medicine, and I also have always desired it." The parent may have exerted no obvious direct influence, but in numberless unplanned indirects pointed the son's career toward medicine. How to detect real from fancied strong motivation is a challenge. Often the

defect manifests itself only by a failure to master the work of the medical school, following painful efforts to succeed.

The coupling of intelligence with emotional stability, and of aptitude with motivation, requires further sound character and lofty ideals, objectivity tempered with warm kindness, and industry born of devotion to work. Perhaps these attributes may never be measurable. Yet we must never cease trying.

It would be well if we could estimate these desiderata of a medical student and physician even before he has completed his premedical studies, but not, in my opinion, for the reason commonly given. We are told that a very early knowledge of a student's qualifications for the later study of medicine might save him future disappointment, and also prevent him from "wasting time" in premedical studies instead of pursuing another line of education. I agree with the desirability of avoiding disappointment, but I have little sympathy with the "wasted time" concept, unless education for life is wasted time for the would-be physician.

The kind of education which best prepares a student for medical school also prepares him well for other pursuits. In such general education I would include natural science prominently. To-day it is fashionable, at least in the United States, for advisers of potential medical students to say, "Premedical students should not take too many science studies; they should acquire a good general education," as if education in natural science were of a lower order culturally than is education in the humanities or social sciences. Such educational advisers of to-day are akin to certain of the humanists of the past, who dismissed, without ceremony, science as a factor in general education. Thomas Huxley (1899) called them "Levites in charge of the ark of culture and monopolists of liberal education." He decried the accepted reference to the Renaissance as the "Revival of Letters," saying "... as if the influences then brought to bear upon the mind of Western Europe had been wholly exhausted in the field of literature. I think it is commonly forgotten that the revival of science ... was not less momentous."

Perhaps a legitimate reason why a student should not devote too much time to science in his preparatory studies is that by limiting the time he devotes to the humanities he may never appreciate that the humanities have no more proprietary claim than does science upon the dramatic, the imaginative, the beautiful. No epic poem displays a majestic sweep excelling that of Darwin's evolutionary history. The balance and perfection of composition of a painting are equally apparent in what Walter Cannon called "The Wisdom of the Body."

The burden of my thought is that we regard science, and teach science to prospective physicians, without apology for its utilitarianism, and as an indispensable ingredient of human culture.

Conclusion

Let us venture the hope that this conference may contribute some measure of advance towards a better selection of those most qualified to become physicians, who possess not only intelligence but emotional stability, not only aptitude but motivation, not only industry but warmth and kindness. Let us further hope that we may make some progress toward an improved preliminary training of future physicians; an education which includes the humanities and the social sciences, and also gives prominence to the natural sciences, not merely as pragmatic tools, but as an indispensable ingredient of the cultural development of a physician, a lawyer, a clergyman, or any other productive citizen of the modern world.

AIMS AND CONTENT OF THE MEDICAL CURRICULUM

UNDERGRADUATE MEDICAL EDUCATION

BY

Sir ARCOT MUDALIAR, M.D., LL.D., D.Sc.
F.R.C.O.G.

Vice-Chancellor, University of Madras

It is significant of the times that a symposium on undergraduate medical education should have been sponsored by the World Medical Association with the active co-operation of the World Health Organization and other international associations. Since the World Health Organization started work on an international scale in the field of prevention and cure of disease, it has become increasingly clear that the personnel of the medical profession must possess a minimum basic qualification if they are to participate effectively in the furtherance of programmes in the different countries concerned. In its preamble the World Health Organization's concept of health has been clearly defined as "a state of complete physical, mental, and social well-being and not merely the absence of disease or infirmity." This implies a wider concept of undergraduate medical education than that which was accepted 30 or 40 years ago.

The objectives of medical education have undergone significant changes during this period and the duties and responsibilities of the basic doctor have widened and increased. His concern is no longer the cure of the individual patient entrusted to his care. The preventive aspects of disease have long been emphasized, and it has been suggested that during the whole period of his clinical studies the student's attention should be directed to the role of preventive medicine in the promotion of health. It must, however, be admitted that in many schools little or no real progress has been made, because to learn the fundamentals of preventive medicine one should go to the field, to the very source where the problems are being tackled. They cannot be learnt by didactic lectures or through references made during clinical demonstrations.

Medicine and Society

In recent years it has been realized that another aspect of medicine deserves increasing attention—the study of social pathology in relation to the causation and incidence of diseases and their prevention. Public health has been largely concerned with communicable diseases—their causes, distribution, and prevention; while social medicine is concerned with all prevalent diseases which have their epidemiologies and their correlations with social and occupational conditions, and should ultimately be regarded as to a greater or less degree preventable. Social medicine is thus concerned with the pathology of families, groups, societies, or larger populations. The medical student has therefore to be familiarized not only with the pathology of the diseased condition in the patient but with those more important conditions in the home, family, and community whose prejudicial effects may have been the causal factors of the disease and may unfavourably influence smooth convalescence and recovery, if they do not actually promote its recurrence.

Clinical and Preclinical Studies

In will therefore be seen that during the past half-century there has been a changing concept of the relation of medicine to society. It must necessarily follow that this change of concept should influence the trend of medical education and reorientate the methods pursued in undergraduate medi-

cal education. The course of undergraduate medical study is conventionally divided into two parts—the preclinical and the clinical. In the light of present-day requirements this would seem to be an artificial distinction, and the greater the degree of integration between preclinical and clinical subjects of study the greater will be the young undergraduate's appreciation of the fundamental medical sciences and their application at a later stage of the studies.

Anatomy and physiology as basic medical sciences are undoubtedly of great importance to a proper appreciation of the clinical studies at a later stage. But to the young undergraduate in medicine the study of these subjects is of importance and interest more in their applied aspects and in their relationship with a clearer understanding of their application in clinical medicine and surgery. It is obvious that reform in the present curriculum that would integrate the basic sciences with the clinical courses is necessary, and, with this end in view, the simultaneous use of the patient as a means of stimulating the student and aiding his memory would be of great value. Thus some of the time now devoted to the preclinical sciences might well be used to give the student an opportunity of gaining some clinical insight, his time being employed with more profit in the performance of blood counts, urine analysis, and the observation of such pathological factors as would enable him to gain a firmer knowledge of the underlying physiological principles.

Likewise, during the clinical period some time must be surrendered to the basic science faculties to permit the presentation of such anatomical, chemical, and physiological information as would be better appreciated at that stage by the clinical student. Most medical teachers will agree that, whenever possible, the content of courses in the premedical curriculum, particularly science courses, should include a generous amount of medical orientation. It would add to the student's interest and enthusiasm, tend to unify the educational process, and this could be done without any violence to the values of discipline in pure science.

It is hardly necessary to state that the study of pathology has developed into one of the most important basic medical sciences. Herein the undergraduate is introduced to disease: he sees the damage that is wrought by various factors and studies the changes in tissues in various stages of disease and the reaction of the tissues in their effort to conquer it. The gross and microscopical study of disease tissues thus helps him to a better appreciation of the laboratory sciences and clinical medicine. The same applies to bacteriology, which has grown at such a rapid rate that, along with chemistry, a new chapter has been added to the study of factors which control reproduction in bacteria. A good foundation, therefore, in this basic medical science and its techniques is essential for any well-trained physician.

One of the chief problems connected with the medical curriculum is the place that should be given to the specialties. With the ever-increasing number of specialties, there is always a demand that a study of these subjects should form an integral part of the medical curriculum. The result has been that the undergraduate syllabus is overloaded with a miscellaneous variety of factors. In the anxiety to get the undergraduate to know something of the ever-increasing number of specialties the necessary time is not available for him to get a thorough grasp of the fundamentals of medicine and surgery and to become really familiar with the methods of diagnosis and of rational deductions.

Supervised Work

It is true that the amount of time devoted to didactic lectures has been steadily decreased, to enable the undergraduate to spend more time in supervised work with patients in clinical clerkships. Whether these clerkships are in the wards or in the out-patient department is not so important as the character of the supervision and guidance he receives from interested and inspiring teachers. The object of the clerkship is to provide an opportunity for a student to follow his case long enough to gain a lasting understanding of the natural history of the disease and the methods by

which it can be treated. With the rapid extension of laboratory tests of great accuracy there is a tendency to rely more and more on laboratory reports and less and less on the examination of the patient; the history of the illness, the family history, the environmental conditions, and the exercise of a wise clinical judgment. In many cases, of course, laboratory findings are required to arrive at correct conclusions, but the student must never be allowed to forget that the most essential consideration in arriving at a correct diagnosis is to study the patient in all his aspects and not to come to conclusions on laboratory tests. The laboratory must serve as a good servant and not be permitted to become the overlord.

As the student advances in his use of observation and deduction great help can be gained through conferences, seminars, clinical lectures, ward rounds, and case presentation by students themselves; these should all be regarded as essential elements of a well-conducted clerkship. Equally essential is it for the student to realize that the knowledge and experience of other professional and technical persons associated in the service of the patient are of great value. Nurses, medical social workers, dietitians, dentists, and others have a contribution to make to the students' better understanding and appreciation of the patient. The clinicopathological conference is the foundation of all educational progress for clinical clerks as well as for interns, residents, and the whole staff: it is at these conferences that the test of good and bad medical practice and teaching can be judged. There is no substitute for it so far as intellectual discipline and stimulus to professional improvements are concerned.

The Aim of Teaching

The aim of undergraduate medical education is not to provide training in the highly specialized fields of medical and surgical treatment but to give a thorough grounding in the knowledge and synthesis of general medical and surgical diagnosis. Let it be realized that undergraduate medical teaching serves only to lay the foundation for the creation of interest in a subject of ever-increasing complexity and to arouse in the student a psychological curiosity to develop the basic methods and principles that have been ingrained in him.

The successful medical practitioner is a perpetual student, and, in the light of the many developments that are taking place, thanks to the impact of the discoveries of basic sciences on medicine, it can easily be realized that it is not the knowledge of many unrelated facts but the analytical and the progressively expanding mind which will help the student to keep continually in touch with all receptive ideas in the field of science, particularly in its relation to medicine. The chief emphasis, therefore, should be on developing the student's broad understanding, scientific aptitude and approach, powers of accurate reasoning, judgment, resource, initiative, and a determination to put to test the knowledge that has been gained through study and observation.

It is from this point of view that the whole programme of undergraduate medical education should be reviewed. If specialization at the undergraduate level hinders the organization of a unified curriculum, if the curriculum tends to create any rigid barriers between basic medical sciences and the clinical instruction which should follow later, if it does not help to relate the education to the broader culture and science of the times both in the field of preventive medicine and in that of its social implications, then undergraduate medical education will have failed of its purpose. Medical students should be stimulated and inspired by modern concepts of social medicine to realize that they are responsible citizens of the future who should apply their profession, and the knowledge that they have gained, to the benefit of humanity.

An Interesting Period

One of the most important periods of a medical student's career is the period of internship. He looks forward to this with great interest. The intern is not burdened with

a schedule of classes and prospects of formal examination. He is free from the inhibitions of his undergraduate stage of study, and he has the joy of working with experienced clinicians and seeing how they combine the science and art of medicine in the treatment of their patients. The internship should strengthen and not weaken the student's appreciation of high scientific and ethical standards of practice. In the past, and as it still is in some schools, while the internship was regarded as a part of undergraduate medical education, it was almost entirely concerned with curative medicine. It thus failed in its objective, because internship, properly regulated, should contribute to a better appreciation of the possibilities of preventive and social medicine, and put the intern into closer contact with the life of the patient in respect of environmental conditions, his occupational hazards, and the manner in which he can be rehabilitated. The internship should therefore be utilized as an opportunity of studying community medicine in all its many ramifications through public and private agencies, and should serve as an experience in the practice of preventive as well as curative medicine, in community medicine as well as in hospital and in the out-patient department.

Conclusion

Thus it will be seen that no part of medical education is so important as that of the undergraduate, and, if the foundations are not well and truly laid, and the broad basis of the objectives of undergraduate medical education not thoroughly appreciated, the role that the future practitioner will be called upon to play will not be fulfilled and the usefulness of the trained doctor will be limited. Medical schools, the teaching profession in the faculties, and all concerned have to realize, therefore, the need for reorientation of the policy of undergraduate medical education, as indeed of all education in the field of medicine.

TECHNIQUES AND METHODS OF MEDICAL EDUCATION

BY

ALBERTO HURTADO, M.D.

Faculty of Medicine, University of San Marcos, Peru

It is an honour and a privilege, which I greatly appreciate, to preside over one of the sections of the First World Conference on Medical Education. I interpret this high distinction as one of the many indications that the medical profession is really one large institution, without geographical or racial barriers, making a generous effort to achieve a better mental and physical health for mankind. I have not the time to refer specifically to some of the techniques and methods which are actually used in or must be introduced into medical education. The distinguished list of contributors to this section, the variety of subjects to be considered, and the subsequent discussion which they will elicit are indicative that this important phase of medical education will be adequately investigated. It is almost unnecessary to say that our considerations will be closely related to those made in other sections. Methods and techniques are dependent, in part or wholly, on the premedical preparation of the students, the orientation and contents of the medical curriculum, and the new trends in preventive and social medicine. For these reasons it appears to be more pertinent, as a sort of introduction to our work, to comment briefly on the general aspects of the problems we face when we attempt to discuss medical education.

As a means of emerging from the widespread social unrest and poverty brought about or aggravated by the two great wars which divided the world into bitter factions, and in an effort to prevent the repetition of such catastrophes, international organizations and local governments are giving constantly increasing attention to the improvement of health conditions. It has become an accepted fact that man has the fundamental right to demand adequate protection against the development of disease and the best possible care when he is ill. Hospitals are being built all over the world, and new tendencies, such as socialized medicine, are attempting to solve the problems of preventing and curing illness. But there is little doubt that these efforts, justified as they undoubtedly are, lack in most cases the necessary basic foundation, which is the recognition that a good medical education is an essential factor for the successful accomplishment of health and social programmes. Large sums of money could be saved and a greater benefit obtained if Governments and the public were educated in the belief that a sound training of the men who will be immediately responsible for the effectiveness of such programmes was an essential requisite.

Need for Readjustment

It is not illogical to affirm that medical education must be regarded as a major health problem of a nation and must have a high priority in its solution. This is especially true in countries where educational standards fall below those considered to be acceptable. It is important to insist on the benefits of employing, as much as possible, local men in carrying out medical work in a given country. However, this major problem is not easy of solution. It has been repeatedly pointed out that medical education is in a transitional or critical period, and there is universal agreement on the urgent need of readjustment. Unfortunately there is not the same agreement on the way to bring about this readjustment. In reviewing the vast literature on the subject one is impressed with the emphasis with which every writer tries to uphold his personal ideas, and the writers and the ideas may be counted in hundreds and even thousands.

Several factors are apparently responsible for the present situation of uncertainty and confusion. Knowledge and understanding of them are necessary for the adequate evaluation of the methods and techniques which it is convenient to use in teaching medicine. These factors may be separated, from a general point of view, into the quantitative and the qualitative. To the first group belongs the tremendous advance in the knowledge related to the so-called basic sciences or preclinical courses. Some of these, such as anatomy, chemistry, physiology, bacteriology, and pharmacology, have long been accepted as part of the medical curriculum, and others, such as mathematics and physics, especially the latter, have given enough proof of their right to be included, at least up to certain degree, in such a group. In the clinical courses are included the great body of information which must be given to the students concerning the new concepts in psychiatry and social and preventive medicine; care of man when exposed to warfare; use of new therapeutic agents, including antibiotics, vitamins, and hormones, and the new surgical and medical procedures developed for the restoration of health.

From a qualitative point of view we have the close approach of preclinical to clinical courses; the interpretation of symptoms, signs, treatment, and prognosis in physiological terms, which introduces a dynamic rather than a static estimation of illness and its effects; the rapid development of an integrated concept in the consideration of the healthy and sick human body and mind, a concept which threatens to abolish the barriers between the classical departments and the time-honoured sequence in the curri-

culum; and, finally, the acceptance of the importance of considering the patient not as an isolated individual but as part of the family and society, from the points of view of both the consequences and the clinical peculiarities of the disease.

A Complicated Task

Thus the teacher of medicine faces to-day an extremely complicated task. He has to give to the student a constantly increasing factual knowledge within a period of time which has not changed for decades. One method followed is the elimination of certain facts in favour of others, either new or considered more important, within the general orientation that medical education cannot pretend to impart anything but the most essential material, leaving for the postgraduate period the acquisition of further knowledge, especially in what concerns the practical application of general principles. It is evident that this method of solution cannot go on indefinitely. It is based, in part at least, on a false premise, because it implies that new facts mean necessarily the elimination of previous ones. This is not always the case. Knowledge does not advance only by replacement; often it does so by addition. At the rate of our present advance in medical sciences it will occur, rather sooner than later, that the medical student leaves the school with only an elementary vision of what is necessary for him to know. Most medical educators are reluctant to consider a lengthening of undergraduate education. On the other hand, pre-medical training and postgraduate instruction have in recent years received a more liberal extension. One cannot escape the thought that the same consideration will probably have to be applied to undergraduate medical education, especially in those countries in which it is carried out in only four years.

Habits of Thinking and Reasoning

But the problems to be solved do not relate only to factual knowledge. Frequently, and with ample justification, it is indicated that the medical student must be taught the habits of thinking and reasoning, and the ability to discriminate on the relative value of the numerous contributions which are constantly being made to our knowledge. Some writers have extensively discussed the relative importance of these two aspects of medical education: learning facts and learning to think. Each has been given priority over the other. We must accept, however, that both are important, intimately connected, and dependent on each other. One cannot think and reason well if an appropriate body of knowledge does not back these intellectual functions.

The complexity of medical education is increased by the fact that its objective is not only the training of practitioners, either general or specialized. The medical school is the proper place for the selection and preparation of future teachers and investigators. This role is vital for the continuation of progress, for the necessary renewal of teaching personnel, and for the fulfilment of one of the most basic functions of a university, which is the undertaking of research. Everybody agrees that research gives to the teacher a greater authority and a better framework of mind for his thinking and makes him a greater inspiration to his students. But there is no uniformity of opinion concerning several points. How soon should the selected student be attracted to research? Is a limited investigative activity desirable in the curriculum? Is it convenient for the future teacher or investigator to enter early in the field of his choice, or is it better for him to acquire previously a general experience? What methods should be used to evaluate the future qualities of students? These and many other questions demand a closer study.

Conclusion

Medical education presents problems such as those briefly mentioned, which may be considered to be universal in character, which can be formulated in general terms, and which are apt to be applied wherever medical training is

carried out. But local conditions may complicate in a varying degree the solution of these problems. In most countries of Latin America, and possibly in some other regions of the world, an excess of students and economical factors complicate the picture. An erroneous concept of democracy has frequently opened the medical schools to all those who merely wish to pursue a medical education. The result has been the admittance of a number of students entirely incompatible with a high efficiency in the training, and this situation has brought about all the evils of mass education, in which the personal and highly useful contact between the teacher and the student is practically suppressed. The limitation of funds available for teaching and research makes difficult the introduction of the necessary reforms and the proper use of men adequately trained. In addition, geographical and social conditions are still responsible for large areas of inadequate medical and sanitary attention, which results in an uneven distribution of the graduates, who seek the large populated centres in which they find a better scientific environment for their professional activities.

Fortunately, facing these handicaps there is, in the medical school authorities and members, and in the medical profession in general, a sincere desire and a determined intention to raise the educational standards to the level found in those countries which have marked out the pathways in this field. These sentiments explain the presence in this meeting of men who have come from our distant continent. Allow me to conclude by expressing my confidence in the ultimate result of these deliberations, and my best wishes, participated in, I am sure, by all of you, for the success of this conference, which represents a united effort to raise the educational standards of our profession.

PREVENTIVE AND SOCIAL MEDICINE*

BY

RENÉ SAND, M.D.

Emeritus Professor of Social Medicine, University of Brussels

In the hospital as well as in private practice the physician deals essentially with sick people, so that the codes of ethics drawn up by the medical profession in the various countries define the doctor's duties towards his patient, not in a more general sense towards the person who consults him in health or disease. So had Hippocrates in the *Oath*, although elsewhere in his work he maintains that the first duty of the physician is to protect and cultivate health.

When, about a century ago, sanitation was revived and put mainly in the hands of the engineer, and when medical health officers were appointed, the doctor still served the cause of health by giving advice as family physician. Unfortunately, the advent of specialization has nowadays reduced the part played by the general practitioner.

Preventive medicine in the strict sense of the term—that is, preventive medical procedures—appeared with Jenner and his first immunization, followed a century later by the preventive examinations of pregnant women, infants, and school-children. Occupational medicine was launched by Ramazzini in 1700, medico-social surveys and statistics by Villermé in 1828.

In the century and a quarter which has elapsed since these pioneer days, preventive and social medicine—the terms are often used as synonyms for reasons of con-

*This paper was received for publication just before Professor Sand underwent an operation which prevented him from coming to London as one of the Vice-Presidents of the First World Conference on Medical Education. The news of his death was received as this issue of the *Journal* went to press.

venience—have proved their case, and if weighed against curative medicine would no doubt be found more effective and less costly. However, they occupy only a small place in medical teaching; and they come late in the curriculum, at a time when the student's mind is already monopolized by the clinical and laboratory aspects of disease. Besides, having had no instruction in the social sciences, he feels lost in a strange country.

Signs of Improvement

Here, as in so many other fields, institutions have lagged behind needs. Hospital and medical practice are still turned mainly towards cure. The Faculty is still made up of a large group of clinicians, a large group of laboratory workers, and a solitary professor of public health. Yet signs of change are appearing. The importance given to preventive medicine by the Report of the B.M.A. (*The Training of a Doctor*), and by the Goodenough Report, as well as by similar documents elsewhere; the creation of departments, institutes, and chairs of preventive and social medicine in various countries; the part assigned to these disciplines by W.H.O. and other international organizations—all point in the same direction.

If the social elements in many medical schools are still comparatively neglected it is because the training takes place in the hospital, from which these elements are absent, and because few members of the Faculty have studied social sciences and acquired experience in social work. However, a growing number of hospitals have almoners, and use them to demonstrate the circumstances and needs of the patients. Besides, the idea is spreading that a much greater part of the training should be given in the out-patient department and in the home itself, either by associating the students with the daily work of general practitioners, as Professor Crew does in Edinburgh, or by sending the students to observe domiciliary cases.

Need for Change

The lack of training in the social sciences calls for a radical change: in his first university year the student is taught mathematics, physics, chemistry, and biology, which are required for the understanding of health and disease; he should study also psychology and sociology, not only because he will need this initiation to play his full part as a doctor but because everyone, and more especially a university graduate, should understand himself and the world in which he lives. Biology teaches us to understand our body; psychology to understand our mind and our behaviour; sociology to understand the structure and life of the groups, small and large, of which we are members. So long as psychology and sociology remained mainly speculative their practical use was limited. More realistic to-day, they have become indispensable to the statesman, the employer, and the parent, to the judge, the Army officer, and the doctor.

On the background of biology, psychology, and sociology, acquired in the first year, the principles of preventive and social medicine should be taught at the same time as the basic sciences, anatomy, and physiology. The aim of medicine should be defined as the maintenance and culture of physical, mental, and social health, with the repair of damaged health as the second consideration only. The nation-wide and permanent achievements of preventive medicine and public health should be put in parallel with the remarkable but individual and temporary successes of curative medicine.

Later, when the student enters the hospital, the part played by social, economic, and occupational factors should be explained by the internist, the surgeon, the obstetrician, the paediatrician, the psychiatrist, with the help of the almoner, and preferably also of the professor of preventive or social medicine; and this teaching should take place in the clinical lessons, in the daily rounds of the wards, in the out-patient department, in the dispensaries and clinics, and in the home itself.

various faculties.* In Figs. 1 and 2 the distribution of Oxford medical students may be compared with the general distribution at two men's colleges, and in Figs. 3 to 6 students of dentistry and mechanical engineering at Birmingham are contrasted with those reading chemistry and physics. It will be seen that Oxford medical students and Birmingham students reading dentistry and mechanical engineering have one thing in common, they are largely mesomorphic. This is in sharp contrast to the physicists and chemists, who are largely ectomorphic.

These differences in preponderance according to faculty are summarized in the accompanying Table, in which further data may be found concerning undergraduates in the faculties of English, history, chemistry, chemical engineering, physics, and mathematics. In the left-hand part of the table the

* Mesomorphic where mesomorphy was rated four or more, mesopenic where rated less than four, on the seven-point scale.

physical categories are those of primary component dominance, in the right-hand part physiques are divided into those with mesomorphic ratings of four or more on the seven-point scale, and those which may be described as mesopenic with ratings of less than four. This form of classification may bring to mind Tanner's (1952) finding that Oxford students are somewhat more ectomorphic and considerably less mesomorphic than American students.

Taking both universities together, it may be seen that half the medical students were primary mesomorphs and roughly

*The somatotype is expressed as three numerals, each a rating on a seven-point scale (seven being maximal and one minimal) of three so-called primary components of physique—endomorphy, mesomorphy, and ectomorphy. Endomorphy, in brief, represents roundness of physique and the capacity to become fat; mesomorphy describes the development of bone, muscle, and other tissues of mesodermal origin; while the rating on the third component, ectomorphy, indicates the degree of linearity of physique. The third component correlates positively and closely with the ponderal index height divided by the cube root of weight; it attains primary dominance in young adults when the ponderal index exceeds 13.5 (height in inches, weight in pounds). With ponderal indices less than 13.5, weight may be present mainly in the form of fat when endomorphy is primarily dominant, or mainly in the form of bone and muscle in the case of mesomorphs. The component rated second highest is said to be secondarily dominant. Thus, apart from shared primary and shared secondary dominance, the six main groups of physique are endomorphs, both mesomorphic and ectomorphic; mesomorphs, both endomorphic and ectomorphic; and ectomorphs, both endomorphic and mesomorphic. Sometimes it is more convenient to group physiques according to the weakest component, and this is indicated most concisely by speaking of endopenes, mesopenes, or ectopenes respectively. Alternatively the degree of endopenia, mesopenia, or ectopenia may be indicated by a statement of ratings included. For full details reference should be made to *Varieties of Human Physique* (Sheldon et al., 1940).

two-thirds of them had a mesomorphic rating of four or more. This feature no doubt underlies hospital Rugby football tradition. More than three-quarters of Oxford medical students and Birmingham dental students and mechanical engineers were rated high in mesomorphy. In contrast to this over half the chemists, mathematicians, and physicists were ectomorphs, in each case more than half being rated mesopenic. In view of this striking contrast between chemists (35.5% mesomorphic) and engineers (76.8% mesomorphic) it is entertaining to find that the distribution of chemical engineers lies half-way between that of chemists and that of engineers. Oxford English students and historians belong to the only other faculties tabled but so far unmentioned. In each case about half were ectomorphic and a slight majority mesopenic.

Task of Education

That completes the physical data to be presented here. But perhaps it is worth touching for a moment on the possible bearing this has on education generally. Perennial arguments more often than not are founded on temperamental differences. Where choice of faculty is concerned these differences have now been shown reflected in physique, and it is in this way probable that battles between science and humanism are perennially provoked. It is, for example, exactly along these lines that the whole success of university education in meeting present-day needs has lately been questioned.

In the House of Lords Lord Pakenham (1952) said: "The Government should consider how to broaden the outlook of the scientists and humanists. We have met the challenge of the scientific age in the wrong way. We have produced two nations—one of scientists, the other of non-scientists." The difficulty should, he thought, be tackled in the schools, and he sought to prolong all-round education during the first year at the university. Earl Wavell (1952) offered instead a mixed honours degree course as a solution to the problem. He said he was not concerned about the scientists who got a first-class honours degree. The solution would be to persuade two-thirds of those who obtained a second-class degree to read science, and he thought the time had come for the universities to do some strenuous thinking, and perhaps adapt their constitution to meet the new needs. Both speakers recognized special aptitudes, but both wanted all-round ability and interest as well.

It is therefore in order to ask two questions, in answer to which the somatotype distributions are not entirely reassuring. First, "Is there an adequate supply of central somatotypes with all-round interests and sufficient ability to satisfy demand?" If the central somatotypes cannot be "produced," then others must be persuaded to emulate them, and the universities should separately expose scientists to the genial humanizing enzyms of society, while adding scientific experiment and perhaps unpalatable precision to the diet of liberal arts men. This brings up the second question: "How effective is education likely to be in giving powers of leadership and managerial ability to mesopenic ectomorphs in whom these qualities are least often found, except possibly in academic surroundings; can education succeed in humanizing sociophobic ectomorphs who most often find easy personal relationships difficult; last, can teaching inculcate a scientific outlook in mesomorphs who, though capable as managers, are temperamentally less inclined to academic science?"

This is the task, and in both cases the genetic straw from which these particular bricks are to be fashioned will, like other raw material, greatly affect the final product. Should everyone try to climb uphill towards the central peak of university or universal education, or should impetus be added to inclination, should technical specialists be trained in their own institutes, and managerial students in theirs, with less confusion of purpose? Whichever line is taken it should be advantageous to recognize the nature of individuals who pass through the mills of syllabuses. At the present time it seems probable that too high a proportion of mesopenes

are chosen by the current machinery of selection to meet the national need for leadership in industry; after obtaining a university degree they not unnaturally prefer a niche with academic freedom to the more strenuous daily demands of industrial life.

Somatotype estimates of Oxford undergraduates were made while I was physician in charge of a pilot student health service at the Institute of Social Medicine, Oxford. Measurements on Birmingham students were made by kind permission of the senior university medical officer, Dr. R. H. Bolton, and I am indebted to his staff and to the following students who assisted me during the week of routine examinations: E. Anthony, J. A. Binnie, G. T. Brown, R. H. Cawley, H. R. Dobson, M. A. Harper, J. L. Pearce, M. G. Saunders, D. W. Theakston, G. B. White, G. T. Whitfield, and J. W. Woolley. My thanks are due also to Mrs. C. C. Standley and Mrs. S. McIntosh for their help in analysing the measurements.

Medical Memorandum

Ileo-ileal Intussusception Due to Meckel's Diverticulum and Complicated by Volvulus

Any increase in the bulk of a segment of intestine may cause it to become twisted on its mesentery. Among the causes of this increase in bulk which have been reported as causing a volvulus are the ingestion of large volumes of cereal food (Kerr and Kirkaldy-Willis, 1946), the presence in the bowel of a mass of worms or some other foreign body, and a tumour of the bowel or its covering (Allen and Welch, 1947).

In the case reported below the increase in bulk was due to an ileo-ileal intussusception, the head of which had entered the ascending colon. The intussusception itself was caused by the invagination of a Meckel's diverticulum containing a polyp of gastric mucosa. Clark (1944) reported a similar case.

CASE REPORT

A schoolboy aged 9 was admitted to hospital complaining of abdominal pain which had started 15 hours earlier. The pain was situated to the right of the umbilicus and was of a dull and persistent nature; it had been mild at first, but had steadily grown more severe. He had eaten a meal after it started but with no enjoyment, and had been sick twice, bringing up small quantities only. The vomit contained the pulp of an orange which he had eaten 24 hours previously. The bowels had been open normally in the morning, and there was no disturbance of micturition. This was the first attack of its kind that he had suffered. There was nothing relevant in the past history.

On examination the boy was strikingly pale; his temperature was 97.4° F. (36.3° C.), pulse 90, and respirations 20. The tongue was moist but covered with a white fur; there was no fetor oris. He appeared to be most comfortable lying on his left side. The abdomen was not unduly fat, and a lump was visible to the right of the umbilicus. There was no visible peristalsis, respiratory movement of the abdominal wall was free, and acute tenderness and guarding were present over the lump, but not elsewhere. The mass, which was about 2 in. (5 cm.) in diameter, had a smooth surface and appeared to be bilobed; it was freely

mobile and slightly more resonant to percussion than its surroundings. No signs of free fluid were present in the peritoneal cavity, and bowel sounds, though reduced in quantity, were normal in character. There were faeces in the rectum, and blood was not found on the examining finger. No abnormality was found in the respiratory or cardiovascular system. Plain x-ray films of the abdomen in the erect and supine positions showed no significant abnormality.

The provisional diagnosis was not certain. The presence of a position of relief (Evans and Bigger, 1947) suggested intestinal volvulus, but intussusception was thought to be a possibility.

Operation.—The abdomen was opened through a right paramedian incision, and two purple, distended loops of intestine—one the caecum, the other a coil of ileum—presented themselves in the wound. The caecum and ascending colon were attached to the posterior abdominal wall by a mesentery 2 in. (5 cm.) long and, with the terminal ileum, were rotated on this mesentery through 360 degrees in a clockwise direction. This volvulus was reduced without difficulty and the bowel immediately resumed its normal colour. It was then found that an ileo-ileal intussusception was also present, the junction of the intussusciens and intussusceptum being about 6 in. (15 cm.) from the ileo-caecal valve, while the head of the intussusceptum was palpable in the ascending colon 1½ in. (3.8 cm.) above the base of the appendix. This intussusception was reduced with some difficulty, and it was found that there was a Meckel's diverticulum at the head of the inner layer. The invaginated intestine was deep purple in colour, and it became apparent that the proximal 3 in. (7.6 cm.) was not going to recover viability. The whole affected length was therefore resected and a side-to-side anastomosis made about 6 in. (15 cm.) from the ileo-caecal junction. The abdomen was closed without drainage.

Intestinal suction with intravenous fluid and electrolyte replacement was kept up for three days, at the end of which time peristaltic sounds became audible in the abdomen and an enema produced a good result.

The patient went home on the eighth day after operation. When seen one month later he was in good health, with the wound soundly healed.

The operation specimen was a length of ileum 12 in. (30.5 cm.) long. Apart from ½ in. (1.25 cm.) at each end, it was deeply congested with blood. At ½ in. (1.25 cm.) from the proximal end, on the antimesenteric border, was a diverticulum about 1 in. (2.5 cm.) deep and ½ in. (1.25 cm.) in diameter at the base. Arising from the interior of the tapering apex was a soft pedunculated polyp ½ in. (1.25 cm.) long and ¼ in. (0.6 cm.) in diameter. The microscopical report by Dr. John Dean stated: "Sections of small intestine show extensive haemorrhage into all coats. The polyp of the Meckel's diverticulum is covered by mucosa of gastric type with conspicuous oxyntic cells."

COMMENT

According to Harkins (1933) the mortality from intussusception due to Meckel's diverticulum is half as high again as that from the idiopathic variety. He attributes this to slowness in diagnosing the condition. The effect of the superimposed volvulus in the present case was to make the symptoms severe and the signs obvious, so that the need for operation was at once apparent.

Reviews

MODERN UROLOGY

Modern Trends in Urology. Edited by E. W. Riches, M.C., M.S., F.R.C.S. With foreword by Lord Webb-Johnson, K.C.V.O., C.B.E., D.S.O., T.D., M.B., LL.D., F.R.C.S. (Pp. 476; 215 figures. 75s.) London: Butterworth and Co. 1953.

This book, edited by a distinguished urologist, is a most important work on this branch of surgery. The editor has made no attempt to produce a complete textbook of the specialty, but such have been the advances in the last few years in so many of the diseases constantly met with in urology that a book giving a full account of all of them must be almost a complete work on the subject. The discussion is not confined to those diseases which give rise to most problems and differences of opinion on their aetiology, pathology, and treatment, but the writers also fully describe those methods of investigation and treatment, including operative, which have been accepted in recent years as of especial value. The inclusion of the most recent work and the speed with which this book has been produced and published have overcome the main disadvantage of so many publications on recent advances in treatment—that much is out of date before the book appears. And, by no means the least important of its qualities, the book gives an account of the lines along which research is being directed and the trend this specialty is taking in its development.

The editor has shown great wisdom in the choice of contributors, several of whom are from overseas; each is an acknowledged authority on the subject he has written about. The large number of excellent illustrations and photographs makes the descriptions of techniques and operative procedures easy to follow. This book will be found of the greatest interest to all urologists as well as to general surgeons who wish to keep abreast of advances in this specialty.

J. E. SEMPLE.

MUCOSIS

Fibrocystic Disease of the Pancreas: A Congenital Disorder of Mucus Production—Mucosis. Edited by Martin Bodian, M.D. (Pp. 244; 133 illustrations. £3 3s.) London: William Heinemann Medical Books, Ltd. 1952.

This monograph by a team at the Hospital for Sick Children, London, represents 10 years' study of a disease that has aroused much interest in recent years. It is based on a series of 116 cases, of which 68 were fatal and 62 came to necropsy. Few pathologists can have had so large an experience of fibrocystic disease of the pancreas, and the authors have performed a useful service in presenting the fruits of this experience and in bringing together in convenient form all the more important facts and theories that must otherwise be sought among a large literature in the journals.

On the vexed question of pathogenesis, they present evidence in support of their conception of "mucosis" as the fundamental disorder, to which all the other lesions and manifestations are secondary. This is an inborn abnormality of mucus-secretion, in which all mucous glands may participate. The greater prevalence of mucous glands in the alimentary and respiratory systems accounts for the predominance of clinical manifestations referable to those systems. The pancreas is only one of many organs affected; the fibrosis, atrophy, dilatation of ducts, and loss of exocrine secretion are results of obstruction of small ducts by abnormally viscid mucus. The greater severity of the pathological changes in the pancreas than in other organs may be explained by release of intracellular enzymes from damaged acinar cells. The authors have found evidence of mucosis already present at birth in many mucus-secreting organs, and they believe that respiratory infection, which is so constant a feature of this disease, is dependent on

this abnormality of mucus-secretion and not on malnutrition due to pancreatic insufficiency. The importance of respiratory infection as a cause of malnutrition and death is emphasized, and an improved prognosis is expected from the use of the newer antibiotics, though not cure of the fundamental disorder. The study of familial incidence has produced strong evidence that the disease is genetically determined and transmitted by a recessive gene.

The book is beautifully produced and profusely illustrated from the authors' own cases. It is a valuable contribution to the literature of the subject.

A. R. MACGREGOR.

CLINICAL PSYCHIATRY

Clinical Psychiatry for Practitioners and Students. By Ian Skottowe, M.D., M.R.C.P., D.P.M. "The Practitioner" Series. (Pp. 395. 36s.) London: Eyre and Spottiswoode. 1953.

The sea of psychiatric literature is a stormy one, blown by contrary winds and moved by unfamiliar currents. So at least it seems to the medical man who would embark on it, and the many charts available do not always inspire confidence. For, like the charts of Columbus's day, they are apt to make up in conjecture what they lack in observation. There is always need for an up-to-date guide to the subject, written in familiar language and interpreting current trends with clarity and without bias. Dr. Skottowe's objective is to provide just such a guide for the physician, and there is no doubt that his common sense and facility for putting first things first will have a strong appeal. This is no mere compilation but a well-integrated account of the commoner psychiatric disorders and their treatment. The author, sitting on the sidelines of psychiatric controversy, has been able to take a broad view of the game, and his descriptions at times are reminiscent of Osler.

The book will be of particular use to newcomers to psychiatry whose first appointment is in a mental hospital, where opportunities for seeing the earliest manifestations of psychiatric disorder and cases belonging to the more specialized branches are limited. The method of presentation, founded on the writer's personal cases, contains much that is original, but there is little that does not seem natural or logical. The attitude to physical methods of treatment and their limitations is realistic, and the aims of psychotherapy are seen as an extension of the attitude of the physician to his patient rather than as a mystery beyond his capacity to know. There is a pleasing absence of prolegomena, and Dr. Skottowe goes straight to the heart of his subject. None the less his discussion, for instance of the view that psychosis is in the main of the same stuff as psychoneurosis, gives an opportunity to convey his attitude far better than an abstract approach would have done. This is an excellent introduction to psychiatry as it is actually practised and will be of use to student and postgraduate alike.

VIRUS MULTIPLICATION

The Nature of Virus Multiplication. Second Symposium of the Society for General Microbiology held at Oxford University, April 1952. Edited by Sir Paul Fildes and W. E. Van Heyningen. (Pp. 320; 33 electron micrographs. £1 15s.) Cambridge: The University Press. 1953.

The concept of viruses as micro-organisms led logically to the belief that they multiplied by binary fission, and this belief persisted until quite recently, when apparently contrary evidence has led to its being abandoned. It is true that the agents belonging to the psittacosis-lymphogranuloma group, which from their size and the readiness with which they stain lend themselves to study by means of the ordinary microscope, appear to multiply by the simple process of division. But by almost common consent they have been removed from the Virales and placed with the Rickettsiales, where their orthodox reproductive behaviour can no longer disturb the harmony in the virus group. For there are other views to-day on how viruses multiply, and

they are described and discussed in this book. These new concepts have been derived very largely from investigations made with the bacteriophages—or bacterial viruses as they are often called—which have been chosen for this purpose because of the ease with which they and their hosts, the bacteria, can be handled in the laboratory. It is hardly surprising, therefore, that a consideration of bacteriophage reproduction should have occupied such an important position in this symposium. S. E. Luria, André Lwoff, Raymond Latarget, J. K. S. Boyd, Sir Paul Fildes, and his colleagues D. Kay and W. J. Joklik, all eminent in this particular field of research, contributed papers which now appear in this volume.

There seems to be general agreement that in the early stages of bacteriophage multiplication there is a replication of non-infective sub-units which are subsequently reassembled to form the complete fully virulent phage. And investigations made with influenza virus have led to very similar conclusions. L. Hoyle, who has been responsible in this country for much of the work on the reproductive behaviour of this virus, describes and discusses the evidence. A finding which has been common to these investigations, whether made with the bacteriophages or the influenza viruses, has been the disappearance of infective virus during the early stage of the reproductive cycle. Shortly after entering the cell, and for a period of time which has varied with the virus under study, it has been impossible to recover infective virus from the cells. It is during this latent or eclipse phase that the virus is thought to be multiplying in the form of non-infective sub-units or provirus, and it is on the existence of this incomplete form of the virus that the belief in a complex growth cycle largely rests. In a most interesting article Forrest Fulton discusses critically the evidence for a complex growth cycle, and concludes that the hypothesis is far from being established. He is of the opinion that it may well be shown eventually that viruses and bacteria multiply by essentially the same procedure.

Many other aspects of this most interesting subject are considered in this volume. Among these are the fundamental ones of protein synthesis and of nucleic acids in virus multiplication, the metabolic aspects of this problem, and the multiplication of insect viruses. This book will be of interest and value not only to virus workers but to the greater circle of microbiologists as well.

S. P. BEDSON.

GUIDE TO PARASITOLOGY

A Guide to Human Parasitology for Medical Practitioners. By D. B. Blacklock, C.M.G., M.D.(Edin.), D.P.H.(London), D.T.M.(Lpool.), and T. Southwell, D.Sc., Ph.D., A.R.C.Sc., F.Z.S., F.R.S.Ed. 5th edition, revised by T. H. Davey, O.B.E., M.D.(Belf.), D.T.M.(Lpool.). (Pp. 228; 3 coloured plates and 120 illustrations in the text. £1 5s.) London: H. K. Lewis. 1953.

This well-known textbook has been revised by Professor T. H. Davey to bring it into line with modern knowledge. It remains, however, a guide to clinicians and those taking courses in tropical medicine or public health. Professor Davey has added a note on prevention to the account of each parasite, and has included or expanded notes on several parasites without altering in any sense the essential character of the original text.

With its many practical expositions and forthright advice it is of undoubted value to the general practitioner, who will require to be told what to do rather than find nice opinions on the best means of doing it. In this the initial chapters on parasitological technique excel. The instructions are precisely set forth in the manner most easily understood and accomplished by the tiro.

The omission of flagellate-culture methods seems a mistake, for the text mentions them as a diagnostic method for *Leishmania*. It is also hard to understand the preference for the more difficult of the Romanowski stains over the almost foolproof Giemsa stain. The morphology and life histories of the parasites are set out clearly and with a commendable economy, and their chief distinguishing fea-

tures are enumerated in that most useful of guides, the diagnostic table. Parasitology is taken to include the spirochaetes, the protozoa, and the helminths. One surprising omission is made. While a short note is accorded to *Sarcocystis*, no mention is made of *Toxoplasma*. If the latter has been relegated to the mycologists, surely the position of the former must be in grave doubt.

A parasitologist might rashly desire to expand certain descriptions, but when the purpose of the work is recalled it is left only to congratulate Professor Davey on retaining the essential morphological simplicity of the original text in the face of the multiplication of our knowledge of the biology and physiology of these parasites.

R. S. BRAY.

THE SPINAL CORD

The Spinal Cord. A Ciba Foundation Symposium. Consulting Editors: J. L. Malcolm, M.B., Ch.B., B.Med.Sc., and J. A. B. Gray, M.A., M.B., B.Chir. Editor for the Ciba Foundation, G. E. W. Wolstenholme, O.B.E., M.A., M.B., B.Ch., assisted by Jessie S. Freeman, M.B., M.S., D.P.H. (Pp. 300. 112 illustrations. 30s.) London: J. and A. Churchill. 1953.

The Ciba Foundation during the past four years has arranged a number of symposia to which distinguished workers from Britain and abroad have been invited, and has published the papers and subsequent informal discussions with a minimum of editing. The occasion for such a meeting to discuss present-day problems in the physiology of the spinal cord was the presence in England of Professor J. C. Eccles, and this book contains the proceedings of the meeting, which was attended by about 50 research workers. The 20 papers are on various controversial topics in the neurophysiology of the spinal cord and nerve roots; they include two on the action of anticholinesterases, and one with a direct clinical bearing on nerve conduction in poliomyelitis. The discussions seem to have been lively and provocative. This volume should be of value to those doing experimental research in neurophysiology, but it is difficult reading for the clinician.

J. W. ALDREN TURNER.

REPORT ON STRESS

Second Annual Report on Stress. By Hans Selye, M.D., Ph.D.(Prague), D.Sc.(McGill), F.R.S.(Canada), and Alexander Horava, M.D.(Lausanne). (Pp. 526. \$10.) Montreal, Canada: Acta, Inc. 1953.

This volume is the second of a series of annual supplements to the book *Stress (The Physiology and Pathology of Exposure to Stress)* by Professor Selye. An additional author, Dr. Alexander Horava, is now responsible for this annual publication. The same general form as in the first *Annual Report* is preserved. The first section of the book is on the stress concept as seen at the moment; it includes the principal objections to the concept, definitions and terminology, and data on "stressor agents and adaptive hormones." The second part is on the special physiology and pathology of stress and is arranged according to the various systems and functions of the body.

This volume is notably different from its predecessor and has become to a large extent a classified index of literature pertinent to the subject of stress. Pp. 40-300 consist largely of such classified data, description having been reduced to a few introductory paragraphs and comments through the various sections. The book gives an up-to-date account of Selye's views on the general adaptation syndrome and the so-called diseases of adaptation. It also makes available the benefits of the extensive library in the Montreal Institute. Some 5,000 papers, published mainly in the course of the last two years, have been covered in this way. It may be recommended as a reference source to the extensive literature that has grown up around the subject of stress and pituitary-adrenal reactions. Though expensive it is very well produced, and should be available at least in the libraries of all medical institutes.

FIRST WORLD CONFERENCE ON
MEDICAL EDUCATION

By the time this issue of the *Journal* is published the First World Conference on Medical Education will have all but come to an end. Those responsible for planning and organizing it will be all too uncomfortably aware of the mistakes and the shortcomings, of the occasional creaking in the machinery, of the rough edges in the programme. A series of accidents in the early phases of the work of the Conference last year worked to the disadvantage of those upon whom the responsibility ultimately fell. But under the guidance of Sir Lionel Whitby, who took charge of the situation just a year ago, most of the difficulties were overcome, except that the time lost in preparation was something that could not be recaptured. A conference such as this had no precedent to guide it, no set of "recent advances" round which to crystallize discussion. Of course the pattern of medical education—a pattern worked on throughout the centuries—was bound to determine the shape of the Conference.

What was said during the past week will be recorded and summarized in the *Proceedings* to be published by the Oxford University Press, and reported more briefly in this *Journal* and in many others. The *Proceedings* will, we believe, be an important addition to the documentation on medical education. Many excellent reports on this question—such as those of the Goodenough Committee, of the Royal College of Physicians, of the British Medical Association—may turn out to be more of a piece, more definite in direction, less disturbed by divergencies of view. They represent the majority opinion of a group of experts and witnesses. They are neat and tidy. But the *Proceedings* of this week's Conference will lack this neatness and tidiness, will not erect what appear to be irremovable signposts, will refreshingly fail to seem to utter the last word on a subject perennially fresh and challenging. This week's Conference was a public debate on medical education at which individuals said what they thought about this or that. Ideas have been thick in the air, and some of them will settle in suitable soil. Ideas have a great force:

they effect a change in men's thinking, and at no time more than at the present was such a change needed in medical education.

Those who look for the short cut to higher education in the outcome of this week's work will be disappointed. But the stimulus to thought, and so ultimately to action, is there. What Sir Richard Livingstone, in his address on Monday, called "the philosophy of the first-rate" must permeate medical education and influence the choice of men and women who teach the young and fill the positions in medicine which fashion the future. In an age when a spurious egalitarianism is preached, when the collective mind is thought by some to have virtues superior to those of the individual mind, Sir Richard's philosophy comes as a necessary challenge. In an age of safety first—the welfare-state age—the mediocre is elevated, and the second-rate and the third-rate seep upwards to dilute what is first-rate, and debase the coinage of thought and intelligent intercourse. As Sir Richard Livingstone puts it: "People learn what is first-rate by contact with it." That is what is needed above all in medical education—and any kind of education. The character of a headmaster will affect generations of young men. As Emerson put it, "An institution is the lengthened shadow of one man." The student learns something incalculable when he comes into contact with the first-rate; and the first-rate is uncommon and appears in unexpected places. This is something that no one can provide deliberately, produce to order. But if the idea is there, if the ideal is kept bright, then more and more people—teachers and students—will be discontented with the second-rate.

What is a first-rate quality in the practising doctor is not necessarily a similar quality in a research worker, in a lawyer, or in an archbishop. But archbishops are rare and doctors are common. Yet the qualities Sir Lionel Whitby spoke of in his presidential address as desirable in the student and so in the doctor are not common; but they are qualities, he observes, that must be looked for in the selection of students—a subject thoroughly discussed this week. Sir Lionel opposes any narrow view of the objective of undergraduate medical education; and surely he is right if we as a profession adhere—as we try to adhere—to Sir Richard Livingstone's "philosophy of the first-rate," and are guided by this in the choice of students. The aim of the teacher is admirably summed up thus by Sir Lionel:

"The undergraduate teacher should aim at producing an educated person grounded in principle and method, able to see what the whole of medicine stands for and

means, trained to observe with his hands and his senses, encouraged to think logically and critically, instructed in the use of the instruments of measurement, and equipped with a basic knowledge upon which he will continue to build for the rest of his professional life."

To do all this the teacher of undergraduates must himself be an educated person, and it would be unwise to assume that this is always the case. Teacher and taught will find a basic language of communication only if they have drunk deep of the Pierian spring, if their ears are attuned to the overtones of the civilized mind. And it was significant that many speakers in the plenary session on Monday and in the discussion on "General Education in an Age of Science" on Tuesday underlined Sir Richard Livingstone's dictum that "an education which ignores the humanities is disastrously incomplete." Once qualified the practising doctor cannot hope—and does not want—to live a life of lettered ease; but what ease he may find can be enriched if as a boy at school he has been given a glimpse of the treasures of human thought and emotion. Only if his mind is so rounded off will he be to his patient something more than an applied scientist. One sees in all this a check and balance to the laboratory, a reaction against intense specialization, a swing back to the more simple observational art of the clinician. To strike a balance between the old and the new, between the art and the science, to achieve the Greek mean of "nothing too much," to use wisely the probing weapons of modern science and technology in seeking out the causes of disorders of the body and mind calls for a combination of scientific scepticism and human compassion occasionally brought to perfection in a character such as William Osler's. And the guide to this is Sir Richard Livingstone's "philosophy of the first-rate."

It may be that the study of the classics is on the wane, and the schoolboy and schoolgirl are no longer so drilled in the grammar of Latin and Greek as their parents, or at least as their grandparents were. And if the stripling no longer learns to decline the Latin for "table" and the Greek for "youth," he is being taught that history is something more than dates and the deaths of kings and queens. The historian a thousand years hence may see civilization to-day as a phase of the Socratic era, and the specialist then in medical history may, in exploring the archives of our minute of historical time, note that in the First World Conference on Medical Education Professor John Fulton and Colonel S. M. K. Mallick expressly devoted their attention to the impact of the past upon the present, to the continuity of our uneven medical story.

A SIGHT OF GENERAL PRACTICE

In most teaching centres in Britain it is only very recently that the undergraduate curriculum has been designed to include some preparation specifically for general practice. Some still offer the student nothing, though one pioneer—namely, Edinburgh—has for many years given practical instruction in the conditions likely to be met with beyond the hospital gates. Most teaching hospitals provide at least lectures and sometimes even the opportunity to live in a general practitioner's family for a week or so, and an inquiry carried out recently by Mr. R. W. Heslop for the British Medical Students Association shows that those medical schools not yet giving instruction in general practice have a slightly hang-dog air and promise schemes soon or when they have studied the problem further. There is little doubt that some such instruction is to the student's benefit; at any rate the B.M.S.A. finds that students themselves welcome it.

When the G.M.C. forbade the employment of unqualified assistants in 1891 it brought to an end the apprenticeship as one method of gaining the requisite knowledge for qualification. Perhaps that was no great loss, for Dr. Alfred Cox, who himself entered general practice that way, has recorded¹ that many of those dispenser-assistants were grossly exploited and few of them ever qualified. With the passing of apprenticeship and the coming of recondite specialization in so many branches of medicine, however, many young doctors have felt much anxiety on first entering general practice—not only because they know little of the organization of general practice, for that is to be expected, but because they know so little even of the maladies their patients bring to them daily. Too often the disorders receive scant mention in the textbooks, examination papers, or hospital wards, and they should be among the principal subjects of such teaching as is given. Introducing the results of its survey, the B.M.S.A. states its belief "that it is desirable for a medical student to see how a general practitioner lives and works." No doubt it is, but the emphasis needs slightly changing lest students waste valuable teaching time in treating their visit to the general practitioner much as they might a visit to the Zoo. In the avoidance of this danger the important work of Edinburgh² is an example that other medical schools could study with profit. Arrange-

ments that had existed for over 100 years for teaching in dispensaries were replaced in 1948, as a consequence of the Health Service starting, by a teaching general practice. The emphasis here is on teaching. The student learns much about the ailments often to be met with in general practice, what patients first complain of, and what they have to contend with if they remain at home instead of going into hospital, and they also learn about the special agencies, such as those run by the local authority, for helping the sick, the pregnant, the destitute, and so on. The Americans seem to have gone beyond even such a considerable scheme as this with their home care programme at Richmond, Virginia, and their home medical service at Boston, described respectively by Professor Kinloch Nelson and Dr. James M. Faulkner at the First World Conference on Medical Education this week. Both schemes operate in large indigent populations without family doctors, and the main feature of both is that the medical students go out to the homes in response to calls received at a centre. They remain in touch with their hospital readily enough in case of emergency—in one scheme by wireless—and are well supervised at a distance. These arrangements are thus very similar to those by which students in Britain often learn their midwifery, though the lack of large doctorless populations here precludes our developing anything quite like them.

The College of General Practitioners has rightly said³ that "an insight into the nature of general practice, and some first-hand experience of it, form an essential part of the basic training of all doctors, whatever their future may be." And of interest here is the Edinburgh insistence that the students least likely to end up in general practice are those who above all receive special instruction in it. Some acquaintance with the best type of general practice—and Barber⁴ has emphasized that this first vivid impression must be of the highest quality—will moreover do something to offset the dependence on intricate mechanical equipment that the student almost inevitably acquires in his long peregrination through wards, theatres, and laboratories—from which perhaps he will ultimately emerge only to practise in a small private house on the outskirts of a market town. His medicine need not be the less scientific there, but it probably will be if his medical school did not teach him something about applying scientific principles in the kind of practice he will experience.

General practice nowadays demands "appropriate postgraduate study"⁵ such as in an assistantship, and no amount of undergraduate instruction can of itself fit a man for it any more than it can for other kinds of practice. Indeed, it would be undesirable to design a curriculum aimed at producing a certain kind of

doctor. The introduction of the intern year and of the trainee assistant scheme in the National Health Service is a recognition of the need for practical experience after qualification but before the assumption of full clinical responsibility. Consequently advocates for teaching undergraduates about general practice may, without tempering their enthusiasm, at least moderate their demands on the curriculum. A helpful view is the B.M.A. Committee's⁵ that "the undergraduate medical course should be primarily concerned with the training in those basic principles of medicine which are a necessary foundation for all forms of medical practice." Certain basic principles are exemplified particularly in general practice. Being on the alert for the early diagnosis of many diseases—pneumonia, for instance—is one. And to continue trying to teach these principles entirely from hospitals is to put an unnecessary strain both on the curriculum and on the student's imagination.

INDUSTRIAL HEALTH AND THE UNIVERSITIES

The first university department of industrial medicine in Great Britain was set up in Birmingham in 1935 and closed down after four years. Undeterred by this experience the Nuffield Foundation later established chairs of industrial health in Manchester and Newcastle, and a subdepartment under the professor of public health in Glasgow. The grants, which were to be spread over ten years, are beginning to run out, and the universities will soon have to decide what the future of these departments is to be.

The generous contributions of the Nuffield Foundation and the formation of a Social Medicine Research Unit by the Medical Research Council and of chairs of social medicine in the universities of Oxford, Edinburgh, Birmingham, and Sheffield were all signs of a progressive policy, inspired by the war, to promote research and teaching in social and industrial medicine. But the outlook to-day is not so bright as it was. The public health services are now in the doldrums and the expected development of industrial health services has not taken place. Consequently fewer doctors are taking the D.P.H. with the prospect of practising in this country, and the D.I.H. courses have ceased at Glasgow, Edinburgh, and Manchester. In fact very few university departments of social and industrial medicine can at present be justified by their postgraduate teaching, and with the need for economies in university expenditure on medical teaching and research these new departments may be the first to feel the knife. The Institute of Social Medicine at Oxford has already had its scope considerably reduced.

If cuts in expenditure are inevitable, then there is a case for spreading them out as fairly as possible. The place that departments of social medicine and industrial health should occupy in undergraduate training is far from unimportant: by teaching a discipline demanding a broad approach to the aetiology, prevention, and treatment of disease they can do much to counteract the effects of overspecialization. In this connexion it is surely significant that one of the four principal sections in this week's Conference on Medical Education was devoted to a consideration of the teaching of social and preventive medicine. In his contribution on the teaching of occupational health Professor A. J. Lanza, of New York University, described how the universities and medical schools in the U.S.A. are attempting to fit this relatively new subject into the curriculum.

The light burden of formal teaching, particularly in industrial health, gives departments of social and industrial medicine special opportunities for research: and it is only on the results of research that industrial health services, together with such teaching as there is, can be well founded. Professor R. C. Browne's report¹ of the first five years' work of the Newcastle department of industrial health shows the great opportunities which these departments could have for helping local industry, as well as advancing knowledge. The industrial area of Newcastle, with its large mining community and shipyards, has many serious industrial health hazards—such as miners' nystagmus, pneumoconiosis, and accidents—which Professor Browne and his colleagues have studied. They have also in the smaller industries investigated less serious problems such as dental erosion from tartaric acid dust and the toxicity of cadmium stearate used as a plastic stabilizer. These latter studies, which offer more hope of immediate results than those of miners' nystagmus and pneumoconiosis, can provide an excellent training in research methods for the less experienced; and they might well encourage local industries to support these departments financially. Although the Medical Research Council has at least ten units engaged principally in industrial health research, these have to serve national interests and cannot be expected to deal with the local needs of industry. But the universities, with a tradition for giving intellectual leadership to their communities, should be in a position to meet these needs, and they should not without careful thought cease their support for work which cannot or will not be done readily by anyone else.

The university departments, through their close contact with the medical schools, must attract those

who can be trained to do research. Failure and unsatisfactory results must be expected while the quest continues for new research methods, especially needed in the social and psychological studies of groups of industrial workers. Professor Aubrey Lewis² has mentioned the methodological difficulties of this type of work and emphasized that these researches still necessarily fall far short of the neatness and precision of a laboratory experiment in the physical sciences. The universities have a great chance, not apparently being taken by the Medical Research Council or the Factory Department of the Ministry of Labour, of initiating "operational" research, such as experimental industrial health services for groups of small factories. It is not yet known to what extent it is necessary, and practicable, to provide these services for the smaller workshops. If there is to be a comprehensive industrial health service it should be based on evidence and experience rather than on opinion and fantasy, and the sooner there are more of these experiments the sooner will industrial health services continue the development which started during the war and which has since largely lost its impetus. It would be most unfortunate if for economic reasons other departments of social and industrial medicine suffered the fate of the Oxford Institute of Social Medicine at a time when they can guide and encourage public and industrial health services in one of the most difficult periods of their history.

TRAINING IN METHODS OF RESEARCH

"The spirit of science is self-critical and self-corrective," said Dr. Chauncey D. Leake at the World Conference on Medical Education this week, and he might have said that the same spirit should imbue the practice of medicine. But how this spirit should best be set before undergraduate students is debatable. Nowhere are these qualities better exemplified than in experimentation. Yet everyone would agree with Dr. Gustav Nylin that "the introduction of an additional subject, 'Scientific Methods,' would be inexpedient," for such methods are better learnt by precept and practice than as a subject with its inevitable accompaniment of textbooks and mnemonics. But students might well be given some instruction in statistics, as Professor Bradford Hill suggested. This term, so forbidding at first sight to many people, shows a friendlier countenance when Professor Hill outlines what he has in mind as "a short elementary course . . . requiring no mathematical ability and designed to familiarize the students with statistical ideas and the most commonly used elementary methods." He would rightly add some instruction in the use of that great repository of national statistics collected by the Registrar-General. Dr. P. Bonnevie, supporting Professor Hill's ideas, added that in his opinion undergraduate medical education ought to

¹ First Quinquennial Report, Nuffield Department of Industrial Health, University of Durham.

² *Edinb. med. J.*, 1951, 48, 214.

be "statistically-minded throughout the whole curriculum." Perhaps the phrase hinted rather at special pleading, but many would agree with him if he meant that students should be taught, first, the importance of exact measurement and enumeration, and secondly how all measurements are, to a greater or less extent, at the mercy of chance. For the once immutable normal values and natural laws seem to have dissolved into unpretentious averages.

The benefits of some kind of research as a part of medical training were also to the fore in the lively conference¹ on the technique of medical teaching held earlier this year at the Postgraduate Medical School, London. Professor Rosenheim expressed the opinion that every registrar should be given a research problem, however simple, and he made the important point that a registrar seconded for research should not, if ultimately found unsuited to it as a career, feel that his time had been wasted; on the contrary, he should be enlightened and stimulated. The old argument about whether a teacher should hold his post by virtue of his impressiveness as a teacher or his brilliance as a research worker is relevant here, for it is not only registrars who will be refreshed by contact with research. Professor W. Melville Arnott was able to tell the World Conference this week that "one of the most vitalizing influences on medical education . . . has been the increasing emphasis on practical research experience" as a qualification for teaching. Imaginative lecturing is a delight and a benefit to students, but, if given in a medical school where research is apathetic or secluded, it is unlikely to implant in the students' minds that inquiring, sceptical, judicious enthusiasm for the science of medicine without which its art is pastiche.

As the techniques of scientific investigation have multiplied there has grown up a tendency to look on research as something rather remote from practical medicine, even esoteric. Yet, as Sir Cecil Wakeley² said last year: "The essence of clinical research is that it is carried out by a clinician," and the general practitioner "has far better opportunities for studying and recording the natural history of disease than any other man." He outlined various reasons, well known to family doctors, why any kind of scientific inquiry is often beyond them, and suggested remedies. And perhaps the newly founded College of General Practitioners will be able to provide them with just the help that many of them need to observe and record systematically the innumerable facts and problems of medicine at present escaping attention. In addition they—and indeed all clinicians—may soon look hopefully to the Clinical Research Board to be set up jointly by the Medical Research Council and the Government Health Departments.³ It is to provide funds and guidance for the investigation of clinical problems, and of these there are very many both common and pressing which, as Professor Robert Platt has pointed out,⁴ are entirely neglected—and incidentally he threw out many fertile ideas for research into them. Again, to the improvement of clinical science that such inquiry would bring must be added the pleasure of

carrying it out. If doctors are to remain something more than those signposts to hospital departments that some have complained of in recent years, a certain amount of training in the methods of research when students or housemen will help them to keep their vision fresh.

HUMOUR IN MEDICAL EDUCATION

The treasury of medical humour is richer and more often raided than that of any other profession. It is cynical, boisterous, only occasionally smug; it lies beyond the finger of prudery; its true standard of drollery is high, judged by the impact of jokes understandable to the general public; and it has the praiseworthy quality of rarely laughing at a patient but usually at the befogged doctor or student.

The trudge of the student towards qualification is lightened by this warm humanitarian humour as much as the path of Chaucer's pilgrims to Canterbury. The medical students in literature are rightly a pack of gay dogs—Roderick Random, Silly Barney, Jack Hopkins (with his remarkable case of the rattling child). Raskolnikov could never have been studying medicine. Humour flourishes in medical schools, most easily in the hot and arid climate of the lecture-room, where the mildest witticism is seized gratefully by students struggling against fierce gusts of information. The gay lecturer is remembered more easily and probably longer than his solemn colleague; a simple test for the former anatomy student is to recall the convolutions of the lingual nerve round Wharton's duct, and then try to remember structures lying in more proper relationship.

It is unnecessary to labour the value of humour in teaching, for the humourless man can never bring himself to crack a joke and the humorist finds his large, impressionable, and captive audience always irresistible. A few entertaining teachers possibly dilute their instruction with reminiscence instead of spicing it, and would be better if disciplined into a middle course—like Mr. Eric Linklater when he taught English literature. His classroom lay above that of his fierce senior, who swept angrily to the door, "a galleon under sable canvas," to complain either when Mr. Linklater's brilliance sprang a roar of laughter or when his flatness brought the students drumming on the floor with their feet.¹

Humour from the lectern depends largely on the character of the lecturer, some of whom build up a public personality as painstakingly as a politician. Former physicians beguiled their students into learning medicine with displays of cleverly controlled eccentricity, and surgery has been taught most effectively by the apparently bluff and ruthless operator. A uro-genital surgeon, now dead, characteristically began discussing a case of haematuria with the memorable cry, "A glass of bloody water, gentlemen!" And, when the surprising diagnosis was later made by his assistant exclaiming from the cystoscope that there was a clinical thermometer in the bladder, the dressers were impressed

for ever with the necessity of surgical calm by his snapping from the scrubbing-up basins, "Then what's the temperature?"

Modern medicine is becoming precise and prosy, and the "characters" that strode so largely down the stony Edwardian corridors have disappeared like E. F. Benson's pleasantly cranky Cambridge dons. Students now rarely force themselves to learn medicine by skilfully imitating their chief—down to his last gesture and aphorism—amid a delighted circle in the saloon bar. Some subjects still lend themselves irresistibly to lecture-room humour—obstetrics, for example, where the single-handed problems of birth may be stamped on the student's mind by presenting them in outlandish surroundings, so that he sees himself sharing a rowing-boat with a woman in labour, or galloping by camel to attend a tented delivery in the alarmingly under-doctored stretches of the Sahara.

The value of "audience participation" has long been sensed by good lecturers, for every class, like every squad of recruits, contains one "funny man" eager for distinction by becoming the lecturer's butt. "Tomkins will tell us," repeated whenever the whole class is shamefully baffled brings a laugh as surely as a B.B.C. comic's catch-phrase; but it is just and agreeable that Tomkins should sometimes score off his flagellator. A nervous lecturer may disregard his audience, as an edgy golfer is said to ignore his opponents in a championship. Another has only one joke, which is yearly relished by his students and is often all they remember of him for the rest of their lives.

Medical humour fortunately appears rarely in textbooks: writing humorously is a serious pursuit, and the amateur's jokes freeze and perish in the coldness of print. But the anecdotal footnote is an admirable tag for identifying a drab bundle of facts. It is no disrespect to Professor Samson Wright to remark on the number of readers of his textbook who can recall the scholar of the twenty-four privies, and the amorous management of the odour from the axillary sweat-glands.² An extended witty dissertation is a *tour de force*, and few medical writers are capable of it. A remarkable example is James Bridie's essay on the umbilicus, which Fellowship candidates or idler readers should seek out in a former issue of the *Journal*³ as an ideal of polished information and smooth medical humour.

INSURANCE HELPS

With income tax at its present level few doctors can afford to pay boarding-school fees for more than one child at a time out of their ordinary yearly earnings. In round figures it will be necessary to find about £1,500 per child during the public school period and a further substantial sum for the university or medical school years. If there are two or more children to educate at the same time then the family man must make an early decision on the style of education he desires for his children and on the measures he proposes to adopt in order to provide fees at the appropriate time. Many schools will take a lump sum in commutation of fees, and, broadly, if £100 per annum can be set aside from

the birth of the child to the age of entry into a public school the total so provided will be sufficient to meet the school fees.

Insurance companies have designed special educational policies to help parents, and these policies have the advantage of offering some relief from income tax. The policy is usually arranged on the life of the father, and thus school fees are secured even in the event of his death. A typical contract would provide £100 (or multiples thereof) per annum for five years, beginning when the child is 14, for an annual premium of £31, assuming the policy was effected at the birth of the child and the age of the father was 32. Tax relief on this premium at current levels would be £5 12s., making the net annual cost £25 8s. If the parents hope to send the child to a university, then the term of the policy can be lengthened as desired with a corresponding upward adjustment in cost. Another benefit which can be incorporated in an educational policy is a maintenance payment, if the father dies at an early age, until the school fees become payable.

Policies of this character go some way to meet the difficulties of paying for children's education, and there are other types which provide for the needs of the child in the more distant future. All such policies can be arranged to suit individual wishes, but it is always as well to seek expert advice—for instance, from the Medical Insurance Agency—when such a policy is under consideration.

COMMISSION IN THE ISLE OF MAN

The Isle of Man is well known as a holiday resort. One of its charms in this respect may be a local habit of mind which, when translated from the native Gaelic, means "time enough" or "to-morrow will do." That this outlook can also infect serious affairs less happily is evidenced by the story told in this week's *Supplement* on p. 83. A body, called a Commission, appointed by the Manx Government to consider an economic principle of some intricacy and with many attendant implications, seems to have set about its business with little appreciation of how to treat an important national association which asked to give evidence. The Secretary of the Association is to be congratulated on producing at such short notice the memorandum printed in the *Supplement*. It shows no signs of the hasty preparation that was forced upon him. It is to be hoped that it will assist the Commission in its responsibilities and will indicate to it that its deliberations are of more than just parochial importance.

We record with deep regret the death on August 23 of Professor René Sand, emeritus professor of social medicine in the University of Brussels. He was taken ill about ten days before the First World Conference on Medical Education began. The introductory remarks to the Section of Preventive and Social Medicine which Professor Sand was to have given on August 25 as one of the Vice-Presidents of the Conference are published elsewhere in this issue. Professor Sand's place as Vice-President was taken by Professor A. Stampar, of Zagreb.

FIRST WORLD CONFERENCE ON MEDICAL EDUCATION

OPENING CEREMONIES AND INAUGURAL SESSION

The First World Conference on Medical Education was opened at Friends House, London, on Monday, August 24, and continued for the ensuing five days. It was held under the auspices of the World Medical Association, in collaboration with the World Health Organization, the Council for International Organizations of the Medical Sciences, and the International Association of Universities. The international character of the event was illustrated by the programme of papers, whose authors came from 32 countries. The British Medical Association was the host organization. The general theme of the Conference was undergraduate medical education, and the subjects of the sectional discussions were: requirements for entry into medical schools; aims and content of the curriculum; techniques and methods of medical education; preventive and social medicine. The keynote addresses by the Vice-Presidents at each of the Section meetings are published elsewhere in this issue.

The President of the Conference was Sir Lionel Whitby, the Deputy President Professor W. Melville Arnott, and the Chairman of the Organizing Committee Dr. T. C. Routley, of Canada.

Sir LIONEL WHITBY, in opening the Conference, said that he was deeply conscious of the honour of presiding over so important an assembly. He expressed his great appreciation of the support given to the Conference by H.M. Government and by certain international organizations whose representatives would presently address them. More than 400 delegates from many countries were in attendance, and it was a great pleasure to the British Medical Association to be the host.

"We are out to try to discover how best to teach the young men and women who are going to be the doctors of the future. During this week teachers of medicine and educationists from all parts of the world will put forward their views not only on medical but on general education; they will discuss techniques of teaching as well as the extremely important social implications of medicine at the present day.

"Each session will have its rapporteur as well as its reporter, so that not only will the Conference be accurately reported but the value of each series of contributions made will be assessed."

Welcome by Ministry of Health

Miss P. HORNSBY-SMITH, M.P., Parliamentary Secretary to the Ministry of Health, conveyed a welcome on behalf of the Minister.

"The interest of the Ministry of Health in this Conference is paramount, since we are responsible in this country for the National Health Service, the quality and efficiency of which in its major sphere must depend in the last resort on the humanity, integrity, knowledge, and skill of the doctors working in it.

"I am glad to record that the National Health Service does to some extent repay the debt it owes to the universities and medical educationists by providing those clinical facilities which are an essential part of our training in this country and which are so necessary if students are to be taught in the British tradition. To this end the Ministry, through the Health Service, maintains the great teaching hospitals in London and the provinces. Many educational opportunities are also provided in non-teaching hospitals, which in great measure accept responsibility for newly qualified doctors in their pre-registration year. . . .

"Great and far-reaching changes have taken place in the art and science of medicine in our lifetime, many indeed within the last two decades. Many of the old methods by which students have been taught in the past are now out-of-date. In this country we have always specialized in practical bedside teaching, while others have laid greater stress on the academic approach. Yet both are now in difficulties with the accumulating mass of scientific fact and the multiplication of specialist technique. Many vital problems face you to-day, problems which cannot be shirked and which will in the ensuing days provide worthy exercise for the great minds here assembled."

Sir ANDREW DAVIDSON, Chief Medical Officer of the Department of Health for Scotland, after apologizing for the absence of the Secretary of State and conveying his good

wishes, said that a glance at the names on the conference programme, with the eminent medical teachers from so many countries, suggested that the success of the conference was already assured. They in Scotland were justly proud of their four university medical schools and their position in medical teaching and the high standard of their products. It had often been said that medical education was a Scottish national industry with a large and prosperous export trade. Between the two wars about one-third of all doctors who graduated in the United Kingdom received their education in Scotland, even though that country had only one-ninth of the total population.

"The World Medical Association and the World Health Organization, together with the B.M.A., are to be congratulated on their efforts to focus attention on what, after all, is the fundamental problem of health services everywhere. Their combined operation is timely; with the advance of medical science, the scope of medical education continues to widen. New subjects take shape and are added to an ever-expanding curriculum. The time has surely come to define more clearly the objectives of medical education and to adjust the curriculum to the attaining of those objectives. It may appear simple to add new subjects to the medical course, but may it not create recruitment difficulties if the already lengthy and arduous course becomes longer and more strenuous?"

At the present time the universities were changing over from a five-year to a six-year course, and after allowing for the pre-registration period and the two years of military service the young doctor had a very long time of training before he settled down to his career. Already there were signs of reduction in the number of applicants for admission to medical schools, though several years would be necessary to show whether the reduction was a temporary phenomenon or a significant trend.

Miss FLORENCE HORSBRUGH, M.P., Minister of Education, who could not be present, sent a message of good wishes.

Professor CHARLES HARRIS, as representing the University of London, joined in the welcome. He said that in London, in addition to the postgraduate institutes, there were 12 undergraduate schools, which gave them the opportunity of trying out a variety of methods in medical education. In London, for example, the study of pathology was carried out in the clinical years, whereas in Cambridge, from which university they drew many of their clinical students, the students had already spent a considerable period learning pathology and bacteriology. He said how grateful they were in London to those who had organized the conference and how anxious they were to profit by the results of their deliberations.

Welcome by British Medical Association

Dr. E. A. GREGG, Chairman of Council of the B.M.A., said how glad he was to associate his organization with these welcoming addresses. They of the B.M.A. had a very lively interest in the conference, not only because of the nature of the subjects discussed, but also because the germ of the conference was planted by Dr. Clegg, the Editor of the *British Medical Journal*, who first suggested to the World Medical Association that the subject was one which might well receive their attention. The result was that they found themselves that day embarking on this important and most useful conference. It was also a matter of gratification to find their Past-President, Sir Lionel Whitby, in the chair. The B.M.A. were not strangers to the subject of this conference. They had already done a great deal of work in this field, particularly through the committees presided over by Sir Henry Cohen.

Dr. DAG KNUTSON, Chairman of the Council of the World Medical Association, in joining in the welcome, said that this was a conference and not a congress. A conference was a meeting where those assembled tried to clarify their views

rather than to arrive at definite solutions. They were well aware that definite solutions of the problems of medical education could not be reached, but he hoped that at the end of the conference they would go away with a better understanding of each other's problems. The World Medical Association had not been alone in preparing for this conference, and he expressed gratitude to the two other international bodies already named which had collaborated, and also to the British Medical Association for its preparatory work.

Dr. M. G. CANDAU, Director-General of the World Health Organization, said that it was with special pleasure that his Organization came to this conference. There was no need to emphasize the importance of the problems to be discussed during the next few days. The physician must be aware of all the sciences which had their impact on medicine, but he must also be steeped in the cultures of his country and his time. In education more than in any other human endeavour it was vital to be responsive to new ideas. One of the most important ways was by making the experience gained in one country known to educationists in other lands.

Professor J. MAISIN, President of the Council for International Organizations of the Medical Sciences, also joined briefly in the welcome and said that he hoped the conference would form the corner-stone of a new edifice of medical education.

Professor S. C. ROBERTS, Vice-President of the International Association of Universities, said that his association was still in its first youth, but, as its name implied, it had a vital and genuine interest in all branches of education at university level, and among those branches one of the most important was, of course, that of medical education. He joined in offering his congratulations to those who had organized the conference.

Presidential Address

Sir LIONEL WHITBY then delivered his Presidential Address, which was entitled "The Challenge to Medical Education in the Second Half of the Twentieth Century." The address is published in full in the opening pages of this issue.

Dr. L. GARCIA TORNEL (Barcelona), in responding, said that the name of the President of the conference, Sir Lionel Whitby, was well known far beyond his own country. The university with which he was associated was also held in high honour. The name of Cambridge was a symbol of the triumph of the true university spirit. He could not enter in detail into the President's Address, but he wished to underline what Sir Lionel had said about the need for vocation in medicine and also in teaching. The task of the teacher was one of the most difficult in the world. It entailed sacrifice and responsibility. It was for the teacher to inspire and influence youth. If a career in medicine were undertaken without any true vocation it would be disastrous. In conclusion he paid a warm tribute to the British medical profession.

What is Education?

The first of three addresses given during the Monday afternoon session, all of them published elsewhere in this issue, was by Sir RICHARD LIVINGSTONE, formerly President of Corpus Christi College, Oxford, who took as his title "What is Education?" (p. 454).

The response was made by Dr. M. POUMAILLOUX, counsellor of the Federation of French Medical Syndicates. He said that Sir Richard Livingstone had expressed certain ideas which were dear to himself. Much had been said about the reform of medical studies with which they were concerned to-day. There was one point on which they had been able to achieve virtual unanimity—namely, the necessity of pursuing classical studies. Perhaps these studies were more necessary to-day than formerly, when the "superstition" of technical studies distorted the situation more than was often realized.

The problems they had to meet were more and more difficult. Such was the growing complexity of the profes-

sion that it was virtually impossible to give a young man a sufficient education in all the branches of medicine. Speaking as a teacher, he felt that students were not interested in the details of the curriculum but in the major aims which governed the study.

What were the aims of young people? Why had they chosen the medical profession? Were they disappointed on their first contact with medicine or their patients? The choice of career was made very often as a result of the trust and confidence a student had in his teacher. Young people to-day had hearts as warm and enthusiasms as fervent as in earlier generations, but materially and economically they or their parents were encountering greater difficulty.

The aim of medical studies must be to enable the doctor to treat his patients. To this end the fundamental studies must be pathology and therapy. Medicine must be learnt at the bedside of the patient. It could not be wholly learnt at hospital. What did they learn at hospital of the living conditions of their patients? All those upon whom fell the call and the responsibility of caring for patients should be people whose heart and soul were as highly developed as their intelligence. Therefore those young people whose heart and soul would never be equal to their task should be eliminated from the medical schools.

Finally, while an effort should be made to harmonize curricula, any overall uniform method must be avoided. Each country had its different characteristics and needs. "We should not try in any way to create physicians who will be the same everywhere, for such would be considered excellent in some countries and deplored in others."

The History of Medical Education

The second address was by Professor JOHN F. FULTON, Sterling Professor of the History of Medicine at Yale, whose subject was "The History of Medical Education" (p. 457). The response was by Professor A. SPINELLI, senior surgeon, United Hospitals, University of Rome, who spoke appreciatively of Professor Fulton's account of Salerno—a school which inspired scholars for centuries after its foundation—and the schools of Paris and Montpellier, of Bologna, Ferrara, and Pisa, the various schools in Germany, Switzerland, and Denmark, and Oxford and Cambridge in England. Oxford and Cambridge had brought English culture to a very high level, and he spoke of the pleasure with which members of the Conference had visited Cambridge on the previous day.

Medicine—Technology or Profession

Colonel S. M. K. MALLICK, Principal of the Dow Medical College and Civil Hospital, Karachi, gave the final address, on "Medicine—a Technology or a Profession" (p. 461).

Dr. T. C. ROUTLEY, general secretary of the Canadian Medical Association, made the response. He stated that he had recently sent a questionnaire to 200 Canadian doctors on whether medicine was a technology or a profession, and of the 153 who had replied 151 had insisted that it was a profession, while two stated that as practised to-day it was more and more degrading itself into a technology. He quoted some of the comments received in reply to the questionnaire: "Technology completely lacks the comprehension of the doctor-patient relationship." "Medicine is not an exact science, therefore it can never be described as a technology." "If we do not insist on science being a secondary and ancillary service to the art of medicine we shall let a great profession down." "A patient requires more than technology—kindness, sympathy, understanding, human interest."

A great responsibility, said Dr. Routley in conclusion, rested upon the profession of medicine to maintain the professional position which the practitioners of medicine must for ever occupy.

On the second day, August 25, the Conference met in four Sections. The proceedings of the first day of the sectional meetings are reported in the following pages.

PROCEEDINGS OF THE SECTIONS

SECTION A: REQUIREMENTS FOR ENTRY INTO MEDICAL SCHOOLS

After the keynote address from the chair by the Vice-President, Dr. VICTOR JOHNSON (United States), this section discussed the requirements for entry into medical schools.

General Education in an Age of Science

Mr. T. E. B. HOWARTH (Winchester College), opening the discussion, said that we in this country were committed to a system involving a high degree of early specialization and the educational segregation of the more intelligent children. It came as a shock to some other countries that an English schoolboy started on intensive preparation for the medical profession as early as 15 or 16. Not more than a quarter of his school studies would be devoted to subjects other than biology, physics, chemistry, and mathematics.

The general education of the scientist should include as much guidance on the human situation as was possible and a realization of the fact that man was a religious being. Right in the forefront of the young scientist's general education should be placed a study of man's striving towards God. The young scientist might not believe in the religious or philosophical system he was studying, but he would at any rate learn why many other people did so.

Dr. CHAUNCEY D. LEAKE (University of Texas) discussed the general education of the medical student. The future doctor should know some mathematics and physics. As for chemistry, he should understand the principles of quantitative and organic analysis and synthesis, and physical chemistry. To this hard core it would be wise to add some training in psychology. The future doctor should know something of the history of science and have an appreciation of the principles of economics. Finally, some exercise in the various fine arts greatly assisted in maturing taste and judgment.

Dr. T. B. DAVIE (University of Capetown) said that students would not attend courses of lectures designed to improve their cultural background.

Dr. HOWARD BERK (U.S.A.), Dr. ST. GEORGE B. DELISLE GRAY (United Kingdom), Dr. P. GLORIEUX (Belgium), Professor J. G. ORCOYEN (University of Madrid), and Professor FELIX HURTADO (Cuba) also spoke.

The Doctor a Humanist

Professor A. SANDOZ (France) urged that it should be remembered that the work of the future doctor would not be limited to the study of physiological functions and biological reactions, but would bear on the whole man, mental and spiritual as well as physical. A doctor was necessarily a humanist; if this were not so he would be no more than a veterinarian.

Dr. ALAN VALENTINE (U.S.A.) declared that unless scientists, and especially medical scientists, proclaimed the value of human culture and human self-realization, there might come to be no real general education in this age of science.

Dr. MOGENS PIHL (Denmark) spoke of the teaching in secondary schools. In his country they believed that too much specialization before the university was a bad thing. The secondary schools in Denmark had a modern, a classical, and a science side, all of them qualifying for the study of medicine. It was an advantage if the medical student had attended the science side, but such pre-training was not necessary.

Mr. J. L. STRUTHERS, a medical student from St. Bartholomew's Hospital, hoped that students would be given instruction in writing and speaking their own language.

Mr. S. A. BARNETT (University of Glasgow), Dr. THOMAS STAPLETON (St. Mary's Hospital Medical School), Professor D. E. CAMERON (McGill University), and Dr. G. MOUTHON (France) also took part in the discussion.

Methods of Selection in United States

Dr. DONALD G. ANDERSON (American Medical Association) described the system for selecting students for admission to medical schools in the United States. The basic structure of education consisted of eight years of elementary school, four years of high school, and four years of college. At the end of this period the successful student was awarded the B.A. or B.Sc. degree. In medicine, three years of college work was the minimum preparation on which a student might enter the medical school. The length of the medical school course was four years. The total number of students in the United States applying for admission to medical schools in any one year was now slightly more than twice the total number of places available.

Dr. M. PRYVES (Hebrew University, Jerusalem) said that a new arrangement at the Hebrew University was the establishment of a special class of one to two years' duration in the framework of the university to which candidates in medicine, dentistry, pharmacy, and biology would be freely admitted. The curriculum would be composed of subjects in the sciences and the humanities in a balanced form.

Mr. D. H. PATEY (Middlesex Hospital) said that the highest form of selection for any medical student was to be a woman and to get into Oxford or Cambridge. These women were intellectually the cream of the country from the point of view of selection. His impression was, however, that they were a good average, not, as he would have expected, outstanding. Here was an opportunity to test a fine sieve of selection against the end-result.

Dr. J. C. VILLAGRANA (Mexico), Dr. P. GLORIEUX (Belgium), Dr. FELIX HURTADO (Cuba), and Dr. S. C. SEN (India) also took part in the discussion.

Competition for Entry

Professor A. P. THOMSON (Birmingham University) maintained strongly that medicine was in itself a humane study. He said that a selection committee should vary in personnel—if one had a fixed committee one got a fixed type of student. He felt that a knowledge of mathematics, and at an advanced level, was necessary for the medical student. To-day any student who succeeded in obtaining a place in a university on the ground of his talents might usually rely on a grant from public funds to meet a substantial part of the cost of his fees and maintenance. As a result, in his own faculty during the last seven years they had never received fewer than 2,000 applications a year for about 100 places.

Professor Thomson said that in present conditions it was difficult to find a place in university medical schools for candidates who had acquired distinction in other directions before they were attracted to medicine. It was perilously near heresy for him as a member of the General Medical Council to suggest that first-class honours graduates in mathematics or philosophy might be admitted as medical students on special terms. Nevertheless, in his own judgment, the regulations were too rigid.

Professor A. SPINELLI (Italy) said that in Italy they considered children studied too much Latin and Greek and too little chemistry and physics. They believed that selection should take place in the secondary schools on the results of teachers' and school doctors' reports and tests.

Dr. MYRON E. WEGMAN (Director, Division of Education and Training, Pan-American Sanitary Bureau) said that the requirements had to be judged in terms of the primary education in a country.

Professor ORCOYEN (Madrid) reported that a selective course for those seeking to study medicine, pharmacy, etc., had reduced the number of candidates for medicine by 50%, and increased the numbers of those who entered the Faculty of Law.

The discussion was continued by Dr. M. POUMAILLOUX (France), Dr. T. B. DAVIE (South Africa), Professor HANS NEUFFER (Germany), and Dr. L. G. TORNEL (Spain).

SECTION B: AIMS AND CONTENT OF THE MEDICAL CURRICULUM

After the keynote address from the chair by the Vice-President, Sir A. L. MUDALIAR, this section discussed the aims and content of the curriculum.

The Teaching of Anatomy

Sir CECIL WAKELEY (President of the Royal College of Surgeons) said that the only way of learning human anatomy was by careful dissection of the whole body, but this could rarely be attained because of the shortage of subjects for dissection and the large number of students in the schools. The ordinary practising doctor did not require to have a detailed knowledge of the human body, but it was absolutely essential that the surgeon to-day, more than ever before, should have an intimate knowledge of anatomy. It was for the Government to see that an adequate number of cadavers were forthcoming. Those who specialized in surgery must take a course in basic medical sciences before they sat for the Primary Fellowship of any of the Royal Colleges. During this science course the student should dissect or take part in dissecting the whole of the body.

Professor NILO PESONEN (Finland) thought that even the best demonstration preparations could not replace the benefit derived from the dissection of specimens by the student himself.

Dr. J. V. BASMAJIAN (Canada), Professor M. TALAAT (Egypt), Professor W. GREULICH (U.S.A.), and Dr. J. W. PATTERSON (U.S.A.) took part in the discussion.

The Teaching of Physiology

Professor W. J. E. JESSOP (Royal College of Surgeons in Ireland) said that the problem of designing a general course in physiology could only be solved by close co-operation between the professor of physiology and those responsible for shaping the courses in the related special subjects. A good general course in physiology must stress principles rather than details, encourage reasoning and criticism rather than memorizing facts, and arouse the student's interest.

Professor HAROLD SCARBOROUGH (University of Wales) said that medicine was a scientific discipline and medical education should be an exercise in the application of the scientific method. That had to be emphasized at a time when it was beginning to be suggested that more of students' time should be devoted to training in the social sciences and even occupied at an early stage with visits to patients' homes.

Professor M. TALAAT (Egypt) and Professor J. N. P. DAVIES (Uganda) also spoke.

Integration of Physiology and Anatomy

Professor S. ZUCKERMAN and Professor H. P. GILDING (University of Birmingham) gave a paper on the integration of physiology and anatomy as a single subject in the medical curriculum. In arranging this integration at Birmingham, they had, wherever possible, eliminated courses of lectures which were either purely anatomical or purely physiological. The time devoted to the dissection of the body had been reduced to three terms instead of the original five. Under the Birmingham system the second M.B. examination was divided into two parts, the first of which was taken at the end of the first three terms and comprised macroscopic and microscopic anatomy. The second part of the examination was taken at the end of the fifth term and was mainly concerned with physiological and biochemical matters.

Dr. P. HAGEN (Australia) said that he did not think there were any preclinical teachers not prepared to agree that some measure of integration of the two subjects was desirable.

Professor LUANG B. BIDYABHED (Thailand) and Professor W. J. E. JESSOP (Ireland) spoke in agreement.

Pathology: The Basic Clinical Science

Professor J. H. BIGGART (Queen's University of Belfast) said that many schools were convinced of the value of an introductory course in clinical medicine and surgery when

the student first entered hospital. During this period, which, he thought, should be of six months' duration, the student should have courses in bacteriology and general pathology. Then should come a course in special pathology. The student should witness the examination of the patient and the study of his disease by a number of specialists, each of whom brought to the problem his own particular methods and knowledge. Three terms of such a combined integrated course should suffice to cover special pathology, medicine, surgery, and therapeutics, a great deal of paediatrics, and social medicine.

Professor H. SIEGMUND (W. Germany) said that pathology should be taught in such a way that it gave a scientific background to the practice of medicine. Dr. H. G. WEISKOTTEN (U.S.A.) and Dr. ROBERT A. MOORE (U.S.A.) both stressed the importance of students carrying out experimental work, and Dr. D. N. BARON (Middlesex Hospital) also spoke during the discussion.

Pharmacology and the new Therapeutics

Professor E. J. WAYNE (Sheffield University) described the course in pharmacology and therapeutics as it had gradually evolved at Sheffield. Immediately after the second M.B. examination in physiology and anatomy, a short introductory course of 10 lectures in pharmacology was given so that the student might understand the relationship of the subject to his previous studies and know something about the drugs which he is beginning to see in use in the wards. This was followed by lectures in pharmacology during five terms. After a year's interlude, he attended a course in therapeutics in which the subject was considered from a practical point of view. A special feature was the criticism of advertisements in the current medical journals, which students undertook themselves in front of their colleagues. The prescriptions in the *National Formulary* were also rigorously criticized and students were asked to suggest improvements.

Dr. SUPHI ARTUNKAL (Turkey) told how pharmacology and therapeutics were taught in Istanbul. The two departments were in the hands of the same professor and the subjects were taught for approximately 70 hours each, during the same period. The courses took place in the theatre of the therapeutic clinic, which had a capacity of 75 beds and an out-patient department.

Professor CHAUNCEY D. LEAKE (U.S.A.) said that the subject of pharmacology had become one of vast confusion because of the enormous flood of new drugs. It might help if drugs were classified on the basis of their four primary uses—for diagnosis, prevention of disease, cure, and the alleviation of disease.

Medical Statistics

Professor A. BRADFORD HILL (London School of Hygiene and Tropical Medicine) said that the only teaching of statistical methods necessary in the medical curriculum for the embryo doctor was a short elementary course requiring no mathematical ability and designed to familiarize students with statistical ideas and the most commonly used elementary methods. He desired to see the undergraduate taught to weigh figures critically, and not to accept them without thought at their face value, how to look carefully for possible bias in a given set of data, and how far in any instance it was reasonable to pass from the particular to the general. This syllabus could be put into not more than 10 lectures accompanied by some practical work.

SECTION C: TECHNIQUES AND METHODS OF MEDICAL EDUCATION

After the keynote address from the chair by the Vice-President, Professor A. HURTADO (Peru), this section discussed the techniques and methods of medical education.

Hospital Bedside Teaching

Professor L. A. HULST (University of Amsterdam) said that the very fact that there were diseases and patients

whom it was better to treat elsewhere than in hospital showed that the medical pattern in a hospital differed from that which the student would find in general practice. The intending general practitioner was trained mainly in diseases which he would not treat and might rarely see. Hospital teaching was not only one-sided in this respect but also it confronted the student with entirely different patients. Professor Hulst further insisted that the hospital bedside teaching of medicine should be concerned with only those patients who were properly in a hospital bed and not with patients who required rest in bed in order to recover.

Dr. STANLEY DORST (University of Cincinnati) believed that the teaching hospital must have a cross-section of clinical medicine. The chief of the department of medicine should be in charge, with clinical teachers available in the proportion of one to seven or eight patients. These requirements were fulfilled in most American schools. He insisted on the importance of ward rounds, followed by a seminar led by the physician but with the whole group participating.

Dr. M. POUMAILLOUX (France) thought that the undergraduate should not wait unduly long before examining the patient at the bedside. If he kept to the technical side of medicine for too long he would see his patient only as an interesting case. Dr. VICTOR SORIANO (Uruguay), Dr. HANS NEUFFER (President, West German Medical Association), Professor A. J. CRAIG (Malta), Dr. E. HUSFELDT (Denmark), Dr. DAG KNUTSON (Sweden), and Professor M. MULLER (Lille) also spoke.

Teaching in the Operating Theatre

Professor Sir GEOFFREY JEFFERSON (Manchester University), in an address on the importance of bedside learning, discussed teaching in the operating theatre. Attendance of the student dressers *en masse* at operating sessions was stupid, but the student whose case it was should be present. He must learn at close quarters. The surgeon could refresh the student's anatomy and demonstrate the pathology of the condition. Few teachers did this very well.

Sir Geoffrey Jefferson added: "It was only when I began to operate myself that I knew what it was that I wanted to know."

Mr. H. D. MOORE (Leeds) said that he had noticed that as a specialty became divided from general surgery the scope of cases became more and more limited and the student lost a great deal. This applied particularly to thoracic surgery. Dr. HANS NEUFFER (West Germany) said that every student should undertake three months' nursing. Dr. P. VALDONI (Italy) sent a written communication.

The Out-patient Department

Dr. DAG KNUTSON (Karolinska Hospital, Sweden) spoke of the use of the out-patient department or polyclinic for educational purposes. The cases at a polyclinic were different from those in the wards—generally of a less serious nature. Patients came demanding a quick answer, and decisions had to be made swiftly. Polyclinics, therefore, gave the student new and useful experiences.

Professor HERMANN CHIARI (University of Vienna) said that in the polyclinic the diagnosis should be made in as uncomplicated a manner as possible. Mr. M. R. EWING (London) said that many of the inadequacies of surgical treatment were made manifest when patients were followed up in the out-patient clinic. Dr. VICTOR SORIANO (Uruguay) and Professor G. A. RANSOME (Malaya) also contributed to the discussion.

Teaching in the Home

Professor KINLOCH NELSON (Richmond, Virginia, U.S.A.) described how the Medical College of Virginia joined up with the city health department to provide medical care for the indigent through a continuity of service between home, clinic, and hospital.

Dr. JOHN HUNT (honorary secretary, College of General Practitioners) said that an important addition to medical

education during the next twenty years would be an introduction of all medical students to family doctoring by general practitioners. It was the exception for the undergraduate to see a general practitioner at work.

Dr. F. M. ROSE (Preston) said that teaching of medical students in the home would help not only the future general practitioner but also the budding specialists.

Dr. G. O. BARBER (United Kingdom) said that he hoped some young students on contact with general practice would feel discontented and would aspire to a higher standard.

Dr. J. A. PRIDHAM (chairman of the Medical Education Committee of the W.M.A.) considered that, just as students were trained in dermatology, internal medicine, and the like, so they should be taught that general practice could fully engage their mind and heart.

Dr. ST. GEORGE B. DELISLE GRAY (United Kingdom) said that many young specialists to-day knew nothing about general practice. Dr. E. M. DIMOCK (University College Hospital) said that many people found general practice difficult because it introduced tasks of which they had little experience, and they were dispirited. Dr. A. TALBOT ROGERS (United Kingdom) described the working of the trainee-assistant scheme in this country. The scheme was working well. Professor IAN AIRD (Postgraduate Medical School) said that many specialists he knew were great men and yet had had no experience of general practice. If they had been tempted into that field the world might have been deprived of their special gifts.

The Clinico-pathological Conference

Dr. BENJAMIN CASTLEMAN (Massachusetts General Hospital) described the clinico-pathological conference—a teaching exercise utilizing the specific case history of a patient, the nature of whose disease has been established either by surgery or necropsy. A selected person or the whole group analyses the case and a diagnosis is made on the basis of the analysis. The weekly conferences at the Massachusetts General Hospital for the staff and senior students are conducted by the pathologists, with occasional suggestions from the clinical staff. The pathology resident officer who examined the specimen or did the necropsy prepares the clinical abstract, and the "discusser," who analyses the case and explains and interprets the meaning of the signs, symptoms, and findings, is one who has no knowledge of the patient. The conferences bring out clinical details and clinico-pathological correlations not found in textbooks.

The discussion was continued by Professor G. A. ELLIOTT (University of Witwatersrand), Professor A. GARRETTON-SILVA (Chile), Professor VICTOR SORIANO (Uruguay), and Professor A. HURTADO (Peru).

The Laboratory in Teaching

Dr. J. W. PATTERSON (Western Reserve University, Cleveland) described a new teaching programme at his medical school. The first year of the programme dealt with normal structure, function, growth, and behaviour, and the patient-physician relationship. The next two years was concerned with deviations from the normal and with the introduction of the student to disease. The third phase was a review of the basic material at the bedside and the care of patients. During the second six months of the first year on one day each week the students, working individually or in small groups, were expected to complete a simple problem, survey the literature related to it, organize an experimental test, evaluate the findings, and present the results to their colleagues.

Professor L. P. GARROD (St. Bartholomew's Hospital) said it should not be forgotten that no amount of planning or integration could take the place of the acquisition of factual knowledge. In pathology and bacteriology students should be given every opportunity to do as much practical work as possible.

Dr. F. JEAN VINTER, secretary of the Universities Federation for Animal Welfare, and Dr. HARRY LILLIE, of Dundee, also spoke.

SECTION D: PREVENTIVE AND SOCIAL MEDICINE

Before the section began discussing the teaching of preventive and social medicine, Professor A. STAMPAR (Zagreb), a Vice-President of the Conference, spoke from the chair. After describing developments which had led to international collaboration in the field of medical education, he said that preventive and social medicine still did not find a proper place in the curriculum of many medical schools, but they had an opportunity to discuss it at the Conference, and to try to find a solution to the problems involved.

The news of the death of Professor René Sand was received with much sorrow during the morning session. The chairman paid a tribute to Professor Sand, and the company stood for a minute in silence.

Present Status

Professor-emeritus H. PÉQUIGNOT (Paris) gave an account of the instruction given in French faculties of medicine in hygiene and in preventive and social medicine. He said that traces of such instruction in the faculties of medicine were to be found even in the period before the Revolution, and during the nineteenth century chairs of hygiene were established. In a number of the faculties there existed side by side with the chair of hygiene special chairs in industrial health, sometimes associated with forensic medicine. Preventive and social medicine did not now constitute a separate specialty; it was rather a new dimension of all medicine and of all medical work.

Professor WILSON G. SMILLIE (Cornell University) said that all great physicians had fully recognized that medicine was a social science and an essential community service. Preventive medicine must be taught, as curative medicine was taught, at the bedside, in the clinic, and in the home. At Cornell University each student was assigned to one family which he followed throughout a year, and it was his duty to study their way of life; he had an adviser with whom he discussed all special matters.

Professor A. LESLIE BANKS (University of Cambridge) said that as long ago as 1868 the Board of Medical Studies at Cambridge recommended to the Vice-Chancellor that one of the four topics to be submitted to the candidate for his M.D. thesis should be State medicine. Since that period, and indeed within our own lifetime, the outlook had changed completely. The State had swung from an attitude of *laissez-faire* to an intense interest in the personal health and welfare of the individual. The research worker, clinician, and specialist in preventive medicine had so extended their spheres that they now overlapped. In spite of differences between the various schools, the teaching of public health in Great Britain had now been replaced by the wider concept of social and preventive medicine.

Professor J. H. TUNTLE (University of Groningen) thought that it was inevitable that a great deal of curative practice would go permanently to specialists, but ample compensation for this loss might be found in the field of social medicine and in that of scientific investigation. The integration of social medicine with the undergraduate teaching of clinical and laboratory medicine was a *sine qua non* if the family doctor was to be preserved from extinction.

Professor EDWARD GRZEGORZEWSKI (W.H.O.) thought that, looking at medical education from an international observation point, it was obvious that the trend towards preventive and social aspects of medicine was almost universal. In face of inherent conservatism, medical schools were slowly accepting the idea, and this must be followed by practical measures.

The Teaching of Preventive Medicine

Professor G. A. CANAPERIA (High Commission for Hygiene and Public Health, Rome) gave a brief description of the teaching of preventive and social medicine in Italy. Hygiene was taught to Italian medical students during the fifth of their six years of study, but by this stage the mentality of the student had already turned to therapeutic medicine, and

when finally faced with the discipline of social medicine he was already too much accustomed to the consideration of individuals only from the clinical point of view.

Professor G. E. HOBBS (University of Western Ontario) said that the level of health development in Canada was so high that the content of teaching in prevention must be different from what it was in areas which had not reached this level. The schools in the Dominion presented the wide variety of conceptions which were to be found in any area where traditionally health control had passed to a stage of maintenance, and where the classical preventable diseases were no longer major health problems.

Dr. G. O. BARBER (United Kingdom), Dr. J. L. TROUPIN (W.H.O.), Professor ALAN M. CRITCHLEY (Iraq), Professor FELIX HURTADO (Cuba), Dr. E. M. DIMOCK (United Kingdom), and Professor THOMAS FRANCIS (Michigan) took part in the discussion.

Social Medicine as an Academic Discipline

Professor T. MCKEOWN (University of Birmingham) first discussed the advantages which the use of experimental animals offered to the research worker. These included the use of pure stock—which made it possible to establish certain laws of inheritance—the control of environment, and the use of large numbers. The only serious disadvantage was uncertainty about the applicability of results obtained in the laboratory to man. He went on to say that there was a large class of problems appropriate to biological inquiry in which it seemed inconceivable that advance could be made by mere statistical methods unless the people using them were primarily biologists who turned to the collection of human data as an alternative to laboratory investigation. The task of assembling good data on man was one to which the department of preventive and social medicine should direct its attention.

Professor A. STAMPAR (Yugoslavia) gave his definition of social medicine as a "science dealing on the one hand with mutual relations between social and economic conditions in the health of individuals and groups and on the other hand with measures of medical and social care for preventing disease and promoting health." The teacher of social medicine should be on equal footing with the holders of other chairs in the medical faculties.

Social Medicine in the Curriculum

Professor F. A. E. CREW (University of Edinburgh) said that the role of social medicine in the curriculum was to enable the student to acquaint himself with: (1) the human family, its biological significance and social function; (2) the social function of medicine; (3) the existing machinery of medicine in a selected country; (4) the diseases of major social importance in the selected country; and (5) the inter-relationship of medicine and statecraft in the field of human ecology.

Dr. G. W. GALE (South Africa) drew a comparison between social aspects of medicine in the so-called underdeveloped countries and in the more highly organized communities. He then went on to describe the recently established medical school at Durban, where primarily Africans and other non-Europeans received training. It was proposed to make use of several health centres in the teaching of social medicine.

Dr. W. P. DEARING (U.S.A.) said that no system of medical science and thought in the world to-day could claim the capacity to solve all health problems; some diseases of world-wide prevalence, such as malaria and enteric infections, could not be dealt with effectively without the application of engineering and sanitary science. Others, such as the nutritional deficiency diseases, could not be dealt with effectively without attention to economic and social conditions.

Dr. ROBERT SUTHERLAND (Leeds University) said that before a medical student went on to study clinical medicine he should study preventive medicine. Throughout his study detail should be subordinate to an understanding of the whole man.

THE ENROLMENT IN MEDICINE

Increase in Registrations

The total number of names in the current *Medical Register* is 83,914, an increase of 1,658 over the corresponding figure on January 1, 1952. The number is higher by 6,343 than the average for the last 10 years, and higher by 15,248 than the average for the last 20 years. In 1933 the total number on the *Register* was 56,741. The number added by registration in 1952 (4,493) was the highest on record, having been greatly increased by Commonwealth registrations, which numbered 1,452, three times as many as the year before. As against this there were in 1952 an unusually large number of removals under section 14 of the Act of 1858—the section which prescribes that names shall be removed after a stipulated period in the absence of any answer to the inquiry whether there has been cessation of practice or change of address. The number removed under the penal sections of the Act is no greater than it was 20 years ago, though in the meantime the total on the *Register* has increased by 40%.

Of the persons whose names were added to the *Register* in 1952 1,848 of their registrations were in England, 673 in Scotland, and 506 in Ireland. The following Table gives the position of the *Register* at the end of each of the last 10 years:

Year	Registration	Added by Restoration	Death or Removal	Total
1943	3,532	13	1,091	71,882
1944	2,971	11	1,218	73,646
1945	2,666	11	1,190	75,133
1946	2,237	14	1,092	76,292
1947	2,787	10	1,160	77,929
1948	3,968	16	5,621	76,292
1949	3,109	19	1,280	78,140
1950	3,160	45	1,123	80,222
1951	3,075	29	1,070	82,256
1952	4,493	46	2,881	83,914

The unusual removal figures for 1948 were due to removals from the temporary list following the passage of the Medical Practitioners and Pharmacists Act of the previous year and the transference of many of the names to the permanent list.

The Student Entry

The total number of students beginning the medical curriculum proper during the year 1952-3 is estimated—the returns from some of the schools are not complete—at 2,512, which is about 50 fewer than the previous year. The annual entry during the last seven years has been between 2,500 and 2,700. During the early years of this century, up to the time of the first world war, the annual entry of students was about 1,400.

The training of medical students is shared between the teaching hospitals and the universities. In London the 12 undergraduate teaching hospitals, and in England and Wales, apart from London, the 10 teaching-hospital centres in association with the universities, have been designated as teaching centres. In Scotland hospitals are not designated as teaching hospitals; all of them come under the jurisdiction of the five regional hospital boards, but provision is made for inclusion on the boards of management of nominees of the university on which the region is centred. In Northern Ireland the duty is laid upon the hospitals authority—a body corporate—to provide the Queen's University, Belfast, with adequate facilities for medical teaching.

Provisional Registration

Under the Medical Act, 1950, full registration is not granted without proof of experience—namely, a certificate that the applicant has been engaged in employment in a resident medical capacity in one or more approved hospitals or institutions (including an approved health centre) for the period prescribed by the regulations of the General Medical Council. January 1, 1953, was appointed as the day after which a newly qualified person would not be eligible for full registration unless and until he had, after passing his qualifying examination, served as house-officer in one or more such approved hospitals or institutions for 12 months.

The proposed form of certificate to be given by hospital authorities for submission to the licensing bodies when a provisionally registered practitioner has satisfactorily completed a period of employment as house-officer has been circulated to licensing bodies, examining boards, and medical schools for their observations, and is as follows:

It is hereby certified that.....of.....has been employed as shown below in a resident medical capacity (as defined in section 2 of the Medical Act, 1950) in the under-mentioned approved hospital or institution for the period specified, and that his service while so employed has been certified by a member of the consultant or specialist staff as satisfactory.

Note: the signature below should be that of an officer of the board of governors, hospital management committee, or other employing body authorized to act in this behalf.

Title of hospital or institution.....
Description of post(s).....
Periods of employment: from.....to.....
Signed.....Official position.....Date.....

The suggested form of certificate of experience to be given by licensing bodies in support of an application for full registration is as follows:

Under subsection (2) of section 2 of the Medical Act, 1950, it is hereby certified that the.....(University or other Corporation) are satisfied:

(1) That.....has, after passing a qualifying examination, been engaged in employment in a resident medical capacity in one or more approved hospitals or approved institutions as defined in the Act for a period of not less than 12 months—namely, months;

(2) That during the said period the applicant has been engaged in medicine for a period of not less than six months—namely, months;

(3) That during the said period the applicant has been engaged in surgery for a period of not less than six months—namely, months.

(4) That any time spent in midwifery which has been counted for the purpose of the foregoing paragraphs (2) and (3) as time spent in medicine or as time spent in surgery is a period not exceeding six months—namely, months.

(5) That any period of employment in a health centre which has been reckoned towards the completion of the periods in medicine and in surgery is a period not exceeding six months—namely, months.

(6) That the service of the applicant while so employed has been satisfactory.

Signed.....Official position.....Date.....

The certificate has to be signed by an authorized officer of the university or corporation granting the qualifying diploma by virtue of which the applicant claims registration.

The General Medical Council has expressed itself satisfied that the compulsory internship schemes adopted in New Zealand and in the Union of South Africa may be regarded as substantially equivalent to the United Kingdom scheme for the purpose of ensuring that newly qualified practitioners shall acquire, as a condition of full registration, such experience as is specified in the Medical Act, 1950. Accordingly full registration is given to practitioners who have been registered in New Zealand or in South Africa after rendering appropriate service under the compulsory internship scheme in operation in the country concerned.

The Council has set up a committee, consisting of the president (Sir David Campbell), Sir Henry Cohen, Dr. H. G. Dain, and Sir Cecil Wakeley, to consider and determine applications for the registration of Commonwealth and foreign practitioners which are not determinable under its general resolution.

Fees for Registration

The fees payable to the General Medical Council for registration under the Medical Acts are £5 5s. on provisional registration, and on full registration in the case of a person already provisionally registered, £6 6s., or in the case of any other person, £11 11s. Any person registered by virtue of section 7 of the Medical Practitioners Act, 1951, of the Republic of Ireland pays no fee on provisional registration, and pays a fee of £6 6s. on full registration.

On temporary registration by virtue of section 8 of the Medical Practitioners and Pharmacists Act, 1947, for a period of six months or less the registration fee is £2 2s.; for any period between 6 and 18 months, £5 5s.; and over 18 months, £11 11s.

On the insertion in the *Register* of any higher degree or additional qualification or of an additional recognized Commonwealth or foreign diploma, a fee of £1 is paid, and a fee of £2 on the entry of a recognized diploma in public health, sanitary science, or State medicine. The fee for restoration to the *Register* after erasure under section 14 of the Medical Act is £1.

The address of the General Medical Council is 44, Hallam Street, London, W.1.

UNDERGRADUATE EDUCATION

The Provisional Year

The year 1953 has seen the introduction of the pre-registration year as required by the Medical Act, 1950. The general testimony of the schools is that the introduction has been effected with the minimum of trouble. Thus from Leeds the Senior Administrative Officer in the Faculty of Medicine tells us that, "thanks to the co-operation of the regional hospital board and the hospital management committees in the region, the scheme got off to a very satisfactory start." From the Welsh National School of Medicine the Provost says that the filling of approved posts in approved hospitals in terms of the Act has been carried out with little difficulty, leaving a certain number of vacancies for young practitioners from other schools. From Bristol the Dean writes that the medical students first to be affected by the Act have had no difficulty in finding posts, as the number of approved posts in the region considerably exceeds the number of students qualifying annually. Most of them have obtained posts in Bristol itself, and only three, for personal reasons, have gone outside the south-western region. So with other provincial schools.

In London the Dean of Guy's states that pre-registration appointments are available for those newly qualified, and every encouragement is given to men of promise to obtain the higher degrees and diplomas. The Secretary of St. Thomas's says that, of the first big batch of students qualifying, those who failed to get pre-registration appointments at St. Thomas's have had little or no trouble in obtaining suitable posts outside. He adds that the new regulations appear to create only one difficulty, and that is of maintenance before the first appointment is obtained, and between that and the subsequent one.

The Sub-dean of London Hospital Medical College also states that the introduction of pre-registration house appointments has not so far produced any major difficulties, but he considers it unfortunate that the General Medical Council should have been unable to put newly qualified men on the *Provisional Register* until the university or college concerned had conferred its degree or had officially met to issue the diploma. This has resulted in an unfortunate delay between qualification and starting work, and all the financial and other difficulties which are bound to result from such a time lag. He goes on:

"In general, the most obvious weakness in postgraduate training at the present time is that men are called up into the Forces 12 months after qualification. The number of London Hospital graduates who have not in the recent past done two six-months house appointments is very small, and, therefore, pre-registration does not make much difference to them, but the majority would welcome the opportunity of 18 months of house appointments whether they later go into practice or into a specialty. In the former case most men wish to hold a house-physician's and a house-surgeon's post, and then spend six months in a midwifery appointment with a view to taking the diploma of the Royal College of Obstetricians and Gynaecologists. The men who have decided to specialize also require an uninterrupted 18 months' work after qualification, and it should be noted in this respect that the Royal College of Physicians, for example, will not allow a candidate to enter for the membership until he has

been qualified 18 months. We feel that very great advantages in postgraduate training would result from an extension of the deferment from National Service after qualification from the present 12 to 18 months, and, although no doubt this would produce administrative difficulties in the transitional stages of such an extension, eventually the Forces themselves would benefit from having better-trained junior medical personnel."

LONDON UNDERGRADUATE SCHOOLS

The University of London comprises twelve undergraduate medical schools, each of which is connected with a principal teaching hospital and with one or more—in two cases with as many as five—associated or constituent hospitals.

It was intended, as stated in the Educational Number of the *British Medical Journal* last year, that from October, 1953, revised regulations for the preclinical courses for the M.B., B.S. degrees would be introduced in the medical schools of Guy's, Middlesex, Royal Free, St. Bartholomew's, St. Mary's, St. Thomas's, and University College Hospitals. It has not, however, been possible to implement these new regulations of the University, and the new preclinical curriculum has had to be indefinitely postponed. Therefore the procedure for entry at these schools remains unchanged for the coming year. The University has also decided that the new regulations shall not come into force in October, 1954.

There follows some account, for which we are indebted to the respective deans or secretaries, of the individual schools.

At *Guy's Hospital Medical School* the first three years of preclinical studies are designed to prepare the student for the clinical work which will follow, and particularly for the eventual practice of medicine. There is a close link between the medical school departments and the wards. Oxford and Cambridge students are admitted for the three clinical years. The aim at *Guy's* has always been to encourage responsibility from the moment the student enters on ward work. A three-monthly series of clerkships is arranged in the general wards and in special departments, so that students accept supervised responsibility for patients, and the emphasis is on bedside and out-patient teaching rather than organized lectures. There are, however, lectures and demonstrations organized by the directors of the departments of surgery, medicine, obstetrics, paediatrics, and anaesthetics, to cover the whole curriculum. Pre-registration appointments are available for the newly qualified.

Middlesex Hospital Medical School, owing to the University's decision that the new regulations for the preclinical curriculum shall not at present come into force, is continuing to admit students on the same lines as in the past, that is to say, either for first M.B. work, or, if they have obtained this examination externally, direct to the second M.B., and, in the case of students from Oxford and Cambridge, direct to the clinical course. These latter students are admitted in October or April each year, the preclinical students starting only in October. At the beginning of the clinical course all students attend the introductory course for three months before starting their ward appointments. On qualification there are numerous provisional registration posts available within the hospital. By the beginning of the next session a small extension to the department of anatomy will have been completed; this will afford increased facilities for the teaching of histology. The new Institute of Clinical Research and Experimental Medicine will also open in October and will provide the medical and surgical staff of the hospital with excellent facilities for research. The number of applications received for admission to *Middlesex* remains far in excess of the number of places available. Students wishing to apply for admission to either the preclinical or the clinical course are advised to do so eighteen months or two years before the date at which entry is required.

Final-year Students and General Practice

A scheme has been introduced this session at the *Royal Free Hospital School of Medicine* by which clinical students in their final year^a may spend a fortnight with a general

practitioner, attending surgeries and rounds, and learning something of the organization of a practice. It has now been possible at the Royal Free to make a start on converting the rooms in the old buildings left empty on the transfer of two departments to the new wing. This work should be completed in the summer vacation. At the hospital a new clinical lecture theatre has been erected, with a seating capacity of 150, and the extension of the Obstetrical and Gynaecological Department at Liverpool Road is now almost ready for occupation. The number of applicants for admission remains much greater than the places available, but it is now possible to admit a larger number of students in the first year. From October the school will be admitting a group of students from the Royal Dental Hospital School for the preclinical course only. The school received during the year a legacy of some £50,000 through the generosity of the late Dr. Annie McCall. The fund is being used to found the Annie McCall Postgraduate Fellowship in Midwifery, open to any woman graduate, and having a value of not less than £1,000 a year, which may be held by one recipient for a period not exceeding three years. Fifty-five students have gained qualifying degrees during the past twelve months, including one with honours in medicine and one with honours in obstetrics and gynaecology. The preclinical teaching staff numbers 47, and the clinical 82, these being members of the clinical staffs of the Royal Free Hospital teaching group. The students last session numbered 472 (including 12 postgraduate). The annual intake is approximately 120.

The current academic year opened at *St. Thomas's Hospital Medical School* with an entry of 87—44 first-year, 10 second-year, and 33 clinical students. During the past year 88 students qualified with a university degree, while in 1951-2 45 old members of the school achieved higher degrees or diplomas (13 the Membership and 15 the Fellowship of the Royal College of Surgeons, 13 the degree of Doctor of Medicine, and 4 that of Master of Surgery). Statistics are definitely showing that from the academic point of view the second-year entries are much higher than those who start as premedical students. The qualification rate of Oxford and Cambridge graduates remains very high. There have been no major changes in the school during the past academic year. Two new temporary lecture theatres which should be ready by October will help to relieve the congestion during full term and make examinations much easier to administer, as they will now cause no upset of teaching. In the hospital itself at long last some new building has started. The school and hospital are now stabilized after the upheavals of the war, and both are looking forward to a period of reconstruction. Planning is going on for the school, and it is hoped that future generations will see buildings worthy of the beautiful site that the hospital is fortunate enough to occupy.

No special developments have to be recorded at *University College Hospital Medical School* during the past year. There has been no falling off in the number of applicants for places, and it has in fact been difficult to keep down the entry to the ideal number to be taught on the available hospital beds. It is perhaps worth recording that for the first time in the history of this school Part I of the London final examinations was held here as an internal examination. The school has acquired a new playing field at Hendon.

At *St. Mary's Hospital Medical School* the number of applicants still greatly exceeds the number of places available, and during the last session nearly 700 applications were received, out of which 105 students were admitted. Work has begun on the alteration of nine houses in Sussex Gardens which will provide residential accommodation for 80 students. The alterations should be completed by the middle of the session, and, as almost half the students at the medical school live in lodgings, a hostel so near at hand will be greatly appreciated. It is hoped that work on a further nine houses, to provide accommodation for 88 students, will start as soon as the first part of the hostel is open, and this will mean that eventually the majority of

students who at present live in lodgings will be accommodated in the hostel. Dr. K. W. Cross, senior lecturer in physiology, has been appointed reader in human physiology in succession to Dr. J. L. Malcolm, who will be taking up a post at the National Institute for Medical Research in October. Dr. A. d'A. Bellairs, lecturer in anatomy in the University of Cambridge, has also been appointed reader in anatomy in place of Dr. J. J. Pritchard, who is now professor of anatomy at the Queen's University, Belfast. The course of lectures on preventive medicine has been revised and expanded, and a number of visiting lecturers have been invited. Preparatory arrangements are being made to celebrate the centenary of the school next year.

Revised Clinical Curriculum

The year has seen the introduction at the *London Hospital Medical College* of a revised clinical curriculum. This now consists of the introductory course, a year of in-patient clerking and dressing, a three-months pathology course, and then a year in special departments, following which there is a period of up to five months during which the student attends general out-patient departments and also has a chance to reflect on his studies before going up to his finals. This is clearly resulting in a great improvement in the facilities for study in the major special departments of the hospital. The number of applicants for places at the London has remained very much the same as in recent years, though some signs of reduction had been expected by now. As usual, about half the students joining the school have obtained first M.B. exemption from school, and the remainder come to the school after one year at Queen Mary College, one of the schools of the University. There is a slightly increasing tendency for students to leave school with exemption from two parts of the first M.B., and thus they have to spend one year studying biology. The demand from postgraduate students for general teaching at the London Hospital continues to be high, and the course in advanced medicine from January to March is very well supported.

St. George's Hospital Medical School has for some time submitted to the handicap of cramped and inconvenient premises on the assumption that rebuilding was imminent. When it became obvious that no such project would be completed for at least a decade, the school, with the help of the University of London, embarked on a plan of reconstruction at Hyde Park Corner, of which the greater part has now been completed. The administrative offices and students' refectory and club were moved over a year ago to larger premises adjoining the school in Knightsbridge, while the old buildings were converted for the use of the department of pathology. The school now has an excellent building of three stories with adequate space to house pathological teaching and research. Increased facilities for clinical teaching are still needed, but, in view of the recent designation of another hospital, the situation should improve before long. In the meantime by rigidly restricting the entry to 45 students a year it is possible to maintain the *St. George's* tradition of personal instruction to small classes at the bedside.

Progress in Cramped Quarters

Charing Cross Hospital Medical School has had yet another year of progress in many different directions. Particularly in the clinical years additional facilities have become available so that those who graduate are given every opportunity to have first-hand knowledge of medicine in its widest aspects. The teaching staff of the school fully realize the importance of the application of theoretical knowledge to the practice of medicine, and this is borne in mind throughout the whole of the years of instruction. It is realized that the examination results furnish only one method of assessing the results of such a policy, but they have the merit of giving a statistical basis of assessment.

When it was found that the University of London was unable to furnish the money necessary for opening the

departments of chemistry, physics, and biology, or to start the new integrated course for premedical subjects, immediate arrangements were made with the Northern Polytechnic for first M.B. students to undertake their studies in a special class devoted to Charing Cross students; 85% of those who took this course completed their first M.B. The second M.B. subjects of anatomy and physiology were given an equally satisfactory pass-list.

During the clinical period the curriculum has been made more practical and realistic in several directions. The facilities for instruction in midwifery have been increased by an arrangement whereby students attend domiciliary confinements in London, and, now that the Kingsbury Maternity Hospital is part of the Charing Cross group, rebuilding is taking place at Kingsbury, which will in the near future furnish an up-to-date unit sufficient for teaching institutional midwifery to all the students. The time for which students are attached to selected general practitioners in their final six months has been reduced to three weeks. Increasing experience shows the extreme value of this tuition, and it is regarded enthusiastically by most of the students and practitioners concerned. The students themselves have responded to these increased teaching facilities by working hard. Of the 27 candidates who presented themselves for the first time at the M.B., B.S. (Lond.) examination on the last occasion, 22 qualified at the first attempt (incidentally including all the women). Two further successes in the M.S. (Lond.) examination now place this medical school almost at the head of all the medical schools in London for the number who have obtained the M.S. degree in the last three years.

The one great difficulty is still the cramped quarters in which the school is situated, but every effort is being made to find new accommodation and to alleviate the conditions under which everyone is working. Although the purchase of the 47 acres at Northwick Park for the site of the new hospital and medical school has now been completed, financial stringency makes it improbable that a start on the actual buildings can be made for some little time. Meanwhile during the summer vacation the school is being made more habitable by redecoration of the whole of the inside and outside of the present buildings in the heart of London.

The preclinical departments of *St. Bartholomew's Hospital Medical College* are now situated in Charterhouse Square. Here and at the hospital adequate facilities are available for instruction in all subjects, including pathology and midwifery. Over 100 hospital appointments are available each year to students who have passed their qualifying examination. Clinical appointments are available for undergraduates each quarter. Scholarships and prizes to the value of £2,000 are awarded annually.

Facilities for Research

King's College Hospital Medical School provides the clinical training for students reading for the degrees of London, Oxford, and Cambridge. The hospital serves a large residential area and has one of the busiest out-patient departments in London. The preclinical subjects are taught in the Faculty of Medical Science, King's College, London, where students are admitted for either the first or second M.B. course. At the college the students have the advantage of full college life and of associating with students of all the faculties.

The clinical curriculum is kept under constant review, and in January of this year some modifications were made in the clinical introductory course, to which great importance is attached. Upon the successful results of a pilot scheme every student now has the opportunity of seeing at first hand something of the work of a general practitioner. It is hoped that more time may be allotted to this valuable experience when the scheme is fully established.

Progress has been made in facilities for research at King's College Hospital Medical School. The Cowburn Research Fellowship has been established with a fund of about £35,000. Regulations have been approved and the first

Cowburn Fellowship is now being advertised. A suite of rooms in the hospital is being adapted to provide additional research accommodation, and research projects are assisted on the recommendation of the recently established King's College Hospital and Medical School Joint Research Committee. The larger part of the funds for research are provided by the hospital from its endowment funds; the Medical School Council has also made available for research certain of its trust funds.

The medical school has made arrangements with the Faculty of Medicine of the University of Toronto for an exchange of medical staff. The first exchange will take place this summer, when one of the King's registrars will leave for Toronto and King's will receive a doctor from that city, the holder of a Markle scholarship. A new demonstratorship in morbid anatomy has been established with the object of providing experience in laboratory methods and research for intending clinicians.

King's College Hospital is fortunate in having 23 approved intern posts available every six months for its newly qualified students. No difficulty has been experienced in securing posts elsewhere for the few students who have not been appointed to pre-registration posts within the teaching hospital group. During the 12 months up to May of this year 45 students gained qualifying degrees in medicine and dentistry in the Universities of London, Oxford, and Cambridge, including two with honours. Forty-seven students obtained the diplomas of the Conjoint Board.

At *Westminster Hospital Medical School* the number of clinical students in attendance is 203, of whom 16 are women. Sixty-six students are carrying out their preclinical studies at King's College, Strand, with a view to entering Westminster for the clinical period. Some 600 applications were received last year for an annual entry of 65; half are working for London University degrees and the remainder for Oxford and Cambridge degrees. There are 430 beds at Westminster Hospital for clinical practice allocated to general medicine, surgery, and obstetrics. The orthopaedic, the ophthalmic, and the ear, nose, and throat departments are also in the main hospital. Special instruction in paediatrics is provided at the Westminster Children's Hospital, where there are over 100 beds. The University has conferred the title of Reader in Bacteriology on Dr. B. W. Lacey, and of Reader in Morbid Anatomy on Dr. A. D. Morgan, and has added Mr. P. D. Trevor-Roper to its list of teachers recognized in ophthalmology. Mr. H. E. Lockhart-Mummery has been appointed to the newly instituted post of tutor in surgery.

The scheme of occasional lectures to the firms in general medicine and general surgery by distinguished visitors from other institutions has been continued at Westminster with success.

Forty vacancies a year in the Westminster Hospital teaching group have been recommended for pre-registration purposes and competition for these is keen. Visits to the surgeries of general practitioners and the use of the Nelson Hospital, Wimbledon, for midwifery instruction, by permission of the St. Helier Group Hospital Management Committee—both reported last year—have continued with success, and, in addition, members of the general medicine firm attached to St. Stephen's Hospital, Fulham, reside there in turn for part of the three-months period. This innovation has proved popular and is undoubtedly in the interests of the students. The various students' clubs are vigorously alive.

ENTRY AT OXFORD AND CAMBRIDGE

Oxford University Medical School.—The number of preclinical students is restricted by decree. Selection of candidates is made by a central university committee; their names are put forward by the colleges, and preliminary acceptance by a college is essential for any prospective medical student. Students reading medicine at Oxford must in addition qualify for a B.A. degree. Most medical students do this by taking

the final honours school of animal physiology, which normally occupies them for one year after they have taken the first B.M. examination in organic chemistry, anatomy, and physiology. After taking the B.A. degree most students do a course of general pathology, bacteriology, and pharmacology, lasting two terms, before going on to their clinical studies. The clinical section of the school has a very limited entry, so that a high degree of personal supervision and opportunities for practical experience may be ensured. Usually about two-thirds of the clinical students are drawn from the Oxford preclinical entry; the remainder come from other universities. The University hopes by assembling such a mixture of students to minimize any risk of parochialism among students who receive their entire medical training at Oxford. The Radcliffe Infirmary (505 beds) is the main teaching hospital, and is an active centre of clinical research, but practical instruction is given also in the other members of the United Oxford Hospitals Group (1,250 beds) and in the Wingfield Morris Orthopaedic Hospital and the Littlemore Hospital for mental cases. In both medicine and surgery students spend half their time in a "firm" of four students and half in a "firm" of eight.

Cambridge University Medical School.—Admission to the University of Cambridge may be secured only by members of the colleges and of Fitzwilliam House. Most of the colleges will not admit candidates for the degree of M.B. and B.Chir. unless they have passed or secured exemption from three parts of the first M.B. examination. All college entries are subject to a university quota, and the number wishing to enter still exceeds the number of places available (about 220 per annum). Before a candidate can be admitted to the final M.B. examination he must obtain honours in a tripos (or if over standing for honours standard, in Part I of the natural sciences tripos), must reach a qualifying standard in anatomy and physiology (or pass a qualifying examination in those two subjects), and must pass an examination in pharmacology. Part I of the final examination—the basic subjects of pathology, pharmacology, and therapeutics—may be taken after two years and three months of clinical study. Part II, comprising medicine, surgery, and midwifery and gynaecology, may be taken two years and nine months or more after beginning clinical studies. Excellent facilities for bridging the gap between the preclinical and clinical periods are provided by the Long Vacation courses in elementary clinical methods and introductory psychology (including practical demonstrations) held each year in July and August. The course in elementary clinical methods is concentrated on instruction in the simple technique of making a proper examination of patients attending the general and special departments of a hospital; it includes lectures on the career of medicine, the social background of disease, epidemiology, and the practice of medicine in the home.

MEDICAL SCHOOLS IN ENGLAND AND WALES

An Intelligence Test on Entry

An innovation has been introduced in the *University of Birmingham Medical School* in that students on admission into the second year (the first preclinical year) are required to undergo an intelligence test conducted by the professor of education. As a result of this, each student at the outset of his career is given an intelligence quotient, and in the light of his subsequent performance it is hoped to gain information whether tests of this kind are likely to give any worth-while forecast of the student's aptitude for medicine. The tutorial system, which was instituted last year at Birmingham, whereby members of the clinical staffs of the hospital offer to undertake the role of tutors for groups of four or five undergraduates during their years of hospital work, has made a good beginning.

There have been two other interesting innovations at Birmingham. One of these, which was started a year ago, is a scheme on a voluntary basis whereby students in their final year may be attached to a general practitioner for two weeks in order to familiarize themselves with the work of general practice. The scheme was inaugurated by an informal discussion over a buffet supper to the participating practitioners and students, and many helpful suggestions for the future were made. The scheme is regarded as an improvement on the formal teaching of the intricacies of general practice by a university department. The other innovation was an exchange of students for two weeks with the University of Lyons. It is stated that the visit of the British students to the French university was not only enjoyable but instructive and helpful, giving them an insight into clinical work on the Continent.

The number of applications received for admission into the Birmingham Medical School shows little sign of falling, but the remark is made that, generally speaking, the quality of the applicants is not as high as formerly. The necessary arrangements to satisfy the requirements of the Medical Act, 1950, have worked smoothly, and all newly qualified graduates are in pre-registration posts. To endeavour to obtain the fullest possible working co-operation between the Faculties of Medicine and Science, the clinical research unit, which is expected to be opened before the end of the year on the Queen Elizabeth Hospital site, will not only have accommodation for research work in the clinical departments but later a department of microbiology in the same building, to house members of the Faculty of Science who are interested in that subject. This is a notable year in Birmingham Medical School history, for both the Vice-Chancellor and the Vice-Principal of the University are not only medical men but Birmingham graduates.

Student Exchange Scheme

At the *Medical School of the University of Durham* the number of applications for admission during the academic year beginning in October next has been approximately the same as last year, and competition for entry has therefore been quite keen. Most candidates apply for direct entry to the second-year course by qualifying for exemption from the first M.B., B.S. examination by virtue of passes in the subjects of chemistry, physics, and biology at the advanced level in the general certificate of education examination. Plans for the first stage of necessary extensions to the medical school have now been approved and building operations authorized. The extension of the present building will provide much needed additional accommodation for the department of physiology and for the teaching of pharmacology. Student activity has been as keen as ever. The annual meeting of the British Medical Students' Association was held at Newcastle-upon-Tyne last year, and was very successful. The Durham Medical Students' Union has again arranged a student exchange scheme with the Medical School at Oslo, and several Norwegian students have been welcomed at Newcastle during the summer vacation.

The session 1952-3 in the *Medical Faculty of the University of Bristol* has seen an increase in the number of students in the Faculty in that the maximum number of students who could be accommodated were admitted to the dental school and an additional year has been added to the veterinary school. The first students to take veterinary medicine at Bristol University are about to enter their final year. Work is about to begin on additional laboratories and a lecture theatre in the department of medicine. The main operating theatres in the Royal Infirmary have been equipped with new sterilizers, and air-conditioning has been installed. Research has carried some members of the staff far afield. A team from the pharmacology department, under the auspices of the Medical Research Council, visited Uganda to make some metabolic studies, and another from the department of anatomy is at present studying in Switzerland the effects of altitude on bone marrow. Some changes

have been made in the regulations for dental qualifications. In future the candidates for the diploma as well as the degree will be required to matriculate, and will take the same examinations up to the final. The B.D.S. course will be six months longer than that for the L.D.S., and the final B.D.S. examination will have an extra section to be taken at the end of five and a half years' study.

The intake of medical students at the *University of Liverpool* in 1952 was 71 men and 23 women. Of this number 46 were admitted to the first year of study and 48 to the second. It is stated that the number of applicants seems to be increasing, but the main factor in this apparent increase is the growing practice of candidates to apply to several medical schools. A new clinical curriculum has come into force the main features of which are: (1) that the present Part III of the final M.B. examination will be discontinued, forensic medicine becoming a subject (with pathology and bacteriology) of Part II, and public health a subject of the final qualifying examination; and (2) that systematic lectures during the first five clinical terms will be given only at 9 a.m., the students spending the rest of the day in the hospitals to which they are assigned, whereas previously they returned to the medical school for an afternoon lecture.

A new medical school building is in course of construction. The first part, which will be ready for occupation towards the end of 1954, will house the departments of pharmacology and bacteriology. The framework of the new block consists of reinforced concrete columns and prestressed concrete floor beams—a technical development in construction used for the first time in this country. This year the University of Liverpool celebrates the fiftieth anniversary of the granting of its charter. Sir Ronald Ross and Sir Charles Sherrington were members of the first senate.

Changes in M.B. Courses

The *School of Medicine at Leeds* admits 75 students each year, and the number of persons seeking admission still greatly exceeds the number of places, though it is remarked here, as it was at Birmingham, that there seems to be a shortage of really good candidates. During the last year the first M.B. course reverted to three terms, and consisted of four subjects—physics, chemistry, zoology, and botany. The content of the chemistry course is greater than that of many other degree (first M.B.) courses, and it is considered an advantage that candidates should have studied this subject at advanced level in the general certificate of education, although the minimum requirement is that they should have passed at ordinary level. Complete exemption from first M.B. is not often given at Leeds. As from next October the second M.B. course will be a five-term instead of a six-term course. The revision of the clinical curriculum is under consideration, and it is hoped to start detailed plans in the coming session.

Developments in the school are hampered to a large extent by lack of accommodation. In order to overcome this the University is continuing its policy of adapting houses in the neighbourhood into research laboratories. In particular the departments of biochemistry and medicine will, it is hoped, soon be given additional accommodation in this way; and as soon as possible more accommodation will be given to the departments of medical physics, radiology, and anaesthetics.

Of the changes made in ordinances and regulations of the *Faculty of Medicine at Sheffield* only two appear to call for notice here. Pathology and bacteriology will each now form a separate part of the third M.B. examination; and when the degrees of M.B., Ch.B. are awarded with "honours" there will in future be no division into first class and second class. The University has accepted an offer from Boots Pure Drug Company, Limited, to establish an annual prize in pharmacology in memory of the late Sir Jack Drummond. While no extensive new building can yet be reported at Sheffield, the adaptation of existing pre-

mises has permitted considerable enlargement of the department of biochemistry. On the hospital side the expected opening in the autumn of the Charles Clifford Dental Hospital will greatly increase the clinical facilities open to the dental school. During the year the school suffered a loss through the death of Mr. J. E. Stacey, a noted clinical teacher of obstetrics and gynaecology, and the resignations, on their appointment to chairs in other universities, of Professors E. J. Wayne and H. N. Green.

In the *Manchester Faculty of Medicine* 97 new students were admitted in October, 1952, 17 of them direct to second-year courses. The formal entrance requirement in mathematics has been discontinued, but it is strongly felt that applicants for admission to medical study should not underestimate the importance of appropriate preparation in mathematics. The discontinuance of the formal faculty requirement enables intending applicants to get appropriate preparation in this subject in the most convenient way on advice from their schools. The regulations governing Parts II and III of the final M.B., Ch.B. examination have been modified in the light of experience. Candidates who present themselves in all four subjects of the final examination may in certain circumstances be allowed to pass in any two or three of these.

The Clinical Sciences Building in York Place, Manchester, is now complete and occupied by the departments of pathology, medicine, social and preventive medicine, occupational health, oto-laryngology, rheumatism research, and obstetrics and gynaecology. The space vacated in the medical school will ease the problems of accommodation, and extensive alterations are being carried out in the old building.

Welsh National School of Medicine

The new regulations for the degrees of M.B., B.Ch.(Wales) are now affecting students entering the clinical years of study in the *Welsh National School of Medicine*. The change of date for ending the preclinical period and beginning the introductory clinical course in the transitional summer term has brought with it inevitable difficulties in connexion with not only those students of the school who fail in anatomy and physiology at the first attempt in March but also with students from some other schools who wish to pursue their clinical studies at Cardiff. Satisfactory solutions are, however, being devised. Further, the complete revision of the curriculum and time-table which has been undertaken has involved much work for the clinical dean and the office staff. It looks as if the gradual change from the old to the new system will take place smoothly enough.

The amendment of the M.D. regulations is under active consideration with the object both of raising the standard of the examinations and of throwing the degree open to a wide group of graduates by placing more emphasis on a thesis or published work and less on clinical proficiency.

The very large undertaking of preparing a scheme for an entirely new medical and dental teaching centre has reached the end of its first stage, and a long and detailed report has been submitted to the Welsh Board of Health and the University Grants Committee. As it is intended to hold an architectural competition, no preliminary plans have been prepared, but the report is mainly in a form appropriate to the preparation of schedules for such a competition.

The annual intake of medical students at present is 65. The number admitted each year to studies for the B.Pharm. is 35, to the course for health visitors 23, and to systematic instruction in midwifery 54 pupil midwives. Co-operative arrangements with the teaching and regional hospitals for short-term visits of consultants to the school have been successfully conducted throughout most of the year.

For the first time in the history of the school the chair of obstetrics and gynaecology has been made whole-time. It has been filled by Mr. Archibald Sutherland Duncan.

SCOTTISH AND IRISH SCHOOLS

In *Glasgow University* the last full year of students who followed the former five-year curriculum have qualified this summer and there will be only a small number of medical graduates from this school until July, 1955, when the first year of students pursuing the six-year curriculum will have completed their course and be due to graduate. Within the teaching establishment no new senior posts have been created, but retirement under the age limit is this year producing more than the usual number of changes in senior teaching personnel. The junior teaching staff has been augmented by a number of additions in the lecturer grade to the establishments of several individual departments.

There have been no changes of major importance during the year in the arrangement of the curriculum, but some minor reorganization of classes in the specialties has been undertaken with a view to spreading this instruction over a longer span of the whole clinical period. The main development in the Faculty of Medicine during the year has concerned the veterinary school. The first year of veterinary students to complete their university curriculum will appear for graduation in July, 1954.

The number of applications for admission in 1953 at *Edinburgh University* to the course leading to the M.B., Ch.B. degrees has continued to be high in relation to the number of places available. The degree course occupies six years, and the stage has been reached where students begin in October next the final year of this curriculum. First-year students for degrees in medicine, dentistry, and veterinary medicine attend the same first-year course, which has now been revised to permit students to take the first professional examinations in two parts, one in March and one in June, instead of all four subjects in June as formerly. With effect from June 2, 1953, there will be a new requirement that two copies of theses for the degree of M.D. must be lodged.

More places are now available in the School of Dental Surgery at Edinburgh for the five-year course leading to the degree of B.D.S. The five-year course for the degree in veterinary medicine and surgery (B.V.M.S.) began in October last.

In the *School of Medicine of the University of St. Andrews* instruction in the subjects of the clinical years of study is given in Dundee, while the premedical and pre-clinical subjects can be studied in either Dundee or St. Andrews. The annual intake of students to the Faculty of Medicine is limited to between 70 and 80 entrants to ensure that the hospital facilities available are sufficient to allow of adequate clinical instruction being given to each undergraduate as advised by the Goodenough Committee.

In October, 1948, the six-year curriculum, recommended by the General Medical Council, was introduced, and the necessary rearrangement of work in the later years of study has now been completed. The Dean of the Medical School at Dundee expresses the view that so far the introduction of the National Health Service has had but little influence upon the undergraduate; it has, however, called for a complete reorganization of postgraduate instruction with a view to the training of specialists.

At both St. Andrews and Dundee there are excellent student residences which accommodate graduates from any of the faculties. Medical students in their early years are encouraged to reside in these so that there is a width of contact among the undergraduates at this university which is of great educational value. In addition, the William Low residence for medical students, situated near the principal teaching hospital, is devoted exclusively to undergraduates in their clinical years of study. The University of St. Andrews has instituted chairs in social medicine and in child health, so that in this respect also the

recommendations of the Goodenough Committee have been fulfilled.

In the session 1952-3 at the *School of Medicine, Aberdeen*, there were 541 students. By resolution of the *Senatus Academicus* and approved by the University Court a candidate for examination in the subjects of the first M.B., Ch.B. degree examination must enter for all the subjects together. A candidate who fails to pass in all three subjects at one Diet of Examination may obtain exemption from further examination in one or in two of the subjects provided that he attains a higher standard than the ordinary pass mark in such subject or subjects. Final-year medical students are attached to general practitioners in the district for one month in order that they may gain experience of general practice. The new building in Old Aberdeen in which the department of chemistry and related departments are to be housed has been opened since last September.

At the *Queen's University of Belfast* the maximum number of students (including dental students) who can be admitted to the medical school in any one year is 108. The six-year curriculum in the medical school now includes a special course in clinical tuberculosis for final-year students. Arrangements have also been made for a series of undergraduate lectures by a general practitioner. Next year a scheme for domiciliary midwifery will be introduced. Instruction will be undertaken by a panel of six general practitioners. The new Institute of Clinical Science at Belfast is approaching completion and will be occupied during the coming academic session. It will add greatly to the facilities for teaching and research.

The entrance requirements at Queen's are: (a) the passing of the matriculation examination in five subjects, three of which are compulsory—namely, English, mathematics, and a modern language; (b) if the five subjects do not include Latin, the passing of this subject at a qualifying examination; and (c) the passing of the premedical examination in physics and chemistry or other examinations recognized by the University as equivalent thereto.

The *School of Physic, Trinity College, Dublin*, provides a complete training in the medical sciences in preparation for the degrees of M.B., B.Ch., and B.A.O. of the University of Dublin. Medical students are required to take a modified Arts course leading to the degree of B.A. All courses and degrees are open to men and women alike. External students are not accepted. Outstanding recent developments at Trinity College have been the establishment of the Moyne Institute of Preventive Medicine and of the new school of social medicine.

The constituent colleges of the *National University of Ireland* are those of Dublin, Cork, and Galway. Between 200 and 300 students graduate in medicine from these colleges each year.

The Royal College of Surgeons in Ireland admits to the pre-registration classes approximately 100 students each year. The normal method of entrance is by competition in the preliminary examination, but a limited number of places are given to those with exceptional qualifications and to certain students selected by the Colonial Office, to which all colonial students should apply, since, owing to limitation of numbers, they cannot be admitted to the entrance examination. Nearly all students take the Irish Conjoint Board's examination, but some take in addition the London examinations. Medical examinations are carried out on students at the beginning of the pre-registration year, and again before the clinical years begin. Two doctors give free medical care to students.

During the past year the laboratory space for chemistry and physics has been doubled, two rooms for advanced work have been added to the anatomy department, and much additional apparatus has been obtained for the pathology department. This is the first experience of the intern year, and no difficulties have been encountered. The address of the Royal College of Surgeons in Ireland is St. Stephen's Green, Dublin.

APPOINTMENTS OVERSEAS

The Colonial Medical Service

Openings in the Colonial Medical Service occur in all parts of the world, the largest number being in Africa, Malaya, and the Caribbean area. Candidates must be British subjects holding medical qualifications registrable in the United Kingdom and should have had at least 12 months' postgraduate experience in hospital before appointment. For the permanent service candidates must be under 40 or 45 years of age, varying according to the age of retirement in the territory (in most territories 55). Short-term contract appointments are available for candidates above the age limits or those who do not wish to commit themselves to a Colonial career from the outset. In many Colonial territories there is a scheme whereby doctors in the National Health Service may take up temporary posts up to six years without loss of N.H.S. pension rights. A gratuity is payable at the end of the overseas service, but those eligible for and desirous of transfer to the permanent and pensionable establishment of the Colonial Medical Service may so transfer. Officers appointed to the permanent service are normally required to take a course in tropical medicine and hygiene either before going overseas or during their first furlough.

A large number of specialist appointments exist in the Colonial Medical Service. These are normally filled from the service, and senior administrative appointments are almost entirely filled by the promotion of serving officers. The total number in the various Government medical departments amounts to some 800 European medical officers and an even larger number of officers appointed locally. Vacancies for women doctors arise from time to time, particularly for those with special experience in obstetrics, school health, child welfare, and nutrition.

Full particulars of terms and conditions of service may be obtained from the Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1.

Other Appointments Abroad

Medical schools overseas employ doctors from the United Kingdom as teachers. The recruiting agency for certain of the Colonial medical schools is the Inter-Varsity Fellowship for Higher Education in the Colonies. Some overseas hospitals, such as King George V Merchant Seamen's Hospital, Malta, and the British Hospital, Lisbon, also employ British doctors, and short-term resident appointments are frequently advertised by Dominion and American hospitals. Medical staffs are also employed by certain commercial undertakings working abroad, including local engineering firms, development corporations, and mining companies. The larger shipping companies offer employment on a more or less permanent basis for about 100 ship surgeons. Application should be made to the various companies at their head office.

A small number of British doctors are attached to certain of the British embassies and legations in capitals in Eastern Europe and the Near East, where they undertake medical care of the staffs and their families and sometimes of other British subjects.

Missionary Medicine

Medical missionary work offers opportunities to medical men and women who wish to give their services where the need is greatest. A doctor who has this service in view is advised to spend 18 months or two years in resident appointments after qualification. Special missionary training is required by some of the societies. Although offers for life service are preferred, the service should be for terms of 18 months to five years, according to the country and the climate. Opportunities for postgraduate study are offered during furlough. Applications from students or qualified men and women should be made either to the secretaries of one of the denominational or interdenominational societies, through the local branch of the Student Christian Movement, or to the chairman, Medical Missionary Board of the Conference of British Missionary Societies, Edinburgh House, Eaton Gate, London, S.W.1.

MEDICAL SERVICE OF THE L.C.C.

The largest local authority in the country, the London County Council, employs about 100 whole-time medical officers in its Public Health Department, and also nearly 500 part-time medical officers. The duties of those holding whole-time appointments in the higher grades are mainly administrative. Generally speaking, the senior officers have graduated through the clinical field, and have special knowledge in at least one branch of the service. The assistant medical officers are mainly engaged in the school health and maternity and child welfare services. Suitable qualifications are the D.C.H. and the C.P.H. or D.P.H. Arrangements are made for some of the officers to have clinical responsibilities at hospitals and to gain experience of environmental health services in the metropolitan boroughs.

The part-time officers are employed in a variety of work—for example, in residential nurseries, welfare institutions, staff examinations, sessional work at clinics, and in school medical inspection. By arrangement with the London School of Hygiene, the Institute of Child Health, and several undergraduate schools, students have the opportunity of gaining experience in the Council's various services.

The salary of the medical officer of health to the Council is £4,000 a year, and that of the deputy medical officer is at present on the scale of £2,050-£250 (biennially)-£2,550.

For divisional medical officers the salary scale varies according to the population of the division (London is divided into nine such areas). In divisions which have a population of up to 400,000 the scale is £1,500-£50-£1,900, and for those with a population of over 400,000 it is £1,600-£50-£1,950. There is one exception to this general pattern—namely, a divisional medical officer who is also medical officer of health of the two metropolitan boroughs comprising his division. His scale is £2,400-£100-£2,600, then plus £50 to £2,650. This officer has two assistant divisional medical officers (£1,470-£1,770 and £1,170-£1,420), each of whom is also deputy medical officer of health of one of the boroughs. The scales of other assistant divisional medical officers are £1,350-£50-£1,650, up to 400,000 population, and £1,400-£50-£1,700, over 400,000. The scales for other grades are: Senior principal medical officer, £1,950-£112 10s.-£2,175; principal medical officers and psychiatrist (whole-time), £1,650-£50-£1,950; senior assistant medical officers, £1,250-£50-£1,500; and assistant medical officers, £850-£50-£1,150 (at present under review following an award of the Industrial Court).

DEGREES AND QUALIFICATIONS

All the universities confer degrees and diplomas admitting primarily to the *Register*. The abbreviations for registration following a pass in the final examination in the universities are M.B., Ch.B. in the universities of Birmingham, Bristol, Leeds, Liverpool, Sheffield, the Victoria University of Manchester, and the four Scottish Universities; M.B., B.Chir. in the University of Cambridge; M.B., B.S. in the universities of Durham and London; B.M., B.Ch. in the University of Oxford; M.B., B.Ch. in the universities of Wales, Belfast, the National University of Ireland, and the University of Dublin; and L.Med., L.Ch., also in the University of Dublin.

About 30% of those who pass the final or qualifying examinations do so under the auspices of one of the three Conjoint Boards—English, Scottish, and Irish. Candidates for the English Conjoint are examined by the Examining Board in England of the Royal Colleges of Physicians and of Surgeons (Examination Hall, Queen Square, London, W.C.1). The diploma is M.R.C.S.Eng., L.R.C.P.Lond. The Board's examinations are held four times a year. The Scottish Conjoint Board furnishes the triple qualification of the Royal Colleges of Physicians and of Surgeons of Edinburgh and the Royal Faculty of Physicians and Surgeons of Glas-

gow (L.R.C.P.&S.Edin., L.R.F.P.S.Glas.). These three bodies have an arrangement by which, with one series of examinations, students may obtain the diploma. Details may be obtained from the Registrar, 18, Nicolson Street, Edinburgh, 8. The joint licence in medicine, surgery, and midwifery is issued by the Royal College of Physicians of Ireland and the Royal College of Surgeons in Ireland (L.R.C.P.I.&L.M., L.R.C.S.I.&L.M.). Regulations can be obtained from the secretary of the Conjoint Board, Royal College of Surgeons, St. Stephen's Green, Dublin.

The Irish Conjoint Board differs fundamentally from the English and Scottish Conjoint Boards in that it has a large teaching school under its control. After passing an approved examination in general education, candidates for the qualifying diplomas are required to do a one-year course in chemistry, physics, and biology, these subjects being treated with special reference to their applications in medicine. After passing the pre-registration examination in these subjects a five-term course in anatomy and physiology is followed. There is then a preclinical term in which an introductory course is carried out at the hospital, and this is followed by three years' clinical work. There are three professional examinations. Candidates are accepted from most of the recognized schools at home and abroad, but in practice 99% of the candidates are from the schools of surgery which are controlled by the Royal College of Surgeons in Ireland with the co-operation of the Royal College of Physicians of Ireland in matters which are within the province of medicine proper.

The Society of Apothecaries of London (Apothecaries Hall, Black Friars Lane, E.C.4) confers a diploma registrable under the Medical Act, 1886 (L.M.S.S.A.Lond.). Examinations for the final subjects are held monthly, except in September, and examinations in anatomy, physiology, and materia medica are held quarterly.

The licentiatehip of the Apothecaries Hall of Dublin (95, Merrion Square, Dublin) entitles to registration under the Medical Act, 1886. It enables the holder to practise pharmacy as well as medicine, surgery, and midwifery, which means that he may, if he so desires, open a medical hall. The Hall is an examining body only. The students who take its examinations are students of a medical school. The reference to pharmacy may be misleading; it concerns only people who are qualifying to become apothecaries—that is to say, doctors, not pharmaceutical chemists.

Diplomas in medicine and surgery registrable in the Commonwealth List are granted by the Universities of Sydney, Queensland, Adelaide, and Melbourne; Ceylon Medical College; the University of Ceylon; the University of Hong Kong; the Royal University of Malta; the University of New Zealand; the universities of South Africa, Capetown, and Witwatersrand, and (in the case of degrees granted on or after October 24, 1947) the University of Pretoria; the King Edward VII College of Medicine, Singapore, the University of Malaya; and the Punjab University, Pakistan. Diplomas of the Universities of Alberta, Manitoba, the Dalhousie University, Nova Scotia, the College of Physicians and Surgeons, Manitoba, the Newfoundland Medical Board, the Provincial Medical Board, Nova Scotia, and the Medical Council, Prince Edward Island, are registrable, provided registration is sought either after examination in the Province concerned or after examination held by the Medical Council of Canada and acceptance by the provincial authorities. Membership of the Colleges of Physicians and Surgeons of Alberta and Saskatchewan is also registrable. The M.D., C.M. of Halifax Medical College is registrable if obtained before August 31, 1911. With some exceptions and subject to dating, the registrable qualifications of the universities of India are recognized. The M.B., B.S. of the University of Rangoon, Union of Burma, if granted on or after December 10, 1936, is registrable. The registration, if previous to January 3, 1948, before the Union of Burma became a foreign country to which Part II of the Medical Act, 1886, applies, is in the Commonwealth List; if after that date, in the Foreign List.

Higher Qualifications

A full list of degrees, diplomas, and courses of instruction for higher qualifications, with details of regulations, and fees and courses, appears in the *Medical Practitioners' Handbook*, published by the British Medical Association.

The Royal College of Physicians of London (Pall Mall East, S.W.1) confers its Membership (M.R.C.P.Lond.) by examination. The pass for Membership is a written examination in the form of a paper on questions of medical anatomy, pathology, and principles of medicine; a paper on questions on the practice of medicine, including the principles of public health, and on psychological medicine; a clinical examination in the clinical wards of a hospital; and an oral examination. Fellowship of the College is gained by election by the Fellows.

The Royal College of Surgeons of England (Lincoln's Inn Fields, London, W.C.2) grants its Fellowship (F.R.C.S. Eng.) to those who pass its primary and final Fellowship examinations. The primary examination, partly written and partly oral, is held in January and July, and the final examination, written, practical, and oral, and including examination of patients, in May and November.

Medical graduates who desire to specialize in obstetrics and gynaecology may apply for entry to the Membership Examination of the Royal College of Obstetricians and Gynaecologists (58, Queen Anne Street, London, W.1). A minimum of three years' residence in hospital posts recognized for the examination is required before application is made. The Fellowship is granted to Members who are judged by the Council to have advanced the science and art of obstetrics and gynaecology. The College also grants a diploma in obstetrics (D.Obst.R.C.O.G.) to practitioners who pass an examination after having special experience in obstetrics in resident appointments recognized by the College.

The Royal College of Physicians of Edinburgh (9, Queen Street) requires of its candidates for Membership that they shall have been qualified for at least two years. The examination is in the principles and practice of medicine and also in a selected department of medicine. Fellows must have been members of the College for at least three years.

The Royal College of Surgeons of Edinburgh (18, Nicolson Street) has a two-part examination for its Fellowship: the first a written paper and oral examination, and the second, a written paper, a clinical and practical examination, and an oral examination in the principles and practice of surgery and in an optional subject.

The Royal Faculty of Physicians and Surgeons of Glasgow grants, after examination, a Fellowship *qua* physician and a Fellowship *qua* surgeon (F.R.F.P.S.G.). Candidates for a Fellowship in medicine must have been qualified for not less than three years and have been engaged during one of those years in full-time clinical work in a recognized hospital and have spent two other postgraduate years in approved medical work. The examinations are clinical, written, and oral. For admission to examination for the Fellowship in surgery the requirements are similar to those for the Fellowship in medicine examination, and the examination is clinical, written, and oral.

The Royal College of Physicians of Ireland grants its Membership on examination. The Fellowship, for which the members of the College are eligible, is granted by election.

The Royal College of Surgeons in Ireland requires two examinations—primary and final—for its Fellowship. The first is in anatomy, physiology, and pathology, and the second in surgery.

All the universities confer the higher qualifications of Doctor of Medicine and Master of Surgery. Liverpool has the degree of Master of Orthopaedic Surgery. At Durham the regulations for the degree of Doctor of Surgery ceased to operate from 1952. The new regulations provide that in order to qualify for the degree of Doctor of Surgery a candidate must be of at least six years' standing from

admission to the degrees of M.B. and B.S. of the University, and the degree will be awarded primarily in consideration of individual contributions to surgical knowledge either published or in the form of a thesis on a subject or subjects concerned with surgery approved by the Board of the Faculty of Medicine. At Leeds the degree of Master of Surgery may be conferred upon Bachelors of Medicine and of Surgery of the University of not less than five years' standing. Candidates for the degree are required to pursue a course of advanced study and research for two years, one year of which may be part-time. University requirements for the higher qualifications vary and particulars should be obtained from the one selected.

The Faculty of Radiologists offers a Fellowship (F.F.R.) to medical graduates of five years' standing who have spent at least one year in general clinical work at approved hospitals, hold a radiological diploma, and, since obtaining it, have practised radiology exclusively for at least two years. Candidates are required to pass an examination. Those who hold higher medical or surgical qualifications may be exempted from the examinations in general medicine, general surgery, and pathology.

POSTGRADUATE EDUCATION

Facilities in London

To provide postgraduate education in London, supplementing the provisions at the undergraduate medical schools and teaching hospitals, a joint board has been set up through which the three Royal Colleges and the British Postgraduate Medical Federation co-operate. Each of the three Royal Colleges arranges courses of lectures in the clinical aspects of its specialties and provides expert advice and guidance on suitable hospital appointments and programmes of study for candidates for its higher qualifications. At the Royal College of Surgeons there is residential accommodation for postgraduate students. The services of the staff at the central office of the Federation (2, Gordon Square, London, W.C.1) are available to all postgraduates, including those from the Commonwealth and Empire, and foreign countries. The Federation is arranging a fourth series of advanced lectures, to be delivered two afternoons a week at the London School of Hygiene and Tropical Medicine during the autumn and winter terms of the 1953-4 session. The lectures are designed specially for research workers and specialists in training and are open to all registered medical practitioners without fee. Further details appear in the advertisement pages of this issue.

British Postgraduate Medical Federation

The British Postgraduate Medical Federation, which is a school of the University of London, comprises the Postgraduate Medical School at Hammersmith (with its university departments of general medicine, general surgery, and pathology) and 14 specialist institutes, each concerned with some clinical branch of medicine or surgery and associated with the special postgraduate teaching hospitals. These institutes are in various stages of development, and the numbers of students who can be admitted to the clinical practice of some of the hospitals are limited. Resident clinical appointments are available in the teaching hospitals to suitable students of the institutes, and these provide the most valuable form of postgraduate education. There are opportunities for research by selected graduates. At all the institutes courses of instruction are given throughout the academic year. These are suitable for graduates in the early stages of their specialist education and also for those who have completed their practical training. Two or more years of hospital work in general medicine and general surgery after graduation are normally advisable before beginning work in the special branches.

The work at the institutes is of an advanced type and comprehensive enough to enable graduates with suitable practical experience to prepare for higher degrees and

diplomas. Emphasis is placed on clinical and laboratory teaching, supplemented by lectures and demonstrations. The Federation awards annually a number of travelling fellowships to graduates working in medical schools or hospitals of the University of London, for the purpose of studying abroad. In addition refresher courses and other forms of continuing education for general practitioners are arranged at hospitals throughout the four metropolitan regions. This is done with the assistance of regional advisers in postgraduate medical education.

It is essential for prospective postgraduate students from abroad to make their arrangements well in advance. Those sponsored by their governments, universities, or other official bodies receive first consideration in the allotment of vacancies. Established specialists from overseas who are here for a short time, and who wish to see something of the practice of this country, are always welcome; they are regarded as visiting colleagues, and the experts in their respective specialties are always ready to receive them and demonstrate their work and teaching. An information bureau of postgraduate activities in London and other university centres is maintained. The director of the Federation is Professor Sir Francis Fraser.

The Postgraduate Medical School of London (Hammersmith Hospital, Duane Road, W.12) has university departments in medicine, surgery, and pathology. The teaching in the clinical departments, based on ward work, is continuous and is supplemented by lectures during three 10-week terms starting in January, April, and October. A course for the University diploma in clinical pathology, lasting one year, is available for a limited number of selected students. The department of radiology of the hospital provides courses for the diplomas in medical radiology of the Conjoint Board. All these courses begin in October. Long-term and short-term tuition in anaesthetics is provided for a small number of students.

The Specialist Institutes

Below are very brief particulars of each of the specialist institutes, with the name of the hospitals with which they are associated.

Institute of Psychiatry (Bethlem Royal and Maudsley Hospitals, Denmark Hill, London, S.E.5).—Training normally covers two or three years after experience elsewhere in general medicine and is based on responsible hospital duties under supervision. Regular series of lectures and demonstrations given throughout university terms. Clinical training continues throughout year and includes seminars and case discussions. Students who, having had previous experience, do not wish to take comprehensive two-year course are able to attend limited series of lectures and clinical instruction. A course in technique and clinical application of electroencephalography is held jointly with Institute of Neurology two or three times a year. There are facilities for original investigations under supervision in the clinical departments and in the psychological, neuro-anatomical, electro-physiological, and biochemical departments.

Institute of Laryngology and Otology (Royal National Throat, Nose, and Ear Hospital, Gray's Inn Road, London, W.C.1, and Golden Square, London, W.1).—Comprehensive full-time course lasting eight months held twice a year, beginning February and September: first three months devoted to a study of the basic sciences of the specialty and the following five months to the clinical aspects. Part-time advanced revision course, lasting 10 or 12 weeks, suitable for students preparing for higher qualifications, held twice yearly, beginning February and August.

Institute of Ophthalmology (Judd Street, London, W.C.1; associated with the Moorfields, Westminster, and Central Eye Hospitals).—In addition to teaching by attendance on hospital practice, a routine lecture and tutorial course, normally covering two terms of approximately 18 weeks each, is held twice a year, beginning in March and October. The first part is devoted to anatomy, embryology, histology, physiology, optics, and elementary clinical instruction, and the second part to bacteriology, pathology, operative surgery, medical ophthalmology, and all aspects of ophthalmic disease. Clinical teaching and lectures are given at a higher level for advanced students. There are facilities for research for suitably qualified candidates.

Institute of Child Health (Hospital for Sick Children, Great Ormond Street, London, W.C.1; Queen Elizabeth Hospital for

Children, Hackney; and Postgraduate Medical School, Hammer-smith).—Provides tuition throughout the year in three terms of three months each, beginning in January, April, and October. In addition a series of lectures by specialists and experts in various spheres is given each term.

Institute of Obstetrics and Gynaecology (Queen Charlotte's Maternity Hospital, London, W.6; Chelsea Hospital for Women, London, S.W.3; and Department of Obstetrics and Gynaecology, Postgraduate Medical School).—Teaching based on ward work, supplemented by lectures and demonstrations during two terms of three months' duration beginning in March and September. Short intensive courses of a fortnight's duration, held in June and December each year, suitable for students preparing for higher qualifications.

Institute of Neurology (National Hospital, Queen Square, London, W.C.1, and Maida Vale Hospital for Nervous Diseases, London, W.9).—Teaching mainly by attendance on the hospital practice, supplemented by lectures and demonstrations. Two whole-time courses in clinical neurology held annually, beginning in January and October. Clinical instruction in neurosurgery given throughout the year. Courses of clinical demonstrations (two weekly) held several times a year. Advanced students appointed as clinical clerks in the wards or attached to special departments and research laboratories.

Institute of Orthopaedics (Royal National Orthopaedic Hospital, Great Portland Street, London, W.1).—Complete training in orthopaedics to selected graduates already trained in general surgery and basic sciences is offered by means of clinical appointments covering a period of two or three years, with opportunities for research. For graduates requiring a less extensive period of education in the specialty, and especially for those who have acquired practical experience overseas or elsewhere, a series of advanced courses is held each year, beginning in October, and each lasting 7 to 10 days. Twice a year, in April and September, a short revision course of a week's duration is held in advanced clinical orthopaedics. The country hospital at Stanmore, as well as the central hospital in Great Portland Street, is attended by postgraduate students.

Institute of Dental Surgery (Eastman Dental Hospital, Gray's Inn Road, London, W.C.1).—To train dental practitioners in the special branches of preventive and therapeutic dentistry. A six-months course for candidates preparing for the F.D.S. of the Royal College of Surgeons begins in January and July.

Institute of Cancer Research (Royal Cancer Hospital, London, S.W.3).—Postgraduate lectures and courses of instruction are held for students studying for the M.Sc. degree in biophysics and for the D.M.R. Facilities are afforded to those wishing to pursue research in the clinical and pathological aspects of cancer. Facilities are also available for research into the physical and biological foundations of medical radiology. There are laboratories for chemical, biochemical, and histological investigations into cancer and allied diseases.

Institute of Diseases of the Chest (Brompton Hospital, London, S.W.3, and London Chest Hospital, E.2).—Students may enrol for one term or more on an approximately half-time course, and arrangements are made for students who intend to specialize in diseases of the chest to attend a whole-time comprehensive course during the two terms, beginning in October and January. Courses consist of clinical work in wards and out-patient departments, lectures, and demonstrations. A small number of students with adequate experience can be accepted for training in thoracic surgery. Part-time instruction in radiology of the chest for trainee radiologists only is given each term.

Institute of Cardiology (National Heart Hospital, Westmoreland Street, London, W.1).—Six appointments of registrar type offered each year to physicians in training as cardiologists who already have a sound grounding in general medicine. General physicians may enrol for full-time or part-time instruction for one term of approximately three months. Three intensive courses of lectures and demonstrations, each lasting a fortnight, are held in February, June, and November.

Institute of Dermatology (St. John's Hospital for Diseases of the Skin, Lisle Street, London, W.C.2).—Throughout the year clinical teaching takes place in the out-patient department twice daily, and ward instruction is given in the in-patient unit at the Eastern Hospital. There are also facilities for study and tuition in pathology, including mycology, radiotherapy, physiotherapy, and clinical photography. A short course of lectures is given in the summer months, and a longer and more systematic course in the winter. In addition, courses of clinical demonstrations are given for candidates for higher degrees and diplomas. Discussion on cases of special interest, to which students attending the courses are invited, takes place once a week.

Institute of Urology (St. Peter's, St. Paul's, and St. Philip's Hospitals, London, W.C.2).—Comprehensive instruction is given in the wards, out-patient departments, operating theatres, laboratories, etc., throughout the year. Advanced intensive course of one to two weeks' duration held in June. Week-end courses of demonstrations and lectures held in January, April, and October for higher examination candidates. Courses of lectures and demonstrations of clinical and laboratory material are held from time to time in co-operation with members of the Medical Society for the Study of Venereal Diseases, each course of two months' duration. During these courses the practice of the venereal department is open to students. In the winter a series of lecture-discussions on urological subjects of interest to the whole profession are held. Limited numbers of clinical assistants are appointed from time to time to individual surgeons for personal tuition.

Institute of Basic Medical Sciences (Royal College of Surgeons of England).—Comprises the departments of anatomy, physiology, pathology, and pharmacology of the Royal College. The Institute co-operates with other specialist institutes of the Federation in providing facilities for practical work and instruction in the basic medical sciences. There are opportunities for research for selected graduates. Full-time or part-time courses of three months' duration, suitable for candidates for higher degrees and diplomas, begin in April and October.

At this last institute and at several of the others there are revision courses periodically.

Fellowship of Postgraduate Medicine

The Fellowship of Postgraduate Medicine (60, Portland Place, London, W.1) provides general information on postgraduate work, and arranges courses for, though not restricted to, candidates for the higher degrees. These include general medicine, general surgery, proctology, obstetrics, and children's diseases. Some are full-time courses lasting from one to two weeks; others are spread over longer periods and are intended particularly for postgraduates who are not free for full-time study. The Fellowship also arranges week-end courses, occupying the whole of a Saturday and Sunday. These are given in various hospitals and include such subjects as general surgery, general medicine, orthopaedics, rheumatic diseases, and infectious diseases.

Facilities at Oxford

Postgraduate medical education for general practitioners takes very much the same course at the United Oxford Hospitals and in the region as it has done for the past two years. Sir Robert McCarrison, the director of studies of the Postgraduate Medical Education Committee of the University, has decided to cut down the number of set courses and is anxious that such courses as are likely to take place should have the form of a "seminar" in which general practitioners attending will be asked to examine patients and thereafter discuss their findings and suggestions for treatment with the specialists and other practitioners present.

The programme of the United Oxford Hospitals for 1953-4 includes ward-rounds in medicine, surgery, gynaecology, and tuberculosis; clinical demonstrations in chest diseases, paediatrics, infectious diseases, psychiatry, geriatrics, neurology, and orthopaedic surgery; conferences in clinical pathology; antenatal and post-natal clinics; and out-patient clinics in child welfare, venereal and skin diseases, and plastic surgery. All these demonstrations are open to general practitioners, who may attend on occasions convenient to themselves, whether these be spread over the academic year or concentrated into periods of a week or more. Short courses or conferences on special subjects are arranged for general practitioners if there is sufficient demand for them. The address of the Postgraduate Medical Education Committee is 11, Keble Road, Oxford.

Postgraduate Facilities at Cambridge

The School of Postgraduate Teaching and Research at Cambridge comprises the departments of medicine, experimental medicine, radiotherapeutics, and human ecology. In

the John Bennett Clinical Laboratories pathological and biochemical services of the United Cambridge Hospitals are provided by university teaching officers under the direction of the professors of pathology and biochemistry. New accommodation for the medical school administrative headquarters and the department of medicine has been provided during the year on a site in the grounds of Addenbrooke's Hospital. The new premises include a haematological laboratory, a chemical laboratory, consulting- and examination-rooms, accommodation for the regius professor of physics, the lecturer in medicine, the research chemist and research students, and administrative offices for the medical school. The transfer to new premises brings together under one roof for the first time the medical, administrative, research, and technical staffs of the Department of Medicine and the Medical School.

Between October and July in each academic year special sessions are devoted to teaching by all members of the consultant staff of the United Cambridge Hospitals. A small number of undergraduate students are admitted to these teaching sessions. Other teaching activities include a clinico-pathological conference held on the third Wednesday of each month which affords an opportunity for general practitioners and others to meet the staffs of the teaching hospital and of the various departments of the medical school. One-day symposia on subjects of particular interest to general practitioners are held monthly on Saturdays throughout the academic year. These symposia usually take the form of lecture-discussions followed by case demonstrations. Residential courses in midwifery are available for undergraduate and postgraduate students at the maternity hospital.

All postgraduate courses and symposia are open, without fee, under a scheme of the Ministry of Health, to practitioners who are under contract with an executive council of the National Health Service, and who have not less than 500 (or in the case of a rural practice 250) persons on their N.H.S. lists. It is no longer necessary for a practitioner to submit an application for approval to the Ministry of Health before attending these symposia unless he wishes to claim for the employment of a locum tenens. A practitioner who does not qualify for a grant under the Ministry of Health postgraduate scheme is charged a fee at a rate corresponding to that which would otherwise have been payable by the Ministry. The director of postgraduate education for the Cambridge region is the regius professor of physics, Sir Lionel Whitby. Practitioners desiring further details of postgraduate facilities should apply to the secretary of the Medical School, Tennis Court Road, Cambridge.

Postgraduate Facilities in Edinburgh

The Edinburgh Postgraduate Board for Medicine (Surgeons' Hall, Edinburgh, 8) organizes courses in internal medicine and medical sciences as well as short refresher courses for general practitioners. The Royal College of Surgeons of Edinburgh is holding under the aegis of the Board two 10-weeks courses in the medical sciences, one starting on October 5, 1953, and the other on January 4, 1954. The fee is 25 guineas. The next 12-weeks course in the medical sciences organized by the Board will begin in July, 1954, and the fee will be 30 guineas. The next fortnight refresher course for general practitioners will probably be held during the first part of May, 1954, but so far no definite arrangements have been made regarding this.

The University of Edinburgh does not offer courses in preparation for the higher degrees in medicine and surgery, but courses for the diplomas in public health, tropical medicine and hygiene, radiodiagnosis, radiotherapy, and psychiatry are given. An intensive course for the diploma in psychiatry, lasting five weeks, will begin in October, 1953, for the examinations in December, 1953, and April, 1954. While this course is primarily intended for those registered as candidates for the diploma of the University, it is open to others who may be interested to apply for permission to

attend. The courses for the diplomas in medical radio diagnosis and radiotherapy now occupy a full-time period of two years' study. The University offers a three-year course leading to a certificate in medical illustration.

Postgraduate Courses in Other Universities

At Sheffield the University's own postgraduate committee continues to give attention to appropriate matters domestic to the locality, and a Regional Postgraduate Medical Committee, centring upon the University, has been set up to deal with the region as a whole. The question of interchange of senior registrars between teaching and non-teaching hospitals is one of those under active consideration. Weekly ward-rounds for general practitioners are held at the United Sheffield Hospitals and the City General Hospital. No diplomas in radiology are awarded by this university but courses are available in preparation for the D.M.R.C. and D.M.R.T. of the Conjoint Board. Numbers have recently been insufficient to justify the organization of definite courses in preparation for the M.R.C.P. or F.R.C.S., but suitable instruction may be provided, by arrangement, for approved candidates.

At Leeds postgraduate education for general practitioners takes the form of week-end courses, some four of which are given each year. This year it is hoped to organize a series of extended refresher courses not only in Leeds but in other large medical centres in the region. These will comprise one half-day session a week for six weeks in both the teaching and major regional hospitals.

At Liverpool similar arrangements are proposed for next session with regard to postgraduate courses. Last session the number of students attending the courses was as follows: general surgery (14), orthopaedic surgery (13), anaesthesia (15), public health (9), radio-diagnosis (12), radiotherapy (3), and tropical medicine and hygiene (33). Three short refresher courses for general practitioners were also held, each consisting of four weekly sessions. The first, on obstetrics and gynaecology in general practice, was attended by 58 practitioners; the second, on recent advances in general medicine, by 55; and the third, which was on two subjects, children's diseases and therapeutics, was attended by 42 practitioners.

A postgraduate course for general practitioners was held in the Medical School of the University of Durham and the associated hospitals during April and May. It consisted of eight consecutive weekly half-day sessions in various subjects, and was so arranged as to bring forward the latest developments in each. The demand for admission to the course was great, and many applicants had to be refused; the number attending was limited to 25.

Highly successful courses for general practitioners have been arranged for Sunday mornings by the Medical Faculty of the University of Bristol. At Manchester refresher courses for general practitioners have been held in obstetrics and medicine, also an intensive course in industrial health. Postgraduate study facilities have been provided at Manchester for a number of students from overseas. In the Welsh National School of Medicine at Cardiff postgraduate instruction for practitioners is given regularly in certain departments, and postgraduate courses in tuberculosis attract large numbers.

In Glasgow the Postgraduate Medical Education Committee, representing the University and the Royal Faculty of Physicians and Surgeons, proposes to offer during the coming session an eight-weeks part-time course of instruction in anatomy, physiology, biochemistry, pathology, and bacteriology. The course—a total of about 160 hours of instruction—is suitable for candidates preparing for the primary examinations for the surgical fellowships. It is organized chiefly for the junior staff of hospitals in the Western Region, but it is also open to other applicants. If desired, an honorary part-time clinical attachment will be arranged for members of the course who have no hospital appointment. Short courses in other specialties are arranged from time to time, including in the coming session a short

course in chemotherapy and a course in mental deficiency. Refresher courses for general practitioners are held, consisting largely of clinical demonstrations, but including a few lectures on modern methods of therapy. The director of postgraduate medical education is Professor G. M. Wishart, whose address is the University, Glasgow, W.2.

The Queen's University of Belfast holds a two-weeks refresher course in September of each year for general practitioners. Postgraduate instruction is also given at the recognized teaching hospitals for graduates who are proceeding to higher degrees.

Beginning in October, 1953, the Royal College of Surgeons in Ireland will give a four-months course in anatomy, physiology, and pathology in preparation for the Primary Fellowship examinations. There will be two courses in each year, one starting in October for the February examination and the other in March for the July examination. These courses will be full-time, and it is hoped to make them fully comprehensive. Details of the courses are printed with the regulations, and copies may be had from the Registrar of the College, St. Stephen's Green, Dublin.

MEDICAL PSYCHOLOGY

The Tavistock Clinic (2-4, Beaumont Street, London, W.1) is an out-patient clinic comprising two departments—the adult department for the treatment of patients with neurotic and personality disorders, and the department for children and parents in which difficulties in parent-child relationships and in the personality development of children are treated. A number of senior registrar and registrar appointments in both departments provide systematic training in adult psychotherapy and child psychiatry. The Clinic also offers a two-year extramural course for psychiatric registrars and consultants in the principles of psychotherapy and psychopathology, with special reference to group treatment (adults). There are courses also for general practitioners: an introductory weekly discussion group on principles of psychological medicine and the doctor-patient relationship applied to their own work, and a more advanced course, including case supervision, for those wishing to gain more experience in the treatment of neurotic and psychosomatic disorders in their own practice. In addition there is elementary and advanced training in the Rorschach method of personality diagnosis (open to psychiatrists), as well as general courses of training for clinical and educational psychologists, child psychotherapists, social workers, and speech therapists. The Clinic welcomes visitors, and has facilities for offering Associate status to interested overseas psychiatrists, psychologists, and social workers who are in Great Britain for further training. Full particulars may be obtained from the Training Secretary at the address given above.

The National Association for Mental Health (39, Queen Anne Street, London, W.1) arranges training courses in child psychiatry. Fellowships are given to enable qualified psychiatrists to obtain special training in child guidance at a recognized training clinic, and these are tenable at a number of clinics in Great Britain. The association also runs a number of other courses, especially for those whose work is among the subnormal and the mentally defective.

The Institute of Psycho-Analysis (63, New Cavendish Street, London, W.1) furnishes a part-time course, lasting about four years, in psycho-analytic theory and technique. It includes a personal analysis, attendance at lectures and seminars, and clinical work under supervision. The Institute does not set out to teach all aspects of psychiatry, and general psychiatric experience must be obtained at other clinics and hospitals.

The training given at the Institute of Psychiatry, associated with Bethlem Royal and Maudsley Hospitals, is referred to in the account of postgraduate facilities in London, given on page 499.

Courses in psychiatry are given at various universities.

RESEARCH CAREERS

Some practitioners forsake the prospect of clinical medicine for a career in the scientific aspects of practice or in medical research work. The first step in such a career is usually a junior post in the laboratory service of a teaching hospital or in one of the centres of the Public Health Laboratory Service (see below). The salaries offered are often at the registrar level, providing for promotion from junior registrar to senior registrar; or appointment and remuneration may be in the hands of a university with salaries in the demonstrator and lecturer classes. A career may also be entered upon at an earlier phase by the relatively few students who in their pre-qualification period have shown an aptitude for research and who may enter the service of the Medical Research Council or obtain a scholarship or grant. The biggest outlets are clinical pathology and university appointments associated with teaching and research. For all of these there is no finer training than that arising from the handling of the immense volume of routine pathological work that passes through the laboratories of any large hospital. Aptitude for research is often manifested or confirmed during this period of training and may determine the future career by differentiating between an academic life in the employment of the Medical Research Council and a practical career devoted perhaps to clinical pathology in a local hospital. Aptitude for teaching is also revealed during this period and may determine a future career in the university sphere, culminating in a readership or professorship. Applications should be addressed to individual universities, corporations, or other bodies advertising vacancies.

The Medical Research Council

The Medical Research Council, established 40 years ago as the Medical Research Committee, is appointed to administer the funds provided annually by Parliament for the promotion of research in medical science. The members are appointed by the Committee of the Privy Council for Medical Research. The Council is not constitutionally a Government department; it selects and appoints its own staff, who are not Civil Servants. Its sphere of action in promoting medical research is unrestricted by territorial or departmental limitations of function. It maintains close touch with Government departments having responsibilities for public health, and collaborates freely in subjects of common interest with its sister research organizations—the Department of Scientific and Industrial Research and the Agricultural Research Council—and with cognate organizations in other countries.

Some 18 of the 50 research establishments of the Council are concerned with clinical problems, and the Council's activities in promoting clinical research are soon to be greatly extended through the medium of a clinical research board to be set up as part of the recently published arrangements for encouraging clinical research in the National Health Service. The Council's central research establishment, the National Institute for Medical Research, has separate divisions of biochemistry, chemotherapy, bacterial chemistry, physiology and pharmacology, human physiology, experimental biology, bacteriology and virus research, physical chemistry, biophysics and optics, and biological standards. The interests of the Council's other research units range from fundamental laboratory subjects, such as biophysics, chemical microbiology, and radiobiology, to various aspects of social and industrial medicine.

The close association of most of the Council's establishments with hospitals and universities is valuable from many points of view, especially in the opportunity it provides for collaboration in joint schemes of research. Senior members of the Council's staff are often given the status of honorary physicians of the hospitals in which their units are situated, while members of units accommodated in university depart-

ments are in many cases given honorary university appointments and participate to a limited extent in teaching.

The Council's total scientific staff numbers just over 450, of whom about one-third are medically qualified. The average research unit consists of from 5 to 10 scientific workers with a number of technical and clerical assistants. They are located mainly in hospitals and universities. Plans for expanding clinical research in the National Health Service have recently been published (see *British Medical Journal*, July 18, p. 140).

Emoluments

The aim of the Medical Research Council is to provide the opportunity for careers which are equivalent to those offered in the universities to men and women of equal ability and experience. The Council's salary scales for scientific appointments are based on this principle; although there is no common scale for all the universities in the United Kingdom, the Council's salary grades correspond approximately with the ranks of professor, reader, senior lecturer, lecturer, and demonstrator. Thus the emoluments of the director of one of the Council's clinical units are equivalent to those of a whole-time professor of medicine with an honorary contract as a consultant in the National Health Service. The salary of a non-clinical director would normally be equivalent to that of a major non-clinical or purely scientific chair. Apart from the directors, there are other posts in the Council's larger establishments, and particularly at the National Institute for Medical Research, which carry remuneration at or near the professorial level.

For the most part, salaries are not fixed in relation to particular posts but rather with reference to the qualifications, experience, and responsibilities of the individuals. Promotion to a higher grade may be awarded on such grounds without change of post.

New appointments to the scientific staff, except in the cases of senior posts, are normally made for definite periods, usually of three or five years at a time. At a later stage, when an adequate degree of seniority has been attained, the Council may, in suitable cases, express the intention of continuing employment until the normal retiring age of 60 has been reached, with the possibility of extension to 65.

Superannuation provision—normally under the federated superannuation scheme for universities, but in certain cases under the National Health Superannuation Scheme—is made in respect of appointments except those of recent B.A., B.Sc., and M.A. graduates, who may have to wait a year. In addition to maintaining its own staff the Council makes very large numbers of short-term grants in support of specific research projects carried out by independent research workers in universities, hospitals, and elsewhere. The Council also awards clinical research fellowships, scholarships for training in research methods, and certain travelling fellowships. These last are awarded either on an agency basis for other bodies or from private benefactions entrusted to the Council.

Public Health Laboratory Service

On behalf of the Ministry of Health the Medical Research Council administers the Public Health Laboratory Service, which was originally set up as an emergency service in 1939, and has since become permanent; there are over 50 separate laboratories in England and Wales. In addition to their more routine duties members of the staff of the Service, whose salary scales are normally equated with those of the National Health Service, undertake research problems on bacteriology and epidemiology. Furthermore, the Service maintains a number of special laboratories which act as reference centres for particular infections, and these engage largely in research.

A booklet giving details of the opportunities for appointment to the scientific staff of the Council, and of the awards of grants, fellowships, and scholarships, may be obtained from the secretary, Medical Research Council, 38, Old Queen Street, London, S.W.1.

Other research institutions in London are the Asthma Research Council (King's College, Strand, W.C.2); the Chester Beatty Research Institute (Royal Cancer Hospital, Fulham Road, S.W.3); the Empire Rheumatism Council (Tavistock House North, Tavistock Square, W.C.1); the Lister Institute of Preventive Medicine (Chelsea Bridge Road, S.W.1); and the Wellcome Research Institution (183-193, Euston Road, W.C.1).

MEDICAL AUXILIARIES

The Board of Registration of Medical Auxiliaries (B.M.A. House, Tavistock Square, London, W.C.1) was set up many years ago, principally at the instance of the British Medical Association. The desirability of having a national register of trained persons engaging in technical work or practice ancillary to that of the medical profession was obvious. The register includes radiographers, dispensing opticians, chiropodists, speech therapists, orthoptists, dietitians, physiotherapists, and biophysical assistants. The Board is a registering and disciplinary, but not an examining, body; examining bodies in the various branches are approved by the Board and appoint representatives to its council. The Board's function is to co-ordinate the work of the various auxiliaries, to ensure that they are qualified, to maintain and improve their standard of training, and to effect liaison between them and medical practitioners.

All the many thousands of persons whose names appear on the register hold a qualification in their branch which is recognized and approved by the Board. With the exception of the chiropodists, all those on the register undertake not to carry out any medical auxiliary work except under the direction and control of a medical practitioner. The chiropodists confine their practice to the treatment of malformed nails, superficial excrescences, and the like.

The qualifying bodies for the respective branches are the Society of Radiographers, the Association of Dispensing Opticians, the Society of Chiropodists, the College of Speech Therapists, the British Orthoptic Society, and the British Dietetic Association. Established periods of training are imposed. Radiographers and chiropodists, for example, have two years' training, and speech therapists a three-years whole-time course, all of it at recognized centres.

The Chartered Society of Physiotherapy (Tavistock House North, Tavistock Square, London, W.C.1) maintains its own national register, and approves schools for training and examinations.

THE ARMED FORCES

The conditions of service in the medical branches of the armed Forces have recently been under active discussion and the decision was not available at the time the information for this Educational Number had to be prepared.

Royal Army Medical Corps

Entry into the Royal Army Medical Corps is in the first instance by means of a short-service commission, and subsequently, for male officers, by selection to a regular commission on completion of six months' combined national service and short service. The appointment to a short-service commission is in the rank of lieutenant, with promotion to captain on completion of one year's service. All previous follow-up service as a medical officer counts for promotion. Candidates must ordinarily be under the age of 45. The period of short-service commissions is eight years, of which any period from two years upwards may be spent on the active list, and the remainder on the Regular Army Reserve.

Short-service male officers on completion of six months' total service as medical officers may apply for a regular commission. The active-list period of the short-service commission and other service will count towards ultimate retired

pay or service gratuity on appointment to a regular commission, but such officers are not entitled to any short-service gratuity. Further details may be obtained from the Under-Secretary, War Office, and a personal interview with a representative of the Director-General, A.M.S., is available at Lansdowne House, Berkeley Square, London, W.1.

Professional Training of Army Officers

Medical officers commissioned in the R.A.M.C. receive postgraduate training at the Royal Army Medical College, Millbank, London, S.W.1. The College has a director of studies and tutorial staff for the teaching of Army health, pathology, tropical medicine and entomology, military surgery, Army psychiatry, radiology, dermatology, and venereology. Regular R.A.M.C. officers between their eighth and tenth years of service pass through the senior officers' postgraduate course of professional studies. Those who satisfy the College council that they are suitable may proceed to individual specialist training for one year, undertaken in general in selected teaching schools or hospitals.

The department of Army health at the College provides facilities for special study in the maintenance and enhancement of the health of the Army. Officers intending to specialize in Army health are given the opportunity of taking the D.P.H. during their specialized course, and are assisted in obtaining their D.T.M.&H. The department of pathology provides lectures, demonstrations, and practical classes covering laboratory diagnosis and pathological aspects of general, tropical, and preventive medicine and military surgery. The syllabus of the department of military surgery covers both general and regional surgery and includes the surgery of tropical diseases and the management of surgical conditions peculiar to service both at home and abroad.

Naval Medical Service

Entry into the Naval Medical Service as acting surgeon-lieutenant is, in the first instance, on a short-service basis for four years, with a gratuity on leaving the Service. Short-service officers who wish to make the Naval Medical Service their permanent career may apply for transfer to the permanent list. Courses for postgraduate study are arranged not only at naval hospitals but at the more important centres of postgraduate instruction.

The rank of acting surgeon-lieutenant is borne for one year and thereupon the rank of surgeon-lieutenant is conferred on the officer with such additional seniority, up to a maximum of two years, as can be awarded to him in respect of house appointments and comparable medical experience before entry. Promotion to surgeon lieutenant-commander is granted after eight years' continued service, and further promotion is by selection.

Further information may be obtained from the Medical Department of the Navy, Queen Anne's Mansions, St. James's Park, London, S.W.1.

Medical Branch of the Royal Air Force

Medical officers in the Royal Air Force serve at three main types of station—flying, training, and maintenance—and also at hospitals and other medical units. The station medical officer is responsible for the medical care of the station and supervises hygiene and sanitation. He also undertakes the medical indoctrination of the air crews, further training of medical staff, and the general medical administration. Service families may elect to go on his list as N.H.S. patients. Service hospitals provide a full range of facilities for both in-patient and out-patient diagnosis and treatment. There are rehabilitation units and specialized medical units such as the R.A.F. Institutes of Pathology and of Aviation Medicine.

Further information can be obtained from the Director-General of Medical Services, Air Ministry, Kingsway, London, W.C.2.

TO SAFEGUARD THE PRACTITIONER

The young practitioner immediately on registration should join one or other of the defence and protection organizations mentioned below. This duty is more than ever incumbent upon him in view of the increased litigiousness of the public since the coming of the National Health Service. The caution applies not only to the general practitioner but to the member of a hospital staff, seeing that hospital-employing authorities do not undertake the defence of any member of a hospital medical staff against whom a legal action may be brought, as, for instance, for alleged negligence. However careful a practitioner may be, he is never immune from the chance or accident which may involve him in litigation or the threat of it, and a single successful action against him may ruin him financially; even an unsuccessful action may cause him heavy expense, anxiety, and perhaps some loss of reputation.

The Medical Defence Union (Tavistock House South, Tavistock Square, London, W.C.1) has a membership of 38,750. Membership is open to medical and dental practitioners, and there is special provision for the protection of overseas practitioners practising in any part of the world, with the exception of America. The work of the Union has been increasing by leaps and bounds during the past three years. It provides advice and financial indemnity for any member threatened with or involved in litigation raising a question of professional significance or, more commonly, based upon a charge of professional negligence. The accumulated funds are £112,155, and the subscription income is mounting annually, though costs of litigation and settlements out of court are increasing at an even more rapid rate. Since its foundation the Union has spent just upon half a million on damages and costs incurred in protecting members.

The Medical Protection Society (Victory House, Leicester Square, London, W.C.2) has a membership of over 28,000. Membership is open to registered medical and dental practitioners, including those practitioners who are provisionally registered under the Medical Act, 1950. There are special provisions for members practising overseas and also for practitioners who visit the United Kingdom for postgraduate work. Members are afforded advice and assistance in all matters of professional difficulty, with unlimited indemnity against legal expenses incurred in defending and conducting cases on their behalf, and also against costs and damages in those cases in which adverse verdicts result. This indemnity is secured by financial resources exceeding £150,000 and a reinsurance with Lloyd's underwriters. From year to year the work of the Society increases steadily and larger amounts of costs and damages are paid on behalf of members.

The Medical and Dental Defence Union of Scotland (113, St. Vincent Street, Glasgow, C.2) has a membership of 7,300 throughout Scotland, England, and Northern Ireland. The total assets amount to just upon £40,000. The policy of the Council has always been to give careful consideration to the interests of its members who have claims made against them for negligence and to advise when requested regarding any business, legal, and professional matters arising from their practice.

Advice on Insurance

The Medical Insurance Agency (B.M.A. House, Tavistock Square, London, W.C.1) is not an insurance company, but it is a recognized agent of all the leading insurance offices, and is thus able to obtain for members of the medical profession the best terms available in the insurance market at any given time. The Agency, which is conducted on a non-profit basis, advises on all forms of insurance—personal, household, and practice—and a special pension and insurance plan has been arranged with a panel of leading British offices to provide benefits of a special character to supplement National Health Service superannuation schemes. Special terms exist for the purchase of houses, equipment, and motor-cars.

DIPLOMAS IN PUBLIC HEALTH AND TROPICAL MEDICINE

Most of the universities offer a full-time course in public health, lasting for nine months and beginning in October. In Durham there is a part-time course both for the Certificate and for the Diploma in Public Health, which is proving very successful and appears to be more popular than the whole-time course. Nine practitioners registered for the C.P.H. last October and eight of these passed the examination held in March. The D.P.H. course at Durham began in April and will continue until March, 1954, when the examination for the diploma will take place. The necessary instruction is organized by the Department of Public Health, which is closely associated with the child health, industrial health, bacteriology, and other departments of King's College, Newcastle-upon-Tyne, for the purpose of providing specialized teaching in the various subjects covered by the syllabus. The next complete course for the certificate and diploma begins in October, 1954. At Leeds the D.P.H. continues to be a part-time course of five terms, and it is hoped that a new course will begin in October of this year. From the Welsh National School of Medicine it is stated that inquiries about the C.P.H. and D.P.H. courses have fallen to a low level. The Royal Army Medical College, Millbank, London, is a recognized teaching institute for the D.P.H. and D.T.H.

London School of Hygiene and Tropical Medicine

The work of this school is organized in ten main departments—namely, applied physiology, bacteriology and immunology, biochemistry, clinical tropical medicine, entomology, human nutrition, medical statistics and epidemiology, parasitology, public health, and the Ross Institute of Tropical Hygiene. The course for the University of London's postgraduate certificate and Diploma in Public Health, designed primarily for medical practitioners who intend to enter the public health service in Great Britain, begins in October each year and lasts for nine months. The examination for the certificate is held at the end of the first three months. In addition to the subjects covered by the D.P.H. syllabus the students are entitled to choose for special study one of the following subjects: industrial health, tropical hygiene, institutional administration, medical statistics and epidemiology, and local government. The industrial health lectures and practical work are recognized both by the Conjoint Board and by the Society of Apothecaries as fulfilling in part the requirements for entry to the Diploma in Industrial Health examination. Students who intend to enter for this examination, however, are required to make their own arrangements for attending clinics in accident surgery, dermatology, and ophthalmology. There are no vacancies for the D.P.H. course beginning this autumn.

The course for the University of London postgraduate Diploma in Bacteriology provides advanced instruction for graduates in medicine who intend to follow a career in bacteriology. The course begins in October and lasts for nine months. The course for the Conjoint Board's Diploma in Tropical Medicine and Hygiene is a continuous one of five months' duration and is open to qualified medical practitioners. It is held twice a year, commencing at about the beginning of October and the beginning of March.

The course for the University of London's postgraduate C. and D.T.M.&H. starts at about the beginning of October each year. Both the preliminary and the final courses extend over a period of not less than four months' study. Candidates for the final part of the course, who must have had at least 12 months' experience of medical practice in a tropical country, are required to specialize in one of the following elective subjects: clinical tropical medicine, medical biology in relation to tropical medicine, and tropical hygiene.

During the last year at the school 496 students from 33 different countries were admitted to the various courses, and 22 degrees and 201 diplomas were obtained.

In the department of public health the curriculum for the D.P.H. has been entirely changed since the second world war. There is now a preliminary course of one term, taking the form of a general introduction to the scope and character of the public health and social services, and in the final course, which occupies two terms, the main purpose is to develop the student's knowledge of the public health services to-day and to bring him closely into touch with the practical problems of public health administration. Much of the work during these six months is in the form of practical instruction or else entails independent study by the student. Practical work under the direct supervision of medical officers of health is a constant feature of the final course.

Liverpool School of Tropical Medicine

At the Liverpool School of Tropical Medicine (Pembroke Place, Liverpool, 3) men and women students of any nationality who hold a medical qualification approved by the university are admitted to examination for the D.T.M.&H. Other students are also admitted to special courses in parasitology and entomology. The examination for this diploma is held twice yearly, in December and in April. The fee for admission to the examination is £6 6s., and for each subsequent examination, £5 5s., and the fee for the diploma £3 3s. The fees for the courses of instruction are £42 for the D.T.M.&H. course and £21 for the revision course. Each of the two courses for this diploma has been reduced from five months to three months. The school also gives courses of instruction in public health, parasitology, and entomology for students taking the D.P.H., and courses of instruction in veterinary parasitology and entomology for students taking the M.R.C.V.S. diploma and the B.V.Sc. degree.

Edinburgh University has courses for the D.T.M.&H., lasting two terms, beginning in October. Diplomas in industrial health are granted by a number of bodies, including the Royal Faculty of Glasgow and the Scottish Conjoint Board, and full-time postgraduate courses are arranged at certain universities.

Royal Institute of Public Health and Hygiene

The Royal Institute of Public Health and Hygiene furnishes courses of instruction for the C.P.H., beginning in March and October, and for the D.P.H., beginning in January and August. It also furnishes courses for the Diploma in Industrial Health (the course for Part I of which is the same as, and runs concurrently with, the course for the C.P.H.). For the C.P.H., lectures are given by specialists on the various sociological aspects, and in the D.P.H. the practical work is carried out at a county borough. The D.I.H. course entails visits to all types of factories and to coal-mines.

PROFESSIONAL SOCIETIES

British Medical Association

The British Medical Association (Tavistock Square, London, W.C.1) was founded in 1832 to promote the medical and allied sciences and to maintain the honour and interests of the medical profession. Its membership is about 67,000, and it covers 85% or more of the working profession of the country. It is recognized by the Government, local authorities, and other organizations as the representative body of the profession. Members are elected by the Council of the Branch for the area in which they reside, or, if they are serving with the Forces or for other reasons are non-resident in a Branch area, they are elected by the Central Council. Newly qualified practitioners are admitted to membership at a lower subscription until the end of their fourth year after registration. The Association has important Branches in Australia and New Zealand and flourishing local units in many parts of the British Commonwealth. The Medical Associations of Canada and South Africa are affiliated to the B.M.A.

The policy of the Association is determined by the Representative Body, which is composed of representatives from all the Divisions. A Constitution Committee is about to be set up to consider and report on the reorganization of the Representative Body, which, with the growth of the Association, has become somewhat unwieldy in size. The Council is the Association's executive; its method of election has been recently revised to ensure as equal a representation of the regions as possible, as well as to afford opportunity for the election of a certain number of members on a national basis, and to include representation of the medical branches of the fighting Services, the public health service, and the Overseas Branches.

The principal work of the Association is carried out through a large number of standing and special committees. The Central Consultants and Specialists Committee (which also has a regional organization) acts with the Royal Colleges on all matters arising under the National Health Service Acts affecting consultants and specialists. The General Medical Services Committee acts as the executive of the Conference of representatives of Local Medical Committees in all questions affecting practitioners rendering general medical service under the Acts and is the recognized mouthpiece of the profession in this field. The Public Health Committee, which has a working agreement with the Society of Medical Officers of Health, deals with all matters relating to the public health service. Other committees of the Association are concerned with private practice, ethical questions, and the encouragement of medical science and research, and there are joint committees with other bodies, for the consideration of matters of mutual interest.

The privileges of members of the Association include participation in all its activities, central and local; the weekly receipt of the *British Medical Journal* and its *Supplement*; the use of the Association's house and library at Tavistock Square, London, and elsewhere in Great Britain, and in certain Overseas Branches; and the help of a highly skilled and experienced staff at Headquarters in the many difficulties and problems which arise in practice.

In addition to the *British Medical Journal* the Association publishes a number of specialist journals and abstracts. The library of the Association contains 65,000 volumes, and 1,600 periodicals are received regularly. The library has a large lending and circulating service and is available for reading and reference purposes to members calling at the Association House.

Medical Practices Advisory Bureau

In 1948 the Council of the Association set up a Medical Practices Advisory Bureau, which is functioning at Headquarters under the direction of a member of the medical secretariat. It acts as a central source of information concerning openings in the various fields of medical practice; introduces partners, assistants, and locum tenents; and advises on all individual and personal problems associated with entry into and carrying on of the profession. The facilities of the Bureau are available to any doctor and are free of charge to members of the Association. Inquiries should be addressed to the medical director of the Bureau either at the head office of the Association in London or at the branch offices, 33, Cross Street, Manchester, 2, or 7, Drumsheugh Gardens, Edinburgh.

Empire Medical Advisory Bureau

The Council has set up at Headquarters at Tavistock Square two organizations, one for welcoming and providing a personal advisory service for practitioners visiting this country from the Dominions and Colonies, and the other for performing a similar function for practitioners from countries outside the Commonwealth.

The Empire Medical Advisory Bureau invites all medical visitors from Commonwealth countries to get in touch with it, if possible before arrival, and to call at the Bureau as soon as possible after arrival and talk over with the medical

director (Dr. H. A. Sandiford) any points on which they may need advice or assistance. Last year 788 visitors were interviewed personally by the director, and many hundreds of others were seen by his staff. Altogether over 2,000 visits were paid to the Bureau by old and new visitors during the year. Personal contact is maintained with medical schools, postgraduate institutions, hospitals, and other bodies able to assist overseas visitors in the educational field. A register of suitable hotels and lodgings is maintained by the Bureau, and general information is afforded concerning travel, customs duties, facilities for sport, exhibitions, and the like.

The other organization is the International Medical Visitors Bureau, also located at B.M.A. House, under the directorship of Dr. Sandiford. Here again information is obtainable on postgraduate education, visits to hospitals and clinics are arranged, and assistance is given to visitors in finding accommodation and in many other respects.

Society of Medical Officers of Health

The Society of Medical Officers of Health (Tavistock House South, Tavistock Square, London, W.C.1) is a society of medical officers engaged in public health work in all its branches. It publishes an official organ entitled *Public Health*. There is reciprocal representation on the Association's Public Health Committee and the Society's Council, and the Public Health Committee acts in conformity with an agreement with the Society of Medical Officers of Health under which medical-political activities in this field are undertaken by the Association.

Medical Women's Federation

The Medical Women's Federation (Tavistock House North, Tavistock Square, London, W.C.1) works closely with the Association, and is represented as such by the one woman member on the General Medical Services Committee. The Federation is the only professional organization consisting solely of medical women, and is thus in a position to represent the interests of women doctors and to deal with problems affecting them as a minority in the profession. It also considers and investigates medical matters of special concern to women doctors. The Federation has active local associations all over the kingdom, including a large London association, and an association of its Overseas members. These associations meet regularly, and the *Journal* of the Federation is published quarterly for private circulation among its members.

In addition to the bodies above named there are, of course, the many societies devoted to medical science, headed in London by the Royal Society of Medicine and the Medical Society of London, whose province it is, mainly by papers and discussions and publication, to advance the science and art of medicine generally in one or other of its specialties; there are the medical benevolent societies (the Royal Medical Benevolent Fund, Epsom College, and the Sir Charles Hastings Fund and the Dain Fund of the British Medical Association), and the defence and protection societies, which are the subject of a separate article (page 504).

The third edition of the "British Code of Standards in Relation to the Advertising of Medicines and Treatments" has now been published. The Code has the approval and support of the Newspaper Proprietors' Association, the Newspaper Society, the Advertising Association, the Institute of Incorporated Practitioners in Advertising, and other organizations. The introduction to the Code of Standards urges that newspapers and other advertising media should not accept advertisements for any product or treatment from any advertiser or advertising agent who disregards the provisions of the Code in any form of advertising or publicity relating to that product or treatment. The Code lays down general principles relating to advertisements for medicines and treatments, describes the restrictions imposed by statute, and gives a list of sixty diseases, illnesses, or conditions for which medicines or appliances should not be advertised.

MR. W. D. HARMER, 80

St. Bartholomew's men in particular, laryngologists in general, a host of former students who sat under a most inspiring and encouraging teacher, as well as a large company of grateful patients and friends, will join in good wishes to Mr. William Douglas Harmer on the attainment of his 80th birthday on August 25.

In the closing years of the last century Mr. Harmer left his native Norfolk (where the records of his family go back

to the reign of Henry IV, but without previously a doctor among them), by way of Uppingham School and King's College, Cambridge, to make his name at St. Bartholomew's in London, in which hospital his career has been largely spent, and on the staff of which he is now the senior surgical consultant. It was in general surgery that he first made his mark. In 1901 he took the M.C.(Cantab)—changed in late years to M.Ch.—and contributed his first articles to his hospital journal on general surgical subjects. In due course he was elected assistant surgeon at Bart's and became warden of the Medical College. He succeeded Sir D'Arcy Power as surgeon in charge of the throat department, and was in fact the virtual founder of that department as a separate entity. The first paper he wrote in his special field of surgery appeared in 1907; it was on a subject to which he often returned in his writings—malignant disease of the larynx. The article was followed by many other contributions, some of them describing original forms of treatment. His great experience in this sphere was summed up many years later in his Semon Lecture in the University of London, when he took as his theme the treatment of malignant disease of the upper respiratory and alimentary tracts. His name appears in various textbooks and journals as the author of articles on the surgery of the nose and throat, notably in Carson's *Modern Operative Surgery*. With Dr. N. S. Finzi, the well-known radiologist, he devised a technique of interstitial radiotherapy which is still in use and is known as the Harmer-Finzi operation. The two also founded one of the first consultative clinics to combine surgery and radiotherapy in the treatment of malignant disease—an example followed by other departments at St. Bartholomew's and elsewhere.

A lion-hearted surgeon, Mr. Harmer has been a most inspiring teacher, and the young men he has trained have remained devoted to him. Many of them have served on the staffs of London and provincial hospitals. After his relatively early retirement from active work at Bart's (in order to allow a colleague to be head of the department for a time, since otherwise they would have had to retire together) he continued to serve as surgeon to the Mount Vernon Hospital, and he is still in consulting practice in Portland Place. After the death of his brother in 1932 he was called upon to assume the chairmanship of the family business in Norwich, and he gave that new responsibility close attention until quite recently.

Douglas Harmer has been an active participant in many forms of sport—a good shot, an excellent fisherman, a three-handicap golfer (with wooden clubs of his own making), proficient on the ice (in his youth he skated from Cambridge to Peterborough—an achievement which, it is said, subsequent winters have not permitted anyone to repeat), and an enthusiastic skier, who in 1909—when Davos had scarcely been heard of—went on a long ski-ing expedition in the wild mountains of Montenegro, where the "madness" of the Englishman was suspected as a cover for subversive activities. He is now a keen gardener at his home at Littlestone-on-Sea in Kent, where he can sometimes be seen grafting apple trees in a March gale. Mrs. Douglas Harmer, whom he married 47 years ago, has for many years taken a prominent part in the work of the Ladies' Guild of the Royal Medical Benevolent Fund. One of their three sons, Mr. Michael Harmer, is a surgeon in London.

Over two thousand years ago the Roman writer Varro, who himself lived to 88, said that his 80th birthday warned him to pack his baggage. But Mr. Harmer's baggage is still well spread about and in full employment, and we trust that it will be long before he considers the time has come to begin putting his things together.

Correspondence

Because of the present high cost of producing the *Journal*, and the great pressure on our space, correspondents are asked to keep their letters short.

Bornholm Disease

SIR,—Dr. Gilbert Dalldorf (*Journal*, August 1, p. 287) asks if there is any information available in Great Britain of concurrence or competition of poliomyelitis and Bornholm disease. I have been interested in these diseases for some years, and the following information may be of value.

It is difficult to give an entirely accurate indication of the incidence of the two diseases, because in hospital practice one tends to see all the poliomyelitis and little of the Bornholm, whereas in general practice it is difficult to see the overall picture in a sufficiently wide area and in a sufficiently large number of patients. At the Harborough Road Infectious Diseases Hospital, Northampton, from 1949 to 1951 I saw all the cases of poliomyelitis admitted from Northamptonshire and North Buckinghamshire, which include a mixed rural and industrial population of approximately 400,000. These amounted to approximately 200 cases. During that time, although on the look-out for the disease, I saw or heard of only a few cases of Bornholm disease. It may well be that other cases occurred and were treated by general practitioners, but certainly there was no epidemic corresponding to those of poliomyelitis. I formed the impression that the cases of Bornholm disease occurred outside the epidemic period of the poliomyelitis, either a few weeks before or after.

On the other hand, in the Oxford Hospitals covering a comparable population, again mixed industrial and rural, with the additional University population, poliomyelitis is a relatively infrequent disease, but large epidemics of Bornholm disease have occurred, especially in the years 1950 and 1951. In the latter epidemic Warin *et al.* demonstrated the presence of a Coxsackie virus of the B group.

Again in 1947 in military hospital practice I saw numbers of cases of poliomyelitis, but no Bornholm disease, from the

Catterick military camp.² This camp is in close geographical proximity to the rural area of Wensleydale, in Yorkshire, where Pickles³ made his original observations on Bornholm disease, but there is little actual contact of populations, as most of the troops spend their leisure hours in the larger towns to the north and east, or on leave in other parts of the country. I made an inquiry among the general practitioners of Wensleydale, and gained the impression that there was little or no poliomyelitis in this dale, which runs some 20 miles into the Pennine Hills, but that there had been cases of Bornholm disease for some years previously.

These facts seem to be in conformity with the views quoted by Dalldorf that there is in fact clinical and epidemiological evidence of competition between these diseases. This competition does not appear to completely exclude the other disease, in my experience, but that may be due to the fact that I have not localized the cases sufficiently accurately in season of year or geographically. Bornholm disease is well known for the extremely localized nature of the outbreaks, and it may be that poliomyelitis cases in Oxford in the year in question did in fact come from parts of a town or county unaffected by the former disease.

In 1949 and 1950 in Kettering, Northamptonshire, I was able to find evidence of Coxsackie virus Type A₂ infection by complement-fixation test in five cases diagnosed as non-paralytic poliomyelitis, and follow-up of contacts revealed 25 cases of illness all with positive complement-fixation tests to this virus comprising the following: paralytic poliomyelitis, 6; non-paralytic poliomyelitis, 10; Bornholm disease, 6; infective hepatitis, 3. Antenatal controls from the same town in 1950 gave only two positive complement-fixation tests in 35 tested.⁴

During 1950, out of 92 cases of poliomyelitis from Northamptonshire and North Buckinghamshire, I obtained specimens of sera from 80 patients which were tested in the laboratory of the late Dr. Marshall Findlay for evidence of complement fixing antibodies to the Coxsackie virus Dalldorf Type A₁. Of these approximately 60% were positive and the percentage of positives was the same in both paralytic and non-paralytic cases. In the same year I was able to trace only seven cases of Bornholm disease, and these all had complement-fixing antibodies to the Dalldorf Type A₁ Coxsackie virus in high titre of 1 in 20 or greater than 1 in 20. Unfortunately these cases were not tested for evidence of antibodies to the Coxsackie virus B types, such as has been found in association with Bornholm disease elsewhere.

The whole ecological relationships of these viruses needs to be carefully investigated, but work in this country is at present very considerably handicapped by lack of adequate virological laboratory facilities. I have the impression that competition does in fact exist between poliomyelitis and Bornholm disease, but whether this is a direct interference phenomenon between the poliomyelitis virus and the Type B3 Coxsackie virus, or whether there is yet another stage in the process such as an interference phenomenon between a Coxsackie virus Type A found to be associated with poliomyelitis in Northamptonshire and the Type B Coxsackie virus of Bornholm disease, would seem to need further investigation. It is not only in this field that further work is necessary, but also in discovering whether there is any ecological relationship between the Coxsackie viruses, the poliomyelitis viruses, and the yet undiscovered viruses of cases of meningo-encephalitis which appear to have become so much more common in the past three years.

One last observation concerns the severe epidemic of poliomyelitis in Denmark in 1952, when the Island of Bornholm had the highest number of notified cases of poliomyelitis, 140 per 100,000 population.⁵ Is it just chance that this island which gave its name to the disease some 20 years or more ago should be so affected with poliomyelitis? Pickles refers to Wolter's description of remarkable epidemics named "Haffkrankheit" which affected fishermen on the shores of the Frisches Haff, a narrow gulf communicating with the Baltic, as belonging to the same family of diseases as Bornholm disease, with the important difference of a substantial mortality among the sufferers. Wolter identified these outbreaks with one in 1529 in the Haff of Stettin, part of an epidemiological phenomenon known as the "English sweat," and in an attempted elucidation of the aetiology brought in the theory formulated by Sydenham and expounded by Pettenkofer that epidemic disease is "conditioned by place and time." In conclusion I quote Pickles⁶ on Bornholm disease: "Epidemic myalgia is of importance only as a mimic of well-known dangerous conditions, but the resemblance to this more serious malady (Haffkrankheit) is close, and it would be imprudent to conclude that future appearances of the disease may not have a more ominous significance."

Clearly much more research is required into the ecological factors of these diseases and particularly the questions of virus interrelationships, virus interference, and virus exalta-

tion. Dare we hope that this country will not lag behind the fine example of virus research set by America?—I am, etc.,

Oxford.

Medical Semantics

SIR,—The Arabic origin of *nucha*, *mater*, *basilic*, and *cephalic* is not my suggestion, as Dr. A. M. Woolman (*Journal*, July 25, p. 225) seems to think. The problem has long engaged those interested in Semitic philology and arises from the strange fact that these words are not found in any classical text. *Basilic* and *cephalic* first appear in a ninth-century translation of Galen into Latin from the Arabic. The subject is fully discussed by Hyrtl (*Arabische u. Hebräische in der Anatomie*, Vienna, 1879) and by Rabin and Singer (*Prelude to Modern Science, being a Discussion of the History. Sources etc. of the Tabulae Sex of Vesalius*, Cambridge, 1946). Rabin and Singer think these words came through rather than from the Arabic, but their origin is anybody's guess. As to *mater*, Dr. Woolman has misunderstood me. This word seems to be a translation into Latin of the Arabic word meaning *mother*.

Whether Germany is north, south, or east of the British Isles is immaterial. The point is that the classical stream, like most streams, did not run in a straight line but was kept south of Central Europe by the Alps. This is an elementary fact of history and geography. Dr. Woolman says that "most German doctors have a more thorough knowledge of Latin than their English colleagues." This I am prepared to believe. It has, however, nothing to do with the fact that intermittently for 1,900 years England was bathed in the classical stream—by the Roman occupation and later by the Norman conquest and the close association with France in the Middle Ages—for the most part of which period countries to the north of the Alps were in a state of barbarism. It is just because Germany was outside the mediaeval classical stream and not because of any superiority in classical education of to-day that, in Dr. Woolman's words, "in English medical writings the Latin terms are often anglicized, in Germany the original Latin is usually employed." Innumerable instances could be given. In order to come into line the Germans had to substitute *ulcus* for *Geschwür* because they had no such word as *ulcer* in ordinary speech. Dr. Woolman thinks *Erreger* more convenient than *offending organism*. *Erreger* is not primarily a medical term but a term in general use meaning agitator, exciter; *offending organism* is new to me.

When I said that German words are clumsy I was, of course, speaking as a non-Teuton. We, after all, are in the great majority. Whether *Schnecke* is more elegant than *cochlea* is a matter partly of taste, partly of nurture. I think I am correct in saying that to the majority of non-Teutons German medical words are as cacophonous (*missklanglich*) as they are cacoptic.—I am, etc.,

Breast-feeding in the Oxford Survey

SIR,—It is, I think, unfortunate that the study which Dr. Alice Stewart and Dr. Celia Westropp have made of the relationship of bacterial infections to artificial and breast-feeding in infancy (*Journal*, August 8, p. 305) should have been published in a journal which is the main source of medical news in general practice. I do not doubt the validity of their conclusions in relation to the case material of their survey, and at one point they remark, "That breast-feeding has advantages to both mother and child which will not show on a weight chart no paediatrician will seriously deny" (I do not know why it should be only paediatricians who might deny it, nor why they should be inclined to do so light-heartedly). But elsewhere they say that the survey

presents a new challenge to the advocates of natural feeding, and I think that many will conclude, after reading this paper, that we have been mistaken in thinking that breast-feeding is of great importance for infant health, and that it matters very little that infants should be fed on a bottle.

I do not think that any reasonably informed doctor has claimed, since the need for sterile technique in bottle-feeding became recognized, that breast-feeding produced infants who were heavier or larger than those who were fed on cow's milk, but we have been accustomed to advance two arguments in persuading nurses and colleagues (not mothers, who rarely need persuasion) that it is worth while to study the subject of human lactation so as to be able to offer useful advice. The first argument has rested on a rather large body of evidence that breast-fed babies are less liable to respiratory and enteric infections; the second argument depends on the rapidly accumulating evidence that successful breast-feeding is an important feature in the development of a good relationship between mother and child, which is the foundation of a good personality. The latter conception is not merely a romantic picture entertained by artists, poets, and sentimentalists, but is quite as intellectually satisfying as the story of scurvy and vitamin C.

The variables are so many in a study of the kind which Dr. Stewart and her colleagues have been making, and the application of mathematics to such material has become so esoteric, that one is naturally hesitant to criticize a conclusion made upon the authors' own ground. Nevertheless, I do not feel inclined to discard the accumulated evidence of the past that the feeding of an infant at its mother's breast has a value in protecting him from the effects of bacterial infection. No doubt the position is altering rapidly, as the hazards of bacterial infection in the first year are reduced, but the social gradient in respiratory infection remains as a sign that very many infants do not receive the best nurture. As the authors themselves point out, the survey excluded weakly infants and provided quite unusually good medical supervision of bottle-feeding. I think that the observations of Dr. Stewart and Dr. Westropp deserve to be noted as a check on what may be a too great readiness to rely upon work which is now out-dated in respect of this one feature of immunity to bacterial disease. But I fear that their paper may easily become a conscience-quelling text for those who do not want to bother themselves about the physiology of lactation.—I am, etc.,

DUNCAN LEYS.

Farnborough, Kent.

Tropical Diseases in Britain

SIR,—I have reread the annotation on this subject (*Journal*, May 16, p. 1096), certain points in which have been taken up by Professor W. Melville Arnott (*Journal*, May 30, p. 1219) and others.

It is unfortunate that in tropical Africa, where I served for many years, a blood film may not confirm the diagnosis of malaria, even in those who have not been taking one of the suppressives. In fact, it is surprising how many of the worst cases have negative films. One has little choice in such cases, and quinine or mepacrine must be given as soon as the film has been taken. There is an old and very true saying that "many a man has gone to his grave because of negative blood films." It certainly is true in the case of infants, so much so that it is prudent to give quite a large number of "febrile tooth-cutting" cases a quinine or mepacrine injection. This is better than finding the child dead, the blood film having been negative and a tooth really on the way through, but no quinine having been given.

There is no mention in the annotation of the type of patient who takes mepacrine or proguanil daily and who, sooner or later, gradually feels more and more depressed and weary, loses appetite, and feels that he no longer seems to be able to stand the heat. This is an example of imperfect suppression, but the parasites seldom come into the peripheral blood to give a positive film. Two things can be done: (a) stop suppressives and let an overt attack come up, treating this when it comes, (b) keep taking daily proguanil and add to it a full course of mepacrine or quinine. There will be no positive blood film, but there will be such a suspicious improvement that neither the M.O. nor the

patient will have much doubt about what has been wrong. A "therapeutic" diagnosis, but, I venture to say, by no means unwarrantable.

I agree with Dr. Bruce Nicol (*Journal*, August 1, p. 288), and consider that the paragraph in the annotation on amoebiasis is so sweeping that the following paragraph on liver abscess does not quite smooth things down.

It is easy to state that persistently recurring diarrhoea, sometimes with the passage of blood and mucus, should raise suspicion of *E. histolytica*. I wonder how often your writer has seen such signs. In the course of some 23 years in Uganda I was stationed for much of the time in districts with an appallingly high incidence of amoebiasis, and found acute symptoms in only a small proportion of the thousands of patients seen—probably no more than 10%. In acute cases the diagnosis is easy, as the free-living *E. histolytica* is present, and "an experienced pathologist" is not necessary. We all had to become reasonably proficient in laboratory (routine) work, and I think we "got by" fairly well. The type of case which gives us most difficulty is that of amoebiasis with no localizing signs at all. This is the patient with loss of appetite, tiredness, inability to concentrate, easily upset, and mentally irritable. He has never to his knowledge had an attack of diarrhoea. He has been in districts known to be heavily involved, however, in his younger days. He may be suffering from liver amoebiasis, as is suggested in the annotation, but equally may have an old-standing infection of his caecum or, less commonly, his sigmoid. Daily stool tests for weeks will be negative. As Dr. Bruce Nicol states, and as I stated some years ago,¹ one grain (65 mg.) of emetine parenterally will produce cysts next day. These are usually uni- or binucleated—i.e., early—and are easily explained. When conditions in the host become bad, the amoeba encysts and goes on its way to find another more receptive host. The bad conditions are created by the dose of emetine. Prior to this, the amoebae have been pursuing a more or less placid existence, well away from the lumen of the large intestine, and are not likely to encyst in large numbers in order to escape to the exterior, being in no need of any change.

I suppose that this is "therapeutic" diagnosis, but, in defence of my own test, I do not agree that it is to be deprecated. Following a positive result, one grain (65 mg.) of emetine is given daily for another two days. There is no need to risk myocardial damage by giving more than three emetine injections. All signs, vague and definite, will disappear and the patient, much better, should then change to one of the other drugs, such as chiniofon ("quinoxyl"), di-iodohydroxyquinoline ("dihaloquin"), etc. If the stools are negative after an emetine injection, my experience over the years leads me to believe that the patient is unlikely to be suffering from old amoebiasis.

Incidentally, did Dr. Nicol find out this little test by himself, or is he one of the few who have adopted it after perusal of my letter in 1946? I have used this test frequently since 1929 with very few failures. I have mentioned it to numerous colleagues, but few seem to have adopted it. Those who did were very satisfied. Perhaps I may hope that others may record their views on the test after a fair trial. I have every reason to believe that the test, devised by me without any knowledge of any other worker doing so, is my own, but I shall await the comments of others.—I am, etc.,

Bridge of Earn, Perthshire.

Neonatal Asphyxia

SIR,—Endotracheal intubation of the newly born is usually left to the anaesthetist. For this reason the technique is more often associated with neonatal asphyxia following delivery by caesarean section. Nevertheless, neonatal asphyxia is by no means peculiar to operative or instrumental means of delivery.

Having used the method over a period of several years, I am impressed with its value in certain particular circumstances. Most striking is the effectiveness of pharyngeal toilet under direct vision. Even more impressive is the certainty with which a good colour can be achieved with intubation and inflation. Follow-up of cases where necropsy has afforded an opportunity to look for injury has revealed no local haemorrhages, emphysema, or trauma resulting from the intubation and inflation. The trachea has been free from damage even after intubation lasting several hours.

The ordinary anaesthetic rebreathing bag is too big for use with the newly born, and an ordinary surgeon's rubber glove taped to the "T" piece has been quite suitable in practice.—I am, etc.,

Watford.

J. NOEL JACKSON.

SIR,—Your annotation on neonatal asphyxia (*Journal*, August 8, p. 328) is fascinating because it shows the wonderful ingenuity that is being shown in overcoming asphyxia by methods far out of reach of the general practitioner, who is most likely to meet the condition. But it is also depressing because apart from an initial reference to "central depression" there seems no reference to the fundamentally important work of the late Sir Joseph Barcroft,^{1,2} who not only showed how the condition normally arises but also gave pretty clear pointers to the way it should be treated.

In December, 1948, I expressed the hope that the considerable correspondence following a letter I had written³ would "ensure that the practical application of Sir Joseph Barcroft's discoveries will no longer be neglected in midwifery teaching, practice, or textbooks"; but it seems to have been a vain hope. He showed that, while oxygen is, of course, necessary for the full control of the brain over respiration, in the foetus of the sheep the earliest respiratory responses came not from oxygen lack but from cutaneous stimulation, at first a single spasmodic gasp (34th day), then one accompanied by two or more contractions of the diaphragm, then two gasps, gradually increasing in number and rapidly till a full respiratory rhythm following cutaneous stimulation is established (50th day) several days before (65th day) occlusion of the cord—that is, asphyxia—will initiate respiratory movements. He even showed at what level in the brain these various responses occur, and that later on asphyxia seemed progressively to depress the functional cerebral level, so that the greater the degree of asphyxia the more primitive the response going back from full respiration to a succession of gasps, a single gasp, and finally none at all. Most of us have at some time or another seen newborn babies in each of these states.

The clinical bearing of these discoveries is clearly that, though the baby is giving occasional gasps or none at all as a result of asphyxia, the lack of oxygen will not initiate respiration, whereas stimulation will or may. Your annotation calls this cutaneous stimulation "little better than punitive," but Sir Joseph in his *Linacre lecture*² says "pain (if such a word can be applied to an organism so anoxaemic that it can have no real consciousness) can have a dramatic effect. There can be no more specific reaction than that of the gasp in a refractory rabbit's foetus when the ear is firmly pinched." Even though oxygen is given to an asphyxiated baby it will, in fact, only be giving its primitive responses to stimuli until full respiration is attained; and this may take a long time, much longer, in fact, if the very gentle methods you advocate are adopted and the reasonable stimuli used in the past are avoided. The first cry is probably a rough dividing-line between these two quite distinct methods of respiration, though there is no doubt that a little stimulation will notably increase the vigour of the cry and aid expansion of the lungs.

There is another way of attacking this problem, to which I have drawn attention many times previously and which had the approval of Sir Joseph. This is to inject some convulsant drug which will so raise the sensitiveness of the depressed cerebral functions that they will respond to stimuli to which they were previously inactive. It is true that you do mention the use in narcosis of N-allyl normorphine, which I cannot find in the latest *Extra Pharmacopoeia*. You also mention, without much conviction, the use of nikethamide. Now nikethamide does happen to be a mild convulsant, but nothing like so effective or consistent as leptazol, and for nearly 20 years I have used with great success a preparation of this ("cardiazol ephedrine") and urged its adoption for nearly 14. Within a few seconds it takes the infant from the non-breathing or occasional gasping stage to full respiration and vigorous crying, so that in most cases the ingenious and complicated devices you describe are quite unnecessary, and it can be used anywhere. Incidentally, injection into the ventricular cavity is simpler, quicker, and more certain than intravenous injection, and perfectly safe.

However, the main purpose of this letter is not to recapitulate details which ought by this time to be matters of common knowledge, but to suggest that if our pundits persist in disregarding fundamental information about the physiology of respiration in the newborn it is no wonder that, as you noted (*Journal*, July 25, p. 199), while the maternal

mortality rate has been quartered in the last 20 years, the stillbirth rate remains unchanged. The intrinsic importance of this subject, as evidenced by the recent report of the Medical Research Council, and also the personal distress caused through stillbirth and neonatal mortality (for my first child was stillborn), are my only excuses for sending you another long letter giving salient points which your annotation seems to ignore.—I am, etc.,

W. N. LEAK.

Aureomycin in Ophthalmology

SIR,—I read with considerable interest the article on "Aureomycin, Chloramphenicol, and Terramycin in Ophthalmology," by Professor Arnold Sorsby, Dr. Joseph Ungar, and Mr. R. P. Crick (*Journal*, August 8, p. 301), but must express surprise that such a conclusion with regard to aureomycin should have been reached on so little evidence. The writers state: "It may be concluded that, of the newer antibiotics, aureomycin is of little value in ophthalmology."

As a clinician who has used aureomycin over several years I may say that in my experience aureomycin is the antibiotic of choice in ophthalmology, and I know that many of my colleagues agree with this.—I am, etc.,

H. CAMPBELL ORR.

Wolverhampton.

Dangers of Ethanolamine Oleate Injection Treatment for Varicose Veins

SIR,—In view of the frequency with which injection treatment for varicose veins is carried out, the following case is of interest as a reminder that such a procedure carries a risk.

A married woman aged 45 years, with three children, was referred to the out-patient clinic for treatment of varicose veins. She complained of pain and swelling below the left knee and said that she had injured her left tibia when young. There had been no previous injections for varicose veins. The patient, who was menstruating, appeared to be a healthy woman with a moderately severe degree of varicose veins below the left knee; she was considered suitable for injection, and 6 ml. of ethanolamine oleate B.P. was given slowly with the patient standing on a chair. (Material from this same bottle had previously been used without incident to inject other patients.) She got down off the chair without difficulty and was asked to report the following week for a further injection. She walked out into the waiting-room, but collapsed two or three minutes later and was found to be unconscious. She had three epileptiform convulsions in quick succession and became pulseless. Resuscitation methods, including cardiac massage through an incision in the diaphragm and intracardiac injection of adrenaline, were without avail. At necropsy, about six hours after death, no evidence of pulmonary, air, or fat embolism was found. The brain appeared normal. There was no thrombosis of the varicose veins at the injection site, and only a little surrounding haemorrhage. In spite of a further examination of the principal organs microscopically the only abnormalities found were the presence of some thick mucus in the trachea and bronchi, emphysema and anthracosis of the lungs, and some petechial haemorrhages on the posterior surface of the heart. The remains of the bottle of ethanolamine oleate were cultured aerobically and anaerobically and found to be sterile.

After death it was discovered that the patient was a chronic asthmatic and that she had had an acute attack of asthma the night before, for which she had taken a tablet of isoprenaline. The most probable cause of death seems therefore to be an allergic reaction to the injection. Since the patient had had no previous injection of ethanolamine oleate, one must speculate that she had become hypersensitive in some other way to the "foreign" protein formed later by the interaction of serum protein with ethanolamine. Perhaps hypersensitivity had arisen by previous inhalation of some complex substance having radicals similar to the relatively simple chemical substance ethanolamine.

On discussing this tragedy with our colleagues we have obtained verbal case histories of several other severe complications following injections of ethanolamine oleate. They

AUG. 29, 1953

CORRESPONDENCE

BRITISH
MEDICAL JOURNAL 511

include severe collapse followed by status asthmaticus in a patient with no previous history of asthma, collapse and convulsions in two soldiers immediately after injection, and haematuria the day after injection in another patient. All these patients had received previous injections and all made complete recoveries.

It is clear that the use of ethanolamine oleate is not free from danger. It should not be used in asthmatic patients and adrenaline should be available for immediate use.—We are, etc.,

A. LUTTON.

Shrewsbury.

Phenylbutazone

SIR,—So much has been written of the dangers of phenylbutazone ("butazolidin") that it was with no little trepidation that we first administered it to a patient who had suffered from rheumatoid arthritis for 27 years. However, she was having so much pain and disability that we began with two tablets thrice daily for two days, and then dropped to one twice daily for two days, and one per day from then on. The results were more than gratifying. The pain disappeared and much increase in the movement of hands and feet was experienced. The improvement continued on the low dose of one tablet per day. The patient felt that, to use her own words, she "could walk like a young one." She was encouraged to cut the dose even further, and now only takes a tablet when a return of pain threatens, about once per week or ten days.

This case was so encouraging that we determined to try the effects of low-dosage phenylbutazone on another patient who had suffered from rheumatic pains for 25 years. She began with one tablet morning and evening for the first day and one per day after that. On the fourth day, all smiles, she reported that she had been free from pain since the second day. She was advised to keep to the one tablet a day if necessary, but to try to cut the dose even further. After returning from a holiday she has taken only four tablets in all during the last 21 days. She has no pain, has been climbing hills which her husband thought impossible for her, and feels and looks much younger. She can now wear size 4½ in shoes, whereas for the last 20 years she could only wear size 6. A third patient, a martyr to rheumatoid arthritis for 20 years, was discharged unchanged from hospital after six weeks' treatment by cortisone, etc. Small-dosage phenylbutazone so relieved his pain and disability that he has been able to attend to business quite comfortably. A fourth patient, a woman with a crippled right ankle which would not respond to other treatment, can now stand on her toes and dance under the regime of two phenylbutazone tablets on the first day and one as necessary thereafter.

The above are only four cases out of over 20 which have benefited in a marked degree by low-dosage phenylbutazone. Two cases would not tolerate the preparation at all. None of the remainder has shown the least sign of ill effects. One cannot but wonder whether the high dosage of two tablets thrice daily is necessary. It will be interesting to try on our next patient the effects of one tablet twice a day the first day, one daily for a week, and then one tablet only if the pain threatens to return. On such low dosage might not the troublesome side-effects of this so useful therapeutic agent be largely eliminated?—I am, etc.,

Kirkcubbin, Dumfriesshire.

BOWMAN EDGAR.

Control of Tachycardia by Quinine

SIR,—The report of a case of paroxysmal tachycardia controlled and prevented over a period of two years by the use of daily prophylactic quinine hydrochloride may be of interest. I have never read of the use of quinine, used in the same way as for malaria prophylaxis, being effective in preventing attacks of paroxysmal tachycardia, but it is possible that having spent the last three and a half years in a fairly inaccessible part of West Africa I am not as well informed as I should be. Certainly the books at my disposal here make no mention of it except quinine's inferiority to quinidine in stopping an attack.

The patient was an American male, aged 30, of unusually good physique and a good all-round athlete and football player. Attacks of "palpitations" began at the age of 24, and at first

came only once or twice a month, and only after considerable physical or nervous strain. They lasted five to ten minutes and then disappeared. The patient ignored the symptoms so far as possible, and no one else took them seriously either, which was not surprising considering his general athletic prowess at that time. At the age of 25 the patient came to Sierra Leone and spent three exceedingly strenuous years as a missionary, trekking, building roads, and travelling great distances by jeep. The attacks increased slowly in frequency. He had a year in America and returned in July, 1951. At this time I was stationed with the patient, and for the first time heard his history. By now he was getting four or five attacks a week lasting up to 25 minutes in duration, and his work was beginning to be interfered with. During an attack, which was always in the late afternoon, he would become breathless, pale, and distressed. On examination during an attack he had no abnormal physical signs other than a pulse of 170 which did not vary with exercise. No electrocardiogram was available. In view of the relationship between quinine and quinidine I put the patient on quinine hydrochloride, 5 gr. (0.32 g.) daily, and took him off proguanil, which he had been taking ever since coming to West Africa. From the day the change-over was made the attacks ceased absolutely, in spite of the fact that for the last two years the patient has undertaken heavier work than ever.

I should be interested to know whether others have found that attacks of paroxysmal tachycardia can be controlled by the use of oral quinine in this way and, conversely, whether there have been cases of this cardiac irregularity frequently observed among the many thousands of people who have for years in the Tropics been taking their quinine regularly, and without any apparent ill effects to their general health. Of course I am referring to cases that have no apparent associated organic heart disease.—I am, etc.,

H. L. MACLURE.

Magburaka, Sierra Leone.

Tic Douloureux

SIR,—In reply to Dr. David M. Zausmer (*Journal*, August 8, p. 340), may I make a plea to reject the term "facial neuralgia" in favour of the vintage name "tic douloureux," not because "tic douloureux" is more accurate, or precise, or scientific: it is none of these things. But it is fifteen thousand times more interesting and colourful and evokes a phantasmagoria of twisted and contorted beings from the Hunchback of Notre Dame to Captain Hook, and all the Seven Dwarfs rolled into one.

Moreover, the very sound of the syllables "doul-our-eux" (which should be rolled well over the molars before they are finally delivered with a sad and mournful look) is calculated to subdue even the most agitated patient. And that, after all, is half the cure.—I am, etc.,

FRANK S. RICKARDS.

Lancaster.

Hops in Ale

SIR,—It is true that the use of hops in brewing ale was forbidden in the sixteenth century, as Drs. J. S. Cookson and Anne Lawton have stated (*Journal*, August 15, p. 376). It is not correct, however, that their use in brewing was forbidden altogether.

Ale in the Middle Ages, and in many places until the eighteenth century, was brewed with malt, yeast, and water only. Containing no such preservative as hops, it must often have turned sour a few days after reaching prime condition. Hence, probably, the attempts (in due course forbidden by regulations) to keep stale ale from becoming undrinkable by adding hops. The art of flavouring and preserving malt liquor by boiling it with hops before fermentation was introduced into this country from the Continent at the end of the Hundred Years War. This beverage, beer, first met with opposition in the City of London, but soon came under royal protection. A writ was issued in 1436 in the name of Henry VI ordering the City authorities to proclaim that the "drink called beer is a notable, healthy and temperate drink" and that anyone maligning it would be punished. This did not prevent the occasional "die-hard" in dietetics, like Andrew Boorde, from fulminating against "bere, the naturall drynke for a Dutche man," and lauding ale as "for an Englysshe man the naturall drinke . . . it doth ingendre grose humoures; yette it

maketh a man stronge." But beer gained steadily in popularity and the unhopped ale had disappeared by the end of the eighteenth century.

The terms "ale" and "beer" were apparently becoming less distinctive in the latter half of the sixteenth century, for a letter from Leicester to Burleigh during one of Queen Elizabeth's progresses states: "We were fain to send to London, and Kenilworth, and divers other places, where ale was; her (the Queen's) own bere was so strong as there was no man able to drink it."—I am, etc.,

London, W.1.

C. L. SHAW.

Hop Dermatitis

SIR,—The valuable observations of Drs. J. S. Cookson and Ann Lawton (*Journal*, August 15, p. 376) on hop dermatitis seem to suggest that the hop-cone and fresh hop-oil contain a primary irritant. The very high incidence of minor dermatitis (1 in 30 in a "light season") suggests a primary irritation rather than allergic hypersensitivity, which might perhaps account only for the most severe cases. It would therefore be interesting to know whether normal subjects were patch-tested with hop-cones and with fresh hop-oil; and also to know what dilution of hop-oil would still produce a positive reaction in the affected persons. Primary irritation by the oil would explain the positive patch-tests in patients whose dermatitis was really due to resins, and would account for the unexpected positive reactions obtained with those substances.

This question is of theoretical as well as practical importance. It has been supposed that hardening, if it occurs at all, occurs only in respect of primary irritants and does not result where there is a high degree of allergic sensitivity. A good many plants or their juices are primary irritants.—I am, etc.,

London, W.1.

F. RAY BETTLEY.

Acute Appendicitis in Infancy and Early Childhood

SIR,—I read with great interest the valuable article by Mr. G. L. Bunton on acute appendicitis in infancy and early childhood (*Journal*, July 11, p. 71). The following case emphasizes all the points discussed.

I was asked to see a baby of 5½ months suffering from gastro-enteritis. As those were the days before antibiotics the child had been treated with sulphonamide tablets, which it was no longer able to retain, and a small-bowel washout. She had been ill two and a half days. The first symptom was that of recurrent colic with attacks of screaming and drawing up of her legs. The attacks came in waves. She then started to pass loose, mucous stools which became more frequent. On the second day she began to vomit.

She was a bottle-fed baby with no history of any dietetic errors. She was an only child looked after by a conscientious children's nurse and had no history of a possible source of infection of the gastro-intestinal tract. The child was screaming and drawing up her legs. She was vomiting boiled water. Her temperature was 103° F. (39.4° C.) and her pulse fast. She was flushed and toxic to look at. She hated being moved, and if left in her cot lay curled up. Her ears, throat, urine, etc., showed no source of parenteral infection. On abdominal palpation she was acutely tender over the right iliac fossa and drew up her right leg each time this area was palpated. She was operated on for acute appendicitis and made a complete recovery.

This case illustrates the very important points in Mr. Bunton's article. Appendicitis in very young children is not quite as rare as books often make us believe. Diarrhoea can be the presenting symptom in infants. In the young baby abdominal pain of acute appendicitis presents a picture of colic coming in waves causing screaming attacks with the flexion of legs. If left alone the baby will lie curled up to try to ease the abdominal pain. In the very young a considerable rise in temperature and pulse can be associated with appendicitis. The clinical picture of a young baby vomiting, passing loose frequent stools accompanied by abdominal colic, can so easily be mistaken for "gastro-enteritis," which, after all, is not a disease but a symptomatic title.—I am, etc.,

Dublin.

MADELINE R. EPSTEIN.

POINTS FROM LETTERS

"Fibrositis"

Dr. COLIN R. PORTEOUS (Liverpool) writes: I was interested to read the account of the discussion on "fibrositis" in the second plenary session at the Annual Meeting of the B.M.A. at Cardiff (*Journal*, July 25, p. 205). I have sometimes wondered whether a proportion of cases of agnogenic "fibrositis" are due to infarction of a small area in the erector spinae muscles following occlusion to one of the posterior branches of the lumbar or intercostal arteries. At necropsies I have occasionally noticed atheromatous plaques around the mouths of the paired arteries arising from the posterior wall of the abdominal aorta.

Bathing Caps for Males

Dr. M. D. WARREN (London, W.5) writes: In the last two weeks I have treated four cases of otitis externa and one case of a flare-up of otitis media. The symptoms in all five cases had come on after swimming, and all the cases were males. I suggest that this preponderance in males is due to the fact that they do not wear a bathing cap. If this is so, then perhaps much illness and discomfort could be avoided if men could be persuaded to wear a type of bathing cap that would protect their ears. I would suggest a pattern similar to a scrum cap seen on the rugby field.

An Interesting Phenomenon

Dr. B. N. PAJGAR (Thornton Heath) writes: I do not know if anybody has mentioned before the very interesting phenomenon whereby a person can see with the naked eye his own blood corpuscles actually in circulation in the blood vessels and capillaries. If a person sits or reclines facing the light, and half closes his eyelids so that a little light is allowed in, then he can see the corpuscles flowing and swaying in rhythm to the circulation. They are grouped in varied numbers and shapes, but mostly agglutinated in clumps or spiral lines, presumably the shape of the capillaries. The walls of the capillaries can be clearly seen, with blood cells lying inside and sometimes outside the lumen. Occasionally larger and solitary cells are seen, probably the white blood corpuscles.

Malaria

Dr. ROBT VAN SOMEREN (Nyeri, Kenya) writes: I have just seen the *Journal* of May 30 and can thoroughly endorse the letter of Professor W. Melville Arnott (p. 1219) on malaria. Last week I was revisiting my old station, Jinja, where the immense dam is being constructed at the Owen Falls, and was interested in two particulars. Mosquito gauze to houses and mosquito nets seemed to be very little used, reliance being placed on flitting each room, especially under the beds, with D.D.T. I did not notice any mosquitoes. Also, where formerly *Simulium damnosum* was rife and a curse rendering life on the west bank of the Nile particularly unbearable, not one was noticed, owing to the wide spraying of the banks with D.D.T.—from planes, I understand. Should there be any recurrence, respraying is carried out. To one who knew the conditions 40 years ago the change is remarkable and reflects the very greatest credit on the present medical staff who are responsible for this wonderful work.

Mist. Amygdalae

Dr. A. H. TURNER (Ruabon, Wrexham) writes: I have tried in vain to get someone to supply mist. amygdalae. This quite simple preparation was in the B.P. up to 1914, if not later. During the last war almonds became scarce, but they are obtainable now and there does not seem to be any reason why the mixture should not be obtainable. My local chemist cannot supply it and about half a dozen front-line manufacturers say they cannot do it.

Cancer and the Public

Dr. M. N. PAI (London, W.C.2) writes: The sting of Lord Horder's letter (*Journal*, July 18, p. 148) is in its tail. That 76% of the general practitioners did not even bother to reply "Yes" or "No" is an index of the indifference of the overwhelming majority of practitioners to the cancer problem and their lack of co-operation in this humanitarian work. As regards the public, the campaign for road safety has not diminished the number of preventable accidents, and lay education in cancer is unlikely to achieve any useful purpose. There is a real danger that such education may lead to vexatious demands on the part of querulous patients for "full and complete investigation" for every minor symptom, and, if this is not done to their satisfaction, to an increase in the incidence of litigation neurosis. Errors either in diagnosis or in treatment may be followed by actual litigation against doctors and hospitals.

Obituary

J. W. STRUTHERS, LL.D., M.B., F.R.C.S.Ed.

Mr. J. W. Struthers, a past-president of the Royal College of Surgeons of Edinburgh, died at his home at Gullane, East Lothian, on August 15 at the age of 79, after a long illness.

John William Struthers was born on May 3, 1874, the son of the late Sir John Struthers, professor of anatomy in the University of Aberdeen from 1863 to 1889 and, later, president of the Royal College of Surgeons of Edinburgh. He was educated at Loretto, and remained a staunch supporter of his old school throughout his life, acting as governor for many years. After graduating M.B., Ch.B. at Edinburgh University in 1897, he decided to specialize in surgery, and became a Fellow of the Royal College of Surgeons of Edinburgh two years later. Appointed assistant surgeon to Edinburgh Royal Infirmary in 1913, he was promoted to the charge of wards in 1924, retiring from the active staff in 1939. He served the University of Edinburgh as a

lecturer in clinical surgery, and in 1930 was appointed a member of Faculty and of the Senatus. The honorary degree of LL.D. was conferred upon him by the University in 1946. During the first world war he served first with a Red Cross hospital at Rouen and later at Salonika as a major in the R.A.M.C. For his services he was awarded the Serbian Order of St. Sava.

Mr. Struthers received his surgical training at a time when the only specialties recognized were gynaecology and obstetrics, ophthalmology, and oto-rhino-laryngology. He had the advantage, therefore, of a broad basis for his training and became a very able general surgeon. He was a remarkably accurate diagnostician, and this was due as much to his persistence and his capacity for taking infinite pains as to his sound knowledge of pathological processes. As an operator he was conservative in his methods and careful in their execution, making no attempt to impress the onlooker. He took a special interest in diseases of bone, and, in association with his friend, the late Dr. James Walker Dawson, histologist in the laboratory of the Royal College of Physicians of Edinburgh, he carried out important pioneer work in the elucidation of the pathology and treatment of generalized osteitis fibrosa: he was among the first surgeons in this country to carry out the removal of a parathyroid adenoma in the treatment of this disease. The importance of this work was recognized by the allocation of an entire number of the *Edinburgh Medical Journal* to descriptions of it. At the request of the Department of Health and in association with Dr. H. E. Seiler he carried out a survey of the hospital facilities in the south-eastern region of Scotland: this was shortly before the introduction of the National Health Service.

The Royal College of Surgeons of Edinburgh was one of the great interests of his life, and he maintained this interest until shortly before his death. He was secretary and treasurer for 14 years before serving as president from 1941 to 1943. As secretary he had the welfare of the College very close to his heart and devoted a great deal of his time to its affairs. He was responsible for many improvements in the premises, including the decoration of the library, the lighting of the hall, and the alterations in the main entrance. After his retirement from the office of president his advice was much sought after and highly valued by his successors in office. A member of the British Medical Association for 56 years, he was president of the Edinburgh Branch in 1931-2. When the Association held its Annual Meeting at Edinburgh in 1927—a meeting which coincided with the celebrations in Edinburgh of the centenary of the birth of Lister—he acted as a vice-president of the Section of Surgery.

Outside his profession Mr. Struthers had many interests and many friends. He was a man of broad culture, widely read, fond of music, and in his later years devoted to gardening. He had a highly critical mind and was intolerant of the second-rate or of any form of humbug, but he was always more critical of his own work than of that of others. Possessing a remarkable faculty for graphic verbal description, he could give highly entertaining thumb-nail sketches of his colleagues and others. He took great trouble in the preparation of his clinical lectures and was a stimulating and popular teacher in spite of, or possibly because of, his occasional caustic comments. As an examiner he was very searching and skilful in assessing the knowledge of the candidate, but in marking tended to be generous rather than otherwise. In his younger days he was good at most games and was a notable golfer: he won the Argyll Robertson medal—a scratch medal competed for annually by the Fellows of the two Royal Colleges in Edinburgh—no fewer than ten times. On the golf course, and also in hospital and the Students' Union, he was commonly known as "Jock" Struthers, and this name is a good indication of the affection with which he will be long remembered by those who knew him.—W. Q. W.

G. S. PARKINSON, C.B.E., D.S.O., M.R.C.S., D.P.H.

We record with regret the death on August 18 of Brigadier George Parkinson at the age of 72. He served with distinction in three wars, and in the nineteenth-thirties was a well-known and popular figure at the London School of Hygiene and Tropical Medicine, where he was assistant director of the public health department, vice-dean, and, later, dean for a short period.

George Singleton Parkinson was born in 1880 and educated at Bath College. At the beginning of the South African War he volunteered for service and gained the Queen's medal and five clasps. When he returned to this country he became a medical student at Bristol, qualifying in 1906. Two years later he entered the R.A.M.C. Developing an interest in hygiene, he took the D.P.H. in 1913, and during the first world war he served in France and Belgium on the headquarters staff of the First Army. Mentioned in dispatches three times, he was awarded the D.S.O. in 1918. The French Government decorated him with the Croix de Guerre

and the Médaille de la Reconnaissance, and he was also appointed Chevalier of the Order of St. Avis. After the war he was medical officer of health at Gibraltar for four years and then returned to the Royal Army Medical College, Millbank, as assistant professor of hygiene. In 1928 he retired from the R.A.M.C. with the rank of lieutenant-colonel, and shortly afterwards joined the staff of the London School of Hygiene and Tropical Medicine as assistant director of the public health division, then being built up by Dr. (later Sir Wilson) Jameson.

Parkinson's geniality and kindness—qualities which perhaps obscured but far from blunted his shrewdness and powers of observation—won him a great number of friends among the students and staff at the school. He was an ideal adviser to young postgraduates anxiously in search of a career, and the trouble he took in dispersing their doubts and difficulties was repaid by the affection in which he was held by all whom he had helped. He had a great regard for the world-famous school with which he had linked his fortunes, and watched its reputation grow with affectionate loyalty. When in 1940 Sir Wilson Jameson became Chief Medical Officer at the Ministry of Health Parkinson was very proud of the honour of being chosen to act as dean, an office which he held until he returned to the R.A.M.C. in 1943. Those who were present in 1950 at a dinner in the Savoy Hotel given in honour of Sir Wilson Jameson and Brigadier Parkinson will remember how moved Parkinson was by the sincere tribute which was then paid to him by students who took the D.P.H. course at the London School of Hygiene between the years 1929 and 1939.

Parkinson had previously been re-employed by the Army for a short time at the beginning of the war in 1939 as director of hygiene in the Eastern Command, but in 1943 he was appointed director of the Public Health Subcommittee of the Allied Military Government in North Africa with the rank of brigadier, and he served later in Sicily and Italy in the same capacity. For his services he was appointed C.B.E. in 1945. He was awarded the Typhus Commission Medal (U.S.A.) in 1944 and the Croce del Merito of the Italian Red Cross in 1947. For some months in 1951 he acted as technical adviser to the Greek Government in Athens.

Parkinson's name was well known in the public health world both for his work at the London School of Hygiene and as co-author with Sir Wilson Jameson of the popular *Synopsis of Hygiene* from its third to its ninth editions. He was a lecturer in public health at the London School of Medicine for Women and an examiner for the D.T.M. and H. of the Conjoint Board. An honorary life member of the British Red Cross Society, he was the author of the Society's *Manual of Hygiene and Sanitation*, and he was also a Commander of the Order of St. John of Jerusalem. In recent years Parkinson took an active part in the work of the Foot Health Educational Bureau.

In 1911 he married Hilda, daughter of the late Thomas Chisholm Jack, of Edinburgh. There were no children of the marriage.

G. S. E. writes: The sudden death of Brigadier Parkinson will have been a sorrowful shock to the wide circle of friends who have been associated with him in his varied activities. I met him first in 1917 in France when as deputy assistant director of hygiene on the staff of the First Army he was the helpful adviser of many civilians who, like myself, had been commissioned to the R.A.M.C. sanitary sections. Even in those days he had decided that on his retirement from the

Army he would attach himself in some way to the public health service; so as a step in that direction he welcomed his appointment at the end of the war to the military post of M.O.H., Gibraltar. After retiring from the R.A.M.C. he served for some time as assistant secretary in the office of the Society of Medical Officers of Health, in which capacity he made himself familiar with problems of public health administration. He was a foundation member and the first honorary secretary of the Society's Services Group (then known as the Navy, Army, and Air Force Hygiene Officers Group). Before long his merits were recognized by his appointment as assistant dean of the London School of Hygiene and Tropical Medicine. In this congenial post his genius for friendship made him a valuable influence in creating among successive generations of students from all parts of the Empire a loyal pride in their membership of the school. The preceding obituary notice records Parkinson's distinguished military services. My desire has been to pay tribute to the devoted and unselfish co-operation given by him during nearly 40 years to all those engaged in public health work. Above all, "Parky" deserves to be remembered with affection for years to come by many who have enjoyed his unfailing good fellowship.

Dr. ROBERT LOVE BLAIR died at his home at St. Annes-on-Sea on July 15, in his 56th year. Born in 1897, he was educated at Giggleswick School and at Liverpool University, where he graduated M.B., Ch.B. in 1923. After acting as a house-surgeon at the David Lewis Northern Hospital, Liverpool, he entered general practice at St. Annes, where his father was already a well-known practitioner, and was appointed honorary surgeon to the St. Annes War Memorial Hospital. Dr. Blair was hard-working and conscientious to a degree, and was devoted to his patients and they to him. It was said that he bore their burdens for them, and there is no doubt that his zeal on their behalf contributed largely to the series of illnesses which culminated in his death. He found time, however, for other interests. He played Rugby for the Fylde club, and he was a keen golfer and an ardent follower of cricket. He took great interest in local youth clubs and was a past-president and chairman of the local Y.M.C.A. A courteous and kindly man, he was a good doctor and will be greatly missed.—D. K. L.

The medical profession in Hull has lost one of its most loved and respected members by the death on July 24 of Dr. G. F. BRIGGS at the age of 81. George Frederick Briggs was born on October 8, 1871, and after studying medicine at Cambridge University and at St. Bartholomew's Hospital qualified in 1898. He held several house appointments before settling in practice with his father, a well-known general practitioner in Hull and a member of the city council. Dr. Briggs was one of those family practitioners to whom patients turned for help in all kinds of trouble. His opinion as an experienced practitioner was always valued by those who knew him most intimately, though he was a diffident speaker in public. One of his many endearing characteristics was a very gentle sense of humour. During the last war, when he was already turned 70 and when house-surgeons were difficult to get, he came to assist as an anaesthetist at the Children's Hospital. One morning he arrived looking particularly cheerful, and when this was remarked on he said: "I have just come from seeing an old lady of 95 who has been a patient in our practice, my father's and mine, since well back into the last century. Her daughter, herself quite an elderly woman now, received me and shouted into her mother's ear, 'Mother, this is young Dr. Briggs come to see you.'" He was a deeply religious man and a much respected office-bearer in his church for a great many years, but there also he was always humble and unassuming. The high esteem in which he was held was evidenced by the large number of medical men who contrived to attend the funeral service at an hour when most are usually busy. The sympathy of all his colleagues will go out to his widow and the family of two daughters and three sons, one of whom is practising medicine.—T. R. R.

Dr. MABEL CATHARINE POULTER, who died on July 31 at the age of 89, was for many years a medical missionary in China and India. She was born on October 30, 1863, and was educated at Queen Margaret College, Glasgow, and at Glasgow University, where she graduated M.B., Ch.B. in 1898. In the following year she began her work at Hoki-chiang (now Futsing), in the Fukien province of China. Futsing is a small city some sixty miles south of Foochow, and when Dr. Poulter arrived there the local people were very distrustful of foreigners and she had an uphill task. At the China Medical Conference in 1915 Dr. Poulter read a paper outlining her obstetric experiences in Futsing. When she first went to China she found the methods used to assist a birth crude in the extreme and dangerous to the health of mother and child. It was not until 1902 that women were persuaded to enter the hospital at Futsing for confinement, and then only four responded to the invitation. But the annual intake increased gradually until in 1913 the number of hospital confinements was 247. In 1921 the medical mission at Futsing was handed over to the American Methodist Episcopal Mission, and it was with great regret that Dr. Poulter relinquished her work there. In twenty-three years she had built up an excellent hospital, putting to the best possible use such equipment as she could obtain and using her ingenuity to devise gadgets in place of equipment which could not be provided. The handicaps she overcame would have seemed insuperable to most people, but Dr. Poulter had a vigorous and vital personality and would never have thought of giving in. She was a fine teacher and did great work in making the nursing profession acceptable to the girls and women of China. On leaving Futsing she returned to England for a time, but in 1925 she went out to India, working first at the Church of England Zenana Hospital at Bangalore. She continued to work at a number of hospitals in various parts of India until 1934, when she retired from active medical practice.

The death on August 10, after a short illness, of Dr. F. W. MORTON PALMER at the age of 76 removes one of the older generations who, despite his modesty and instinct for self-effacement, had exercised no little influence in both medical and lay circles in Devonshire. He inherited a medical tradition extending over a quite exceptional number of generations, the medical members of which all looked to Guy's Hospital as their alma mater, and he naturally took the same direction, via Merchant Taylors' School and Jesus College, Cambridge, to both of which he won scholarships. But before beginning his medical studies he took an honours degree in mathematics, being 36th wrangler in 1899. At school he had "sat at the same desk" in mathematics with his friend James Jeans (later Sir James Jeans, the astrophysicist), and they entered Cambridge together, pursuing the same subject. Morton Palmer then turned to the study of medicine and took the Cambridge M.B., B.Chir. degrees in 1905, proceeding to the M.D. in 1909. After graduating in medicine, he held the appointments of house-physician and ophthalmic house-surgeon at Guy's Hospital and clinical assistant to out-patients at the Evelina Hospital for Sick Children. In 1905 he was the editor of *Guy's Hospital Gazette*. He settled in general practice at Teignmouth in 1907 and remained there for thirty years, becoming a leading figure in the life of the town. His work there was interrupted by service as a captain in the R.A.M.C. with No. 1 Casualty Clearing Station in the first world war. In 1937 he retired to live at Totnes and thus became free to pursue intensively his work in the Order of St. John, which he had taken up twenty years previously. From 1939 to 1945 he was the county casualty officer for civil defence; he then organized the hospital car service for Devon, and in 1947 he became county commissioner of the St. John Ambulance Brigade. His services were recognized officially in 1952, when he was promoted to Knight of the Order of St. John of Jerusalem. He was an honorary life member of both the British Red Cross Society and the St. John Ambulance Association. In addition, he gave valuable, unremitting service for many years on a number of com-

mittees, such as the board of the Royal Devon and Exeter Hospital, to which he was nominated by the Exeter Division of the British Medical Association, and later on the management committee of the Royal Western Counties Institution. He was chairman of the house committee of Totnes Hospital at the time of his death, which took place in the hospital. Morton Palmer was an active member of the B.M.A. He was chairman of the Exeter Division in 1930-1; in 1937 he was elected president of the South-western Branch; and from 1941 to 1950 he was chairman of the Torquay Division. He also represented his Division at the Annual Representative Meeting in 1942. The Torquay Medical Society, too, valued his services, and for a time he was its president. In all these activities he was recognized by all with whom he came in contact as the wise counsellor, possessing as he did exceptional clarity of mind and unhurried judgment; and his remarks, though always brief and quiet, in revealing those qualities necessarily carried weight. In private life he was a Fellow of the Society of Antiquaries and a prominent authority on church architecture. His wife died in 1937, just after his retirement from general practice, and he leaves a son, Dr. B. C. Morton Palmer, who is in practice at Cophorne, Sussex, and a daughter, who was closely associated with him as assistant in all his work and to whom, therefore, in particular the deep sympathy of all must go out.—F. A. R.

Universities and Colleges

UNIVERSITY OF DUBLIN

SCHOOL OF PHYSIC, TRINITY COLLEGE

P. J. MacCarthy has been approved at the examination for the degree of M.D.

The following medical degrees were conferred on July 2:

M.B., B.Ch., B.A.O.—S. Baigel, N. J. Ball, Freda B. Bonner, J. H. C. Colquhoun, D. G. Crawford, Ouida M. S. d'Abreu, J. McN. Fullerton, Joyce M. Fullerton, D. V. Furlong, Margaret E. E. Graham, Lilian G. N. Hanbridge, Mary M. Heaf, R. F. B. Howarth, M. Jeffries, G. A. C. Keenan, B. E. Kendall, Beulah R. Knox, C. J. Lidstone, U. D. B. H. Longford, D. A. Lyder, Margaret E. McMullin, Kathleen M. MacWilliam, D. M. McWilliams, H. G. S. Medlicott, J. C. Milliken, J. M. Kingsmill Moore, N. A. J. Mullen, Edna La C. Murphy, P. H. Osterberg, Peadar O'Toole, P. Panayotou, J. A. R. Pollock, G. P. Pretorius, S. E. J. Ross, R. J. W. Ryder, E. J. Stales, Sheine M. Schwartzberg, J. F. Scott, W. J. C. Stevenson, Patricia A. Throup, F. L. A. Townshend, C. E. H. Treston, Sylvia L. E. Tyler, A. E. Vercueil, Dorothy C. Williamson.

UNIVERSITY OF MANCHESTER

The following candidates have been approved at the examinations indicated:

M.D.—Muriel I. R. Knox, N. P. Lancaster, B. J. Leonard (with commendation), H. Weisl (with commendation).

Ch.M.—G. K. Tutton.

FINAL M.B., Ch.B.—J. R. A. Mitchell (with honours and distinction in medicine), G. W. Ashcroft, E. L. Barrett, M. L. Bishop, A. D. Clift, R. L. Cumming, Sheila P. Dain, G. S. Davis, D. Dean, L. S. Deane, H. T. Fay, E. J. H. Foster, R. P. Gannon, Molly Gibson, D. Goldsborough, A. H. Gowenlock, A. J. Gurtler, Kathleen C. Hall, Anne P. Hollins, K. S. Holmes, G. Hopkinson, B. G. Howarth, Mary P. H. Jepson, D. A. J. Keen, B. V. Lee, Joan M. Leeming, A. L. Levy, Elizabeth U. Macgregor, Sheila M. Mackridge, Inez R. Mendelson, P. Mulvey, Jean Oldham, D. J. Parish, R. Pell-Ilderton, J. Perkins, L. Proger, B. Prendergast, J. H. Price, Barbara A. Renwick, R. B. Rosenberg, Daphne J. Savage, J. A. Southam, Elizabeth M. Thomas, R. R. Thomas, Mary Timperley, June A. Vaux, Sheila Wightman, D. Wild, D. Wilde, W. K. Willan, T. H. Williams.

UNIVERSITY OF WALES

In Congregation on July 18 the following degrees were conferred:

M.B., B.Ch.—W. H. Allen, Jane I. K. Binnie, P. A. C. Bootman, N. P. Braun, W. G. Brown, D. L. Crosby, Marian H.

Dadaczynski, A. B. David, D. R. Davies, S. L. Davies, Joan M. Evans (with commendation), L. T. I. Evans, H. J. Grosz, Margaret J. Hicks, R. M. Hodges, D. R. Hughes, H. J. Hughes, J. H. Hughes, J. A. Hutchison, G. A. S. Ireland, J. F. C. Jacobs, D. S. Jones, J. T. Jones, W. P. T. Kime, W. J. Manson, Valerie Matthews, Dilwyn C. Morgan, J. G. Morgan, J. E. Morris, R. A. Owen, Glenys O. Parry, E. E. Payne, H. A. Rees, I. D. G. Richards, J. M. Richards, A. G. Roberts, Denise Y. Sheppard, J. W. G. Smith, W. G. C. Strawbridge, J. R. Tighe, D. B. M. Williams.

ROYAL COLLEGE OF PHYSICIANS OF LONDON

At a quarterly comitia of the College held on July 30, with the President, Sir Russell Brain, in the chair, the following Fellows of the College were elected officers for the ensuing year: *Censors*, K. E. Harris, F. P. Lee Lander, J. R. H. Towers, T. C. Hunt; *Treasurer*, W. G. Barnard; *Registrar*, Sir Harold Boldero; *Harveian Librarian*, E. C. Dodds, F.R.S.; *Assistant Registrar*, M. I. A. Hunter.

Sir Charles Symonds was appointed Harveian Orator and Dr. F. H. K. Green Bradshaw Lecturer, both for 1954. The following lecturers were also appointed: Lumleian (1954), Professor D. M. Dunlop; Goulstonian (1954), Professor A. W. Woodruff; Oliver-Sharpey (1954), Professor M. L. Rosenheim; Mitchell (1954), Dr. J. L. Livingstone; Bertram Louis Abrahams (1954), Professor E. B. Verney, F.R.S.; Langdon Brown (1954), Dr. E. F. Scowen; Croonian (1955), Sir Horace Evans; Fitzpatrick (1955), Dr. C. E. Newman; Watson Smith (1955), Dr. G. B. Dowling.

The Baly Medal for 1953 was awarded to Dr. K. S. Lashley for his services to physiology and for his work on the localization of function in the brain.

The Bisset Hawkins Medal for 1953 was awarded to Dr. W. N. Pickles for his study, while in general practice at Aysgarth, of the epidemiology of a rural community.

Sir Russell Brain was reappointed the College representative on the governing body of the British Postgraduate Medical Federation.

Membership

The following candidates, having satisfied the Censors' Board, were admitted Members of the College: C. P. T. Alexander, M.B., Joan Angus, M.B., B. H. Bass, M.D., Lieutenant, R.A.M.C., M. Bodian, M.D., B. A. Bradlow, M.D., D. G. Campbell, M.B., H. Cohen, M.B., D. G. Cottom, B.M., S. R. A. Dodu, M.B., M. L. Doran, B.M., A. C. Fairburn, M.B., Lieutenant, R.A.M.C., A. G. Freeman, M.D., A. S. Grimble, M.D., N. A. J. Hamer, M.B., R. Hill, M.B., J. P. T. Jaywardena, M.B., I. A. Kellock, M.D., T. C. K. Marr, M.B., F. J. Meagher, M.B., D. Mendel, M.B., Ruth D. Revill, M.D., J. R. Roberts, M.B., Sylvia M. Saddington, M.B., M. H. Sheard, M.B., H. C. Smellie, M.B., J. D. Tange, M.B., P. P. Turner, M.D.

Licences

Licences to practise were conferred upon 112 candidates (including 23 women) who have passed the final examination in medicine, surgery, and midwifery of the Conjoint Board and who have complied with the by-laws of the College: J. E. Ambrose, P. D. Arnold, P. J. Atkinson, A. A. Azie, Barbara E. G. Bapty, P. A. Barker, K. E. Barrett, N. L. Beisly, P. B. Biddell, C. E. S. Bill, E. D. Bird, B. Black, S. B. Boyle, M. Bray, A. M. Brill, J. R. Brook, Jane Buchanan, Pamela M. Butcher, V. G. Caiger, J. L. H. Capper, B. W. Cole, B. E. Cooke, S. Cooklin, A. G. Cope, I. D. Craig, H. R. Dickman, A. W. T. Eade, Helen W. East, B. I. F. Eminson, N. O. Eve, H. T. Fay, K. W. Giles, J. A. M. Goodwin, M. V. Gruchy, Jean L. Harney, J. A. Harrison, Pamela M. Harrison, B. D. Hick, Sheila M. Hindle, J. M. Hughes, D. S. Hutton, P. T. Jackson, Verna S. James, P. O. Jones, H. McP. Kidd, K. C. King, Margaret A. King-Davies, Solange M. M. Labesse, Pamela F. Lind-Smith, J. S. Lloyd, I. L. Loch, Gillian A. J. Lomax, D. B. Longmore, R. L. J. Lovick, G. P. Lowther, J. R. McNeill, D. I. Macpherson, Angela M. M. Manning, N. W. Marshall, G. F. Mayall, R. L. Meyrick, Audrey Millar, Evelyn J. Mitchell, J. B. Montgomery, W. K. C. Morgan, B. K. A. Muller, P. T. Nicholas, Sheila Nourse, R. E. Onwumere, G. Parkes, A. F. W. M. Pooler, A. T. Porritt, T. B. Priestley, C. Protheroe, Margaret J. Purser, C. O. Quarcoopome, Priscilla A. Ridge, D. P. W. Roberts, G. S. Roberts, G. F. C. Rosser, R. Routledge, J. W. Scopes, H. G. Scott, F. E. Shaw, Eileen M. Shuttleworth, M. Singh, G. F. Slocumbe, F. E. Sparshott, Elizabeth J. Steele, G. R. Stevenson, E. L. Stout, R. J. Sturt, C. Sumner, C. K. Sutcliffe, J. E. Taylor, S. H. Taylor, H. T. Thomas, A. D. Thursz, Naomi Turner, D. W. Warrell, Dorothy A. Wescott, J. T. Wheeler, L. Wilkinson, C. A. Williams,

Jennifer M. T. Williams, G. C. E. Wilson, P. M. Wine, J. R. Wood, N. W. Wood, S. M. Worrall, R. W. P. Yates, W. O. C. Young.

Diplomas

Diplomas in Anaesthetics, in Child Health, in Laryngology and Otology, in Medical Radiodiagnosis, in Medical Radiotherapy, in Pathology, in Psychological Medicine, and in Tropical Medicine and Hygiene were granted jointly with the Royal College of Surgeons of England to the successful candidates whose names were printed in the report of the meeting of the Royal College of Surgeons of England held on July 9 (*Journal*, August 15, p. 400).

Diplomas were granted, jointly with the Royal College of Surgeons of England, to the following successful candidates:

DIPLOMA IN INDUSTRIAL HEALTH.—R. Bradley, G. R. Holtby, H. Mowschenson, R. Whitelaw.

DIPLOMA IN OPHTHALMOLOGY.—I. Ali, Doreen A. Birks, F. H. Budden, B. C. Dench, R. L. Douglas, S. M. Drancz, S. F. El-Jarrah, O. O. F. Fooks, Ann Garratt, S. Gebert, G. L. Harper, Joan M. Hickley, T. K. Howat, H. Jackson, R. F. Jones, T. G. Jones, W. T. Levy, Aileen B. MacClancy, R. J. McWilliam, A. Majid, M. S. Nirankari, P. K. Ray, A. T. Ryan, S. M. Sadig, H. J. Scott, Winifred A. Sterndale-Bennett, Faye V. Tallack, R. E. Tingey, Sheena E. Tompkins, G. A. O'Reilly.

DIPLOMA IN PHYSICAL MEDICINE.—J. B. Millard, J. E. F. Perera, A. C. Pinkerton.

DIPLOMA IN PUBLIC HEALTH.—A. R. Basu, J. Belej, S. G. Gordon, Louise M. E. Hogg, Dorothea Koffman, C. R. A. Martin, I. H. C. Morton, R. D. Pearce, J. D. Pickford, Eleanor M. Sawdon, A. K. Sen, J. A. Slattery, W. R. Waldron, W. Wollen.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

At a meeting of the Council of the College on July 30, with Sir Cecil Wakeley, President, in the chair, Dr. W. D. M. Paton was appointed Professor of Pharmacology, and Dr. Joseph Bamforth Research Pathologist in the College.

Dr. George Crile, jun. (Cleveland Clinic, U.S.A.) was awarded a Moynihan Lectureship.

Mr. J. J. Jones (King's College Hospital) was awarded the Hancock Prize.

Diplomas were granted, jointly with the Royal College of Physicians of London, in Public Health, in Ophthalmology, in Industrial Health, and in Physical Medicine to the successful candidates whose names are printed above in the report of the meeting of the Royal College of Physicians of London on July 30.

Hospitals were recognized under paragraph 23 of the F.R.C.S. regulations as follows: General Infirmary, Burton-on-Trent, revision, resident surgical officer and house-surgeon for six months; for *casualty training*, casualty officer for six months. Southern Hospital, Dartford, paragraph 23c, senior house officer, ear, nose, and throat. Queen Elizabeth Hospital, Gateshead, house officer (casualty) to be recognized for six months' casualty training and not, as hitherto, for general surgery. Western District Hospital, Glasgow, redesignation, surgical registrar has now become senior house officer; for *casualty training*, junior hospital medical officer (casualty), for six months. Hertford County Hospital, surgical registrar for twelve months; two house-surgeons, each for six months. Western General Hospital, Hull, senior house officer and junior house officer, both for six months; registrar for six months. Royal Northern Hospital, London, for *general surgery*, resident surgical officer for twelve months; two house-surgeons for six months; for *casualty training*, senior casualty officer for six months; two casualty house-surgeons for six months; for *unspecified training*, orthopaedic house-surgeon for six months. West Kent General Hospital, Maidstone, revision, two house-surgeons for six months; for *casualty training*, casualty officer for six months. Norfolk and Norwich Hospital, revision, for *general surgery*, senior surgical registrar for twelve months; two general surgical registrars for twelve months; two general house-surgeons for six months; for *casualty training*, senior casualty officer for six months; for *unspecified training*, house-surgeon to orthopaedic department for six months. West Norwich Hospital, additional recognition, general surgical registrar for twelve months. Pontefract General Infirmary, for *casualty training*, casualty officer for six months. King's Mill Hospital, Sutton-in-Ashfield, resident surgical officer (registrar) for six months. Hallam Hospital, West Bromwich, decennial revision, surgical registrar for twelve months; two house-surgeons for six months.

A name in the list of recipients of the Diploma in Laryngology and Otology printed in the *Journal* of August 15 (p. 400) was misspelt: S. Sytcha should read S. Sychta.

Vital Statistics

Poliomyelitis

Poliomyelitis notifications (uncorrected) in the week ending August 15 (32nd week of the year) were as follows: paralytic, 186 (181); non-paralytic, 132 (116); total, 318 (297). This is an increase of 21 compared with the previous week, the figures for which are in parenthesis. The individual districts which have notified 20 or more cases in the year to August 15, with incidences per 100,000 in parenthesis, are as follows: Southend-on-Sea C.B., 42 (27.85); Liverpool C.B., 45 (5.69); Birmingham C.B., 50 (4.47); Coventry C.B., 97 (37.16); Leicester C.B., 28 (9.79); Lewisham M.B., 24 (10.57); Blackpool C.B., 22 (14.94); Camberwell M.B., 20 (11.04); Islington M.B., 22 (9.35); Bournemouth C.B., 29 (20.87); Bristol C.B., 20 (4.51); Nottingham C.B., 21 (6.76); Taunton M.B., 24 (69.36); St. Pancras M.B., 21 (15.04).

There was little change in the momentum of the seasonal rise during the 32nd week. The increase in the number of paralytic cases notified was 5 only. In recent years the zenith has been reached in the following weeks: 1952—33rd week; 1951—29th week; 1950—34th week; 1949—41st week; 1948—39th–41st week; and 1947—36th week.

Graphs of Infectious Diseases

The graphs below show the uncorrected numbers of cases of certain diseases notified weekly in England and Wales. Highest and lowest figures reported in each week during the nine years 1944–52 are shown thus ———, the figures for 1953 thus ———. Except for the curves showing notifications in 1953, the graphs were prepared at the Department of Medical Statistics and Epidemiology, London School of Hygiene and Tropical Medicine.

Infectious Diseases

A fall was recorded in the number of notifications of infectious diseases in England and Wales during the week ending August 8. The largest decreases were 857 for measles, from 3,587 to 2,730; 260 for scarlet fever, from 950 to 690; 243 for whooping-cough, from 4,107 to 3,864; and 117 for dysentery, from 334 to 217.

A decline in the incidence of measles was recorded in every area of the country; the largest fall in the number of notifications was 210 in Lancashire, from 671 to 461. The largest falls in the notifications of whooping-cough were 89 in Yorkshire West Riding, from 321 to 232; 80 in Essex, from 442 to 362; and 66 in Staffordshire, from 112 to 46; while the only large rise was 76 in Kent, from 187 to 263. A small fall in the number of notifications of scarlet fever was recorded throughout the country; the largest decline was 61 in Lancashire, from 139 to 78. 22 cases of diphtheria were notified, 11 more than in the preceding week. The chief feature of the returns of diphtheria was a rise in Lancashire from 2 to 7.

For the second consecutive week 3 cases of paratyphoid fever were notified in Worcestershire, Martley R.D.

297 cases of acute poliomyelitis were notified during the week, and these were 14 more for paralytic and 13 more for non-paralytic cases than in the preceding week. The largest returns were London 34 (Greenwich 5, Islington 5); Essex 22 (Southend-on-Sea C.B. 3); Warwickshire 21 (Coventry C.B. 10, Birmingham C.B. 6); Lancashire 20 (Liverpool C.B. 4, Blackpool C.B. 3); Kent 18 (Dartford M.B. 3); Somersetshire 17 (Taunton M.B. 5, Yeovil R.D. 3); Sussex 14; Surrey 13; Yorkshire West Riding 11 (Sheffield C.B. 4); Southampton 10 (Bournemouth C.B. 3, Portsmouth C.B. 3).

The largest returns for dysentery were Yorkshire West Riding 30 (Bradford C.B. 10); Lancashire 29 (Liverpool C.B. 11); Middlesex 24; London 23; Surrey 19.

The largest outbreak of food-poisoning reported during the week was Southampton County (Winchester M.B. 133).

Week Ending August 15

The notifications of infectious diseases in England and Wales during the week included scarlet fever 488, whooping-cough 4,681, diphtheria 22, measles 2,123, dysentery 217, paratyphoid fever 10, typhoid fever 10, and food-poisoning 389.

INFECTIOUS DISEASES AND VITAL STATISTICS

Summary for British Isles for week ending August 8 (No. 31) and corresponding week 1952.

Figures of cases are for the countries shown and London administrative county. Figures of deaths and births are for the 160 great towns in England and Wales (London included), London administrative county, the 17 principal towns in Scotland, the 10 principal towns in Northern Ireland, and the 14 principal towns in Eire.

A blank space denotes disease not notifiable or no return available. The table is based on information supplied by the Registrars-General of England and Wales, Scotland, N. Ireland, and Eire, the Ministry of Health and Local Government of N. Ireland, and the Department of Health of Eire.

† Includes primary and influenzal pneumonia.
‡ Includes puerperal pyrexia.

Medical News

Supply of Cortisone and A.C.T.H. to Hospitals.—The Ministry of Health has informed certain hospitals in England and Wales of forthcoming changes in the scheme of distribution made possible by improved supplies of cortisone and corticotropin (A.C.T.H.). A substantial part of the additional amounts of these hormones which will become available from the beginning of September is to be reserved for patients suffering from diseases in which these hormones may prolong life. Conditions so far included in this "obligatory maintenance" category are: adrenal deficiency (Addison's disease, post-adrenalectomy state, etc.); pituitary deficiency (Simmonds's disease, etc.); lupus erythematosus (systemic forms); polyarteritis nodosa; pemphigus; exfoliative dermatitis; and sarcoidosis. Supplies of cortisone and corticotropin for the treatment of patients suffering from the above conditions will be available only through the hospitals which receive regular monthly allocations, and inquiries should be addressed to these hospitals. The hormones cannot be sent either direct to doctors or to hospitals not included in the Ministry's list.

Memoirs on Endocrinological Subjects.—The Society for Endocrinology has issued the first of a series of periodical memoirs on endocrinological subjects. It is on "The Thyroid Gland," and is a record of a conference held in London last February jointly by the Society and the Endocrinological Section of the Royal Society of Medicine. Copies of the memoir may be obtained from Pitman Publishers, Parker Street, London, W.C.2, price 5s.—3s. to members of the Society (postage extra). The new series will be used for publishing proceedings of the Society's conferences, special reviews, or other material for which separate publication is desirable. The main object is to effect speedy publication in subjects which are being rapidly transformed by current research.

Family Doctor.—"Back to School" is the theme of a special section in the September *Family Doctor*. In the medical section there are articles on the obsessional personality, swollen ankles, and poliomyelitis. There is advice on preparing for breast-feeding, and the series on "How Your Life Began" is continued.

COMING EVENTS

International Paediatric Congress.—The seventh International Paediatric Congress is to be held in Havana, Cuba, from October 12 to 17. The main subjects for discussion at the conference will be "Epilepsy in Infancy and Childhood," "Diagnosis of Congenital Malformations of the Heart and Great Vessels Susceptible of Surgical Treatment," "Problems of the Premature Infant," "Complications of Primary Tuberculosis," and "Metabolism and Nutrition Problems." Those wishing to attend the meeting are requested to inform the Organizing Committee of the Congress, Hospital Mercedes, Vedado, Havana, Cuba, as soon as possible.

NEW ISSUES

Archives of Disease in Childhood.—The next issue (Vol. 28, No. 140) will be available in a week's time. Issued bi-monthly; annual subscription £3 3s., single copy 12s. 6d.; obtainable from the Publishing Manager, B.M.A. House, Tavistock Square, London, W.C.1.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Chadwick.—On August 3, 1953, at the Withington Hospital, Manchester, to Sybil, wife of Dr. David Chadwick, a son.
Hennessy.—On August 1, 1953, at the Keresley Branch, Coventry and Warwickshire Hospital, to Doris (formerly Drewry), wife of J. D. Hennessy, M.Ch., F.R.C.S., a second daughter—Karen Amy.
Parker.—On August 10, 1953, at the Birmingham Maternity Hospital, to Barbara (formerly Owens), M.B., B.S., D.A., and Bernard Parker, M.R.C.O.G., a second son.

DEATHS

Badger.—On July 30, 1953, at Edinburgh Royal Infirmary, Charles William Badger, M.B., Ch.B., of Carnethy, Penicuik, Midlothian.
Day.—On July 30, 1953, at Edinburgh, Charles Lionel Day, M.B., B.Ch., B.A.O., D.P.H., Lieutenant-Colonel, R.A.M.C.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Fats and Atherosclerosis

Q.—What are the therapeutic implications of recent work showing a relationship between certain serum lipo-proteins and atherosclerosis? Should the management of cases of coronary disease be altered to take account of this work?

A.—For a long time it has been known that there is a loose relationship between a high blood cholesterol and atherosclerosis, but the blood cholesterol could not be lowered by means of a low-fat diet. Thus in cases of coronary disease in which a high blood cholesterol was demonstrated there seemed little point in advising a low-fat diet. The work of John Gofman, however, has thrown a new light on the problem, for he has shown that it is not cholesterol *per se* that matters, but certain large fat molecules which may be separated out by means of the ultra-centrifuge. He and his colleagues have further established that the amount of these large fat molecules in the blood can be lowered appreciably by means of a fat-free diet. Thus there is now some scientific evidence to justify advising patients with coronary disease to adopt such a diet, although statistics have not yet demonstrated that a low-fat diet does in fact improve the prognosis of coronary disease.

Passive Immunity in Infants

Q.—Against which of the common infectious diseases is an infant protected by maternal antibodies transmitted through the placenta, and for how long does such immunity generally last? Does this protection depend on the mother having had the disease in question?

A.—It is common knowledge that specific infectious diseases like scarlet fever and diphtheria among bacterial infections, and measles, mumps and chicken-pox among virus infections, rarely occur in the first six months of life; and this phenomenon is attributed to the passive transfer of antibody from mother to child via the placenta. Most of our precise information about passive immunity comes from studies on the presence and amount of diphtheria antitoxin in the blood of mothers and their newborn offspring; these studies have shown that the level of antitoxin in the infant's blood at birth is at least as high as that of the mother's. The antitoxin disappears at a regular rate from the infant's blood (it is reduced to half its previous level approximately each month), and the time of its final disappearance naturally depends on the initial concentration; ordinarily it ceases to be demonstrable after three to four months. Thus this temporary immunity of the child is dependent on the presence of antibody in the mother's blood and presumably the same holds good for other infections. Antibody is most likely to be present in the mother's blood following a clinical attack of a systemic infection like measles, or repeated subclinical attacks as probably occurred in diphtheria when this disease was more prevalent. It is less likely to persist after more localized infections; for example, in whooping-cough the infection is mostly of the respiratory mucosa and antibodies probably do not persist into the adult life, since whooping-cough is one of the few specific infections that can occur early in infancy. It may be added that certain infectious diseases like infective hepatitis, poliomyelitis, and influenza rarely occur as typical clinical syndromes in infancy, but this may not mean that a child is insusceptible to infection by the agents of these diseases.

Intrathecal Penicillin

Q.—What is the recommended maximum dose of penicillin for intrathecal use in adults and in children? What risks attend exceeding these doses?

A.—20,000 units of penicillin is the maximum dose which can be given safely by lumbar puncture in the treatment of meningitis in adults, and the dose by cisternal or ventricular puncture should be smaller. This dose provides for concentrations in the C.S.F. which are above the level needed for inhibition of the pneumococcus for 24 hours, provided there is no leakage from the theca nor a subarachnoid block. In practice the usual intrathecal dose of penicillin is 10,000 units. Larger doses of intrathecal penicillin have been stated to cause convulsions and to increase the signs of meningeal irritation.

For children also the maximum dose should be 20,000 units; for babies and small infants 10,000 units. Crystalline penicillin is perfectly safe in these amounts, although smaller doses are generally adequate.

Vicarious Menstruation

Q.—Does vicarious menstruation really occur, and, if so, what are the commonest sites? What treatment is advised for it?

A.—Extragenital tissues cannot behave exactly as does endometrium, but some do occasionally bleed cyclically in relation to ovarian function, and in that sense vicarious menstruation is a real clinical entity. It is nevertheless rare, and this is particularly true of the substitutional type where the extragenital bleeding replaces uterine bleeding. Vicarious menstruation is mostly supplementary to uterine loss and takes the form of epistaxis in at least 30% of cases, the epithelium over the inferior turbinate bones being readily influenced by oestrogen. The commonest site after the nose is the alimentary tract, particularly the stomach. Other less common sites for bleeding are the lungs, breasts, gums and lips, kidneys, skin, retina, and conjunctiva. Vicarious menstruation is more likely to be seen at the two extremes of menstrual life and in hysterical and neurotic subjects.

It is always necessary to exclude a primary blood disorder and also a local organic cause for the haemorrhage. If none is found and unless the bleeding is heavy and uncontrollable, no special treatment is necessary. If the bleeding site is accessible—for example, the nose—cauterization is sometimes indicated. Empirical treatments advised include the administration of calcium and vitamin C or K. In very exceptional cases, as for example when retinal haemorrhages threaten sight, suppression of ovarian function might have to be considered.

Car Sickness in Small Children

Q.—What is the best way of preventing, and, if necessary, treating, car sickness in small children?

A.—Car sickness, like sea sickness and air sickness, may affect children at any age—even earliest infancy. Although there is undoubtedly a psychological element in many cases, its occurrence in infants shows that it has also an organic basis. Much of the success (and failure) of many of the remedies used is due to the psychological effect or approach. To judge of the real value of any remedy, therefore, its effect in early infancy must be assessed. On the whole, best results have followed the use of an antihistaminic. Dimenhydrinate ("dramamine"), promethazine hydrochloride ("phenegan"), and mepyramine maleate ("anthisan") have all proved extremely effective. Clearly they are better used prophylactically than therapeutically.

Treatment of car sickness involves stopping the car and allowing the child to get out in the fresh air. An open window or roof, attention to the exhaust system of the car

to ensure freedom from noxious fumes, equal and adequate pressure in the tyres, and care in cornering are all factors which may help in preventing car sickness. In older children reading while the car is in motion is sometimes responsible for nausea, which may proceed to emesis. Vomiting is less common when the child is sitting in the front seat. In the case of small children, if the journeys involved are short, the children should be allowed to stand on the seats and look out of the front windows. For long journeys, a good meal taken shortly before starting, together with a dose of anti-histaminic appropriate to the child's age, may be sufficient to promote drowsiness, and the journey may be begun with the child lying down comfortably on the back seat and going quietly to sleep.

Lice in Prison

Q.—As medical officer to a prison I am concerned with the problem of preventing the spread of lice of all varieties. Normally we expect to admit an average of three prisoners with pediculosis pubis daily plus a not always ascertainable number of cases of pediculosis corporis and capitis. We isolate these cases until treatment is complete. The present procedure with regard to prisoners' clothing is that all except blue suits goes through the steam disinfecter. The blue suits are sprayed with liquid D.D.T. and kept in a special room which is sprayed with D.D.T. daily. This is because the suits turn brown when treated in the steam disinfecter. Are these precautions adequate?

A.—Human body-lice spend nearly all their time on the undergarments, especially those next to the skin. Only in exceptionally heavy infestations is more than an occasional stray louse found on an outer garment such as a serge suit. It is therefore satisfactory to apply a residual insecticide, such as D.D.T., to the undergarments only; sooner or later the lice are bound to be contaminated.

The procedure described in the question appears quite adequate. However, several points call for comment: (1) The temperature required to destroy insect life is much lower than for many bacteria. The eggs of lice are killed by exposure to 54° C. for five minutes, or 50° C. for half an hour. Higher temperatures or longer exposures are, of course, necessary in practice, to allow the heat to penetrate the garments. Correct exposure could be determined by experiment and would almost certainly be below the level causing damage to blue suits. (2) "Liquid D.D.T." is presumably D.D.T. dissolved in kerosene. Neither in solution nor as a powder is D.D.T. lethal to nits, though it may persist long enough to kill the young louse on hatching. (3) In other parts of the world, strains of lice immune to D.D.T. have been reported, and it is important to look out for this phenomenon here. These resistant lice may survive an exposure of 24 hours to 10% D.D.T. powder.

Anaesthesia in E.C.T.

Q.—Is an anaesthetic really necessary for electro-convulsion therapy?

A.—In electro-convulsion therapy some retrograde amnesia is the rule and patients rarely have any unpleasant memory of the previous treatment. There is therefore little need for an anaesthetic in these circumstances. However, it is now common practice to "soften" the convulsion by the previous administration of a relaxant. In the case of curare and gallamine triethiodide ("flaxedil"), if these drugs are given in a dose just sufficient, say, to make snapping of the finger a little difficult, no anaesthetic is really necessary. When, however, succinylcholine chloride ("scoline") or "brevidil" is used, the fibrillary twitchings which precede the muscular paralysis may be quite unpleasant, and the previous injection of a little thiopentone becomes necessary. An average dose of thiopentone for a healthy male would be 0.2–0.25 g., followed immediately by the succinylcholine, after which the convulsion is induced.

Sweating in Shock

Q.—Why do shocked patients sweat?

A.—Sweat glands are innervated, anatomically, by the sympathetic nervous system, although there is doubt as to whether the physiological transmitter at the post-ganglionic nerve ending is acetylcholine or noradrenaline.¹ Shock is associated with a reduced circulating blood volume, and, as a compensatory measure, vasoconstriction of the cutaneous blood vessels is induced by intense sympathetic overactivity. Although teleologically unfortunate, this efferent sympathetic discharge also involves the fibres supplying the sweat glands and results in the characteristic pale, moist skin of the shocked patient.

NOTES AND COMMENTS

Beeswax.—Mr. C. C. TONSLEY (Editor, *British Bee Journal*) writes: My attention has been drawn to the item "Beeswax" ("Any Questions?" August 1, p. 296). While I do not disagree with the answer generally which is supplied to the question, I would like to remedy one error which has been stated. In modern beekeeping paraffin wax combs are not given to the bees. If anything but beeswax were offered to bees they would immediately tear it down and build natural comb in its place. Experiments with which I have been associated, where both plastic and metal combs were given to the bees in an effort to get them to use them, resulted in the bees first coating either the plastic or the metal with a thin layer of beeswax before using them, and unless crowded for space they ignored them. In America there is what is called a three-ply foundation made which is given to the bees to draw out into combs. This, however, consists of two outer sheets of pure beeswax with a thin sheet of carnauba wax sandwiched between. The bees draw this outer beeswax into their comb but they do not reach the midrib of vegetable wax.

Vaccination in Pregnancy.—Dr. NORMAN TAYLOR (Geneva) writes: The question recently asked on vaccination in pregnancy (July 25, p. 235) did not include reference to the dangers of yellow fever inoculation during pregnancy, as these two operations are nowadays so often required together and urgently. I presume, on theoretical grounds, since they are both live vaccines, both are equally capable of producing undesirable consequences.

OUR EXPERT writes: Although yellow fever vaccine consists of living virus, there is no evidence of its producing any toxic effects in a pregnant woman, and therefore there is no contraindication to its administration during pregnancy.

Isopropyl Alcohol.—The Isopropyl Alcohol Regulations, 1927 ("Any Questions?" July 11, p. 108), which govern the use of the substance, were suspended in August, 1950. They have not been annulled and therefore, if necessary, could be reimposed.

Corrections.—In the review of *Operative Thorakoskopie* (*Journal*, August 1, p. 265) it was stated that Jacobaeus was a Croatian surgeon. He was, in fact, Swedish.

The reference to Dr. E. Parry Jones in Mr. H. Vincent Corbett's letter in the *Journal* of August 8 (p. 340) was to his book, *Kielland's Forceps* (1952, Butterworth, London), and not to his letter which appeared in the *Journal* of June 6 (p. 1278).

BRONCHIAL CARCINOMA: INCIDENCE AND AETIOLOGY*

BY

RICHARD DOLL, M.D., M.R.C.P.

Member of the Statistical Research Unit of the Medical Research Council

A little over a hundred years ago Dr. Gavin Milroy took an active part in the establishment of the Epidemiological Society. The object of the Society was to study "epidemic and endemic diseases, with special reference to the investigation of (a) the various external or physical agencies, and the different conditions of life, which favour their development or influence their character, and (b) the sanitary and hygienic measures best fitted to check, mitigate, or prevent them." In 1850, interest was focused on the great epidemic diseases, but the methods Milroy urged—the collection of statistical data on the natural history of disease over large areas and over periods of years followed by inductive reasoning from the observed facts—are as applicable to-day to the study of lung cancer as they were then to the study of plague, typhus, and cholera. And the rapid increase which has been recorded in the mortality from lung cancer suggests that it is urgent to determine the measures "best fitted to check, mitigate, or prevent" it.

Incidence

No figures are available for assessing the incidence of lung cancer in Britain, other than the mortality statistics of the Registrars-General. Because of its great fatality, the number of persons dying from it is nearly equal to the number affected, and, from this point of view, mortality statistics provide a reasonable estimate of the incidence. They are, however, subject to the inaccuracy inherent in the certification of causes of death.

The salient feature of the reported mortality is the extent to which it has increased in the last 50 years—and particularly in the last 25 years. In 1900 the crude annual death rate attributed to lung cancer in England and Wales was 8 per million persons; by 1925 it had risen to 20 and by 1950 to 278 per million.† In other words, the recorded rate increased two and a half times in the first 25 years, and 14 times in the next 25 years.

By 1950, 12,241 deaths were attributed to lung cancer in one year—10,254 in men and 1,987 in women. As a site of cancer, in both sexes taken together, the lung was second in importance to the stomach, but it was easily the most important site in men—giving rise to 28% more deaths than were attributed to cancer of the stomach and to more than double the number attributed to cancer of the colon. Of all cancers in men, 24% were classified as having arisen in the lung, but at ages 45–54, when lung cancer was relatively most

frequent in proportion to other cancers, the proportion was 40%.

Compared with non-malignant diseases, lung cancer was recorded as a more common cause of death in men than hypertension or respiratory tubercle; but only a third as many deaths were attributed to it as were attributed to coronary artery disease. Of all male deaths in 1950, 4% were attributed to lung cancer; at ages 45–54 the proportion was 10%.

There is no reason to suppose that these figures have yet reached their maxima. On the contrary, the trend in mortality rates suggests that lung cancer will reach an even more prominent position. It is difficult to estimate the actual number of deaths which will occur. Trends do not always continue smoothly. For example, the trend in male mortality at ages 35–44 showed an almost steady increase from 1920 to 1946, when the rate reached the level of 166 deaths per million men. In 1950 the rate might have been expected to be about 190 per million, whereas in fact it remained the same as four years earlier. If future experience proves that the mortality in men aged 35–44 has, in fact, become stable, it is to be expected that the increase will also cease in the older age groups, but only after progressively longer periods of time have elapsed.

The maximum mortality from lung cancer, unlike that from every other major form of cancer in men, is not in the oldest age group. At present it lies in the age group 65–74, and in 1931–47 was a decade earlier (Fig. 1). Over the last 20 years the age distribution has become somewhat closer to that of the other major forms of cancer. If it can be assumed that the death rates under the age of 45 have now become stable, and that the trend in the age distribution continues until the distribution is similar to that of, say, cancer of the stomach, a rough estimate can be made of the number of deaths which will eventually be attributed to lung cancer. On such assumptions—admittedly highly speculative but, I think, not wholly unreasonable—the number of deaths, for a population of the same age and sex composition as at present, will eventually reach 20,000. In fact, the future population will almost certainly contain a higher proportion of old persons, so that the number recorded in 20 years' time may be as great as 25,000.

Increase in Incidence

The evidence that lung cancer has become more frequent derives from necropsy studies as well as from vital statistics and clinical series. Figures from Leeds General Infirmary

*The Milroy Lectures delivered at the Royal College of Physicians of London on February 10 and 12, 1953. (Abridged.)
†By 1952, the rate had reached the level of 321 per million.

published by Bonser (1934) and brought up to date by Watkinson (personal communication) show a rise in the proportion of necropsies at which a bronchial carcinoma was found from 1.4% in 1928-32 to 4.0% in 1949, and from 7.5% of all cancers found at necropsy to 16.9%. Figures from St. Mary's, St. Bartholomew's, and the Glasgow Western Infirmary also show increases over the last 15 years (Daff, Doll, and Kennaway, 1951). The only contrary experience recently recorded is that of Bryson and Spencer (1951); earlier reports are purposely not considered, as they would not seem to be relevant to a problem which has presented itself in an acute form only since they were written.

Fig. 1.—Mortality from lung cancer among men at different ages, 1911-50.

Bryson and Spencer's material was collected from the necropsy records of the Central Histological Laboratory of the London County Council over a period when the number of necropsies performed increased rapidly (from 684 to 1,723 a year), although the number of patients admitted to the 26 hospitals concerned fell by a quarter. It seems likely that, in fact, the type of subject coming to necropsy changed considerably, and this is borne out by finding that the proportion of cancers which arose in the large intestine increased from 5% to 13%. If, therefore, Bryson and Spencer's material suggests that bronchial carcinoma did not increase between 1936 and 1947, it also suggests that cancer of the large intestine did—which is contrary to the evidence of mortality statistics and to all clinical impression.

The increase recorded by vital statistics is partly due to the increasing proportion of the population who live to the cancer age. This, however, accounts for only a small part of the increase. If the sex and age distribution of the population in 1950 had been the same as it was in 1931, the general rate for the population would have been 236 per million instead of 278 per million; that is, there would still have been a five-fold increase in 19 years (Fig. 2).

Fig. 2.—Death rate from lung cancer in England and Wales, 1900-50. A=Estimated death rate in 1950 with population of age and sex distribution as in 1931. B=Estimated death rate in 1950 with population of age and sex distribution as in 1901.

It has been held that the great increase in the recorded mortality in Britain may be due to the successive introduction of radiography, bronchoscopy, pneumonectomy, cytological examination of the

sputum, and diagnostic thoracotomy. It would indeed be strange if the consequent increased facility in diagnosis had not been reflected in a more general recognition of a clinically obscure disease. It must also be recognized that improvements in therapy of the infectious diseases—particularly of pneumonia—must have reduced the number of deaths occurring from the early complications of lung cancer and so allowed a greater proportion of the cases to proceed to a readily diagnosable stage. In illustration of the close relationship presumed to hold between the lung cancer death rate and the standard of medical diagnosis and certification, Rigdon and Kirchoff (1952) have shown that the correlation coefficient between the death rate and the number of patients per physician in the 48 States of the U.S.A. is -0.66 : that is, the fewer the patients per physician the higher the lung cancer death rate.

In recent years Willis (1948) in Britain and Clemmesen and Busk (1947) in Denmark have, like Steiner (1944) in the U.S.A., expressed the view that the increase is spurious. It seems, however, as pointed out by Heady and Kennaway (1949), that Willis based his opinion on evidence collected before 1933—that is, before the greater part of the increase was recorded, while Clemmesen has revised his opinion (Clemmesen, Nielsen, and Jensen, 1953) and Steiner has been convinced that a real increase has taken place locally—for example, in Los Angeles (Steiner, Butt, and Edmondson, 1950).

Reasons for believing that there has been a real increase are:

(1) The increase in the recorded death rate still continues, despite the long period which has elapsed since attention was drawn to the importance of the disease.

(2) The disease is now so common that had the increase been entirely spurious it would be necessary to postulate that 50 years ago 95% of the fatal cases were wrongly certified.

(3) Necropsy examinations conducted under the supervision of single eminent pathologists, at teaching hospitals where over 90% of the subjects who died came to necropsy—for example, St. Mary's, London, and Leeds General Infirmary—have also shown considerable increases in the proportions of bronchial carcinomas to all cancers and to all necropsies.

(4) The increase has been persistently greater in men. Passey and Holmes (1935) suggested that this might be due to the greater facilities for medical attention available to men under the National Health Insurance Act, but in the few years that have elapsed since the introduction of the National Health Service Act, in July, 1948, the disparity has become even greater (Fig. 3).

(5) The age distribution of lung cancer in men is different from that of all other major types of male cancer, and has been changing in form while its incidence has been increasing. Korteweg (1951) notes that the trends in England and Wales are in conformity with the hypothesis that a real increase has occurred and that successive generations have been exposed to extraneous carcinogens to different extents. The same phenomenon has been observed in Denmark (Clemmesen, Nielsen, and Jensen, 1953).

Fig. 3.—Death rates from lung cancer in England and Wales, 1900-50.

(6) The death rates in town and country have, in England and Wales, retained the same relation to one another.

(7) The mortality among doctors, who may be presumed to be as carefully investigated as any section of the community, has been practically the same as that for the whole population (Kennaway and Kennaway, 1947; Dublin, Spiegelman, and Leland, 1947).

It cannot be said that all workers are agreed on the conclusions to be drawn; Rigdon and Kirchoff (1952), for example, continue to believe that the increase is wholly spurious. At the International Symposium on the Endemology of Lung Cancer held last year at Louvain, however, it was agreed that "a significant part of this increase is absolute and represents a real increase in the number of people suffering from cancer of the lung" (Council for International Organizations of Medical Sciences, 1953), and the conclusion of the Symposium seems to me to be reasonable.

How much of the increase is real after standardizing for age and sex remains uncertain. The extent of the change in the last five years, when the importance of the disease has been recognized and facilities for diagnosis have been readily available, suggests that the real increase is likely to be large. I believe it may well be more than half. On the other hand, I would think it certain that some of the increase is nosological and some is due to the therapeutic advance which prevents death from pneumonia before the presence of the underlying growth is evident.

Possible Explanations of the Increase

The importance of the conclusion reached is that it holds out hope for prevention. An increase of the rapidity and extent of that presumed to have occurred cannot be accounted for on the basis of a changing inherent constitution. Some potent environmental factor must have become prevalent, and therefore, when the factor is identified, it may prove possible to reduce its influence.

Factors which have been considered are (1) atmospheric pollution with (a) the waste products of domestic chimney and factory smoke, (b) the exhaust fumes of vehicles, and (c) the dust from tarred roads; (2) the smoking of tobacco; and (3) the after-effects of certain respiratory infections—for example, influenza of the type associated with the 1918-19 pandemic and tuberculosis.

Animal Experiments

The effect of these and other factors has been studied extensively in animals. Unfortunately, although lung tumours have been described in many species, there is no laboratory animal which spontaneously develops tumours comparable to the ordinary squamous or anaplastic carcinoma of the bronchus of man. For example, the common pulmonary tumour of mice, which has been the subject of most experiments, is a papillary adenocarcinoma and, according to Grady and Stewart (1940), is of alveolar rather than of bronchial origin.

Many substances, when fed to mice, painted on the skin, or injected parenterally, increase the incidence of this tumour—the most effective method generally being intravenous injection. Not all strains of mice respond in the same way; strains with high and low incidences of spontaneously occurring pulmonary tumours have been separated and different strains react in different ways to the application of the same substance. Many—though not all—of the hydrocarbons known to be carcinogenic under other conditions have been shown, on testing by these methods, to produce pulmonary tumours. The most potent is urethane.

Tumours more like the human type have been produced in mice by Andervont (1937), by the insertion of a piece of cotton thread impregnated with 1,2,5,6-dibenzanthracene directly into the lungs; by Smith (1950), by the implantation of lung tissue from embryo mice along with

solutions containing methylcholanthrene or dibenzanthracene into the thigh muscles of adult animals; and by Lisco and Finkel (1949), by the administration of radioactive cerium (Ce^{144}) in the form of an aerosol.

Substances derived from sources suspected of being implicated in causing human lung cancer have been tested by exposing mice to atmospheres containing the test substance in the form of dust or smoke, or by skin-painting. McDonald and Woodhouse (1942) found an increased incidence of pulmonary tumours in mice exposed to inhalation of soot collected from the air of an English city, and Leiter, Shimkin, and Shear (1942) produced sarcomas in mice at the site of inoculation with extracts of soot collected from the air of several American towns. Campbell (1934) found a greatly increased incidence of pulmonary tumours in mice exposed to an atmosphere heavily laden with the dust from tarred roads, and many animals also developed carcinoma of the skin, presumably from contact with the dust externally; road dust from which the tar had been extracted also increased the incidence of the tumours, but to a less marked extent (Campbell, 1937). Mice kept in an atmosphere of tobacco smoke by Campbell (1936) in Britain and by Lorenz, Stewart, Daniel, and Nelson (1943) in America showed no significant increase in the number of tumours.

In contrast, Essenberg (1952) has recorded an increased incidence in mice exposed to high concentrations of cigarette smoke. The mice came from a strain with a high spontaneous incidence, and tumours were obtained in 21 out of 23 (91%) in the experimental group against 19 out of 32 (60%) in the control group. It may be significant that the cigarette smoke was drawn directly into the animal box in Essenberg's experiment, whereas in the other experiments it was introduced through tubing. In no case have the conditions reproduced those to which men are exposed in smoking, nor can they do so unless animals are trained to smoke. Tar obtained from tobacco burnt at temperatures normally reached in pipe-smoking has resulted in the production of carcinomas when applied to the skin, both in mice (Flory, 1941; Graham, Wynder, and Croninger, 1952) and in rabbits (Sanders, Thomson, Cooper, and Lamb, 1932). The tumours have not been produced easily, but there is no doubt that tobacco tar can contain a carcinogenic agent. Experiments in which animals have been exposed to the exhaust fumes of cars have proved negative (Campbell, 1936; Twort, 1939).

The application of these results to the study of human lung cancer is problematical. In the first place, the pulmonary tumour of mice is histogenetically different from bronchial carcinoma, and tumours which more closely resemble the human type have been produced only by methods which do not appear likely to have any direct counterpart in naturally occurring carcinogenesis. The rarity of bronchial carcinoma in animals accords with the theory that the tumour in man commonly arises from some specifically human activity. In the second place, it is clear that most of the sources suggested as responsible for the production of bronchial carcinoma—atmospheric soot, dust from tarred roads, and tobacco tar—can be shown, by selected methods of application, to contain substances which are carcinogenic for some animals. Whether they are of importance in the production of the human disease can be determined only by observations on man.

Incidence in Different Parts of the World

It is always difficult to compare vital statistics from different countries, and particularly so when they relate to a disease like lung cancer, which is not easy to diagnose with certainty by clinical methods. Necropsy statistics have the advantage that the diagnoses can be relied on, but the populations from which the subjects are drawn are seldom known with accuracy, and much bias may be introduced into the figures, for this reason, without there being any evidence of its nature.

TABLE 1.—Death Rates from Lung, Respiratory, and Non-respiratory Cancers in Various Countries, 1949

* 1947. † 1948.

Necropsy series.—England and Wales: St. Bartholomew's, 1945-8, St. Mary's, 1945-8, Leeds General Infirmary, 1945-9. Scotland: Western Infirmary, Glasgow, 1945-8. Holland: Amsterdam and Rotterdam, 1951 (Korteweg, personal communication). U.S.A.: Los Angeles, 1943-6 (Steiner, Butt, and Edmondson, 1950); Texas, 1945-9 (Rigdon and Kirchoff, 1951). Iceland: Reykjavik, 1940-50 (Dungal, 1950, and personal communication).

Not all countries which publish vital statistics separate lung cancer from other cancers of the respiratory system. Of those that do, the highest rates recorded in 1949 were in England and Wales (251 per million) and in Scotland (228 per million), the next highest in Holland, Switzerland, and the U.S.A. (all around 110-120), and the lowest in Iceland (58†) and in Norway (54). Differences of this size (4½ to 1) cannot be accounted for by demographic differences. If, for example, the English rates had held for populations of the sex and age distributions of the U.S.A. and Norway, the death rates would have been 223 and 239 per million and still much higher than the rates actually recorded in those countries.

The forms of respiratory cancer other than cancer of the lung have, in all probability, different aetiologies; lung cancer, however, accounts for such a high proportion of all respiratory cancer that important differences in the mor-

The rates for all forms of cancer other than respiratory give an indication of the reliability of the national statistics. All forms of cancer may be relatively infrequent in some countries, but, in view of the great variety of factors responsible for the production of cancer in different sites, conditions favouring a generally low rate are unlikely to be common. A low rate for all non-respiratory cancers in conjunction with the low rate for respiratory cancer must arouse the suspicion that many cases are not diagnosed; a high rate for all non-respiratory cancers with a low respiratory cancer rate will, on the other hand, suggest (though it does not prove) that the respiratory rate is reasonably reliable. If necropsy studies in the same country also indicate a low proportion of lung carcinoma the impression will be strengthened.

With these considerations in mind, it would be unwise to attach importance to the low respiratory cancer rates reported from Italy, Spain, and Chile. On the other hand, in both Norway and Iceland there is no deficiency of diagnosis of cancer generally, and it seems reasonable to believe that the extremely low rates reported for lung cancer are real. In Iceland, moreover, Dungal (1950) found a very low proportion of lung cancers at necropsy at the University Clinic (where necropsy is routinely performed on all patients who die).

Very low incidences at necropsy have been reported from many parts of the world for which vital statistics are lacking (Table II). Gharpure (1948) found no case of lung cancer among 4,321 necropsies performed in Bombay during 1926-46, and Strachan (1934) found none among 1,901 necropsies on native South Africans. In this context, it is of interest that the death rate from lung cancer among the non-white population of the U.S.A. is of the same order as that among the white population, so that the apparent difference found between Europeans and native Africans is unlikely to be due to heredity. The average age at death in the Indian and South African native cases must have been much less than that in recent European series, and this, alone, will have considerably reduced the proportion found to be cancer of the lung. Nevertheless, an appreciable number of cancers were found in the sites which commonly give rise to cancer among Europeans, and it is unlikely that no case of bronchial carcinoma should have occurred in such large series if the condition was as common in India and South Africa as it is in Britain.

tality from respiratory cancer are likely to simulate underlying differences in the mortality from lung cancer. Figures for the death rate from respiratory cancer are shown in Table I for all those countries for which the statistics are published.

Table I also shows the death rates from all forms of cancer other than respiratory and, for some countries, the death rates from lung cancer alone and the proportion of bronchial carcinomas among all cancers found at necropsy in recent series—that is, in necropsies performed since 1940.

†The rate for Iceland is for 1948.

Fig. 4.—Lung cancer. Death rate in different countries, 1920-50. Rates for the countries shown in parentheses were close to the rates for the countries with which they are grouped.

Differences Between Town and Country

Important differences in incidence have also been noted between sections of the population within individual countries. Though mostly less dramatic than the differences between countries, they have hitherto been of greater value in elucidating the aetiology of the disease, since it has been possible to define more precisely the differences in environment to which the separate groups have been exposed. For example, differences in mortality have been noted between countrymen and townsmen and between the inhabitants of towns of different sizes. According to the Registrar-General, the death rate from lung cancer in 1950 was twice as high among the male inhabitants of Greater London as among men living in rural districts, and the difference was more pronounced in the older age group. The rates for other parts of the country fell between the Greater London and rural rates, in exact order of town size (Fig. 5). Female rates show the same trends, though the differences are less marked and the trends somewhat blurred, possibly owing to smaller numbers. Comparison of the relative differences at different periods shows that these differences have remained remarkably stable despite the great increase in the recorded mortalities.

Stocks (1952) has analysed the urban death rates for the period 1946-9 and has demonstrated a progressive increase with the increase in the number of inhabited houses. Within Greater London, he found that the boroughs with the highest mortalities were situated to the north and east of the town's centre. This, he suggests, may be related to the direction of the prevailing wind, which is from the south-west—and might therefore be expected to shift the area of maximum smoke density to just that part of the town in which the highest mortalities occur.

As always, when drawing conclusions from vital statistics, it must be asked whether the differences can be purely nosological; whether the "factor" is nothing more than a greater facility for diagnosis in the larger towns. This seems unlikely. In the first place, it would hardly be expected that diagnostic acumen should be so closely dependent upon the exact size of town; secondly, there is the stability of the urban:rural ratio; and, thirdly, there is direct evidence obtained by Doll and Hill (1952). They found, among 1,465 patients

with carcinoma of the lung and the same number of matched control patients with other diseases, that the proportion who had ever lived for any long period in the country was lower among the carcinoma patients, irrespective of their present place of residence. That is to say, among patients residing in Greater London at the time of interview a lower proportion of those with lung carcinoma than of those with other diseases had ever lived for 10 or more years in a rural district—and similarly for each other place of present residence. The differences were small and not statistically significant, but they were all in the same direction, and provide some support for the belief that the risk of developing lung cancer is, in fact, lower in the countryside.

The observation of a town and country difference is not confined to Britain. Clemmesen, Nielsen, and Jensen (1953) have reported an even more pronounced difference between the capital and rural areas of Denmark. In their opinion, however, the difference is not constant, but may be explained by the spread of a new carcinogenic factor to the countryside, 10 years after it had begun spreading in the capital.

In Norway, the difference between urban and rural areas—as definite as in Britain, despite the low total incidence—is also increasing. Mortality statistics, for which I am grateful to Professor Kreyberg, provide the following comparisons:

Ratio of Death Rate in Town and in Country

		1931-5		1946-50	
Men	..	1.8:1	..	2.5:1	
Women	..	1.1:1	..	1.5:1	

It seems, therefore, as if differences are constantly in the same direction, but that there may also be local differences which modify the trends in different countries.

Three substances known to be carcinogenic under suitable conditions have been identified in town air. According to Dawson (1952) radioactive material is present to the extent of $30-100 \times 10^{-12}$ curie per m.³. Activity in the open air of towns is not much greater than in rural areas, but within closed rooms the activity may be doubled, and in extreme cases, as in an underground shelter, it was found to be 100 times greater. Even this value is, however, only one-tenth of the tolerance concentration—unless it proves (as it may do) that the limit at present accepted is set too high.

The amount of arsenic varies, according to Goulden, Kennaway, and Urquhart (1952), from 0.04 µg. of As₂O₃ per m.³ in Bristol to 0.16 µg. per m.³ at Beckton, in London.

Fig. 5.—Death rate from lung cancer in different areas of England and Wales, 1950.

It is, however, difficult to ascribe any one value to a town, as there are considerable variations between stations within towns—for example, the concentration in the air at County Hall, London, was only a third of that found at Beckton and only slightly greater than that recorded in Bristol. The total amount inspired by a town dweller per year is estimated by Kennaway to be 0.5 mg., which is only one-tenth of the amount in the maximum official dose of Fowler's solution (0.5 ml.).

According to Waller (1952), benzpyrene is present in town air, in amounts varying from 0.013 $\mu\text{g. per m.}^3$ in Bristol to 0.046 $\mu\text{g. per m.}^3$ of air in the centre of London. Again, however, variations in the concentration make it necessary for many readings to be obtained before a fair estimate can be made of the content of the air of a town as a whole. Winter concentrations are three to four times greater than summer concentrations, and great increases are obtained during fogs. In Waller's opinion the variations in benzpyrene content suggest that most of it is derived from the smoke of domestic fires. Some has, however, been detected in motor exhausts, and, since the sizes of the particles in exhaust smoke are concentrated over a limited range of small sizes, this source could be of greater biological significance than appears from the proportion which it contributes to the total air pollution.

Occupational Risks

The classical method leading to the isolation of chemically pure carcinogens is the observation of specially high cancer risks in specific occupations. With lung cancer, exceptional risks have been recognized in several unrelated industries. These are: mining of various ores in Schneeberg (Germany) and in Jachymov (Czechoslovakia); chromate production; nickel-refining (in Clydach, S. Wales); asbestos manufacture; and the production of gas. To these should probably be added the handling of inorganic arsenic and, possibly, occupations providing excessive exposure to iron dust, with or without added exposure to silica.

The risks involved have been estimated only for chromate workers and gas-workers. Brinton, Frasier, and Koven (1952), extending the initial observations of Machle and Gregorius (1948), have compared the sickness and mortality experience of insured workers in the seven chromate-producing plants in the U.S.A. with the whole sickness data obtained by the U.S. Public Health Service and the death rates for the U.S. population. They found that the mortality from lung cancer among white males employed in the plants was 14 times the expected, and among coloured males it was 80 times the expected. According to Bidstrup (1951) the risk is unlikely to be as great in the British chromate industry.

Doll (1952) studied the causes of death among 2,071 male pensioners of a London gas company and found that the number of deaths from lung cancer was approximately double that expected by comparison with male inhabitants of London of the same age distribution—that is, 25 deaths against 13.8. Confidence that this small excess is real derives from the observation that for all other causes of death studied the numbers observed were not significantly different from those expected; it is also of the same order as that determined by Kennaway and Kennaway (1947), when they drew attention to the possibility of there being a risk in the gas industry.

Of the other occupational risks, that incurred in the Schneeberg and Jachymov mines is likely to have been the highest; as much as 50 to 75% of all deaths among the miners may have been due to lung cancer (Haerting and Hesse, 1879; Lange, 1935; Peller, 1939). The risk in the Clydach nickel refinery—at least till the reorganization of the plant in 1924—must also have been considerable (Chief Inspector of Factories, 1949). In the manufacture of asbestos and arsenical sheep dip the risk is more likely to have been of the same order as that involved in the pro-

duction of gas. For example, Gloyne (1951) found that of 52 men dying with asbestosis, about 20% gave evidence of the presence of a primary lung cancer, whereas among men with other forms of pneumoconiosis the proportion was 7%. As is shown later, there are reasons for believing that the incidence among men with pneumoconiosis is generally close to the average.

The evidence of the existence of a risk of lung cancer in the handling of inorganic arsenic derives from an investigation by Hill and Fanning (1948) into the causes of death among men employed in a factory making sheep-dip. They traced five deaths due to lung cancer among these men, whereas they estimated, by comparison with the causes of death in other workers in the area, that there should have been only one.

The existence of special cancer risks in most of these industries is not surprising, since the workers in them have been exposed in the past (and in some cases still are exposed) to unusual concentrations of known carcinogens. According to Evans (1950) the mean concentration of radon in the air of the Jachymov mines is about 3×10^{-6} curie per m.^3 , while the tolerance concentration is at the most 10^{-7} curie per m.^3 —that is, one-thirtieth of that found in the mines. Hueper (1952) has produced sarcomas in mice at the site of injection with suspensions of finely dispersed nickel powder, and nickel must be presumed to be deposited in the respiratory passages on the decomposition of nickel carbonyl, a gas produced in the refining process at Clydach. Gas-workers are exposed to coal tar—one of the most prolific sources of carcinogenic hydrocarbons and including benzpyrene. Finally, arsenic is known to produce cancer of the skin in man when ingested over long periods, and large quantities (up to 1,000 $\mu\text{g. per m.}^3$) were found in the atmosphere of the sheep-dip factory (Perry, Bowler, Buckell, Druett, and Schilling, 1948).

No direct evidence is available on the nature of the carcinogenic factor in the chromate and asbestos industries.

The position with regard to iron-workers is obscure. Turner and Grace (1938) found that foundry-workers, smiths, and metal-grinders had a mortality from lung cancer higher than that of any other occupational group in Sheffield; and Turner and Martin (1949) found that out of 32 cancer deaths among grinders with silicosis the lung was the primary site in 19. Metal-grinders also suffered a high mortality from lung cancer in Kennaway and Kennaway's (1947) material. These observations might be thought to imply that silicosis predisposed to lung cancer, but this has been convincingly shown not to be true (Miners' Phthisis Medical Bureau, 1936; Kennaway and Kennaway, 1947). If there is any excess among special groups of metal workers it must be presumed to be due to some other, and more specific, industrial hazard.

An attempt has been made to discover whether any other common occupation carries a special risk by interrogating patients with and without bronchial carcinoma about their past occupations. The questions were asked as part of a general investigation into the aetiology of bronchial carcinoma which has been described previously (Doll and Hill, 1950, 1952). Altogether 1,357 men with bronchial carcinoma and 1,357 men with other diseases were interviewed. Occupations in which the men had been employed for three or more years were recorded; no account was taken of time spent in the Services unless the patient had served as a regular, and no analysis was made of employments under the age of 20, when changes of occupation were frequent. Many men had worked in two or more occupations for the minimum of three years, so that the number of occupations recorded was greater than the number of men interviewed—2,281 for the men with lung carcinoma and 2,415 for the same number of men with other diseases. Of all the 76 groups into which the occupations were classified, there were only two in which the differences between the numbers c-

bronchial carcinoma and of control patients who had been employed in them could be considered, by the usual statistical criteria, to be significant. The occupations recorded of the bronchial carcinoma patients included 80 in coal-mines and 16 in the police forces; of the control patients, there were 113 in coal-mines and 32 in the police forces. In view of its correspondence with the results of the analysis of the national mortality data made by Kennaway and Kennaway (1947), the deficiency of coal-miners among the bronchial carcinoma group may reasonably be taken to confirm that coal-miners are subject to a lower incidence of bronchial carcinoma than other industrial groups. The deficiency in the cancer group of men who had been employed as policemen may, in the absence of other evidence, be attributed to chance, since there is nothing surprising in finding one difference of this extent when so many groups have been studied.

The most important excess in the cancer group occurred in men who had been directly concerned with the production of gas; the cancer group contained 23 such men, the control group 14. Other evidence has shown that gas-workers are exposed to a special risk of lung cancer, and the present figures are corroborative—although, by themselves, not statistically significant.

The closeness of the numbers in the two disease groups who had been employed in many of the other occupations is striking. This is particularly so for occupations which might have been expected to be disproportionately represented in the lung-carcinoma group, if exposure to the dust of tarred roads or to motor exhaust fumes was responsible for many cases of the disease.

	Men with: Lung Carcinoma	Other Diseases
Motor mechanics, garage hands	19	25
Drivers of cars, lorries, or buses	105	101
Bus and tram conductors	10	21
Van drivers (horse)	33	25
Other road transport	17	25
Roadmen, council labourers, dustmen	39	39

The failure to find any difference in the relative proportions of men employed on the roads or in the service of cars is of interest. It accords with the conclusion of Kennaway and Kennaway (1947) that none of the open-air occupations, where there was special exposure to road dust, had a high incidence of cancer of the lung.

The results provide little or no support for the suggestion of Wynder and Graham (1951) that painters and what they describe as "hot" metal workers may suffer special risks.

	Men with: Lung Carcinoma	Other Diseases
Painters and decorators	70	59
Furnacemen, foundrymen, and smiths	26	23
Other metal workers	150	157

The evidence from a study of occupational factors is therefore that the development of bronchial carcinoma may result from prolonged exposure to a number of atmospheric carcinogens; some of these substances, like radon, benzpyrene, and arsenic, are present in town air—though in very much lower concentrations than occur in industry; others, like nickel, are peculiar to specialized industrial processes; others are as yet undetermined. So far as it goes, the evidence is against the hypothesis that motor fumes and road dust are responsible agents.

Although one occupation—the refining of nickel—is also responsible for a high incidence of cancer of the nasal sinuses, it is a remarkable fact that none of the occupations known to be associated with a high incidence of lung cancer appears to carry any increased risk of laryngeal cancer. It is probable, therefore, that the factors which are responsible for the production of carcinoma of the bronchus and for carcinoma of the larynx are independent.

Sex Ratio

According to all reports the incidence of lung cancer is much greater in men than in women. The extent of the

difference is, however, uncertain. In this country the mortality statistics of the Registrar-General gave, in 1950, a ratio of 5.2 male deaths to every female death, and the proportion has been increasing steadily, though slowly, from year to year. During the first half of 1949 Mackay's (1951) study of in-patients discharged from a number of selected hospitals (mainly teaching hospitals) gave a ratio of 5.1 to 1 and the national cancer registration scheme (which is believed to cover about half the cases in the country) gave, in 1946, a ratio of 6.9 to 1 (Stocks, 1950). Much higher ratios have been recorded in recent clinical series—varying from 7.3 to 1 to 12.6 to 1 (Fulton, 1949; Mason, 1949; Brooks, Davidson, Thomas, Robson, and Smithers, 1951; Doll and Hill, 1952).

The inconsistency may be partly due to the inclusion of a proportion of inaccurately diagnosed cases in the national

FIG. 6.—Lung cancer. Ratio of male : female death rates at different levels of incidence in different countries. Ratios for the countries shown in parentheses were at each level of incidence similar to the ratios for the countries with which they are grouped.

figures (though this should not apply to the cancer registration scheme), but it may also be due to the process of selection, which to some extent accompanies the collection of any clinical series—for example, through the exclusion of out-patients, the relative exclusion of the very old, or the availability of male and female beds.

Experience of the full and accurate registration scheme which is now operating in Denmark suggests that the true ratio is probably somewhat—though not much—higher than that indicated by death certificates, and it is reasonable to believe that the true ratio in the United Kingdom is, at the present time, of the order of 6 or 7 to 1.

At the beginning of the century the sex ratio, judged by mortality data, was as low as 1.3 to 1. In Norway the ratio is to this day not much greater. Generally it would appear that in all countries the higher the incidence of the disease the greater the male preponderance (see Fig. 6). It is notable that the relation between the sex ratio and the total incidence is not the same in all countries, but that in some a given degree of male preponderance is reached at a lower general level of incidence. It seems probable, therefore, that the factor mainly responsible for the increase is one to which men are particularly exposed and that the extent of the relative difference in exposure of men and women varies from country to country.

(Part II will appear next week with list of references).

SOME APPARENT ANOMALIES OF POTASSIUM METABOLISM

BY

IAN W. MacPHEE, M.D., F.R.C.S.

Lecturer in Surgery, University of Liverpool

The importance of potassium in the body economy has for long been a matter of interest only to the physiologist. Within recent years, however, the recognition of serious potassium depletion in clinical conditions has aroused interest in potassium metabolism in health and disease. Our knowledge of this important cation has been derived from a wide variety of experimental and clinical observations, and the time seems ripe for a brief summary of the more important contributions.

Potassium Deficiency

In 1915 Benedict showed that potassium was lost along with nitrogen in fasting states, and, later, similar observations of potassium loss in diarrhoea (Butler *et al.*, 1933) and in diabetic coma (Atchley *et al.*, 1933) were made. The relationship of potassium to muscle contraction and muscle metabolism has always been of interest. In 1936 Brown and Feldberg showed that potassium liberated acetylcholine at ganglionic synapses. Fenn and Cobb (1936) found that, after indirect stimulation of the muscles of anaesthetized rats, potassium was lost from the muscle cell in exchange for sodium. These changes were reversed after rest, indicating that no irreversible damage had been done to the muscle. Cuthbertson *et al.* (1939) showed that, following operative fracture of the femur in rats, large amounts of potassium were lost in the urine, associated with an increased excretion of nitrogen and phosphorus. They observed that the potassium loss was relatively greater than the nitrogen loss, and seemed to be far greater than could be accounted for by the local changes at the site of injury.

The observations of Mullins *et al.* (1941) on the sodium permeability of the red cell indicated that the older concept of the impermeability of the cell to the cation sodium was not correct. Miller and Darrow (1941) showed that deoxycortone acetate reduced the muscle potassium content of rats and increased the muscle sodium content. This exchange of sodium for potassium in the cell was also demonstrated by Heppel (1939) and Miller and Darrow (1940a) in animals fed on a low-potassium/high-sodium diet. It was later observed in some clinical conditions such as alkalosis (Gamble *et al.*, 1945; Darrow, 1945), and in some types of infantile diarrhoea (Darrow, 1946).

By this time the loss of potassium in clinical conditions, often associated with signs of paralysis, had become recognized. Brown *et al.* (1944) observed a low serum potassium in chronic nephritis, associated with attacks of paralysis. Similar paralysis as a result of diminished extracellular potassium was described by Holler (1946) in treated diabetic coma. Govan and Darrow (1946) reported large losses of potassium in infantile diarrhoea, and observed that treatment with potassium improved the clinical state. In the development of hypokalaemia during the treatment of diabetic acidosis, Greenman *et al.* (1949) suggested that the dilution of extracellular potassium by intravenous infusions, the continued loss of potassium in the urine,

and the migration of potassium from the extracellular to the cellular phase might all contribute to the final clinical picture.

Potassium loss has also been observed after saline infusions (Stewart and Rourke, 1942; Gamble, 1942), after major surgical operations (Blixenkron-Møller, 1949; Wilkinson *et al.*, 1950), in *p*-aminosalicylic acid therapy, using the sodium salt (Cayley, 1950), in the use of ion-exchange resins (Dock and Frank, 1950), in idiopathic steatorrhoea (Lubran and McAllen, 1951), in pyloric stenosis (Hawkins *et al.*, 1951), and in chronic nephritis (Davidsen *et al.*, 1951). It seems probable that the potassium loss in such widely divergent conditions may be due to a few factors common to many clinical states. No matter the cause, the symptoms of hypokalaemia in all these conditions are similar, and are well summarized by Darrow and Pratt (1950): (1) weakness and hypotonia of skeletal muscle, leading finally to paralysis; (2) dyspnoea with gasping respirations; (3) cyanosis, chiefly respiratory in origin; (4) abdominal distension; (5) nausea and vomiting; (6) cardiac enlargement with systolic murmurs; (7) increased pulse pressure with Corrigan pulse; (8) elevated venous pressure with signs of cardiac failure; and (9) electrocardiographic changes.

Many of these signs of potassium deficiency are common to deficiencies of other electrolytes and of water, and are not, therefore, always convincing evidence of potassium lack. This matter is considered later, but it is important to appreciate that the electrocardiographic changes can be of considerable aid in diagnosis. These changes have been studied carefully by Frenkel *et al.* (1947), Nadler *et al.* (1948), and by Tarail (1948), and they have correlated the following changes with progressive deficiencies of potassium in the serum: (1) prolonged Q-T interval; (2) decreased height or inversion of the T wave; (3) rounded and prolonged T wave; (4) depression of the ST segment; and (5) inversion of the P wave, extrasystoles, and heart-block.

Hyperkalaemia

The toxic effects of increments in the extracellular potassium have also been widely studied. Hyperkalaemia is a danger only in renal failure and after the injection or absorption of potassium salts. Miller and Darrow (1940b) observed that the toxic effects of injected potassium salts in experimental conditions are directly related to the increase in concentration of that cation in the serum, and only indirectly to the muscle potassium content. This was confirmed in cats by Crismon *et al.* (1943). Folk *et al.* (1948) confirmed that the serum potassium content accurately reflects the potassium content of the extracellular fluids. The effects of increments in the extracellular potassium were studied by Winkler *et al.* (1938). They showed that, in dogs, the electrocardiographic changes due to the toxic effects of extracellular potassium could be directly correlated with the serum potassium concentrations. Briefly they noted: (1) increased amplitude and reduced duration of the T wave regularly appeared at concentrations of 5-7 mM of potassium per litre; (2) depression of the ST segment at 8-10 mM per litre; and (3) intraventricular block began at concentrations of 10 mM per litre, the P wave disappearing at 9-11 mM per litre, and cardiac arrest ensued at 14-16 mM per litre.

By depleting the muscle potassium, Miller and Darrow (1940a, 1941) were able to show that rats could be made resistant to the toxic effects of injected potassium salts. They concluded that this depletion of cell potassium enabled this cation, when injected in excess, to enter the cell, thereby protecting the extracellular fluid from a lethal rise in concentration.

Normally the kidney prevents toxic increases in the potassium concentration in the extracellular fluid. The excretion of potassium, as indicated by Smith (1951), is complicated. Potassium reabsorption occurs in the proximal tubule, but it has been necessary to postulate tubular excretion in the distal system, and this, though normally slight, is increased in all conditions of increased extracellular potassium. As Smith points out, this is the first instance in which experimental evidence has made it necessary to postulate the simultaneous reabsorption and excretion of any substance by the kidney tubules. Durlacher and Darrow (1942) showed that the life of nephrectomized animals could be prolonged by procedures which had previously depleted the body potassium stores. They concluded that the mechanism of this prolonged survival was therefore due to the delay in the post-operative rise in the serum potassium. These experiments were in agreement with the clinical data already available, indicating that some of the toxic effects in renal insufficiency were due to an increase in the serum potassium concentration (Winternitz *et al.*, 1940; Addis and Lew, 1939).

The purpose of this paper is to attempt some correlation of these various facts about potassium exchanges in clinical conditions and to analyse the means of diagnosis at our disposal.

Clinical States of Potassium Deficiency

Deficiency may be induced by prolonged reduction in intake or by abnormal loss. In many conditions, such as surgical operation, diarrhoea, and pyloric stenosis, both these factors are operative, and hasten the onset of the condition. As has been indicated above, the work of Benedict and later observers has shown that the protein catabolism associated with starvation also increases the loss of potassium from the body.

The loss of body fluids containing potassium may also hasten the onset of potassium deficiency. Gastric juice contains about 16 mEq of potassium per litre as well as hydrochloric acid. The starvation associated with pyloric stenosis, resulting in diminished intake, increased urinary output, and potassium loss by vomiting is a good example of the forces acting to precipitate potassium deficiency. If, in addition, saline infusion is liberally used in treatment it is hardly surprising that symptoms of potassium lack become manifest. Deficient intake, loss by the gastrointestinal tract either as stomach contents or diarrhoea fluid, and excessive loss during starvation can all be readily understood, and measures can be taken to estimate the potassium loss and to employ replacement therapy. It is with the urinary potassium loss that we are particularly concerned here.

Tarail and Elkinton (1949) have shown that, even in deficiency states, the kidney appears to have a limited minimal excretion of potassium. Unlike sodium, therefore, the kidney seems unable to conserve potassium when it is most required. This continued excretion in the urine in a patient already depleted of potassium is an important factor in producing severe deficiency. It has also been shown that a major surgical operation markedly increases the excretion of potassium in the urine (Blixenkron-Møller, 1949; Wilkinson *et al.*, 1950). These writers have also shown that the phase of increased potassium excretion can be detected earlier than the phase of protein catabolism, and that the potassium loss is greater in proportion than the nitrogen loss. These effects are very similar to the experimental observations of Cuthbertson *et al.* (1939) on trauma in rats.

I have shown that this urinary potassium loss occurs also in the first three days after relatively minor operations such as interval appendicectomy and inguinal herniorrhaphy (MacPhee, 1952). In this series of patients the blood loss was minimal, hydration was adequate, and intravenous saline infusion was not necessary, thereby preventing the potassium loss shown by Gamble (1942)

to result from such treatment. This potassium loss may amount to as much as the equivalent of 10 g. of potassium chloride in the first three post-operative days. As a result of these observations and the associated sodium, chloride, and water retention, the eosinopenia, the increased 17-keto-steroid excretion, and the elevation in blood sugar in these patients, I have suggested that the electrolyte changes are the result of increased adrenocortical activity. It is probable that, provided the adrenal cortex is functioning, these metabolic changes are the natural response of the body to trauma. Such observations are in accord with the well-known hypothesis of Selye (1950), and, as he suggests, may occur in a wide variety of disease conditions and "stresses."

It is too early yet to say whether the increased potassium loss in such conditions as diabetic coma and other acute medical conditions is due to this "stress response" or not. Gamble (1942) has suggested from the work of Darrow that, in conditions of extracellular dehydration (as in infantile diarrhoea), potassium along with water is withdrawn from the cell. Wilkinson *et al.* (1950) suggest some similar mechanism to account for the increased potassium excretion after major surgical procedures. As I have indicated, however, this does not seem to be the operative mechanism in minor surgical trauma, as no appreciable changes were detected in the plasma volume or extracellular fluid space volume, and slight increases were detected in body weight, indicating water retention in the body. Further evidence in favour of the stress mechanism in acute medical conditions has been obtained by Prunty (1949), who observed evidence of increased adrenocortical activity in acute porphyria.

Diagnosis

Although there is no complete agreement on the mechanism leading to urinary loss of potassium in these widely disconnected conditions, the fact that potassium deficiency may supervene is now well recognized. The diagnosis of incipient potassium deficiency, however, remains difficult. The reasons for this have not been made clear. Apart from the electrocardiographic evidence, the signs and symptoms detailed above are often similar to the disease initiating the potassium loss. In addition, sodium chloride and water lack may precipitate cyanosis, abdominal distension, and peripheral circulatory failure, and must be considered as factors in addition to the concomitant potassium deficiency.

Concentrations of potassium in the serum below 3.5 mEq per litre are generally thought to indicate a deficiency of the cation. It is not generally appreciated, however, that the serum potassium concentration may be essentially normal when there is considerable cellular potassium depletion. I have now seen on several occasions electrocardiographic evidence of potassium deficiency associated with a "negative" potassium balance in the presence of a normal extracellular potassium concentration. Danowski *et al.* (1949), in accurate balance experiments, have shown that positive cell balances of potassium were recorded in patients who had normal serum levels of the ion. In the clinical experiments previously noted I have shown that the post-operative serum potassium concentration did not fall below 4.5 mEq per litre in my series, although a large increase had occurred in the urinary excretion of potassium. Frequently, indeed, the serum potassium was observed to rise during this phase. I believe this indicates that potassium is derived from the cells in the post-operative phase as rapidly as, or even more rapidly than, it is excreted by the kidney. This would account for the apparently anomalous findings of potassium deficiency in the presence of a normal or near-normal serum concentration of the ion.

In view of these observations and the experimental records cited above, it may be said that, in the early stages at least, the symptoms of potassium depletion are due to a reduction in the intracellular potassium and not in the serum potassium. It is therefore unwise to wait for biochemical evidence of potassium depletion in the serum before

considering potassium deficiency. Provided renal function is adequate, potassium deficiency must be expected in all patients who have undergone major surgical procedures, especially if oral feeding is not possible by the fourth post-operative day; if deficient potassium intake has occurred before operation; if potassium loss is augmented by vomiting, diarrhoea, dehydration, or saline infusion; and if potassium is not supplied at least in maintenance doses. If oral feeding is not possible the potassium loss in the urine, intestinal aspiration, and diarrhoea fluid should be estimated, and the appropriate quantity of potassium supplied.

One further point in regard to potassium deficiency needs to be mentioned. Low concentrations of serum potassium have recently been recorded in association with paralytic ileus. Streeten and Ward-McQuaid (1952) have published observations on this subject, but were unable to prove conclusively that paralytic ileus is always due to serum potassium deficiency. The paralytic ileus which results immediately on the perforation of a peptic ulcer is not associated with a serum potassium deficiency and it seems improbable that this should be the case. (In the absence of other evidence, a reflex "neurogenic" basis must be postulated.) Such a condition, if untreated, is rapidly followed by peripheral circulatory insufficiency due to sodium chloride deficiency which itself increases the ileus (Streeten and Williams, 1952). In the early stages such an ileus will recover rapidly after saline infusion. If, however, the ileus is allowed to persist untreated, the intestinal aspirations and the frequently associated operation may precipitate a potassium deficiency which will increase the tendency to ileus.

The fact that the early stages of potassium deficiency are not necessarily associated with a low level of serum potassium indicates that some method of determining the cellular potassium concentration is required. Electrocardiographic evidence is helpful. In the study of potassium loss after operation associated with normal serum potassium concentration I attempted to measure the erythrocyte potassium concentration (MacPhee, 1952). By estimating the serum potassium and the potassium content of lysed blood, and by utilizing haematocrit readings, the red-cell content can be measured. Although able to detect increases in the erythrocyte sodium immediately after operation, no constant changes were observed in the erythrocyte potassium. Such studies, though pursued in only a small series, seem to indicate that the erythrocyte potassium cannot be satisfactorily used as an index of muscle potassium content.

Treatment of Potassium Deficiency

Potassium deficiency states exist usually with deficiencies of other ions, and the object of treatment is to correct the total ionic imbalance rather than to correct any particular deficit. Any discussion of potassium replacement therapy alone must therefore, of necessity, be brief, and in general terms only.

If an adequate diet containing meat and vegetables can be taken there is little need to supply potassium by other means. If possible it is best to supply any potassium deficit by mouth, thereby allowing absorption as required and preventing a too rapid rise in the extracellular potassium concentration. Serious potassium deficiency, however, usually arises in cases in which oral feeding and therapy are not possible.

Elkinton and Tarail (1950) have estimated that the usual potassium deficiency encountered in the adult may vary from 228 to 936 mEq, roughly about 8-36 g. of potassium. They suggest that, if replacement therapy is to be undertaken by the intravenous route, no more than 20 mEq of potassium per hour in a solution with a maximum strength of 80 mEq per litre should be administered. As an example, a solution containing 4.5 g. of the monohydrogen phosphate (K_2HPO_4) and 1 g. of the dihydrogen phosphate (KH_2PO_4) added to a litre of water supplies 60 mEq of potassium per

litre. In severe deficiency states 250 ml. of this solution may be supplied each hour, provided adequate means of checking the serum potassium concentration are available.

A chloride deficiency in association with the potassium deficiency is often present in pyloric stenosis. In such cases potassium chloride (KCl) provides a suitable means of rectifying the cation and some of the anion deficiency. Each gramme of potassium chloride contains 13.4 mEq of potassium.

If the potassium deficiency is associated with severe sodium depletion, as in prolonged vomiting of intestinal contents, Darrow's solution provides a suitable method of treatment. This "K-lactate" solution contains 4 g. of sodium chloride, 2.7 g. of potassium chloride, and 52 ml. of molar sodium lactate per litre. The solution can be given in a four-hour period, but, as the potassium concentration is about ten times that of the serum, it is safer to prolong the administration over a somewhat longer interval.

It will be readily appreciated that the parenteral therapy outlined above cannot be followed unless renal function is adequate and unless the concentration of potassium in the serum can be rapidly estimated as treatment progresses.

Increased Extracellular Potassium

Unlike the effects of potassium deficiency, the toxic effects of increased body potassium are usually related to the extracellular concentration of the ion. As already indicated, the toxic effects can be correlated directly with the serum potassium concentration. As a result, the curious anomaly of potassium intoxication may occur during the treatment of cellular potassium deficiency. I have seen a case of pyloric stenosis in the late post-operative period complicated by paralytic ileus, and with an initial serum potassium concentration of 3.5 mEq per litre, showing signs of potassium intoxication as a result of too rapid parenteral replacement therapy.

In clinical practice increased concentration of potassium in the serum is encountered mainly in states of renal insufficiency and in oligaemic shock.

Anuria and Severe Oliguria

The experimental work on this subject has already been considered. In spite of the experimental evidence obtained by Durlacher and Darrow (1942), they did not believe that fatal increases in concentration in the extracellular potassium were the cause of death in anuria. In association with Winkler *et al.* (1938) they thought that the symptoms of potassium intoxication were totally different from those of uraemia.

The cause of the increase in extracellular potassium is an interesting problem. An exogenous source can be excluded, because the rise in the serum potassium can be observed when such patients are starved. Elkinton *et al.* (1949) showed that the rise in extracellular concentration was derived mainly from intracellular potassium. It has been assumed that this increase in extracellular potassium in the anuria associated with mismatched transfusion results from haemolysis and the liberation of potassium from the red cells. There are many objections to such a theory. The rise in serum potassium is rarely noticeable in the first day

Chart showing effect of peritoneal dialysis on blood urea and serum potassium concentration in patient with severe oliguria.

or two after the transfusion. The Chart demonstrates this point in such a case, and shows that the rise is progressive in the later stages. The Chart also illustrates the effect of peritoneal dialysis in reducing the blood urea, but not in reducing the serum potassium concentration when a solution such as Ringer's is used as the dialysate. It is also interesting to note that the patient remained clinically well, though suffering from severe oliguria, until the eighth day, when symptoms of uraemia began to appear. At this time the blood urea concentration had been greatly reduced by dialysis, the carbon dioxide combining-power of the plasma had returned to 60 volumes%, and the plasma chlorides had risen to 82 mEq per litre. Though this is not direct evidence of potassium intoxication, the uraemic symptoms were certainly associated with the increase in the serum potassium. When recovery ensued after thirteen days' oliguria, the serum potassium rapidly returned to normal.

In view of the fact that the rise in extracellular potassium in such states is a progressive one, I believe that increased adrenocortical activity may be the cause of the potassium withdrawal from the cells. The "stress" origin of such a cell depletion would be in line with the mobilization of potassium from the cells after trauma, operation, and other tissue injuries. There is as yet, however, no real proof of this mechanism. The gradual rise in the serum potassium could be explained in other ways. For example, after crush injuries much potassium may be liberated from the damaged muscle. Potassium may also be derived from the cells during the protein catabolism of starvation. The mechanism therefore remains in doubt.

Treatment

Kolff (1950) has shown that *subnormal* serum potassium concentrations may actually be produced in uraemia in patients on a Borst diet (high carbohydrate, low protein). Fenn (1939) showed that potassium is deposited in the liver along with glycogen. Experimental evidence suggests therefore that after injections of carbohydrate a movement of potassium from the extracellular to the intracellular spaces takes place. This may be a part of the merit of a treatment such as that of Bull *et al.* (1949), in which a high carbohydrate intake is advocated.

If the extracellular potassium concentration has already reached toxic levels before adequate treatment is begun, some form of dialysis may be necessary. Intestinal dialysis as described by Black and Stanbury (1948) is a most suitable method of reducing the extracellular potassium concentration in such cases. Peritoneal dialysis is cumbersome, and may be dangerous.

Summary

Potassium deficiency may occur as a result of deprivation of the ion, by excessive loss though vomiting, by diarrhoea, or in the urine.

The loss is accentuated by saline infusion, operation, injury, and perhaps by other stress conditions.

The symptoms of potassium deficiency may occur when the serum potassium concentration is still within the normal range. The symptoms are therefore due to cellular potassium depletion.

The erythrocyte potassium concentration is not an index of the muscle-cell potassium content.

Symptoms of potassium intoxication are directly related to the extracellular potassium concentration, and not to the cell potassium content.

ADDENDUM.—In the recovering phase of renal cortical necrosis when diuresis ensues, it has always been our experience that excess potassium is rapidly cleared from the extracellular fluid. In a recent case, however, I have observed a potassium and non-protein nitrogen retention after the onset of diuresis. In this case the urine continued to approximate to a glomerular filtrate for several days. On

theoretical grounds it was believed that, in the presence of a satisfactory urinary output, the excess potassium and nitrogen would be cleared by giving cortisone. This was done, and a dramatic fall in the serum potassium and non-protein nitrogen was observed. If the urine volume had not been sufficient, however, it would have been dangerous to use cortisone.

"Egg white is the most alkaline natural fluid known, having a pH of about 9.5; this high alkalinity confers on it a definite bactericidal character, which is enhanced by the presence of certain proteins, such as lysozyme, a known antibiotic. The pH of yolk is about 7, and the whole egg therefore should act as an electric cell or battery because of the difference in acidity between the yolk and the white. The yolk, having an excess of positive hydrogen ions over the white, as it is more acid, ought to be at a positive potential relative to the white and should correspond to the positive pole of a cell. This difference in electric potentials within an egg can be demonstrated directly with the aid of a sensitive galvanometer. . . . The potential difference between yolk and white varies considerably from egg to egg and with the age of the egg; it is about 1/10 of a millivolt."—From a lecture given by D. P. Riley, D.Phil., at the Royal Institution on November 7, 1952.

Serial sections have been examined, but they do not show any lesion of the blood vessels of the part. The appearances suggest a primary lesion of the muscle fibres, resulting in disintegration of the fibre, unassociated with vascular damage" (Figs. 1 and 2).

FIG. 1.—Haematoxylin-eosin ($\times 200$). Biopsy of gastrocnemius muscle showing localized necrosis of fibres surrounded by oedema and lymphocytic infiltration. One fibre is seen shrunken and separated from the sarcolemmal sheath.

FIG. 2.—Mallory's phosphotungstic acid haematoxylin ($\times 330$). Same specimen as Fig. 1 showing strictly localized necrosis of muscle fibre with loss of striation and staining. The unaffected part of the fibre and the surrounding fibres show well-preserved striation.

The Literature

Up to the time of our observation, we could find only six case histories of this disease. Two further cases were ascribed to this syndrome (Millikan, 1939; Bywaters and Dible, 1943), but in one a clinical description was not available, and in the other the diagnosis was retrospective after death. Since 1946 five further cases have been described, three of them in the same family.

We owe the first description of the disease to Meyer-Betz (1910).

A 13-year-old boy was admitted to hospital in a state of collapse and apparently moribund. The disease started suddenly with abdominal pain, bleeding from the nose, and vomiting. He became very weak and a few hours after the onset voided some black urine. The family history revealed nothing. His past medical history showed that at the age of 10 his urine appeared to contain blood for two days, but he was not obviously ill.

From that time he had "haematuria" once or twice a year, lasting for two days and associated with severe muscular weakness. About nine months before admission he had a more severe attack: he could hardly move and his urine was black. Four months before admission he had an attack of abdominal pain associated with severe weakness lasting for about 14 days. His mother noticed at this time that his legs and feet were swollen.

On examination the child could barely move. The lower extremities were more affected and were almost paralysed. The feet were in talipes equinus and the calf muscles contracted and hard. Passive movement of knee and hip caused pain. The elbows could not be straightened and there was limitation of wrist movement. The patellar reflexes were absent. All the muscles involved felt hard and tender to pressure. There was mild anaemia, with moderate leucocytosis.

The urine voided at the time of admission was chocolate-coloured and turbid, and showed a heavy deposit. There was some detritus, believed to be red cells, but no actual red cells were seen. A few granular and hyaline casts were also present. The test for albumin was strongly positive and spectroscopically the pigment resembled both oxyhaemoglobin and methaemoglobin. The output of urine was severely reduced during the first day, but its colour rapidly became paler and by the end of the second day the pigment had disappeared. At this stage hyaline, granular, and red-cell casts were seen in abundance. Gradually the urinary output rose and the child recovered. The contractures disappeared in this order: hands, flexors of left arm, flexors of right arm; last to disappear were the contractures of the most severely affected calf muscles. Within three months of the onset the child appeared to be normal again.

Two minor attacks involving only the calf muscles and leading to discoloration of the urine were also observed.

Meyer-Betz noticed the striking similarity between this condition and "paralytic equine haemoglobinuria," and, although unable to confirm the nature of the pigment, he was aware that myoglobin was involved.

The cases since observed closely resemble the first. The pattern is the same and the variation is only in the severity of the episodes. The Table summarizes the main features.

The onset is sudden. With minor attacks there is bilateral but not necessarily symmetrical involvement of the muscles of the lower limbs. The attacks, which are frequently repeated over a period of months or years, often follow exertion after a period of rest in bed. The calf muscles are most often affected; they are painful and feel wooden as if in tonic contracture. The feet are in the position of a ballet dancer, and the attack is followed within a few hours by transient myoglobinuria. The duration and intensity of myoglobinuria is proportional to the severity of the attack and to the extent to which the musculature is involved. It may well be that minor attacks are more common than hitherto believed, and are missed because the staining of the urine is not noticed. The attacks are not associated with neurological changes, either sensory or motor. There is no oedema or involvement of the overlying skin. The course is generally afebrile, except in severe attacks in small children. Normal red- and white-cell counts appear to be the rule, and the urine shows no red cells or stromata to account for the blood-stained appearance.

Major attacks differ only in extent. The involvement of muscles spreads upwards until all the skeletal muscles are affected; this leads to the apparent paralysis which is included in the name of the syndrome. Myoglobinuria is more intense and prolonged.

Even the most severe cases on record ended favourably; renal failure seems to be unusual. The attacks have a tendency to recur, but in several of the cases they became less frequent and ultimately disappeared. The remote prognosis is more difficult to assess. Case 1 was well—apart from some residual contracture of the calf muscles—a year later, when last seen. Case 2 had three lesser attacks in the next two years. We have been able to follow up Case 3 in France 16 years later, as her father is a medical practitioner. She had one severe and two milder attacks within three years of the onset, and then recovered completely. The other cases could not be traced.

Details of Cases in the Literature

Author	Case No.	Age	Sex	Family History	Course and Remarks
Meyer-Betz (1910)	1	13	M	None	History of several minor attacks. In hospital with very severe attack involving whole body. Later two minor attacks while under observation. Complete recovery a year later.
Hittmair (1925)	2	41	F	"	Onset with sudden major attack, starting in legs, ascending to trunk and arms. Recovery in 14 days. Second major attack a year later, followed by a lesser attack, and finally minor attack during following year. Recovery.
Debré et al. (1934)	3	21	F	"	Major attack with generalized paresis. Febrile. Calves most affected. 10 months later identical attack. Milder attack a year later and a minor attack after a further 3 months. Complete recovery.
Huber et al. (1938)	4	4	M	"	Single attack of medium severity affecting lower limbs. Slight fever. Recovery.
Louw and Nielsen (1944)	5	4	M	8 members of 5 generations affected by sex-linked recessive muscular disease starting in childhood. ?Progressive muscular dystrophy	History of repeated minor attacks involving calves only. Seen with minor attack at age of 10. Recovery. Myoglobin confirmed.
Scherwin (1945)	6	38	M	None	Three attacks with atypical distribution and course. Oedema and red skin over muscles involved. ?Polymyositis. Outcome not known.
Elek and Anderson (present case) (1946)	7	41	F	"	Single minor attack. Myoglobin confirmed. Recovery.
Hed (1947)	8	20	M	3 males of 6 siblings affected; 2 males healthy. No other family history of muscular disease. Mother diabetic	Several minor and some major attacks from age of 15. Attacks related to exertion on fasting. One mild attack observed. Abnormal sugar tolerance curve. Myoglobin in urine confirmed.
"	9	19	M	Brother of Cases 8 and 10	History of minor attacks from age of 16. Related to exertion while fasting. Abnormal sugar tolerance curve. Carbohydrate-free diet for 24 hours was followed by severe attack. Myoglobin confirmed.
"	10	18	M	Brother of Cases 8 and 9	History of minor attacks consisting of pain in legs and dark urine. Related to exertion.
Wissler (1948)	11	6	M	3 brothers suffered from a form of muscular atrophy. 2 died	Single attack of medium severity observed. Slight fever. Myoglobin confirmed.
Kreutzer et al. (1948)	12	39	M	None	History of repeated fleeting attacks. 3 attacks of medium severity observed. Attacks could be brought on by stretching of muscles. Myoglobin confirmed. Recovery, but no follow-up available.

Differential Diagnosis

The relative ease with which myoglobin can now be identified spectroscopically sets myoglobinuria apart from any form of haemoglobinuria. Although all of them are uncommon, there are several conditions known in which this pigment or its decomposition products appear in the urine. In all these the primary lesion is in skeletal muscle. If there is a sufficiently severe lesion of muscle and enough

circulation for absorption to occur myoglobinuria will ensue. Myoglobin is readily excreted by the kidneys (Camus and Pagnez, 1902); its threshold is stated to be about 20 mg. per 100 ml. Above this value its excretion in dogs is proportional to the concentration in the blood (Yuile and Clark, 1941), which means that myoglobin is cleared about 25 times more rapidly than haemoglobin. The least amount to produce visible discoloration of the urine is about 40 mg. per 100 ml. This rapid excretion explains why in all but the most severe and widespread lesions of muscle the staining of the urine is very transient.

The conditions in which myoglobinuria is one of the cardinal signs may be summarized as follows (modified from Björk, 1949): (1) Paroxysmal paralytic myoglobinuria; Haff disease. (2) Dermatomyositis with myoglobinuria; myositis following carbon monoxide poisoning; myoporphyria. (3) Progressive muscular dystrophy. (4) Traumatic myoglobinuria: (a) "crush syndrome"; (b) electrical high-voltage accidents; (c) arterial occlusion with ischaemia.

Haff disease is undoubtedly the commonest cause of myoglobinuria in man. It occurs in East Prussia (Starfinger, 1924; Ewig, 1924; Meyer, 1924), Sweden (Berlin, 1944), and Karelia (Basharina and Kyrochkina, 1949). Its clinical features closely resemble the condition described by Meyer-Betz, and the histological findings, described by Kaiserling (1932), consist of focal lesions of individual muscle fibres. The pigment in the urine has been identified as myoglobin (Assmann et al., 1933; Jeddoloh, 1939).

Dermatomyositis may also be associated with myoglobinuria, as in the case described by Günther (1924) and possibly also in Paul's (1924) case. In both the disease was characterized by rigors and high fever, and the severity of the muscular lesions was greater in the upper than in the lower extremities. Both terminated fatally. It may be that Scherwin's (1945) case should also be ascribed to this group, since there was oedema of the skin over the affected muscles. Myoglobinuria was not confirmed in any of these three cases, and the clinical picture was unlike that of paroxysmal paralytic myoglobinuria.

Carbon monoxide poisoning causes a severe form of myositis, sometimes with myoglobin in the urine (Günther, 1921, 1940; Brass, 1944).

Myoporphyria is less well established as a disease entity; cases associated with muscle atrophy and loss of myoglobin have been described (Vanotti, 1935-6; De Langen, 1943; Belloni, 1947). Similarly the relationship of progressive muscular dystrophy to paralytic paroxysmal myoglobinuria is at present undefined. The resemblance of the distribution of the lesions was noticed early (Meyer-Betz, 1910; Kreutzer et al., 1948). Louw and Nielsen (1944) found evidence suggestive of progressive muscular dystrophy in the family of their case and a similar family history in another case (Wissler, 1948). Furthermore, some authors are of the opinion that the primary injury in progressive muscular dystrophy is in myoglobin metabolism (Meldolesi, 1937; Meldolesi et al., 1939).

The only group of known aetiology is that of traumatic myoglobinuria. Originally observed in the first world war (Frankenthal, 1916), it was studied by Minami (1923) and Husfeldt and Bjerring (1937) and later most extensively by Bywaters and his associates (Bywaters, and Delory, 1941; Bywaters and Beall, 1941; Bywaters, Delory et al., 1941; Bywaters and Popjak, 1942; Bywaters, 1944; Bywaters and Stead, 1944). Severe crush injuries or physical punishment (Langen, 1946) may cause necrosis of muscle, which, if severe enough, terminates fatally through renal failure. High-voltage currents similarly cause damage to skeletal muscle, often to a greater extent than the external injuries would suggest. Myoglobinuria and renal failure have been observed (Fischer and Rossier, 1947; Fischer and Fröhlicher, 1947). Ischaemic necrosis due to arterial thrombosis, embolism, or even spasm may simulate the conditions of traumatic myoglobinuria (Bywaters and Stead, 1945).

Aetiology

Little is known about agents causing acute necrosis of muscle. Myoglobinuria is, however, a common condition in animals (Minett, 1935). One form affecting horses is known as "paralytic myoglobinuria" (Fröhner, 1884; Camus and Pagniez, 1902, 1904; Camus, 1903), and the pigment has been identified (Carlström, 1931). The large muscles of the hind part are most severely affected and the onset is sudden. In "enzootic myoglobinuria" of horses (Wirth, 1921; Hobmaier, 1926; Stang and Wirth, 1928; Deubel, 1932; Bédaride, 1933) the muscles of mastication are affected. There is stiffness and swelling but no paralysis. Draught oxen and young calves suffer from "white muscle disease" (Vawter and Records, 1947), while lambs and young pigs suffer from a form of acute muscular necrosis, but the pigment has not been found in the urine (Hobmaier, 1926).

Foxes suffer from a disease known as Chastek paralysis, while in districts afflicted with Haff disease cats and even birds may suffer from it. The so-called "intermittent paralysis" of horses is said to be due to thromboses in the abdominal aorta (Carlström, 1931).

While the chain of events starting with acute muscular necrosis and leading to myoglobinaemia and myoglobinuria can easily be traced in all these conditions, and in recent years much has been learned about the renal lesions accompanying this sequence, practically nothing is known about the aetiology of acute focal muscular necrosis. In equine paralytic myoglobinuria excessive lactic acid formation was blamed, and this suggestion is reflected by Hed's statement that in his cases abnormal carbohydrate metabolism was responsible. Since the mother suffered from diabetes, the association may well have been accidental. Furthermore, there is no evidence of faulty carbohydrate metabolism in any of the other cases (Kreutzer *et al.*, 1948). Millikan's observation regarding excessive blood potassium levels is likely to be the result rather than the cause. Nor is there convincing evidence that human paroxysmal paralytic myoglobinuria is a hereditary condition. Its course and the long-term good prognosis make it unlikely, but this point cannot be settled until more information is available.

The condition resembles Haff disease in its clinical course, the low incidence of uraemia, and the histological changes found in the muscles, and may be a sporadic form of it. Haff disease is epidemic and so far all the outbreaks have stopped before it could be decided whether a virus or a toxic agent was responsible. Eating tainted fish is believed by many to be the cause. In this respect it may be noteworthy that Chastek paralysis of silver foxes, in which there is severe damage to muscles, is due to feeding on certain raw fish. The symptoms of this disease can be produced experimentally by a diet deficient in vitamin B₁, and recovery follows administration of this vitamin. A substance, probably a protein, has been recovered from fish that inactivates vitamin B₁ (Ågren, 1944). So far intravenous aneurin has not been tried either in Haff disease or in paroxysmal paralytic myoglobinuria, but on the basis of this theory it should bring about rapid recovery. Apart from our case, there is no information available about the lesions in the muscle as they appear in the acute phase, since no biopsy has been taken in any of the other cases. In one of Hed's cases a biopsy between attacks showed no abnormality except for a little diffuse increase of fibrous tissue between the muscle fibres. This suggests that, whatever the aetiological agent, the paroxysms of myoglobinuria represent the onset of necrosis in the muscles, possibly aggravated by exertion.

Summary

Paroxysmal paralytic myoglobinuria is briefly reviewed and a case illustrating the syndrome described.

The disease occurs in minor and major forms, which differ only in the extent of the lesions. Minor forms are characterized by painful tonic spasms affecting the lower

limbs, mainly the calf muscles, followed within a few hours by transient myoglobinuria. This pigment is suggested by the colour and by the absence of red cells or stromata. Major attacks consist of pseudoparalysis of the whole body, and are rarer. The disease has a tendency to recur, but the prognosis is good. The pathological changes in the affected muscles consist of focal necrosis. The aetiology is unknown.

We thank Sir Claude Frankau for permission to publish this case; Professor Theo. Crawford for his pathological investigations and for the use of the photomicrographs; and Dr. J. C. White and Mr. T. Pringle for the biochemical investigations.

SPLENECTOMY IN THREE CASES OF MYELOPHTHISIC ANAEMIA

BY

C. MERSKEY, M.D., M.R.C.P.

AND

O. E. BUDTZ-OLSEN, M.D.

(From the Departments of Medicine and Physiology, University of Capetown)

Myelophthisic anaemia, a comprehensive term denoting anaemia associated with reduced cell formation by the bone marrow and compensatory haemopoiesis in other organs, is generally accepted as the one absolute contraindication to splenectomy. The spleen is regarded as the main focus of the extramedullary haemopoiesis, and therefore essential for the maintenance of the patient's life.

This paper describes three patients with myelophthisic anaemia in whom splenectomy was performed. One of them benefited greatly from the operation, one temporarily, whilst the third, although not improved, did not appear to be materially harmed. It is suggested that the improvement caused by the splenectomy was due to the removal of an important haemolytic component of the anaemia.

Case 1

A white man aged 31 complained of having felt tired at the end of the day's work for a few weeks before coming to hospital in February, 1950. Food "felt too hard for his stomach," and on several occasions he vomited immediately after a meal. There was no blood in the vomit. His appetite diminished, but he noticed no loss of weight. During the five days before admission he felt increasingly weak and had three attacks of shivering and sweating. Since the age of 16 he had suffered from occasional epistaxes. About a year before admission these nose-bleedings occurred every morning for a period of a few months. In 1944 he contracted malaria while in the Navy, and he had what was possibly a second attack in 1946, and a recurrence three months before admission. In 1947 he was examined for life assurance and was told that his spleen was enlarged. Since then he had been aware of a lump in his abdomen, but had no pain in that region and noticed no alteration in the size of the lump. There was no relevant family history.

On examination the patient was seen to be well nourished, with a sallow slate-brown pigmentation of the skin. Small lymph nodes were found in the cervical, axillary, and epitrochlear regions. The spleen, firm but not tender, extended into the left iliac fossa and 2.5 cm. across the midline. The firm edge of the liver was felt 3 cm. below the costal margin. While in hospital he had an irregular fever occasionally reaching 102° F. (38.9° C.). No malaria parasites or leishmania protozoa were found in blood and bone-marrow smears. Wassermann and Berger blood reactions, blood cultures, and *Brucella* agglutination tests were all negative. Serum proteins and liver-function tests were normal, and there was no excess of bilirubin in the serum. Radiographs of the whole skeleton were normal.

On admission the blood findings were: P.C.V., 22%; haemoglobin, 7 g. per 100 ml.; leucocytes, 3,500 per c.mm. (neutrophils 62%, eosinophils 2%, lymphocytes 28%, monocytes 8%); platelets, 63,000 per c.mm.; reticulocytes, 2%. The blood smear showed marked anisocytosis and poikilocytosis. In the first smear no immature cells were found, but after a few days 2 normoblasts per 100 leucocytes were counted and a similar number were regularly seen afterwards.

Eight sternal and iliac crest punctures failed to produce bone marrow. A sternal trephine biopsy was therefore performed, and the histological examination of the material obtained showed some fibrous tissue and some cells resembling histiocytes, but no haemopoietic tissue.

Course and Treatment.—On February 22 the patient had a severe epistaxis which reduced the volume of packed red cells to 18%. He was given 3 pints (1.7 litres) of blood, and the next day the volume was 28%. One month later the volume had dropped to 22%. On March 30 he was given 4 pints (2.3 litres) of blood and left hospital. He was readmitted on May 18, when his packed cell volume had dropped to 15%. He was again given 4 pints (2.3 litres) of blood, which raised the volume to 35%. Subsequently he was treated outside hospital, where his condition steadily deteriorated. From information obtained it appears that he received 18 pints (10.2 litres) of blood during the next three months. On August 21 splenectomy was performed by Mr. M. Cole-Rous, acting in consultation with Dr. B. G. Shapiro. The spleen weighed 3,300 g., and histological examination showed the changes of Gaucher's disease, increased haemosiderin in the swollen histiocytes, and myeloid metaplasia. After the operation the patient's condition improved rapidly. He returned to work in October, 1950, and has since, without treatment of any kind, felt perfectly fit.

On October 20, 1952, more than two years after the splenectomy, a blood examination showed: P.C.V. 49%; haemoglobin, 16.2 g. per 100 ml.; leucocytes, 9,100 per c.mm. (myelocytes 4%, neutrophils 56%, eosinophils 2%, basophils 1%, lymphocytes 29%, monocytes 8%); platelets, 430,000 per c.mm.; reticulocytes, 6%. In the blood smear one erythroblast and three normoblasts per 100 leucocytes were counted.

Comment.—This patient presented with Gaucher's disease of unknown duration, a grossly enlarged spleen, a slightly enlarged liver, and a haematological picture of myelophthisic anaemia. In spite of numerous blood transfusions his condition deteriorated rapidly, but after splenectomy a dramatic improvement took place. More than two years after the operation he lives a normal life and his blood picture is virtually normal, although the leuco-erythroblastosis might be interpreted as evidence of persistent extramedullary haemopoiesis.

Case 2

A white man aged 66 was admitted on February 25, 1952, with a typical history of gout of eight years' duration: repeated attacks of excruciating pain and swelling of the metatarso-phalangeal joint of his left big toe, with occasional involvement of his left ankle and at one stage his left elbow. Undue strain, exercise, or alcohol might bring on the attacks, which responded promptly to the administration of colchicine. Within three weeks of the onset of the gout he began to feel tired and out of sorts and easily became short of breath. His doctor found "a large spleen and anaemia," and his blood count at the time was: red cells, 4,300,000 per c.mm.; haemoglobin, 12.2 g. per 100 ml.; white cells, 6,920 per c.mm. (neutrophils 65%, eosinophils 4%, basophils 1%, lymphocytes 27%, monocytes 3%). The peripheral blood smear showed anisocytosis, poikilocytosis, and an occasional normoblast. The platelets appeared to be normal. He was given iron by mouth, liver injections, and x-ray therapy to the splenic area, and, although the treatment did not materially alter his blood picture, he felt well during the following years, apart from his attacks of gout. Two months before admission he became increasingly short of breath. After an attack of whooping-cough the dyspnoea was even more noticeable, and this was his only symptom. There was no history of gout or other relevant diseases in his family.

On examination the patient was obviously pale. His joints appeared normal except for an enlarged olecranon bursa at the right elbow. No enlarged lymph nodes were felt. His blood pressure was 125/55 mm. Hg. The spleen was firm, smooth, not tender, and was enlarged to 13 cm. below the

costal margin. The liver was felt 5 cm. below the rib margin and appeared to be of normal consistence. Special investigations showed: Urine, normal; blood urea, 68, 47, and 28 mg. per 100 ml. on different occasions; serum uric acid, 7.8 mg. per 100 ml.; serum creatinine, 2.76 mg. per 100 ml.; serum albumin, 4.7 g. per 100 ml.; serum globulin, 3.1 g. per 100 ml.; serum van den Bergh, direct and indirect negative; thymol turbidity, 1; thymol flocculation, 1; colloidal gold, 0. Radiographs of the pelvis, femora, and skull were normal.

Blood examination showed: P.C.V., 25%; haemoglobin, 8.5 g. per 100 ml.; leucocytes, 2,500 per c.mm. (neutrophils 55%, lymphocytes 45%); platelets very scanty; reticulocytes, 2%. The peripheral blood smear showed anisocytosis, poikilocytosis, and occasional myelocytes and normoblasts.

Five attempts to obtain bone marrow by needle biopsy failed. Trephining of the sternum was done, and, surprisingly, the marrow was found to be extremely cellular and

FIG. 1.—Red-cell survival curves of Case 2.

FIG. 2.—The packed cell volumes of Case 2 before and after splenectomy.

of normal composition. The differential count of the marrow gave this result: Myeloblasts, 0.66%; promyelocytes, 1.33%; myelocytes, 4.66%; metamyelocytes, 7.33%; eosinophil myelocytes, 0.66%; neutrophils, 33.33%; eosinophils, 1%; lymphocytes, 8.33%; monocytes, 1%; early erythroblasts, 2%; late erythroblasts, 13.66%; normoblasts, 26%. The report on the histology of bone-marrow sections read: "Histologically there is definite evidence of myelofibrosis. The trabeculae are thickened with prominent cement lines, and, whilst osteoblastic activity is on the whole slight, woven bone is being formed in some areas. Myelofibrosis, on the other hand, is absent, there being occasional foci only of plump fibroblasts. The bone marrow is very cellular, with numerous blasts and more mature cells of both red and white cell series. Megakaryocytes appear to be in excess."

Red-cell survival was estimated by the Ashby technique (Dacie and Mollison, 1943), and was found to be shortened (Fig. 1).

Course and Treatment.—Ferrous sulphate, 18 gr. (1.2 g.) daily, was given for two months without improvement of the patient's anaemia. He was given a transfusion of 4 pints (2.3 litres) of blood, which resulted only in a brief improvement (Fig. 2). After the transfusion his gout became worse and the dosage of colchicine had to be increased to control his acute symptoms. After further transfusion splenectomy was performed on May 2, 1952, by Mr. E. Malherbe. A small spleniculus, a lymph node at the hilum of the spleen, and a small piece of liver were also removed. The spleen weighed 1,600 g., and histological examination revealed pronounced myeloid metaplasia with gross excess of megakaryocytes. Evidence of blood destruction was shown by changes in the cells lining the splenic sinuses and the presence of altered pigment. A differential count on smears made from splenic pulp gave this result: Myelocytes, 6.33%; metamyelocytes, 6%; neutrophils, 12.66%; lymphocytes, 70%; monocytes, 1%; normoblasts, 4%. Numerous megakaryocytes were seen. The lymph node showed evidence of blood destruction by the presence of altered blood pigment and active macrophages, but haemopoiesis was trifling. The sinusoids of the liver contained a large number of megakaryocytes, but there was no indication of haemopoiesis.

The patient's gout flared up after the operation, but was controlled by three days' treatment with A.C.T.H. followed by colchicine. The survival rate of transfused red cells was now normal (Fig. 1); the improvement is also reflected in the almost steady packed cell volume without further transfusions (Fig. 2). The patient has felt well, and has been practically free of the symptoms of gout. A blood examination on October 21, nearly six months after splenectomy, showed: P.C.V., 27%; haemoglobin, 9.5 g. per 100 ml.; leucocytes, 38,000 per c.mm. (myelocytes 2%, metamyelocytes 7%, neutrophils 74%, basophils 1%, lymphocytes 16%); platelets, very numerous; 9 normoblasts per 100 leucocytes were counted.

Comment.—This patient showed the classical picture of gout combined with the syndrome of myelophthisic anaemia. The hyperplastic bone marrow in this combination is apparently rather characteristic (Reifenstein, 1945; Merskey, 1949), but in this case there was definite myelofibrosis. There was a very close association between the onset of gout and the beginning of the symptoms due to anaemia; furthermore, once the spleen was removed and the blood count stabilized the gout virtually ceased. It is likely that the gout was related to the intensity of the haemolytic process. The haemolytic element in the increasingly severe anaemia was clearly demonstrated by the short survival of transfused red cells, and the part played by the spleen in this phenomenon may be inferred by the return to normal of the red-cell survival time after splenectomy. This improvement was reflected in the clinical condition, and the patient lived a normal life. The remission was not complete and on October 23 he was readmitted for another blood transfusion of 6 pints (3.5 litres) of blood. Sixty-seven days after this transfusion he was again transfused with a similar volume of blood, but only 51 days elapsed before blood was again required. During the last transfusion period he was on continuous cortisone therapy (75 mg. a day after an initial loading dose).

Case 3

A white woman aged 58 was referred to hospital because of unexplained anaemia and splenomegaly. She had been given the usual haematinics without improvement and had been maintained only on blood transfusions. She had suffered from mild hypertension for years, and for the past four years had complained of general weakness. One year previously an obscure episode occurred during which she may have vomited a little blood. She thinks that her doctor did a venesection and removed a "a pint or two of blood." After that she was unable to walk for six months, and

then she slowly recovered a little. She could not recall losing blood in other ways. Her appetite had been poor for months.

On examination she was seen to be anaemic. Her heart was slightly enlarged and her blood pressure was 170/90 mm. Hg. There was no adenopathy. The spleen was firm and smooth, but not tender, and was enlarged to the level of the umbilicus. The liver was felt 5 cm. below the costal margin. Gall-stones were demonstrated by a cholecystogram, but the gall-bladder excreted the dye fairly well. Barium enema and two barium-meal examinations gave normal results.

Blood examination showed: P.C.V., 15%; haemoglobin, 6.4 g. per 100 ml.; leucocytes, 3,300 per c.mm. (myelocytes 1%, metamyelocytes 4%, neutrophils 33%, eosinophils 1%, basophils 1%, lymphocytes 58%, monocytes 2%); platelets, numerous; reticulocytes, 4%. The blood smear showed marked anisocytosis, poikilocytosis, and polychromasia. Two erythroblasts and seven normoblasts per 100 leucocytes were counted.

Marrow puncture was attempted in two areas of the sternum and in two sites on the left iliac crest. The fluid

FIG. 3.—Haemoglobin levels and transfusion requirements before and after splenectomy in Case 3.

obtained appeared to be identical with the peripheral blood. Trephining of the sternum was done; smears made at the operation also appeared to be similar to the peripheral blood. Sections of the marrow showed the changes of myelofibrosis. The medullary cavity was traversed by thick bony lamellae and the scanty residual spaces contained some fibrous tissue, oedematous adipose tissue, a few osteoclasts, and an occasional lymphocyte and plasma cell. Myeloid cells were practically absent.

Course and Treatment.—The patient was kept under observation for some 40 weeks. Repeated blood transfusions were essential to keep her alive (Fig. 3). Splenectomy was therefore performed by Mr. J. Heselson. The spleen weighed 1,400 g., and the striking histological feature was active haemopoiesis, both myeloid and erythrocytic. Megakaryocytes were numerous. Erythrophagocytosis was slight, but there was an excess of haemosiderin pigment. The walls of the sinusoids were thickened, and within the sinusoids themselves haemopoiesis appeared to be proceeding. For a short time after the operation the patient felt a little better, but her blood-transfusion requirements remained unaltered (Fig. 3). Cortisone was tried in full dosage for six weeks without effect. The patient was still alive more than a year after the splenectomy, but her blood status had not improved.

Comment.—This was clearly a case of myelophthisic anaemia with myelofibrosis of unknown origin in which the patient could be kept alive only by repeated blood transfusions. Splenectomy did not improve the condition, but it did no harm.

Discussion

These three cases conform to the diagnosis of myelophthisic anaemia. The complete syndrome consists of a reduction of all the formed elements of the blood with some,

usually few, immature red and white cells in the peripheral blood—the so-called leuco-erythroblastosis. Bone marrow is difficult or impossible to obtain by needle biopsy, and when trephining is done the marrow is often found to be fibrosed or sclerosed and the cellular composition is characteristically similar to that of the peripheral blood. Areas of hyperplastic marrow may be found. The spleen is grossly enlarged and there is slight hepatomegaly. Splenic puncture may assist in the diagnosis by demonstrating the myeloid metaplasia (Moeschlin, 1951). Radiography of the skeleton may show increased density of the bones.

The commonest cause of the syndrome is encroachment on the bone marrow by foreign cells as in carcinomatosis or the lipoidoses, as in Case 1. Poisoning of the bone marrow by chemicals such as benzene or carbon tetrachloride may give rise to the condition; and, finally, a group of cases is found in which the aetiology is obscure, and this group has therefore been given a confusing array of descriptive names: myelofibrosis, agnogenic myeloid metaplasia, aleukaemic megakaryocytic myelosis, etc. Case 3 apparently belongs to this ill-defined group.

If the conception of hypofunction of the bone marrow with compensatory extramedullary haemopoiesis is correct it would seem logical to believe that the removal of the main focus of this haemopoiesis, the spleen, would be deleterious to the patient. Splenectomy in myelophthisic anaemia has therefore persistently been condemned (Downey and Nordland, 1939; Carpenter and Flory, 1941; Bodley Scott, 1949; Wintrobe, 1951; Learmonth, 1951; Moeschlin, 1951; Chatterjea, Arrau, and Dameshek, 1952; Whitby, 1952). When the operation has been carried out the results have been poor, if not disastrous. Hickling (1937) reviewed 27 reported cases: in 15 the patient died a few days after the splenectomy, while those that survived the operation did not improve and most were dead within a year.

As an exception to this general rule a few cases of myelofibrosis and myelofibrosis have been described in which splenectomy was beneficial (Engell, 1947; Edwards, 1951; Franks, 1952; Andersen and Sørensen, 1952), and of the three cases reported above one showed great improvement, one temporary improvement, and one did not deteriorate.

From the evidence presented, especially the rapid elimination of transfused cells in Case 2, it would seem that in some instances of myelophthisic anaemia an important element of haemolysis plays a part in the pathogenesis, and that this red-cell destruction may outweigh the haemopoiesis in the spleen. Whether this haemolysis is a manifestation of "hypersplenism" is an academic point beyond the present discussion. The important fact is the demonstration that in some cases of myelophthisic anaemia the overwhelming haemolysis may be arrested by the removal of the spleen and the patient's condition thereby improved.

The problem must now be to decide which cases to choose for splenectomy. Morrison *et al.* (1951) would limit the operation to cases in which splenic myeloid metaplasia is absent, but this criterion seems too rigid. If the patient is losing ground in spite of repeated blood transfusions, and especially if it can be demonstrated that the red-cell elimination is exceedingly rapid, the question of splenectomy should seriously be considered.

Summary

Three cases of myelophthisic anaemia are described—one due to Gaucher's disease, one associated with gout, and a third of unknown aetiology. The first was greatly improved after splenectomy, the second was temporarily improved, and the third, while little better, did not deteriorate.

Splenectomy is generally contraindicated in myelophthisic anaemia, but it is suggested that with evidence of rapid cell destruction, possibly demonstrated by a short survival rate of transfused cells, it is worth while considering splenectomy as a last resource.

We have to acknowledge the assistance given to us by Professor F. Forman, in whose department this work was carried out. The red-cell-survival studies were done in conjunction with the C.S.I.R. research unit (Professor J. F. Brock). The cases were in the charge of the following clinicians, and we are indebted for their constant co-operation: Drs. M. Cole-Rous, J. Heselson, W. P. U. Jackson, A. Landau, E. Malherbe, M. Nellen. The histological examinations were kindly carried out by Professor J. G. Thomson, Dr. G. Selzer, and Dr. R. G. F. Parker. We were both in receipt of grants for research expenses from the Staff Research Fund, University of Capetown. The work was done with support from the Lady Tata Memorial Trust.

VALUE OF PRIMIDONE IN EPILEPSY

BY

C. W. M. WHITTY, D.M., M.R.C.P.

(From the Department of Neurology, Radcliffe Infirmary, Oxford)

Since the introduction of primidone ("mysoline"; 5-phenyl-5-ethylhexahydropyrimidine-4:6-dione) as an anticonvulsant drug some two years ago, two papers have appeared on its use in the treatment of epilepsy. A report of its initial trial at the David Lewis Epileptic Colony was given by Handley and Stewart (1952). Of the 40 patients treated all of whom had had prolonged treatment with other drugs, 12 had complete abolition of all types of attack over the six-months period of trial, and a further 11 showed a reduction of two-thirds or more. Butter (1953) recorded his results also from a special hospital for epileptics, where 58 patients had been treated. Again all had had extensive previous treatment. During 15 months only 3% had their fits abolished, but 50% derived some benefit. The results in both these reports must be regarded as very promising in view of the type of case treated. The present paper records our experience in the treatment of both symptomatic and idiopathic epileptics from the routine out-patient practice of a neurological clinic.

Case Material

Seventy patients of whom detailed records were available are considered here, though a further 12 have been treated; 43 were male and 27 female, and their ages ranged from 4½ to 60 years. Twelve had post-traumatic epilepsy—four from closed head injuries and eight from brain wounds; 10 had symptomatic epilepsy from proved brain lesions such as neoplasm or vascular accident; the remaining 48 cases were regarded as idiopathic. In Table I the cases are grouped according to the predominant type of fit or fits that they had. However, all those listed as having focal fits did have

TABLE I.—Results of Primidone Treatment in Different Types of Epilepsy

Group	Much Improved	Im-proved	No Change	Worse	Total	Treatment Abandoned
1. Grand mal only	11	14	2	2	29	2
2. Grand mal and petit mal	1	5	2	0	8	0
3. Psychomotor attacks	0	2	2	0	4	0
4. Grand mal and psychomotor	4	2	2	1	9	1
5. Petit mal only	2	2	3	1	8	2
6. Focal attacks	2	4	1	0	7	0
Total	20	29	12	4	65	5

an occasional grand mal with the focal attack as an aura. The 31 patients in group 1 had mainly grand mal—10 with a definite aura; 8 (group 2) had both petit and grand mal; 4 (group 3) had psychomotor epilepsy; 10 (group 4) had psychomotor and grand-mal attacks; 10 (group 5) had petit mal only; 7 (group 6) had focal attacks—2 motor, 3 sensory, and 2 visceral.

Dosage.—This varied from 1.5 to 0.375 g. a day. At first a routine of three or four 0.25-g. tablets a day was used, but later an initial dosage of half a tablet thrice daily was adopted, as this produced less drowsiness. It was noted in some early cases that the substitution of primidone for phenobarbitone and sodium hydantoinate produced a modification of the attacks, but not always an actual reduction. As a result hydantoins were tried in conjunction with primidone, and the combination appeared to be more effective. In general, therefore, our initial dosage scheme has become primidone, 0.125 g. (2 gr.) and hydantoin, 0.05 g. (½ gr.) each thrice daily, and this is adjusted in the light of clinical response. A combination of primidone and barbiturates, though occasionally used, has often proved unduly soporific. Primidone alone, however, has been used in 15 cases, with definite improvement in seven.

In five cases toxic symptoms caused the drug to be abandoned in from 10 days to two months of the start of treatment. Of the remaining 65, 12 were treated for less than six months, 23 for six to 12 months, 16 for 12 to 18 months, and 14 for 18 to 24 months. All had had previous treatment, usually for some years, with barbiturates, hydantoins, and sometimes troxidone; and it was because fits continued despite this that primidone was tried.

Results

The results of treatment in each of the six types of attack are shown in Table 1. Those whose attacks were abolished or so reduced as to be negligible so far as their ordinary activities were concerned were regarded as *much improved*; when attacks were reduced by 50% or more they were regarded as *improved*. Reduction was assessed by comparison with the frequency during the year previous to starting primidone. Only those whose actual attacks were increased were labelled "worse," other toxic effects of the drug being considered separately. It will be seen that the best results were obtained in the grand mal and grand mal and psychomotor groups. There are, however, aspects of the drug's action which do not emerge from these figures alone. In groups 1 and 4 there was sometimes a striking improvement in general social behaviour—irritability and perverseness being noticeably reduced. Relatives often remarked on this, and it is important in assessing the drug's value as a remedy in epilepsy rather than solely as an anticonvulsant. In three of the four cases of group 5 who showed improvement, this was unexpectedly delayed. In one, for instance, there had been no improvement after three months and treatment was to be abandoned at the next visit two months later. However, by then attacks were beginning to lessen, and nine months after the onset of treatment they had been completely abolished.

TABLE II.—Results of Primidone Treatment in Traumatic, Symptomatic, and Idiopathic Epilepsies

Type of Epilepsy	Much Improved	Im-proved	No Change	Worse	Total	Treatment Abandoned
Traumatic	4	7	0	0	11	1
Symptomatic	0	5	4	1	10	0
Idiopathic	16	17	8	3	44	4

In Table II the results are compared in the idiopathic, traumatic, and symptomatic cases. There is no significant difference between the traumatic and idiopathic. Of the symptomatic ones, five (two improved, two no change, one worse) had a presumed progressive organic cause so that their poorer response was to be expected. These also weight the overall results in Table I.

In Table I cases are grouped on a clinical basis. However, since the electroencephalogram (E.E.G.) pattern appears to correlate more highly than the clinical description of the attack with response to the oxazolinediones, results are given in relation to E.E.G. records in Table III for the

TABLE III.—Clinical Results of Primidone Treatment in Relation to Varying Electroencephalogram Patterns

E.E.G. Pattern	Much Improved	Improved	No Change	Worse	Total
3 cps. wave and spike	3	2	1	1	7
2-4 cps. bilateral paroxysm	2	1	1	0	4
Generalized dysrhythmia	2	2	1	0	5
Localized or focal spikes	9	14	6	3	32
Atypical wave and spike	4	9	3	0	16
Bilateral theta paroxysm	0	1	0	0	1
Normal record	0	1	0	0	1
Total	20	29	12	4	65

65 patients who continued treatment. There does not seem to be any great difference in the clinical response of the varying E.E.G. patterns.

Those cases with localized or focal spike discharges and atypical wave and spike rhythms most often had these abnormalities in leads from the temporal regions. Clinically, also, they showed a high incidence of psychomotor attacks and the milder conduct disorders sometimes associated with epilepsy. In general, therefore, they represent what have recently tended to be described as "the temporal lobe epilepsies." The record of some improvement in 23 out of the 32 cases is therefore of special interest.

When alterations in seizures are considered in detail in a given case an interesting point emerges. In grand mal attacks with an aura, the grand-mal element may be controlled while the aura continues or even becomes aggravated. In one patient a series of brief sensory attacks in one arm usually lead up to a grand-mal convulsion. For the first few weeks of treatment the sensory attacks became prolonged, so that for some 12 hours a continuous sensation occurred, similar to the previous attacks, but no grand mal developed and the sensation slowly cleared. Addition of hydantoin curtailed this aura, and some months later there were no grand-mal attacks and only occasional brief sensory attacks. A similar effect was noted in three other patients. In one the prolongation of an abnormal sensation was so unpleasant that she refused to continue the drug.

Toxic Effects

In general primidone seems singularly free from toxic effects, and when they occur they are usually mild and transient.

Routine blood counts and urine tests were done in the first 15 patients, but as they showed no abnormality they were abandoned for subsequent cases. Thirty-six patients complained spontaneously of drowsiness at the start of treatment. A further 22 mentioned this in reply to questions. It usually cleared in a week or two, but 12 patients

were still troubled by it months later. A few also described mild confusion and inability to concentrate. In three this was so marked as to constitute a mild confusional psychosis, and in all three of them paranoid trends appeared. In two the drug was abandoned because of this and in the third it was restarted in a smaller dose, with benefit. Two patients had an urticarial rash soon after starting the drug; blood counts were normal and the rash did not reappear when the drug was begun again after an interval. Transient nausea, giddiness, and ataxia occurred in four cases, and, in one, treatment had to be given up. In two vomiting was troublesome: one refused to continue the drug because of this, the other continued with a smaller dose after an interval, with no return of sickness.

Two patients who omitted the drug abruptly and without medical advice developed marked increase in their grand-mal attacks—in one amounting to a mild status epilepticus. It seems best to curtail primidone gradually if possible. In this respect it may be similar to the barbiturates and hydantoins, and unlike troxidone, which does not carry this risk of provoking status epilepticus if stopped suddenly.

Apart from the five cases in which treatment was given up early for the reasons mentioned above, in four it was omitted after three to six months because the fits seemed to be worse; and in a further ten, after a trial of six to nine months, as there was no improvement.

Conclusions

Primidone seems to be of some value in all types of epilepsy. However, the impression is gained that it is less useful in petit mal than in grand mal, while the proportion of psychomotor cases which are improved is especially gratifying, since this type is usually resistant to other anticonvulsants. It may be that it will find a special application here; though more prolonged experience is required, because temporary improvement from any change of drug has so often been misleading in the past.

Apart from its anticonvulsant action, it seems to benefit the milder behaviour disorders, those angularities of conduct from which some epileptics seem to suffer. The relatively high incidence of these in the "temporal lobe epilepsies" suggests that neuronal circuits in this region may be especially implicated and that the drug may act specifically on these. Its evident though mild soporific effect, since this is shared with other anticonvulsants, cannot wholly account for the benefit.

The results reported here are the more striking because this series is a highly selected one, most cases having failed to respond adequately to all the usual anticonvulsants. However, the absence of any serious toxic effects suggests that primidone should be given adequate trial as the drug of first choice in the routine treatment of epileptics.

Summary

Results of primidone treatment in 70 cases of epilepsy whose response to other anticonvulsants had been unsatisfactory are given—48 were idiopathic, 12 traumatic, and 10 symptomatic. Thirty-one had grand mal, eight mixed grand and petit mal, 10 petit mal only, 14 psychomotor attacks with or without grand mal, and seven focal attacks. Forty-nine cases showed improvement, and this occurred in all types of attack. In view of the usually poor response of psychomotor attacks to anticonvulsants, some improvement in eight out of 13 patients who continued treatment is of special interest. Toxic effects are usually mild and transient. In five cases they caused early cessation of treatment, in two probably unnecessarily.

Thanks are due to Imperial Chemical Industries Ltd. for early supplies of the drug for clinical trial; and to Miss F. M. Taylo and Miss F. Boselli for taking the E.E.G. records.

PARAPLEGIA DUE TO PAGET'S DISEASE (OSTEITIS DEFORMANS)

BY

R. G. ROBINSON, G.M., M.B., F.R.C.S.

(From the Department of Neurosurgery, Dunedin Hospital,
Dunedin, New Zealand)

Osteitis deformans, or Paget's disease, may affect any part of the skeleton in those of older years. While involvement of the spinal column is frequent, it is unusual for compression of the spinal cord to be produced. It is probable that this complication is commoner than the literature would indicate, as it occurs in an age group in which accurate assessments of the nervous system are rarely made. Two cases are described and their relationship to the usual pattern of the disease discussed.

Case 1

A woman aged 64 was admitted to Dunedin Hospital on January 21, 1952. Three and a half years ago she had begun to notice a nagging pain in the small of her back. This was followed by increasing pain in the hips and knees. About a year ago she had had burning pains in both legs, and her feet had felt numb and lifeless. Walking had become difficult, and eventually she had had to use two sticks. For a year her balance had been bad and she had had numerous falls, in spite of the sticks. She had not noticed that her legs were really weak until six months ago, when she found that she could not lift them up to get into a motor-car. Her left leg had had spasms, when it would cross over the right. She had had increasing trouble with her micturition for six months. Sometimes her water ran away without control and at other times she had great difficulty in passing it. At the time of admission she was getting about the house with difficulty. She had consulted Sir Robert Jones for bow legs at the age of 13.

On examination she was seen to be a short woman with marked bow legs. Her heart was moderately enlarged; her blood pressure was 130/65 mm. Hg. The jugular veins were not engorged. There were crepitations and rhonchi throughout both lung fields. Her ankles were not swollen, the liver was not palpable, and there were no clinical manifestations of any neoplasm. She had a moderate lower thoracic kyphosis with a slight scoliosis to the left. Apart from slight deafness the cranial nerves were normal. Both legs were very spastic, with adductor and flexor spasms that were severest in the right leg. All movements were present in the lower limbs, but the power was very poor. There was a pronounced level of hypalgesia to all forms of sensation at L1. This faded off and there was hypalgesia at T8 on the right and at T11 on the left. Vibration was absent over the spinous processes up to T10. The lower abdominal responses were absent but the upper ones were present. The tendon reflexes in the legs were exaggerated, but no clonus was obtained. Both plantar responses were extensor.

The blood picture was normal. Serum alkaline phosphatase was 12.8 units. Lumbar puncture showed a pressure of 120 mm. H₂O with a slight rise to jugular compression. The fluid contained 10 polymorphs per c.mm. and 80 mg. of protein per 100 ml. X-ray examination showed: fine osteolytic stippling of the skull; minor congestive changes in the chest; increased size of heart as in pulmonary heart disease; a mixture of sclerosis and osteoporosis of T9 and T10 with slight collapse, and similar changes at L3 (? osteitis deformans, ? secondary carcinoma); normal lower limbs. A myelogram from below showed a complete block at T11.

Operation. This was performed on January 24 (anaesthetist, Dr. J. Ritchie). To supplement the general anaesthesia, hexamethonium bromide was used as a hypotensive

agent. A low thoracic incision was centred over T10 and T11. In separating the muscles there were numerous small blood vessels passing from the muscles to the bone that had to be controlled. The laminae and spines of T9 and T10 were massive. The laminae of T9 and T10 were completely removed and part of those of T8 and T11. The thick bone was soft and very vascular. When the bone had been removed it was obvious that there was a small kyphus with its apex at T10. The spinal theca was opened and appeared commodious. There was no evidence of any tumour, and it was possible to pass a fine rubber catheter for 8 in. (20 cm.) upwards and downwards without any difficulty. The dura mater was sutured and the wound closed in layers. It was not necessary to give a blood transfusion. The pathological report (Dr. R. Rodda) on the removed bone showed the typical changes of osteitis deformans.

After the operation there was slow improvement. When discharged home on April 2 the patient was able to walk but still used two sticks; bladder function was normal; tone of both legs was normal and the power slightly reduced; pain and temperature were felt everywhere; cotton-wool sensation was diminished in both feet; vibration was absent up to the anterior superior spines; position sense was very deficient in the ankles and toes; knee- and ankle-jerks were increased; the abdominal responses were all present; the plantar responses were extensor and there was knee and ankle clonus in the left leg.

When re-examined on June 5 she was walking well and used only one stick. Movements of the knees were still a little weak, the left more than the right. There was a trace of ataxia in the left leg. Vibration was absent in both lower limbs, but all other forms of sensation were normal. The right plantar response was flexor and the left extensor. Moist sounds were heard all over the chest.

Case 2

A man aged 65 was seen in consultation on October 16, 1951. In 1941 he had had an attack of congestive cardiac failure. At that time it had been noticed that he had an advanced osteitis deformans of the skull and spine. During 1945 he was admitted to hospital again, complaining of difficulty in walking. It was noted that both legs were weak and ataxic. All forms of sensation were poorly appreciated in the legs. The knee-jerks were absent and the plantar responses were flexor. By 1947 the weakness of his legs had increased and there was bowing of the right femur. X-ray films of both thighs showed severe osteitis deformans. He was fitted with a spinal brace. In 1949 he was admitted to hospital with retention of urine. The prostate was normal to palpation. Cystoscopy showed a fibrous bladder-neck and marked sacculation of the bladder. His bladder function improved and no active treatment was given.

He was again admitted to hospital in 1950 with urinary retention, and a transurethral resection of the prostate was done. A microscopical examination of the fragments showed senile hyperplasia. In spite of the resection he continued to have difficulty in passing his water. In the previous six months his leg weakness had rapidly increased and he had become bedridden. He had frequent attacks of breathlessness.

On examination he had a noticeably enlarged head and a very big right femur. His spine was rigid and there was an upper thoracic kyphosis. He had paraplegia in extension and was not capable of any voluntary movement in the legs. There was a marked hypalgesia to all forms of sensation to T11. The abdominal responses were absent. The plantar responses were extensor and there was bilateral ankle clonus. His bladder was palpable at the umbilicus. The blood pressure was 200/100 mm. Hg, and the apex beat of the heart was felt 1 in. (2.5 cm.) outside the nipple line. There was considerable oedema of both ankles and he had severe dyspnoea on slight exertion. X-ray examination at that time showed gross osteitis deformans of the right scapula, pelvis, femurs, lumbar spine, thoracic spine,

and tarsal bones. There was left ventricular enlargement. A diagnosis of paraplegia due to osteitis deformans of the spine was made. In view of his poor condition he was regarded as unfit for laminectomy, and a gloomy prognosis was given.

He was seen next on August 28, 1952. There had been some improvement in his general health. He no longer had attacks of breathlessness, although his ankles swelled intermittently. He had not walked for about eighteen months. He was able to pass water, but it often leaked away, and there had been attacks of cystitis. Both legs were painful and his buttocks were uncomfortable. He had noticed that his head was still getting bigger and that his dentures no longer fitted. He was a permanent inmate of a "chronic" hospital.

On examination his blood pressure was 220/120 mm. Hg, and the apex beat was felt 1½ in. (3.8 cm.) outside the nipple line. There was no evidence of any congestive cardiac failure. His bladder was palpable at the umbilical level. He had a marked upper thoracic kyphosis. His head was big and the right femur was massive. There was a complete paraplegia in extension. There was considerable hypalgesia for all forms of sensation to T7 on the right and to T11 on the left. The abdominal responses were absent and the plantar responses were extensor. Fresh x-ray films showed that the disease had progressed and that the lumbar spine was ankylosed. The cervical spine was normal. Further, many ribs and the tibiae and fibulae were affected.

The paraplegia was of such long standing that little could now be expected from decompression of the spine. The cardiovascular reserves were small and so no operative treatment was advised.

Literature

In 1877 Sir James Paget described the bone disease that bears his name. Thereafter sporadic cases were recorded in which neurological symptoms had complicated osteitis deformans. Wyllie (1923) gave the first verified account of spinal-cord compression due to osteitis deformans of the spine. Kay, Simpson, and Riddoch (1934), besides having had two cases of paraplegia in 34 cases of osteitis deformans, had seven other cases with less severe neurological signs. Schwarz and Reback (1939), Turner (1940), and Teng, Gross, and Newman (1951) have surveyed the literature. The total number of published cases was 37. Further cases have been published, and Petit-Dutaillis (1951) gave details of three cases treated operatively. Fairburn (1951) had a case in which symptoms recurred after successful laminectomy and which was improved by further operation. Godlewski (1948) had a case of cervical spinal-cord compression successfully treated by head traction with skull callipers. With the above two instances, the total number of published cases of compression of the spinal cord due to osteitis deformans is 44.

Discussion

Teng *et al.* (1951) gave the incidence of paraplegia as 1 out of 131 cases of osteitis deformans, on hospital admissions. The true incidence would be much less, as osteitis deformans is diagnosed commonly without recourse to hospital admission. Gutman and Kasabach (1936) found 59 cases of osteitis deformans in the wards and out-patient department of a hospital that treated 200,000 new cases in the same period. Some cases were symptomless and the radiological changes were found in the course of examinations for other conditions. Osteitis deformans occurs equally in the two sexes (Kay *et al.*, 1934; Gutman and Kasabach, 1936). Spinal complications have usually been recorded in males. Case 1 is exceptional in being female, and is the fourth such case. The age spread has been from 36 to 77 years, with a maximum incidence in the sixth and seventh decades. In the spine, Paget's disease is most frequent in the lumbar vertebrae and then in the thoracic vertebrae; affection of the cervical spine is uncommon

(Gutman and Kasabach, 1936). Paraplegia develops mainly in patients with thoracic spine involvement. Wyllie (1923) showed that there was an overall enlargement of all components of the vertebrae with the exception of the spinal canal. This was consistently narrowed. The most frequent site for the paraplegia was in the upper half of the thoracic spinal cord. Schwarz and Reback (1939) indicated that, for the whole spine, the interpeduncular spaces were narrowest between the third and tenth thoracic vertebrae. There is the additional factor of a kyphus due to collapse of the softened body of the vertebra. This is well shown in Case 1, in which the spinal-cord compression occurred at the apex of a small kyphus. The vertebrae affected were the ninth and tenth thoracic, which is lower than usual. The roominess of the lumbar spinal canal is the reason why narrowing in this area rarely causes nervous signs. Case 1 had incidental involvement of the third lumbar vertebrae, but a rubber catheter was able to pass this site without difficulty. It is rare for the whole of the thoracic and lumbar spines to be affected, as in Case 2. The ultimate fusion of the adjacent vertebrae occurs when the intervertebral disk is replaced by the pathological bony process (Turner, 1940).

The usual history is of a slow and persistent interference with the functions of the spinal cord. The onset is insidious, and may be masked by the pains and failing mobility that characterize many cases of osteitis deformans. The duration of symptoms has been a year in most cases. Both of the above cases had long histories; in Case 1 it was three and a half years, and Case 2 had had osteitis deformans for seven years and neurological symptoms for six of them. Otherwise the progression of symptoms was typical in both cases. It was unfortunate that more attention was not paid to the nervous system in Case 2 when the bladder symptoms became troublesome. There are no special features of the spinal-cord compression except for the predilection for the upper thoracic segments.

The radiological features of osteitis deformans are well known. In Case 2 the emphasis was on an osteoporotic expansion of the many bones involved. There was radiological evidence that the whole lumbar spine was ankylosed. It may be difficult to differentiate the localized form of osteitis deformans from secondary deposits due to cancer. In Case 1 there was a combination of a sclerosis and a porosis with expansion of the pedicles, arches, and spinous processes of the affected vertebrae. On radiological grounds a carcinomatosis of the spine could not be excluded.

The condition most likely to cause confusion in the diagnosis is a benign spinal-cord tumour. Infective processes and malignant tumours cause a more rapid disintegration of nervous function. Turner (1940) pointed out that usually it was not the clinically obvious case of osteitis deformans that developed paraplegia. Although there may be evidence of a widespread bony involvement on radiography, the radiological features are typical enough to make the diagnosis reasonably certain. The presence of deafness is an additional diagnostic feature in many cases. All the clinical evidence in Case 1 pointed to a non-tumorous cause, in spite of the radiological uncertainty. While Case 2 has not been confirmed operatively, the long history and the affection of so many bones leave little doubt that the paraplegia is due to osteitis deformans of the spine. Among the recorded cases of paraplegia due to osteitis deformans the association of this condition with a benign spinal-cord tumour does not seem to have been made.

The only satisfactory form of treatment is removal of the affected spinous processes and laminae of the vertebrae. Myelography is desirable as a pre-operative measure, to confirm the level of compression and to exclude another lesion. When many vertebrae are implicated it may not be expedient to do an extensive laminectomy, and myelography would show the site of compression. The laminectomy can be very bloody owing to the vascular nature of the diseased bone. These patients come into an age group in which cardiovascular and respiratory diseases are

common. Osteitis deformans is associated with a special form of heart failure due to high output (Edholm, Howarth, and McMichael, 1945). The results of laminectomy depend on the duration of symptoms, and little improvement will occur when the paraplegia has been present for a long time. Out of the 44 cases in the literature, laminectomy was done 25 times, with three (12%) deaths, and 18 cases have shown improvement after surgery. An important complication is the recurrence of the paraplegia after the initial relief. This has happened in at least three cases.

Case 1 had chronic bronchitis and pulmonary heart disease, but she tolerated the operation well. Her recovery from the paraplegia was slow, but at the end of five and a half months she had only slight neurological deficiency. Case 2 was not operated upon when first seen, owing to his congestive cardiac failure and poor general condition. It was surprising to find him alive ten months later. Although his cardiovascular state has improved, he has been bedridden for eighteen months. It is extremely unlikely that any improvement in his paraplegia would occur if decompression was done at this date. The general risk is considerable and it has been decided that he should not be submitted to operative intervention. Sarcomatous change is a real contingency that cannot be obviated.

Summary

Two cases of paraplegia due to osteitis deformans of the spine are described.

The literature is brought up to date.

The differences between the two cases and the general pattern of the disorder are discussed.

I am grateful to Dr. John Willis, of Palmerston North, for referring Case 1 and to Dr. Ian M. Macgregor, medical superintendent, Silverstream Hospital, for access to the clinical notes of Case 2.

The results of the first real test of the Emergency Bed Service's warning system are considered in the report of the service for the year ended March 31, 1953. The year under review includes the great London fog of last December, which resulted in a quite unprecedented rush of applications, and this was followed at the end of January by the influenza epidemic. Throughout this time of crisis, the warning system worked remarkably well, but the report says: "Although an outstanding success, experience has shown, however, that improvement is possible. At present the issue and cancellation of the warnings is solely dependent on the admission rate, and the winter has shown that this tends to result in the warning being put on rather too late and taken off too early. A modification of the scheme is being worked out whereby account is taken not only of the admission rate, but also of the number of applications being received and of the number of admissions made only after referring the case to the medical referees." Applications over the year as a whole increased, and analysis tends to confirm that this was owing to a rise in sickness rather than in the number of doctors using the service. The report also contains numerical details of the applications and admissions during the year.

J. A. MACFARLANE, M.B., F.R.C.S.Ed.

Senior Surgical Registrar, Law Hospital, Carlisle

Gall-stone ileus is stated by various authorities to be the cause of 1-2% of all intestinal obstructions (Illingworth and Dick, 1941). Vick (1932) found that in over 6,000 cases of intestinal obstruction 0.68% were due to gall-stones. The high mortality, said to be over 50%, is due to delay in diagnosis and to the advanced age of the patients. Few of the reported cases were diagnosed pre-operatively. Several cases have been reported with multiple stones in the small intestine, but in only a small minority has a second intestinal obstruction occurred. Maurice Lee reported such a case in 1945. The stone usually ulcerates through between the gall-bladder and the duodenum, where it passes down into the small intestine, becoming impacted at the lower ileum. Wakefield, Vickers, and Walters (1939) in 141 post-mortem examinations found the fistulous track in 101 cases.

Case History

A housewife aged 57, 1 para, was seized by violent epigastric pain followed by vomiting two days before admission. These symptoms soon eased but returned on the day of admission, the pain this time being colicky in nature and central in situation. It was associated with severe and persistent vomiting. There was no relevant previous history apart from a dislike of fatty foods.

On examination the patient was dehydrated, with a dry, furred tongue. The abdomen was slightly distended, and on auscultation continuous loud peristaltic sounds were heard. Two enemas were given with negative results. After a diagnosis of acute intestinal obstruction of unknown causation, a laparotomy was performed.

First Operation (J. A. M.).—A distended loop of small bowel presented itself through a right middle paramedian incision. This loop contained a gall-stone which was impacted about 2 ft. (60 cm.) from the ileo-caecal valve. As it was too hard to crush, it was milked up into the distended loop and removed through a longitudinal inci-

Photograph of the two gall-stones.

sion. No other gall-stone could be felt in the small intestine. The gall-bladder area was not examined. Up till the ninth day the post-operative course was uneventful. The patient was taking nourishment and her bowels were working normally. On the tenth day, however, she complained of epigastric pain and vomiting. During the following 10 days she had attacks of incomplete intestinal obstruction, with colic, vomiting, and constipation one day followed by the passage of diarrhoea and flatus the next. It was thought that she had a post-operative obstruction due to local peritonitis and kinking, and attempts to relieve it by intestinal decompression were made. By the twentieth day it was decided that as she was not improving a further laparotomy should be performed.

Second Operation (Mr. W. J. M. Brandon).—The abdomen was opened through the previous wound. A second much larger stone was removed from the same area as before. The post-operative course this time, though slow, was uneventful.

The first stone was pyramidal in shape, faceted at its base, and 1 in. (2.5 cm.) in diameter. The second stone was shell-shaped and 1½ in. (3.8 cm.) in diameter (see photograph).

Comment

In this case the stones must have been lying silent for some time in the gall-bladder, the smaller stone ulcerating through first, the larger one taking 10 days longer to force its way through the preformed fistula's track. If the significance of the large facet on the base of the first stone had been realized, an earlier diagnosis of the post-operative symptoms could have been made. Both these stones were radio-opaque, as tested post-operatively. This is unusual. The sex of the patient, the lack of previous history, and the intermittent type of intestinal obstruction are typical features of this condition.

Summary

A case is reported in which 20 days after an operation for gall-stone ileus a second stone was removed from the small intestine. The patient eventually recovered.

I would like to thank Mr. W. J. M. Brandon, consultant surgeon, Law Hospital, for his help and permission to publish this case.

Medical Memorandum

Mercuric Chloride Poisoning Treated with Dimercaprol

Mercuric chloride poisoning with suicidal intent is fortunately no longer fashionable in this country, although it still seems to be common on the Continent and in America. While Longcope and Luetscher (1949) in America reported on 61 cases of mercuric chloride poisoning treated with dimercaprol (B.A.L.), collected over a period of three years, no reports have, to my knowledge, been published in this country. It therefore seems of interest to make known the following case.

CASE REPORT

A man aged 37 swallowed 2 g. of mercuric chloride with suicidal intention at 1 a.m. on May 6. He vomited repeatedly shortly after taking the tablets, but the vomit is said not to have contained solid particles of the substance, but only to have been stained blue. About one hour later he passed a large amount of pale urine and began to have cramps in his hands and feet. At 10 a.m. he had violent abdominal colic with bloody stools. He then took fright and sent for a doctor. He was admitted to hospital one hour later.

He was seen to be a rather underweight man of slender build, but there was no evidence of shock and no gingivitis; the tongue was coated but not dry. The pulse was regular and the blood pressure 110/80. The bladder was not palpable suprapubically, but no urine had been passed since 2 a.m. He complained of some abdominal colic and of painful cramps in his limbs.

He was given an immediate injection of 100 mg. of dimercaprol, and two hours later a further 200 mg. The injections were repeated at four-hourly intervals for four doses, and then 100 mg. was given four-hourly for a further four doses. The patient reported very shortly after the first injection that the cramps in his limbs were abating and he had no abdominal colic and no bloody stools.

The first specimen of urine was obtained at 10 p.m. in scanty quantity and loaded with protein; the sediment contained casts in most unusual numbers, some hundreds to a field. Next day the patient felt comfortable. His blood pressure was 120/70. The urinary output was still scanty and showed gross proteinuria, and blood urea was 46 mg. per 100 ml. The urinary output increased considerably from the third day, but there was a heavy trace of protein in the urine up to May 11. His blood pressure was stable at 120/70. On May 15 the sediment still contained a few casts. The patient was allowed up, and was discharged home on May 19.

The total dose of dimercaprol given was 1.6 g. over a period of 72 hours.

COMMENT

Although early vomiting may have prevented full absorption of the dose taken, it is likely that the consequences would have been fatal without appropriate treatment. Among a series of 86 cases of mercuric chloride poisoning reported by Longcope and Luetscher (1949), without treatment with dimercaprol, there were 27 deaths; death occurs in most cases of poisoning with 1 g. and more of the compound. Suppression of urine after an early diuresis, and bloody diarrhoea, point to a heavy absorption of the poison.

Following on the original publication by Peters *et al.* (1945) on the value of dimercaprol in the treatment of arsenical poisoning, Waters and Stock (1945) pointed out its possible use in the treatment of poisoning with other heavy metals, including mercury. Further, Gilman *et al.* (1946) investigated experimentally in cats and dogs the protective action of dimercaprol in poisoning with mercury, and reported favourably on it. The first and most important contribution to human therapeutics was by Longcope *et al.* (1946). They treated 23 cases of mercuric chloride poisoning with one death; one patient who recovered had swallowed 20 g. of the poison. Longcope and Luetscher (1949) reported a further 38 cases so treated, with only one other death. The dosage recommended by them is of 300 mg. for the first injection and a further two or three injections of 150 mg. at four-hourly intervals. A very important point is that treatment should be started at the earliest time within two or three hours from taking the poison. The one death reported occurred when treatment was delayed until 13 hours after poisoning.

Dimercaprol is known to produce toxic symptoms itself if given in a dose of 5 mg. and over per kg. body weight. These symptoms comprise nausea, vomiting, headaches, generalized aches and pains, burning sensations in the mouth, nose, and eyes, sweating, restlessness, weakness, and pains in the limbs, jaws, and trunk muscles. The heart rate is often increased, and there may be a rise in both systolic and diastolic blood pressure. These signs and symptoms subside within four hours (Peters *et al.*, 1945). The initial dose of 300 mg. recommended by Longcope may be expected to produce toxic symptoms in a number of patients of rather slender build; these symptoms have not been reported in the treatment of acute arsenical and mercuric poisoning, perhaps because the drug combines very rapidly within the body with heavy metals and is no longer available in free form. In comparison with the extreme danger to life of poisoning with mercuric chloride the risk of toxic reaction from the first large dose of dimercaprol is certainly inconsiderable.

The case described above made a remarkable recovery, as treatment was delayed for 12 hours and the first dose of the antidote was inadequate.

Reviews

TEXTBOOK OF DERMATOLOGY

Dermatologie. By Professor Robert Degos. (Pp. 1,160; 301 figures. 8,600 francs.) Paris: Editions Médicales Flammarion. 1953.

This is an outstanding book in the great French tradition. It is comprehensive, but throughout bears the stamp of personal observation and experience. Many of the verbal descriptions are masterpieces, and these are supported by black-and-white pictures which are uniformly of the highest class both in photographic technique and in portrayal of their subject. The photomicrographs of histological sections are of equal calibre. Where required there are concise discussions in small print of the more scientific aspects of pathogenesis—for example, the relation of heparin to mast-cells, and the chemical aspects of melanogenesis. More attention is paid to foreign contributions to dermatology than in many French books, but though the author has read widely he has also read critically. Nowhere is the sense of personal experience more marked than in the sections on treatment, where the author's comments help the reader to determine which treatments are of actual rather than theoretical value. One might even wish that the author had had the courage to leave out some of those rather speculative forms of treatment which he obviously feels do not work in practice. He critically assesses such recently introduced agents as A.C.T.H. and the antibiotics, though he does not mention mepacrine in the treatment of lupus erythematosus. The whole book is beautifully produced on excellent paper, and bound in a stout loose-leaf cover so that supplementary pages may be added from time to time.

With such an excellent production it seems almost churlish to criticize, but it is hoped that anything which is said here may be construed as constructive and not destructive. The arrangement in chapters is based purely on the descriptive nature of the lesion—for example, erythematous lesions, papular lesions, scaling lesions, etc.—and the book suffers from defects inherent in such a system. Thus observations on syphilitic lesions are scattered throughout at least eleven different chapters, which entails many cross-references, while accounts of such varied conditions as warts, urticaria, Darier's disease, and filariasis are all found in one chapter. Even this system breaks down, and the author is forced to have such chapters as "Malignant Haematodermia" and "Naevi" which do not conform to one type of clinical lesion. It would surely be easier for the reader and make for clearer thinking if the book were arranged aetiologically, even though some difficulties might result. The other major criticism is that the book does not convey to the reader the importance of psychological factors in many dermatoses. There are references to "chocs émotifs" and "troubles nerveux," but these are only in passing, and no account is given of such fundamental work as that of the Guy's school on the asthma-eczema complex or Klaber and Wittkower on rosacea. In patients with constitutional eczema no mention is made of psychological treatment either by a sympathetic dermatologist or a trained psychologist, nor of phenobarbitone.

Other omissions noted are any reference to thorium X, or to dithranol in the treatment of psoriasis, nor is any mention made of cholinergic urticaria and Grant's work, nor of recent work by O'Brien and Sulzberger and others on prickly heat. The proof reading in French has been excellent, only one slip being noticed (*naïéance* on p. 445), but, though better than most French writings, English names are still spelt wrong, even "Whitefield," and there are several examples of unusual accentuation—e.g., pemphigus érythématosus (p. 445).

But these are trivial points in what is undoubtedly one of the best textbooks of dermatology produced in any language for many years.

F. F. HELLIER.

EXPERIMENTAL HYPNOSIS

Experimental Hypnosis: A Symposium of Articles on Research by many of the World's Leading Authorities. Edited by Leslie M. LeCron. (Pp. 483. \$6 or £2 5s.) New York and London: The Macmillan Company. 1952.

In the numerous recent books on hypnosis, it is presented variously as a method of treatment scorned by orthodox medicine and offering new hope for suffering mankind, as a mystery exclusive to master minds, as a sort of back door to the occult world, or as a branch of medicine meriting a Royal Society of its own. The drama of the hypnotic séance has been apt to get into the writer's style, and he presents himself either as a high priest in triumph or as a misunderstood man who has to appeal to the layman for a fair hearing.

The editor of this book has succeeded in avoiding these difficulties and in marshalling 20 contributors who present, for the most part, objective evidence, much of it original, on aspects of hypnosis which can be subject to experiment. Experiments on different techniques, the state of the nervous system at different levels of hypnosis, its effects on memory and efficiency in mental tests, on the time sense, on the formation and extinction of conditioned responses, and on autonomic and secretory function are all discussed. There is a reasoned appreciation, supported by experiment, of the possibilities of misuse of hypnosis for antisocial ends and an account of the results of its use in dentistry and obstetrics. Particular interest attaches to the editor's own work on age-regression and the results of educational tests given to subjects who have been told they are of school age.

All books on hypnosis have a lay circulation, especially among the morbidly interested, and the authors recognize this. But they discuss the sort of questions which are commonly asked by the intelligent and stable layman and the medical research worker, and give a general view of the present state of experimental work in a readable form. Continuity between the contributors is provided by a foreword to each article by the editor, who has produced a book of great interest to the general medical reader.

ALEXANDER KENNEDY.

TEXTBOOK OF GYNAECOLOGY

Textbook of Gynecology. By Emil Novak, M.D., D.Sc. (Hons.), F.A.C.S., F.R.C.O.G. (Hon.), and Edmund K. Novak, M.D., F.A.C.S. Fourth edition. (Pp. 800; 522 illustrations. £3 8s. 6d.) London: Baillière, Tindall and Cox. 1952.

In writing this fourth edition of his textbook of gynaecology Dr. Emil Novak has enlisted the help of his son, Dr. Edmund K. Novak. If this is a sign of advancing years and preparation for retirement on the part of the senior author, the book itself shows no such signs. It remains distinguished by the charm, enthusiasm, fluency, and well-ordered knowledge of the master. Some may argue that the pattern is more orderly than Nature intended or indeed shows, but the examination candidate will not have any such misgivings and will be thankful to have all scientific doubts and discrepancies disguised or hidden away.

Anyone meeting this book for the first time and without its title page would have no difficulty in recognizing it as written by the author of *Gynecologic and Obstetric Pathology*, which was first published one year earlier. The two books are similar in style and layout, and many of the illustrations are identical. This is considerably larger because, in addition to the systematic accounts of various diseases and their pathology, it includes many chapters on essentially clinical problems such as menstrual disorders, sex and marital relations, discharge, backache, sterility, and endocrine upsets. A chapter on female urology is contributed by Dr. H. S. Everett.

Since the book is designed for undergraduates and general practitioners, all details of surgical treatment are deliberately and properly omitted. Many undergraduates will probably consider that for their purposes the other aspects could well have been abbreviated. But more

advanced readers will find the book extremely attractive, and, except for those interested only in pathology, it is rather better value than its elder sister, for it contains nearly as much pathology and much more besides.

T. N. A. JEFFCOATE.

HISTORY OF NEUROLOGICAL SURGERY

The History and Development of Neurological Surgery. By Ernest Sachs, M.D. (Pp. 158; 50 figures. £1 10s.) London: Cassell and Co. 1953.

This is a very brief account of the development of neurological surgery from the earliest times to the present day. The first half of the book is on the interesting but relatively unimportant surgical measures undertaken from the earliest times to the advent of the Listerian era; into the second half are crowded all the remarkable advances made during the past hundred years. The reader will probably wish that the author had expanded the latter half to twice or three times its present size. Nevertheless, by the inclusion of 540 references, the way is left clear for anyone to follow up any particular subject in which he is specially interested.

Due credit is given to the outstanding pioneer work of Victor Horsley and Harvey Cushing, but we thought it inaccurate to attribute to the latter the devising of the trans-frontal method of approach to the pituitary fossa. Frazier, by modifying MacArthur's technique, first popularized the trans-frontal approach, though no doubt Cushing modified the details of the method.

It is well said that during the war of 1939-45 neurological surgeons for the first time came into their own, and that in that war results of treatment of head injuries were far better than ever before. If the author had compared mortality from penetrating head wounds in the first and second world wars the figures would have been most impressive, for it is known that the mortality was reduced from 50% to less than 10%. Half a page is given to a description of the improvement in the treatment of spinal injuries, but there is no mention of the remarkable work of Ludwig Guttmann, whose ingenious and active methods of rehabilitation have revolutionized the outlook for many of those who were formerly left to linger on in misery until death relieved them.

The book is illustrated by fifty attractive illustrations. On p. 36 occurs the word "escerotics" where the sense demands "escharotics," and the curious word is repeated in the index. We thought this might be an American form of the more common term, but could not find it in an American dictionary and must presume it is a misprint.

ZACHARY COPE.

BONE TRANSPLANTING

Die Konservierung von Knochengewebe für Transplantation. By Hans Roth. (Pp. 222; 233 figures. £4 3s.) Vienna: Springer. 1952.

An active field of research is at present provided by studies on the behaviour of tissues and organs transplanted from their normal site, or from one individual to another. Interest in the subject is stimulated by hopes of widening the scope of the surgical use of grafted tissues in the replacement of anatomical or physiological defects in the body. Blood transfusion is a frequently employed transplantation, while such tissues as skin, corneal tissue, bone, cartilage, blood vessels, and endocrine glands are being used or studied, and the possibility of grafting intact organs, such as the kidney, is under active investigation.

The author of the present volume, a surgeon of the university clinic at Basle, discusses in some detail the preservation of bone tissue for transplantation. This is prefaced by a good general account of the behaviour of bone transplants as seen in experimental studies. The author summarizes most of the important work in this field, and in addition describes experimental studies of his own. He also recounts his extensive experience with clinical bone grafts and with the organization of a "bone bank" for the preservation of the necessary grafting material.

Innate chemical and immunological differences appear usually to prevent more than the transient survival of cells when transplanted from one individual to another, and it is of interest that the regular and effective use of bone as a grafting material depends on factors other than cell survival on the part of the transplant. Indeed, bone now has to compete with a range of non-biological synthetic substances as a grafting material, and its advantages depend chiefly on its influence as a stimulus to the development of new bone by the tissue in contact with the graft. Grafted into the skeleton, the ultimate fate of a satisfactory transplant is complete replacement by newly developed living tissue which becomes functionally incorporated into the structure of the bone.

The healing process is much the same whether the transplanted bone comes from the individual into which it is grafted, from another individual of the same species, or even from a different species. Available information suggests, however, that the rate of repair is more rapid when the graft is an "autotransplant," but the convenience of using "preserved" bone from another individual is such that this type of graft (that is, a "homotransplant") finds frequent clinical use.

After his account of general studies with experimental transplants the author outlines the technique he has developed for the operation of a "bone bank" and for the clinical use of the material from it. He uses corpse bone, removed with aseptic precautions and preserved by refrigeration in liquid paraffin at a temperature of about -15°C . Dr. Roth has used such material on more than 100 occasions in a wide variety of orthopaedic operations.

This book is accurately written and excellently produced, with an index and a good bibliography. It is certain to be of considerable interest and use to those concerned with any aspect—clinical or experimental—of bone transplantation.

H. A. SISSONS.

TREATMENT OF BURNS

On Burns. Compiled and edited by Nathan A. Womack, M.D. (Pp. 178. £2.) Springfield, Illinois: Charles C. Thomas. Oxford: Blackwell Scientific Publications. 1953.

This book is the story recorded on tape and "gently edited" of a 14-day conference held in the State University of Iowa in 1951. As an authoritative work on the treatment of burns it is disappointing, though as a detailed record of a good conference between surgeons and research workers it is admirable.

The only clinical material carefully analysed is a study of 200 severely burned patients treated in one hospital from 1930 to 1950. This was a period of great change in methods of treating these injuries, and relatively few of the 200 had been treated by accepted modern methods. One contributor, Dr. Truman Blocker, is an obvious enthusiast for exposure treatment of acute burns, but the argument and evidence he presents for this method are not altogether convincing. His chapter might well have been matched by an equal enthusiast for a carefully undertaken occlusive method of treatment, but the book contains no authoritative evidence on this matter, nor does it indicate that both methods have their place in local treatment. The conference discussed most of the important problems associated with the treatment of thermal injury in peacetime, and it will be of interest to all who are concerned in this.

The symposium was an outgrowth of a discussion of a State Advisory Committee for Civil Defence, concerned with stock-piling material for the medical care of thermal injuries in any future war with modern weapons. It sought only to get a clearer understanding of accepted hospital methods of handling thermal injuries. The main value of the book to readers in Britain is that it is an excellent example of a realistic approach to a civil-defence problem by the State of Iowa, an example that could well be followed by the regions and their hospital authorities here.

MENTAL ILLNESS IN TWINS

Mental illness has to-day yielded relatively few of the secrets of its more common forms, and, though the theory of demoniacal possession and the wages of sin may have given place to dianetics and the importance of guilt-feelings, the proportion of theory to observation is often still very high. The only antidote to this is sound observation, and for those who can tolerate the pains of scientific doubt the unsolved problem of the major psychoses has acted as a stimulus to the gathering of reliable information, to consideration of predisposing and exciting causes, and to planned observation of the natural history of the morbid process. In this respect the progress of research into schizophrenia and cancer—to take two common diseases—is remarkably similar; there are advances in empirical treatment and accumulation of much information, but the main problem awaits solution. In both the constitutional approach has led indirectly to advances in the science of genetics, because it was a necessary preliminary to establish the extent to which inherited factors could predispose to disease and the extent to which a morbid predisposition could be modified by factors occurring during life and by the effects of treatment. In the same way, also, it has been necessary to investigate genetic factors in normal tissue growth and, in the study of the mental disorder, the inherited factors in the growth of normal personality, of which that of the schizophrenic is a caricature.

It is seventy years ago since Francis Galton¹ gathered information about the intellect, temperament, and character of twins and showed that identical twins were more alike in these respects than binovular ones or siblings of different age. In 1926 Dahlberg²

reported his findings in a large number of normal twins and discussed the applicability of twin studies to the problem of hereditary and environmental influences. Since then a series of workers have successively brought new principles to light and developed new techniques in this specialized field of study.

If a pair of uniovular twins are separated at birth and brought up in different environments, and if both develop schizophrenia at the age of 17, one after an unhappy love affair and the other after working hard for an examination, it appears at first sight that a few more of such examples would make the evidence for a wholly genetic aetiology for the disease overwhelming. The matter is, however, not as simple as that, and it was Luxenburger³ who pointed out how deceptive might be the conclusions drawn from the isolated reported case. While recognizing that such cases, selected because of exceptional interest, are of great value in indicating possibilities, he showed that they are of relatively small importance in estimating the general significance of inherited factors. For this reason he embarked on a study of unselected twins by collecting from hospitals over a large area of Germany the names of all the patients with schizophrenia who happened to be twins. Taking uniovular and binovular twins together, Luxenburger found that for every pair of twins in which schizophrenia appeared in both there were four pairs in which only one twin was affected—in other words, there was a concordance rate of 20% as against 80% in cases collected from the literature. But only uniovular twins can be regarded as genetically identical, and the later studies of Lange,⁴ Smith,⁵ and Rosanoff⁶ on criminal, mentally defective, schizophrenic, and manic-depressive twins suffered from the defect that there was no satisfactory criterion of ovularity. Rosanoff made the important suggestion that separate gene-borne predisposing and activating factors might account for the irregular familial distribution, especially in manic-depressive states. In the later work of Conrad⁷ and Stumpff⁸ the ovularity was more carefully investigated. In 1939 Juda⁹ reported on a study of mental defectives and showed that conditions hitherto thought to be due to birth trauma occurred in both twins when one had been delivered without difficulty. In general the concordance for states of mental deficiency accompanied by physical stigmata was very close. A further advance was made in 1941 by Essen-Møller¹⁰ in Sweden, who observed in a series of unselected twins that in schizophrenia especially there might be concordance in the fact of breakdown, but that the clinical picture sometimes differed very greatly in the pairs studied. In other observations, especially those of Kallmann,¹¹ the

high concordance in both schizophrenia and manic-depressive psychosis was confirmed, and from his material it became clear that in spite of the great aetiological importance of heredity recovery may occur, and this may be related to treatment.

In 1936 Dr. Eliot Slater set out to plan a survey of unselected twins appearing in the London mental hospitals and psychiatric units, a study which would be free from the objections to previous inquiries and in which, for the first time, the relationship of normal personality to psychotic symptoms would be considered. He also included psychoneurotic disorders and psychopathic personalities in the scope of his inquiries. The results, now published as a monograph¹² by the Medical Research Council, represent the conclusion of an enormous task carried out with a constant appreciation of the dangers of loose thinking and of the need to compile records which would be of use to later workers in the same field. It is not too much to say that Dr. Slater, in working out his methods and presenting his results, has made contributions to this branch of study which are applicable throughout all medical research. Altogether there were 295 patients, born from multiple births, about whose twins the necessary information was collected, and a full clinical study was made of each pair. The greatest care was taken to establish ovularity, and an original method of converting finger-print characteristics into terms of figures was worked out and proved to be a reliable index of similarity. Attention was paid to personality traits as well as to the symptoms of psychiatric disorder, and the case histories were condensed into summaries without great loss of content. The results are clearly given, and the protocols are such that further results of interest will be obtainable in the future as specific problems are thrown up by later work.

Fortunately the results of Slater's consistent and dispassionate approach emphasize the great importance of environmental factors on individuals rendered vulnerable to disease by their heredity and show that they can be helped to adjust themselves to life in spite of the inborn handicap. This evidence should make those concerned with treatment less hesitant to face the facts of genetics, and less inclined to therapeutic pessimism when the constitutional element is clearly great.

Slater has also shown that, with certain limitations, research on twins, especially when combined with clinical studies, is a valid approach to the problem of heredity and environment in mental disease. So far as specific diseases are concerned, the concordance for schizophrenia in uniovular twins was 76% compared to Kallmann's 86%. From this it is deduced that

heredity plays a major part in predisposition to this disease, but the case studies indicate that the personality of the individual and the experience of his lifetime have much to do with whether the disease becomes manifest or not. Among the psychopathic and psychoneurotic twins the concordance rate was lower, but the actual form of the disorder was more often similar—and this appears to be related to the strong evidence in this study that the basic make-up of the personality is largely determined by heredity. It will take some time to digest and apply the results of this survey, but there is little doubt that the Medical Research Council, in sponsoring this work, has assisted Dr. Slater to present a report which will doubtless rank as a classic in methodology and in the objective presentation of clinical material. It will, in addition, notably increase the ratio of observation to theory in the very speculative field of the aetiology of mental disorder.

FIRST WORLD CONFERENCE ON MEDICAL EDUCATION

Modern history may justify scepticism about the usefulness of large international gatherings, but those who had the duty of thanking the organizers of the First World Conference on Medical Education—held in London last week under the auspices of the World Medical Association—spoke with a sincerity which was clearly in tune with the feelings of the delegates. The 600 representatives who came to the Conference from 59 countries and 92 medical schools or universities seemed confident that medical teachers at least could disregard the barriers of distance and language and meet as one group of people with a common purpose—the improvement of the practice of medicine.

The results of a conference of this size cannot be quickly assessed and packed tidily away into compartments labelled "premedical studies," "pre-clinical studies," "clinical studies," and so on. In general the delegates had no difficulty in agreeing that changes were needed in medical education, but, as Dr. Victor Johnson remarked, it is easier to move a graveyard than change the curriculum. The course of medical study is like a slab of butter: it can be pressed into various shapes, and pieces lopped off at one end can be slapped on at the other, but the volume remains the same. The Conference heard many suggestions about the shape the curriculum should take and about the places where a reduction appeared possible and, more commonly, where additions were essential. No one had the temerity to

say that a perfect curriculum could be devised for any one country, let alone the world, but all were agreed that efforts to improve medical education should be unceasing—which seems to indicate that the first world conference on this subject will not by any means be the last.

In last week's *Journal* we commented on the purpose of the Conference and published Sir Lionel Whitby's presidential address and other papers read at the opening plenary session. Elsewhere in this issue we continue our report of the proceedings of the Conference (pp. 556 to 565)—a report that has necessarily to be curtailed, for over 200 speakers contributed to the discussions during the week. The final assessment of the work of the Conference will have to await the publication of its *Proceedings*, but there can be no doubt that it fulfilled the hopes of those who originated the idea. At the concluding plenary session the vice-presidents and rapporteurs of each of the four sections gave most thoughtful and informative reviews of the week's work, and their addresses will be reported in full in next week's *Journal*.

In the section which discussed "Requirements for Entry into Medical Schools," the case for educating prospective medical students in the humanities was of course put strongly, but, as Dr. Raymond Whitehead, the rapporteur of the section, pointed out in his remarks, the section felt it was worth emphasizing that education in science had its own cultural value—a view which those with no scientific training often conveniently ignore.

In this section the topic which provoked the most lively discussion was that on the selection of students. Plato thought that the ideal State should have a ruling caste nurtured and trained for government. The ideal medical student could be produced only by the same Utopian methods. Teachers are perhaps in danger of expecting too much from their students, and, as Dr. Whitehead said, they should be content to see only one or two divine attributes in them, remembering that "they are merely ourselves when young." The main purpose of selection is to pick out those who will educate themselves. The view that self-education was all important in the making of a doctor—both before and after graduation—was repeated time and again throughout the conference. A medical student from the Netherlands even went so far as to say that examination failures were often due to the fact that students were too hampered by their teachers and not allowed to find their own way about.

In his comments on the work of the second section—"Aims and Content of the Medical Curriculum"—the vice-president, Sir A. L. Mudaliar, wisely

reminded his audience that the content of the curriculum matters less than those who teach it. There was no lack of constructive suggestions about how the teaching of some subjects—anatomy and physiology, for instance—could be combined and about how the whole curriculum could be integrated. Dr. Morgan Jones, the rapporteur of this section, called attention to the general feeling that the fragmentation of the curriculum must not be allowed to go any further and that the study of medicine must be made a comprehensible whole once again. There are many ways of teaching the basic sciences and of relating this teaching with clinical problems, but, as Dr. Morgan Jones summed it up, "for the study of the practice of medicine in its broader aspects, there is no substitute for clinical clerkships, out-patient clinical work, and the study of the patient in his home and occupational environment."

Medical educators, like all other teachers, must remain constantly aware that the road they are travelling can very quickly become rutted. Professor A. Hurtado, the vice-president of the section considering "Techniques and Methods of Medical Education" urged the importance of experimentation in teaching as in all medical subjects. Many interesting schemes which are being tried out in various parts of the world were described during the meeting of this section, and there was a lively discussion about the place of teaching in the patient's home. This reflected the general awareness of the danger that the student may come to regard a patient in a hospital bed as a case—interesting or commonplace—but there was agreement that teaching in the home should not be designed as a preparation for general practice any more than teaching in the hospital should be designed as a preparation for a specialist career. The aim of all teaching should be to turn out what one speaker described as "the basic doctor," who on qualification would be prepared to launch out into the study and, later, practice of that branch of medicine for which his inclination and talents fitted him. As Professor Hurtado said, it would be entirely erroneous to try to fit pregraduate education into some predetermined plan of postgraduate activity. This section agreed on the value of the clinico-pathological conference as a tool of medical education and heard several experts talk on the management of group discussions. In presenting his report as rapporteur of the section Professor Ian Aird said that at times it was essential for the teacher to descend from his lofty isolation and let his students argue and discuss, "merely correcting their errors and guiding the direction of their common flow of thought." Several speakers emphasized the necessity for close personal association

between teacher and student, but not much was said in debate about the tutorial system which Sir Lionel Whitby recommended in his presidential address. This entails the selection from among the teaching staff of "tutors" to guide the steps and supervise the work of a group of students. No doubt future conferences will return to this theme.

The fact that preventive and social medicine was allotted a section of its own at this conference may have occasioned some surprise, but, as Professor Stampar said, it also gave much satisfaction to those who have long believed in the importance of social medicine, not only as a subject in the medical curriculum, but also as a background to hospital and family practice. As a matter of fact speakers in every section seemed anxious to comment on the new slant which medicine was taking as the result of a more perceptive understanding of the relationship between health and social welfare. That social medicine still does not receive enough attention was a common complaint, but even those who agreed with this complaint were not too sure of the exact place of social medicine in undergraduate education. The influence of socio-medical studies is of course now pervading the whole curriculum, and this influence is bound to become stronger. Why, then, are some clinicians still hostile to this subject? Dr. Charles Fletcher, the rapporteur of this section, gave one possible answer to this question:

"Experts in social medicine do not find it easy to expound their subject, which, though precise and objective in many aspects, also contains many conceptions that are still imprecise. Its advocates are thus tempted to talk in indigestible phrases, whose meaning, I suspect, is often as doubtful to them as to the rest of us. Such terms must be repressed if medical men are to listen, and social medicine must base its claims on a clear exposition of effective and comprehensible achievement."

It is only fair to add that contributors to the discussions of this section clearly showed that they possessed the powers of exposition which social medicine particularly demands.

When the Conference came to an end last Saturday no one doubted its success. Disagreements in debate were numerous, but there was no acrimony. The many social occasions, graced by the presence of the delegates' wives and families, were true demonstrations of international amity. Above all, there was an optimistic conviction that medical teachers, united by their strong professional bonds, common purpose, and humanistic tradition, could, and would, exert a strong influence for the good in world affairs.

DEFICIENCY OF POTASSIUM

The amount of potassium in the body, as measured by the technique of isotope dilution, is about 40 mEq. per kg., or some 2,800 mEq. in all.¹ The amount in the extracellular fluid, 4 mEq. per litre, is very small, and 97% of the potassium in the body is in the intracellular fluid. Potassium is normally lost through the skin, the bowel, and the kidney. The kidney can adjust to a very low intake,^{2,3} though it may take a few days to do so, but a loss from the skin and the bowel, of the order of 10 mEq. daily, continues.⁴ During starvation the potassium liberated by the breakdown of body tissues may be enough to cover the inevitable losses and to maintain a normal concentration in the body fluids,⁵ though the total amount in the body is obviously reduced. On the other hand, moderate deficiencies of potassium may arise with artificial diets that exclude potassium but provide adequate calories and protein.^{2,3,4} Mr. I. W. MacPhee discusses in this issue (p. 528) the mechanisms involved in the production of potassium deficiency. Large deficits, amounting to 30% of the total,^{6,7} may occur when the losses from the body are abnormally large. This happens, for instance, when fluid is lost from the gastro-intestinal tract by vomiting, aspiration, or diarrhoea, or through a fistula; and also when the normal renal mechanism for conserving potassium is upset by acidosis⁸ or alkalosis.⁹ Some forms of renal disease themselves lead to large losses of potassium.¹⁰ Moreover, perhaps because of an increase in the excretion of adrenocortical hormone, the renal conservation of potassium is not so efficient in ill persons as in the normal.

A deficiency of potassium may thus complicate many diseases, but symptoms attributable to it have been capricious in their incidence and have been relieved, at least temporarily, by doses of potassium that were small compared with the total deficit. For example, a deficit of 800 mEq. is equivalent to 60 g. of potassium chloride, but severe symptoms, if present at all, may disappear after the first dose of 10 g. The clinical effects depend partly on other changes in electrolyte metabolism as well as on the extent of the deficit of potassium. Potassium shortage is compensated by a retention of sodium in place of potassium

in the cells and is associated with an alkalosis in the extracellular fluid,² shown by a high bicarbonate and a low chloride concentration in the plasma. Under these conditions symptoms may be slight, but if sodium is not retained and if there is a complicating acidosis symptoms may become obvious once the deficit of potassium exceeds some 10–15% of the total body potassium.⁶ Mental apathy and stupor, anorexia, nausea, and symptoms of intestinal atony are among the more prominent. With very gross deficiencies such symptoms may occur even without a complicating acidosis, and Dr. J. S. Logan gives an instance elsewhere in this issue (p. 532). He suggests that a gastric ileus in his patient, who had had a gastro-enterostomy, may have been attributable to the deficiency of potassium.

The large amounts of potassium required to correct a deficiency cannot be given quickly because a sudden rise in the concentration of potassium in the extracellular fluid may stop the heart. Fortunately the urgent manifestations of a potassium shortage can be reversed with relatively small amounts of potassium, provided the compensatory mechanisms for a potassium deficiency can operate. Therefore if sodium deficiency and acidosis complicate the picture they must be corrected. A low plasma bicarbonate content points to the need for saline. Although urgent symptoms may abate with minimal treatment, it is still desirable to correct the potassium deficiency completely, for, even when compensated by sodium retention, it may cause myocardial lesions¹¹; it may be responsible for apathy, anorexia, constipation, and intestinal atony in convalescent patients; and it may predispose to oedema.^{6, 12}

Normal diets provide 50–100 mEq. of potassium daily and will gradually restore a deficit. With smaller intakes or with continuing losses supplements of potassium may be needed, but, when possible, intravenous administration must be avoided. But when intravenous therapy is essential the amounts of potassium provided by Ringer's solution and the like are quite inadequate for the treatment or prevention of a deficiency. The usual practice is to give a solution containing 2.7–3.1 g. (70–80 mEq.) in a litre slowly over four hours. Logan points out that intravenous therapy may be avoided by giving potassium per rectum.

The ideal course of action is to prevent major deficiencies from arising in patients who are in danger. At present the diagnosis of potassium deficiency rests above all on the history of abnormal losses. The losses can, however, be replaced as they occur, and for this Cooke and Crawley¹³ have devised two simple solutions for patients who are losing gastric or intes-

tinal secretions. The appropriate solution is given intravenously in a volume equivalent to that lost. Surgeons may welcome this means of avoiding a difficult biochemical problem when patients are unable to take potassium salts by mouth.

A NEW ADRENAL COMPOUND

The various types of biological activity which reside in the suprarenal glands can be tracked down to their origins in certain chemical fractions, and from these concentrates 29 separate crystalline steroid substances have been isolated. The chemical constitution of all but one of these substances has been determined, and during the last year or so nearly all of them have been synthesized. Of these 29 compounds, about 7 have shown themselves able to prolong life in adrenalectomized animals and to prevent the occurrence of at least one of the major side-effects of adrenalectomy. When subjected to different methods of assay these seven key compounds have shown considerable differences in their main modes of action, which are, however, often roughly divided under the headings of "mineraloid" and "gluco-corticoid" activity. The most potent of the gluco-corticoids is hydrocortisone (17-hydroxycorticosterone), and until now deoxycortone (D.C.A.) has proved itself the most active of the mineralo-corticoids. Corticosterone takes a half-way position between these two substances. So far, the two most potent of the gluco-corticoids, hydrocortisone and cortisone, have been recognized as being the substances whose effect on the pathological processes of rheumatoid arthritis and certain other rheumatic diseases is greatest. Nevertheless, it is recognized by clinicians that even for this purpose it is probable that more effective substances, or combinations of substances, may emerge as the physiology of the adrenal gland and its secretions become better understood.

Examination of blood from the suprarenal vein has shown that corticosterone and hydrocortisone are released from the gland in amounts which make it very probable that it is these two compounds which are responsible for the normal adrenal carbohydrate metabolism. On the other hand, similar observations have not supported the original idea that mineralo-corticoid activity is principally regulated by deoxycortone. It now seems that the steroid fraction which is mainly responsible for the mineraloid activity of the normal gland is a new compound, to which the name "electrocortin" has been provisionally attached by Simpson and Tait of the Middlesex Hospital Medical School. Since, however, this compound is contained within the "amorphous fraction" of the glandular secretion, it has previously been impossible to investigate the effect of this fraction on the human or animal body.

On August 25 Professor T. Reichstein, who in 1951 shared the Nobel Prize for Medicine with Drs. P. S. Hench and E. C. Kendall, announced at the Eighth International Congress of Rheumatic Diseases held in Geneva that he has been able at last to produce this

substance in pure crystalline form. The process of crystallization is at present long and complicated, and no doubt it will be some time before therapeutic trials of electrocortin can be started. The outlook, however, is promising, since it would appear that from now on the three main hormones of the normal adrenal cortex will be available in pure form, and clinicians will be able to administer them in controlled fashion, varying the relative dosage in accordance with the needs of the body. They may thus shortly be able to reproduce the normal functioning of the adrenal cortex in those diseases, including the rheumatic group, in which this form of therapy can be shown to be of major therapeutic importance.

SELECTION OF STUDENTS BY INTELLIGENCE TESTS

Sir Frederic Bartlett, who last week addressed one of the sections of the First World Conference on Medical Education on the use and value of intelligence and aptitude tests, threw aside his distributed paper, which was concerned with general and fundamental considerations, and made the first public statement on the results of a long-term investigation which the Medical Research Council set on foot a little more than five years ago on all aspects of the selection of medical students in Great Britain. A small research group was organized under Dr. A. D. Harris, with its headquarters in the experimental psychology laboratory in Cambridge. The initial plan contemplated a five years' study. The design was to apply representative tests of intelligence to a reasonably large population of prospective medical students before any of them had taken their first medical examination, then to follow these students through all their pre-clinical and clinical medical examinations to their first years in professional practice. The tests used were all of familiar type, fully meeting the usual conventional requirements, and of proved reliability. Complete results were now available, said Sir Frederic Bartlett, for a comparison of test performances with examination records in the first and second M.B. examinations. The conclusion was that the predictive capacity of tests of this kind for the first two medical examinations as conducted in this country was, with one possible exception, entirely negligible. They could, as the situation stood at present, add nothing of importance to existing methods of selection based upon school records and interview. To rely upon them alone or principally would be "fantastically silly." The association between test and examination success was even lower for the second than for the first M.B. There might be a number of reasons for this, but it was difficult to avoid the conclusion that test results might become of smaller and smaller significance the longer the time that had elapsed since they were achieved.

There was, Sir Frederic Bartlett added, one possible exception to this generally unpromising story. There were always a few candidates—less than 5% in this country—who for a variety of reasons slip through the meshes of the net of school record and interview and

proceed to a career of almost unrelieved failure. The figures obtained in this investigation showed a critical point of intelligence-test score below which a candidate was exceedingly unlikely to pass the first examination, and in no such case, out of some 600 candidates already followed up, had the second medical examination been passed. Whether for this small minority—already indicated by other means, but not quite decisively—it was worth bringing in some existing procedure of testing was a practical question which must be decided by the relevant controlling medical authority in each country. Sir Frederic Bartlett's opinion was that it was worth while. Neither the organization nor the cost involved would amount to much, and a good deal of frustration and discontent on both sides might be avoided. The story was still incomplete. The results of the "finals" had still to come along, and it was possible that the tests would prove of greater predictive value at that stage, though Sir Frederic Bartlett thought this unlikely for two main reasons. In the first place, there was evidence that test performances became less indicative of contemporary capacity with lapse of time, and, secondly, in this country at any rate, the distribution of successes in medical finals was so widely different from that in any known intelligence test that considerable agreement between the two was nearly impossible.

AUSTRALIA'S HEALTH SERVICE

Health matters were a major issue in the 1949 Australian election, which brought the Liberal and Country Party Government into power. The Health Act of the preceding Labour Government had been strongly opposed by the medical profession and received its death blow from a decision of the Australian High Court, which ruled that part of it was unconstitutional. The present Government in four years has introduced various health measures under regulations. It now proposes to consolidate these in a Bill to be introduced in the coming session of the Federal Parliament. The Minister of Health of Australia, Sir Earle Page, has described the proposed health service to the General Assembly of the World Medical Association at The Hague this week. His address is summarized in the opening pages of the *Supplement*.

Apart from public health, and measures for the medical care of the poor which any society would accept as a charge on the community, Australia has taken the bold step of pinning its faith to the voluntary principle. The Australians are a vigorous people and might be expected not slavishly to copy the health schemes of other countries. They believe that the voluntary method is the right one for them and that it brings out the best qualities of their people. Their scheme has been based on sound foundations: the agreement and co-operation of the medical profession were secured before it was introduced; and it was introduced in stages and not placed in final form on the Statute Book until considerable experience had been obtained. The progress of the scheme will be watched with interest all over the world.

REFRESHER COURSE FOR GENERAL PRACTITIONERS

THE ANXIETY STATE

BY

E. A. BENNET, M.C., M.A., M.D., Sc.D., D.P.M.

Physician, Bethlem Royal and Maudsley Hospital; Psychiatrist, West End Hospital for Nervous Diseases

An anxiety state is nature's way of announcing that life—the common life of mind and body—is disturbed and uneasy. Patient and doctor alike might welcome more precise, more self-evident indications of conflict and discord. The patient may have nothing to show for his illness—how willingly would he change it for a broken leg—and the doctor, having tried everything, may grow impatient. Nevertheless, we have in the anxiety state an authentic illness which creates a vast amount of unhappiness and incompetence.

The medical student seldom receives sufficient instruction about the psychoneurotic patient, and those seen in hospital are often atypical, with inadequate personalities. The physician brushes them aside impatiently or jokes about them. The phrase "Only nerves" suggests that "nerves" is a well-known and at the same time a discreditable complaint, best disregarded, and this is supported by the tags "A flight into illness," "Escapism," etc., which pass from one textbook to another. The student—immature and unaware of the complexities of emotional experience—with no further guidance from his teachers is unable to overcome acquired prejudice. It may be years before he outgrows his cynicism and appreciates the plain fact that reasonable, respected, and successful people are liable to neurosis. Thus he is apt to suspect an obscure physical complaint when he is consulted by a successful business man who complains of giddiness or palpitations. The young doctor learns late that intellectual brilliance and great organizing ability do not give protection against morbid anxiety. Unaware of this, he leads his patient into paths of expensive investigation, useless treatment, and probably into invalidism.

The Attitude of the Doctor

The purpose of this article is to describe the features of the anxiety state and to suggest how it may be handled by the doctor who has no special training in psychiatry, and in particular the lines along which the interview can be conducted.

Each doctor inevitably displays his own attitude of mind towards neurosis and so towards the anxiety state which is the commonest form of neurosis. But the attitude adopted is significant, since it affects the capacity to recognize the complaint. Recognition has two aspects: the knowledge of the characteristics of the condition; and, secondly, an acceptance of the fact that the anxiety state is in itself an illness and entitled to care and attention.

The sick mind, like the sick body, should be helped by considered rather than by casual methods. The doctor in general practice has not the time (and few have the experience) to use formal psychotherapy, but he can acquaint himself with the general conclusions reached by others about the neuroses. Patients should not be referred to a psychiatric clinic or to see a specialist at the first sign of trouble. The majority need never be, provided the practitioner knows how to interview patients with symptoms of neurosis. Technique is of less importance here than in any other branch of medicine. Personal consideration and a friendly approach can make the examination of therapeutic value, for in the relation between patient and doctor lie the essentials of cure or improvement.

Those people who are by nature mentally dull and therefore unable to compete on equal terms in the world are liable to contract the anxiety state. They are much benefited by our support and encouragement and by the simple prescriptions we may provide. Most sufferers with anxiety states, however, are of good intelligence, and they can be given considerable help by the family doctor who recognizes that, though sick, they are reasonable. The understanding of their puzzling illness may well be a first step towards helping them to resume responsibility for their lives. The doctor who stubbornly relies on mere common sense comprehends the anxiety state with difficulty. An unknown factor is ever present in the clinical picture—namely, the unconscious motives and the hidden mental conflict. The patient may be told of this so that he will cease to blame his environment or the shortcomings of his family. Every branch of medicine has its unknown aspects, but medical aid is not therefore withheld.

Features of the Anxiety State

Emotion plays the leading part in every anxiety state and emotion inevitably has its physical counterparts. Accordingly we always get a combination of psychological and somatic elements, although the prominence of one symptom—such as persistent pain—may distort the picture.

The somatic features, usually mentioned first, resemble closely the physical accompaniments of fear: palpitations, flushing, sweating, increased blood pressure and pulse rate, pain, giddiness, tremors, diarrhoea, polyuria. When the anxiety is protracted, headaches, nausea, and other digestive troubles, vaginismus, impotence, and lassitude may be prominent. Blundering jerky movements and restless foot movements may indicate muscular tension due to morbid anxiety. Usually one or two of these symptoms will be to the fore and fluctuations are common. The psychological symptoms include lack of concentration, unreliability of memory, apprehension, and feelings of unreality or of unreality in the external world and, as a consequence, a dread of insanity.

The anxiety may be centred on specific situations. This may become evident when we ask about travelling; whether the patient dislikes going to theatres or crossing the street; whether he has any particular fears, such as a fear of knives, of blood, of poison or diseases—for example, syphilis, cancer. Such morbid fears are usually called phobias. They are often given special labels such as *claustrophobia* and *agoraphobia*, implying wrongly that they have an origin different from other forms of morbid anxiety. The purpose of the phobia is protective, and the situation or eventuality on which it is focused is shunned. If the patient cannot side-step the dreaded situation he is thrown into a panic.

The patient is often in dread of a situation where he is called on to make a direct response. For instance, should he have to drink a cup of tea his hand shakes—a distressing symptom. Again, he is unduly alarmed at being shut in a lift or a railway carriage from which there is no immediate escape. The dread of going out alone, travelling alone, and many similar situations illustrates the subtlety with which an unconscious, unknown problem is projected upon the environment.

The anxiety-ridden patient feels that many of his symptoms are unreasonable and out of proportion to the circumstances. He agrees with his doctor who reassuringly tells him that there is nothing to worry about. But his symptoms are not the result of forethought and are impervious to

logic. Such symptoms, however—palpitations, pain, etc.—alarm the patient, and his demand for medicine seems to him eminently sensible.

Morbid anxiety has a retarding effect on thought and action, and this helps us to distinguish it from normal anxiety—that is, anxiety which spurs us to fitting effort and achievement, as when the student, anxious about his examinations, works harder. Yet morbid anxiety is reasonable, although the reason is hidden, unconscious.

The Interview

The busy practitioner shudders when a patient says, "I'd better start at the beginning, Doctor." He foresees an egotistical and wandering monologue, and so cuts the interview short. The embarrassment and futility of such interviews can be overcome if we make it a rule to examine the minds as well as the bodies of those patients whose symptoms suggest "nerves." A sympathetic relationship, which is at the same time one of detachment, must be established. Without it there can be no appreciation of the patient as a person. The quality and the value of the interview depend on the personality of the doctor, his sincerity, and his capacity for understanding. Having ascertained the reason for the visit and the immediate circumstances—age, marriage, business, general health—a brief chronological survey of the patient's development, noting the personal and family history, school career, and employment record, should be obtained. In a few minutes it is possible to judge how the patient has met the customary demands of life.

We turn next to the present illness and inquire in particular about its onset, duration, course, and response to previous treatment. The emotional climate in which an illness begins is invariably important.

Previous ill-health should be noted and resemblances to the present illness. Special attention should be given to illness of a like kind in a member of the patient's family. His father may have died of cancer; his mother may have had headaches, indigestion, and a "dicky heart." The danger of psychological infection is considerable.

A fear of insanity haunts some patients and they are relieved when the subject is mentioned. They want to know if their illness is "mental." Reassurance should be deferred until the examination is finished, when it can be given with conviction—provided there is no evidence of psychosis. Similarly, the subject of suicide should be raised with the depressed patient, particularly if there is early morning waking and self-depreciation. Such inquiry will not influence the patient towards suicide, nor will he be deflected from it by the (untrue) remark that those who speak of committing suicide do not do so. Nearly all depressed patients have suicidal thoughts; and, in face of the responsibility which the family doctor is called on to bear in the management of a suicidal patient, he is justified if he calls in a specialist.

"How has the illness changed you? Were you a different sort of person previously?" Inquiries of this type are often productive. The doctor's own attitude to the conduct of life will be fully evident by the tone of his questions. If this rings true, the patient will speak freely on any subject.

The physical examination, an essential part of the investigation, is best made when rapport has been established, rather than at the beginning of the interview. The relevance of the state of mind to that of the body becomes evident when seen against the background of personal development and social adaptation.

During the examination the intelligent patient should be given some explanation of his illness: that emotion always affects the functioning of the body and this may become pronounced at times (for example, blushing, tachycardia, polyuria), and that the symptoms are not "diseases" but upset and disturbed normal processes. The patient with palpitations may think he has heart disease. Perhaps he has been told that he has high blood pressure or that his heart, although sound, is not quite healthy. Behind the fear

of going out alone may be the fear of falling down dead. Most laymen believe that life hangs by a thread if there is anything whatever the matter with the heart. The patient with abdominal pain may think he has cancer, but is afraid to ask lest his fear be confirmed. Doctors are often too reticent, too cautious, and even disposed towards a bad prognosis. Optimism is usually more justified than—to the patient—ominous silence. Notice the relief of the patient on hearing: "Your heart is sound, anyhow"; "There is no growth, no sign of cancer." Organic disease may be accompanied by an ill-defined feeling of anxiety arising probably from reduced efficiency, so the physical examination should be thorough. But with the anxious patient it should not be repeated without good reason. Disordered emotions, rather than organic disease, are far more likely to be present, and the danger of treating an anxiety state as an organic illness is considerable.

The number of intellectually dull persons in the community is high, and they often contract anxiety states or other neuroses. Failure to pass routine school examinations and frequent changes of work suggest intellectual and social defect. The doctor will often get a shock if he asks a few simple questions in mental arithmetic or in general knowledge. (A smartly dressed girl of 16 insisted that there were 20 half-crowns in 30 shillings.)

Too much should not be expected from explanation and reassurance. The friendly and genuinely interested doctor increases the patient's self-respect when he listens to him, explains modestly, and gives reassurance only after careful examination. But the anxiety state may well need special treatment, and this should not be withheld in favour of sending the patient for a "complete rest"—a form of management with little to commend it.

Hypnotics and sedatives, as supplementary aids, are valuable. But when given again and again, without any effort at enlightenment, the patient is encouraged to accept "nerves" as a permanent disability. When the patient has some insight into the nature of his illness the sedative is given as a temporary measure to allay tension and not as a "nerve tonic."

Patients may mention the housing shortage and financial and business worries as "getting them down." While these are important, they are usually secondary to the patient's relation to his family and others, which if not central is again and again a crucial matter in the anxiety state. The tire-some elder sister, the alcoholic parent, the unhappy marriage, may be linked with the illness although the patient has not observed any association. The doctor should not attempt to sort out family troubles, but his patient will be helped by speaking of them and helped far more than by a tonic and advice not to worry.

An interview conducted on these lines will take perhaps half an hour. But it results in a clear picture of the patient as a whole, and in the long run time will be saved. A patient can get lasting benefit even in one interview, particularly in the early stages of the illness, provided he is given some element of insight into his illness. During the interview the doctor should bear in mind the importance of an affirmative diagnosis in the anxiety state—that is, a diagnosis which rests upon the presence of morbid anxiety. A diagnosis of "functional" or "nerves" reached by the exclusion of organic disease is of little value, as it gives no information about the nature of the illness or the person who is ill.

Relatives quite reasonably ask about their demeanour to the patient: should he be "made to do things" or "given-in-to"? The cue here—and the same holds for every medical interview—is that the patient should be accepted as being ill and thus entitled to help and encouragement. The patient will lose courage if bombarded by good advice and allusions to will-power.

Psychiatric illness is seldom clear-cut, and so the interview is designed on general lines and is suitable for a wide range of patients. It is well to cast the net wide, for apparent irrelevancies often turn out to be important.

FIRST WORLD CONFERENCE ON MEDICAL EDUCATION PROCEEDINGS OF SECTIONS

The Conference continued to meet in four Sections, which held simultaneous meetings on August 26, 27, and 28. Their proceedings are reported below in continuation of the reports in last week's Journal (pp. 486-9)

SECTION A: REQUIREMENTS FOR ENTRY INTO MEDICAL SCHOOLS

Wednesday, August 26

Section A, presided over by Dr. DONALD G. ANDERSON, continued its discussion on the general theme of the requirements for entry into medical schools.

Teaching the History of Science

Professor A. PAZZINI (University of Rome) insisted that the teaching of the history of science was not a question of the assimilation of names and dates, but rather of enabling the student to understand the evolution of science, the development of ideas, and the creation of a scientific consciousness. He was followed by Professor M. MOUQUIN (University of Paris), who stressed the value of films and museum panels.

Dr. MOGENS PIHL (Denmark) rejected compulsory teaching of the history of science and favoured an historical study of specialized subjects rather than a general course. Professor L. JUSTIN-BESANÇON (France) thought that films on historical subjects should be televised. Dr. MORRIS FISHBEIN (University of Illinois, U.S.A.) said the history of medicine must be written in the biographies of great doctors, and wanted the development of ethics and medical law taught as separate disciplines. Professor F. A. SONDERVORST (Louvain) reported that the Belgian Committee for the History of Science had invited the Government to set up chairs in the history of medicine in all four universities. Dr. M. M. WEAVER (University of British Columbia) considered that the incoming medical student benefited by a prescribed course in the history of medicine. Dr. ST. GEORGE B. DELISLE GRAY (United Kingdom) and Professor JOHN P. HUBBARD (University of Pennsylvania) also spoke.

Teaching Scientific Methods

Professor GUSTAV NYLIN (Stockholm) pointed out that it was inconceivable that the undergraduate student could be given a comprehensive knowledge in each branch of his studies. The introduction of an additional subject, "Scientific Methods," would, in his opinion, be inexpedient. But it would be productive and practical to allow time in each branch of medical education to give striking and inspiring examples of the manner in which scientific methods had evolved. Professor H. SCHULTEN (West Germany) also spoke on this subject.

The Value of Mathematics

Professor P. BONNEVIE (University of Copenhagen), in speaking under the title "Science is Measurement," said that this had been explained by the Programme Committee as covering the problem of including some mathematics in the premedical period so as to prepare the student for his introduction to medical statistics at a later period. But the subject had another meaning—the use of mathematics as a tool for all natural and social sciences, by reducing observations to figures and attempting to record experiences in terms of quantitative laws.

Miss DIANA DYASON (Lecturer in the History and Methods of Science, University of Melbourne) then described her experimental premedical course.

Thursday, August 27

Biology a Fundamental Study

On Thursday morning the place of biology, physics, and chemistry in medical education was discussed, with Dr. EDWARD L. TURNER (Washington) in the chair.

Professor JEANE VERNE (University of Paris), speaking on the role of biology in student training, described how the teaching of this subject was carried out in France. At present the premedical year closed with an examination. Owing to the great numbers seeking to enter the medical profession it had been proposed that in the large schools the examination should be replaced by a competition. But such a competition might well favour students with superficial knowledge and work to the disadvantage of others who had in them the makings of an excellent doctor.

Professor W. BARGMANN (University of Kiel) did not favour the teaching of biology to medical students only, as proposed in Germany. Before entering the university, pupils must be acquainted with the world of organisms. It was the task of the schools to provide basic knowledge of biology.

Miss M. L. JOHNSON (University College) doubted whether biology, as usually taught, really developed the powers of observation. Students saw things which they thought were there, and failed to see things which they thought ought not to be there.

How Much Physics and Chemistry?

Dr. H. C. BURGER (University of Utrecht) outlined the course of medical physics which was given at his university. Fifty lectures were given in the first year, and practical work was done on 16 afternoons. The teacher in medical physics must also be a research worker in close relation with the medical world.

Professor E. C. DODDS (University of London) said it was obvious that the whole of the teaching of chemistry should be aimed at an understanding of the structure and properties of those substances which occurred in the body and took part in metabolic processes. It was upon this field that chemical education should be concentrated. It was also necessary to study the chemical structure of drugs.

Mr. J. B. JEPSON (University of London) defined the aim as being enough chemistry to enable practitioners to appreciate advances in medical science. Dr. C. D. LEAKE wanted more chemistry.

Dr. W. E. S. MERRETT (Principal, Kano Medical School, Nigeria) said that as a physiologist he wanted students to know the hydrodynamics of the movement of fluids through tubes, but such things came only in advanced courses of physics and chemistry. One answer was to teach these subjects, but with a special medical bias.

Dr. A. S. M. NAYAR (Madras) and Dr. M. TALAAT (Egypt) also spoke.

Introduction to the Social Sciences

Professor T. S. SIMEY (University of Liverpool) said that the social sciences amplified the natural sciences and showed the student the way in which scientific method could be applied to the study of persons. He hoped that the social sciences would develop in the medical course as a simple means of enabling the student to understand those aspects of human nature which were important to the medical practitioner in his work.

Selection of Students

Dr. A. E. SEVERINGHAUS (Columbia University, New York), in a paper read by Dr. ALAN VALENTINE, stated that in the United States no group of applicants for entry to a profession were more carefully screened than those who wished to enter the medical schools. In 1952 there were 16,760 applicants for 7,425 places.

"I look for a quality which, for want of a better term, I call 'warmth,' but I feel wholly unequal to the task of trying to tell you how I arrive at a decision in this matter."

Friday, August 28

Intelligence and Aptitude Tests

In the final session, Sir FREDERIC BARTLETT, former professor of experimental psychology at Cambridge, opened a discussion on the value of intelligence and aptitude tests. He considered that an attempt ought to be made to find a form of tests in which the "answer" must exhibit not only a final issue but also the steps by which it was approached and eventually achieved. Sir Frederic gave the first public statement on the results so far achieved in the Medical Research Council's long-term investigation of the selection of medical students. He confined himself to that part of the investigation which was concerned specifically with the use of tests. The tests used were AH5, a Cambridge high-level intelligence test widely standardized on students of university type; a group of pattern-perception tests; and the well-known N.I.P. Group Test 33. The correlations between test performances and examination results lay between 0.2 and 0.4 for the first M.B. (the higher figure representing only a very small part of the total population); and between -0.1 and 0.3 for the second M.B. To rely on such tests alone, or principally, would be fantastically silly—unless, of course, there was something wrong with the examination. There might be many reasons for the association between test and examination success being even lower for the second M.B. than for the first M.B., but it was difficult to avoid the conclusion that test results might become of smaller and smaller significance the longer the time that elapsed since they were achieved. The view that tests of this kind revealed stable, relatively unalterable, human properties was almost certainly wrong. Once a doctor got into the world it did not seem as if it was intelligence which counted for a great deal, but personality. Ability tests, however, might be useful if applied at a late stage of training, not compulsorily but for guidance.

Professor E. ASK-UPMARK (University of Upsala, Sweden) reported that in Sweden they had found a definite correlation between the record of a student in anatomy and his record in the clinical years.

Professor G. PATRICK MEREDITH (University of Leeds) said that university examinations did not depend entirely on intelligence. They depended a great deal on hard work and character.

Dr. H. E. THELANDER (University of California) had found that tests which tested a person under stress were the ones most likely to correlate with performance. Others speaking in the discussion were Dr. J. VAN LENNEP (Belgium) and Professor W. M. MILLAR (University of Aberdeen).

The Method and Value of the Interview

Dr. S. G. VENGSAKAR (Tapiwala National Medical College, India), considering the method and value of the interview, defined the purpose of an interview as being to provide the applicant with an opportunity to display his personal qualities. The candidate should be given every opportunity to present himself favourably.

Professor GORDON KING (Hong Kong) compared the results of two "selected" years of students with two "unselected" years of students at Hong Kong, the former students being admitted after interview, the latter only on the results of the matriculation examination. The 1946 (unselected) group of students was an older group whose determination to study medicine had remained alive through five years of war, and a high proportion survived to sit the final examination. In the remaining three years (selected and unselected) little difference was noticed. Further, over 70% of students in the lowest gradings, according to interview, and only 20% of those in the highest, survived to sit for the final examinations.

Dr. T. A. DIVINE (Leeds University) commented that one could find from a personal interview the appearance of a candidate and his background, and assess his motive. Dr. E. R. BOLAND (Guy's Hospital Medical School) agreed that personal judgments could be fallacious but believed more accurate than inaccurate ones were made. He would rather

Dealing with the interview as a method of selection, Dr. Severinghaus said that at his school about one-quarter of the applicants were interviewed, and no student was admitted without an interview. However, an experienced interviewer was necessary.

Professor S. SUNDERLAND (University of Melbourne) said that there was a need for more well-trained doctors; at the same time suitably qualified students were presenting themselves in ever-increasing numbers. It seemed odd that the reaction to such a situation should be to embark on a policy of selection for entry into medical schools. The stage had now been reached where students were being coached for interviews. Interviews were not used at any subsequent stage of the student's career, and it was therefore unfair to emphasize them when he was applying for entry to the course. Melbourne University had decided to base selection solely on examination results at the end of the first premedical year. It resulted in overcrowding, but it gave all prospective medical students a chance to compete under substantially the same conditions.

Professor W. W. GREULICH (Stanford University, San Francisco), a member of an admission committee, said he had been impressed by the number of times the estimate of a candidate by equally critical, equally qualified people had differed. Dr. W. G. SMILLIE (Cornell University) and Dr. S. G. VENGSAKAR (India) also spoke.

Dr. DENIS BRINTON (St. Mary's Hospital, London) described the selection of students in the United Kingdom. The procedure was divided into three stages: perusal of application form and confidential report; the interview; and the student's first year in the school. Not a few psychologists had been critical of the value of the interview, because the test was incapable of standardization and control. But as yet there was no scientific means of measuring personality. Experience had shown that a student who failed the premedical examination seldom avoided worse trouble later.

Student Selection in India

Professor S. S. MISRA (Lucknow University) said that there were now in India 29 undergraduate medical colleges, as compared with 16 in the undivided India of 1947. About 2,000 undergraduate students were admitted every year for a five-year undergraduate course. Not more than between 30 and 40% of these students qualified in the minimum period. There were about 50,000 qualified doctors in the country, with its population of 350 millions—a ratio of 1 in 7,000. Even with the increased number of medical colleges and admissions it was not expected that there would be more than 2,000 newly qualified medical men each year—a totally inadequate number. Student selection was based on an assessment of previous scholastic achievement, and an additional premedical test. The low admission age (17), the lack of insistence on a more liberal education, and the absence of an aptitude test were responsible for the admission of many unsuitable students.

Dr. T. B. DAVIE described observations being made at the University of Capetown. Professor M. TALAAT (Alexandria University, Egypt) noted the importance of selection of teachers. Dr. DAG KNUTSON (Stockholm), Dr. MUSA GHANTUS (Lebanon), and Dr. ST. GEORGE B. DELISLE GRAY continued the discussion.

Describing student selection in Canada, Dr. M. M. WEAVER (University of British Columbia) said that medical schools in Canada were reluctant, or refused completely, to accept into the final four years in medicine anyone younger than 19 or older than 30. Lack of emotional stability or some other personality disorder might be a determining factor in the rejection of a borderline applicant. Other factors which it had been found helpful to discuss with borderline applicants included health and physical adequacy for the medical course, reading habits, the applicant's reason for wishing to become a doctor, and what he intended to do after qualification.

Dr. M. D. PENAS (University of Santo Tomas, Manila, Philippines) and Dr. MARCEL POUMAILLOUX (Paris) also spoke.

select a wife after a 20-minute interview than on the results of a competitive examination. Dr. JOHN B. LAGEN, also supporting the interview, said that when selection at the University of California was based entirely on marks there was a total "mortality" of 20-25%. During the last seven or eight years, with a selection interview, the mortality had been 7 or 8%. Professor W. M. MILLAR (University of Aberdeen) said an interview afforded the student the opportunity of making a good human relationship with some members of the faculty at the outset of his career.

SECTION B: AIMS AND CONTENT OF THE CURRICULUM

Wednesday, August 26

Section B, with Sir A. L. MUDALIAR in the chair, continued its discussion on the aims and content of the curriculum.

The Doctor is Human

Professor W. MELVILLE ARNOTT (Birmingham) said that it was sometimes suggested, mainly, he suspected, by those who because of poor education or intellectual indolence had fallen behind, that the scientific element in medical practice was in some way antagonistic to human kindness. This was a mischievous slander which carried little weight among intelligent people. It was just as much a crime against science as against humanity for a doctor to fail in human kindness or in sympathy. The doctor must realize that even though he could do little or nothing to stay the course of an illness his very presence gave comfort and support to the patient and the relatives. All these and many other less tangible elements in good doctoring could not be taught as formal items in the syllabus, but they could be inculcated by example.

Professor W. LÖFFLER (Switzerland) was inclined to the view that one of the chief troubles in medical teaching was that some people overestimated the practical side and others the theoretical side; it seemed advisable to synthesize the two. Any educational system must also be in accord with the mentality of the country concerned.

Dr. S. C. SEN (India) thought the time had come when medical ethics should form a very important part of the medical curriculum.

Mr. A. B. GILMOUR (Hon. Secretary of the British Medical Students Association) said that general practice was the one branch of medicine of which students knew nothing until they were qualified. They would like to have a greater knowledge of the atmosphere of general practice and all its difficulties.

Other speakers were Dr. E. ASK-UPMARK (Sweden), Dr. JOSE A. BUSTAMANTE (Cuba), Professor LEON GERIN-LAJOIE (Canada), Dr. DAG KNUTSON (Sweden), Dr. J. A. PRIDHAM (U.K.), and Dr. J. L. TROUPIN (U.S.A.).

The Introductory Clinical Course

Professor L. JUSTIN-BESANÇON (University of Paris) spoke on the introductory clinical course, in particular the influence exercised on the preliminary instruction by a knowledge of the nature of the practice which the student would follow after qualification. Must the young doctor whose career might be spent in clinical practice in a village or small town be required to undergo the full round of training in laboratory work, microbiology, radiology, and so forth? He urged that the conception of medical instruction must allow for differences, alike in method and in purpose.

Sir LIONEL WHITBY (Cambridge) spoke of the fundamental need to stimulate and encourage students' powers of observation. A student's introduction to clinical medicine in the wards should not begin with his learning the names of diseases, but with his learning how to express what he had seen, felt, or heard. Complete familiarity with the normal led quite naturally to an extremely quick observation of the abnormal.

Dr. A. C. DORNHORST (U.K.), Professor FELIX HURTADO (Cuba), Dr. DAG KNUTSON (Sweden), Dr. J. G. ORCOYEN (Spain), and Dr. M. PRYWES (Israel) also contributed to the discussion.

Teaching of Psychological Medicine

Professor D. EWEN CAMERON (McGill University) said that the teaching of psychological medicine in the undergraduate curriculum could not be exclusively concerned with hysteria and mental deficiency, with schizophrenia and manic-depressive psychoses. They would entirely fail to rise to the challenge of the times to produce physicians fit to lead the great enterprises of modern health if they so limited themselves.

Professor A. MILLAN (Mexico) emphasized the need for students to understand the mind as well as the body of patients. A patient seeking a physician's aid was not merely an animal whose symptoms could be linked with a disease.

Professor A. LAMACHE (Rennes) considered it absolutely necessary that those who studied the body should study also the psychological mechanisms which were constantly in operation; while Professor D. DE SOUZA (Brazil) thought that the emphasis should be on the student and not the patient, the first essential being that the student should know and understand himself in order to have an adequate appreciation of a patient's emotions.

Other contributors to the discussion included Dr. JOSE A. BUSTAMANTE (Cuba), Dr. OLIVER COPE (U.S.A.), Dr. M. ISELIN (France), and Dr. CHAUNCEY D. LEAKE (U.S.A.).

Thursday, August 27

Medicine and Surgery as One Discipline

On Thursday morning Dr. OLIVER COPE (Harvard) discussed the teaching of medicine and surgery as one discipline. He considered that much might be gained if the departments of medicine and surgery were willing to combine in the teaching of undergraduate medicine. A number of diseases, such as those of the gastro-intestinal tract and the endocrine organs, were traditionally taught by both departments. Consultation could be readily achieved, and where differences in point of view still existed combined group teaching by interneers and surgeons could be arranged. The difficulties of such a situation were largely emotional.

"The interneer would not be bothered with his technical-minded colleague, the surgeon. The surgeon, considered by tradition intellectually inferior by the interneers, would be anxious, ready to have his feelings hurt, and therefore assertive from the start. But it is worth a try."

Professor A. ASENJO (University of Chile) agreed that the teaching of internal medicine and surgery should be carried out as one discipline, only separated into parts dedicated to treatment and to examination with very specialized techniques. This teaching should be carried out not only in hospital but in family surroundings.

Dr. J. A. MACFARLANE (Canada) said that if they were not to give consideration to the easement in some way of the medical curriculum then students were going to continue to spend more and more time going to lectures and tutorials.

Professor PATRICK KIELY (Ireland), Dr. T. SCHAFFER (South Africa), Dr. M. ISELIN (France), Dr. S. C. SEN (India), and Dr. A. P. THOMSON (Birmingham) also spoke in the discussion.

Teaching of Minor Surgery

Mr. WILLIAM GISSANE (Birmingham Accident Hospital) declared that the term "minor surgery" implied neither importance nor respectability—a bad introduction to the presentation of any subject in undergraduate teaching. Such an introduction had some other shortcomings. There was no purposeful attempt to build on the knowledge the student had already gained in the departments of physiology, anatomy, bacteriology, and pathology. "Minor surgery," as generally taught, placed too much emphasis on the operat-

ing act, the use of tools, the names of splints and patterns of bandages, and not enough upon the surgical principles behind the act and the use of the tools.

Dr. M. ISELIN (France) said that the student must be taught to know the type of surgery he could perform himself as distinct from that for which it was necessary to have recourse to surgical specialists.

Dr. ST. GEORGE B. DELISLE GRAY (U.K.) regarded minor surgery as that which could be—and should be—carried out by the general practitioner.

Professor A. SPINELLI (Rome) said that it was agreed in his country that students wasted their time in attending the performance of major operations. Further contributions to the discussion were made by Professor F. A. SONDERVORST (Louvain) and Professor L. G. TORNEL (Spain).

The Teaching of Obstetrics

Professor DUGALD BAIRD (University of Aberdeen) said that the teaching of obstetrics varied according to the organization of obstetrical services from one country to another, and according to national customs and the stage of evolution reached. In Britain, on the assumption that only a proportion of graduates, and only those who had had postgraduate experience, would practise midwifery, undergraduate training was now much more general and less technical than it used to be.

The standard of management of pregnancy and labour in the best maternity hospitals was now so high that the general practitioner must find it increasingly difficult to compete unless he had had special training or had constant practice under favourable conditions.

Mr. H. K. PACEY (New Zealand) then described obstetric trends in his country, where there were a well-organized medical service and a national maternity service that had operated with great smoothness since 1940.

Dr. F. M. ROSE (U.K.) was of opinion that in the teaching of the medical student the dangers inherent in pregnancy and parturition were sometimes overstressed. This country was maintaining a very expensive hospital service, and maternity beds were sometimes needlessly filled with cases which could quite well be confined at home.

Dr. MARY ESSLEMONT (Medical Women's Federation) suggested that, as they were so few, all the maternity patients in teaching hospitals should be reserved for the medical students; it was possible to arrange for patients in non-teaching hospitals to be available for midwives.

Other speakers on this subject were Dr. ST. GEORGE B. DELISLE GRAY (U.K.), Dr. G. MOUTHON (France), and Dr. J. G. ORCOYEN (Spain).

The Teaching of Paediatrics

Professor ALAN MONCRIEFF (University of London) raised the question, "Is paediatrics a branch of medicine?" In general terms paediatrics was medicine at a special age period. Usually it came into the second year of clinical studies, after a basic period of six months had been spent in internal medicine and a similar period in surgery. The General Medical Council would like to see midwifery also precede paediatrics. Clearly work on the newborn baby must be concurrent with midwifery, and this was a useful introduction to child health. It would appear that paediatrics should come somewhere towards the middle of the second year of clinical studies, after general medicine, surgery, and obstetrics, but before the specialties. With regard to the new compulsory year, a paediatric post might be suitable in the second half of this year, but not for the first six months.

Professor G. M. H. VEENEKLAAS (Netherlands) said that lectures should be given less frequently.

Dr. F. M. ROSE (U.K.) said that hospitals were reluctant to admit young children unless it was vitally necessary, or in cases where separation from the mother was not an important factor. Consequently, instruction in paediatrics

might be enriched by teaching on material from general practice where one encountered cases not normally admitted to hospital.

The Place of the Specialties

Dr. H. G. WEISKOTTEN (Chairman of Council on World Education and Hospitals, American Medical Association) said that practice in the specialties had become so popular that from 60 to 70% of the recent graduates of medical schools of the United States of America had been undertaking intensive graduate programmes and then limiting their practice to a specialty. Many were complaining that the graduates looking forward to general practice now received inadequate training in the specialties during their intern or residency period. This was particularly true with regard to their training in dermatology, which was said to be a subject they had to deal with in 15% or more of their patients. In the United States too little emphasis had been placed upon the educational value of out-patient clinics.

Dr. W. W. S. JOHNSTON (Australia) said that teachers in specialties should constantly keep in mind the necessity for a balanced view so that the subject concerned was properly related to general medicine as a whole.

Lieutenant-Colonel SANGHAM-LAL (India) thought there was a tendency nowadays for cases to be referred to specialists unnecessarily, but there was also a definite risk of patients being treated by their general practitioner for far too long before being referred to a specialist. Who was better qualified than a general physician to train students in knowing where to draw the line?

Dr. S. C. SEN (India), who said it was far more difficult to be a good general practitioner than a good specialist, felt that less importance should be given to the specialties.

Professor W. MELVILLE ARNOTT (U.K.), Professor E. HUSFELDT (Denmark), and Dr. F. M. ROSE (U.K.) also spoke.

Teaching of Tropical Medicine

Dr. L. E. NAPIER (formerly professor of tropical medicine, Calcutta) referred to the doctors who went to the war areas in 1939 and successive years and found they were ill-equipped because they had not got a sufficient grounding in tropical diseases as a result of their undergraduate training and experience in temperate climates. It was necessary in a contracting world for treatment of tropical diseases to form part of the curriculum.

Sir GEORGE MCROBERT (U.K.) emphasized the particular importance of students in temperate climates being taught the fundamentals of malaria and amoebic dysentery, and other speakers shared the view that it was necessary for students to be made familiar with general questions of tropical medicine.

The Intern Year

Sir DAVID CAMPBELL (President, General Medical Council) said that it was odd to find one of the subjects chosen for discussion at the Conference "Is an intern year necessary?" He thought that was settled. The idea of the intern year was very old. In connexion with the study of medicine at Salerno the Emperor Frederick II in 1221 decreed that no one should study medicine unless, *inter alia*, his five years' medical course had been followed by an additional year of practice under the supervision of an older practitioner. No doctor who had served an internship in a teaching hospital could fail to appreciate that he had had a vital educational experience. Among other advantages of making internship compulsory was the fact that it imposed fairly and squarely on the universities the duty of approving hospitals and posts and of keeping an eye on the nature of the training and experience to be had therein.

Dr. M. PRYWES (Israel) said that since an intern year had been made compulsory in his country the standard of medicine in hospitals there had been very substantially raised.

After the discussion on this subject the Section adjourned for the day.

Friday, August 28

The Undergraduate and General Practice

On Friday morning the first paper was one in which Professor A. L. RICHARD (University of Ottawa) introduced the subject of the undergraduate and general practice by giving a definition of the general practitioner. After listing certain requisites of knowledge and skill, he said that the general practitioner should always be able to do something for his patient, if it was only to have an insight into the probable developments of the patient's disorder. A large part of the success and usefulness of the general practitioner would depend upon the influence which he exerted upon his patients, the confidence which he infused, his power to explain, persuade, and inspire. These powers were more easily wielded by a man of general culture and education than by one who had had only training in the field of exact science.

Dr. E. A. GREGG (Chairman of Council, British Medical Association) said that there were many motives which led men and women into medical practice, but he thought there were still quite a few people who went into it with the desire of devoting themselves to the welfare of their fellow human beings, and that idea was well worth cultivating in the young student. The teaching of the family doctor should be *eminently practical*. Most emphasis should be laid upon his acquiring skill and ability in using his eyes and hands and in thinking while doing so. The main place in which a doctor learnt his work was not the medical school or the wards, but the out-patient department.

Dr. RICHARD SCOTT (University of Edinburgh) described a unit for teaching general practice which had been established in Edinburgh in 1948 in order to demonstrate the indivisibility of medicine and to illustrate the social aspects of health and sickness. The primary concern of this unit was not, he explained, vocational training for future general practitioners; rather, it provided an opportunity for senior students to be confronted with a patient-doctor situation which they could resolve only by integrating for themselves a great deal of what they had learnt elsewhere.

Other speakers were Dr. J. R. ELLIS (U.K.), Professor A. LAMACHE (France), Mr. R. W. HESLOP (British Medical Students' Association), Dr. J. CASTRO-VILLAGRANA (Mexico), and Drs. ST. GEORGE B. DELISLE GRAY, A. TALBOT ROGERS, and F. M. ROSE (U.K.).

The Balanced Curriculum

Sir HENRY COHEN (University of Liverpool) said that our overcrowded and confused curricula showed that we had vacillated between whether the aim of the undergraduate curriculum was to produce a good general practitioner or to lay the foundations of a medical career whatever branch of medicine was later to be followed. Spectacular discoveries in diagnosis and treatment had made increasing specialism in their techniques inevitable. Meningitis, pneumonia, malaria, subacute bacterial endocarditis, and diphtheria, to mention only a few infections, must be portrayed to-day in patterns which were unknown 20 years ago. The use of special procedures had enabled exploration by x rays into practically every crevice and cavity of the human body. With so vast an increase in the corpus of medical knowledge it might well be asked how could the doctor be any longer expected on qualifying to be an efficient practitioner of medicine, surgery, and midwifery. The undergraduate curriculum could not embrace the whole theory and practice of medicine; it could not attempt to teach the techniques required in the practice of specialties. It must limit its aim to laying the foundations of the doctor's training. Since medical knowledge was ever expanding, the undergraduate curriculum must favour the acquisition of enduring habits of work and thought and of enthusiasm for study, so that the doctor would remain a student throughout his professional life. The growth of knowledge in both medicine and in

educational methods meant that a curriculum could never be final; it was always moving to that end, but it never arrived.

Professor TOMIO OGATA (Japan) said that if medical students were taught only what was essential, fundamental, and necessary for their future activities, and nothing more, they would not feel satisfied. They should be informed—not necessarily taught—about certain phases of actual progress in medical science.

Dr. JOHN BURTON (U.K.) said that *doctor* meant *teacher*, and one of the sources of imbalance in most curricula was the fact that the student was regarded as an empty vessel into which knowledge had to be poured, and never as the doctor who had got to be the teacher of the future.

Professor PATRICK KIELY (Ireland) asked if they were not overemphasizing the itinerary which the student should carry in his pocket as against the ideology which he should have in his mind.

Dr. J. G. ORCOYEN (Spain) and Dr. L. BINBAYYA BIDYABHED (Thailand) also spoke in the discussion.

SECTION C: TECHNIQUES AND METHODS OF MEDICAL EDUCATION

Wednesday, August 26

The general theme in Section C was the techniques and methods of medical education. The Wednesday morning session was devoted to medical illustration, and many examples were shown of visual aids, the cinematograph film, and the still picture. Professor A. GARRETTON-SILVA (Chile) presided over this session.

Visual Aids in Education

Dr. P. N. CARDEW (St. Mary's Hospital) said that visual methods of education had in the past proved a controversial subject, especially when applied at university level of study. There had been a feeling that while they might be suitable for schoolchildren the written or spoken word was more dignified and appropriate for a learned profession. Yet many newly qualified doctors remembered the symptoms of a disease by visualizing a certain page of their favourite textbook. The visual memory was receptive and tenacious but could as easily be confused by poor illustration as stimulated by the expert use of visual symbols. Dr. Cardew described the varied uses to which lantern slides, still pictures, and motion pictures could be put.

Dr. KENNETH SODDY (World Federation for Mental Health) discussed the uses of the one-way observation screen. Its main value clinically was in the observation of the behaviour of young children, but, with the patient's consent, it had obvious uses in the field of psychological medicine.

The Moving Picture in Medical Education

Mr. RALPH P. CREER (American Medical Association) said that educational psychologists were of opinion that the rate of learning was based on experience; therefore one of the most effective methods of teaching was to provide direct experience or an adequate substitute. That was where the use of the motion picture came in, for many types of previously unobtainable experiences were now only as far away as the motion picture projector.

But, like other aids to teaching, motion pictures had their limitations. They placed a new responsibility on the teacher, for they involved special preparation and a new method of teaching.

The Still Picture

Professor TOM JONES (University of Illinois) discussed the group of visual teaching media referred to as still pictures. These included all forms of inanimate pictorial representations, from simple blackboard diagrams to full colour photographs and drawings. Still pictures were more widely used to-day in medical schools than either motion

pictures or three-dimensional material. It would be difficult to imagine anatomy, pathology, and surgery being effectively communicated without photographs and drawings.

Tracing the history of medical illustration, Professor Jones said that probably no single event had contributed so much to the advancement of medical knowledge as the basic discovery of photography with all that it implied. With the necessity of crowding into a curriculum all the material now considered necessary for the training of a physician or surgeon, newer methods of teaching had to be found. Language must always be the main stream of communication, but, to quote a report on the use of audio-visual aids in the U.S. Armed Services: "The concepts of more learning in less time, of greater retention, and of more realistic instruction have reinforced the contention that learning can be facilitated and made more meaningful through appeal to all the senses."

Among those who took part in the discussion or made comments on the examples shown were Professor G. P. MEREDITH, Professor ROBERT CRUICKSHANK, Mr. C. E. ENGEL, Dr. PATRICK COLLARD, Dr. PETER HANSELL, Dr. JOHN BURTON, Dr. ROBERT OLLERENSHAW, and Mr. A. B. GILMOUR, honorary secretary of the British Medical Students Association.

Thursday, August 27

The Lecture and Group Discussion

On Thursday morning, with Professor A. Hurtado in the chair, Professor G. P. MEREDITH (University of Leeds) discussed the art of lecturing and of organizing discussions. He listed three main reasons for the ineffectiveness of many lecturers: faulty delivery; the forcing of words to perform functions for which other media were more appropriate; the distribution of the lecturer's attention over too many techniques. The lecture was not the appropriate medium for the presentation of factual information. Its primary function was the communication of theoretical concepts. His impression was that in university teaching generally there were too many lectures. The effect of the lecture should be the establishment of a new concept or group of concepts in the mind of the student. On the other hand, the discussion group was adapted to exploring the implications of concepts and to answering all those questions which immediately arose in the mind when new concepts were grafted on to old knowledge.

Mr. K. H. McALLISTER (Further Education Organizer, Somerset County Council) said that group discussions ensured a flow of ideas. With the lecture it was often the bright members of the audience who were the pacemakers, and the teacher adjusted himself to their standard.

Professor IAN AIRD said that at a recent conference in London on the application of group methods in medicine a hundred medical teachers separated themselves into four groups, each with a non-medical educationalist to guide it. The technique was a little difficult at first, but it quickly became obvious that it might have a real and practical application to clinical medicine. Dr. JOHN BURTON (Director, Central Council for Health Education) said that the group discussion method had the advantage of putting the teacher in a position of finding out what his students really knew, what were the emotional barriers to their learning, and how he could adjust his teaching to their levels and concepts. Further, in a discussion group, a teacher was examining while he taught. Dr. VICTOR SORIANO (Uruguay) said that in his school the lecture and discussion group systems were combined, and the lectures always ended with questions. Professor S. S. MISRA (University of Lucknow) said that he had found that frank confession by the teacher that he could not answer a student's question did not diminish the teacher's prestige.

The Full-time Teacher

The full-time system of appointment to the teaching staff in the Faculty of Medicine, as followed at the University of Chicago, was described by Dr. L. T. COGGESHALL, dean of the Division of Biological Sciences in that university. The

physicians so appointed were free to follow their three major interests and responsibilities, namely, teaching, engaging in scientific research, and giving medical care, "without the limitations and distractions" generally imposed by private practice. The system had been successful in fulfilling the primary functions of a medical school, though the speaker admitted that such a system might not be universally applicable to the purposes of medical education.

Professor H. B. WULFF (Lund University) said that if doctors and money were available the full-time system was excellent, but it was a good thing, nevertheless, for many schools to have well-paid teachers, not full-time, but allowed a strictly limited private consulting practice.

Professor FELIX HURTADO (Cuba) said that the full-time system was inappropriate in his country because such a professor would be unduly limited in his experience of patients.

Dr. FRANK FREMONT-SMITH (New York) said that the main disadvantage of the full-time system was that it tended to isolate teachers from the realities of medical practice in the communities which surrounded their medical schools, and therefore there was a tendency for them to teach a practice which would be far removed from what most of their students encountered later in their career. Mr. D. H. PATEY (Middlesex Hospital) said that in England consultants got very good payment for the work they did under the National Health Service system, and therefore there was an opportunity for those connected with hospitals to devote their major energies to teaching and research. Professor E. HUSFELDT (Denmark) held that the university professor should have some private practice. Dr. M. POUMAILLOUX (Paris) said that a doctor who devoted the whole of his life to hospital practice and had no private practice had no normal conception of medicine as it was to-day.

The Place of the Textbook in Teaching

Professor MAURICE MULLER (University of Lille) said that the teaching of medicine could be divided into three parts: primary teaching leading to a doctorate, supplementary teaching enabling the doctor to keep his knowledge up to date, and higher education which led to hospital and university appointments. In each stage different textbooks were needed.

Professor J. E. DEBONO (University of Malta) said that he had no quarrel with textbooks in general, but he had some quarrel with the textbook—the book which the student considered to contain all necessary knowledge. This was a snare and a delusion. Textbooks were not meant to be read right through, but to be dipped into. Professor H. WENDEROTH (Germany) and Professor J. N. P. DAVIES (Uganda) also spoke.

Library and Reference Services

Lieutenant-Colonel FRANK B. ROGERS, director of the Armed Forces Medical Library, Washington, discussed the value of library and reference services in undergraduate medical education. He said that in the United States more than half the schools gave instruction in the use of the library and in bibliographical methods. The librarian could show the student that there were better ways of finding material than by paging aimlessly through volume after volume of likely journal titles.

Mr. C. C. BARNARD (Librarian, London School of Hygiene and Tropical Medicine) said that the library should be an integral part of a school and the librarian a member of the teaching staff. He outlined a scheme which was in operation at his school consisting of three lectures on library usage, with demonstrations on the use of the catalogue.

Professor JOHN F. FULTON (Yale) emphasized the importance of the library in medical school curriculum. Dr. F. A. SONDERVORST (University of Louvain) raised the question of the relative value of central and departmental libraries. He found that students preferred scattered local libraries, each dealing with different branches of study in the various departments of the university. Dr. H. E. MACDERMOT (Editor,

Canadian Medical Association Journal) referred to the Osler library—not a memorial library but Osler's own library—in Montreal. This was of great interest to students and other visitors, to whom it was shown by a man who knew it intimately. Professor J. N. P. DAVIES (Uganda) spoke of the need for creating in the library a pleasant atmosphere, with good lighting, comfortable chairs, and works other than medicine. The library should be open for very long periods, and located conveniently to the medical school.

The Medical Museum

Dr. C. J. HACKETT, Director of the Wellcome Museum of Medical Science in London, spoke of the role of teaching museums in undergraduate education. The contents of such museums should be broadened to include all aspects of medicine. Specimens of pathological conditions, parasites, drugs, and the like, and illustrations and diagrams should be brought together with carefully prepared summaries so that the student might see a disease as a whole, from cause to prevention. He suggested the establishment of a Medical Museums Bureau on a national or international basis for the dissemination of information on museum techniques and for originating and exchanging illustrative material and specimens.

Professor E. F. D'ATH (University of Otago, N.Z.) said that most of the teaching medical museums were in the main pathological museums, having been developed as adjuncts to the teaching of pathology. With the co-operation of other teaching departments the museum could be broadened in scope and made more attractive.

Professor M. MARTINEZ-BAEZ (Mexico), Dr. B. CASTLEMAN (Massachusetts General Hospital, Boston), Professor TOM JONES (University of Illinois), Miss SYLVIA TREADGOLD (Guy's Hospital), and Dr. LEWIS (South Africa) also joined in the discussion.

Teaching the Teacher

Dr. R. D. LAWRENCE (King's College Hospital) said that some attention had been paid in recent years to the question of the selection and training of the teacher, but there had been almost nothing done in this country to ensure that teachers of medicine could teach or to help them if they could not. Teachers of medicine were chosen on account of various qualities and achievements, but not for their teaching ability. Training in teaching did not exist. It was sometimes said that good teachers were born and not made. That was an axiom in which he did not believe. The teacher should have a ready flow of words, a capacity for logical arrangement, and an ability to keep what he taught at the student level. He must also have a character and personality which interested the students, and be able to tease them and laugh with them. Dr. Lawrence referred to the deplorable diction and delivery of many lecturers, and suggested week-end courses for teaching teachers to teach.

In the course of a brief discussion Professor IAN AIRD mentioned an experiment which was being tried out in London whereby it was proposed to give certain men exercises in lecturing and bedside teaching. Dr. F. FREMONT-SMITH (New York) said that the teacher-pupil relationship was analogous to the parent-child relationship, and must be a two-way process of communication. Dr. W. HOWARD HUGHES (United Kingdom) suggested that the schools of the future which produced the finest teachers would be those which had the best extra-curriculum activities, including sport and dramatic societies.

Friday, August 28

The Examination Paper

The final session in Section C began with a discussion on the examination paper.

Professor IAN AIRD (University of London) said that practical examinations in medicine were, to his mind, too short and hurried, and the examination paper might well be used as a sieve or filter to reduce the number of candidates presenting in the practical examinations.

"After having read many thousands of examination papers, I feel competent, not to say whether the writer of the examination paper was a good doctor, but often to say quite confidently, on the result of the written examination alone, that a candidate should not be allowed to practise medicine. If a candidate proved himself in the written examination to be in error on a number of important facts, or not to be provided with a satisfactory number of facts on a given subject, or if he proved to lack understanding of an essential pathological or therapeutic process, that candidate should, on the result of the written examination alone, be rejected, and not present himself for the other parts of the examination. This would allow a longer time than at present available for the practical, oral, and clinical examination of doubtful candidates."

Professor MUNAWAR ALI, President-elect of the Pakistan Medical Association, considered that undue importance was given to the examination paper. The insistence on 50% marks in each component of the examination to avoid failure was unsound in principle. The type of question in vogue at present should be replaced by questions that could be answered on the basis of a general knowledge of medicine gained by the students through their clinical observation and study of patients, not merely on the strength of the cramming of textbooks.

Dr. J. L. TROUPIN (World Health Organization) said that in dealing with his students at examinations he had told them that they were at liberty to bring any textbooks or notebooks they wanted, and to make any inquiries, even over the telephone. The students thought it a jest, but they invariably said that they preferred an examination where they did not have books and could use only what they had learned.

Professor BEATRICE JOLY (University of Ibadan, Nigeria) suggested that the final examination might be regarded as a useful method of evaluating teaching and teaching ability as well as student proficiency. The examination papers in any particular subject should be available to the senior members of the department, by whom they should be assessed very carefully with a view to criticizing the teaching which had contributed to the examination results.

Others who made brief comments were Dr. S. S. MISRA (India), Professor F. AKKRAWI (Bagdad), and Professor M. D. PENAS (Philippines).

Practical and Oral Tests

Professor A. GARRETON-SILVA (University of Chile) discussed methods of testing the degree of knowledge acquired by the student. Some of these methods were of a general character, common to all subjects; others were of a special character. In the preclinical period the criterion of progress was the laboratory work done by the students under the vigilance of the professor and his teaching staff. In the clinical period the best criterion was the care of a patient by the student together with the professor, but here it was essential that the student should share the responsibility for such care.

Dr. R. A. MOORE (Washington University) described a multiple-choice examination which was gaining favour in the United States. This meant putting questions to the students and suggesting a number of answers, one, or perhaps more, of which was correct, and the student was asked to say which in his view was the proper answer. The answers were graded electronically so that no error on the part of the assessor came in. He also described a method of comparing one school with another, taking a mean for all the students.

Why Students Fail

Mr. T. R. HENN, Senior Tutor, St. Catherine's College, Cambridge, in a thoughtful paper, discussed the reasons for student failure. He was inclined to think that any one of more of a number of possible "traumatic" conditions, fostered by the strain of the social and intellectual life of a university, were finally brought to a head, as it were, in a false attitude to the university, to the examination, and the final degree which the examination represented. Those of them who were concerned with the universities could do much to ensure that only intellectually suitable students were admitted, though it was seldom possible to investigate psychiatrically a likely predisposition to a breakdown, nor

would it be advisable to attempt anything of the kind. And who would dare to exclude a potential Shelley or Baudelaire? What conflicts would analysis have revealed in John Donne or Milton? What was possible was to develop in teachers and students a sane attitude to all examinations. Mr. Henn went on to speak of ways in which examinations and the preparation for them could be set in a fairer perspective.

Touching on suicides among university students, Mr. Henn said that the incidence at the older universities in this country was higher than at the younger, probably reflecting the higher standard of entry and of examination, and perhaps the different rhythm of living. Sexual disturbances were not, in his experience, an important cause of failure.

A student, Mr. A. P. OOMEN (Netherlands), said that the relation between medical students and their teachers should not be just the same as that which existed between other students and their teachers—that is to say, that the teachers gave of their wisdom and knowledge and the students just took it in. The making of good doctors was not, in the first instance, a question of absorbing knowledge, but of developing a wiser, better, and more understanding man.

Professor D. E. CAMERON (McGill University) mentioned some of the reasons why students failed. One of the reasons was the development of neurotic or even psychotic difficulties. There was the student who "blew up" in an anxiety state at examinations. What guarantee was there that he would not "blow up" later on at an operation or a delivery? There were students who showed a major change in motivation during the course of their studies, perhaps as a result of marriage and a wife who discouraged them from pursuing a medical career. Again, the woman student had a most confusing role to play. She had to compete with and act like a man, and was often prevented from participating, as her sisters could, in social life. An unusual number of problems arose in the case of the woman student.

The discussion was continued by Professor AKKRAWI (Bagdad), Professor E. ASK-UPMARK (Sweden), and Professor VICTOR SORIANO (Uruguay).

SECTION D: PREVENTIVE AND SOCIAL MEDICINE

Wednesday, August 26

In Section D, under the presidency of Professor A. STAMPAR, the discussion was continued on preventive and social medicine.

The Teaching of Epidemiology

Professor THOMAS FRANCIS (University of Michigan) opened the proceedings with a paper on the teaching of epidemiology. He suggested that epidemiology should be introduced into the curriculum as a study of pathogenesis: ideally, the teaching of epidemiology should permeate all phases of medicine which related to pathogenesis and its applications. Of one thing he was sure, that the more epidemiology was recognized as and believed by the instructors to be an integral part of medicine and medical research rather than some esoteric or merely intellectual activity the greater its effectiveness would be.

Dr. J. WICKSTRÖM (Finland) said that the importance of epidemiology was little acknowledged in practice. At none of the ten medical schools in the Scandinavian countries was there a professorship of epidemiology; lecturers were in charge of the instruction, and one could not expect an adequate competence in education where such a system prevailed.

Professor ROBERT CRUICKSHANK (St. Mary's) said that there were three main avenues along which medicine had made progress—namely, laboratory experiment, clinical signs, and the epidemiological method. Only in recent years had it been realized how applicable the epidemiological method was to a whole variety of diseases. There was the danger of mistaking applied bacteriology for fundamental principles. A great deal was taught about the modern methods which

the laboratory used, but this did not constitute the teaching of epidemiology, which was essentially the pathogenesis of disease in the community. He outlined the teaching of preventive medicine at St. Mary's.

Professor P. BONNEVIE (Copenhagen) said that epidemiology was a part of hygiene, which was concerned chiefly with the environment and the action and attitude of man towards it. Dr. P. S. WOODRUFF (Adelaide) emphasized the importance of the student's participation in epidemiological studies. Professor STAMPAR did not consider that there should be special chairs in epidemiology; the subject should be included in hygiene and social medicine.

Demography and Vital Statistics

Professor AXEL STRØM (Oslo) discussed the teaching of demography and vital statistics. Seminars and colloquies were the methods best suited for teaching these subjects. Lectures were, in his opinion, less valuable.

Dr. PETER PAU (Trinidad) said that he had found an acquaintance with games of chance a useful introduction to statistics in the teaching of students. He had also enjoined his students to study crowds, as at football matches, in order to familiarize themselves with the notion of epidemic disease.

Professor STAMPAR mentioned that as an examiner he had been struck by the fact that many students were quite unable to state the population of their own town or county or the birth and death rates.

Teaching of Medical Genetics

Dr. J. A. FRASER ROBERTS (Stoke Park Colony, Bristol) contributed a paper on the teaching of medical genetics, a knowledge of which, he said, was of practical importance in learning and practising medicine. Instruction should not be postponed to postgraduate courses, and the genetics taught in connexion with biology should be supplemented by teaching on medical genetics during the clinical years. Five or six systematic lectures should suffice.

Dr. M. POUMAILLOUX (Paris) read a short contribution to the discussion sent by Professor M. LAMY, of Paris. In France, in the introductory year, during which the natural sciences were taken, twenty lectures were devoted to animal genetics, but until the recent establishment of a chair in medical genetics at Paris (of which Professor Lamy is the holder) there was no teaching in genetics from the human point of view.

Dr. J. B. JEPSON (Middlesex Hospital) emphasized the contribution which the course in chemistry given in medical schools should make to the teaching of medical genetics and of social medicine. The occurrence and importance of variation, genetical and otherwise, could be readily demonstrated as part of the course in chemistry and biochemistry, and it was here, in the first instance, that it should be emphasized as an important factor in clinical and social medicine.

Thursday, August 27

Social Psychiatry

The proceedings on Thursday began with a paper by Professor H. C. RUMKE (University of Utrecht) on the teaching of social psychiatry. Such teaching, he said, should be part of the whole teaching of medicine. Social psychiatry was not a matter only for the student who intended to be a psychiatrist or a specialist in mental health, but also for those who wished to be general practitioners. The more the general practitioner knew about social psychiatry the higher his standing would be. The speaker gave a survey of the teaching of the subject in his own university.

Dr. J. L. HALLIDAY (Department of Health for Scotland) said that there was widespread failure to appreciate the psychology of and social approach to sickness, and to understand what action of a therapeutic or preventive kind such an approach indicated. When the enormous mass of recurrent illness and chronic invalidism was realized it was evident that psycho-social medicine—a term he preferred to

"social psychiatry," which was too exclusive—needed to be incorporated in the curriculum.

Dr. PETER PAU (Trinidad) described some of the difficulties of social medicine in the West Indies, the tracing of family patterns, and the ascertainment of taboos. Professor W. G. SMILLIE (Cornell University) mentioned the useful findings obtainable through the students' health service. Illness among students was often the result of emotional stress. By enabling the student to understand himself and his fellow students he was the better equipped to understand his future patients. Dr. R. SUTHERLAND (Leeds) said that it was often difficult to elicit the underlying tensions in an interview with the patient, and here he had found a use for the tape recorder.

Social Environment and Individual Illness

Professor A. QUERIDO (University of Amsterdam) said that, notwithstanding the development of technical methods and the attention these received in teaching, the individual patient with his complaints and symptoms was the pivot of all true clinical instruction in the art and science of medicine. How could the social factors which had contributed to the illness of a patient be assessed in clinical teaching? And how could the social factors which might assist the patient's recovery be properly evaluated? It was a problem of integrating social data in the same way as the data resulting from x-ray or pathological investigation were integrated. But what specialist was to do this integration? Was the social worker or almoner comparable with the radiologist or pathologist? He was doubtful whether the social worker could bring the teaching up to the standards of medical education.

Professor YOSHIO KUSAMA (Keio Gijuku University, Tokyo) said that when his department in his school of medicine was organized in 1928 it was called "preventive medicine." To-day it was called "hygiene and public health." The public health discipline for undergraduate medical students in his country was not markedly different from what it was in others.

Home Setting in Medical Education

Dr. J. M. FAULKNER (Boston University School of Medicine) described a programme devised at his university which brought students into direct participation in the care of patients in their homes. The programme was organized as the home medical service, which was a division of the Department of Preventive Medicine. This service was an extension of the out-patient department of the Massachusetts Memorial Hospital. It provided medical care in the home for the indigent in a circumscribed area of Boston immediately surrounding the hospital; this was a slum district, with a population of about 50,000. Fourth-year students were assigned to the service, full time, for one month. In addition each third-year student was assigned a patient from the service whom he followed for two years. About 15,000 visits were made annually to about 5,000 patients, 85% of whom were treated at home.

Professor MARCEL GRAFFAR (University of Brussels) said that at the end of the war his university decided to set up a chair of social medicine as distinct from the chair of hygiene. Of this chair the late Professor Sand had been the first titular holder. The co-existence of the two chairs had been entirely successful, and each professor had co-operated with the other. Professor Sand had realized the need for complementing theoretical instruction by practical exercises, and since 1947 the students in their penultimate year had been sent out into the field to study social problems and to make routine reports on their observations.

Among others who took part in this discussion were Dr. JOHN PEMBERTON (University of Sheffield), Dr. E. M. DIMOCK (University College Hospital), Dr. K. NELSON (Richmond, Virginia), Dr. JULES P. DE MELLO (Nairobi), and Dr. DAG KNUTSON (Stockholm).

Professor STAMPAR said that in Zagreb the students were expected to go out in groups to the villages.

Teaching of Occupational Health

Professor A. J. LANZA (Department of Industrial Medicine, New York University Postgraduate Medical School) mentioned the difficulties which had attended efforts to introduce industrial medicine into the undergraduate curriculum. It might well be that before this was achieved the scheme of medical school education would have to be reshaped. In the meantime they kept on trying to establish their "beachhead" in the third or fourth year classes.

Dr. RICHARD SCHILLING (Nuffield Department of Occupational Health, University of Manchester) pleaded for the integration of all the specialties bearing on this subject. One of the great factors encountered in occupational health was the unwillingness of many workers to place themselves under medical care owing to their fear of being deprived of their employment. The teaching of occupational health should be an integral part, with social medicine, of all clinical teaching, and was most effectively given by clinicians.

Professor P. BONNEVIE (University of Copenhagen), Professor THOMAS FRANCIS (University of Michigan), Dr. J. J. GILLON (Medical Inspector-General of Industry in France), and the Chairman (Professor STAMPAR) took part in the discussion.

Student Health Services

Sir ALAN ROOK, senior health officer, Cambridge University, suggested some ways in which use could be made of the student health service for giving practical tuition. One way would be for the instruction of medical students in immunological procedures. Mantoux testing and B.C.G. vaccination of the students themselves, at present done by student health officers, could be used for teaching. He indicated various other ways in which the student health service could be used for the dissemination of knowledge of social and personal hygiene.

Dr. P. S. WOODRUFF described the student health services in Adelaide, and Dr. PETER PAU (Trinidad) those obtaining in the West Indies.

Infant and Child Care

Dr. MARIJ AVCIN (Yugoslavia) opened a brief debate on infant and child care as a medico-social problem.

Professor JOHN CRAIG (University of Aberdeen) said that both the teaching of social medicine and researches into social conditions were becoming more difficult because the more obvious environmental diseases in this country occurred less often. But many questions remained without an answer.

Every student should spend at least a month with a family doctor on his rounds, getting some insight into conditions in the homes of the people. Ward and out-patient work, visits to families in their homes, attendance at child welfare and aftercare clinics, were all useful teaching agencies for medico-social knowledge. Most helpful of all was the teacher himself. Each teacher should strive, therefore, to know his own region intimately, its history and geography, its climate and diseases, its culture and its social problems.

Dr. ROBERT SUTHERLAND said that health education should start with paediatrics, and Dr. MCLENNAN quoted the advice of a paediatric teacher to his students: "Never believe a word the mother says."

Friday, August 28

The Teaching of Nutrition

The first address in the closing session of the Section was by Dr. H. M. SINCLAIR (Oxford) on the teaching of nutrition. The emphasis on nutrition in the preservation of health, he said, was by no means new—witness the teaching in the school of Salerno in the twelfth century. The best method of stimulating an interest in nutrition was probably not by postgraduate study but by a year's research at the

end of the training in physiology and biochemistry. This period of research had proved very valuable at Oxford, where the degree of B.Sc. was available for it.

Mr. HARRY LILLIE (Scotland), Dr. PETER PAU (Trinidad), Dr. DAG KNUTSON (Stockholm), and Dr. ROBERT SUTHERLAND also took part in the discussion.

Housing in Relation to Health

The Section then turned to the housing question, on which there was a paper by Professor J. M. MACKINTOSH (London School of Hygiene and Tropical Medicine). Instruction to the medical student concerning housing should be given in such a way as to stir the student's interest and imagination, and should be related to health and sickness. The primary aim in teaching undergraduates about housing conditions should be to illustrate by example the ill effects, both mental and physical, of bad housing. The best approach was the historical one: the student should be shown by illustration and subsequent visiting what slums were and how they had grown and the methods by which they could be eliminated. The discussion took the form of statements about housing conditions in several countries, particularly in the East.

Integration of Preventive and Social Medicine

The final paper was on the integration of the teaching of social medicine and preventive medicine in the curriculum. Professor J. P. HUBBARD (University of Pennsylvania) said that social medicine was not a separate discipline with a discrete body of knowledge; rather it was an attitude which permeated the entire medical curriculum. It was founded in the basic sciences and in clinical medicine; it drew also upon the social sciences, and in its application called for a health team which included not only the practising physician and the health officer but also the visiting nurse, the social worker, and many others with specialized skills.

Professor STAMPAR, from the chair of the Section, in closing the proceedings, said that he himself had learned a great deal from the many original contributions which had been given, and it was evident that social and preventive medicine was gaining ground in the education of the medical student.

CONCLUDING PLENARY SESSION AND CLOSING PROCEEDINGS

After the four Sections had finished their work the Conference assembled in plenary session on Friday afternoon and Saturday morning, August 28 and 29. Sir LIONEL WHITBY, the Conference President, was in the chair during Friday afternoon, and Professor W. MELVILLE ARNOTT, the Deputy President, presided on Saturday, when Sir Lionel Whitby had to leave for Canada. At these concluding sessions the four Sectional vice-presidents, Dr. Victor Johnson, Sir A. L. Mudaliar, Professor A. Hurtado, and Professor A. Stampar, addressed the Conference, and they were followed by the rapporteurs, Dr. Raymond Whitehead (Section A), Dr. A. Morgan Jones (Section B), Professor Ian Aird (Section C), and Dr. Charles Fletcher (Section D). Each rapporteur summarized the work of his Section and there was then a general discussion on it. Some comment on the remarks of the vice-presidents and rapporteurs is given in a leading article at p. 549, but a full report of their speeches will be given in next week's *Journal*.

During this session the President referred to the death of Dr. René Sand, who was to have presided over Section D, and the Conference stood for a few moments in silent tribute. An obituary notice is printed at p. 571.

Closing Proceedings

On the last day of the Conference, after the final discussion, Professor Melville Arnott said from the chair that there was no doubt whatsoever that the Conference had been very well worth while. He was quite sure that nobody was happy or complacent about medical education, and the

Conference had caused—and would continue to cause—much earnest thinking. But he hoped it would be remembered that plans could never triumph over individuals, and that they would not be hypnotized into too much planning.

Dr. T. C. ROUTLEY, chairman of the Organizing Committee, said that Dr. E. Grey Turner, the indefatigable secretary of the Local Arrangements Committee, had informed him that the entire proceedings had been recorded on 200,000 feet of magnetic wire. But the really permanent record would be in the minds of those who had attended. It was just three years ago that Dr. Hugh Clegg brought forward the idea of this World Conference. The idea "took legs," but the "legs" had new roads to traverse and no road maps to guide them. The result, however, had more than justified the labours entailed. He acknowledged with the sincerest appreciation all who had assisted—the World Health Organization, and the collaborating bodies, the Council for International Organizations of the Medical Sciences and the International Association of Universities; the industrial corporations who had made substantial gifts; the authors of the papers; the interpreters who had rendered excellent service; the Society of Friends, in whose house most of the meetings had been held; the host organization, the British Medical Association and its officers and employees, who had given the most unselfish service; the officers of the Conference, its vice-presidents and rapporteurs, and those who had entertained the members at a succession of social events. He also expressed gratitude for the service, continuing through the years and emphasized in the present Conference, of the secretary-general, Dr. Louis Bauer, and his executive assistant, Miss M. L. Natwick, and finally for the work of Dr. Hugh Clegg, secretary of the Programme Committee, who would continue to labour in the preparation of the published proceedings.

The meeting by prolonged applause endorsed Dr. Routley's remarks, and the Conference then terminated.

SOCIAL OCCASIONS

As host organization to the First World Conference on Medical Education the British Medical Association led off the round of receptions and visits with a reception at B.M.A. House on August 22. The Great Hall was filled with a gathering of delegates from all over the world, many of them accompanied by their wives and families. The guests, who numbered nearly 500, were received by the President of the B.M.A., Mr. J. W. Tudor Thomas, and Mrs. Tudor Thomas, and by the Chairman of Council, Dr. E. A. Gregg, and Miss M. Gregg. On Sunday, August 23, there was an excursion to Cambridge, where the visitors had lunch in Trinity College and tea at Downing, where Sir Lionel and Lady Whitby were the hosts. During the week the Conference was in session receptions were given by the Government, the Royal Society of Medicine, the University of London, the London County Council, and the Ciba Foundation. There was also a sherry party at B.M.A. House given by the Medical Women's Federation to medical women from overseas. On the afternoon of August 25, when the delegates had a half-holiday, there was a river trip down the Thames to Greenwich. At the Conference Banquet on August 28, held at the Dorchester Hotel, Sir Lionel Whitby was in the chair. Sir A. L. Mudaliar gave the toast to the World Medical Association, and this was seconded by Dr. M. Poumailloux. The response was made by the secretary-general, Dr. Louis H. Bauer, who said that he believed the doctors of the world had done more to improve international relations than all the diplomats put together. Dr. Dag Knutson proposed the health of the guests, and Miss P. Hornsby Smith, Parliamentary Secretary to the Ministry of Health, replied. In congratulating the organizers she said that few conferences had commanded the substantial and responsible editorial comment which the First World Conference of Medical Education had achieved. Professor A. Hurtado proposed the toast to the president, and Sir Lionel Whitby made a brief response.

AIDS FOR THE DISABLED

[BY A SPECIAL CORRESPONDENT]

Among the attractions at the first International Congress of the World Confederation for Physical Therapy, which opens at the Central Hall, Westminster, on September 7, is an exhibition of self-help devices, splints, and gadgets for the disabled. The exhibition remains open until September

FIG. 1

widely known, deserve special notice as they are so useful, so simple, and so highly valued by the patients who need them.

The American Physical Therapy Association is exhibiting a collection of aids selected from the many which have been developed in the United States. They include devices to help various types of cripple with the activities of daily living, such as dressing and undressing, toilet, eating, communication, getting about the house, and doing housework. A gadget seems to have been devised to overcome every rehabilitation obstacle.

FIG. 2

12, and it should prove of great practical value to anyone responsible for the care of disabled persons. The exhibits have come from the United States, Canada, and South Africa, as well as from many parts of Britain. It is possible to describe only a few of them here.

The British Red Cross is showing several gadgets and adaptations for the home-bound cripple. The padded eating utensils and the long-handled toilet aids (Fig. 1), although already

There are several exhibits from the Canadian Physiotherapy Association. From the Physiotherapy Department of Ottawa Civic Hospital there is a detailed description of an adaptable bed which can be tilted to 85° by a jacking system to allow a patient to put his feet to the ground and stand up without effort. The bed appears to be sturdy and easily constructed. Other exhibits are splints adapted to take attachments when there is complete loss of control of wrist and hand and an adjustable chair for cerebral palsy patients. Another chair shown by the Canadian Physiotherapy Association is most ingenious (Fig. 2). It consists of a framework on wheels with two overhead bars whose height can be raised on a ratchet. The patient is wheeled underneath the bars, from which shoulder straps are attached to large comfortable axillary pads. The patient is then wound up to standing height, in which position walking re-education can be begun, with no fear of falling.

From the Royal Victoria Infirmary, Newcastle-upon-Tyne, there is a simple device for the retraining of plantar flexion in cases of fractured calcaneus. There are some examples of Mr. Norman Capener's (Exeter) "lively" splints. Each splint is made to suit the individual problem. Its object is to allow both physiological rest and an appropriate amount of function. There is no doubt that similar

splints could be more widely used. The Central Council for the Care of Cripples is showing gadgets to assist crippled housewives do their housework and manage their kitchens. Mr. H. A. Turnbull, M.C.S.P., has sent details of a crutch attachment (Fig. 3) for use by a patient who needs a crutch but cannot control one because of insufficient grip in the hand. This should prove useful in the right case.

Other exhibitors include the World Veterans Association, the Chartered Society of Physiotherapists, and the Association of Occupational Therapists, as well as departments of physical medicine and individual doctors and physiotherapists.

The exhibition demonstrates very clearly how self-help devices have developed along similar lines in different countries and at different centres. On the other side of the Atlantic there seems to be a tendency to encourage the use of aids at an earlier stage than in Britain; perhaps economic pressure demands this. At all events the Americans certainly lead in this field, especially where a complicated gadget is needed.

It may be hoped that the exhibition will stimulate the production of a comprehensive catalogue of self-help devices. This is badly needed, as at present information about them is widely scattered and certainly not easily available to the general practitioner.

FIG. 3

Correspondence

Because of the present high cost of producing the Journal, and the great pressure on our space, correspondents are asked to keep their letters short.

Vitamin A in Bread

SIR,—Without wishing to involve you or myself in a discussion on the relative merits of "white" (that is, low extraction) and "brown" (that is, high extraction) bread, I venture to ask you not to perpetuate the long since disproved error that wheat flour contains any vitamin A. You do this in the annotation under the above heading (*Journal*, August 15, p. 385) when you say that "the processing of white flour" removes "practically all the vitamin A." Anyhow, it would be carotene in one or other of its biologically active forms, and not vitamin A, that would be present in purely vegetable material, but it was shown by Zechmeister and Cholnoky¹ more than twelve years ago that none of the carotenoids in wheat was identical with any of those known to have biological (vitamin A) activity, of which much the most important is β -carotene.

The carotenoids in vegetable and animal tissues are closely associated with, or actually dissolved in, the fatty material present; in wheat this is, for all practical purposes, confined to the germ and is the wheat-germ oil. The carotenoids of this oil were submitted by Zechmeister and Cholnoky to careful chromatographic fractionation and found to contain practically nothing but xanthophyll, which is devoid of all vitamin A action.

Readers who wish to check my authority for these statements can do so in any standard book on the carotenoids, such as that by Karrer and Jucker, translated by Braude.² They will find that these authors give the natural sources of different carotenoids. The sources given for α -carotene, β -carotene, γ -carotene, and cryptoxanthin, the only four biologically active carotenoids of importance, do not include wheat.

You, Sir, will, I am sure, support me in the view that it is especially wise to have one's facts right when discussing matters, such as the colour of bread, that seem to arouse irrelevant emotions.—I am, etc.,

Greenford, Middlesex.

A. L. BACHARACH.

Gas Flows in Anaesthesia

SIR,—The article by Drs. G. Herington and E. James (*Journal*, August 8, p. 317) brings me to the point of making the following observations which, though they can scarcely be original, I have not yet seen anywhere in print.

It is common to read the statement in anaesthetic literature that anaesthesia was maintained with nitrous oxide-oxygen in the ratio 2:1 or 3:1, but generally no mention is made of the rates of flow of the gases. One assumes that the patient is intended to breathe a 3:1 mixture from the reservoir bag, but probably it was in fact the readings of the nitrous oxide and oxygen flowmeters which were in the ratio of 3:1, and this is not by any means the same thing. The larger the gas flows the closer does the ratio of the percentages of the gases in the bag approach that of the flowmeter readings. But with small flows, as used in closed-circuit-with-a-leak systems, this may be far from being so, because oxygen is metabolized at a variable rate and disappears from the system into the soda lime canister as carbon dioxide, whereas nitrous oxide, being inert, circulates continuously once equilibrium has been attained.

Now in the case in point nitrous oxide-oxygen anaesthesia was continued when "saturation with nitrous oxide was considered adequate . . . with 1 l. of nitrous oxide to approximately 300 ml. of oxygen . . .", which is a ratio of approxi-

mately 3:1. Assuming in this case a basal oxygen consumption of 200 ml./min., and equilibrium to be complete, the bag mixture would settle at 1,000/(300-200) or 10/1=9.1% O₂. Were the basal oxygen utilization only 50 ml. greater the ratio becomes 20/1=<5% O₂. To obtain an oxygen percentage equal to that of air requires either that the oxygen flow must be raised to 450 ml./min. (in this case), or that nitrous oxide be retained by the patient at the rate of 600 ml./min., which will only occur in the initial period of the anaesthesia. Doubling the flow rates to 2 l./min. and 600 ml./min. respectively, while leaving the ratio of flowmeter readings unchanged, raises the oxygen content of the bag mixture from 9.1% to 16.8%.

In practice, of course, one can only guess the oxygen consumption of a patient on the table. Thus it seems to me that in all cases it is important to note the actual rates of flow of the gases rather than the percentage of gases that the anaesthetist intended to administer.—I am, etc.,

Pewsey, Wilts.

J. C. AINLEY-WALKER.

The Pain of Transurethral Manipulations

SIR,—I agree with your correspondent Dr. E. C. Atkinson (*Journal*, August 22, p. 440) that transurethral manipulations are extremely painful and distressing without adequate anaesthesia. Many years ago I came to the conclusion that in the male procaine and cinchocaine were very inadequate, and consequently whenever possible I used a general anaesthetic or a low spinal.

However, this has been changed by the introduction of lignocaine hydrochloride ("xylocaine"). A 2% solution kept in the urethra for 15 minutes gives a very satisfactory degree of anaesthesia. I now find it necessary to use a general anaesthetic only when I am treating by diathermy a growth or dealing with a nervous patient.—I am, etc.,

Ballygally, Co. Antrim.

H. CALVERT DALES.

Generalized Actinomycosis with Possible Cardiac Involvement

SIR,—We thank Dr. Kevin Anderson (*Journal*, August 8, p. 340) for pointing out that *Actinomyces bovis* does not form spores. Nor, may we add, does it grow aerobically in normal methods of blood culture—that is why the spore-bearer grown aerobically was rejected.

We regret that our final generalization was argued to the particular, although we maintain that the principle put forward in our final paragraph still holds good.—We are, etc.,

RONALD S. SAVIDGE.

DONALD M. DAVIES.

Bury.

Appendix in the Hernial Sac

SIR,—I should like to submit the following details of an uncommon case.

A healthy labourer, aged 62, was admitted to hospital on July 14, 1953, complaining of a large tender lump in his right groin. He had had bilateral herniae for 20 years controlled by an adder-headed truss. Some months previous to his admission he noticed the right side swell and "come down" but he did not bother to do anything about it in the way of medical treatment. Three days prior to admission he felt pain and tenderness which made him stop work and go to his doctor. On examination a lump 4½ by 3 in. (11 by 7.5 cm.) was found in the right groin in the position of the external ring. The skin over it was reddened and warm. The swelling was firm and it was impossible to get above it; there was an impulse on coughing and it was irreducible; it did not extend into the scrotum. The left external ring was weak and there was a cough impulse, but no visible lump. Bowel habits were normal and at no time had there been vomiting or abdominal pain.

The case was diagnosed as an irreducible right-sided hernia, probably omentocoele and non-obstructed. At operation there was a large hernial sac which contained a gangrenous, grey-green coloured appendix, 7 in. (17.5 cm.) long. It was hard and contained several faecoliths. It was traced as far as the caecum, which was lying in the neck of the sac, and there ligated and excised in the routine manner. The sac was also ligated

and excised, but no formal repair was carried out in view of the infected contents. The subsequent convalescence of the patient was uneventful and he was discharged home on July 28.

I have questioned several people, and, while they assure me they have heard of the occurrence, none can say they have seen such a case at operation. It would be interesting to know the frequency of the condition. I am grateful to Mr. J. A. O'Connell for his permission to publish the facts of the case and his help in the drafting of this letter.—I am, etc.,

Mullingar, Eire.

T. E. WINCKWORTH.

A Visual Aid

SIR,—When I first studied neuro-anatomy as an undergraduate I found that I had become acquainted with various cross-sections of the brain and brainstem—but I had difficulty in visualizing these sections in relation to one another and especially in relation to the nervous tracts.

The photograph shows a model I have made which illustrates the pyramidal system in an attempt to clarify the formation of the internal capsule and the subsequent distribution of its crossed and uncrossed fibres. In this way, for example, it becomes more or less straightforward to show why the fibres from the lower part of the motor area must occupy the anterior position in the genu and thereafter lie medial to the remainder of the pyramidal tract in the midbrain. I feel that once the elementary conception of the inter-

relationship of the structures is grasped it becomes easier to know what one is looking for in the dissecting-room, and I venture to suggest that such a model would have cleared up many of the initial difficulties I encountered. Comments on its teaching value would be welcomed.

This model, in which coloured threads distinguish the various subdivisions of the pyramidal tract, was made with the help of my orderly, Bdr. J. Shaw, to whom my thanks are due.—I am, etc.,

Newcastle-upon-Tyne.

J. G. COLLEE.

Spectacles

SIR,—I read with great interest Mr. J. H. Doggart's able review on spectacles (*Journal*, August 15, p. 388). I had feared that the art of spectacle prescribing was being relegated to the status of a merely technical accomplishment, and I derived much satisfaction from so authoritative a declaration that it is not so, and that it involves definite clinical, as well as technical, considerations. This needed saying, and Mr. Doggart is to be congratulated for saying it.

At the same time I think he may have gone too far in the direction of deprecating current views on the value of an eye examination in certain conditions, particularly head-

aches. It may be true to say that most headaches are not due to eye trouble, but I think it is a pity to suggest that many examinations for the exclusion of refractive errors are superfluous. The headache, it is true, may not be due to a refractive error, but it may be due to some other cause either of ocular origin or of some other origin showing ocular signs. I suggest that an examination of the eyes is an essential part of any thorough investigation into a case of headache of unknown origin. Also, I should like to suggest that the wearing of glasses gives relief from headaches in a great many patients whose headache is neither of refractive nor of heterophoric origin. Many such patients show signs of, or give a history of, conjunctival hyperaemia. This is aggravated by prolonged fixation, whether in driving, reading, or televising, and results in headache. Why glasses should give relief in such cases I do not know, but I have no doubt that they do, and I do not think that in most cases the relief is of psychological origin.

With regard to migraine, whilst I agree that it is not of refractive nor even of ocular origin, the diagnosis of the condition is not always a simple matter, so protean in its manifestations is it, and I think it is useful to have an ophthalmic examination in doubtful cases.—I am, etc.,

London, W.1.

R. U. GILLAN.

SIR,—It is a pity that Mr. J. H. Doggart in his admirable exposition of the orthodox principles for prescribing spectacles (*Journal*, August 15, p. 388) has overstressed the dogma that headaches of ocular origin are uncommon and implied that only large refractive errors or those causing obvious symptoms need correction. This is unfortunate for two reasons: first, because it may hinder the recognition of some headaches which are easily relieved, and, secondly, because it weakens the true case against prescribing unnecessary spectacles. The suggestion that because large refractive errors often cause no discomfort small ones may not do so is misleading. Small errors probably cause more headaches than large ones, and a few people are acutely sensitive to visual imperfection although many are tolerant or indifferent to it.

As Mr. Doggart says, the history will usually supply a clue, but not if inquiry is limited to the effects of long spells of close work. There are two main sources of ocular fatigue—prolonged concentration and flickering lights. Watching the cinema, particularly a colour film, may give a useful guide to the effect of the latter. Ocular discomfort from the glitter of moving objects may be severe enough to provoke nausea and is responsible for one form of travel sickness. From my own experience I can aver that fishing rippling water on a bright day is a potent cause of headache, and had I realized this 25 years ago I could have avoided a grievous end to many an enjoyable day.

The question of migraine is more difficult. Headaches of ocular origin, especially those associated with ocular muscle imbalance, may cause vomiting and may thus improperly be labelled migraine. Their relief by spectacles has probably fostered the belief in the association of migraine with refractive errors. Of course, as Mr. Doggart says, migraine is not due to refractive errors—its fundamental cause is still unknown—but attacks may be provoked in those who are subject to it by many diverse stimuli, and it appears that, just as some are engendered by emotion, a few may follow ocular fatigue. It seems reasonable, therefore, to investigate this possibility when the history may suggest it.—I am, etc.,

Redruth.

CHRISTOPHER HEATH.

Manual Methods in General Practice

SIR,—I would be grateful for the space in which to correct Dr. R. Barbor's misquotation (*Journal*, August 15, p. 395) from my letter (*Journal*, July 25, p. 222). Dr. Barbor writes that he cannot agree with my statement that "the proportion of total patients seen who require physiotherapy is 5%." That is not my statement. My actual words were:

A new generation

The introduction of Chloromycetin was the beginning of a new era in the history of medicine. Its discovery and isolation in the Parke-Davis Research Laboratories and its subsequent synthesis on a large scale manufacturing basis can be counted among the really great events in chemotherapy. Moreover, the ever increasing use of Chloromycetin provides convincing evidence of the effectiveness of this latest Parke-Davis contribution to the advance of medicine.

CHLOROMYCETIN

The first synthetic antibiotic

Parke, Davis & Company, Limited Inc. U.S.A. Hounslow, Middlesex
Telephone Hounslow 2361

but when INFECTIONS are

Inject SECLOMYCIN

...and you inject sodium and procaine penicillins and streptomycin simultaneously. This is precisely the attack called for to combat infections of mixed bacterial origin that fail to respond fully to penicillin or streptomycin alone—notably infections of the urinary tract, peritonitis and infected wounds.

Both preparations are issued in dry form for aqueous injection, and are available in 'single-dose' vials; Estomycin is also available in a special 'single-dose' vial for infants.

Estomycin and Seclomycin are trade marks of Glaxo Laboratories

GLAXO LABORATORIES LTD., GREENFORD, MIDDLESEX, ENGLAND

Glaxo Laboratories: Manufacturers of medical products and foods. Agents or associate companies in almost every country in the world.

Inject ESTOMYCIN

...and you inject both the 'lung selective' penicillin ester—penethamate hydriodide—and streptomycin. Here is a combined attack that is highly effective against mixed infections of the lung—typically, bronchitis (both acute and chronic), bronchiectasis, pleurisy, pulmonary abscess and pulmonary tuberculosis complicated by secondary infection.

FOR MILD FORMS OF PAIN

"Aspirin and phenacetin are effective and useful, and a sedative effect is obtainable if a barbiturate is combined with them... The reputation of codeine as a pharmacologically useful drug is at present running, for the analgesic effect of the compound tablet of codeine B.P. is probably due more to its content of aspirin and phenacetin than to the ½ gr. (8 mg.) of codeine present. It is a weak analgesic even when given in full doses." (Brit. Med. J. 1952 (Oct. 25th) ii, p.928)

Tercin combines aspirin and phenacetin with a barbiturate. It is intended for the relief of all those mild forms of pain for which tablets of Aspirin, Phenacetin and Codeine have hitherto been prescribed.

Its cost to the National Health Service is no greater than that of Tab. Codein. Co. B.P.

Tercin is available in tablets containing aspirin 5 gr., phenacetin 3 gr. and butobarbitone ½ gr. For dispensing only, 200 at 4/10, and 1000 at 24/- (Prices to pharmacists in Great Britain).

'TERCIN'

DOSAGE: One or two tablets as required. A total dose of eight tablets daily should generally not be exceeded.

Literature and samples are available on request to the Medical Department

THE BRITISH DRUG HOUSES LTD. LONDON N.1
Tren/B/1

"Only 5% of the total number (of patients) seen in that time were suffering from 'soft-tissue lesions.'" Of course I saw patients who required physiotherapy for arthritis of various joints, but these were not "soft-tissue lesions," while the physiotherapy they required consisted of methods of treatment other than "manual methods," which was the subject under discussion.

The relatively small number of patients I diagnosed as suffering from prolapsed intervertebral disk were suffering from prolapsed intervertebral disk, and the fact that they required to be seen and treated by a consultant orthopaedic surgeon confirms the severity of their condition. As I endeavoured to show in my letter, not all who have back-ache are suffering from prolapsed intervertebral disk.—I am, etc.,

London, N.W.3.

PHILIP HOPKINS.

The Intervertebral Disk

SIR,—Disk injuries, and arthritis of the apophyseal joints, are part of the penalty man pays for his temerity in assuming an erect, plantigrade posture. Treatment should be based on this ontological conception: the child crawls before it walks. My routine of treatment, employed many years before the disk lesion was described, is: (a) three or four days in bed, with a firm pillow tied to the small of the back; (b) two weeks' hands-and-knees crawling for some 3 to 10 minutes three times a day; (c) two further weeks of hands-and-feet crawling, to strengthen further the erector muscles. With this technique manipulation is rarely required, the patient effecting the reduction himself by active movement. I usually give two or three paravertebral injections of lactic acid, with or without procaine, in the acute phases. Not infrequently, the relief of pain is dramatic, but I am somewhat sceptical of the Pauline conversion, as the patient is apt to give up the exercise too soon.

A few precautions may be mentioned. The knees should be padded and gloves worn. If postural scoliosis is present, crawling is done in a circle, away from the convexity. Outside the home the door should be locked: one patient circling his desk in this undignified attitude was surprised by his secretary—with disturbing consequences.

There is of course nothing original in this treatment, which is merely the adaptation of Klapp's exercises for lesser degrees of scoliosis. If it fails, the ruptured disk is almost certainly irreducible, and laminectomy is called for.—I am, etc.,

Sunderland.

W. GRANT WAUGH.

Blood Transfusion Accidents

SIR,—I regret that the Consulting Pathologists Group Committee has prevailed on you to publish a "statement" (Journal, August 15, p. 390) on blood transfusion accidents. It is an anonymous statement, not even "approved" or "agreed" by the Group, and its authority is therefore nil—because the authority with which any "statement" is invested depends on the wisdom and experience of its authors. Unfortunately, non-medical readers are apt to assume that the wisdom of a medical committee is the sum of the wisdom of its members—whereas we know that their collective wisdom is rarely greater than their highest common factor.

In fact, the statement is inaccurate in some technical matters. Cross-matching in saline and albumin does not exclude incompatibility, because the antibody anti-Duffy fails to agglutinate Duffy-positive cells in saline or albumin, but can be detected only by the anti-globulin technique, which is not even mentioned in the statement. There is still some argument about the relative reliability of tile and tube methods for ABO grouping,^{1,2} and it seems reasonably certain that the capillary method of Rhesus testing is not less reliable than is the tube method.^{2,3}

Transfusion is intended to save lives, and in some hospitals transfusion is sometimes needed within 30 or 45 minutes, even now when dextran is freely used. I believe that there may be more than one technique which is reasonably safe in skilled hands, and I have the strongest objection

to being told by some anonymous pundit that this is not true, the more especially when the pundit himself makes erroneous statements.

It is now generally accepted that most transfusion accidents are caused by bad organization, carelessness, or ignorance. The Group Committee might find it more profitable to represent to the Ministry, to regional boards, and to boards of governors that in no hospital should grouping and cross-matching be done in the ward sideroom by a house officer, but that in every hospital the organization of transfusion must be the responsibility of a consultant pathologist who has time, space, and staff to supervise the work properly.—I am, etc.,

London, N.W.10.

Heparin in Intravenous Infusion

SIR,—It is well known that difficulty is often experienced in maintaining a continuous intravenous infusion over a prolonged period owing to the onset of local thrombophlebitis, but it is much less well known how useful heparin can be in minimizing this complication. For several years I have used heparin with considerable success for this purpose. It may either be injected with a syringe into the flasks immediately before use or, alternatively, the flasks may be prepared in advance by the pharmacy department. A dosage of 1½ to 2 units per ml. of intravenous fluid is recommended. Using heparin in a strength of 1,000 units per ml., 0.75 to 1 ml. should therefore be added to each half-litre flask. If a stronger solution is used—for example, 5,000 units per ml.—the volume required for each flask is so small that it is difficult to measure accurately. Furthermore, it must be suitable for intravenous use. The risk of haemorrhage is not increased, because the heparin, administered in small amount and at a constant rate, has sufficient concentration only to act on the vein proximal to the needle or cannula. When it enters the general circulation it is too dilute to have any effect on the clotting time and is soon eliminated. It is safe to give heparin in this way shortly after, or even during, operation provided that the infusion has not to be run quickly. Should this become necessary, then the flask must be changed to one without heparin.

By this safe and simple method, time, painful thrombosis, and the consequent loss of a patent vein can be avoided. It is worthy of wider application.—I am, etc.,

Manchester.

H. F. SMITH.

Familial Hypertrophic Pyloric Stenosis

SIR,—It was with great interest that I read the article by Mr. T. Fenwick on familial hypertrophic pyloric stenosis (Journal, July 4, p. 12). I recently had a similar case, though without an extensive family history. Perhaps it is worth recording briefly as another example of the type of association Mr. Fenwick has described.

The patient, a male aged 54, presented with an eight-year history of periodic lower sternal and epigastric pain, leading to nausea, and associated with acid regurgitation and vomiting. Recently there was loss of appetite and loss of weight. Radiologically he was diagnosed at two examinations as having a prepyloric ulcer with the possibility of malignancy. Exploration was advised. At operation there was a greatly hypertrophied pylorus which was thought at the time to be a tumour. A Billroth I type of gastrectomy was performed. The patient's subsequent convalescence was normal. Pathological examination revealed that the tumour showed a rather thin mucous membrane which was rather engorged and with more polymorphonuclear infiltration than normal, but no actual ulceration. The main abnormality, microscopically as well as macroscopically, was in the markedly increased thickness of the pyloric musculature. The individual muscle fibres themselves were abnormal, in that they were swollen and stained irregularly, giving the impression of being broken when viewed lengthwise, and of a ring shape when cut across. There also appeared to be marked separation by fluid of the individual fibres. No evidence of malignancy was seen. The conclusion was that it was pyloric hypertrophy.

When I discussed the findings with the patient and explained to him that the trouble had not been an ulcer but an enlarged muscle at the exit of the stomach causing obstruction, he said that his eldest child, a boy, had been rushed off at the age of 4 months to hospital and had had an operation for a similar condition. This has kindly been confirmed for me by the hospital concerned, which reports that the baby had a Ramstedt operation for pyloric stenosis at the age of 15 weeks.—I am, etc.,

Bath.

S. GLASER.

Reduction of Post-operative Pain

SIR,—I read with interest the annotation (*Journal*, August 15, p. 385) concerning methods of relieving post-operative pain. Reference was made to the use of the drug "efocaine." It is true that this drug gives much longer anaesthesia than most of the other anaesthetics at our disposal, but it certainly has dangers and disadvantages. Three cases have been reported from America, where, following the use of efocaine, serious neurological symptoms developed and persisted, and it is understood that other permanent palsies have been encountered. In these cases intercostal injections have been made in the paravertebral region.

My registrars and I are at present investigating a small series of gastrectomies where the efocaine was injected in the region of the intercostal nerves in the mid-axillary line. In many of these cases the anaesthesia was very prolonged and has given considerable discomfort to the patient. We hope to publish a short account of these cases in the near future.—I am, etc.,

Liverpool, 1.

J. B. OLDHAM.

Sun on the Skin

SIR,—In your annotation (*Journal*, August 8, p. 330) you mention that, although it is not easy to increase tolerance to light by systemic treatment, mepacrine by mouth delays the onset of erythema from ultra-violet light. No mention is made of nicotinic acid, which has quite a marked effect in the prevention of photo-sensitivity; a dose as small as 50 mg. per day has been successful in preventing the onset of light dermatitis in several photo-sensitive patients (for example, the dermatitis associated with pellagra).

You mention that sulphonamides increase sensitivity to light, and I find it rather interesting to speculate on the cause of the pharmacological antagonism between sulphonamide and nicotinic acid, which not only exists in bacterial infections but also in this matter of light sensitivity. Incidentally, I have learned by painful and personal experience never to apply creosote to wooden structures when the sun is shining; any stray drops landing on the skin cause the rapid development of an uncomfortable localized erythema.—I am, etc.,

London, W.1.

R. J. GOURLAY.

Please Wash Your Hands

SIR,—I note with interest the letter from Dr. W. Edwards (*Journal*, August 22, p. 444) regarding free washing facilities in public conveniences. Two years ago I persuaded the Doncaster Health Committee to provide free hand-washing and drying facilities as an experiment in the men's convenience adjacent to the market, which is patronized by stallholders, the majority of whom are engaged in handling food. A wash-hand basin, soap dispenser, and electric hot-air hand drier were provided. The provision of such facilities is restricted to conveniences where an attendant is on duty in order to prevent misuse and damage, and the drier and soap dispenser have to be locked away when the attendant goes off duty, to prevent wilful damage. With these precautions I am pleased to be able to report that the equipment is still intact, is in daily use, and has proved popular. I might add that to reduce further the risk of spread of intestinal disease the flush controls of the w.c.s at this convenience were converted to foot operation in lieu of the usual hand control.—I am, etc.,

Doncaster.

H. L. SETTLE.

SIR,—Your correspondent, Dr. W. Edwards (*Journal*, August 22, p. 444) in his letter on the washing of hands, raises a problem which deserves immediate attention. The fact that gastro-enteritis has become endemic and widespread is a sad reflection on the standards of hygiene and food management in this country. The time has surely come for a new drive for cleaner food.

Food-handlers require constant education and supervision. A revival of the system of granting hygiene certificates to cafés and food stores would be a good thing. The refusal of such certificates, and even closure of the more unsatisfactory establishments, would have a salutary effect on the raising of standards. The handling of articles ready to eat, such as sandwiches and cakes, should be forbidden when once prepared. They should be individually wrapped ready for sale. Our milk is now almost entirely delivered in bottles, and yet our bread loaves are rarely wrapped before delivery.—I am, etc.,

Carmarthen.

J. E. CRANE.

Male Pseudohermaphroditism

SIR,—We have been interested to read the account of a case of male pseudohermaphroditism by Drs. D. C. Beatty, C. J. Champ, and G. I. M. Swyer (*Journal*, June 20, p. 1369). Owing to the rarity of such cases, mention of a similar one encountered by us some four years ago may be of interest.

The patient, a married woman aged 40, had always had amenorrhoea, but, except for the total absence of pubic and axillary hair, she had normal secondary sexual characteristics. As a child she had had treatment for a left inguinal hernia, and she was now admitted to hospital for repair of a right inguinal hernia. A tumour, shown histologically to be a testis, was removed at operation. No ovary or uterus could be felt through the hernial orifice, and bimanual examination showed a loosely attached vagina without a cervix or any nodule suggesting a uterus. The external genitalia were normal.

Further investigation could not be carried out as it was against the patient's wishes. She is one of a family of six girls; three are normal, married and with children; the other two are similar to the patient in that they have had permanent amenorrhoea, and one of them, who is married, has been told by a gynaecologist that she has no uterus.—We are, etc.,

Shrewsbury.

GREGOR H. GRANT.
A. GLANDON WILLIAMS.

Treatment of Patients with Myelosclerosis

SIR,—Dr. R. A. Hickling's account of the clinical features of myelosclerosis (*Journal*, August 22, p. 411) does not refer to the remarkable duration of time of the pathological process in some cases. In 1950 I saw a man, aged 66, with enormous splenomegaly and fairly severe anaemia. A diagnosis of myelosclerosis was confirmed, and a number of transfusions were given which kept the patient alive for a further two years. A striking feature of this case was that great splenomegaly had been detected in 1910, when he was warned not to play football for fear of rupturing the enormous spleen. Apart from abdominal discomfort, no symptoms were noted until March, 1950, when he had a very severe epistaxis.

A man aged 53 was found to have a spleen reaching to the navel 12 years before I saw him. There were no other symptoms and no anaemia, but the leucocyte count was 35,400 with a few abnormal cells and an occasional normoblast. This patient is still in good health, with no treatment, 16 years after the splenomegaly was first noted.

It seems impossible to accept the view of Heller and his co-workers,¹ which is shared by Hutt *et al.*,² that such a prolonged disease could possibly be closely allied to the leukaemias. It is both interesting and important that Dr. Hickling observed improvement after irradiation of the enlarged spleen in cases with leucocytosis and immature cells in the blood. Obviously, therefore, the enlargement of the spleen, which has often been regarded as compensatory, is

not purely so, but his observations seem to support the view of Rohr³ that the abnormal cells in this condition and in the leukaemias are mainly derived from the ectopic foci.—I am, etc.,

London, W.1.

Subacute Bacterial Endocarditis

SIR,—Professor R. V. Christie in his Refresher Course article on subacute bacterial endocarditis (*Journal*, August 22, p. 438) mentioned penicillin used prophylactically before dental extractions. He says, and I agree that it is so, that the usual dose is 500,000 units "an hour or two" before the operation with a similar dose on the two succeeding days.

I have never been able to understand why my medical friends, fully aware of the disastrous nature of the disease, and the harrowing treatment of it should it occur, do not insist on heavy doses for several days before the operation in an attempt to reduce the number of bacteria in the foci before they are stirred up and disseminated by the operation.

By all means continue after the operation as well, but one dose only at some casually indefinite time beforehand seems to me very like locking the stable door after the horse (or the bacteria) has bolted.—I am, etc.,

London, W.1.

F. R. COFFIN.

Symptoms of Malaria

SIR,—The recent correspondence in the *Journal* reminds me that I have frequently observed that the rigors and intermittent fever so characteristic of malaria tend to overshadow the fact that the first attack of malaria is not characterized by rigors and the fever is continuous. The second attack, which takes place six months later, is "classical" in its manifestations.

Gastro-intestinal symptoms frequently usher in an attack, being heralded by vomiting or diarrhoea, and patients who have been exposed to the infection and who present such symptoms should be suspect.—I am, etc.,

Northallerton, Yorks.

J. SHEGOG RUDELL.

Growth Hormone

SIR,—New information on endocrine factors influencing growth is accumulating with increasing velocity (*Journal*, August 15, pp. 353, 357, 383), and the time has probably come to be careful with the use of the term "growth hormone." Somatic growth is the final outcome of the interaction of a vast complex of agencies even in the intact animal; in the mutilated organism additional compensatory factors assume an important role in promoting or inhibiting growth. Thus, by suitable experimental interference, it is possible to demonstrate growth-promoting properties not only for somatotrophin and insulin, but also for thyroxine, cortisone, and testosterone, and consequently for thyrotrophin, gonadotrophin, and A.C.T.H. To call all these "growth hormones" would deprive the term of most of its usefulness. The term should be restricted to hormones having, in the intact and normal animal, a direct action on the somatic cells, in promoting protein synthesis and cell division.—I am, etc.,

Glasgow.

E. GEIRINGER.

POINTS FROM LETTERS

Cortisone in Rheumatoid Arthritis

Dr. H. F. West (Sheffield) writes: Dr. C. L. Cope, in part two of his Refresher Course article on the use of cortisone and A.C.T.H. (*Journal*, August 8, p. 332), said of rheumatoid arthritis that "with such great benefit to be expected in the majority of cases it is clear that the case for cortisone is strong." Unfortunately the "case for cortisone" has not been made out and careful studies have brought no proof that it favourably affects the course of the disease. There is no doubt that many patients benefit from cortisone treatment temporarily, but there is also little doubt that in certain circumstances it may do more harm than good.

Obituary

RENÉ SAND, M.D., LL.D.

The death of Dr. René Sand on August 23 was briefly recorded in last week's *Journal*. For many years he was one of the most prominent figures in the field of social medicine, and his work achieved international fame.

René Sand was born at Ixelles, in Belgium, on January 30, 1877. He graduated in medicine at the University of Brussels in 1900, and after postgraduate studies in Berlin and Vienna was appointed lecturer in pathology at his own university. His interest in social medicine was developing even at this early stage of his career, and in 1912 he founded the Belgian Social Medicine Association. During the first world war he served as a medical officer to units of the Belgian Army, and in 1921 he was elected secretary-general of the League of Red Cross Societies, a position which he held until 1936.

Sand's interest in the international unification of medical services found many outlets in the period between the two world wars. He realized his ambition to found an International Hospitals Association in 1929, and he was its first president. He was also president of its post-war successor, the International Hospital Federation, from its foundation in 1947 until his death. Only a few months ago he was chairman of the Eighth International Hospital Congress in London. A tireless supporter of the health work of the League of Nations, Sand was naturally prominent in the councils of its post-war successor. In 1946 he presided over a technical preparatory committee of the United Nations Organization to study proposals for international action in the health field, and he was one of the Belgian delegates to the conference called in New York by U.N.O. to draw up the constitution of the World Health Organization. In 1950 he was appointed chairman of the W.H.O. Expert Committee on Professional and Technical Education. During the preparation by the International Labour Office of its Convention on Minimum Standards of Social Security, a special W.H.O. consultant group, with René Sand as its chairman, was appointed to review the medical provisions of the convention.

Sand's work to improve the health of his own countrymen was recognized by his appointment as secretary-general of the Belgian Ministry of Health in 1937. He was responsible for the opening of the Institute of Hygiene and Social Medicine in Brussels in 1939. After the war, with the support of the Rockefeller Foundation, a chair of social medicine was established in the University of Brussels, and Sand was its first occupant. He held this position from 1945 to 1952. He also founded the Belgium Committee on Social Work and the International Conference on Social Work, presiding over several of the meetings of the latter organization. Earlier this year he was elected the first president of the Société Belge de Droit International Médical, which has for its object the study and development of international medical law.

Sand was a member of the B.M.A. from 1917 to 1947, and an honorary member of the American Medical Association, the American Hospitals Association, and the New York Academy of Medicine. In 1951 he received the honorary degree of LL.D. at Glasgow Uni-

versity. He contributed many books and papers to the literature of his subject. Best known in this country is his *Vers la Médecine Sociale* (1948), an English translation of which, *The Advance to Social Medicine*, was published in 1952. This is a historical summary of social medicine, which he described as "the final flowering of the preventive and curative art," and a definition of its aims and methods. He also wrote *Health and Human Progress* (1935), *Un Programme de Santé pour la Belgique* (1945), and *La Médecine Sociale* (1950).

René Sand was one of the founders of the present-day concepts of social medicine: he had a unique grasp of his subject and a profound influence on its development outside his own country. His work was recognized by the award of the Léon Bernard Foundation Prize, which was presented to him at the Fourth World Health Assembly in 1951. He was to have been one of the vice-presidents at the First World Conference on Medical Education held in London last week, but illness prevented his attendance, and news of his death reached London while the Conference was in progress. The paper he was to have read as the introductory address to the section of the Conference considering preventive and social medicine was published in last week's *British Medical Journal* (p. 471).

We are indebted to Dr. MELVILLE DOUGLAS MACKENZIE, Chairman of the Executive Body of the World Health Organization, for the following appreciation: Apart from his exceptional personal charm and boundless enthusiasm, Dr. René Sand, an early pioneer in social medicine, had a breadth of vision that was almost unique. He will be long remembered not only for his conceptions of the potentialities of international collaboration in medicine but also for his ideas of the part that medicine, as an art, should play in the social structure of every country. He invariably looked beyond the ordinarily accepted, but relatively narrow, limits in the prevention of disease to the new and wide responsibilities of medicine in the complex social structure of modern life.

He realized, and lost no opportunity of urging, that the full development of medicine could only be reached if its social and psychological aspects received a proper place in the training of medical students.

His lovable personality and his zest for work, combined with his creative imagination, invariably gave him a position as leader in the many fields of national and international social work in which he laboured so incessantly. Chairmanship of the Technical Preparatory Committee for the creation of the World Health Organization, his long activities with the Red Cross, his work in the study of special social problems in many countries, including the United Kingdom and France, as well as his outstanding contributions to social work in his own country, gave René Sand the opportunities he sought, and brought to him the deep satisfaction of creative achievement. In 1951 the Governments of 66 countries formally recognized René Sand's contribution to social medicine when the Assembly of the World Health Organization unanimously awarded him the Léon Bernard Foundation Prize for his contributions to international health. On this occasion he concluded his address with the following words:

"Neither students nor practitioners fully realize that, as Hippocrates already said long ago, in medicine the function of protecting and developing health must rank even above that of restoring it when it is impaired.

"If the nobility of medicine resides in the selflessness of the physician, the hygienist, and their assistant, its greatness resides in the scope of the services which they render; and, from this point of view, the medicine which preserves health has a considerably greater influence for good than the medicine which restores health."

René Sand was a great man and one who was deeply loved by many colleagues in every country of the world.

J. T. HUNTER, F.F.A.R.C.S.

Dr. J. T. Hunter, who held a number of appointments as an anaesthetist at hospitals in and near London, died after a long illness on August 9 at the age of 54.

John Trustcott Hunter was born on September 4, 1898, and received his medical training at St. Bartholomew's Hospital, qualifying M.R.C.S., L.R.C.P. in 1925. He held the appointment of senior resident anaesthetist at St. Bartholomew's Hospital from 1926 to 1928, after which he was in general practice in the London area for some years. He then decided to specialize as an anaesthetist, and the list of hospitals he served is an impressive one. At the time of his death he was honorary consulting anaesthetist to the Metropolitan Hospital; King George Hospital, Ilford; King Edward VII Sanatorium, Midhurst; the Hospital for Tropical Diseases, London; and the Lord Mayor Treloar Orthopaedic Hospital, Alton. Earlier he had held the appointments of senior consultant anaesthetist to the Prince of Wales's General Hospital, Tottenham, and honorary anaesthetist to a number of other London hospitals. Hunter obtained the Diploma in Anaesthetics of the English Royal Colleges in 1944, and four years later he was elected a Fellow of the Faculty of Anaesthetists of the Royal College of Surgeons of England.

In 1939 he was appointed consulting anaesthetist to the plastic surgery and jaw injuries centre at the Queen Victoria Hospital, East Grinstead, where, perhaps, his warm sympathy for all who suffered showed itself most clearly. There he helped patients from some 14 different nations who had suffered facial injuries in the last war to regain faith in themselves and in the future by his constant encouragement and help. A founder member of the Guinea Pig Club at the hospital, he held the affection of all at East Grinstead, where he was known as "Uncle John."

Hunter had been seriously ill for nearly a year before his death, which took place in the hospital at East Grinstead. Big in stature and in mind, he was a born raconteur and an excellent mimic and could be relied upon to enliven any gathering by his presence. His death leaves a gap which will be difficult to fill. The sympathy of all his friends, colleagues, and patients will be extended to his widow.

We are indebted to Dr. A. A. MASON for the following appreciation: All who knew John Hunter have lost a dear friend. Of his professional capabilities, I will say little, for they have long spoken eloquently for themselves. If there was a difficult child to anaesthetize, we sent for John, and watched his gentle induction with pleasure and envy. If a small child was afraid, it was Uncle John who soothed it, turned its tears to smiles and peaceful unconsciousness. If an endotracheal tube would not obey our behest, it was John who guided our fingers. He was an anaesthetist by instinct. He did not attempt to explain why he did things correctly, he just did them. We younger anaesthetists knew the latest theory, but he knew much more—the practice of safe anaesthesia. If the anticipation of trouble is the mark of the good anaesthetist, then John was the prince of all, for he smelt trouble and prevented it before we were even mildly suspicious. His record speaks for itself—3,000 cleft-lip and palate operations over 20 years with the loss of only one child—a record that few will ever equal.

It is, however, as a man that we will miss him most. His geniality and generosity were unsurpassed. An evening with John was an evening of good food, good wine, and robust humour. John enjoyed life and lived it to the full. He was happiest when taking his friends down the river and making them merry. His dinner parties will long be remembered,

for he was a host who gave everything, most particularly himself. My last memory of John—and this was even after he had become seriously ill—was of him standing on the hearth, glass in hand, and surrounded by laughing, happy people; and it was John making them so. One of the best anaesthetists of his day, a man who enjoyed life and lived it well, a raconteur without peer, a man who hurt no one, a man one could always turn to in need, John was an institute—we shall rarely see his like again.

A. SMITH POOL, L.R.C.P.Ed.

We record with regret the death of Dr. A. Smith Pool at his home at Glasgow on August 16 at the age of 59 after a short acute illness.

Alexander Smith Pool was born at Annan on October 13, 1893, and was educated at Annan Academy. He left Dumfriesshire for Glasgow as a young man and in 1914 qualified as a member of the Pharmaceutical Society of Great Britain: it was typical of his industry and application that, although compelled by circumstance to seek part-time employment throughout his period of study, he qualified as a pharmacist before the statutory age of 21. With great courage he commenced business on his own account shortly after qualification, and by working long hours had soon established a flourishing business in one of the industrial areas of Glasgow. In 1919 he again showed his courage by beginning the study of medicine at Glasgow University. After he had completed his first year there circumstances compelled him to transfer to the Anderson College of Medicine—a forced decision which he always regretted. He was still conducting his business, and hurried from his classes to his dispensing every day of the week. On most evenings he left his business between 10 and 11 p.m. to pursue his medical studies till the early hours of the morning. However, he did well at the Anderson College and obtained the Scottish triple qualification in 1926 and secured the appointment of extra-dispensary physician to the Victoria Infirmary, Glasgow. In 1931 he was elected physician to out-patients. He was at first attached to the wards of the late Dr. O. H. Mavor (James Bridie), who appreciated his colleague's worth and frequently referred to Pool's knowledge of pharmacology and "its sane application to treatment." Dr. Pool enjoyed his out-patient duties, and was seen at his best surrounded by a group of students, his eyes sparkling, as he instructed them in the arts of percussion and auscultation.

Early in his medical career Dr. Pool took an active interest in medical politics, and was soon recognized as a good committee man. He graduated quickly to fill with distinction all the positions to which his colleagues could promote him. He was president of the Glasgow and West of Scotland Branch of the British Medical Association at the time of his death; chairman of the Glasgow Division in 1946-7; and from 1943 to 1951 he was a representative of the Division at seven Annual Representative Meetings. He was a member of the Central Council of the Association from 1945 to 1948, and at various times since 1943 he had served on the Scottish Committee, the Scottish Insurance Acts Subcommittee, the joint committee of the B.M.A. and the Pharmaceutical Society, the Joint Standing Formulary Committee, and the General Medical Services Committee and the G.M.S. Scottish Subcommittee. He had also been chairman of the Glasgow burgh panel and local medical committee. Recently he was a member of the Cohen Committee on Prescribing, an appointment of which he was proud.

Alec Pool was forceful and courageous in debate; he hit hard, but without rancour. After a particularly stormy session he would seek out his opponents and, amid laughter, count the points scored on each side. He was most jealous of the position of the doctor in the community. His experience and knowledge of business were such that at times he showed little respect for lay members of committees who presumed to criticize the work of the general practitioner. As one who had been successful in both business and medicine he had no doubts regarding which was the easier to attain. He was appalled by the recent increase in litigation against doctors, and proved himself a formidable opponent to those malcontents who made official complaints against their medical attendants. He never quite adjusted himself to the National Health Service, and only a few weeks before his death he was actively prospecting farming properties to which he looked forward to retiring in a short time. The wheel had come full circle, for he was at heart a countryman and was reared on a farm at Annan. He had only three interests—the practice of medicine, medical politics, and farming; he was eminently successful in two of these fields, but, alas, the third escaped him. The sympathy of his colleagues and friends goes out to his wife and only daughter.—A. B.

After a comparatively short illness, which she endured with her customary fortitude, Dr. ROSEMARY OWEN MORRIS died at Caernarvon on August 15 at the age of 60. Born on June 21, 1893, she was the daughter of the late Dr. R. Owen Morris, of Aberdovey, who was well known throughout the Principality as the active propagandist of the Welsh Tuberculosis Association. After studying music and teaching the subject for a few years, she later became a medical student and obtained the degrees of M.B., Ch.B. at Edinburgh University in 1920. Two years later she took the diploma in public health, and in 1928 proceeded to the M.D. The public health service soon attracted her, and she held posts at Huddersfield, Norwich, and the Cefn Mably Sanatorium, near Cardiff. In 1950 she joined the Caernarvonshire health department and was a most loyal and energetic colleague. A member of the British Medical Association and the Society of Medical Officers of Health, she was also a keen supporter of the North Wales Branch of the Medical Women's Federation. She possessed an abounding sense of humour and always had a cheerful greeting for her colleagues. All her colleagues mourn the loss of a sweet personality whom they admired and respected.—D. E. P.-P.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

In Congregation on June 23 and 24 the following medical degrees were conferred:

M.CHIR.—*G. C. Attenborough.
M.B., B.CHIR.—*J. Cocker, *H. E. D. Lloyd, *J. E. C. Tower, *D. B. Bower, *R. A. Miley, *R. A. Roxburgh, *J. L. Stevens, *A. J. F. Barratt, *R. M. Butcher, *H. F. Cowper Johnson, *R. J. W. Lambert, *M. B. Teal, *P. M. Hacking, *M. B. Heywood-Waddington, *A. R. Kittermaster, *I. B. Lyon, *A. McL. Keil, *P. C. Vivian, *C. M. Yates, *E. R. Davies, *J. P. F. C. Evans, *R. V. H. Jones, *J. S. Lloyd, *W. O. McCormick, *G. Meachim, *D. G. Montefiore, *P. H. Pullen, *I. R. D. Reid, *N. W. H. Young, *A. B. Aistrop, *T. C. Bradford, *M. J. Clarke-Williams, *I. M. J. Mair, *R. Routledge, *D. *Distinction in paediatrics and child health. *Distinction in medicine.

The Services

Major-General R. D. Cameron, C.B., C.B.E., M.C., late R.A.M.C., retired, has been appointed Colonel Commandant, R.A.M.C., in succession to Major-General (Honorary Lieutenant-General) Sir T. O. Thompson, K.C.S.I., C.B., C.B.E., whose tenure has expired.

Surgeon Commander S. M. Whitteridge, R.N.V.R., and Surgeon Lieutenant-Commander D. A. Warden, R.A.N.R., have been awarded the Royal Naval Volunteer Reserve decoration.

INFECTIOUS DISEASES AND VITAL STATISTICS

Summary for British Isles for week ending August 15 (No. 32) and corresponding week 1952.

Figures of cases are for the countries shown and London administrative county. Figures of deaths and births are for the 160 great towns in England and Wales (London included), London administrative county, the 17 principal towns in Scotland, the 10 principal towns in Northern Ireland, and the 14 principal towns in Eire.

A blank space denotes disease not notifiable or no return available.

The table is based on information supplied by the Registrars-General of England and Wales, Scotland, N. Ireland, and Eire, the Ministry of Health and Local Government of N. Ireland, and the Department of Health of Eire.

CASES in Countries and London	1953					1952				
	Eng. & Wales	Land.	Scot.	N. Ire.	Eire	Eng. & Wales	Land.	Scot.	N. Ire.	Eire

* Measles not notifiable in Scotland, whence returns are approximate.
† Includes primary and influenzal pneumonia.
‡ Includes puerperal pyrexia.

Vital Statistics

Poliomyelitis

Poliomyelitis notifications (uncorrected) in the week ended August 22 (33rd week of the year) were as follows: paralytic, 144 (186); non-paralytic, 126 (132); total, 270 (318). This is a decrease of 48 compared with the previous week, the figures for which are in parentheses. The individual districts which have notified 20 or more cases in the year to August 22, with incidences per 100,000 in parentheses, are as follows: Southend-on-Sea C.B., 43 (28.38); Liverpool C.B., 51 (6.44); Birmingham C.B., 55 (4.92); Coventry C.B., 108 (41.38); Leicester C.B., 28 (9.79); Lewisham M.B., 24 (10.57); Blackpool C.B., 24 (16.29); Camberwell M.B., 21 (11.59); Islington M.B., 24 (10.20); Bournemouth C.B., 31 (22.32); Bristol C.B., 21 (4.73); Nottingham C.B., 23 (7.40); Taunton M.B., 25 (72.25); St. Pancras M.B., 23 (16.48); Carlisle C.B., 22 (32.40); and Manchester C.B., 20 (2.83).

There were 48 fewer notifications during the 33rd week than during the 32nd. This decrease, occurring before the zenith was to be expected, is encouraging, particularly as the fall is most marked in the number of paralytic cases (42 less). There is still no sign of dangerous epidemic foci in the larger centres of population.

Graphs of Infectious Diseases

The graphs below show the uncorrected numbers of cases of certain diseases notified weekly in England and Wales. Highest and lowest figures reported in each week during the nine years 1944-52 are shown thus -----, the figures for 1953 thus ———. Except for the curves showing notifications in 1953, the graphs were prepared at the Department of Medical Statistics and Epidemiology, London School of Hygiene and Tropical Medicine.

Infectious Diseases

The largest fluctuations in the trends of infectious diseases in England and Wales during the week ending August 15 were decreases of 607 in the number of notifications of measles, from 2,730 to 2,123, and 202 for scarlet fever, from 690 to 488, and an increase of 817 in the number of notifications of whooping-cough, from 3,864 to 4,681.

The largest falls in the notifications of measles were 149 in Lancashire, from 461 to 312; 91 in Lincolnshire, from 195 to 104; and 57 in Wiltshire, from 94 to 37. The decline in the incidence of scarlet fever was due to small falls in most areas of the country; there were no large fluctuations in the local trends. The largest rises in whooping-cough notifications were 106 in Yorkshire West Riding, from 232 to 338; 79 in London, from 349 to 428; and 70 in Hertfordshire, from 79 to 149; 22 cases of diphtheria were notified, the same number as in the preceding week.

318 cases of acute poliomyelitis were notified, and these were 5 more for paralytic and 16 more for non-paralytic cases than in the preceding week. The largest returns were Warwickshire 36 (Coventry C.B. 21, Nuneaton M.B. 5, Birmingham C.B. 4), Lancashire 31 (Liverpool C.B. 20), Essex 19 (Southend-on-Sea C.B. 5), London 17 (St. Pancras 4), Kent 16, Sussex 16, Southampton County 15 (Bournemouth C.B. 4), Dorset 12 (Poole M.B. 4), and Middlesex 12.

217 cases of dysentery were notified during the week—the same number as in the preceding week. The chief centres of infection were Lancashire 45 (Liverpool C.B. 11), London 34, Middlesex 16, Yorkshire West Riding 14, Surrey 11 (Epsom and Ewell M.B. 10), and Kent 11.

Northern Ireland Quarterly Return

The Northern Ireland Registrar-General, in his return for the quarter ended March 31, 1953, records that the birth rate was 21.3 per 1,000 population, being 0.5 higher than March quarter 1952, and that the death rate was 13.4 per 1,000 population—an increase of 0.4 over the corresponding quarter last year, but 1.3 below the average rate for the first quarters of the five years 1948-52. The higher death rate in March quarter 1953 was mainly due to an increase in the number of deaths from the respiratory diseases, especially influenza, pneumonia, and bronchitis. The death rate from tuberculosis, which has continued to fall, was returned at 32 per 100,000 population, a decrease of 8 com-

pared with March, 1952, and the lowest record for March quarter of any year. One death was registered as due to diphtheria—the first from this disease since June quarter 1951. The number of cases notified was 3 as compared with 2 for the first quarter of 1952.

Week Ending August 22

The notifications of infectious diseases in England and Wales during the week included scarlet fever 431, whooping-cough 4,341, diphtheria 11, measles 1,558, dysentery 235, paratyphoid fever 7, typhoid fever 3, and food-poisoning 339.

Medical News

White Bread.—Statutory Orders which came into force on August 30 have removed the restrictions on the extraction rate of flour, thus permitting a return to the white loaf. The Orders require, however, that calcium in the form of creta praeparata (1 oz. to 20 lb.—1 g. to 320 g.) shall be added to all flours; and that iron, aneurin, and nicotinic acid shall be added to flours of extraction rate lower than 80%, the rate for national flour. Only bread made from national flour remains controlled in price.

Artificial Sweeteners in Food.—In future only saccharin will be permitted as an artificial food sweetener (Artificial Sweeteners in Food Order, 1953). This follows a recommendation from the Medical Research Council. Saccharin is known to be harmless, but according to the Council's Food Adulterants Committee the use of certain other artificial sweetening agents may be dangerous to health.

Edridge-Green Lectures.—The late Mr. F. W. Edridge-Green, who was internationally distinguished for his work on the testing of colour vision (see *Journal*, May 2, p. 998), has left £3,000 to the Royal College of Surgeons. The money is to form a fund to pay for lectures at the College, "to be called 'The Edridge-Green Lectures,' one lecture each year to be on vision or colour vision."

Local Registration in East Africa.—The Uganda Legislative Council has approved a Bill enabling those who obtain the qualification L.M.S. (E.A.) from Makerere College to be registered for medical practice anywhere in East Africa. Before full local registration is granted, however, two years must be served as an intern at an approved hospital, and, after registration, five years in the Government medical service. Dr. J. K. Hunter, who moved the new Bill in Legislative Council, recalled that two years previously the General Medical Council had sent a delegation of visitors to examine the standard of training at Makerere. As a result of what they saw, they had recommended that the Makerere qualification might well become locally registrable. Dr. Hunter added that this was a step towards full recognition by the G.M.C.

Van Meter Prize Award.—The Van Meter Prize Award of \$300 is again offered by the American Goitre Association for the best essays submitted describing original work relating to problems of the thyroid gland. Essays should not exceed 3,000 words in length, and a typewritten copy, in duplicate and double spacing, should be sent to the Corresponding Secretary of the Association, Dr. John C. McClintock, 149½ Washington Avenue, Albany 10, New York, not later than January 15, 1954. The award, which is open to both medical and non-medical workers, will be made at the Annual Meeting of the American Goitre Association in Boston, Massachusetts, next April.

Journal Index.—The half-yearly indexes to Volume I of the *Journal* and the *Supplement* for 1953 are now being sent to members who receive them regularly and to subscribers. Members who have not previously asked for the indexes can obtain copies, post free, on application to the Publishing Manager, B.M.A. House, Tavistock Square, London, W.C.1.

Mr. St. J. D. Buxton is leaving for Greece on September 7. He is going there at the invitation of the United Nations Organization to act as social welfare adviser. He will be away for about a month.

COMING EVENTS

The St. Thomas's Hospital Old Students' Dinner will be held at the Connaught Rooms, Great Queen Street, London, W.C.1, on October 2 at 7 p.m. The chair will be taken by Sir Henry Letheby Tidy. Tickets for the dinner (price 22s. 6d.) may be obtained from the secretary, St. Thomas's Hospital Medical School, London, S.E.1.

Symposium on Child Health in the Tropics.—Immediately following the seventh International Paediatric Congress (Havana, October 12 to 17) a symposium on Child Health in the Tropics will be held at the University College of the West Indies, Mona, St. Andrew, Jamaica, from October 20 to 27. Those wishing to attend or requiring further information are asked to communicate with the secretaries, Symposium on Child Health, Division of Medicine, University College of the West Indies, Mona, St. Andrew, Jamaica, B.W.I.

NEW ISSUES

British Journal of Ophthalmology.—The next issue (Vol. 37, No. 9) will be available in a week's time. The contents include:

ROLE OF OXYGEN IN THE GENESIS OF RETROLENTAL FIBROPLASIA. A PRELIMINARY REPORT. Norman Ashton, Basil Ward, and Geoffrey Serpell.
EARLIEST SYMPTOMS OF DISEASES OF THE MACULA. Marc Amsler.
VISUAL ACUITY AND THE CONE CELL DISTRIBUTION OF THE RETINA. E. R. Harrison.
PLASMA CELL MYELOMA OF THE ORBIT. Edwin Clarke.
CHANGES IN THE REFRACTIVE POWER OF THE CORNEA DURING GROWTH. OBSERVATIONS ON THE RABBIT. Arnold Sorsby and Michael Sheridan.
CURARE AND CURARE-LIKE PRODUCTS IN CATARACT SURGERY. L. P. Agarwal.
PENETRATING CORNEAL GRAFT. ORIENTATION OF THE INITIAL PENETRATION OF THE TREPHINE INTO THE HOST CORNEA. J. C. Michaelson.
DETECTION OF GLAUCOMA IN GENERAL PRACTICE. F. A. Williamson-Noble.

Issued monthly; annual subscription £4 4s., single copy 8s. 6d.; obtainable from the Publishing Manager, B.M.A. House, Tavistock Square, London, W.C.1.

APPOINTMENTS

BLOTT, T. D., M.B., B.S., D.P.H., Assistant County Medical Officer and Medical Officer, Hucknall Urban District Council, Nottinghamshire.
McDOUGALL, JOSEPH HENRY, M.B., Ch.B., D.P.M., Medical Superintendent and Consultant Psychiatrist, Moss Side Hospital, Maghull, near Liverpool.

MANCHESTER REGIONAL HOSPITAL BOARD.—I. MacD. G. Stewart, M.D., M.R.C.P., Consultant Physician, Victoria Hospital, Blackpool; J. G. Thurston, M.B., B.Chir., M.R.C.O.G., Consultant Obstetrician and Gynaecologist, Blackburn and District Hospital; T. D. Culbert, M.B., Ch.B., D.A., Consultant Anaesthetist, United Manchester Hospitals and North Manchester Hospital; D. C. Lindars, M.B., Ch.B., Tuberculosis Physician and Medical Officer in charge of Miniature Mass Radiography Unit based on Salford; J. Rimington, M.B., Ch.B., Tuberculosis Physician and Medical Officer in charge of Miniature Mass Radiography Unit based on Stockport.

NORTH-EAST METROPOLITAN REGIONAL HOSPITAL BOARD.—G. O. Storey, M.B., B.Chir., M.R.C.P., D.Phys.Med., full- or maximum part-time Consultant Physician in Physical Medicine at hospitals and clinics within the Central and Hackney Groups.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Boucher.—On August 18, 1953, at Dorchester, Dorset, to Betty (formerly Thompson), wife of P. R. Boucher, a son.
Davies.—On August 22, 1953, at the Bromhead Maternity Home, Lincoln, to Eva, wife of Dr. Hartley Davies, of High Barn, Welton, Lincoln, a son.
Lucas.—On August 26, 1953, at Bristol Maternity Hospital, to Mary (formerly Campbell), wife of Dr. George Lucas, a daughter—Angela Jane.
Reilly.—On August 24, 1953, at the London Hospital, London, E., to Joy (formerly Petric), wife of Michael Reilly, M.S., F.R.C.S., a son—Christopher Michael.

DEATHS

Clarke.—On August 3, 1953, at Pine Cottage, Foxford, Co. Mayo, Eire, Isaac Clarke, L.R.C.P. & S.I. & L.M., late of Slough, Bucks.
Horne.—On August 10, 1953, at the City Isolation Hospital, Lincoln, Hush Wilson Horne, L.R.C.P. & S.Ed., L.R.F.P.S., D.P.H.
Mead.—On August 16, 1953, at "Bryn-v-Mor," Yarmouth Road, Lowestoft, Suffolk, John Clarke Mead, M.B., F.R.C.S., aged 72.
Pollock.—On August 4, 1953, at East London, South Africa, Andrew Maclean Pollock, M.B., F.R.C.S.Ed.
Rickett.—On August 13, 1953, at Crowmarsh, Oxon., Gerald Russell Rickett, O.B.E., M.D.
Wood.—On August 6, 1953, in Sussex, John Alfred Wood, M.B., B.Ch., of 10, Canterbury Road, Oxford.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Ocular Signs of Drunkenness

Q.—Is the reaction of the pupil helpful in establishing a diagnosis of drunkenness? In most cases I find the pupils widely dilated and only sluggishly, if at all, responsive to light. Is this due to a specific partial paralysis of the third cranial nerve? Could fright or fatigue account for this finding? Are there any other helpful ocular signs of drunkenness?

A.—In this country it is generally accepted that the reaction of the pupil is helpful in establishing a diagnosis of drunkenness. In the early stages of alcoholic intoxication the pupils are dilated; they may be unequal. They often contract sluggishly and may dilate again in strong light even if the light is still directed into the eye. Swedish observers, however, state that the so-called slow reaction of the pupil is a normal phenomenon correlated with the original size of the pupil (Skoglund, C. R., *Acta physiol. scand.*, 1943, 6, 96). In advanced intoxication and in coma the pupils may be pinpoint.

The changes in the pupil in alcoholic intoxication are probably due to the same mechanisms as the comparable changes seen during the stages of general anaesthesia. Since the early stage of alcoholic intoxication corresponds to the "excitement" stage of general anaesthesia, it seems likely that the dilated pupils are in part, at least, caused by an increased secretion of adrenaline. Depression of the parasympathetic system may also play a role. The dilatation of the pupil which occurs in fright is due to sympathetic overaction perpetuated by the secretion of adrenaline. Neither fright nor fatigue would usually give so prolonged an effect as occurs in alcoholic intoxication.

In drunkenness the eyelids are usually swollen and the conjunctivae suffused. Diplopia may occur, but strabismus can seldom be demonstrated by objective tests. Swedish observers regard the presence of nystagmus as the most valuable ocular sign of alcoholic intoxication. A fine lateral nystagmus is said to appear at blood alcohol concentrations of 0.08 to 0.10%. The sign disappears at concentrations of over 0.30%. Its absence is not therefore proof of the absence of alcoholic intoxication.

Recurrent Genital Herpes

Q.—What is the best treatment of recurrent herpes genitalis? Would circumcision help? Is there any danger of a man who is about to marry infecting his wife?

A.—The treatment of recurrent herpes is rather unsatisfactory, particularly the form occurring on the genitals. If the eruption is entirely limited to the prepuce circumcision would be worth trying, but not otherwise. Alternatively, the method of repeated smallpox vaccinations (eight times at fortnightly intervals) should be employed. There is, no doubt, a theoretical possibility of marital infection, but in actual practice this does not often seem to occur. The virus of herpes is very widespread throughout the human race, and it seems likely that recurrent attacks depend more upon the state of immunity of the subject than upon opportunities of infection with the virus. The disease, although a nuisance, is very seldom anything more; for this reason, the risk of marital infection need not be regarded with any great alarm.

Toxaemia of Pregnancy and Blood Groups

Q.—Is there any known relationship between blood-group incompatibilities between husband and wife and the occurrence of toxæmia of pregnancy?

A.—In the past it has been suspected that there might be a relationship between blood-group incompatibility between foetus and mother and the occurrence of toxæmia in the mother. However, it has never been established that there is such a relationship, and the general opinion is that incompatibility of this kind either plays no part at all, or, at the most, accounts for only a few cases.

Trichomonas Infection in the Male

Q.—I suspect a husband of reinfecting his wife with *Trichomonas vaginalis* during intercourse. Is this likely in the absence of a urethral discharge? How should the diagnosis be made in the husband? What treatment should be given to the husband if my suspicions are correct?

A.—*Trichomonas* infection may be present in the male without there being any obvious urethral discharge. The organisms can sometimes be demonstrated by scraping the epithelium just within the urethral meatus with a blunt curette, or in material obtained after prostatic massage. They have also been demonstrated in swabs taken from within the prepuce. In infected cases the urine is said to be typically hazy and containing fine threads; if it is centrifuged lightly the organisms can sometimes be found in the deposit. The material obtained by any of these means is preferably examined immediately both by means of a hanging drop preparation and by means of culture, for which a special medium is necessary. If there is any delay between collection and examination the swab should be kept moist with saline.

There is no specific remedy for trichomonas infection in the male. Various urinary antiseptics such as hexamine have been tried, and so have all the antibiotics and sulphonamides. None is of much value, although claims have been made for aureomycin. In fact there is a good deal of evidence to show that the infection is self-limiting in the male and that it disappears within three months and often in less time than this. The so-called chronic cases are probably examples of reinfection, husband and wife infecting each other in turn. This vicious circle can be broken by abstinence from coitus until the woman is cured, the infection in the male meanwhile dying out of its own accord.

Technique of Bronchography

Q.—What is the best way of performing bronchography?

A.—The selection of the method for bronchography depends on the situation and extent of the area required to be visualized. For example, the major bronchi in the right lower lobe can often be visualized by simply dropping the opaque medium over the back of the tongue while holding the tongue forward to prevent swallowing. This can be done without analgesia, but most people prefer analgesia of the nasopharynx and larynx. Lignocaine is the usual analgesic employed (in 4% solution as a surface analgesic for this purpose). A small piece of rubber tubing is passed through the nose until it rests just above the larynx. The tongue is held forward and the opaque medium slowly injected, tilting the patient to whichever side is necessary. This method is very successful for the right middle lobe and both lower lobes. It is not so successful for the upper lobes, except in the hands of an operator with wide experience.

Direct injection into the trachea just below the cricoid is probably the most effective method. Under local analgesia a fairly wide-bore needle is inserted into the trachea and a few drops of cocaine are injected through it to abolish the cough reflex before injecting the opaque medium. The needle is left *in situ* while the patient is tilted into the various positions.

Heavy viscous media are now being abandoned for bronchography because they remain in the lung for a very long period. Not only may they obscure subsequent alterations in a lesion, but they may also provoke an oil fibrosis. Water-soluble media are now available. These are quickly and completely absorbed, but they are temporarily rather irritating and deeper local analgesia is required to inject them successfully.

Death on the Table

Q.—Who has the legal responsibility when a patient dies under an anaesthetic, the anaesthetist or the surgeon? Is there any difference between Scottish and English law in this connexion?

A.—If a patient dies under anaesthesia, responsibility for the death does not necessarily rest upon either surgeon or anaesthetist. Legal responsibility, in the sense presumably intended by the question, will exist only if either surgeon or anaesthetist has failed in the proper execution of his functions as a skilled professional person.

An anaesthetist is an independent expert. Although not legally responsible if the death has resulted from a genuine and understandable error of judgment, he is expected to exercise a degree of skill, care, and judgment commensurate with his professional qualifications and experience. It is his responsibility to assess the fitness of the patient to support the strain of anaesthesia, to advise regarding premedication, to select a suitable form of anaesthesia, to ensure that the administration is satisfactory, and to have available and apply when necessary the appropriate measures for resuscitation. The decision to operate, the choice of operation, and the actual operative procedure is the responsibility of the surgeon, and, again, legal responsibility for a death will only exist if he has failed to exercise that degree of skill, care, and judgment which can reasonably be expected from a professional person of his particular qualifications and experience.

There is no difference between Scots and English Law in the matter. In both countries, the circumstances of the particular case would fall to be considered, and the important elements are, not understandable errors of judgment, but failure to exercise the requisite degree of judgment, skill, and care.

There is no case on record where criminal proceedings or a successful civil action has been taken against a medical man in respect of a death under anaesthesia, although there have been unsuccessful actions.

Diagnosis and Treatment of Congenital Syphilis

Q.—What surveillance and treatment should be given to the baby of a syphilitic mother who (a) had no treatment during pregnancy; (b) was treated thoroughly during pregnancy?

A.—(a) A baby born of a syphilitic mother who has had no treatment may or may not have contracted the disease, and it should be noted that in those that are born infected there may be no demonstrable *T. pallidum* or clinical manifestations. A child can also acquire the disease during parturition from a mother with an active lesion on the genitalia.

On the clinically normal infant serological tests should be carried out soon after birth and repeated one month, three months, six months, and 12 months later. If all these tests are negative it may be assumed that the child has escaped infection.

In the treatment of congenital syphilis the optimum dosage of penicillin has not yet been established. The dosage recommended varies from 100,000 to 300,000 units of procaine penicillin in arachis oil with 2% aluminium monostearate daily for 10–15 days. In the emaciated infant it is advantageous to give three-hourly injections of aqueous penicillin G (total dosage 200,000 to 600,000 units per kg. of body weight). It is not necessary to follow this up with

arsenic or bismuth. Relapse, clinical or serological, is extremely rare, and in such cases the course of penicillin is repeated.

(b) Thorough treatment of a syphilitic mother during pregnancy will ensure a non-syphilitic baby, but serological tests should, as a precautionary measure, be carried out at the intervals stated above.

Efficiency of Inunction

Q.—Some therapeutic substances are given by inunction. What is the evidence that they are absorbed through the skin and exert a pharmacological effect on the underlying tissues? I have in mind medicaments such as the creams which contain adrenaline, and the mercury inunction of former days. If it is true that certain drugs can penetrate the skin in this way, on what does this property depend?

A.—The evidence that some therapeutic substances are absorbed through the skin is that they are excreted in the urine. Thus mercury can be detected in the urine within 24 hours of its inunction. Methylsalicylate can be detected in the urine within one hour. Sulphur and atropine are also absorbed through the skin when applied as ointments. Some say that iodine is, but some deny it. There is, however, no evidence that adrenaline is absorbed through the skin from a cream containing adrenaline. Drugs can readily be drawn through the skin into the general circulation by electrolysis, but as soon as they reach the dermis they are picked up by the blood stream and dispersed throughout the body. Absorption depends chiefly on physico-chemical properties rather than on chemical constitution. Substances to be absorbed must be soluble in both oil and water.

Masks for Industrial Dusts

Q.—What are the best kinds of mask to use against industrial dusts, such as asbestos powder, which are irritating to the nose and throat? The patient in question develops a dermatitis when rubber is in contact with his skin.

A.—The use of a mask for protracted periods to give protection against dust is not satisfactory, and protection against a dangerous dust such as asbestos should never be left to this means.

When temporary protection is required, however, the use of a dust respirator has value. The standard models are usually fitted with a rubber face-piece, but it is rare for the particular rubber used in these respirators to give rise to skin trouble. There is, however, on the market a much simpler respirator with an aluminium frame and employing cotton-wool as the filter. This is effective in stopping the inhalation of a certain amount of dust, but it has no official approval for use with asbestos. Many of these masks are to be seen at the Home Office Museum, in Horseferry Road, London, S.W.1, where it is also possible to see examples of effective methods of suppressing dust in industrial processes.

Correction.—In Dr. M. E. M. Herford's letter (*Journal*, August 22, p. 441) on breast-feeding in Oxford, the sentence, "Skin infections, particularly eczema, were not frequent in bottle-feds in each age group," should have read, "Skin infections . . . were more frequent in bottle-feds . . ."

BRITISH MEDICAL JOURNAL

LONDON SATURDAY SEPTEMBER 26 1953

In the summer of 1950, when the National Health Service had been in operation for two years and the British Medical Association's report on "General Practice and the Training of the General Practitioner" had just been published, the Council decided that an authoritative review of the actual conditions of general practice should be undertaken. For this purpose it appointed a Special Committee "to review the present position in general practice, its difficulties and its trends, both generally and with reference to the two years' experience of the National Health Service Acts, and to the B.M.A. report on 'General Practice and the Training of the General Practitioner,' and to make recommendations." The Committee instructed Dr. Stephen J. Hadfield to make a survey of a random sample of different types of practice in England and Wales and Scotland. His own account of the results of this appears below. The results of the Postal Inquiry answered by nearly 13,000 general-practitioner principals and the Committee's Report appear in a specially enlarged number of this week's Supplement.

A FIELD SURVEY OF GENERAL PRACTICE, 1951-2

BY

STEPHEN J. HADFIELD, M.A., M.B., B.Chir.

Assistant Secretary, British Medical Association

This is a report of a survey of general practice carried out between February, 1951, and March, 1952. I wish to emphasize, in anticipation of a possible objection that parts of the report are one-sided, that my information was obtained entirely in general practices and from general practitioners. Some of the general practitioners interviewed criticized other fields of practice, and these criticisms are set down in the report, but it was not within my terms of reference to seek answers to them from practitioners in the fields concerned.

The approach to the survey was critical in the hope that the discovery and assessment of shortcomings, faults, and difficulties might lead to action which would eliminate them. Consequently these matters are given considerable emphasis. Where this touches the adequacy or otherwise of the practitioners seen, a final assessment is given towards the end of the report (p. 705), and this should offset any inaccurate impression given in the remainder of the text.

Since the report was completed certain important administrative changes in general practice in the National Health Service have occurred as a result of the Danckwerts award, including the implementation of the Spens recommendations for the remuneration of general practitioners. They should be borne in mind when reading certain passages of the report, which have been left in their original form. Their retention will serve to show how necessary were the changes and will perhaps encourage further improvements in the interest of both patient and doctor.

INTRODUCTORY

A Field Survey of General Practice

The field survey was designed to cover 200 general-practitioner principals in England, Scotland, and Wales. This number was chosen, first, as being large enough to

give a representative picture and to ensure that all types of practice would be visited, and, secondly, as being sufficiently small to be surveyed within a reasonable time by one investigator. The practices seen included various types of town practice, rural practices remote and otherwise, a Highland practice, and a practice on one of the islands off the west coast of Scotland. The number selected was such as to make the survey last over one year, so that practices were seen, so to speak, at all states of the tide.

The purpose of the survey was to obtain an objective picture of the varieties of general practice existing at the current time and how they were being conducted, and to obtain information upon which the types and magnitude of the difficulties existing could be assessed. The method of survey adopted was for the investigator to spend the best part of one normal day with each of the practitioners selected.

I sat in the surgery through one surgery session (in some instances more than one) and then accompanied the practitioner on his normal round. The practitioner's views were obtained during the many opportunities for conversation that occurred during the day.

Although I did not suggest it, approximately half of the practitioners invited me to accompany them into the houses they visited. It was interesting to note that, on the whole, neither in their homes nor in the surgery did patients seem to be in the least upset by the presence of another doctor—in fact, after a brief introduction the patient seemed to take no further interest in my presence. Neither did the patient object when the practitioner, as happened in a number of instances, invited me to examine the patient with him and to join in the consultation.

In ten instances the doctor made it a condition of my visiting him that I would not be present at consultations. My visits to these doctors were thus somewhat shorn

of their objectivity, though in some instances I was taken into the patients' houses instead. The reason usually given was that the doctor "could not submit himself or his patients to such an embarrassing situation as would arise from having a third person present." In one case the practice had changed hands three times in the space of four or five years. This practitioner, naturally, was unwilling to agree to anything that might give rise to further rumours which would seriously impede the rehabilitation of the practice.

In view of this diffidence among a few it was surprising that such a large proportion consented to my presence. It was indeed laudable, for I am prepared to believe that some overcame a natural diffidence in the interests of the survey.

The doctors themselves seemed quite unperturbed by my presence, although one or two of them did tell me afterwards that they had not felt entirely at ease. I always expressed my readiness to leave if the patient clearly preferred it. Such a need, however, seldom arose. Five practitioners had no surgery sessions for me to attend.

Method of Selecting the Practitioners to be Visited

As it was considered essential to visit practitioners in all districts the country was divided into 20 regions. For convenience, this was effected by taking the 19 regional hospital board areas, the twentieth area being made by taking separately the geographical area covered by the Metropolitan Branch of the British Medical Association.

Acting upon the suggestion of Professor Bradford Hill, the names of all principals in general practice in England, Scotland, and Wales were placed in alphabetical order and then sorted into the 20 areas, according to their addresses. Starting from a drawn number, every 64th name was taken, working through from region 1 to region 20. The selection was continued through a list of practitioners in entirely private practice; this gave a random selection of 300 names. The list was then reduced to 200 by casting aside every third name. This, incidentally, created a reserve list of 100 names, one reserve name being specifically allotted to every two practitioners on the main list. The 200 on the main list were the ones to be visited. Only in case of death, retirement from practice, removal from the area, or absence from the practice for the period of the survey was a substitute visited and included in the results.

Where there was refusal to allow a visit no substitute was visited. This happened in six cases, and consequently the number visited fell short of the 200. There being only one substitute for each two doctors, it was found on three occasions that both of the pair on the main list were excluded for reasons other than refusal; thus for one of the pair there was no substitute. In three instances where one was required a substitute was found not to be available. The number visited was further reduced by these factors to 188.

A few doctors who originally refused were subsequently persuaded to change their minds, and when visited were found to be at least as co-operative as the others. There were two refusals with no reason given. Reasons for other refusals were as follows: "That it is a misguided policy to imply publicly that an observer is needed to unearth the significant facts; that it is the

particular attitude of mind of each practitioner himself that is important, not the opinion of an observer." This practitioner added that the presence of an observer would be an embarrassment to himself and to many of his patients, and that the whole atmosphere during the visit would be artificial. Another said he disagreed with the method of obtaining evidence and that he hated anyone sitting in the surgery with him. A third was shortly leaving his practice and thought that there was no point in trying to "tinker with the present set-up, which is founded on a false philosophy at variance with Christianity."

By this method of selection visits were paid from Ross-shire to Cornwall and from Caernarvonshire to Kent, and included a large number of industrial, cathedral, and seaside towns, and a wide variety of rural areas. Some of the practices were large partnerships with full lists, while one or two were very small indeed. The majority of practices varied widely between these two extremes.

The programme of visits was arranged so that as many areas as possible were visited more than once, at different seasons. For example, seaside towns were visited both in and out of season; big industrial and country practices were seen both in summer and in winter. The same practice was never visited twice, as time was insufficient; but, generally speaking, each type of practice was seen at different times of the year. The actual arrangement of the journeys, the choice of where to go next, was haphazard and made by me as I worked through the list. So far as possible I tried to make several visits on each long journey.

It was found possible to visit four doctors, sometimes five, in most weeks. Saturdays and Sundays were not used for visits. After seeing nine doctors in a pilot or preliminary "run," the survey proper was begun on February 6, 1951, and the last practitioner was visited on March 4, 1952.

In part the survey was designed to show to what extent the tenets in the Cohen Report were being followed and also to find out as much as possible about general practice in the country.

Facts and opinions were sought on the same subjects in each practice. So far as possible I categorized the answers obtained in order to facilitate analysis. This categorizing was necessarily vague, but I found it possible to place the answers in the correct category without much difficulty.

In this report the large majority of opinions expressed are those of the practitioners themselves. Some are the conclusions come to by me as a direct result of my observations. Where there is expressed what might be called a personal opinion this is clearly indicated.

I wish to place on record my grateful thanks to all those practitioners whom I was privileged to visit for the helpful way in which they enabled me to carry out my task. In addition I would like to thank most warmly those doctors' wives who gave me hospitality during my visits.

Further, I am grateful to the Council of the Association for making it possible for me to have the experience of undertaking this Survey, to the Secretary and my colleagues on the staff of the Association for their assumption of my duties during my absence, and to the clerical staff for their invaluable help.

The Average Practitioner, 1951-2

There are so many variations in general practice that it is perhaps difficult to draw a picture of the average general practitioner. Nevertheless, the attempt may be worth while. Evidence that wide variations do exist in many directions will be found throughout the whole of the report.

The average doctor lives in a house in the area in which his practice is situated. He has his surgery premises either in his house or in a special wing built on, probably by his predecessor, or he may have a lock-up surgery, with or without a caretaker, in a busier street near by. He may share this with a partner or partners, though he usually has his own consulting-room.

His list will be in the neighbourhood of 2,500 in the town or 1,500 in the country. In addition he has a handful of private patients. He takes the administration and organization of his practice in his stride and does not find that this side of his activities worries him much. Unless he is an extreme individualist he will prefer to have a secretary-receptionist to help him with correspondence, with finding and filing patients' record cards and reports, and with the telephone. He may not be able to have such assistance owing to insufficient income or to lack of accommodation, the latter often being due to the impossibility of obtaining suitable premises or of converting his present place.

In any case, his wife has a considerable burden to bear. Over and above the abnormal strains on his household that a doctor's calling occasions, and in the absence of suitable domestic help, she has to see that the needs of the patient are served. The telephone and the door-bell must be constantly answered. Such is the difficult situation in which many a doctor's wife is placed that she cannot embark upon her morning's shopping without considerable forethought and organization. To go out with her husband is a rarity. Even a visit to the cinema or bridge club requires careful planning, if it is possible at all.

The average doctor will usually be able to overcome this to some extent, and also, outside the busy part of the winter, to ensure himself a very little leisure, by arranging a rota system of duties for the evenings or for half-days. Apart from this he will regard himself as more or less permanently on duty. He will have encouraged his patients to send their messages to him before he sets out on his morning round, but there always remains a nucleus of patients who are unaware or unheeding of the need to assist the doctor in this way.

The average doctor, while telling you that he is quite prepared to deal with any emergencies that come along, would be much happier in his practice, and would probably carry it out to the better satisfaction of himself and his patients, if only he could purge his list of this hard core of inconsiderate trouble-makers. He is genuinely fond of the majority of his patients and is anxious to do his best for them, but he will be the first to admit that there are times when the accumulation of trivial or unreasonable demands at the end of a tiring day may well impair this feeling.

Between 8 and 9 o'clock in the morning he will be taking his breakfast and answering telephone calls for visits. He will be in his surgery promptly at 9, and will see patients until, say, 10.30. This is an average time, during which he will see up to 25 patients. There will

be a bit of everything most days. Perhaps 20 of the patients will have minor ailments or come for follow-up, or be calling merely for a certificate. The other five may be more interesting from the clinical point of view and need more attention. Thus he may spend 15 minutes on one patient and then quite properly deal with the needs of five or six others during the next 15 minutes.

When the patient enters the doctor may need to ask the name, especially if the patient has not recently been under treatment. He will get out the record card, if he has no secretary to do it for him in advance. He will then note the patient's complaint and ask what supplementary questions he may consider necessary. He will not as a rule follow the method of approach which is taught to the medical student, except where he suspects there is something more than a minor ailment to deal with. Of necessity he has learnt to short-cut the detailed method. His knowledge of the patient gives him a start. If he has treated the patient year after year he will know just how detailed his examination need be.

The morning surgery finished, he will make out his visiting-list, with final adjustments to include new calls that have come in. He arranges his round geographically so far as is possible. This is sometimes conditioned by messages which have about them a more urgent ring, or by visits to specially ill patients—for example, the revisiting of a patient to whom he was called during the night.

The possibility, or indeed the likelihood, of his day being disrupted by a midwifery case, an accident, or some other emergency will cause him to tell his household or his secretary in what order he proposes to visit his patients. Thus there is at least some chance that he may be "got" in an emergency. When he and all his partners are out visiting, his wife may quite likely receive an "urgent" message later in the morning. On being told that all the doctors are out visiting but that she will get a doctor to call as quickly as she can, the inquirer may exclaim, "There must be a doctor there: I don't believe it. . . . Send a doctor at once or I will report you." Needless to say such messages are rarely as urgent as they sound.

Doctors vary greatly in the time they take over their visits, quite apart from the requirements of the case or the volubility of the patient. Most doctors, in the towns and in the country, will have 15 to 30 visits a day to pay during winter months, when there is no epidemic raging. In the summer the number may be down to about half that of the winter. In the country a higher proportion of the work is done in visiting, while in the town the majority of patients are seen in the surgery—in some practices the great majority. Distance and accessibility for the patient are the factors here. So that, while on the average the numbers of visits paid are the same in both town and country, the country doctor needs more time for the same number of visits, but his surgery sessions are shorter. In a few town practices the visiting-lists are very high indeed, reaching the forties in quite ordinary times. Practices vary enormously, but these big visiting-lists are not within the average.

Nearly all practitioners told me that, since the N.H.S. began, surgery attendances have increased greatly but visiting-lists have, if anything, become smaller; also that late calls in the evening, many of them unnecessary, have increased, while the actual night calls, those which involve rising from bed, have dropped slightly.

The practitioner has perhaps six hours between morning and evening surgery in which to get his calls done, have his lunch and tea, and travel, the average distance being 15 to 20 miles a day. He will get in and out of his car, say, 25 times a day: if he has many gates to open it will be many more. Thus he can usually manage to see about five patients an hour. Rather, it should be said, he can visit five houses an hour. In some houses he is asked to see two, three, or even four patients where he was expecting to see one. This is a development for which the N.H.S. is responsible. I witnessed this in many a home, just as I also saw much of the multiple consultation in the surgery. These things are very prevalent indeed.

If the various members of the family are paraded into the surgery their cases must be gone into one by one, and more often than not they are trivial in the extreme. When prescriptions are requested for absent members of the family it is often easier for the doctor faced with a waiting-room queue to give a prescription than to enter into an argument about the patient having to come to the surgery in person.

There is nowadays little of the old custom of turning the doctor's visit into a social occasion. There are many offers of hospitality, but there is little time for the prolonged chat. Days vary, but often the end of the visiting-list seems far off and there is anxiety whether the list can be finished in time. It is rarely that a visit to a house lasts more than 10 minutes, and many need not be so long. Some practitioners work much more quickly than others—for example, on the day I was there one visited 27 houses, and drove 12 miles in doing so, in 130 minutes. Another visited 44 houses in 190 minutes. These are exceptional.

At lunch-time, which is normally not longer than half an hour, there may be telephone calls to be made to the hospital, to the district nurse, or to the chemist. A general practitioner's lunch "hour" is hardly ideal for the preservation of a good digestion.

The afternoon round follows the same pattern as the morning—that is, if no emergencies have intervened to upset the programme. If they have, the afternoon is almost certainly an anxious rush. The practitioner will usually make time for a cup of tea before starting his "6 p.m." surgery. Many start this at 5 or 5.30, for the patients are already there and the sooner it is started the sooner it is finished.

To have to pay a further visit or two after the evening surgery is common, though if there is a rota system with partners or colleagues the practitioner may have to do this only on certain days of the week. This is a great advantage, for he can then sit down quietly to his supper and face the evening with tranquillity.

If he has not this freedom he may well have to turn out again after supper. In the winter he usually has to forgo his half-day; there is too much work to be done. Yet the work varies. Except in epidemic times there is seldom a period of high pressure for more than three weeks at a time. Just as the general practitioner is beginning to think to himself that the strain will never end there comes a sudden lightening of the burden. This is sometimes all too short, but is nevertheless welcome. There are, of course, some practices that seem always to be hard-pressed. Summer and winter the lists of visits in these practices and the queues in the surgery are long and there seems to be no let-up. Not in these

practices can one partner go away and leave the other to carry on. He must get a locum. Another practice, much the same on paper, will produce about half the pressure of work. I have seen both sorts in the same town. This must have some relation to the personality of the particular doctor, though I have been unable to define clearly the factors responsible for the difference. Some areas of the country seem to produce more illness or more general-practitioner attendances than others. The impression I gained was that this is due, in certain districts, to an increased incidence of respiratory and rheumatic diseases.

(A) THE RANGE OF GENERAL PRACTICE

Continuity of Treatment

Most practitioners are anxious to keep in as close touch as possible with the progress of the patient, even though the responsibility for the treatment has passed temporarily out of their hands into those of the hospital out-patient and in-patient department. They like to be ready to take over the treatment, convalescence, and rehabilitation after the patient's discharge from specialist treatment. A smooth transference of responsibility is more likely when general practitioners are working with the hospital and where the liaison with the hospital staff is good.

Another aspect is the degree to which a patient is exclusively cared for by one general practitioner for either one or all successive illnesses.

Obviously, in the single-handed practice the patient is exclusively looked after by one doctor. The exception is where a single-handed general practitioner has an assistant and uses him in such a way as to depart from the "one illness, one doctor" principle.

In some partnerships responsibility is divided even in the care of an individual illness. Patients have no means of knowing which of the partners they will see when they call at the surgery. There are no definite times when Dr. A or Dr. B will certainly be present. Patients are seen by whoever is there. The lists of visits to be paid that day are pooled and divided up among the partners in a manner suited to their convenience. This may be on a geographical basis or just haphazard, bearing no relation to which doctor has previously visited the patient, either in the current or in the previous illness. The latter method is used by 9% of practitioners. It is defended on the grounds of necessity in order to make the visiting-lists economical of time and thus allow the work to be dealt with. The point is also made that the patient may well get better treatment by having more than one opinion. A number of patients prefer such an arrangement for this reason. In addition, the doctors in a partnership get to know all the patients and to gain their confidence. This is considered to be a great advantage in relation to emergency calls where a rota system is in operation.

There exist all shades of variation in this matter, the general tendency, outside the strictly personal practice, being to take the middle course, in which, on the whole, one doctor continues to attend any one patient for the duration of any one illness. Then there are those doctors who, from my own observation, I feel confident share the knowledge of all the patients so thoroughly that the method approximates to a working together on the case. There is a world of difference between the partnership that starts the day's work with, "I'll do the

west town and the High Street and you do the housing estate," on the one hand, and the partnership of two whose day starts with, "Will you go and see Jim Budd to-day and see what you think? I found some creps yesterday," on the other.

It is stated by some doctors that the majority of patients get used to being seen by more than one doctor and do not mind. I have no doubt, from my own observations, that this is true of a number of patients.

I saw a small number of doctors who did not know the names of most of the patients who came to the surgery and gave no signs of having had any previous acquaintance with them. Although some doctors describe themselves as "bad at names" I found this complete ignorance was not so noticeable in the practices where patients kept to the same doctor.

In one of the best practices that I saw the work has so increased as to make it necessary to depart from the previously existing state of affairs in which the patient kept to one doctor. In another practice the two partners tended to change the visits round, but were finding that the patients seemed to want the practice to develop into a more personal one. I saw one practice run on group-practice lines. The doctor whom I met kept surgical cases to himself. When he saw a medical case he would hand it over for further treatment to his colleague.

In many cases I found that the partners had a fair knowledge of all the patients in the practice. This seemed more common in the smaller practices. This leads me to another point. In the nature of things, and because the terrain demands it, most country practices are, on the whole, smaller. Thus it is easier for the country practitioner to know the patients of his partner than it is for the town practitioner who has a full list. Also, of course, it is so much more important to be able to arrange visits geographically in the country. In the winter it is often essential in order to get the work done. Views vary concerning the desirability of changing patients or doctors during the course of an illness and whether or not the patients lose anything by it.

In considering this item any treatment by a partner in an emergency is, of course, not taken into account.

Health Education and Preventive Medicine

Almost all general practitioners give inoculations and vaccinations, and when opportunities occur encourage mothers to bring their children for immunization. A small proportion expressly advise patients to take their children to the clinic, for they say they feel it is far better for the child to receive a prick at the hands of a stranger than to be estranged from the family doctor because he has hurt him. One doctor said he thought it created a neurosis. Some said they preferred the clinics to do the injections because it saved them work.

Nearly all the practitioners visited give helpful advice on positive health and preventive medicine when asked by the patient. Some spoke of lack of time. The majority confine their activities in this field to taking what opportunities present in individual consultations and, with some, at antenatal clinics arranged by them in their own surgeries. Nine per cent. are enthusiasts and spend much time in educating the public in matters of health. A few gave me the impression that they

could not be bothered with health education. Nearly all the remainder feel that they are too busy treating disease to preach its prevention. In many cases this is undoubtedly true.

Patients are not, as a rule, receptive to positive instruction; they regard it as preaching and treat it with suspicion. I often noticed that when the doctor's remarks veered from the symptoms and the pills to such things as open windows, suitable clothing, and other precautions a curious blank look came over their faces. This applies especially to mothers of children.

Treatment of the Patient as an Individual

The majority of doctors are of course concerned to assess and to treat the symptoms of which the patient complains. They also show, by questions and conversation, a knowledge of or an interest in the family and occupational background of the patient. This interest in the patient as an individual was particularly conspicuous in about a quarter of the doctors interviewed. Some of these are interested especially in the psychological approach. A few isolated practitioners (6%) seem to have no interest beyond the actual symptoms complained of. In one case at least I felt that the practitioner regarded his patients as something of a nuisance.

Diagnosis

I saw a wide variety of diagnostic methods. Most of the doctors (93%) whom I saw at work carried out some sort of examination in some cases: 69% could be definitely classified, on the evidence before me, as leaving no doubt that all patients received what examination was necessary.

I kept constantly in mind that the extent of the examination needed in any case is conditioned by the fact that doctors know the patients and also may have examined them quite recently.

Some of the senior practitioners, though undertaking little in the way of examination, have obviously developed an instinct or sixth sense. This, coupled with a background of long experience, enables them to use a minimum of effort and yet leave one with the feeling that they are unlikely to miss any serious diagnosis. I found the margin a narrow one between such practitioners and those who, through over-confidence, tended too often to put their trust in spot diagnosis. Among these latter were men who expressed to me their feeling of pride in the way they were doing their work.

Among a small proportion (7%) of both young and old there is a need for revision of the methods of diagnosis they use. There is a need for constant vigilance on their part to determine for themselves whether in fact they are doing their duty by their patients in this matter of clinical examination.

It would be easy to cite a few examples where no attempt was made at examination when it was clearly indicated. To do so would create an unfair impression while ignoring the countless occasions when I witnessed thorough examinations. Suffice it to say that I did see a small number of practitioners whose standard of examination was in the danger zone.

The remainder (24%) vary over a fairly wide range. Some of these seem ready now and again to take a chance, and some of them are forced into this position by the excessive demands upon their services. Yet I

observed that some of the busiest men are the most thorough in examining their patients.

I was told by one doctor (and a similar attitude was noted in several others) that some forms of examination—for example, per vaginam—are not convenient to ordinary general practice conditions. These were left for the hospital to do. Another examines where necessary but considers that surgery conditions prevent its being done easily. Facilities for examination—for example, examination couch—were absent in 11 surgeries. Minor reorganization of the consulting-room or of arrangements for surgery attendances would have made it possible to conduct any necessary examination.

A few doctors have solved this problem by making appointments for "special examinations," as they are called, or by arranging to call at the patient's house. Such arrangements meet with, at any rate, some degree of approval from most. But it may sometimes be forgotten that the patient often comes for such an examination after much marshalling of courage and in the fear occasioned by, say, a mammary lump or an irregular menstruation. The ideal, surely, is for the practitioner to have his premises so arranged that the patient can receive the necessary examination at the first visit and not be sent away with anxiety mounting and having to muster courage all over again. Several times I thought I detected a look of disappointment from this cause.

It was interesting to note how rarely are inspection and percussion used in examining the chest, even among doctors who attain a reasonably high standard of examination in other ways. I was surprised at the prevalence of the method of examining the abdomen through the clothes and with the patient standing. This was adopted sometimes in the absence of an examination couch and sometimes under pressure of work, no doubt backed by a knowledge born of experience as to the time taken by the really well-corseted woman or bewaistcoated man to remove enough garments to permit of a reasonable clinical examination according to the textbooks.

A small percentage of practitioners do not seem to examine their patients except as a rarity. It must be emphasized that their number is very small. Some general practitioners have got into the habit of hurrying through their work. Whereas they may be busy at times, and undoubtedly are, they have developed the habit of not examining patients even when they are not unduly pressed.

A certain amount of spot diagnosis is inevitable in a busy practice, but, as mentioned before, some rely on it overmuch. I saw one doctor in particular try to deal with over a hundred patients in a day. This made thorough examination impossible—for example, it was not possible for him to give a thorough examination of the chest in patients presenting anew with cough.

Lest this account of the shortcomings of a few should lead the reader to conclude that the average practitioner does not examine his patients adequately, it should be stated once again that the majority of the practitioners whom I saw left me in no doubt that all their patients received whatever examination was necessary.

Treatment

Over 90% of the practitioners that I saw are undoubtedly interested and careful in the treatment of their patients. They give the necessary advice, super-

vised rehabilitation, prescribe carefully, and do dressings and emergency treatment. Not for them the mere hurried writing of prescriptions that I witnessed among a few.

About two in every five are anxious to undertake, and do undertake, as much of treatment as comes within what has been recognized as the normal scope of general practice.

I ascertained whether or not the practitioners visited undertake minor surgery. The majority (53%) do not or do only a very little. It is noticeable that in the towns only 27% of the general practitioners do minor surgery, whereas in the country 60% do. Cottage hospitals no doubt play their part in this, but some of the country doctors seen were miles from a hospital. Obviously in the towns the proximity of a general hospital is an important deciding factor.

Some doctors declare that it is preferable, in order to ensure asepsis and the best technique, for minor operations, varicose vein injections, hydrocele tapping, and the like to be performed in hospital. The reasons most often given for not doing minor surgery were, however, lack of time (by no means always borne out by the day's work witnessed) and the absence of a special fee.

Two or three of the doctors seen give physiotherapy in the form of light treatment.

Information to Specialists

An overwhelming majority of practitioners send letters to consultants when referring patients. I sometimes saw the letters. They vary in length; most are confined to a statement of facts and a request for an opinion.

Most consultants or hospital authorities will not accept a patient unless there is an introductory note from the general practitioner. Even so, I noticed that this, of all the questions asked, was normally answered in an affirmative that was almost indignant.

One doctor had been told that he writes too much. Another criticizes his partners for the poor notes they write. I saw three who wrote very short and scrappy notes, one almost impossible to read. Another could not be bothered with a proper letter, for, he said, the consultant could find out for himself. He is one of the few who send a visiting-card with either their diagnosis or the main symptom written thereon.

One doctor says he attaches "great importance to the letter in the patient's interest." He regards it as a passport to the consultant, which takes away something of the patient's embarrassment and fear. A woman doctor expresses herself succinctly thus: "The better the letter I send the better the reply I expect, and get."

The forms used by hospitals for general practitioners to make out-patient appointments interested me greatly; some serve as the letter to the consultant as well. There are several variants. One that is satisfactory to some general practitioners is a letter-card, prepaid to the hospital appointments clerk, which is simple for the practitioner and preserves professional secrecy by reserving the inside sealed part to be used for the doctor's letter. The information required by the clerk is on the outside, and the letter is opened only by the consultant himself. The letters and cards used by many hospitals have not incorporated this desirable feature, so that it is possible for any clinical notes to be read by the lay clerks.

Administration

Ninety per cent. of practitioners seem to take the administrative side of their practices in their stride. Some of them complain of the tedium of paper work, but they keep on top of it either by the exercise of a natural efficiency or by employing a secretary.

I saw only five doctors whose enthusiasm for the administrative side of practice was such that it was almost a hobby. There were five who disliked it intensely and were evidently much harassed by it.

A very large number of the practitioners visited complained bitterly of the volume of advertising matter which arrives daily by post. They wonder by how much this excessive advertising increases the nation's drug bill.

Miscellaneous Duties

I found that 13% of general practitioners combine with their practices considerable activity outside the day-to-day care of patients. The single-handed and the partners seem to be equal in undertaking such pursuits. With partnerships the covering for attendance at medical boards—often some distance away—or at hospital sessions is much easier.

Sixty-nine per cent. of general practitioners undertake what must be an average amount of work under this heading, the commonest forms being life assurance examinations and dental anaesthetics. Occasional attendance at schools and factories was noted also with some frequency.

About one practitioner in six, usually by his own choice, undertakes nothing, or almost nothing, beyond the general care of his patients.

I formed the view that the variety afforded by a modicum of extra tasks is of value to the general practitioner. The man who does none seems less contented, and more affected by what has become the humdrum nature of the task. There is an optimum degree of development of miscellaneous duties, consistent with the conduct of a fair-sized practice and with the preservation of some degree of continuity of treatment of patients. I think that the practices of some of those who do a great deal outside the day-to-day care of patients are inclined to lose something of the individual touch.

Non-Medical Advice

Inquiries under this heading were not quite accurately so named. There is much in the way of personal and family advice that a general practitioner can and does give that is partly medical. It often has a bearing on the medical condition, more particularly, perhaps, in psychosomatic medicine. So that I directed my inquiries to finding out to what extent the general practitioner's advice is sought on matters not purely and entirely clinical; to what extent does the general practitioner fill the role of guide, philosopher, and friend on the non-medical and quasi-medical stage.

I find that about nine out of every ten regard this as a part of general practice. They give advice or help when it is asked for by the patient, or sometimes when it seems to be necessary. It may vary from writing letters for the illiterate to advising about a will. These are two examples that I saw in my survey. Of the nine, one general practitioner will be specially active on the

more social side of his patient's affairs, including activities which properly come into the field of social medicine.

The remaining practitioners (14%) do nothing in this way. Some have too recently started in practice or are still young enough to be regarded as being without worldly wisdom. Others avoid giving "non-medical" advice, saying that it is nothing to do with a doctor, that much of it is the job of a lawyer, that doctors have been too dogmatic in the past and have talked and advised upon matters of which they know next to nothing. Others say that they or their patients have found themselves in difficulties as a result of inept advice; now they avoid a repetition.

Special Interests

Inquiries regarding special interests and the possibility of applying them in general practice were not fruitful: 51% of practitioners have some particular bent, sometimes leaning rather definitely towards a specialty; 65% of these find at least some scope for their interest.

One says he has no scope to pursue his interest—blood counts—because he is not paid for it. Those interested in chests and dermatology complained of the difficulty of obtaining radiological diagnosis and treatment. Time was the factor most often mentioned. The interests covered most of the field of medicine and surgery.

The Scope of Practice

Recent Advances in Medicine

Of those who have been in practice long enough to judge, all but 30% say that the scope of practice has been increased by recent advances in medicine. Nearly all mention particularly the treatment of pneumonia with penicillin and the use of the sulphonamide drugs. One practitioner remarks that recurrences and relapses of pneumonia occur more frequently; thus the work is not lessened as much as might be expected.

Approximately 35% contend that the work has increased from this cause, one saying that this is because he prefers to give all injections himself. On the other hand, another doctor observes that he now has fewer visits with oxygen cylinders to pneumonic patients.

Three doctors say that their scope has been diminished by recent advances in medicine. I did not succeed in getting any very satisfactory explanation for this opinion. One said that there is now so much more that can be done for a patient by the general practitioner if only we had fully equipped health centres and beds.

Increasing Specialization

Sixty-six per cent. are unaware of any effect of increasing specialization on the scope and work of practice. The small number (9%) who feel there is an increase in scope due to this cause are of the opinion that more can now be done for patients by referral to consultants whose interests lie in a smaller and more detailed field. I believe that in giving this opinion they really intend the credit to go to the advances in medicine rather than to the fact that medicine is becoming more fragmented.

One-fifth find their scope diminished by an increased demand by patients for reference to specialists and to specialized clinics. There are, they say, so many different consultants nowadays that there is little of interest left for the general practitioner to do. Also, hospital

work has been taken away in many instances and the general practitioner feels that he is not trusted to do things for his patient. He has to think much more carefully when deciding to whom he should refer the patient. Indeed, he is at a loss sometimes to determine who is, in fact, the proper specialist for the particular case.

The most telling cry of those who find the scope of practice lessened by increasing specialization is that of lack of flexibility of hospital beds. Beds in some hospitals are allotted in smaller and smaller batches to an ever-growing list of "ultra-specialists," thus reducing the number of general beds available for "ordinary" cases.

Co-operation of Public Health Services

Only 4% of practitioners have found that the scope of their practices has benefited by changes in or increased co-operation by the public health service since the introduction of the N.H.S. A few mention the better arrangements made by the medical officer of health for obtaining home helps, entry to convalescent homes, or invalid chairs. One speaks of the assistance he has received in mental and nervous cases. There is appreciation where pathological facilities are provided by the public health laboratory.

A few find their scope diminished through the treatment of children by school medical officers without the general practitioners being informed. Others say that mothers are encouraged by the public health clinics to have their babies in hospital rather than at home under the care of the general practitioner. In one area—except in serious emergencies—patients are not admitted to the city maternity hospital unless they have attended the antenatal clinic. The general practitioner is powerless to arrange an admission.

Some clinics are said to have encroached considerably on general practice. Patients are treated partially at clinics, and then, when they have to take to bed, the general practitioner is called in and knows nothing of what has gone before. One practitioner emphatically stated that, whereas he formerly regarded the public health service as an encroachment on his practice, now that it makes no financial difference he is willing for them to share the burden of work. There are others whose remarks suggest a like view.

The points mentioned above are mostly of detail. The overwhelming majority have found no effect on their practices of any changes in the public health service or of increased co-operation.

It seems appropriate here to introduce the subject of relations between the general practitioner and the public health medical officers. There is little sign that the introduction of the N.H.S. has brought about any change in the relationship between the general practitioner and the officers in the public health service. Forty per cent. report little or no contact with the service, and 41% that relations are satisfactory. The word "satisfactory" is not used in the sense that perfect or near-perfect liaison exists between the two branches of the profession. By so describing the situation many of the doctors merely mean that they have no complaint and that on the rare occasions when they have asked something of the medical officer of health they have got it. Of the remainder 9% consider their relations to be unsatisfactory.

On the "satisfactory" side I heard how general practitioners had been actively helped by the medical officer of health in handling dysentery outbreaks. About one-half say the school medical officers now write to general practitioners and give them the opportunity of arranging for consultants' opinions when required, instead of doing it themselves without passing on the information. In a few cases improved relations are attributed to a change of medical officer of health, in one to the fact that he is now full-time instead of one of the local general practitioners. As an example of the other side of the picture, a general practitioner in a large city complained that the medical officer of health had announced in a newspaper that he was in close touch with the general practitioners and that all was prepared in the event of an epidemic breaking out. The general practitioner states that no such contact in fact exists. Then, again, while the general practitioner was strenuously overworking in the influenza epidemic of January, 1951, he was disgusted to read a statement by the medical officer of health that there was no epidemic in the city.

One general practitioner, in the middle-age group, gave me the impression that he knows nothing about the public health service. He reported that the sanitary inspector was good for disinfection, and that was all he knew. One complains that his medical officer of health is interested only in vaccination returns, while another says that the general practitioners in the area have found it necessary, when anything was required of the medical officer of health, to band together and approach him as a deputation.

I heard a good deal of criticism of the clinics and the medical officers working in them. These latter are said to exercise insufficient care when advising patients, and mothers, to go home and call in the general practitioner. Patients having some slight disability or something that calls for no more than an ordinary message to the general practitioner are given the impression that they must ask the doctor "to come at once." It is complained that there is little appreciation by the doctors in the clinics of how disrupting such unnecessarily urgent messages can be to a general practitioner's work.

The explanation may well be that the clinic doctors are unaware of how liable the patient is to be misled by what is said, or to exaggerate the seriousness of a complaint or illness, especially of their children, and do not word their advice accordingly.

Quite often I heard criticism of the work of the clinic doctors. This greatly disturbs the general practitioner, especially when he is unaware that the patient is under treatment at all. Some complain that the clinics treat the patients up to a point and then send them to their own doctor to "clear up the mess." Other general practitioners say that they get many notes such as "Rash: please treat," or "Temp.: please treat." Some feel that the clinic doctors should be allowed to prescribe some of the simpler remedies under the N.H.S. Others resent the fact that another doctor, unknown to them, should be treating their patients. They object to being sent for when the child, who has been for several days under treatment for a running ear at the clinic, has to be kept at home on account of a temperature. The general practitioner knows nothing of what has gone before. Complaints on these lines were

commonly met with. I think they spell only one thing—a deplorable lack of contact between the two branches of the profession.

Some do not mind a certain amount of encroachment by the clinics, because they are only too glad to shed part of the burden on someone else, and they readily admit it. But the majority prefer to treat their patients themselves.

Many feel that the clinics are not necessary. One says that the public health service is redundant so far as individual medicine is concerned. One medical officer of health had told a general practitioner that he was not interested in individuals. Some feel that the medical officers of health overlook the general practitioner's circumstances; for instance, when they send a request to him to vaccinate a child without sending a parallel notification to the parents to instruct them to get in touch with the doctor.

I found some confusion of thought among a few general practitioners about the responsibilities of the public health service. For instance, some seemed still to think that chest physicians were responsible to the medical officer of health and blamed him for situations which were not within his control. A general practitioner sent a case to the chest physician. He heard nothing more until he discovered later that the district nurse was giving streptomycin and P.A.S. He believed that the public health service was at fault in allowing this to happen without his being informed. I had several complaints of the existence of that mystic attribute "the official mind." There were complaints of delay, such as one of 48 hours in seeing a case of pediculosis. The general practitioner finds it difficult to understand such delays.

Undoubtedly the best relations with the public health service are found where the general practitioner himself is doing part-time work in a clinic in that service. It has the double advantage of his getting to know the public health medical officers, and of his being able to make them see his point of view and appreciate some of the important points of general practice.

Elsewhere, and this covers most places, the general-practitioner service and the public health service are miles apart, with the result that both are becoming less effective. General practice is so wide a field that it can get along without the clinic side of the public health service. This is not to say that it would not benefit from closer co-operation.

From my observations I believe that the clinical side of public health work will not reach maximum usefulness unless and until it is brought much more closely into contact with general practice. It should be at least as closely allied to general practice as is the district nursing service.

It has been pointed out that the information required by public health medical officers for the performance of their duties is possessed by the general practitioner. Often there is a barrier between the two branches which can be made less formidable only by the co-operation of the medical officers of health on the one side and, on the other, by the general practitioner overcoming his existing resentment of the public health service, which is largely due to past errors and misunderstanding.

The medical officer of health needs the good will of the general practitioner, and it is necessary for him and his assistants to set out to obtain it. The general

practitioner needs to understand, too, that the public health service can mean co-operation and help instead of duplication and intervention.

During my investigation I found almost no evidence to suggest an enlightened attempt, either by the public health medical officers or by the general practitioners, to co-ordinate the public health service and the general-practitioner service.

Public Education in Health

"Our Medical Correspondent" has done much harm: "Press articles tend to panic patients": "They have too much 'little learning' and get confused"—these are some of the views expressed by 39% of the general practitioners, who find their patients made more sensitive, more "neurotic," by press articles and radio talks on health matters. Some describe it as "public education in disease." Increased surgery attendances, including demands for drugs mentioned, are spoken of as common consequences.

One doctor believes that many patients are discouraged from going to the doctor because they attach to some of the commonest of symptoms the fear of early cancer that has been instilled into them. Another feels that, although patients are more sensitive, further efforts at enlightenment are worth while. Another disapproves because patients' hopes of cure are raised too high. He feels that it is better for patient and doctor that the art of medicine should remain something of a mystery.

Most practitioners agree that this affects patients in different ways according to their type: 35% say it has no effect upon patients; and only 13% feel that as a result of public education in health patients are more sensible in their approach to their illness and to their doctor.

There is considerable divergence of opinion regarding the desirability and the effectiveness of these approaches to the public, which rather suggests a need for examination of some of the methods used. Perhaps also it suggests that there is a line of demarcation between the use of a medical article which does not rise above the suspicion of being a publicity stunt and the genuine attempt to improve the patient's well-being and state of mind by acquainting him with enough knowledge to understand something of disease processes and to achieve a sense of proportion in these matters.

Effect of N.H.S. on Scope of General Practice

Forty-five per cent. of practitioners applaud the fact that their scope in practice has been widened by the introduction of the N.H.S. Not all of these applaud, or even like, the N.H.S. itself; but on one point they are clear—that they can do more for their patients.

They speak with relief of being able to prescribe what the patient needs and to visit him as often as the condition requires, free from the inhibitive consideration of the patient's purse.

The opinion was expressed to me that, because of the costly new drugs and treatment essential to modern practice, the N.H.S. came in the nick of time. Most doctors are, from this point of view, glad of it.

It is doubtless true that, in the past, essential visits were always made and often not charged for, but the patient no longer needs to be anxious about the size of the doctor's bill. The general practitioner welcomes this. He welcomes also the removal of the financial bar to the calling in of a consultant to a consultation in the patient's home.

Other things, such as the stabilizing of a diabetic, can be obtained more easily. There are even a few practitioners who find that the waits for out-patient appointments are shorter.

A considerable number say that the summer and the winter work have evened out more; advances in medicine keep the winter work down while the "free" service keeps

the summer work up. Nearly all say that actual night calls are fewer but that the number of calls received after the practitioner has set out on his round, and also in the evening, is greatly increased.

The small number (15%) who say that the N.H.S. has diminished their scope proved rather a puzzle. For example, there are several who say that their scope is less because "I no longer do minor surgery," or "I send work to hospital now." Although the time factor (or "lack of time" factor) was quoted as the reason, I was unable to discern any marked difference in the demands made upon these practitioners and upon those who customarily undertake minor surgery. Some say their scope is diminished because they will not do minor surgery without special payment beyond the capitation fee, and these are not necessarily always the ones whose income has become smaller under the N.H.S.

Some who formerly did major surgery find their scope diminished by being no longer permitted to do it. Some have had other forms of hospital work taken away from them. The demands of the patient for hospital and specialist treatment are blamed for reducing the scope of practice. One doctor summed up these feelings by remarking that the N.H.S. tends to inhibit the desire to do more for the patient. Significantly the practitioner who made this remark showed no signs of any such inhibition.

About a quarter of the practitioners say that the N.H.S. has made no difference to the scope of their practices.

Midwifery

General practitioners seem to be divided into approximately equal thirds in their attitude to midwifery: one-third dislike midwifery, and have discontinued it entirely or are anxious to cut it down to a minimum; one-third are not very attracted to midwifery, but, feeling that it is a necessary part of the practice, do some; and one-third are keen on midwifery, regarding it as an essential part of general practice and endeavouring to do as much as possible. Attendance at the actual delivery is not, of course, obligatory, and a number of practitioners, even in this last category, do not find it necessary to attend the delivery in all cases.

Most of the doctors said that they see patients far more often than twice before the confinement, as is required by the regulations, many reverting to their pre-Service custom of monthly and, later, fortnightly examinations. Some find that not having to attend the delivery does, at least, enable them to cope with increased demands in other fields.

A vicious circle seems to be operating. There is a danger that the general practitioner will do less and less midwifery. Some fear that the practice of midwifery will be wrested out of his hands altogether. In most areas more mothers are having their babies in hospital. The reasons are economic and domestic as much as clinical. Then there is a tendency for midwives to deliver women at home in the absence of the general practitioner. He is less in demand because of the entry into hospitals, and in some areas because midwives and antenatal clinics encourage patients not to employ the general practitioner. Thus he is getting less and less experience in midwifery, which is building up the argument that he should not undertake it.

At present there is little pulling together in the matter. Misunderstandings occur and jealousies are aroused. The solution would seem to lie in the improvement of the local co-ordination between the general practitioner, the midwife, and the local authority, with the consultant and hospital service behind them ready to assist where necessary.

Relations with Midwives

Though nearly all practitioners are fairly well satisfied with their relations with midwives there are some indications of deterioration. So much seems to depend on the personality of the midwife and of the practitioner himself, but here and there I heard of lack of co-operation.

Suspensions were expressed to me that a B.B.A. ("Born before arrival") is occasionally deliberate; and there were a few complaints of the midwife failing to notify the general practitioner until the day after the labour.

Some midwives appear to resent the general practitioner's having anything to do with midwifery. One says that the midwife takes booked cases from him by persuading the patients not to attend at his surgery for antenatal examination.

A small proportion of general practitioners have expressed a fear that some midwives are anxious to supplant the general practitioner in the midwifery service. The general practitioner knows that he can complain when his instructions to be called to a case are flouted, as happens in some cases and with some midwives. But he is reluctant to do so, for he knows that the midwives are in a strong position; some are even suspected of favouring an opposition doctor.

Some general practitioners are anxious about this situation. They feel that now and again the midwife tries to take on too much clinically in her efforts to draw the practice of midwifery to herself, to the exclusion of the general practitioner.

One practitioner's real anxiety was that the tendency not to send for the doctor was developed to such an extent that he could not give his trainee assistant any experience in midwifery.

(B) PROFESSIONAL RELATIONSHIPS

Relations with Neighbouring General Practitioners

Most practitioners (70%) report that their relations with neighbouring practitioners are good, improved, or satisfactory. The word "satisfactory" is used broadly. It sometimes means no more than a wave of the hand as their cars pass, and an absence of any difference between them. As often as not there is no occasion for anything more than this to develop; or if occasions do present themselves the doctors are too busy or uninterested to turn them to good account.

The question on this aspect was asked largely because of a suggestion that the N.H.S. had encouraged competition for patients by unethical means. Where this was mentioned it was usually related to the period immediately before and after the introduction of the N.H.S., and is reported to have now disappeared. Here and there (about 5%) suggestions were made that unethical practices still continued.

What is more significant is the frequency with which single-handed practitioners, while pointing no finger of accusation, feel so unsure and suspicious of their colleagues that they are reluctant to co-operate with them, for instance, in the working of a rota. It is not a question of bad relations; it is a suspicion of one another hindering the establishment of good relations. Such single-handed doctors are perceptibly more anxious and less contented in their work, especially in the well-doctored areas. Where partnerships exist there is little anxiety on this score.

On the brighter side of the picture are reports of a decreasing tendency to unethical conduct, of the improvement of co-operation by formation of local general-practitioner associations, or regular (bimonthly) drawing-room meetings of groups of doctors, and of the formation of rotas. These are the result of attempts to overcome problems presented by the N.H.S. Improvement in relations has invariably resulted. The practitioners concerned are delighted and find the innovations valuable in every way.

A good example of improved relations exists in a small industrial town where the four doctors were in opposition to each other. The practitioner visited persuaded them all to join in partnership, the better to meet the problems introduced by the N.H.S. A sound and happy partnership had resulted. I saw a similar result where the practitioners had started with a rota system and developed it into a partnership.

The General Practitioner and the Consultants

Sixty-seven per cent. of practitioners declare that their relations with consultants have not altered since the inception of the N.H.S., and a large majority consider them to be fairly good, though often with some reservations.

The sort of reservation frequently made is, "So long as I can select my consultants all is well." Some consultants regard the general practitioner as a nobody; while one young general practitioner finds that the younger consultants are more approachable and more helpful. Many feel that consultants regard themselves as superior beings. One expressed well the feelings of several when he said that the younger consultant is on the defensive in order to conceal an inferiority complex. He does not like to acknowledge that the more experienced general practitioner knows a great deal. It is complained that the younger consultant has no knowledge of the general practitioner, his work, or how to treat him, and that a gap is forming partly because the consultant no longer depends upon the general practitioner for his living.

Many practitioners, while still able to maintain excellent relations with consultants they have known for many years, are frightened by the gap forming between them and the younger consultants. Deterioration is feared when the senior consultants are replaced by younger men who seem to feel superior to the general practitioner.

Some find improvement of relations arising out of the more frequent meetings with consultants on domiciliary visits. From several quarters, though, I heard complaints that consultants were so busy concentrating on other duties that the patients referred to them at hospital were seen, as often as not, by registrars and house officers. General practitioners feel some frustration when they are unable to get the opinion they want.

I tried to find out to what the general practitioners attribute any gap that is forming between these two branches of the profession.

Exclusiveness of Specialties

Only a small number (18%) feel that the increasing exclusiveness of specialties is causing a gap; 45% had no comment to make; while 37% were of the opinion that this was not a cause. One said that the general practitioner has to watch that the specialist does not miss things that are outside his field. For example, he sends a patient who is hoarse to hospital for investigation and learns he is admitted under the E.N.T. surgeon, laryngoscoped, and discharged as fit. On having the chest x-rayed a week later extensive lung disease is shown to be present. Though it may put the general practitioner on his mettle, he finds it more difficult to select his consultant, and feels that the "tinged" attitude is encouraged by over-specialization. A general practitioner, with experience of house-physicians who refused to see surgical cases in the casualty department, was alarmed about future rifts that might appear.

Personal Contact with Consultants

Only eight practitioners feel that the absence of personal contact with consultants is causing a gap to develop. Most meet the consultants from time to time at domiciliary visits or at medical meetings. The frequency of meetings is usually not very great—a few times a year, perhaps. Twenty-three practitioners have little or no contact with consultants. These include four who do not seek it. Another says he hardly knows the consultants, who are 12 miles distant, and feels there is a gap between them and him. Two say they "have no time for consultants."

The very large majority would agree with the practitioner who told me he "likes to travel to a consultation in the consultant's car, for it gives me an opportunity to obtain from the consultant much valuable information." Of those who were in practice before the N.H.S. 90% formerly met the consultant at domiciliary consultations. The proportion

now is 94%. There are probably many more such consultations nowadays. Almost all practitioners are anxious to "be there," but a few definitely place little value upon the meeting. One says he refuses to have the one consultant in the area who insists on the general practitioner being present. Some say the consultants prefer to "drop in in their own time" and not to make an appointment which the general practitioner can keep.

Only 9% of practitioners find it possible to meet consultants in out-patient departments (before the N.H.S. the figure was 12%). In almost all of these cases there are facilitating circumstances, such as a local hospital to which the general practitioner has entry or where he is a co-member of the staff with the visiting consultants. In others the visits are necessarily only occasional. On the whole, general practitioners find that such attendances are quite impracticable because of a clash of times. Some feel that they would not be welcomed if they were able to attend.

Separation of Postgraduate Training

Nowadays a man who wishes to become a specialist is more or less bound to set his course in that direction immediately on qualifying lest he fail to pick up a favourable wind to take him to his goal. He cannot afford, as formerly, to spend time learning something of the hazards of general practice before setting out. He must, in order to be sure of reaching consultant rank, proceed with little or no knowledge of general practice. Forty-one per cent. believe that this plays a part in separating the general practitioner from the consultant. I personally believe that there has not yet been time for this factor radically to affect the relations between them.

It was made clear to me that a large proportion of the practitioners, while quite happy with the consultants they have "used for years and still meet," are fearful of what relations will be like in the years to come, when many consultants will have had no general-practitioner experience. Several remarked upon the lack of understanding of the general practitioner by consultants who have not been in general practice. Others put it the other way round: that one can tell which consultants have done general practice, and that these are the best, at any rate from the point of view of the general practitioner. It is generally also thought by these general practitioners that such are the best from the point of view of the patient as well. Those without general-practice experience have no appreciation of how patients live, so that their approach to the patient suffers, and they make recommendations which are not practicable outside hospital.

One practitioner has the impression that the young consultant is too interested in the scientific side and does not handle patients well. He talks tactlessly in front of them. One feels that their not having had experience of general practice adds to "their feeling of superiority." Another put it this way—that consultants should have occasional courses from general practitioners in the same way as general practitioners do from consultants. Another says that a consultant with no knowledge of general practice is of no use to him.

Twenty-three per cent. said that all consultants should have some general-practice experience as part of their training, and 5% thought that it was unnecessary. Two felt it was necessary only for the general consultant, as opposed to what they were inclined to call the "technician type." One of these thought it was essential for psychiatrists also. I was told that for consultants to have experience in general practice is necessary for the advancement of medicine.

Rather similar arguments and opinions for and against were obtained when discussing the lack of opportunity for the general practitioner of to-day to graduate, in the fullness of time, into consultant status. One said that even if there were opportunities the general practitioner would be up against such specialized competition that it would not be worth it.

Separate Administration

Only about 10% feel that a gap is being caused by the entirely separate, and to the general practitioner remote, administrative arrangements—the executive councils for the general practitioners on the one hand, and the regional hospital boards for the consultants on the other. Some remark that the general practitioner has no channel through which he can make criticisms or suggestions regarding hospital treatment or services. One practitioner feels that the administration is untidy and that there should be one unit of administration for both consultants and general practitioners. In a number of places I was told that no trouble was likely to occur, because some doctors were on both the local executive council and the regional hospital board.

Though perhaps the figures do not underline it, in far too many areas a hedge is growing between the general practitioner and the consultant. The seeds were probably there before the N.H.S. Outside factors, some necessary and some unnecessary, appear to have given a fillip to their development.

The eye of the newly qualified doctor who wants to be a specialist is of necessity, and in the current fashion, fixed upon the material aspect of his career, and sees any chance of experience in general practice only as a likely obstacle to the achievement of his ultimate goal.

This struck me as an unsatisfactory, not to say dangerous, state of affairs, likely in the future to produce frustration in the general practitioner, to diminish the value of the consultant, and thus react unfavourably upon the patient. I liked the plan of one of the general practitioners whom I visited; he makes a practice of asking the house officers in the local hospital to spend a day with him from time to time in his practice. He finds they welcome it and return to their hospitals much enlightened.

Twenty-eight per cent. complain of failure by the consultant to ensure that the general practitioner receives a prompt report on the patient referred. In addition to these an equal number, while not complaining, receive reports only after a long interval. They seem to be satisfied that they receive reports at all. Twelve per cent. say they feel that the younger consultant, particularly, overlooks the interest of the general practitioner in his patient. I heard few complaints of patients being seen by consultants without reference from the general practitioner. There is little increased tendency among patients to approach consultants direct, and usually when it does happen the latter are careful to communicate with the general practitioner. Only in one town did I find any serious complaint, and this from two or three practitioners about more than one consultant. One quoted an instance in which a patient of his was seen by a physician, referred by him to a surgeon, admitted to a nursing-home, and operated upon without the general practitioner knowing anything about it. While being a fairly common occurrence in this one town, it must be emphasized that such things are almost unheard of elsewhere.

The suggestion that consultants and general practitioners should be under the same or a closely integrated administration would no doubt give rise to many objections, and might almost be regarded as revolutionary. Nevertheless, I came away from my investigations with a feeling of which I could not rid myself. This is that the separate administration of the various parts of the medical profession hampers the efficiency of the medical services and detracts from the value of the service to the one for whom it exists, the patient.

Public Health Medical Officers

Relations with public health medical officers have been discussed earlier in this report.

District Nurses

No practitioner has any complaints about the district nurses. Those who commented were full of praise of their efforts. One suggested that they all ought to have the George Cross.

It appears from remarks made by a number of general practitioners that they are using the district nursing service to a great deal more than formerly. Much in the way of injections (penicillin, streptomycin) is being done by the district nurses. This is usually because the pressure of work on the general practitioner is so great. In some I detected what I thought was rather too much readiness to delegate these tasks. In most cases it arises from the fact that the nurse is visiting the patient daily, anyway, and it is thus no hardship to ask her to give the daily injection.

Relations with Health Visitors

Seventy-two per cent. of the practitioners whom I asked (I did not introduce this subject until I had seen about 40) have no complaints about health visitors. Neither were there any reports of co-operation worthy of notice. Some of these have no knowledge of health visitors' activities. Twenty-eight per cent. complain bitterly about them. Some regard them as a waste of nursing man-power.

The complaints heard are mostly of interfering with and instituting treatment and of giving advice outside their sphere without consultation with the general practitioner, and of frightening patients. Mothers are advised to stop breast-feeding—one on account of pain in the breast due to engorgement. One health visitor threatens mothers that their children will develop rickets if they do not take cod-liver oil; another tells mothers that their children have some disease or that they need operations.

Then they promise early admission to sanatoria, which the general practitioner knows is next to impossible. The general practitioner probably gets some of the blame for not seeing that the health visitor's promises are carried through. There is criticism sometimes of the general practitioner's treatment, and remarks like, "Your doctor should have prescribed so and so." There is too much prying into how the doctor is treating the patient and too much talk of the illness of neighbours, colourfully expressed, which frightens patients.

These complaints point to an unsatisfactory state of affairs. Better co-operation with the public health services would surely change this situation, to the patient's advantage. I have seen an experimental practice in which health visitor and general practitioner work closely together and have a daily conference. The benefit to the patient inherent in this mutual assistance is at once apparent to anyone who has attended such a conference, as I was privileged to do.

(C) THE GENERAL PRACTITIONER AND HOSPITAL WORK

Since the inception of the N.H.S. there has been a drop in the proportion of general practitioners doing any form of hospital work. Of the practitioners seen, only 28% had done hospital work before the introduction of the N.H.S. the proportion now is 20%. In the towns 23% did hospital work formerly, now only about 16% do. In the country 38% of the practitioners used to do hospital work, and even now 30% do.

A number, though still doing some work in hospital resent having had their scope reduced. One says he is restricted to doing four tonsillectomies a week, even in the face of a growing list of patients needing that operation. Others were formerly on the staff as surgeons, whereas now although they have the use of general-practitioner beds, they are not permitted to do surgery.

Another point of view was expressed by the man who said that the N.H.S. had brought him to the point where he had either to become a specialist or to give up any sort of hospital work. Others feel that they are being steadily pushed out. The stock example of this is the general practitioner who formerly did all the anaesthetics at the local hospital. Now specialist anaesthetists are being appointed.

Most of the hospital work referred to consists of the use of general-practitioner beds in hospitals. Not all practitioners mind not having such beds. Many general practitioners in industrial areas have never been used to

having hospital beds and have hardly considered the matter as a practical proposition. Thus, only one-third of the urban practitioners having no hospital work or beds feel that their practice suffers in any way because of it. Nearly half of the country doctors feel that their practices would be better off for having hospital beds.

The arguments put forward against having beds are that they are unnecessary; that it means "too many cooks"; that a "lot of rubbish" is talked about the need for beds; that there is not time to use them properly in the face of the additional work arising out of the N.H.S. One practitioner says that, while he welcomes the possibility, he feels that the provision of an adequate number of beds in general hospitals is of far greater importance.

A town practitioner says that the taking away of general-practitioner beds is most damaging to general practice. Because of it the general practitioner of the future will be a less good doctor. Another says that the provision of general-practitioner beds would help to overcome his feeling of professional isolation.

To sum up, the urban practitioners do not seem to have any great enthusiasm for beds, except in the smaller towns where beds have been taken away from them. The country doctors are rather more interested so long as they are not placed so far from the hospital that their being on the staff would interfere with their ordinary visiting rounds. In discussing this problem the question of insufficient time kept cropping up. A number feel that the idea is a good one, and to the benefit of general practice, but are doubtful of being able to spare the time for its proper development.

Clinical Assistantships

Four out of every five favour the suggestion that general practitioners should be permitted to do clinical assistantships in hospitals. Most of them stipulate that time should be made to enable them to do it, or that the appointments should be paid. These two provisos are probably closely allied. There were some practitioners who, although interested, stated that the burden of work was such that they might find it difficult to accept such an appointment, even for one session a week, and at the same time continue to give their patients adequate service. The position would obviously be easier in partnerships where the partners were co-operative and would not all wish to undertake clinical assistantships at the same time.

A number expressed the view that it would be economically possible to take up a clinical assistantship only if no diminution of income were involved.

Some expressed the opinion that such appointments would be valuable for younger men only, say up to the age of 40. One says he would like to do it, but feels he would not be made welcome and would be looked down upon by the hospital staff. This mode of expression, which again points to the gap between consultant and general practitioner, kept cropping up in various guises during the whole of the survey.

Another favours clinical assistantships, not mainly because of the clinical value, but more for the advantage it would bring of close contact with the consultant world. Another says it should be compulsory for all practitioners at intervals.

Those unfavourable to the idea think that a general practitioner should stick to general practice, that if he did his work properly he would have no time. Some feel that it would be worthless because clinical responsibility would not be given; that it would not help because it would be specialist cases, not general-practitioner cases, that would be seen; and that what the general practitioner requires much more are general-practitioner beds in a local hospital.

(D) HOSPITAL FACILITIES

Fifty-two per cent. of the practitioners visited feel that practice is obstructed by the inadequacy of hospital services. The inadequacy refers to quantity rather than quality, and is of course closely bound up with staffing and accommodation.

Waits for Out-patient Consultations

According to 60% of doctors the average wait for consultations is two to three weeks; only 10% can expect their patients to be seen in a week or less. Eight per cent. find two months or longer to be the expected wait for an appointment unless the practitioner marks the case urgent. Most practitioners say they do this only in cases in which delay would harm the patient.

Opinions vary on what length of wait constitutes an obstruction or interference with the conduct of the practice. Some regard three weeks as too long, others are content. Just over 20% complain of obstruction.

Some say waits are long only for certain departments. The orthopaedic departments undoubtedly lead the field in occasioning lengthy waits, while usually E.N.T. and psychiatry tie for second place.

With psychiatry, of course, hurry is impossible. Some general practitioners feel that the E.N.T. specialists would be freer to see patients more quickly and to advise and operate on the more complicated cases if general practitioners were once more allowed facilities for operating on tonsils and adenoid cases. The long delay (two years or more) for tonsils and adenoid operations is such a common cry among general practitioners as to provide material for a music-hall joke. Many general practitioners who formerly undertook this work are no longer allowed to. They are not paid, and hospital facilities are denied them.

The long wait in orthopaedic departments was sometimes attributed to the inability of many of the specialists to trust the general practitioner to keep an eye on the patient.

Waits for Admissions

Whereas the greater proportion of doctors visited have constantly with them the bogey of long waits for beds for their patients, only in rare instances did I hear complaint that the admission of a suspected early cancer case was so delayed as to jeopardize the possibility of a cure by early treatment.

The satisfied practitioners are well content if their "cold" surgical cases are admitted within three months of their first being seen by a consultant. All agree on the necessity for maintaining a priority system for admission. For simple hernia, for example, the clerk can wait, while a high degree of priority is given to the collier.

About 70% of the doctors report that the "normal" length of wait for admission for non-urgent cases is six months or more. A few are able to get any type of case into hospital within a week because beds are available and the turnover is rapid. Yet one general practitioner told me that the surgeon to whom he refers his patients has ten patients waiting for each of his hospital beds. General practitioners who are on hospital staffs or in close touch with consultants find things easier.

Several mention that they are driven to using the domiciliary consultation service at times as a method of ensuring that patients are admitted to hospital. This applies rather more to emergency admissions, when it is used as a last resort. Fourteen per cent. of practitioners find serious difficulty in obtaining emergency admissions—12% of country doctors, and more than 14% of town doctors. Considering all that has been heard publicly about this problem, the number of practitioners reporting difficulty seems surprisingly small. The reason almost certainly is that where difficulties do exist they are usually very great.

Where an Emergency Bed Service operates I found a fairly consistent volume of praise for it. Admission is not always obtained by this means, and the service sometimes seems to be awkward. Nevertheless most practitioners find it infinitely preferable to the position of the country doctor who told me he "sometimes has to try four hospitals, each 20 miles away," or of the one who sometimes has to "go on his knees," or of him who has to spend an hour telephoning.

The Emergency Bed Service does not escape criticism. Several practitioners resent being asked to tell a lay clerk the temperature of a patient in whom he has made a diagnosis of acute appendicitis requiring admission to hospital. There are similar objections to "viva voce examinations" by house officers and questions such as, "Have you felt the pulse?" There seems a lot to be said for the principle that if a general practitioner has decided that admission to hospital is urgently necessary then the job of the Emergency Bed Service should be to find a bed and not first to decide whether or not a bed should be found. Presumably the Emergency Bed Service clerks ask certain questions (described as "impertinent" and "silly" by several) because they in their turn are asked these same questions by hospital officers.

Anyone who has had experience as a house officer knows that each area has its small quota of general practitioners who are adept and practised at obtaining urgent admission to hospital for patients whose clinical condition does not warrant it. Nevertheless, only those with experience of general practice can realize what a tremendous relief of anxiety there would be for general practitioner, patient, and relations if hospitals were to agree to see any patient whom the general practitioner regarded as urgently requiring admission. It would be for the hospital to admit him or to arrange his admission to another hospital unless the general practitioner was considered, by a doctor who had seen the patient, to be mistaken. The small number of offenders found to send cases frivolously and frequently could surely be dealt with tactfully by a quiet approach from a doctor connected with the hospital.

Admission of Aged and Infirm Sick

Long waiting for admission to hospital for the aged and infirm sick, and for old people, is almost a universal problem. Eighty per cent. of practitioners complain of the difficulties. Country and town are equally bad. Such expressions as "very bad," "hopeless," and "very time-consuming fixing them up" were evoked over and over again. Some describe the position as desperate and frustrating; the relieving officers who used to do such a wonderful job have disappeared. Particularly worrying has it proved where the local Poor Law hospital has been turned into a general hospital. One doctor said it was not surprising there is a problem: there are now 35 beds for chronic sick in his area, where formerly there were hundreds. Several told me that many on the waiting-list die before they are sent for.

I was told of a medical superintendent who visits the home of every patient who is proposed for the waiting-list. He examines the patient and assesses the degree of priority or urgency of the case. The admission list is maintained accordingly. The effect is said to be to make each general practitioner feel that his patient is being given the same chance of admission as the patients of other general practitioners, and that the worst cases stand the best chance. This method is thought to be fair and to deal with the problem on the right lines. The practitioner who told me of this is far less harassed than most others.

Another complaint I heard was of the unwillingness of the young people of to-day to care for their old folk. In several houses I visited this was apparent. I got the impression that some of the young couples, trying to concentrate on making and keeping a pleasant home for their families, are vaguely frightened of the possible effects of the home being centred round a chronic invalid. They are persuading themselves that the old people would be looked after better in hospital. The enormous increase in the numbers of old people has created an immense problem.

Housing conditions do not permit an easy solution, and lack of hospital beds prevents the most obvious solution. The result is that four out of every five general practitioners are daily grappling with this problem and are bearing a very large proportion of the burden of it. Others are

grappling, too, but the general practitioner and the district nurse find themselves in the hottest part of the fight, and with next to no weapons.

Tuberculosis

Another almost constant worry is the long wait for sanatorium beds. Only 23% say that waits are not long; 7% have no experience or make no comment. The remainder are finding that their tuberculous patients have to wait many months for admission to sanatoria. Attention has long ago been called to this situation, but it still persists.

Fifty-seven per cent. of practitioners are satisfied with the arrangements in their neighbourhood for the domiciliary care of tuberculosis cases. Some are satisfied because they supervise the treatment themselves, giving streptomycin and P.A.S., or sharing this duty with the district nurses.

Thirty-three per cent. speak of insufficient visiting and not enough attention to the patients in their homes. Some say they feel that the chest physicians have too much to do and too few chances of getting a sanatorium bed. As a result the care of patients in their homes is inadequate. They complain that all the care many of these patients get is to attend at the clinic about once a month and there be told that they are to come again in another month to have a further x-ray examination.

Three doctors specifically complain of the difficulty in getting patients visited in their homes, even when pressed, of a delay of a week before a visit was paid to a case of haemoptysis, and of six weeks' delay in visiting another case, despite several telephone calls by the general practitioner. A typical instance of the kind of inattention complained of is that of a patient being visited three times in two years by the "tuberculosis nurse" and nothing else.

Minor Operations at Hospitals

Only 14% complain that there are long waits for getting minor operations performed on patients at hospital. The remainder have no complaint. The complaint does not apply to urgent infective conditions, but only to such conditions as sebaceous cysts and ganglia, the majority of which can usually be borne for a few extra weeks without hardship.

Reasons for Inadequacy of Hospital Provision

Practitioners were asked for their opinions about the reasons for the inadequacy of hospital provision. The majority had no theories to offer or drew attention to the building situation and the shortage of nurses. A few mentioned that nursing as a profession was unattractive and underpaid. Others mentioned general practitioners sending cases to hospital unnecessarily, increase in the local population, and the fact that advances in medicine have made it possible to operate upon patients whose condition would formerly have been regarded as hopeless.

Some remarked on the effect of allotting fewer and fewer beds to more and more specialists in smaller and smaller fields. There is less flexibility of beds and fewer are available for general and emergency work. Teaching hospitals are blamed by some for keeping interesting cases too long, for teaching purposes.

Some attribute many of the difficulties to the fact that the introduction of the free service, coupled sometimes with public education in health, and always with official encouragement to use the service, has uncovered many conditions the existence of which the patients formerly kept to themselves. Now patients are enlightened and encouraged and are presenting themselves for treatment, and they need treatment; and until this back-log is dealt with the hospitals will give the appearance of inadequacy.

Appointments Systems for Out-patients

Most practitioners now find an appointments system operating in the hospital out-patient departments to which they refer patients. Twenty per cent. of these comment unfavour-

ably. Most of them say that patients have to wait just as long as ever they did when they reach the hospital. In fact, the appointments are not kept by the hospitals.

A few say that the appointments system acts like a dam, letting a little through while the water accumulates behind it. The consultants now see only a prescribed and appointed number and the delays get longer and longer.

A favourable comment was that the general practitioner may now grade according to urgency the patients he sends.

Some hospitals send for two or three patients for one appointment and are criticized for thus causing delay. The defence may be that patients on occasion fail to keep appointments and that it is necessary to ensure an adequate flow of patients for the consultant to see.

On balance, I find that the appointments system is favourably viewed. Most general practitioners feel that if further study is given to the problem a more satisfactory system could be evolved.

Direct Access to Radiological Departments

Forty-one per cent. of practitioners are able to send their patients direct to the x-ray department. Of those without such access 53% complain that their practices suffer, especially from the consequent delay in coming to a diagnosis. Of those with no complaint about the lack of facilities, a substantial proportion say that the reading of an x-ray film needs a consultant's opinion as well. Fifty-one per cent. report that they discuss the results with the radiologist. One practitioner finds great advantage in being able to go to the hospital, when he has time, and take part in the screening.

An important point made by some is that when a general practitioner refers a patient for an opinion the consultant of to-day "invariably has an x-ray film done." It is argued that most general practitioners are excellent judges of the need for such investigation; they can be, and should be, trusted with direct access. If they were, the amount of radiology would appreciably lessen.

Direct Access to Pathological Departments

Sixty-five per cent. of the general practitioners have direct access to some pathological facilities. This is by no means always the pathological laboratory of the local hospital. In some areas pathology, often limited in scope but more than the bacteriology required solely for purposes of preventive medicine, is done for general practitioners in the laboratories of the public health service. This is warmly welcomed by them. In one large town, where I visited several practitioners, all spoke appreciatively of the service of the borough pathologist, his eagerness to help, and his interest in the correlation between the patient's illness and the pathological findings. He often visits the bedside.

Fifty-two per cent. of those without such access feel that their practice suffers from this lack. About half of the practitioners, on occasion, discuss the results with the pathologist. While two complain that it is difficult to get in touch with the pathologist and another that the pathologist would not welcome it, others say the reports are adequate and they have no need for such discussion.

Very few (10%) do their own blood counts. Some say they used to do them but have given it up owing to pressure of work. A few do estimations of haemoglobin and sedimentation rates. The large majority of general practitioners consider that their results would be of little value, for they have no time to keep their hand in.

Physiotherapy Service

About one general practitioner in five can arrange for physiotherapy to be given to any patient of his requiring it. Some of these have to send to a physical medicine specialist, but reasonable requests are not refused. The remainder must first refer the patient to a consultant, as it is he who can authorize physiotherapy. In 34% this involves long delays, sometimes because the orthopaedic

consultant cannot see the patient for several weeks, sometimes because of inadequate facilities in the physiotherapy department, sometimes both. In acute conditions the symptoms may clear up before treatment can be started.

In a number of towns and in a few country areas the patient may obtain physiotherapy privately. This may be less costly than repeated expenditure on bus fares to the local hospital. Many general practitioners think a domiciliary service would be better, and instance the time spent in draughty buses and out-patient halls as undoing any good done by treatment. One general practitioner is annoyed at having to send patients 17 miles away to obtain a consultant's recommendation for treatment at a clinic just down the road from his own surgery.

Some think the consultants keep the patients under treatment too long, thus lengthening the wait for others. Three practitioners say that too many facilities for physiotherapy tend to stop patients helping themselves. Some like the "screen" and are not anxious for direct reference.

There is not sufficient physiotherapy for all, but, except here and there, I did not get the impression that this is causing serious hardship.

(E) RELATIONS WITH HOSPITALS

Questions were asked concerning how far hospitals were encroaching on general practice. Only a very small percentage thought that this occurred on a serious scale.

Only 3% of practitioners complain that hospitals see patients without a doctor's letter. This, of course, excludes patients presenting themselves "off the streets" as casualty cases. One in four finds that hospitals tend to some extent to retain cases longer than necessary, keeping them for treatment which could be regarded as in the province of the general practitioner. More than half of these general practitioners do not mind, and are perfectly happy for the hospitals to shoulder the burden. The practice is not always frowned upon, for, as some practitioners say, the hospital doctors often feel that, having started the treatment of a case—for example, incision of an infected palmar space—they are shirking their duty if they do not continue to treat the patient until the condition is almost cleared up. They do not consciously or deliberately take work from general practitioners.

Half the practitioners find the position much improved under the N.H.S., though complaints are still heard that the hospitals do not appreciate the distances patients have to travel to attend daily for simple dressings. Some attribute the improvement to the fact that in the past the hospitals were interested to keep up high attendance records in order to qualify for grants from certain voluntary funds, whereas this no longer applies.

One-third of the practitioners feel that the out-patient departments are crowded with minor cases which should not be there. This causes delay in obtaining early treatment or advice for new and more important cases. A considerable number, including some of those who told me that they no longer do any minor surgery because they "do not get paid specially for it," blame other general practitioners for sending such cases to hospital.

There is some suggestion that hospitals encourage chronic invalidism by telling patients unnecessarily to report back, being afraid of the responsibility of discharging them. The hospitals should realize that they can trust the general practitioner to refer the case again if he is not satisfied.

There is a great deal of complaint regarding the crowding of orthopaedic departments. This point stands out in the replies I received on this subject. Many general practitioners feel that those responsible for seeing and following up patients who are being treated for orthopaedic conditions are too reluctant to let go of them. They are unwilling to trust the general practitioner to keep a satisfactory eye on these patients during the more static periods of their treatment; for instance, while a limb is in plaster. It is common experience that such patients are told by orthopaedic departments, in what is no doubt a laudable attempt

to ensure the most perfect supervision of the patient's treatment, to report back week by week. At these attendances all that happens is that the patient is seen, maybe by the house-surgeon or registrar, asked if the plaster is giving any trouble, and then told to report again in another week. The general practitioners contend that they can be trusted to keep an eye on a plaster and refer the case should they suspect that all is not well. At the same time they feel that the cluttering up of the out-patient department by these queues of unnecessary weekly visitors takes away much of the consultants' and registrars' time that should be made available for seeing and treating new patients.

Ten per cent. say that they are not informed when their patient is referred to another department for further opinion. Some of the remaining 90% say that on occasion they do not hear of the reference until the case is "complete." Some feel that, when they are still in attendance on a patient who is attending an out-patient department or undergoing investigation, it is helpful to be kept informed of what is going on. Not to be so informed clouds their relationship with their patient. Others think that it is too much to require of the hospitals and are quite content to wait until the investigations are complete.

In two practices only was there serious complaint that transport was being used like a daily bus service to convey patients to and from the hospital to receive minor treatment which the general practitioner himself could give. In five other practices the view was aired that transport was being rather wastefully used by the hospital.

Lack of understanding of the problems of the general practitioner is almost certainly at the bottom of most of the complaints (from 27% of the practitioners) that when patients visit hospital they are given the impression that better medicine is available there than at the hands of the general practitioner. One practitioner complained of the maternity hospital; others of similar isolated instances.

Some young house officers are said to regard the general practitioner as a low grade of doctor. The fact that a small proportion of general practitioners misuse the hospitals tends to detract from the esteem in which most of them should be held and to promote careless harmful criticism. I heard of a registrar who, lecturing to students by the bedside, held up the general practitioner's letter and said, in the hearing of the patient: "You need take no notice of this." Then, again, a young consultant, thinking aloud, said that the patient's condition might be due to sleeping tablets prescribed by the general practitioner. This patient and his family have now left the general practitioner and will probably influence others of his patients in the village to do the same.

One practitioner, in speaking of such disparaging remarks, said that his knowledge of his colleagues in the neighbourhood suggested that some of the remarks were true—but he did not say he thought their utterance was justified.

Some think sisters and nurses are at fault. Patients ask them, "Should my doctor have sent me to hospital sooner?" and the sister, sometimes, perhaps, but not always correctly, replies, "Yes," forgetting that the delay in admission is more likely to be due to the long waiting-list than to the general practitioner's inefficiency. One said that he felt sure the nursing staff gave the impression that simple dressings and the like are really properly done only at the hospital. They may not think of the general practitioner and his relationship with his patient, but the latter is only too ready to interpret it as a reflection on the general practitioner. I heard no suggestion that patients are deliberately given such impressions.

The occasional absence of any appreciation of conditions in the home was illustrated by the instance of a woman sent home 10 days after delivery and told to apply treatment to her baby's eye every 15 minutes, day and night.

These complaints can be explained by a lack of knowledge of general practice, a lack of awareness of how easily damage can be done, and a strong element of thoughtlessness.

There is also lack of understanding of each others' problems almost everywhere, but it is only fair to mention the many general practitioners—some of whom have minor criticisms—who state that the hospitals serve them well and are very helpful.

One of the potent causes of harm to the doctor-patient relationship is inadequate liaison between the hospital and the general practitioner, particularly at the time the patient is discharged from hospital. It can also interfere with the convalescence and treatment of the patient.

About one-half of the general practitioners do not complain of the poor liaison, and many of these refrain from complaint only because they feel the staffs of hospitals are hard-pressed.

The large majority receive a letter from the hospital telling them about the patient's progress and treatment in hospital some two to three weeks after he has been discharged. Less than one in five hears within a week.

Less harm is done when the patient sends a message for a visit the day after his discharge. Only thus does the doctor know that the patient is once more under his care. But the patient still remains mystified that his doctor has not heard from the hospital. As the days go by he may begin to wonder what there is about his doctor to explain why the hospital has not bothered to write.

The general practitioner's prestige and the confidence of the patient in him are seriously damaged by this prevalent lack of attention on the part of hospital authorities. Incidentally, teaching hospitals are reported to be the worst offenders. In one large teaching hospital the ward sister, on being asked by a patient on his discharge whether he should inform his general practitioner, says: "No, of course not. We shall be writing." The registrar or house officer is unaware of this promise—or one hopes he is—and does not carry it out, at any rate not for a week or two. The patient waits at home confidently expecting his general practitioner to call, while the general practitioner is quite unaware that the patient is once more under his care. After a few days of waiting a message may be sent. By that time the patient is in no mood to believe the general practitioner's side of the story.

A great deal of harm and embarrassment is caused by such thoughtlessness. As regards the sending of information to general practitioners, only in a few cases did I hear such remarks as, "Very good and prompt," "I am telephoned before patient's discharge." Others report that damage is constantly being done. In a case of miscarriage the patient was sent home the day after admission, but the general practitioner was not informed. General practitioners often complain that they are not notified when a patient dies. The cheery inquiry after a patient's health two days after he has died takes some living down. One practitioner told me of being called to a case of diabetic coma the day after the patient's discharge. He was completely in the dark about the insulin arrangements. I witnessed a similar case with another practitioner late at night. In his case it was hypoglycaemic coma. Timely information from the hospital would have greatly simplified the doctor's task.

Practitioners complain that they lose patients by not visiting them after their discharge from hospital. Many patients will not believe that their doctor does not know of their discharge. To a patient his own case is all-important. Surely the doctor must have been told? Some general practitioners say they suppose the trouble is due to the shortage of typists. To excuse it on these grounds is to postulate that a typewritten letter is essential. It is not.

A number of the practitioners I visited felt that if only house officers could be informed of the implications of these problems they would ensure that general practitioners received, within 24 hours of the patient's discharge, at least the information essential for the continuation of treatment. A fuller account, where necessary, could follow when time permitted.

(F) THE DOCTOR-PATIENT RELATIONSHIP

Nine out of every ten practitioners have friendly relations with their patients. Consultations are conducted on a friendly plane. Though the warmth of the friendliness varies, only 6% of the practitioners visited regarded the relationship as a purely matter-of-fact or business-like one. In one-third of the visits a specially high degree of mutual respect and friendliness between the doctor and the patient was apparent.

Ninety-six per cent. of practitioners believe that one doctor for a family is desirable, and find that such a state of affairs largely holds good in their practices. Sixteen per cent. strongly object to sharing a family with another doctor, and some will go to the extent of requesting patients to leave their list in order to avoid it. One said that he would take this action even though he is most anxious to increase his list. Sometimes there is no alternative, as there is no other doctor in the area.

In some cases both partners attend at various times, which represents some departure from the strictly individual family-doctor principle.

Some women doctors find themselves unable to feel strongly about this, as they acknowledge the desire of the man of the house to have a male doctor. One woman doctor told me she takes only women and children as patients. A young couple may on marriage retain two different doctors. Often the arrival of the first child brings the whole family under the care of one practitioner.

While the majority of practitioners are agreed that the attitude towards them of at least some of their patients has deteriorated, I did not find proof of the current statement suggesting a wholesale disappearance of friendly relations. Seven per cent. find that a substantial number of their patients tend to regard them as a servant, and about 3% notice a marked tendency to be regarded merely as an official. Thirty-two per cent. report a definite tendency to be regarded as a supplier of medicines rather than as a medical adviser, while 22% detect this tendency in a small minority only. From my own observations I believe that in nearly all these 54% of practices this tendency is noticeable among only a minority. Some general practitioners are so easily irritated by such an attitude that they are apt to think it more widespread than it actually is. One doctor described the attitude well when he said, "Some of the patients now merely include me with their errands: rations from the grocer, a call at the shoe repairer's, and a bottle of cough mixture at the doctor's." In about half the surgeries I attended I heard the shopping-list technique in action, often one person calling for a list of needs for two or three.

Twenty-seven per cent. declare that their patients regard them as a friend, and 32% as a "professional man." In many cases the relationship is described as "a bit of both." One woman doctor says her patients regard her as "a doctor, woman, and mother."

Mention was often made of the unsatisfactory attitude among the younger adult patients, but it is presumably possible that better relations may develop, perhaps when the patients are up against it and the general practitioner helps them out. It can hardly be expected that the youthful patient and the youthful doctor will achieve a satisfactory relationship straight away. It is therefore not surprising to find the percentage of those general practitioners in the youngest age group whose patients

regard them as friends is smaller (16%) than in the older age groups (31%). There is little doubt that there exists among the older group a proportion of general practitioners unable to adapt themselves easily to the new service, while the tendency among the middle group is to accept it and adapt themselves more readily. This is perhaps in the nature of things, and may well have a bearing on the doctor-patient relationship.

On my mentioning the word "servant" some said, "I would not tolerate such an attitude," which underlines the truism that it takes the doctor and the patient to make the doctor-patient relationship.

Attitude of Ex-private Patients

Two-thirds of the practitioners find no adverse change in the attitude of ex-private patients. There are, of course, more demands by some who formerly could not afford to send for the doctor so often. The general impression is that there is a settling down after a bad start.

Many practitioners have told their private patients that they are perfectly welcome to join the N.H.S. list. In some cases a knowledge of the patients' purse and pride has led the practitioner to encourage them to join the list. At the same time it has been explained to these patients that the call at the house, rather than a consultation at the surgery, would be made on clinical grounds only.

One in four complain that they are beset by increased demands by their ex-private patients. Now that the service is "free" the family medicine chest and the home doctor are set aside and the general practitioner is summoned. Some find that their patients still want to "dodge the column," to have the frills for which they formerly paid, the prolonged visit (instead of the wait in the surgery), and at a time to suit the patient. Most find little trouble in this direction. They say that patients are learning to adjust themselves and are becoming content with the new arrangements. Some have explained to their patients that it is like the theatre: the show is the same, but they are to see it from the pit instead of the stalls. Quite a large number of practitioners find their former private patients are more considerate and indeed hesitate to send as often or as early as they should for fear of imposing on the practitioner.

About four out of every five practitioners report that either none or a very few—for example, 6 to 20—of their private patients have remained as such. Forty-five per cent. of practitioners feel that the refusal to allow private patients to have drugs and dressings free of charge under the N.H.S. has substantially reduced the number of patients remaining private. It has been quite commonly observed to general practitioners, "I wouldn't mind your bill, Doctor, but I cannot afford the chemist's." A number of practitioners are inclined to be bitter about this matter, feeling that there is more behind it than just an interpretation of the Act, that its enforcement is a shaft deliberately aimed at their freedom.

Though, in the nature of things, what little private practice there is flourishes more easily in the towns, I found no marked differences in the proportion remaining in the towns as compared with country practices, nor in the different age groups.

Forty-three per cent. say they do not wish to have private patients now. The advantages of not having to relate medical care to finance are mentioned. Then, some say that private patients are too much bother, they want too many frills, and that much private practice is

too far removed from real medicine. Twenty-two per cent. are indifferent in the matter or are unable to comment, having little or no experience of private practice.

The remaining 35% are anxious to preserve at least some private practice. They agree it may be exacting, but they believe it to be the correct relationship between doctor and patient, and are prepared to give the frills. Some say that private practice must be preserved or the standard of medicine will drop rapidly; that private practice is the challenge to the doctor to give good value; that the capitation fee lacks this challenge; that in private practice good medicine can be done; that the homely chat and the giving of non-medical advice are most useful.

Some like private patients because they pay better. In some practices the retention of a small proportion of private practice has enabled the practitioner to "keep his head above water" financially.

(G) ORGANIZATION OF GENERAL PRACTICE

Premises

In trying to assess the suitability of doctors' premises I had in my mind an idea of average premises, reasonably comfortable for doctor and patient, with no hindrance to the satisfactory conduct of the doctor's work and with reasonable warmth in both waiting-room and consulting-room. The furniture was also considered in the assessment.

Often the type of accommodation varies with the class of practice or the neighbourhood. The more elegant, homely, and comfortable premises are usually associated with the better-class practices. This factor seems usually to be unrelated to the size of the practitioner's income. Some of those with small "good-class" practices often have the best premises. In many cases this is due to the furnishing having been undertaken when the practice was a private and more remunerative one.

I have not taken into account in this assessment those branch surgeries which are but a house of call, usually consisting of a front sitting-room of a cottage or council house, furnished in traditional style, and used only for the simpler clinical work.

The average adequate consulting-room is clean, reasonably bright, and fairly well decorated, with seats for patient and friend as well as for the practitioner, a couch, and a satisfactory method of heating. There is room to manoeuvre, for examining patients, and for the conduct of minor procedures. Lack of space is sometimes compensated for by the existence of a separate room for examinations. Forty-nine per cent. of the practitioners had premises conforming to the above description. The premises are not usually convenient for the performance of more than minor procedures; nor is it necessary that they should be, for most practitioners do not undertake anything beyond minor surgery in their consulting-rooms. They are adequate for maintaining a high clinical standard. In order to be a good doctor it is not essential to be surrounded by cream paint and chromium plate.

About 17% of the premises seen may be described as being well above what may be considered adequate. In these were found separate examination-rooms, fully carpeted, spacious, elegantly furnished rooms, and newly built surgeries with special rooms for treatment and minor operations.

About 24% of the practitioners have premises which are fairly adequate but in which something essential is

lacking or below standard. In these, for example, I noticed the absence of washing facilities, inefficient heating, or a rather dismal and uninspiring appearance.

I regard 10% as unsuitable. Rooms are dismal and bare, dirty and inhospitable, and often totally inadequate for the number of persons attending. One doctor sees patients in a porch. In some poorly housed districts it seems to be difficult to maintain the standard of the premises above that of the neighbourhood. Any feature of comfort or cleanliness is soon defaced. Some general practitioners are evidently discouraged when they see lines round the walls where greasy heads have rested or marks of nailed boots on the floor. In one instance the doctor has had to bolt his waiting-room chairs together to prevent their being taken. One practitioner did not show me his premises.

It is not always the general practitioner's fault when premises are inadequate. There was the doctor who was seeing his patients in a room about 6 by 12 feet. Two-thirds of the way down the room was a screen, beyond which sat six to eight patients. This was his waiting-room, a small corner being set aside for his secretary-receptionist. The remainder of the room was the consulting-room, in which there were a couch, an instrument trolley, and a desk. The doctor complained bitterly of the arrangement. He formerly had a suite of rooms which he rented, but the property had been sold over his head. He declared that the rent had been raised so high that he had had to leave. He had been unable to find better premises anywhere in the area. He understood that his rent had been raised to make way for the followers of a calling less honourable but more lucrative than medicine.

Sometimes poor premises have had to be substituted for better ones that have been bombed. In some cases landlords are unreasonable and are concerned more with raising rents than with effecting repairs and decorations.

Sometimes a surgery is badly decorated or ill-appointed owing to uncertainty of tenure and consequent unwillingness on the part of the general practitioner to spend money on it. A doctor in a provincial town told me that the rent for his small consulting-room and moderate waiting-room was equivalent to that of a medium-sized London flat. There was no other accommodation in the town and the owner took advantage of this fact.

While present housing conditions prevail a knowledge of the facts is necessary before premises are criticized. Nevertheless, there are a few practitioners who do not appear to appreciate the functional value to their patients and themselves of clean, cheerful, and suitable premises, and some who are so poorly paid that they are unable to make the improvements they know to be desirable.

Equipment

It is quite a hardship upon a new entrant into practice to equip himself with the basic range of instruments and equipment. The established practitioners only rarely need to buy new items. I found that 91% of practitioners have what one might call the full range of essential equipment. The instruments about which I inquired were those for the treatment of wounds and accidents and for the simpler minor surgical procedures, syringes, and the diagnostic instruments, auriscope, ophthalmoscope, stethoscope, sphygmomanometer, and urine-testing apparatus.

A number of practitioners do not have a proctoscope or a vaginal speculum. Others say they have them in the cupboard but that they "never use them nowadays." Nine per cent. have not the basic equipment mentioned above. Sixteen per cent. have more elaborate equipment, including ultra-violet and infra-red apparatus, x-ray plant, or special instruments of other kinds. It must be emphasized that such instruments are not essential to the ordinary conduct of general practice. One young town practitioner said that he would not buy instruments, as it does not pay him to do minor operations.

On the whole the standard of equipment is quite adequate as to essentials and in view of the diminishing range of some practices. The instruments are not always kept attractively, and I have seen many lying about dusty and disused. But when needed they can be cleaned. Many practitioners have electric sterilizers, and those that have not usually have available some method of sterilizing instruments.

Co-operative Arrangements with other General Practitioners

Perhaps the most unsatisfactory feature of some of the rota systems is that they are too large. A well-perfected arrangement, from the practitioners' point of view at any rate, that I saw is one in which ten doctors work not in partnership but "in symbiosis" in one building with ten consulting-rooms. Each has his own practice and shares the message-taking clerks with the other nine. After morning surgery is over one doctor takes all the new messages until the following morning, when the next doctor on the list takes over. Midwifery cases are excepted. The practitioner is on duty for the whole area for one day in ten and for one week-end in ten. At busy times there are always two doctors on duty. It is claimed that, with freedom from worry about extra calls, the general practitioner not on duty can proceed unharassed with his routine visiting, do his evening surgery at the right time, and thereafter enjoy his leisure.

Whatever may be the rights and wrongs in this matter I am left in no doubt that the practitioners who have been able to make some sort of co-operative arrangements with neighbouring doctors have much less anxiety about their work and are happier for being able to enjoy a small amount of leisure. Some have only a casual arrangement, some an arrangement for week-ends only, and some for half-days only. The majority have an understanding only with partners and assistants. Some partnerships help out a single-handed neighbour and require nothing in return.

In some areas the introduction of a rota has done more than ease the constancy of the burden on the individual. It has turned the sourness of professional rivalry into the sweetness of co-operation. Yet in other areas the sourness and the doubts remain. Practitioners are suspicious of one another. I noticed particularly that it was some of the younger men who told that they have tried to arrange a system of mutual co-operation with the other doctors around them but that their efforts have been met with refusal and suspicion.

There is of course, here and there, the individualist. He does not wish to leave his practice to others, not because he is suspicious but because he considers his patients are his own business and his own duty, not to be delegated. If his patient is taken suddenly ill, he prefers to be there, to go himself. There is much to

be said for this attitude. I can only remark upon the less worried mien and the more rested look of the man who can get away from time to time and can return to his practice with a freshened outlook. He is happier than the man who snatches a half-day and returns to his home on a cold evening knowing that there will be three or four (or more) messages on the pad in the hall awaiting his attention.

In one or two instances the practitioner declines to join in a rota because he does not want to be involved in emergency calls which might be well outside his own area. In other cases a rota is impossible owing to distance. A number of country doctors live in professional isolation and need to be on call the whole time. The isolated general practitioner who wishes to have a holiday has no chance of arranging for one or two colleagues to look after his practice and to return the compliment when he gets back. He must have a locum if he wants to go away; often he can neither afford nor obtain one. Inquiries show that it is not more easy to obtain a satisfactory locum nowadays. The main difficulty with locums at the time of the survey was finding the money to pay them, for a locum tenent's fees were the same for all practices, whether the principal's remuneration was high or low, whether his list was large or small.

Appointments System in General Practice

Inquiry was made into the practitioners' custom of seeing patients by appointment. Only 2% of practitioners see their patients by appointment only. Of the remainder one-third never see patients by appointment and two-thirds use an appointments system for special examinations, for life assurance work, and for private patients. The figures show that this practice is about the same in town and country, but that doctors in the two youngest age groups are more inclined (70%) to use an appointments system. The system is used by 58% of the oldest age group.

Employment of Non-medical Staff

One-fifth of the practitioners say they are handicapped by the absence of ancillary help, and by this is usually meant clerical or secretarial assistance. The remaining 80% say they are not. About half the practitioners have some form of help, whether part-time or full-time, suited to their needs, sometimes shared with a partner or partners. About 25% of practitioners would like such help but have not got it. Usually it is a question of finance. There may not be full-time employment and there is difficulty in getting someone to take on the job part-time. A further factor is the impossibility of altering the surgery premises to accommodate clerical help.

The help that is most wanted is someone to get out the record cards and put them before the practitioner while he is seeing the patients. Then there is the taking of messages during surgery hours, to enable the practitioner to carry on with his work undisturbed by calls to the telephone. The replacement of the cards after the patient has been seen and the filing of letters and consultants' reports can also be done by a confidential clerk.

Most large practices have such help. In the smaller practices it is not often a problem because the doctor is more likely to be concerned with dealing with distances and access difficulties than with large numbers of letters and cards. These do not often want clerical

help. It is the middle-sized practice that is the problem, where numbers are sufficient to make the clerical work a time-consuming burden and where remuneration is not enough to allow of the employment of a clerk. About 55% of the town practitioners employ some sort of assistance, while only 40% of the country practitioners do.

Record-keeping

Three out of every four general practitioners pay a reasonable amount of attention to record-keeping. The card of each patient is seen in the surgery (and for this a secretary-receptionist is a great asset), but only one in three finds it necessary or convenient to take the cards out with him on visits or to enter details at the end of each day. The type of notes varies from the very full to the very brief with only essential features recorded. A common custom is to take the opportunity of entering on the card a summary of any particular illness when the patient who has been visited subsequently attends at the surgery, for instance, for the final signing-off certificate.

The remainder seem to pay rather scant attention to records. Some regard record-keeping as a sort of "red tape" imposition. Others say that hunting out and replacing, say, 40 record cards during a surgery add so many minutes to the length of the session. They can afford neither the time to do it themselves nor the clerical assistance to do it for them. One finds "it a nuisance"; another "can't be bothered." The cards are sometimes kept well out of reach. Some record "important things only." Another says that to keep his records properly would occupy him till midnight.

I noticed that a good deal of irritation arose when a practitioner was on the list of more than one executive council. I met one who had patients in the areas of four executive councils. There is a separate pad of E.C.10 forms for each area. The searching for the right pad or the altering of the heading in ink is an unnecessary bother to the busy general practitioner. There would not seem to be much interference with the accountability of prescribing and dispensing if all E.C.10 forms bore no area heading, and were rendered to executive councils according to the address of the chemist dispensing them.

Effect of the N.H.S. on Organization of Practices

The introduction of the N.H.S. seems to have made very little difference to the organization of practices.

Sixty-four per cent. of practitioners say that it has had no effect, and 13% of the remainder were not in practice before July, 1948. Nine per cent. discharged their dispenser, 3% took on a clerk. Many stopped dispensing. Three per cent. opened new branch surgeries and 3% closed them. Twelve per cent. opened new surgery premises or specially altered or improved them. Eight per cent. took on a further partner or engaged an assistant. These are some of the changes that were made to meet the altered circumstances, but in the main the practitioners have just carried on as before.

The Doctor's Wife

The wives of the great majority of the married doctors are involved in duties connected with their husbands' practices. The most usual duties are the taking of messages and answering the telephone and door-bell. Some have a good deal to do in connexion with the practice. They may be concerned with the organization of the practice, with the arrangement of the visiting-list, and

with the filing of correspondence and reports. In short, some wives act as their husbands' secretaries.

A small proportion of wives are almost entirely free from the cares of the practice. This situation is usually found where a caretaker at the surgery takes all the messages and passes them on to the member of the partnership on duty.

Health Centres

Many practitioners are concerned about the way their wives are tied to the home because of the needs of the practice and the patients. A few of them expressed approval of health centres on this account alone. Forty-eight per cent. of practitioners approve of the health-centre idea, and 47% are opposed to it. In some country areas the question hardly applies, as it would be uneconomical to establish health centres in areas with only one or two doctors. A few say it would be good for towns but not for the country. Some favour health centres on account of the provision of diagnostic and ancillary facilities, and one, while not wanting a health centre, would welcome a diagnostic centre to which he could send his cases direct.

The arguments in favour are accentuation of difference between N.H.S. and private practice; development of group practice; better standard of practice; easier relief arrangements; sharing of nursing and clerical assistance; benefits, including improved ethics, from working together, and better accommodation. One practitioner thinks that there would be fewer attendances because it would be more like a hospital and patients are afraid of hospitals.

One doctor, not in favour, gives as his reason that health centres would be too like a hospital out-patient department. One speaks of the disadvantage to general practitioners who are not in the health centre, and another of the untoward effect upon the doctor with the small list when his patients see many more waiting to consult other general practitioners working in neighbouring rooms. Fears are expressed of having to "clock in" or to be controlled in other ways, of patients having to travel farther, and finding themselves beyond "pram-pushing" distance of the health centre. Some concern is expressed lest the practice in a health centre should lose something of its personal touch, that something valuable, yet intangible, would disappear from general practice and never reappear.

Many of the general practitioners are satisfied with their own arrangements, prefer to run their own show, and feel that the institution of health centres would not benefit the patients. One said he would prefer a general-practitioner hospital with consulting-rooms. This would enable close contact with the consultants to be established.

Opinion is almost equally divided on the desirability of health centres. I found no body of opinion which thought that the institution of health centres would be of much positive value to patients unless radiological and pathological facilities were provided. Most practitioners realize that the provision of such facilities, especially radiological, at each health centre housing, say, ten general practitioners would be so costly as to be grossly uneconomical.

(H) GENERAL PRACTICE AND THE N.H.S.

Over the whole range of practitioners visited I found 37% more satisfied and 42% less satisfied since the introduction of the N.H.S. Fifteen per cent. feel neither

one way nor the other, while 6% cannot give an opinion, not having had experience of practice before July, 1948. The percentage of those more satisfied is higher in the youngest age group and lower in the oldest. This finding is hardly in keeping with the inference that might be drawn from the chorus of voices heard and the letters written on the subject.

Those dissatisfied complain of the great pressure of work which prevents them doing all that is necessary for good practice. Two declare that the whole conception is bad; some feel that they would rather be paid for what they do, and object on these grounds. They consider that patients should have a financial interest in the use of the Service. Two or three say they are harassed by patients lodging complaints or by the fear of it. I found this fear cropping up now and again and playing quite a big part in making the general practitioner anxious. There are those who seem unable to put aside the feeling that the complaining patient may well hold in his hand the power of professional life or death for the general practitioner.

Then some, in fact most of those more satisfied, call attention to the fact that there are many things that need improvement or putting right. Some like the N.H.S. better because they can do more for their patients, can prescribe more freely, and can visit as necessary. Also there is no bother with bills now. The frequency with which I heard this matter of bills mentioned with relief suggests that the sending out of accounts was a major anxiety with many practitioners in the old days of private practice. Three express approval on the ground that the N.H.S. is better for the patient. I am satisfied that there are more who feel this too. The reply given by one practitioner is somewhat saddening: he likes the N.H.S. more because he does "not have to bother so much about the patients now."

One young practitioner likes the Service less, but, rather grudgingly, declares that it causes less worry and dissatisfaction than was expected.

Apart from these the remainder of the profession can be described as being receptive towards the N.H.S., ready to like it more and more. They are alert and critical of its shortcomings and often inadequate remuneration, and determined that a good service shall evolve, with full benefit for the patient and contentment for the general practitioner. The two things are not unrelated.

Size of Lists

Only one country doctor visited says he wishes to look after more than 3,000 patients in his practice. Seventy-six per cent. do not want more than 2,000. In the towns the number most popular (27%) is 2,500. Twenty-two per cent. prefer up to 3,000, while 13% are quite happy with 4,000. Some of these latter, apart from a slight concession to the country doctor, genuinely cannot understand how a doctor can be happy with less than 4,000 patients, or how he can find enough to occupy his time. In the practices I visited the distribution of the various sizes of list between practitioners was about the same in the town and the country. In the towns I found that 33% had lists larger than they felt they could deal with satisfactorily, in the country 26%. Forty-two per cent. of the town practitioners and 38% in the country have less than they can manage, while in both town and country about 27% have what they regard as the optimum number of patients.

There are many who are unshakable in their belief that no doctor can look after 4,000 patients in general practice, and 2,500 is the popular figure. I have on several occasions been privileged to witness at work practitioners with 4,000 patients, examining them with care, treating them with skill and enthusiasm, and maintaining friendly relations with them of the kind that is normally regarded as ideal as between doctor and patient. It is pleasant to record that some of these are young men who are doing fine work. They are giving their patients the full range of general-practitioner care, and managing them well. I have seen practitioners who have more patients than they can handle. Some admit it, declaring that they must have them to keep the home fires burning or the youngsters at school. I saw a few who seemed to show no sense of vocation. Their work was hurried and scanty, and there was no attempt to comfort the patient or relieve his anxiety. The concern of these few men seemed to be mainly the size of their lists and the resultant income.

One cannot be dogmatic about the number of patients a general practitioner can care for. Apart from the obvious difference between town and country, I thought I detected that in some areas the work is busier.

Excessive Demands

Nearly all the practitioners visited have among their patients a proportion, usually small, who are constantly at the surgery. Some of these are, of course, the chronic sick—the chronic bronchitics, the dyspeptics, the inadequate personalities, and the like. But there are also those who appear to be attracted to their doctor's surgery as if by a magnet. I saw one or two at least of these patients at nearly every surgery session through which I sat. Sometimes I could spot them myself, and at other times the practitioner would remark, after the patient's departure, "She's up here every week with some little thing or other." They are more commonly women. I was led to wonder, on occasion, what there was behind this urge to be under the doctor, this urge to be slightly ill.

I found very few complaints that could fairly be labelled frivolous. It was exceptional for even the trivial case not to have something wrong. The practitioners themselves are not always agreed on this point: whether, for example, it is unnecessary for the person with a common cold to attend the surgery. Obviously, with certain patients, it is a necessary precaution. The reason for quite a large proportion of "trivial" attendances is to get a prescription so that dressings or medications can be obtained free.*

Opinions on this subject vary widely. There are those practitioners who, sometimes harassed by overwork, seem too ready to find fault. The view was expressed to me that some general practitioners do not realize that there always have been, and always will be, a small proportion of calls that appear unnecessary. The following illustrates how opinions may vary on this matter. I was shown a list of surgery attendances over a period of several weeks, a third of which were marked as being considered unnecessary. But in the fairly lengthy surgery that I witnessed in this practice I felt that only a much smaller proportion could be so designated. Nor did I see such a high proportion as one-third in any other practice.

* The charge for prescriptions was not imposed until after the survey was concluded. It has since been announced that the number of prescriptions issued since the imposition of a charge has not diminished.

Of the truly frivolous I heard little and saw less. Sometimes, of course, although the call itself may be frivolous there is a genuine medical background. A schoolmaster sent for his general practitioner from the school at which he was teaching. On arrival the doctor was told: "I have lumbago and I want an injection so that I can go to the school concert to-night." It takes a good deal of consideration from other patients to counteract the irritation caused by such a call as this one. Almost universal is the experience that actual night (out-of-bed) calls are fewer, but that the number of calls received after the practitioner has set out on his round and also in the evening has substantially increased. Many practitioners, especially those in the fifties, complain that each night call becomes an increasing burden as the years go by.

Just under one-third of the practitioners consider they are subjected to an excessive number of unreasonable demands on their services. The remainder have no such complaint.

Effect of N.H.S. on General Practice

I was asked by the Committee to try to assess whether practitioners were laying the blame for any shortcomings on the N.H.S. when, in fact, the cause was to be found elsewhere. I did expect to find the N.H.S. made into something of a whipping-boy, but I found it so in the case of only about 14% of practitioners.

Lack of time is a frequent cry. It was not always borne out by what I saw of the operation of some practices, but it most definitely was in others. In a substantial number of practices lack of time has reduced the range of the service the practitioner can give to his patients. This is not to say that the patient is not receiving the treatment, for much of this work is now being carried out in hospital out-patient departments.

Of only one in five of the practitioners I saw did I think that their work was so hurried as to interfere at times with its quality. The majority will not allow this to happen. A sense of responsibility seemed to be lacking in only a very few instances. I noticed a tendency to pass cases to hospital which seemed to be excessive in 11% of practitioners. Only in 5% of cases did I find that the practitioner was prevented from indulging in short chats with the patients. Few, however, have much opportunity for more prolonged converse.

Fifty-eight per cent. of the practitioners say that they are working harder than they did before they joined the N.H.S. Thirty-two per cent. say that they are not. Many say that surgery attendances are greatly increased, but not the number of visits they have to pay. Some, having taken a partner, are working about as hard as formerly, which means that much more work is being done in the practice. A typical example is the practitioner who says that he used to have very little work in the summer—say, ten patients in the surgery and three to six visits a day. Now there are always more in the surgery, and he rarely pays fewer than ten visits a day in the summer. Another who says his surgery attendances have increased thinks that the opposite is the case with his visits, because formerly he had a subconscious tendency to overvisit, which the N.H.S. has cured. The amount of work entailed is very difficult to assess. One told me that the day of my visit was exceptionally busy. He saw 12 patients during morning surgery (there was another in the evening), and paid 15

visits. This was in the country, but it struck me as a reasonably comfortable day for any general practitioner. This practitioner, like some others, seems to approach his work in rather a leisurely manner and makes very heavy weather of it. He looked a tired man, and perhaps was. A number of practitioners told me, before I left, that the day of my visit had been "amazingly slack."

Frustration and Loss of Interest

Few human beings are perfectly happy and contented; similarly, few are free from worries and difficulties of some kind or other. Therefore to ask practitioners whether or not they suffered from frustration and loss of interest since the introduction of the N.H.S. was to ask for a gradation of replies.

Some say, "At times I get frustrated." Others mention specific causes of worry and frustration. The commonest is the difficulty in getting patients admitted to hospital. There is an undercurrent of feeling that the organization and administration of the N.H.S. proceed on their majestic way without due regard to the general practitioner or his patient. There is confusion, or there seems to be, regarding who should be blamed for the pin-pricks and the parsimony, for this is how many of them look at it. There is often criticism of their representatives, those who negotiate for them. I have heard more criticism of the profession's leaders than of those with whom they are negotiating.

Wherever the blame should properly lie, the fact that so much criticism abounds indicates that all is not well. Yet the majority (65%) have managed to adjust themselves, at least partially, to things as they are. Buoyed up, as in some cases, by hope of improvements, they have not allowed themselves to suffer from a sense of frustration and loss of interest. Twenty-eight per cent. say they do suffer. The remainder cannot make comparisons with pre-N.H.S. times.

One said talk of frustration was "a lot of rot." Others think general practice is "satisfying," although things are not quite as they would like them. Some bemoan the loss of hospital work, especially major surgery, and of access to pathological and radiological departments. The figures show only slight differences as between the three age groups. I saw one young practitioner who described himself as frustrated because he finds general practice insufficiently interesting academically. Another has lost interest and is thoroughly frustrated. He has been in practice only since July, 1948, but was unlucky in his choice of area, and he is frustrated and lacking in interest because things have not come up to his somewhat rosy expectations.

Questions of finance naturally entered into my conversations with practitioners on some matters, and a section on this aspect of general practice would have appeared in my report. Since the conclusion of the survey, however, the Danckwerts award and the recommendations of the Working Party have been announced. Consequently, to include any account of the views of the practitioners on the distribution of the pool and the methods of payment would now be pointless in the face of the considerable changes that have been effected.

(J) POSTGRADUATE TRAINING OF THE GENERAL PRACTITIONER

Fifty-three per cent. of the practitioners admit to having adequate local facilities for postgraduate training. The percentage in the towns is higher than that

in the country (61 to 34). Thirty-six per cent. say that occasional clinical meetings and lectures are open to them, by which is usually meant four or five a year. Two country doctors do not know what facilities are available to them. Ten per cent. say there are no facilities.

Forty-six per cent. of the practitioners use the facilities occasionally and 38% not at all. The remaining 16% avail themselves to a considerable extent, including attending a postgraduate course, sometimes a set of weekly meetings or lectures, sometimes a fortnight's course away. Some meet regularly with the consultants at the local hospital.

In one or two places I was told that local meetings have been few and far between or have been stopped owing to poor attendance.

There is no great difference in the use of the facilities as between town and country practitioners. The under-40 age group has the highest proportions of those availing themselves of opportunities for instruction. Seventy per cent. of them do so, at least occasionally. In the over-60 age group interest is comparatively poor. Some of them tell me that they are approaching the point when they will retire from practice, and have no enthusiasm for further information.

Many complain that they are too busy to attend, and many that times arranged for meetings are unsuitable. The consultant is said to show preference for the early evening, immediately following an afternoon session, while the general practitioner does not finish until later in the evening. Others say they are too tired in the evening. Evidently there is no ideal time. Then, again, some are unwilling to leave their practice for the time necessary for attendance at a meeting. These include the individualist and the practitioner who cannot come because he is single-handed and has no arrangements with other practitioners for the care of his patients in his absence. Some, of course, live too far away.

There are those who object to going to meetings only to be called away, and complain that this has only to happen once or twice for enthusiasm to be damped. Some are not interested, and others prefer to spend with their families any time they have to spare. Others are just disinclined to join in things, or are shy.

There is some criticism that the subject-matter of the lectures given by the consultants is too academic and too far removed from general practice. Conversely, I was told that the lectures are too simple and not interesting enough. To please more than a small proportion at a time would seem to be difficult. A number of those not interested in lectures say that they believe they can learn all they want from the material they see every day in their practices, and from their contact with the consultants at domiciliary visits. Some declare that they would be best suited by being allowed access to hospitals, where they could see cases under treatment and discuss them with the hospital staff.

Asked whether they would like different facilities for postgraduate training, very few said they would. Most of the requests are for arrangements for time off, especially to travel the longer distances, and for more meetings arranged at more suitable times. Some wish for more clinical meetings, and one suggested lectures by general practitioners on their problems.

Eleven per cent. read a great deal; that is to say, several periodicals and medical textbooks. Seventy per

cent. say they regularly read one or two medical periodicals. This usually includes a weekly and a monthly one. Eighteen per cent. read very little. These figures are fairly constant in the three age groups, with a tendency to rather less reading in the over-60 group. This tendency in this group runs approximately parallel to the interest in postgraduate courses and local clinical meetings and lectures.

A few complain of serious lack of time for reading. Many are pressed at times, but on the whole they are able to do some reading.

(K) A GENERAL IMPRESSION

The Practitioners Seen

The following table presents a picture of the group of practitioners selected, and shows the impression they made as general practitioners.

	Total	%	Class											
			1	2	3	4	5	6	7	8	9	10	11	12
Good ..	81	44	7	10	4	16	12	3	4	7	—	4	11	3
Adequate ..	82	44	3	19	2	12	17	5	1	8	2	3	5	5
Inadequate ..	14	7	1	2	2	2	4	1	—	—	1	—	—	—
No assessment	11	5	1	1	2	2	1	—	2	1	—	—	1	—
	188		12	32	10	32	34	9	7	16	3	7	17	9

	Town	Country	Age Groups		
			25-39	40-59	60+
Good ..	52 40%	29 49%	31 53%	40 40%	10 32%
Adequate ..	58 45%	24 41%	19 33%	49 50%	14 45%
Inadequate ..	12 9%	2 3%	3 5%	6 6%	5 16%
No assessment	7 6%	4 7%	5 9%	4 4%	2 6%
	129	59	58	99	31

This is a summing-up of the quality of service that was, in my judgment, available to patients from their general practitioners. Tables which show that no less than 92% of the practitioners whose work was witnessed were adequate or better than adequate may come as a surprise after reading some of the paragraphs of this report. The apparent discrepancy is due to the emphasis necessarily placed upon faults and shortcomings because of the critical approach to the survey.

Perhaps the most difficult and invidious part of an observer's task is to sum up fairly. He must be fair both to those to whom he reports and to those on whom he is reporting. In retrospect I can say that I did not find the assessment as difficult as I expected. The easiest practitioners to assess are the good ones. They nearly always gave an immediately good impression, which remained confirmed at the end of the day. I did not assess any practitioner as inadequate without substantial evidence. Four per cent. of the practitioners declined to allow me to watch them at work, or I was prevented for other reasons. For example, three practitioners with small practices had no patients to see on the day of my visit.

In the category "good" I placed those practitioners whose skill was evident and whom I found exercising a constant care and thoroughness with every patient, a keen appreciation of the whole man in the patient, together with a friendliness and spirit of kindness and helpfulness. This is not to say that these qualities do not exist in those classified as "adequate," but the standard I set was high. In these others, such qualities

are not present to so high a degree. It has been a privilege to watch these men and women at work. It has been an inspiration to witness in a special few the enthusiasm they have for their work and the constant vigilance they exercise to maintain their standard of excellence.

I have, of course, seen a wide range of personalities. At the other end of the scale there is the practitioner whose sole object appears to be to "get through" his patients with as much dispatch as possible, and to limit services given to the bare essentials. He does not, as a rule, appear to give satisfaction to his patients. He supplies them with a bottle of medicine, and that quickly. He is rarely concerned with anything below a full list, and would, I believe, prefer to give the service he is giving to a large number of patients than offer a wider and more thorough range of service to a smaller number for the same remuneration.

Then there is the man who has in him some of the necessary characteristics, but who has allowed increased pressure of work to weigh him down to such an extent that the service he gives is below what would otherwise be, and probably was formerly, his normal standard. He has allowed his conscience to be stilled by "increased demands."

Ninety-two per cent. of practitioners seen at work were adequate or something better. Some were harassed by a considerable amount of overwork and sometimes by financial anxieties. Such men do not readily reduce their standards, and have sought, rather, to limit their responsibilities. They tend to send to hospital cases requiring minor procedures which formerly, having time, they would have undertaken themselves. Within the limited field to which these have withdrawn, their work is adequate.

For every general practitioner that I class as inadequate there are 10 who are, in my view, adequate. Half of these, that is 44% of the general practitioners (46% of those I saw at work), are good.

I came away from the survey with three major adverse impressions, which are summarized below.

Lack of Cohesion

My foremost impression is that of lack of unity in the N.H.S. and lack of unity in the medical profession. Both of these are jeopardizing the status and the effectiveness of general practice.

I became aware, early on, that unless certain gaps are closed the patient will not derive maximum benefit from the Service.

The human gaps must be closed. The general practitioner, the consultant, and the public health medical officer need to get to know each other and then to learn to work in concert. There is growing up a new generation of consultants, and a still newer one of those who will become consultants. These know little of the general practitioner and are unaware of his difficulties. Neither are they aware how easily these difficulties may be increased. Then the public health service and the general-practitioner service seem to be treading different paths. Where their paths meet there is often doubt and misunderstanding.

The other gaps are administrative. Maximum benefit for the patient cannot result from a trisected service. The feeling I derived from the survey was that bridging the gaps with liaison committees seemed less likely to be the cure than local co-operative effort. I cannot rid

myself of the feeling that the gaps must be filled completely. The N.H.S. is crying out for a unified administration.

Inadequacy of Hospital Services

The hospital services are causing considerable anxiety to the general practitioners in their attempts to obtain treatment for their patients. Hospitals are still contending with a back-log of operations and a more health-conscious public, resulting in increased demands. The aged and the chronic sick are poorly provided for.

Steps to enlarge the scope of general practice might well be the means of easing the load on the hospitals. Better access to radiological and pathological facilities, and general-practitioner beds, would encourage and help the majority of general practitioners.

Increased Demand for Services

At the time of the survey some practitioners were faced with so many demands on their services that they were unable to give the time that was necessary or that they would have wished to give to each case, even the trivial ones.

Much has been heard of the need to reduce the demands by patients on their practitioners. Methods of eliminating unnecessary demands are being sought. From my own observations, and in the opinion of the majority of doctors, the number of frivolous calls is small. On the other hand, the number of calls that might be regarded as trivial is much larger.

What is trivial to a doctor is possibly a matter of anxious importance to a patient. Formerly the question of finance overrode much of this anxiety.

Often the trivial call is a means of obtaining a prescription for something which formerly the patient would have bought from the chemist. The idea that the public are entitled to such medicines from the N.H.S. is now deep-rooted. Apart from the possibility that the token charge for prescriptions will alter it, the demand seems likely to continue at approximately its present level.

The extent of this extra demand means a great deal to some practitioners and affects others but little. Some practitioners are harassed by the amount of work, sometimes of an unsatisfying nature.

At the time of the survey there seemed to be room for a review of the quantity of work to be carried out by the general practitioner in the N.H.S. To advocate any further compulsory reduction in lists does not come easily to one who has seen, as I have, a number of practitioners dealing, single-handed, with a full list and giving a thoroughly good service to all patients.

There seem to be two courses for general practice to take. The first is to make such adjustments to meet the new situation as will stimulate clinical interest anew and give scope for its exercise. The other course is towards the impersonal health service. Some fear the evolution of general practice into some sort of a glorified hospital out-patient department where intimate knowledge of the patient, continuity of treatment, and the idea of the doctor as guide, philosopher, and friend are sacrificed to a hurried impersonal machine. It is for this reason that they express disapproval of the idea of health centres.

A number of practitioners expressed their sensation of being dragged down to a lower level, a feeling of being disregarded and in bondage.

THE PRACTITIONER AND THE HOSPITAL SERVICE*

BY

Sir HENEAGE OGILVIE, K.B.E.
D.M., M.Ch., F.R.C.S.

Consultant Surgeon, Guy's Hospital

Greek and Roman hospitals were little more than hostels in association with the temples, designed to give rest and shelter to pilgrims visiting the shrine, many of whom were sick men. Constantine, the first Christian emperor, closed the pagan hospitals, and thereafter the care of the sick was undertaken as a Christian duty by the monasteries. The oldest hospital in Britain is St. Bartholomew's of Rochester, which was founded in 1078. St. Bartholomew's, Smithfield, and St. Thomas's, Southwark, followed shortly afterwards. These were religious institutions in which the sick were cared for by the monks and nuns of the Order, and in time similar hospitals grew up in association with all the main Orders.

When Henry VIII suppressed the monasteries between 1536 and 1540, most of the hospitals then in existence closed. In London St. Bartholomew's, St. Thomas's, and Bedlam remained, but it cannot be claimed that the few beds these provided and the kind of treatment they were able to offer did more than segregate a few of those suffering from the more revolting diseases, such as leprosy and syphilis and madness, from the gaze of their fellow citizens. There was no hospital treatment in the sense of a service of advice and treatment available to those who needed it. The sick were looked after at home and they got well or died at home, unless they had no home and no friends, when they died in the streets. There was no doctoring, for such men as had a medical training and had been given a licence to practise plied their trade among the nobility and the wealthy. The great mass of the people turned for advice and treatment to unlettered quacks, men who had acquired a shrewd practical outlook and a little more knowledge than their neighbours of the herbs and manipulations of folklore, and who handed out the traditional concoctions and incantations of the alchemist.

A New Spirit

Quite suddenly, and for reasons that are difficult to assess, a new spirit was born at the beginning of the eighteenth century. Led by Sydenham and Boerhaave, medicine was transformed from an abstract philosophy to a scientific study concerned with the causes and treatment of disease. Doctors left the library and the debating chamber to sit by the bedside, to record what they saw rather than argue what ought to or might happen. Men in all walks of life became concerned with their responsibilities as well as their privileges, and found a new interest in seeking to help those who were poor or in trouble. One expression of this new medical outlook and this new spirit of philanthropy was the founding of secular hospitals. Westminster Hospital was founded in 1719, Guy's Hospital in 1725, and before the end of the century eleven new hospitals had been founded in London, thirty-seven in provincial cities, and nine in Scotland.

The movement continued apace. By 1925 there were 909 voluntary hospitals in Britain providing 60,000 beds.

*A B.M.A. Lecture given to the Ayrshire Division on April 12, 1953.

In 1870 hospitals of another class, designed not to provide curative treatment but to care for the aged, the helpless, and the chronic sick, were founded by local authorities under the Poor Law, and by 1925 they provided beds greatly in excess of those in the voluntary hospitals and were undertaking all forms of medical and surgical treatment. The first cottage hospital was built in Cranleigh in 1852. Others of the same type—that is, institutions with from five to thirty beds serving the needs of a small area—appeared in rapid succession. Many were founded as memorials after the first world war. By 1925 there were few towns in Britain with a population of 2,000 or over that did not possess such a hospital.

These hospitals were all established and maintained for a similar purpose, to care for those who, because of the nature of their ailment or their own poverty, could not be looked after at home. Those who were wealthy and had comfortable homes never went to hospitals. They retired to their own bed or in some cases to a convenient room specially prepared as a sick-room. Any treatment, such as cupping, bleeding, or leeching, was carried out by their practitioner. If an operation were needed it was performed by him on a wooden table by the light of lamps held by the domestic staff. There was no essential separation between the doctor who looked after the patient at home and the doctor who looked after him in hospital; indeed, the words "consultant" and "specialist" were unused till the present century. There were no special degrees or diplomas. Practitioners were seeing the same cases, using the same methods of investigation, giving the same treatment, doing the same operations, and using the same language as members of the hospital staff.

An appointment to the staff of a teaching hospital brought with it the privilege of teaching students and thereby training a series of practitioners who would usually call on their old chief for help when faced with a difficult case, or when attending a wealthy or exacting patient. An appointment to a provincial hospital brought with it a certain prestige. Many of these men added to the sum of knowledge by their observations and researches on the nature of disease, and established international reputations by their writings, but they differed from their colleagues, the family doctors, in achievement rather than in kind. Right up to the beginning of the first world war the majority of physicians on the staff of the London teaching hospitals were what to-day would be called fashionable West End general practitioners, who, in addition, saw the patients of other doctors in consultation. General practitioners were constantly in touch with their old teaching hospital, or the hospital of the district in which they practised. They called upon their old chiefs, they attended ward rounds and took part in the discussions, they went to lectures, and they watched operations. The suggestion that doctors in hospital and doctors in general practice inhabited separate worlds would then have been unthinkable.

A New Principle in Treatment

The separation of the general practitioner from the hospital began in the closing years of the nineteenth century. With the notification of infectious diseases, and their treatment in isolation hospitals, a new principle was established, that certain illnesses may no longer be treated in the patient's home by his own doctor. About the same time investigation of diseases began to pass from examination by the ordinary clinical methods, amplified by simple chemical

tests and the use of instruments easily mastered. Radiology and bacteriology appeared, and soon became essential to the study of many problems. They demanded apparatus, laboratories, and equipment that could be supplied and applied adequately only in hospital. The bedside tests of the early part of the century rapidly multiplied into the new science of clinical pathology, which in turn became further subdivided into clinical microscopy, biochemistry, and haematology. The optical instruments designed for the indirect inspection of cavities demanded increasing skill and experience. As information accumulated, as disease groups were disentangled into separate entities and new diseases were discovered, a gradual change appeared in the orientation of hospitals, particularly the teaching hospitals. They were no longer places for treating the sick, but places for research into the cause of disease. Rare diseases were given precedence over ailments of economic importance. Groups of patients were segregated for study. Experimental medicine raised its head. Practitioners, on the other hand, became more and more loaded with non-medical tasks, with certificates for the avoidance of duties and the securing of luxuries.

By the end of the 1914-18 war consultants were a race apart, and special degrees and diplomas, specialist associations, and specialist journals appeared to separate them from their fellows and to indicate the particular sect to which they belonged.

We have seen that in the teaching hospitals, which were becoming more concerned with investigating the unusual rather than treating the important, the general practitioner had become virtually excluded. In the council hospitals, which were rapidly assuming responsibility for the routine treatment of disease, the practitioner was able to have his cases admitted more readily without the somewhat humiliating argument with a recently qualified house officer, but he was equally unable to take any part in their subsequent treatment.

It is necessary at this point to refer to another tendency. With the elaboration of methods of treatment, and particularly with the increasing enterprise, safety, and success of surgical operations, it was becoming apparent that no private house, however well appointed, could offer the facilities for asepsis and for nursing that could be given in a specially designed building. First appeared nursing-homes, many of them built by consultants or groups of consultants to offer to their private patients a service approaching that which their hospital patients had enjoyed for some time. Then, as methods grew more elaborate and the standard demanded still higher, it became obvious that only in a hospital with its attached scientific departments and its resident staff could the highest level of treatment be attained. First private rooms intended for patients of moderate means unable to afford nursing-home fees were added to the ward units, and then whole private wings or private blocks were presented by charitable donors. In these blocks there was no means test. The increasing tendency for all but the simplest treatment, including that of such physiological events as normal labour, to be conducted in the precincts of a hospital brought a further separation between the practitioner and the consultant that was not at first appreciated. It removed the practitioner from the interest and the emoluments of caring for his patients when they became seriously ill, and it gave the consultant attached to a hospital equipped with private beds an automatic increase in income that he did not necessarily deserve.

A Disastrous Barrier

As a direct result of the complete separation of the general practitioner from the hospital, there had developed in many cottage hospitals and in some voluntary hospitals in the smaller towns a policy of excluding all but general practitioners. Such a policy, which was quite frankly mercenary, and had for its main object the retention among a local group of the emoluments and benefits of the private beds, was to a large extent responsible for the artificial and,

as it turned out, disastrous barrier erected by the National Health Service Act between the practitioners and the hospitals. I will cite the imaginary town of X, situated in lovely country at a distance of thirty miles from the manufacturing city and university town of Y. With the development of motor transport X had become a dormitory, where all the wealthy men who earn their money in Y had their country houses. The X War Memorial Hospital was their particular pride. Its buildings were the latest thing in hospital architecture; its equipment was the best that money could buy. Two of the hospital rules were significant. First, that no one might be elected to the hospital staff till he had been in practice in the neighbourhood for a minimum of five years; and, second, that no patient might be treated except by a member of the staff. The first rule excluded anyone with higher degrees, or at any rate with adequate postgraduate training, from appointment to the staff; in practice it meant that staff appointments were for sale, since the purchase of a partnership often included a guarantee of such an appointment. The second rule denied to patients treatment by experts of their own choice—indeed, treatment by experts at all if an expert be defined as one who has made a whole-time study of the art that he practises.

The standard of work in hospitals of the type I have mentioned was in some instances quite deplorable, particularly where surgery was concerned. In the view of many at the time the Act was under discussion, the occurrence of disasters amply justified the closing of cottage hospitals. How wrong this opinion was we have since learned to our cost.

The National Health Service

The final and official segregation came with the National Health Service Act. After July, 1948, the medical profession was split into categories, defined with the verbose exactness of the Civil Servant. Each man, after qualification, preregistration employment, and national service, must enter or be herded into one of several pens, and within that pen he must live until he dies or retires. Of these pens, the lowest is that of general practice. General practice was artificially debased. The general practitioner was made a shuffler of patients' cards, a signer of certificates, a distributor of benefits, a treater of minor ailments within strictly defined limits and with strictly specified remedies, a stooge with a twenty-four-hour working day, liable to be victimized by trivial complaints but forbidden to complain himself. The specialist was artificially elevated. All citizens may demand specialist treatment, therefore specialists must be turned out to fill the demand. We are now in a ridiculous position where a well-trained and competent doctor is forced to refer his patient to a man of lesser ability but marked with the correct rubber stamp, in order that he may carry out treatment that he himself could do very much better. Hospitals have accumulated unmanageable waiting-lists because their beds are blocked by patients undergoing treatment that could very well have been carried out at home, by patients admitted for investigations that the practitioner could have conducted himself had he been granted x-ray and laboratory facilities, and by patients retained merely through the fear of litigation bred by a series of legal decisions that seem to have been given on the simple working rule that the doctor is always wrong.

We have now had five years of experience of the National Health Service. Whatever benefits it may have conferred on the health of the nation, on the hospitals, or on the specialists, its effect on the spiritual side of general practice has been disastrous. I cannot express this better than by quoting the *Medical World Newsletter* of August 16, 1951.

"After undergraduate and formative years of intimate and enthusiastic participation in the whole range of hospital work, and of satisfying and stimulating membership of the hospital team, to enter general practice is to have crossed the professional Rubicon. There is no way back. New and compelling forces and alien but seemingly accepted influences gradually exert their deteriorating and irresistible effects. Idealism and enthusiasm wane in the face of expediency. Clinical disciplines and scientific

methods are weakened and worsened by pressure of economic necessity. Many different factors are responsible for the present unhappy mood in the great body of family doctors, but it is probably fair to say that none is more culpable than the gradual and now almost complete exclusion of the general practitioner from the hospital services."

A Short-sighted Policy

At the time that the chasm started to appear between consultant practice and general practice, the consultant was a man whose interests covered the whole of medicine or the whole of surgery and who had earned his position by some special aptitude of knowledge, wisdom, or technical skill. To-day the term "specialist" is usually used in place of "consultant," and the change of title corresponds to a significant change in training and outlook. The specialist knows a great deal about a small aspect of medicine or surgery. In acquiring detailed knowledge he has lost breadth of vision; in fact, he has become a technician to be employed rather than a wise man to be consulted. There is all the greater need to-day for general physicians, men who can survey a clinical problem as a whole and can from that survey decide which of the many brands of technicians shall be employed to confirm the tentative diagnosis or apply the appropriate treatment. General medicine to-day is passing into the hands of the general practitioner, and it is of paramount importance that his training should be as thorough as possible, and that he should be allowed to continue it through life.

In considering the relationship of the general practitioner to the hospital we must bear in mind three separate aspects of the problem—the education of the student, the training of the postgraduate, and the care of the patient.

Education of the Student

The training of the student is, and always must be, the business of the teaching hospitals, but we have every right to ask them in all seriousness if they know their business. Are they teaching their students the broad principles of medicine and surgery, and training them to look after the sick, or are they wasting their time by showing them diseases they will never encounter, discussing theories that may never come to anything, or talking of research projects that may or may not lead to something in the generation after next? It is the working doctors who care for the sick, but it is the professors who plan curricula and who have the ears of the Government. To a professor there is something slightly indecent and degrading about the care of sick men, yet he decides the manner in which those doomed to this menial task shall be educated. The Government, desirous to reform the training of doctors, appointed the Goodenough Committee to study the problem. Sir William Goodenough was a business man. He was helped by ten very eminent gentlemen, all doctors in the sense that they were on the *Medical Register*. Seven were professors of academic subjects who had never attended a patient since they left hospital. Three were consultants. None were practitioners. The Goodenough Report, as might have been expected, reeks of academism, and succeeded in adding still further to the burdens of the student's training while taking it still further from the needs of his future vocation.

There is a great need to-day to remember that we are teaching men to be doctors. They do not need to be, and they should not be, taught physiology and anatomy as scientific subjects, but as the groundwork of their future study of medicine and surgery. If they wish to become physiologists or anatomists rather than doctors, that is a matter for postgraduate study. They do not need to be grounded in research. What should concern them is not what lies beyond the frontiers of knowledge, but what is already known; to that they can later add the results of research when these have passed from the realm of speculation to that of tested knowledge. They do not need to know more of rare diseases than that they exist, their main outlines, and the place where further information may be

found if it is required. They do not need to study operative technique, but they must know all about the diagnosis of the surgical emergencies and they must know what modern surgery has to offer in the treatment of disease. They need not have more than a passing acquaintance with the specialties, except for midwifery, paediatrics, and dermatology. But they must be taught far more than they know now about the psychology of the normal, about the infectious diseases, about the surgery of trauma and infection, about industrial diseases, about minor maladies, about sex relationships, family planning, and the day-to-day adjustments of married life, and about the legal obligations of the practitioner.

An attempt is already being made in some medical schools, notably in the Universities of Edinburgh and in London—at St. Bartholomew's, St. Mary's, and Charing Cross Hospitals—to give the students before qualification an introduction into general practice, the specialty which most of them will follow and with whose main outlines they should all be familiar. Before long a general practitioner, or a group of general practitioners working in relays, will be appointed to the staff of every teaching hospital. The logical delivery from the morass in which medical education is now floundering is that the training and examination of the future doctor should be taken from the colleges, who no longer represent medicine or surgery but rather groups of highly specialized technicians, and from the universities, whose examinations represent a parochial rather than a national standard, and handed over to a board on which general practitioners are largely represented. The curriculum that would be evolved by such a group would be better than the present one, for it would deal with basic sciences and basic principles, rather than with the fads of the moment or the fancies of the future. It would be shorter—five years should be ample—and would therefore leave more time for specialized postgraduate study. It would turn out men trained to use their five senses to examine and their minds to apply the lessons of experience to the series of problems that would confront them through their working lives.

Training of the Postgraduate

The second aspect of the relationship between the hospital and the practitioner concerns postgraduate education, though in this respect what is wanted is co-operation rather than education. The general practitioner is overworked. He has few professional contacts. He has little time to read. For fifty years after qualification he will be practising an art that is constantly changing, and if he is to continue to practise it successfully he must be able to learn of those changes, and to discuss with others the problems that have faced him.

For the newly qualified a further period of hospital work with added freedom and responsibilities is essential. An advantage of the Health Act is that it should make possible an eventual grouping of the hospitals in a region that will benefit both the teachers and the taught. In the past hospitals have fallen into two main categories: those with many students and inadequate clinical material, and those with abundant clinical material and no students. In the future we may hope that the students will spend part of their training in other hospitals than their parent one, where, with plenty of patients to examine and fresh viewpoints to study, they will learn more than they could in surroundings that have become familiar. I foresee a time when a teaching unit will contain 5,000 beds rather than the 500 to 1,000 it does now, when none but the senior physicians and surgeons will be permanently attached to the parent hospital, when students, registrars, and the junior consultants will serve for periods in various hospitals in the group, and when the teaching will be spread over a wide panel and be available to undergraduate and postgraduate alike.

But, apart altogether from formal postgraduate training and periodic refresher courses which practitioners may attend if they wish, it is essential that the sharp cleft that has appeared within our own time between consultant and

general practice should be filled in, and that the practitioners of a district should be made to feel that they belong to the hospitals of their district and that the hospitals belong to them. At present, in many instances, the only contact is a hastily scribbled note asking for information that the doctor could easily obtain if he had the facilities, and a hastily dictated and stereotyped reply received some days later. Many suggestions have been made how this situation might be improved.

Each hospital should keep a record of all the doctors in the district from which it draws its patients. It should treat them as the Royal Society of Medicine treats its Fellows, sending to each a monthly announcement of coming activities, of such fixtures as tumour clinics, cardiac discussions, and clinical lectures, in which he might be interested. It should make it clear to practitioners that they are really welcome, and teach those twin menaces to co-operation—the soured sister and the bumptious houseman—better manners. It should specially welcome them at ward rounds where their own cases are being discussed; indeed, it might well arrange that of the two weekly rounds one should be for students, the other in the first place for postgraduates and visiting practitioners. It should ensure that practitioners are welcome,*not alone in the wards but in the departments. A reception once or twice a year at which consultants and practitioners could meet on a social rather than a professional basis, and a practitioners' common room where they could meet each other and where some of the textbooks and journals not usually in the practitioner's own library could be consulted, would go far to encourage the spirit of camaraderie.

A further method of bringing the general practitioner into closer contact with the hospital is by clinical assistantships, a scheme in which the Barnet Group Hospital Management Committee has been a pioneer in the London area. At the Barnet General Hospital six general practitioners are appointed to six clinical assistantships—two in medicine, and one each in surgery, obstetrics and gynaecology, dermatology, and paediatrics. The appointments are for a period of six months, which may be extended to twelve. The grading is registrar (part-time), and the clinical assistant attends two sessions a week. The scheme has proved most satisfactory. The practitioners value the educational and clinical contacts and get a better understanding of the internal workings of the hospital and appreciate its difficulties. This, in turn, brings about a better relationship between the hospital and outside general practitioners. The system of clinical assistantship is being extended to other hospitals in the Barnet Group.

Care of the Patient

The third aspect of the relationship between hospitals and doctors concerns the care of the patient. At the present time much of the educative value of practice is lost to the practitioner because he is unable to pursue his investigations to the point where a firm diagnosis is possible, or to treat his patients when they require nursing. On the other hand, the hospitals are inundated with cases of a comparatively trivial nature that the practitioner should have treated, and in examinations that he could just as well have made himself. The answer lies in the provision of general-practitioner beds.

The ideal arrangement in theory, that the practitioner should continue in charge of his patient after he has entered hospital as he did before, is unfortunately impossible in any large hospital for administrative reasons. The doctor's visit forms quite a small part of the work of a ward. Patients must be wakened, washed, and fed, beds must be made, temperatures and pulses must be taken, medicines must be administered, closed periods for bed-pans and visits to the lavatory must be instituted at frequent intervals. The superintendent, the matron, the honorary, the registrar, and the houseman must all make their rounds. Physiotherapists, occupational therapists, clinical chemists, dietitians, clerks, and photographers all come in to practise their particular

trade. Visitors bring noise, chaos, and mess for a couple of hours a day. In a teaching hospital ward rounds intrude, in a non-teaching hospital the turnover of fresh cases and the number of minor treatments is much greater. It is clear that in such hospitals the nursing staff cannot possibly cope with simultaneous visits by eight or ten different doctors. In such circumstances attendance by the practitioner at a ward round when his patient is being discussed provides the only practicable form of liaison.

It is possible that specific beds may be allotted to general practitioners in a large hospital, or that a ward may be set aside for their use, but the difficulties of blending such a unit with the work of the rest of the hospital are almost insuperable. A preferable solution is the general-practitioner hospital or the cottage hospital.

Cottage hospitals were under a cloud at the time of the passing of the National Health Service Act; but those who decided somewhat hastily to close them forgot that the treatment of illness is often more psychological than physical, that confidence and equanimity are the first stage to recovery, and that sick folk will get well in familiar surroundings, near their homes, in touch with their families, and cared for by doctors and nurses they know, when they would pine in the chill antiseptic surroundings of a large distant hospital subjected to the skilled but impersonal attentions of strangers. Cottage hospitals had suffered in reputation chiefly because of the incompetent surgery that was performed in some of them. Admirable institutions were condemned because of the faults of some men who worked in them. These faults will not be repeated now, and the cottage or district hospital, properly run, should provide in every local community lacking a general hospital the answer to the relationship between practitioner and hospital.

The size of a cottage hospital is open to debate, but thirty beds is about the smallest unit that will justify the addition of an x-ray unit and a clinical laboratory, both of which are essential to efficient work. There should be a consulting staff consisting at any rate of a physician, a surgeon, and a gynaecologist working at a neighbouring general hospital, and each of these should make a regular weekly visit, and attend at other times if required to do so. The x-ray plant and the laboratory should be in charge of whole- or part-time technicians, but a consulting radiologist and pathologist should supervise the work. Whether all the practitioners in the neighbourhood are on the staff or only a limited number is a matter for local arrangement.

On the one hand, a smaller staff make for easier administration. On the other hand, no practitioner should be obliged to hand over his patients to rivals, which means that anyone in single-handed practice must have the right to admit patients. In most cases a rule that doctors become eligible for election only when they have practised in the district for five years will allow each firm to be represented.

In such hospitals practitioners will be able to investigate and to treat their own patients, referring to the central hospitals only those presenting unusual difficulty in diagnosis or calling for unusual skill in treatment. In deciding upon a line of treatment it must not be forgotten that it is a principle of the National Health Service Act that every in-patient or out-patient should have the advantage of the advice of the appropriate consultant. Any practitioner can perform minor operations, or ones of greater scope, but it would be well that he should do so with the knowledge and approval of the consultant surgeon to the hospital, and preferably that he should have held the post of clinical assistant to him. In the case of litigation, a practitioner who had operated on his own responsibility without taking advantage of the advice available to him would probably be held liable for any untoward results.

The health centre is not as yet anything more than a glorious dream in the minds of the planners. It has never been exactly defined, but in essence it is a place where doctors of a neighbourhood, by working in a building specially planned for the purpose, can enjoy the advantage of communal

facilities in waiting-rooms, secretarial assistance, and accessory methods of investigation, can see their patients in consulting-rooms designed as such, and can consult each other or the representatives of the public health services, who work in adjacent premises. In many ways the health centre is to the cottage hospital what the out-patient department is to the general hospital, and there are many advantages in placing the two in proximity, though not in the same building. The secretarial and filing staff, the offices of the local health authorities, and the group premises of several firms of practitioners working in rivalry do not fit in with the conception of a hospital, but the need in the health centre for x-ray and laboratory facilities demands proximity. The ideal arrangement would be a separate building in the same grounds, or at any rate in the same street.

Conclusion

Finally, the domiciliary consultation is one of the beneficent provisions of the Act that cannot be used too often. Better than its sister Mercy, it blesses three people—him that asks, him that gives, and him that takes. It helps the practitioner because it enables him to meet the consultant man to man over a live problem, to put all those small points and difficulties that cannot be put in a letter, to set out the personal as well as the medical aspects, if need be to call his bluff and insist on simple instructions in plain English. It helps the consultant because it gives him the opportunity seldom offered in hospital, to study a patient rather than a case, and to appreciate the difficulties with which the practitioner must contend. It helps the patient because it brings Harley Street to his bedroom, and cuts out the fatiguing journey and the long wait of a visit to hospital.

What, then, is the ideal relationship of the practitioner to the hospital? The ideal relationship is one of the friendliest possible contact, of the closest possible co-operation.

The consultant and the practitioner are both men trained in the same basic sciences and working for the same end. They have been parted by the increasing complexity of modern medicine. They have been forced further apart by some of the unintended and unexpected consequences of the new Act. Both are overworked. Both tend to assume a superior attitude which is really an inferiority complex with the bristles out. But both can work together if they try, and the first thing is that they should come together.

GENERAL PRACTICE AND THE HOSPITAL*

BY

J. G. M. HAMILTON, F.R.C.P.Ed.
Assistant Physician, Royal Infirmary, Edinburgh

There seem to be many people who claim—and, for all I know, believe—that all the ills from which British medicine suffers to-day had an acute onset on July 5, 1948. This, however, is to forget that all illness must be examined in the light of the previous history of the patient, predisposing factors, and environment. Changes in social and political climate, medical development, and the accelerated advance of knowledge are all important considerations in the diagnosis and treatment of the ailments of the body and mind of medicine. The chronically precarious financial state of the old voluntary hospitals, the burden on the local rates which the development of the municipal hospitals caused, the rise in the cost to the patient of so many medical services in this

*An address given at the Glasgow Office of the British Medical Association on April 1, 1953.

increasingly complex world contributed their important shares to the drastic experiment initiated five years ago. It is not my purpose either to defend or to condemn the experiment, but rather to offer some thoughts on the problem of rehabilitation, with particular reference to the association of general practice with the hospitals.

During the past 30 or more years there has been an obvious change in hospital staffs. Whereas formerly many, perhaps originally all, senior members of hospital staffs worked as general practitioners for much of their time, now almost none do, and I sense a general attitude that this is as it should be.

This development is usually attributed to the increasing specialization which has been so obvious in the same period. There is doubtless substance in this claim, especially in respect of surgeons, but I do not think the advance of specialization is the whole reason in the case of non-surgical staffs. In Scotland the general physician—that is, the consultant who tries to survey the whole field of internal medicine—is still fighting a successful rear-guard action for survival against the forces of narrow specialism which are dominant elsewhere. However, the ever-increasing number and complexity of diagnostic and therapeutic techniques have influenced the pattern of hospital staffing, for the development of these techniques is inevitably a hospital matter, and therefore expertness—that is, specialism in their uses—is first acquired by the hospital staffs, and the hospital physician acquires skill which the doctor working outside hospital has little chance of attaining, or at any rate can do so only much later. More and more, therefore, the hospital physician has devoted his time to applying these special skills and the experience gained in their application even while still trying to maintain a wide general outlook.

Also the financial and social eminence attainable, at any rate in former days, by top-flight consultants has attracted men into purely hospital and consultant work divorced from the rough and tumble of general family practice.

Hospital Staff and Domiciliary Practice

Be the explanations what they may, we were already, long before the last war, faced with the fact that the general hospitals were for the most part staffed by men who were not engaged in general practice, and indeed in many cases, to their detriment, never had been. This trend has continued, and has probably been accelerated by the war and by the introduction of the National Health Service, so that now there are very few G.P.s on general hospital staffs, and the idea is prevalent that none need apply. The almost universal practice of appointing junior staff—that is, registrars, senior registrars, and others—to whole-time appointments, and the difficulties in the way of any two-way traffic between general and hospital practice, are already breeding a race of young consultants who have not only no experience of general family practice but very little of domiciliary practice of any kind. To my mind this is one of the gravest defects of the Service, since, in the future, consultants will lack a vital element in their training—namely, the experience of attending people in their own personal and domestic environments, experience which contributes so much to the making of a good doctor, and lack of which accentuates the danger of the development of an impersonal and mechanistic approach to what are, after all, intensely human problems.

Since the clinical teaching of undergraduates is almost entirely confined to members of hospital staffs, their increasing lack of experience in family and domiciliary practice

has a harmful effect on the vocational training of the young doctor, which the trainee-assistant scheme does not wholly eliminate.

The absence of practice experience on the part of hospital staffs and the prevalent absence of hospital experience (beyond that acquired in house appointments) on the part of general practitioners have created and are steadily accentuating a cleavage between these two branches of the profession. This cleavage is unfortunate enough in itself, but, unhappily, it is associated with a tendency for one section to lose its respect for the other. The hospital man looks down from his rarefied pinnacle on those who are "only G.P.s" as a quite inferior form of life, and the G.P. regards the hospital man as a "test-tube doctor" who can do little without his laboratory and his investigations and whose advice in the end may be anything from a pronouncement as from Jehovah to the wildest impracticability.

There is nothing to be gained by denying that bad work is done in general practice, since doctors are only human and their qualities and knowledge vary almost infinitely. Equally, and for the same reason, we must recognize that much bad work is done in hospitals. However, we should not legislate only for the bad but also, and more importantly, for the good and the average.

All these are matters which cannot be ameliorated overnight by any administrative action. Improvement can be achieved only by improvement in the climate in which medicine is practised, involving the medical undergraduate curriculum, the qualities and attitudes of the teachers, and the provisions for suitable postgraduate training, as well as the administrative framework. Of educational matters I would only say that vigorous thought, self-criticism, discussion, and experiment are prevalent throughout the profession to an extent greater, I think, than ever before. A healthy portent of things to come.

Administration and Organization

I wish to examine some aspects of the administrative and organizational side of this problem. On the question of the staffing of the general hospitals, teaching and non-teaching, we must not adopt a Canute-like attitude and call for a halt to the tide of specialism and the development of new techniques. For one thing, the tide is probably irresistible, and, for another, if progress were to stop regression would quickly follow into empiricism and superstition, of which indeed there is still all too much. We should not strive to return to the days when the big hospitals were staffed by general practitioners, but should aim at utilizing the best of the old with the best of the new. Young men who hope for a specialist career should be set free from the whole-time bonds which bind them to a rigid time-limited scheme of training in an orderly succession of hospital posts. They should be enabled to do as many of their predecessors did, and, taking such advice as they care, guide their own footsteps and acquire such varied experience as they themselves think necessary or desirable to fit them for successful application for senior posts and for successful and satisfying senior work. They should all be encouraged to gain experience in general practice.

The trainee-assistant scheme should be open to men who at the time of entering do not intend to make general practice their career but who wish to gain this invaluable experience under the guidance and care of good G.P.s. A proportion, at least, of the posts of registrar and senior registrar should be part-time appointments so that the holders would be free to undertake other part-time work in, for example, general practice. If these things were done, and if there were no limit to the number of registrar posts the young men could hold in succession, it would be easier for the registrar who changes his mind and wishes to enter general practice, or who is unsuccessful in applications for senior hospital posts, or who, for that matter, has taken registrar posts to obtain training, experience, and skill as a deliberate step to general practice, to secure an entrance to practice. The stigma of

"stickit specialist" would not adhere to him, and executive councils would not reject him as consistently as they appear to do to-day.

Part-time Appointments

Let us look at the other side of the penny. There should surely be no real or implied bar to the appointment by hospital authorities to junior or senior part-time posts of men who are engaged in general practice, so long as the applicants can show to the satisfaction of the appointments committees that they are suitably qualified and experienced to do the work and are able to give the necessary time from their practice commitments. We may be sure that no one will apply for a part-time hospital post who does not wish it and who cannot give the necessary time, and we may be equally sure that boards will not appoint men whose qualifications and availability do not satisfy them.

It will be appreciated that these two propositions, on registrar posts and on G.P. applications for staff posts, are interdependent. The registrar who is engaged in part-time general practice, or who, after a variety of hospital posts, has entered whole-time general practice, would not be debarred, solely by reason of his engagement in general practice, from applying successfully for a part-time hospital post. Equally, few if any G.P.s would succeed in convincing appointments committees of their qualifications for part-time hospital posts who could not point to recent experience in the appropriate field of hospital work. Such part-time hospital and part-time general practice posts need not be confined to either the junior or senior ranks of the hospital service, but should be open throughout the range, the only criteria being suitability of qualifications and certainty of availability.

It is, of course, unrealistic to imagine that all G.P.s would quickly acquire hospital appointments. Many would not wish them, many could not claim the necessary qualifications, and many with large or even moderate lists could not give the time. Yet it is just as foolish to imagine that because a man is engaged in practice he cannot have acquired the qualifications and interest necessary to maintain his place in a hospital team.

G.P. clinical assistantships in hospital seem to me to offer only a limited usefulness, and that chiefly in the field of postgraduate training. In my view they are not the answer to the problem of the association of the G.P. and the general hospital.

I do not propose to discuss at length the question of remuneration, for I think that, important as it is, it is not fundamental in respect of the matters I have mentioned. Let it suffice for me to say that I believe that the rate for the job should be paid.

Beds for G.P. Use

These preceding thoughts have been in respect of the G.P. on the general hospital staff *qua* staff member. I turn now to the G.P. on the hospital staff *qua* G.P. I think we should accept that, so far as the general wards and units of general hospitals are concerned, there is little likelihood of beds being set aside for G.P. use. Any belief to the contrary seems to me to savour of the Canute-like attitude to which I have referred already. Several considerations bring me to this conclusion. By long tradition the senior physician (or surgeon) of a general hospital unit in Scotland is "the chief," and he carries the overall responsibility for all the patients in his unit. It follows that the remainder of the staff of that unit are, to a greater or less degree, subordinate to him, yet the essential idea of G.P. beds is that the G.P. should be fully responsible for the care of his patients in those beds. If of neighbouring patients one were looked after by the senior physician and the other by his own G.P., it would be impossible to avoid the development of a feeling of two degrees or qualities of medical care, and, however unjust or unfounded this might be, it could only be harmful to all. Nursing and ward-round schedules and the

requirements of student and nurse training would make ward organization nearly impossible if a proportion of the beds were under the charge of a number of G.P.s who, by the nature of their outside work, might well be obliged to visit their hospital patients at all sorts of irregular hours.

On the other hand, there are to my mind many reasons why the G.P. should have beds at his disposal for the care of his own patients. I consider that no measure could be introduced which would do more to improve the climate in which practice is conducted than the provision of G.P. beds. In many country districts there are large or small cottage hospitals staffed by the G.P.s of the neighbourhood, many of whom have expressed themselves to me as at a loss to understand how city practitioners manage to carry on good practice with no hospitals in which they can look after their own sick patients or confine their own parturient women. The American G.P. usually has his local hospital in city or country, and cannot imagine how his British counterpart can do good work lacking such facilities.

Hospital Developments

There is a growing distinction between general practice medicine and hospital medicine, caused partly by increasing specialization and the development of new techniques and partly by social factors such as bad housing, the absence of domestic help, and the increase in the proportion of elderly persons in the population. It is perfectly right to regard the study and selection of patients suffering from valvulotomy, or the treatment of patients suffering from thyrotoxicosis with radio-iodine, to take but two up-to-date examples, as hospital medicine, but, speaking generally, and of course recognizing that there are many exceptions, the treatment of acute pneumonia or congestive heart failure or peptic ulcer, or many cases of sciatica, and a host of other things, have become hospital medicine only because of the social and domestic obstacles in the way of treatment at home. It is not because these are extraordinary conditions or require special skill or special facilities, beyond the range of the patient's family doctor. The G.P. who has a few private patients left is fully capable of looking after such patients in private nursing-homes and is usually prepared to do so; and he could do the same for many of his Service patients if he had beds at his disposal, given the admitted difficulties of looking after them at home.

A most significant result of these hospital developments has been to withdraw from the G.P. many of his patients at the times of greatest clinical interest and to deny him the professional satisfaction of a good therapeutic job done. I hold that nothing has done more than this to promote the much-discussed decline in the status of the G.P. and to turn him into a purveyor of certificates, a finger-post to hospital, and a prescriber for minor ailments.

A more satisfactory distinction would be between "ordinary" medicine—that is, clinical problems which are within the competence of the ordinary, average trained man—and "extraordinary" medicine—that is, matters requiring special skill or special techniques. It is wasteful to use beds in highly organized and elaborately equipped hospitals for the routine care of "ordinary" cases. Indeed, the big general hospitals have become inflated in size partly because they have been gradually obliged to undertake more and more of this work for the various reasons I have suggested. It is often actually detrimental to patients, especially the young, the old, and the nervous, to "hospitalize" them in large and to some extent impersonal and frightening institutions which may be a long way from their homes, and this should not normally be done unless there are overriding medical reasons—for example, the real or suspected existence of some "extraordinary" condition. There must, of course, be room for variation in usage. There can be no objection to the hospital consultant's undertaking the care of a patient with an "ordinary" illness if this is the desire of the patient or his doctor, or if he should be engaged upon a particular research problem.

District Hospitals

I consider, therefore, that there is need not for more and yet more general hospital beds but rather for district or neighbourhood hospitals where the local practitioners could look after their own patients. As I conceive it these should be small and many rather than large and few, so that they would not frighten the timid, would have an atmosphere of belonging to the neighbourhood, and would reproduce so far as possible the atmosphere of district nursing-homes. The services of consultants should be available, as should simple ancillary diagnostic and therapeutic services, and there should be a qualified nursing staff. The district nurse should have her headquarters there. The district hospital should be the district maternity home, where practitioners would deliver their own patients. The maintenance of a good standard of G.P. midwifery surely depends on continuous practice in normal deliveries. The specialist obstetric hospital should be primarily concerned with the abnormal or "extraordinary."

The provision of district hospitals, offering to the urban practitioner, if he should wish to make use of them, the facilities enjoyed by so many rural practitioners, does not seem to me to be a Utopian concept, but an eminently practical one. These hospitals might, of course, be large chromium-plated palaces specially built for the purpose, but they need not be. The utilization and modest modification of existing domestic buildings could provide a perfectly adequate substitute. It is usually stated that a multiplicity of small hospitals is more expensive to maintain than one large hospital, but this is certainly not the whole story. A new large general hospital or a large addition to an existing one must be a new construction, the cost of the building and equipment of which is astronomical at the present time. It is because we usually think of new hospital provision in terms of modern general hospitals, with their complicated equipment, laboratories, and ancillary departments, that we shy at the cost and say it cannot be done in our lifetime. The district hospital on the cottage-hospital model is a much simpler affair which, provided at comparatively modest cost by modification and improvisation, might well reduce drastically the need for the provision of new ultra-expensive general hospitals. Even if over the years the cost were somewhat higher the price would be a small one for the nation to pay if it restored to the G.P. (where he has lost it) the affection and respect of the public and a professional pride in his work.

Conclusion

I do not deny that I have been looking into the future, even the distant future, but I firmly believe that a start must be made soon if the adverse trends of the past and the present are to be halted or modified. I would plead for a reorientation of our thinking on the matter of hospital planning. Too much of our attention has been given to the specialist aspect of hospital development. Regional boards are charged with the duty of hospital planning, but in the nature of things this has meant the planning of specialist services and hospital provisions. No body under the Service, apart from the Government departments, is charged with the duty of planning the general medical service except in respect of the distribution of practitioners. This is a sad omission. We all pay service to the family doctor as the base of the edifice, but I fear it is usually lip-service. Little is done to ensure that the climate in which he works is that which is most conducive to good work—the maintenance of old and the development of new skills.

The new diagnostic and therapeutic techniques of to-day should be the commonplace of to-morrow. Once the sphygmomanometer was owned and used only by the consultant, now it is as much a general professional badge of office as the stethoscope. The anticoagulant treatment of intravascular thrombosis is at present a matter for the

hospital consultant, but there is no reason why it should not come to be understood and applied by the family doctor if reasonable facilities were made available to him. The essential provision, in my view, is the district or neighbourhood hospital. This I consider to be the most powerful way to bring the G.P. back from his backwoods isolation into the general community of advancing medicine, of which his training should entitle him to be a full member.

Medical Memorandum

Acute Inversion of the Uterus Successfully Treated by Intravaginal Hydraulic Pressure

Acute inversion of the uterus is one of the rarest and most serious of obstetrical complications. Only two cases have been recorded at the Sussex Maternity Hospital (receiving an average of 1,500 cases yearly) in the past 25 years, of which this is a record of the second. The former patient died from shock before replacement of the uterus could be attempted. It seems worth while to report the successful treatment of the latter, to emphasize the value of early recognition and the value of modern anti-shock therapy.

CASE REPORT

A 2-para was admitted on February 23, 1950. Her last menstrual period was on May 17, 1949, and the expected date of delivery February 24. The pregnancy was normal; Wassermann reaction negative; blood group O, Rh-positive. Her previous health and confinement had been normal. Regular pains had begun four hours before admission at 5 p.m., when there was no show; the presentation was L.O.P.; and uterine contractions were of fair intensity, one in 10 minutes; and the foetal heart rate was 140. A soap enema was given. At 7.30 p.m. pains became stronger, with a frequency of one in two minutes, and at 10.30 p.m., when she was fully dilated, the presenting membranes were ruptured. Vaginal examination showed persistence of the L.O.P., in the lower third of the pelvis, and at midnight, as there was no rotation or advance, forceps were applied, and with a very easy pull the head was extracted face to pubes. The shoulders and trunk followed easily with no perineal tear, and intravenous ergometrine, 0.5 mg., was given. The uterus appeared to retract well, but on moderate pressure being applied to express the placenta the inverted uterus with placenta attached appeared at the vulva. The placenta and membranes were removed, and the uterus was placed in the vagina, but no attempt at reduction of the inversion was made. Morphine sulphate, $\frac{1}{4}$ gr. (16 mg.), was given, and an intravenous plasma drip started.

On my arrival at 1 a.m. the pulse rate was 140 with reasonable volume and the general condition seemed fairly satisfactory. On abdominal examination the cervix was palpable just above the pubes as a large dimple admitting two fingers. A blood transfusion was substituted for the plasma and the patient anaesthetized with open ether. The completely inverted uterus was found firmly retracted in the vagina.

Reduction by the method of O'Sullivan (1945) was decided on. The introitus being blocked with the left hand, "dettol" solution at 118° F. (47.7° C.) was gently pumped into the vagina by the right, using a freshly boiled Higginson syringe, pumping being continued to replace leakage. From time to time the cervix was examined abdominally for signs of dilatation, and these appeared after about 15 minutes. Continued douching was followed by further dilatation until it was possible to insert the coned hand (*main d'accoucheur*) into the half-dilated cervix, when to-and-fro movement with separated fingers assisted the dilatation. This being complete, the inverted uterus was reduced with the right hand, starting with the part next to the cervix and working to the fundus. When replacement was complete the uterus was grasped abdominally with the left hand and ergometrine,

0.5 mg., was given intravenously, the right hand remaining in the uterus till retraction was established. It was then slowly withdrawn to the vagina, where it encircled the cervix and helped it to contract, to avoid recurrence of inversion. There was very little loss, the pulse rate was 160 and the volume fair, and the condition seemed good. At 5 a.m., when 2 pints (1.1 litres) of blood had been given, the transfusion was discontinued, and at 6 a.m. improvement justified removal to the general ward. At 10 a.m. the pulse rate was 100 of good volume, loss was very small, the uterus well retracted, and the condition good.

Penicillin, 500,000 units, was given three-hourly for the first day and then twice daily till the fourth day, when, after three days of slight pyrexia of 98.8° F. (37.1° C.) and a pulse rate between 100 and 110, the patient had a slight evening rigor, with a temperature of 101.8° F. (38.8° C.) and a pulse rate of 140. No cause was found, a vaginal swab and catheter specimen of urine showing no pathogenic organisms. Penicillin was discontinued and sulphadimidine, 1 g., was given four-hourly. In 24 hours the temperature was normal and the pulse rate 100. No further fever occurred, and in four days chemotherapy was stopped. Involution of the uterus continued normally.

On the thirteenth day a blood count showed Hb 55%; red cells, 3,150,000; C.I., 0.87; white cells, 8,900, with normal differential. A further 2 pints of blood was transfused and the patient was discharged on the nineteenth day in a very satisfactory condition. Post-natal examination on April 17, seven weeks after delivery, showed a well-involuted uterus, mobile and anteverted. The cervix was normal and the perineum in good condition. The menses had not resumed. The patient's general condition was excellent.

The baby was a healthy female, and had regained her birth weight of 8 lb. 12 oz. (4 kg.) on leaving hospital. The feeds were complemented, owing to a poor breast-milk supply.

COMMENT

In retrospect, the management of the third stage should not have been the cause of the inversion. Intravenous ergometrine is in almost daily use and the amount of fundal pressure exerted was very moderate.

Shock disproportionate to the amount of blood lost is the usually prominent and dangerous symptom in this rare and serious complication of childbirth. The shock apparently results from stretching of the nerves in the broad ligament of the inverted uterus. Restoration of the uterus to the normal position as quickly and as gently as possible is the best treatment, since it removes the cause of the shock. The conditions of treatment can, to judge by this case, be fulfilled by replacement of the uterus by intravaginal hydraulic pressure, as suggested by O'Sullivan.

This year's Summer School of the Central Council for Health Education was held at Royal Holloway College, Englefield Green, Surrey, from August 10 to 20. The inaugural addresses were given by Alderman W. E. Yorke, chairman of the council, and Dr. John Burton, director of the council. The programme included lectures on "Health at Home," by Dr. John D. Kershaw, medical officer of health for Colchester; "Health at School," by Dr. C. M. Fleming, reader in education for the University of London Institute of Education; "Health at Work," by Dr. Richard Schilling, reader in the Nuffield Department of Occupational Health in the University of Manchester; "Health Education in Hospital," by Miss K. A. Douglas, matron of St. Mary's Hospital; and "Care of the Aged," by Dr. C. A. Boucher, medical officer, Ministry of Health. Seventy students attended the full course from all parts of this country and from many widely different overseas areas.

Reviews

AIMS OF BIOPHYSICS

Progress in Biophysics and Biophysical Chemistry, volume 3. Edited by J. A. V. Butler and J. T. Randall, F.R.S. (Pp. 386. 17 figures. £3 3s.) London: Pergamon Press. 1953.

In this, the third volume to appear since 1951, the problems of ascertaining molecular structure, with special reference to biological systems, are discussed at length. In addition, the book contains articles on the theory of the ionic double-layer and on transport processes through membranes. In looking through this and the previous volumes we have the impression that the editors have scraped the biophysical pot fairly clean, so that we may expect a pause of several years before progress justifies a new volume.

We may therefore profit by this respite to reflect on just what is meant by biophysics. Physiology concerns itself with the analysis of living behaviour. As our knowledge increases, this analysis may be pushed so far that some phenomena, notably the conduction of the nerve impulse, can be expressed in terms of the concepts of the physical chemist. But in other aspects our knowledge of the phenomena is still too limited to permit of a description in terms of such fundamental concepts, and the physiologist has to limit himself to categories that are still remote from precise definition—reflexes, hormone action, and so on. Correspondingly, physiologists have tended to fall into two very loosely defined and frequently overlapping classes—namely, the *general physiologist*, concerned with the fundamental activities of the cell and trying to interpret them in terms of physical theory, and the *mammalian physiologist*, concerned with those phenomena that depend not so obviously on the fundamental characteristics of the living cell as on their integration in patterns.

A glance at the titles of the articles in the three volumes under discussion would suggest that their objects largely belong to the area covered by the general physiologist, so that one might be inclined to accept the term "biophysics" as a substitute for "general physiology." And, indeed, it was in this sense that the title of biophysicist was first adopted in Britain. But on examining the matter contained in the articles we see that the editors take a rather different view. In essence—and with some exceptions—the articles are concerned with the application of physical techniques to living matter or often to matter derived from living organisms. The emphasis seems to be on technique rather than on the elucidation of vital activity, and consequently the reader is left only too often wondering exactly what progress has been made, and just as often the answer is, Very little. Apparently the editors consider any physicist who uses his instruments on matter of biological origin to be a biophysicist, whether he be an electron-microscopist or a radio-engineer assaying radio-isotopes in a hospital. As a result, the volumes are a strange mixture of genuine physiology written by genuine physiologists, genuine physiology written by people with no claim to the title of physiologist, pure chemistry written by not-so-pure chemists, and so on. As such they must occasion disappointment to every reader—whatever his scientific inclination.

The growth of a new branch from the main stem of an existing science is a natural process, often deplored at first but finally welcomed as a healthy sign of progress. Thus biochemistry is an offshoot of physiology; their ends are similar, but the technical and theoretical requirements of the biochemist have become so highly specialized as to warrant the separation. Biophysics, viewed simply as an outgrowth from physiology, with its exponents trained in the discipline of biology as well as in that of a more fundamental science, should be similarly welcomed. If viewed, on the other hand, as an unnatural segregation of physicists and physical chemists from the main body of their own fundamental science for the primary reason that accident

or design has brought them into biological fields of investigation, one's welcome will not be free of misgivings, occasioned by the fear that such an assembly of scientists, divorced from their colleagues in the basic sciences and regarded with suspicion by the biologist, may degenerate into a sterile association reminiscent of the school of biomathematics in the U.S.A.

A science, or branch of science, should be classified in accordance with its aims and certainly not by its techniques. If we define biophysics according to its aims we shall find that it is no more than animal and plant physiology, and we shall discover that progress in biophysics is by no means so impressive as the rapidity with which these volumes have appeared would lead one to believe.

HUGH DAYSON.

TUBERCULOSIS CLASSIFICATION

The Classification of Pulmonary Tuberculosis. By Milosh Sekulich, M.D. (Pp. 322; illustrated. £3 3s.) London: William Heinemann. 1953.

The purpose of classification is to group together objects of study within a defined field in such a way that thought within that field shall be as precise and action as effective as possible. To this end, classes should be clearly defined in terms understandable and unequivocal to all users. Since classes should be mutually exclusive, their defining characteristics should belong ideally to a single general category. Statements about characteristics belonging to any other general category cannot usefully or legitimately be included within the definition, since such characteristics must, once the defining characteristics have been specified, be the subject of empirical study. Too many classifications in medicine fail to satisfy these desiderata; failure to establish definitions in terms of the smallest possible number of defining characteristics leads to the unnecessary importation into them of propositions which are thus imposed upon the reader *a priori*, although they should, in fact, be treated empirically.

Dr. Sekulich, in his ambitious attempt to provide a theoretically comprehensive classification of pulmonary tuberculosis, has not succeeded in avoiding these pitfalls. Throughout the classification, defining characteristics are inextricably confused with propositions the truth of which ought to be established empirically. For instance, all pulmonary tuberculosis is divided into four principal forms—the inflammatory, the caseous, the fibro-caseous, and the fibrous. This would normally be taken to indicate a morbid anatomical basis for the classification, but these four groups are equated without comment, and without production of any evidence to support the equation, with temporal stages in the development of the disease, the inflammatory and caseous groups being stated to belong to the primary, and the fibro-caseous and fibrous groups to the post-primary stages.

Other curious equations are those of primary with acute and of post-primary with chronic forms of pulmonary tuberculosis. For reasons unstated, fibro-caseous forms are said to spread "by the bronchogenic route," while fibrous forms develop "by haematogenous and lymphatic routes." In the foreword a "law" is stated to the effect that "it is regularly observed that the most recent lesions are absorbed or healed first in the process of regression, and the original lesions last." This may or may not be true, but the reader may reasonably expect that some evidence should be produced in favour of such an interesting proposition, rather than that it should be presented to him *ex cathedra*.

A number of terms of vague or confused meaning are used. "Epituberculosis" should surely be relegated to history now that the clinico-radiological pictures associated with it are known to be due to either atelectasis or non-caseating tuberculous pneumonia. "Tuberculoma" is, in current usage, a loose descriptive term for rounded radiographic shadows thought to be tuberculous in origin. This usage, one may suspect, is mainly a cloak for ignorance, since at least three quite distinct morbid anatomi-

cal types of pulmonary tuberculosis may be associated with such shadows. These terms are so lacking in precision that they should have no place in a classification, unless indeed they are newly defined for some specific purpose. The word "phthisis" is used in the text as a synonym for the fibro-caseous forms of pulmonary tuberculosis, although in the list of definitions of standard terms it is stated to mean "that the tuberculous patient shows the signs of emaciation." The word "fibrocavitaria" is said to denote "a fibrous form in which thin-walled cavities are seen in the absence of obvious caseation"; it is assumed, without presentation of supporting evidence, to be haematogenous in origin. The word "sclerocalcaria" is used in the text without clear definition. A quotation from Laennec provides a good comment: "L'art de raisonner consiste surtout dans une langue bien faite; et rien ne nuit plus aux progrès d'une science que détourner sans motifs suffisants les noms de leur acception reçue, ou d'en créer de mauvais."

A classification of pulmonary tuberculosis is required principally for such practical matters as the comparison of results of treatment, and the analysis of the true significance of notification rates. For this reason, it should not entail the acceptance of theoretical considerations which may not be generally agreed, and which, in their application to some practical instances, may actually be incapable of objective demonstration, but should be based as nearly as possible on simple facts of observation. The most widely used methods of classification are based on no more than extent of disease and the presence or absence of bacilli. Although the applicability of these is limited, they have the virtues of creating no confusion and implying no unproved hypotheses. The classification presented in this book does not possess these modest virtues.

J. G. SCADDING.

RECONSTRUCTION SURGERY

Wiederherstellungschirurgie und Traumatologie (Reconstruction Surgery and Traumatology). Volume 1. Edited by M. Lange. (Pp. 262; illustrated 36 Swiss francs.) Basle: S. Karger.

A new volume having the names of Sterling Bunnell, G. Küntscher, Merle d'Aubigné, and A. Steindler among its contributors must command attention. It claims attention, however, as a new venture and as an attempt to overcome the language difficulty by being trilingual, and Switzerland seems the natural place for its publication. But its endeavour to reach more readers goes no further than the addition of a translated résumé to the articles such as has characterized the Scandinavian publications. To be more truly universal in appeal this should be considerably expanded, as it is probable that none but the trilingual will feel that they get full value from the book.

One-third of it is devoted to medullary nailing, and there are some enlightening comments both by its originator and by Vom Saal, of New York, who supports the conservative school favouring open methods of pin insertion. Both are insistent on strong nails and accurate and tight-fitting pins. Nested nails are recommended for the tibia and humerus. This is perhaps the most complete and interesting section of the book. In the second part there is general agreement about the frequency of necrosis of the femoral head after subcapital fracture—namely, 30%—and Böhler emphasizes that arthritic change is inevitable at some stage in almost all cases. There is no agreement on the value of immediate treatment of fresh fractures with a prosthesis. In the third section, on nerve disabilities, Bunnell discusses the transfer of the flexor sublimis in claw-hand, Merle d'Aubigné the tendon transplants in radial nerve paralysis, and C. E. Irwin the treatment of the hand paralysed by poliomyelitis.

It is stated in the preface that critical comment on the articles by the editorial board will be included in the volume. Discretion appears to have erased such remarks from the first issue. The second, it may be hoped, will unite articles on similar subjects by means of comment from a single mind, and spare more space for résumés. Such

a book thus expanded a little might well effectively replace some of the annual volumes which appear on many subjects and are no more than a glorified index.

HEALING ARTS

Disease and its Conquest. By G. T. Hollis, M.A.(Oxon.). Foreword by Maurice Davidson, M.A., M.D., B.Ch.(Oxon.), F.R.C.P. (Pp. 163. 9s. 6d.) London: Oxford University Press (Geoffrey Cumberlege). 1953.

The Healing Arts and Their Future. By Kenneth Walker. The Changing World Series. (Pp. 222. 12s. 6d.) London: Frederick Muller. 1953.

The first of these books is written by a layman for laymen. The author, Mr. G. T. Hollis, the editor of Oxford Medical Publications, has selected 40 or so medical conditions and written these descriptions of them. The facts given are unexceptionable and succinctly stated, and any doctor will be grateful that such a book is written with accurate lucidity. Whether there is any demand by the public for a book of this sort the author and his publishers must know. If there is such a public, it is a pity that not more has been done here to make the dish more attractive and informing. To write that the introduction of insulin was one of the greatest advances in medicine is undoubtedly true, but to have told a little of the story of Banting and Best would have illuminated a flat pronouncement. And why write discreetly that insulin is obtained from "other sources" and leave undeclared the diabetics' debt to the stockyards?

Mr. Kenneth Walker has also written a book about medicine for the layman. It is lively, stimulating, and intelligent. If the doctor cannot expect instruction from it, he can at least read it with pleasure and without discomfort. Mr. Walker assesses the present state of medicine, surgery, and psychiatry, and forecasts our future powers. Although himself engaged in a mechanistic craft, he rejects so narrow a conception of man and his ill-health, and, like some other distinguished surgeons, proclaims man in three dimensions. Being on the side of the angels, our author naturally ranges himself with the family doctors; he writes nostalgically of their past, sympathetically of their present, and hopefully of their future. This book well justifies its inclusion in a Changing World Series.

D. V. HUBBLE.

WOMEN IN MEDICINE

Storming the Citadel: The Rise of the Woman Doctor. By E. Moberly Bell. (Pp. 200; illustrated. 18s.) London: Constable and Co. 1953.

In no branch of work have women more fully justified their emancipation than in the profession of medicine, and now, with many thousands of them on the Register, it seems incredible that they should have met with so much and so bitter an opposition to their claims to be permitted to practise medicine. When we read of one very distinguished physician who, as late as 1878, raised his hand to heaven and "testified that he had but one dear daughter and he would rather follow her bier to the grave than allow her to go through such a course of study," we marvel at the limited view and bigoted ideas of even the last generation. Nor were the generality of women any wiser, for when Elizabeth Garrett told her parents she had decided to study medicine her mother "shut herself up in her room and cried for two days."

Yet the citadel of male conservatism in medical education was slowly and surely stormed by the patience and persistency of a few brave women—Elizabeth Blackwell, Elizabeth Garrett, Sophia Jex-Blake, Mary Scharlieb, and a few others. This book gives a very readable account of the struggle and should be read by every woman doctor and (to keep them humble) by all men doctors too.

Let us spare a word of praise, however, for the few medical men of enlightened views who helped the women on their way—Sir James Simpson, Mr. A. T. Norton, and a few others, while regretting that they were so few.

ZACHARY COPE.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY SEPTEMBER 26 1953

GENERAL PRACTICE TO-DAY AND TO-MORROW

This week's *Journal* is largely devoted to the problems of general practice and the general practitioner—problems related in part to the intrinsic nature of practice in an age of expanding knowledge, in part to the altered scene resulting from the National Health Service. The greater portion of this week's issue is taken up by reports produced under the guidance and initiative of the General Practice Review Committee set up by the Council of the B.M.A. in 1950:

"to review the present position in general practice, its difficulties and its trends, both generally and with reference to the two years' experience of the National Health Service Acts, and to the B.M.A. report on 'General Practice and the Training of the General Practitioner,' and to make recommendations."

The Committee, under its chairman, Dr. C. W. Walker (a general practitioner in Cambridge), decided to cast its net wide and to gather to the greatest extent possible in a limited time the views of general practitioners and the facts of their practice. It did this in two ways. It instructed the secretary of the Committee, Dr. Stephen Hadfield, one of the B.M.A.'s assistant secretaries, to make a field survey of a representative sample of general practitioners, and he spent a year (February, 1951–March, 1952) investigating 188 practices, combining in this work, in the words of the Committee, "the labour of a Hercules with the wisdom of the Serpent." Secondly, the Committee sent a postal inquiry to 17,616 general-practitioner principals in the N.H.S., and received a response from 12,657, or over 70%. On the basis of these and other inquiries the Committee drew up its own report. It should be stressed that the field survey is the work of one individual, and, as the original contribution of Dr. Hadfield, appropriately appears under his name in our opening pages. Though part of the inquiry set on foot by the General Practice Review Committee, it is not a report of the Committee and responsibility for the findings and opinions in it lie with the author of what is an outstanding contribution to the subject. To lend point to a recurrent theme in Dr. Hadfield's article and in the Committee's report we also publish in our opening pages papers by Sir Heneage Ogilvie and by Dr. J. G. M. Hamilton on the theme of the general practitioner and the hospital. The results of the postal

inquiry and the Committee's own and highly important report appear in a specially enlarged *Supplement*. As the Chairman of Council, Dr. E. A. Gregg, points out in a prefatory note in the *Supplement*, the G.P. Review Committee's report is not a report of the Association's Council: it is a report which the Council has ordered to be printed. There is one last proviso. The survey and the inquiry were conducted before the Danckwerts award was made, an award which has gone far to remove the financial grievances of the majority of general practitioners. This should be borne in mind by those reading the Review Committee's report and Dr. Hadfield's article.

The first thing that may strike the reader of these documents is their objectivity, their honesty, and their sincerity of purpose. The warts and the wrinkles are there in the portrait painted. Many commentators will no doubt pick on this or that item or comment in order to bolster up political and other prejudices. In doing so they will bring discredit on themselves and not on general practice. There is much that is good and some things that are bad in general practice to-day, and this can be truthfully said of any profession and of any section of any profession. The triteness of the truism is removed by the painstaking attempt to identify what is good and what is bad and, where possible, to give it some numerical assessment. To say that 55% of general practitioners are happy in their work may sound a little too precise. But it is fair to infer from this that in the pre-Danckwerts days approximately half the general practitioners in England, Scotland, and Wales were more or less content with their lot—a conclusion at variance with the views of the many propagandists at home and abroad who have tried to discredit the National Health Service. In view of the loose criticisms sometimes levelled at general practitioners the following comment of Dr. Hadfield's is to the point: "Over 90% of the practitioners that I saw are undoubtedly interested and careful in the treatment of their patients. They give the necessary advice, supervise rehabilitation, prescribe carefully, and do dressings and emergency treatment. Not for them the mere hurried writing of prescriptions that I witnessed among a few." He found that some 90% of practitioners considered it their job to act as the patient's "guide, philosopher, and friend," as well as giving him clinical care. He found evidence "of a decreasing tendency to unethical conduct, of the improvement of co-operation by formation of local general-practitioner associations or regular (bi-monthly) drawing-room meetings of groups of doctors, and of the formation of rotas." In one industrial town four doctors previously in opposition to each other had joined in partnership to grapple with the problems introduced by the N.H.S. Of those in practice before the introduction of the N.H.S. 90% used to meet a consultant

in domiciliary consultation: at the time of the survey the proportion was 94%. Of the doctors' premises, Dr. Hadfield found 10% to be unsuitable, and this usually in districts where the housing was generally bad: in one instance the doctor had to bolt his waiting-room chairs together to prevent their being taken away. "I found that 91% of practitioners have what one might call the full range of essential equipment." As to the size of lists, 76% of country practitioners do not want more than 2,000 patients: in the towns 27% were in favour of a list of 2,500; 22% preferred up to 3,000; 13% "are quite happy with 4,000." Fifty-eight per cent. of practitioners said they were working harder than they did before the introduction of the N.H.S. in 1948. In an attempt to summarize his impressions in tabular form Dr. Hadfield writes thus: "Tables which show that no less than 92% of the practitioners whose work was witnessed were adequate or better than adequate may come as a surprise after reading some of the paragraphs of this report. The apparent discrepancy is due to the emphasis necessarily placed upon faults and shortcomings because of the critical approach to the survey."

The picture presented by Dr. Hadfield is that of a hard-working body of men and women doing their job conscientiously in the face of many difficulties and frustrations. It is a picture of men and women imbued with a sense of vocation but often prevented from fulfilment in work because of unsatisfactory conditions—some of them trivial and therefore all the more irritating, and some of them fundamental. It is a picture that justifies a restrained optimism for the future of general practice—restrained because, unless remedies are applied soon and continuously, the present good service the public receives from general practitioners will deteriorate in time. Every profession has its quota of unsatisfactory practitioners. That a few should be outstandingly bad is only to be expected. More care in the selection of students to medical schools is the remedy, and the closely reasoned debate on this in the recent Conference on Medical Education held by the World Medical Association showed that medical teachers are acutely aware of this. But unless the whole environment of general practice is as sound as it can be the best of men will fail to give of their best.

Certain conclusions come out of the survey and report. The first is that unsatisfactory relations with other medical and health workers and institutions impeded the work of the general practitioner; and it must not be concluded that in this the general practitioner is free from blame. He is not the only man who is in step. The second is that the N.H.S., by its rigid tripartite structure, has divided the medical profession more sharply than ever before into three separate professions instead of welding them into one. The third is that the rapid advances in medical science during the past three decades have imposed stresses and

strains on all types of practice, and that these have created problems of their own the solution of which is not made easier by the inflexible structure of the National Health Service. By and large the relations between general practitioners and their patients are good. But the recurrent complaint is that all over the country a persistent few harass the doctor with trivial complaints: "The average doctor . . . would be much happier in his practice . . . if only he could purge his list of this hard core of inconsiderate trouble-makers." In its report the Committee, however, asks a pertinent question: "Who shall say, without examining the patient, whether a condition is 'trivial'?" Nevertheless the complaint represents something real—possibly overwork, possibly a feeling of loss of prestige. As the Committee's report states: ". . . the danger of the present attitude is that the patient is coming to regard the general practitioner not as his adviser but as a person to give prescriptions and certificates and to refer to a specialist any illness of more than a minor nature." Again, the report states: "There is little doubt that there has been at least some deterioration in the doctor-patient relationship."

On the whole relationships among general practitioners themselves seem to have improved; there is a greater readiness to co-operate in the solution of common problems. As the survey shows, there is still a sharp divergence of view between the G.P. and the medical officer of health, a divergence the N.H.S. seems to have widened. In the view of the Committee the remedy seems to lie "to some extent with the initiative of medical officers of health, who are appreciating more fully the need for personal contact. . . . At the same time the Committee wishes to call the attention of general practitioners to the need for reciprocal action in this matter." Complaints, too, are made about health visitors, and the Committee is convinced that a review of the functions and activities of this group of public health officers is called for. There is an apparent weakening of the bonds between general practitioner and consultant. The latter, being now less dependent on the former for his living, is thought to be more aloof. The G.P. gets reports from junior hospital officers instead of from senior consultants. Increased specialization makes it difficult to get the opinion of a "general consultant." The G.P. is kept in the dark about his patient's progress, or even death, in hospital. Added to this is the progressive exclusion of the G.P. from hospitals and hospital work. As a root cause of these and many other difficulties the Committee criticizes the structure of the N.H.S. The administrative separation of the consultants under regional hospital boards, of general practitioners under executive councils, and the separation of the public health service constitute "one of the most important causes of the lack of contact between the three main branches of the profession."

Whatever virtues the N.H.S. may have, it has lessened the sense of unity in the medical profession, has made unification of services unbelievably difficult, and has created as many problems as it tried to solve.

Dr. Hadfield's survey, the results of the postal inquiry, and the Committee's report together make up the most valuable inquiry into general practice that has yet been made in this or any other country. The range of inquiry, the attention to detail, the fearlessness of criticism, and the constructive nature of the many proposals for remedy will engage the attention of individual doctors, professional organizations, and Government departments for some time to come. Underlying the whole approach of the G.P. Review Committee is the desire to make general practice in Britain better than it has been before so that it may continue to attract into its ranks men of the highest calibre, to preserve and enhance the standard of medical care given to the people of Britain. And the Committee wisely sees that this will not be possible until the different medical services under the N.H.S. are unified, until the profession is united, and until full co-operation of all health workers is secured. These desiderata are not yet fulfilled. Whatever divergencies of opinion there may be among various doctors or groups of doctors with this or that aspect of the survey and the report, they will be grateful to the Committee and its chairman, Dr. Walker, and to Dr. Hadfield, for the thorough and masterly way they have carried out the remit of the Council of the Association.

THE G.P., THE CONSULTANT, AND THE HOSPITAL

Throughout the Hadfield survey and the Walker report is a growing rumble of dissatisfaction over the relationship of the general practitioner to the hospital and, to a lesser extent, with the consultant or, rather, specialist. Since July, 1948, there has been a fall in the proportion of general practitioners doing hospital work, and a restriction in the type of work done. There is widespread complaint over the delays in getting patients into hospital, and of the failure on the part of hospital workers to notify general practitioners of the fate of their patients. There is grave dissatisfaction over the lack of hospital provision for the aged and chronic sick and over the delay in arranging adequate treatment of the tuberculous. Some of these complaints and difficulties have no relation to the National Health Service, but the exclusion of the general practitioner from hospital life has, and accounts in no small degree for his feelings of isolation and frustration. Some 52% of the practitioners in the Hadfield survey "feel that practice is obstructed by the inadequacy of hospital services"—that is, a quantitative not a qualitative inadequacy. Only some 14% complained of difficulty in securing admission of urgent cases. Practitioners complain that increasing

specialization means that hospital beds are allotted in small batches to an ever-growing number of specialties. This apparently makes it more difficult than formerly to find a bed for a patient needing treatment. This is linked up with the practitioner's concern over the difficulty of obtaining an opinion from a general consultant, now becoming a *rara avis* and being replaced by a horde of narrow specialists, to the detriment, in the view of many, of medicine. Practitioners asking a hospital consultant or specialist for an opinion consider that more often than was the case they now receive the opinion from a junior member of the staff, often from a registrar whose acquaintance with the conditions of general practice they believe to be meagre or, more usually, non-existent. Nevertheless it may be questioned whether, before the war, many registrars had experience of general practice or whether many consultants had had such experience, at least those on the staffs of teaching hospitals. Though there may be some exaggeration of the position it is interesting to note that 23% of general practitioners in the survey thought that all consultants should have some experience in general practice as part of their training.

The net effect of all this is to increase the sense of isolation of the general practitioner, to make him feel in a position of inferiority, and on this account to encourage him to feel that his patient so regards him. Nevertheless practitioners, while complaining in this way, are sending more patients with minor conditions to hospital. As the Committee's report puts it:

"The habitual transfer of minor surgery to the hospitals is neither necessary nor desirable. The training of the doctor has included instruction in this work, and, in the view of the Committee, it is a part of general practice. The constant sending of cases to hospital results not only in the loss of practical experience but also in a belief on the part of the hospital staff, especially the junior staff, that general practitioners are not competent to perform minor operations."

Some practitioners, however, feel that many of these minor conditions are better operated on in the out-patient department of a hospital than in a surgery. The urban practitioner, with a hospital on his doorstep, is by the nature of things less likely to undertake minor surgery than his country colleague. Again, the country doctor is much more insistent than the town doctor that his work would be better if he had access to hospital beds. The Committee's report strongly favours any arrangement which brings the general practitioner into contact with his patient when in hospital: "This is brought out to most advantage where the general practitioner is on the staff of a local hospital." The Committee regretfully notices a tendency among some practitioners "to accept isolation from hospitals and an impersonal relationship with consultants as an unavoidable result of the N.H.S." It points out that it is the policy of the Representative Body that the general practitioner should be con-

stantly and closely associated with the hospital—a policy which those deeply concerned with the future of general practice will probably endorse. The report advocates access to special departments, clinical assistantships, and the provision of hospital beds for the treatment of “general-practitioner conditions.” These recommendations of the Committee receive strong support in the two articles in this issue by Sir Heneage Ogilvie and Dr. J. G. M. Hamilton—both consultants. Dr. Hamilton urges that so long as the general practitioner can spare the time and has suitable experience nothing should bar his part-time appointment to hospital posts; and he urges, too, that there should be far more flexibility in registrar posts, so that the registrar should also be free, for example, for part-time work in general practice. Dr. Hamilton apparently sees a to-and-fro movement between part-time registrar posts and part-time jobs in general practice; this would do much to break down the barrier which now seems to many to exist between general practice and special or consulting practice. While Dr. Hamilton does not think much will come from appointing clinical assistants to hospitals, Sir Heneage draws attention to what he regards as a successful experiment conducted by the Barnet Group Hospital Management Committee: six general practitioners are appointed to clinical assistantships for six months—two in medicine, and one each in surgery, obstetrics and gynaecology, paediatrics, and dermatology. Each clinical assistant attends two sessions a week.

What are perhaps of most interest are the views of these two writers on the provision of general-practitioner beds. They both urge this, but in doing so Sir Heneage vigorously opposes their use for major surgery. “Operating for a hobby,” he writes, “is a peculiar British sport, and its home has been the cottage hospital. Whatever happens, we must be sure that this horror never reappears among us.” Sir Heneage sees “general medicine to-day . . . passing into the hands of the general practitioner,” and in cottage hospitals of about a 30-bed capacity he would have practitioners looking after their own patients and performing their own minor surgery. Neither Sir Heneage nor Dr. Hamilton considers it feasible to set aside for the family doctor beds in general wards or units of general hospitals. Dr. Hamilton makes a valuable distinction between “ordinary medicine” and “extraordinary medicine.” The latter requires special techniques and special skill available only in hospital and applied by specialists. Dr. Hamilton instances mitral valvulotomy and the treatment of thyrotoxicosis with radio-iodine; as examples of “ordinary medicine” he gives the treatment of acute pneumonia or congestive heart failure or peptic ulcer. Many such conditions have become “hospital medicine” because of social and domestic bars to treatment in the home. Dr. Hamilton, exploring this idea, considers that the

present need is *not* for more hospital beds but for more “district” or “neighbourhood” or “cottage” hospitals, simply equipped and developed in existing private dwellings. This proposal not only has the great merit of providing beds for the use of general practitioners; it also suggests an economical way of easing pressure on expensive hospital beds over the next few years, and possibly of avoiding any unnecessary extension of them. The views expressed by the G.P. Review Committee, by Sir Heneage Ogilvie, by Dr. Hamilton, and by the Representative Body of the B.M.A. all point strongly to one greatly needed reform—the widespread provision of beds for general practitioners where they may give continuous care to patients under their charge and in doing so gain the satisfaction and instruction that come from responsible clinical work under good conditions. At present about three-quarters of general practitioners are denied this.

SOME POINTS IN THE POSTAL INQUIRY

The postal inquiry conducted by the General Practice Review Committee was sent to 18,346 general practitioners, and it may be regarded as satisfactory that 12,657, about 70%, responded. These were divided into groups of between 400 and 500, and each such group was asked to answer two out of a long list of questions drawn up. In addition, just on 400 private practitioners were divided into groups of about 20 and similarly asked questions relating to their work: the response was disappointing, as only 56% of these private practitioners replied. Sixty-seven per cent. of the practitioners worked in towns, and 33% in the country; of the total 12,657 some 45% were single-handed practitioners and 55% were in partnership.

On the whole the postal inquiry bears out the findings of the field survey. There are, however, discrepancies between the two, and the results of the postal inquiry convey a more depressing effect. For example, 61% of doctors answering the postal inquiry said that demands from ex-private patients were excessive, and only 26% of doctors in the survey held this view. According to the field survey 35% of practitioners would like to have private as well as N.H.S. patients; in the postal inquiry this figure was 66%. In the survey 43% of practitioners were said not to want private patients, but only 19% expressed this opinion in response to the inquiry. The survey gave a fairly optimistic picture of the standard of diagnostic procedure, but the Committee in its report observes that “against this good result of objective observation must be set the subjective feeling expressed by a large number of doctors in the postal inquiry that they are unable, through lack of time, to examine patients as thoroughly as they would wish.” According to the survey 19% of practitioners were helped considerably by their wives in the administration of their practices; the corresponding figure in the inquiry was 39%. Some 27% of the practitioners questioned in the survey wanted more postgraduate facilities; but 62% answering the inquiry expressed the same wish—a wide discrepancy.

The Committee regards the survey as providing a more objective assessment of the situation, and in some instances the discrepancies may have resulted from the question being put less ambiguously in the survey.

When it comes to expression of opinion discrepancy is to be expected and the reader will probably be safe in splitting the difference in his assessment of such situations. Where the answer can be “yes” or “no” to a plain fact a closer agreement should be, and is, found. For example, in the field survey 89% of general practitioners were found to have no access to hospital beds; in the postal inquiry the figure was 72%. But of the 246 practitioners (postal inquiry) who had no access to general-practitioner beds 76% believed their practices did not suffer as a consequence; the other 24% said the contrary. In the survey 51% of doctors had developed some special interest in medicine; the corresponding figure in the inquiry is 54%, and it is of interest to note the order in which the inquiry puts these interests: midwifery, paediatrics, anaesthetics, and minor surgery. According to the survey 30% of practitioners assert that the scope of practice had not been increased by recent advances in medicine. It is not quite clear what is meant by “scope,” and maybe different interpretations were made of “recent.” In the inquiry 14% of doctors said that advances in medical knowledge “had had no effect on their practice.” It is difficult to understand just what this means: it may mean financial effect, effect on working hours, effect on interest in work, effect on the doctor-patient relationship.

The analysis in the inquiry of the replies to questions on the care of the tuberculous is interesting. Forty-six per cent. of 313 practitioners were dissatisfied with the arrangements for domiciliary care; 44% were satisfied. Criticisms are made that there is a “great delay between notification and the first visit from the health visitor”; that the tuberculosis officer rarely visits the patients; that the practitioner has not met the tuberculosis officer. One practitioner writes: “It is difficult to know whether one is primarily responsible for the care of these cases or whether the local tuberculosis officer is. In some cases directions and prescriptions are left by the tuberculosis officer and in some cases the practitioner is left to his own devices.” On the other hand many practitioners expressed great appreciation of the value of the work of the tuberculosis officer and his department. Delay in getting patients into sanatoria is one of the gravest defects in the national handling of a serious problem. One general practitioner, in response to the inquiry, summed up his difficulties thus: “The patient falls between two stools. Admission to hospital is not usually possible for a long period, during which time the T.O. does nothing and the patient relies on the G.P. for treatment. The G.P.’s treatment must be non-specific, and in many cases deterioration occurs. Since the advent of streptomycin, with co-operation of the T.O. treatment is sometimes started at home in suitable cases, and this has helped but by no means solves the problem.” Apart from the appalling delays in getting tuberculous persons into sanatoria, there is in the replies to the inquiry a general indictment of the official attitude to the problems of this disease. Two more quotations show at least the deep concern felt by general practitioners and

their sense of frustration at not being able to do more for their patients. “Cases of active respiratory tuberculosis are allowed to remain in dark airless basement flats waiting for months for admission to sanatorium.” And again this: “As methods of diagnosis have so vastly outstripped methods of ‘disposal’ of patients, and as the ‘housing’ problem and overcrowding are as bad in X as anywhere in U.K., ‘domiciliary open tuberculosis’ is a menace to all the remaining occupants of the building—often far too many of them.” And so the sad monotonous story is retold in the faint hope that one day this country will decide to make tuberculosis as rare as diphtheria now is.

There is much else of great interest in the report of the postal inquiry. For example, roughly half the practitioners questioned said they had direct access to pathological and radiological departments, and it is astonishing to note that about half said that their practices did not suffer because of the absence of such facilities. This sharp and even split of opinion is difficult to explain. In reply to a question whether the capitation fee “worked fairly for them as a method of payment, excluding from consideration the actual size of the central pool,” 65% answered “Yes” and 34% “No.” Of those asked whether there should be financial recognition of special skills and of length of experience 54% and 65% respectively said “Yes.” Throughout the survey and inquiry there runs the monotonous refrain of “Lack of time”—lack of time for minor surgery, lack of time for special examinations, lack of time for developing special interests, lack of time for hobbies, lack of time for reading medical journals.

MIDWIFERY IN GENERAL PRACTICE

The sections on midwives and on the practice of midwifery in the General Practice Review Committee’s report, the postal inquiry, and the survey will be read with the closest attention by all those interested in this difficult and often controversial matter. According to Dr. Hadfield about one-third of practitioners dislike midwifery; one-third are not attracted to it but consider it a necessary part of practice; and one-third do as much midwifery as they can because they like it. This corresponds fairly closely to the 76% of practitioners in the inquiry who said they were general-practitioner obstetricians. It would seem safe to assume that whatever the facilities about 30% of general practitioners would avoid (and probably do avoid) undertaking any midwifery in the course of their work. Eighteen out of the 308 practitioners questioned considered it to be an essential part of general practice: “It is the keystone of a successful general practice.” On the other side comes this observation: “I have a large general practice and find that midwifery interferes with ordinary work. I dislike undertaking the responsibility without having enough practice in the branch to keep myself up to date.” There can be no doubt that the practice of midwifery brings a deep satisfaction to those who really love the work; some undertake it chiefly to supplement income and acquire the necessary experience in order to do so.

Relationships with midwives seem to have deteriorated since 1948. “Some midwives,” writes Dr. Hadfield,

"appear to resent the general practitioners having anything to do with midwifery"—a complaint echoed in the inquiry. According to the inquiry 63% of practitioners consider there has been no change in relationship since 1948; 11% believe it has deteriorated. One doctor observes that "midwives since the advent of gas-and-air appliances have taken over practically all midwifery, and, even where one is expected by the patient to attend, the nurses confiscate practically all cases." As against this, another doctor reports an excellent relationship with midwives and attributes this to the team-work spirit, to prompt attendance at calls from midwives, and to insistence on being present at birth in all booked cases.

The Committee gave a lot of time to a careful consideration of the place of midwifery in general practice. "It is firmly of the opinion that midwifery is an integral part of general practice and that every possible encouragement should be given to general practitioners to undertake it." The Committee believes that the drift away from midwifery in general practice in recent years is to a large extent the result of the attitude of those responsible for obstetric services. Social and domestic conditions have encouraged confinement in institutions, and mothers are said to feel safer in a hospital where "everything will be at hand in the event of an emergency." But this makes what "should be a natural physiological process supervised by the family doctor" take on "the aspect of a major illness requiring the care of a special department." If because of unsuitable home conditions a confinement has to take place in an institution it should be possible for the woman to be attended there by her own doctor. (In his paper in this issue of the *Journal* Dr. J. G. M. Hamilton sees this being done in the "district" or "neighbourhood" hospitals he advocates for the use of general practitioners.) The Committee deplores the exclusion of the general practitioner from normal midwifery if only for the reason that this "reduces his ability to deal with the abnormal." Expressing its high appreciation of the work done by midwives, the Committee wants to see the gap between them and general practitioners bridged. "The trouble is that, with the depleted number of domiciliary confinements, some midwives still seem to resent the doctor's attendance at the confinement." As a remedy, team-work is advocated. "At an early date in the pregnancy the patient, her family doctor, and the midwife should meet together in the doctor's surgery and decide whether the doctor should attend at the confinement in any event or only if the midwife finds his attendance necessary." The Committee takes a firm stand against those who wish to prevent by administrative restriction general practitioners, or some of them, from undertaking midwifery. Paragraphs 69 to 87 of the Committee's report set forth a well-argued and most sober presentation of a highly important problem.

SOME CHANGES IN GENERAL PRACTICE SINCE 1948

How far has the National Health Service affected practice since 1948? The first thing that comes to notice are the increased attendances in the surgery, coupled with a slight slackening off of visits to the homes of patients. An irritating feature is the growing number

of late evening calls, offset to some extent by few calls during the night—perhaps related to an increase in institutional midwifery. Another effect is a levelling out of demand for the general practitioner's services over the year, resulting in more work during the summer months than formerly. There is a general criticism that patients with trivial complaints are on the increase: "Often the trivial call is a means of obtaining a prescription for something which formerly the patient would have bought from the chemist. The idea that the public are entitled to such medicines from the National Health Service is now deep-rooted." Increased work from this and other causes means that the practitioner finds less time than he used to to give the patient or his relatives a comforting chat. Less minor surgery is practised than formerly, and this may be related to the absence of special fees for this type of work. Some practitioners, however, think that minor surgery is better done in hospital. Some 45% of general practitioners interviewed in the Hadfield survey applaud the fact that the scope of their work has been widened by the N.H.S., even though many of them do not like the Service: but they feel that it makes it possible for them to do more for their patients. On the other hand, 32% of the "survey practitioners" consider there is now a tendency to regard the general practitioner as "a supplier of medicine rather than as a medical adviser." Some 43% of general practitioners say they no longer wish to have private patients, while 35% are anxious to preserve at least some private patients. "Over the whole range of practitioners visited," writes Dr. Hadfield, "I found 37% more satisfied and 42% less satisfied since the introduction of the N.H.S." There were more younger doctors in the former group and more older doctors in the latter. A disturbing observation is that fear of complaints is making general practitioners anxious. An anxious man cannot do his work as well as he could. There appears to be a growing tendency to co-operation and a decrease in unethical conduct.

Only 14% of general practitioners visited in the survey were prepared to make the N.H.S. "the whipping boy" for contemporary discontents and disabilities. Foremost among these is complaint of delay in getting patients into hospital, inadequacy of hospital provision, of delays and shortcomings in the treatment of tuberculosis, of the growing plight of the aged and chronic sick. The Committee points out that there are still young practitioners who cannot find the kind of practice they want, but—"The Committee cannot help feeling that some young men expect to get on rather too early and too quickly." It also stated this elsewhere in the report: "Not so loudly heard are the voices of those practitioners in middle life who wish to change their practices." The Committee relates this difficulty to the abolition of the buying and selling of practices, and considers that the disappearance of this custom has affected the freedom of all practitioners. The middle-aged man "now has to apply for what is virtually a public appointment, in the competition for which he has been found to be at a disadvantage, possibly for the very reason for which he is seeking a change, that he is over 45 years of age."

THE GENERAL PRACTITIONER AND THE PSYCHIATRIST

A STUDY IN CO-OPERATION

General Practitioners

AND

DENIS LEIGH, M.D., M.R.C.P.

Physician, Bethlem Royal and Maudsley Hospitals

The introduction of the domiciliary visit has in many cases brought about a closer liaison between the general practitioner and the specialist. Visits to the patient's home and to the practitioner's surgery, and close acquaintance with the social structure of the district in which the practice lies, are of particular value when the specialty concerned is psychiatry. Since 1949 a relationship has developed between a group of four partners in a general practice and a psychiatrist which is believed to be mutually beneficial. We shall attempt to describe some of the experiences arising from this association.

Description of the Practice

The practice consists of approximately 14,000 N.H.S. patients. Most of them are from the lower middle class, and they live in a compact highly urbanized area of London, consisting of street after street of rows of houses. Semi-detached houses are uncommon, detached houses even more so, and there is only a sprinkling of flat-dwellers. The district is one of the few in London where large blocks of flats have not been erected since the war. The average house consists of front and back rooms, kitchen-scully, three bedrooms, and bathroom-lavatory. Gardens are not common. An air of respectability pervades the area, and most of the families have lived in the district for many years. The large super-cinema is missing, and instead there is a small old-fashioned picture house. There are few public-houses, and churches are none too evident a feature of the landscape. The whole area, in fact, is a later nineteenth-century residential suburb, with all that this implies. And yet, with all its imperfections, its inhabitants are fond of their district.

Two main surgeries and a branch surgery serve the four partners who run the practice. An efficient full-time secretary is employed, together with a receptionist. All four doctors live in their own houses, away from but within easy reach of the surgeries. The relationship between four temperamentally different doctors is excellent, and the practice appears to the psychiatrist to run smoothly and efficiently. The psychiatrist arrived on the scene in mid-1949 to carry out a domiciliary visit. Since that time all psychiatric cases have been referred to him, as domiciliary cases, as out-patients at the Maudsley Hospital, or as private patients. From this material there emerges a fairly clear picture of the psychiatric problems which beset the general practitioner, and of the help which the psychiatrist can give him and his patients.

Material

Roughly the cases have been divided into three categories—the domiciliary cases, the out-patients, and the in-patients; the last named will, of course, be derived from the first two groups. The private patients form such a

relatively small group as not to merit consideration here. The relevant information is as follows:

	1949	1950	1951
Domiciliary visits	6	22	40
Out-patients	23	23	62
In-patients	2	9	10

As shown, the number of cases in all groups has risen year by year. In 1951 approximately one-fifth of the psychiatrist's total domiciliary practice and one-fifth of his out-patient practice came from this one source. Given a practice of approximately 14,000 patients, the number of referrals (102) in 1951 is certainly not excessive—representing only one patient for every 140 "on the books." Practitioners commonly remark on the large numbers of their patients who, according to their lights, either have "nothing wrong with them" or are "psychiatric cases." And yet the number of cases referred to the psychiatrist by the average practitioner is very much smaller than the number referred by this particular practice. It may be that some doctors patronize several different psychiatric clinics, but this is not usual. The problem seems to be, first, that of selection, and, secondly, the attitude which the general practitioner takes towards psychiatry. Several surveys among medical students have shown that a majority opinion is extremely critical both of psychiatrists and of the claims they put forward. Prominent physicians and neurologists are likewise sceptical or even hostile, and as leaders of the profession must necessarily greatly influence the attitude of the average general practitioner. Much of this criticism is justified, but scarcely the hostility, for it leads to prejudice, and the patient may be an unwitting sufferer as a result. Clearly, a low opinion of psychiatry will deter the practitioner from calling in a psychiatrist.

The selection of cases is in many respects an even more difficult problem. If approximately 60% of a general practitioner's patients present neurotic symptoms, which of them should he refer to the psychiatrist? Or should he refer them to the local chemist for a bottle of medicine? The psychiatrist is also in a difficult position, for it cannot be said that unequivocal indications exist for certain types of therapy. And this is especially so where psychotherapy is concerned. What categories of patients is it worth while for the general practitioner to refer to the psychiatrist? Should the more severe cases have priority over the less severe, or vice versa? The methods of treatment are so time-consuming and arduous that these questions merit serious consideration.

It would be well, then, to consider the types of cases we have dealt with in these three years. They fall largely into four groups: the depressions, the neuroses, marital problems, social problems. Surprisingly enough, schizophrenia and mania, which are particularly associated by the public with mental illness, form only a very small group. Likewise, the psychiatric aspect of medical disorders has on the whole presented little of a problem to the psychiatrist. Although particularly interested in certain aspects of psychosomatic medicine, the psychiatrist has felt that the general practitioner and physician are best suited to care for these cases.

The role of the psychiatrist in the treatment of peptic ulcer, hypertension, ulcerative colitis, asthma, and other disorders in which emotional factors may be of importance has not been clearly determined. Extravagant therapeutic claims in this respect which cannot be substantiated do nothing to improve the relationship of physicians and psychiatrists. Only special research problems in this field have therefore been referred to the psychiatrist. Similarly, the general practitioners have not unduly burdened the consultant with geriatric problems, and particularly with the disposal of old people. So often the psychiatrist is called out when a practitioner cannot get an old person into hospital, or because relatives are pressing him to remove an elderly person—in some cases it must be said because the relatives no longer care to undertake their due responsibilities. If an adequate geriatric service existed the practitioner would find little need for a psychiatric opinion,

for these cases are not often abstruse or difficult problems of diagnosis or treatment. They do not compare with the problems presented by younger patients.

The Depressions

Of the four main types of cases, that of the depressive reactions looms the largest, and here the question of suicide is most often the reason for a consultation. Psychiatrists well know the difficulties of assessing suicidal risk, but it is astonishing how casually many medical men regard a threat of suicide. The casualty officer washes out the stomach of a patient who, let us say, has swallowed 100 aspirin tablets, and then sends the patient home; or the general practitioner dismisses a weeping young woman from his surgery with a bottle of sleeping tablets. These men are not necessarily to be blamed for their lack of psychiatric training. Of course, most patients who threaten suicide do not kill themselves, but every year there are, in fact, about 4,000 suicides in England and Wales. What, then, should the general practitioner decide when confronted with this problem? In this particular practice a psychiatric opinion has been obtained. This procedure has relieved the family doctor of a good deal of anxiety, and has perhaps saved many lives. Only one suicide has taken place in the practice over the three-year period, when it might reasonably have been expected, on statistical grounds, that six suicides would have occurred. It might be said by some doctors that it is over-cautious to refer to a psychiatrist all patients who threaten suicide, and time alone will tell whether this is a correct policy, but even if only one patient's life is saved it surely is a procedure which is worth while.

Apart from those subjects of depression who have suicidal thoughts and impulses, there is a large group of patients in whom the diagnosis is not self-evident. Hypochondriacal symptoms may mask the underlying depression, whilst, at the involuntal period of life in particular, psychiatric symptoms in any form may be the manifestations of a depressive illness. A correct diagnosis will lead to the appropriate treatment, and often to the speedy resolution of the symptoms. The natural tendency of most depressive disorders is to remit, but the process of recovery can be greatly accelerated. It has been the custom in this practice to refer to the psychiatrist all patients who fell into the group of depressive disorders. The following cases illustrate some of the points raised above.

Case 1.—A married woman aged 39 was seen on a domiciliary visit on January 16, 1950. She stated that she was four months' pregnant, and that the baby lay free within the abdomen. In spite of normal periods she believed she was being "torn apart" by the growth of the baby. She had also become depressed and apathetic, and lay in bed all day. She threatened to cut open her abdomen with a knife if the doctor would not "take the baby away." She believed her pregnancy was a punishment for her sins, particularly for her animosity towards her sister. She was admitted to the Maudsley Hospital on January 23. A diagnosis of depressive reaction was made, and she received 10 electric shocks. Complete recovery followed. Two years later a follow-up has shown that she is well, is working, and is symptom-free.

Case 2.—A married woman aged 21 was seen as an out-patient, having been depressed and "weepy" for the past three years, following the birth of her first baby. She complained of aching pains in the head and back, and felt that her body had been damaged during the birth of her baby. She felt that life was not worth living. She was three months pregnant when she married the father of the child, a withdrawn, unsocial Pole twelve years older than herself. Her family history showed that her mother was a hypochondriacal woman who had been unwell since the birth of her last child—her symptoms being almost identical with those of the patient—and that one sister drank heavily and was emotionally unstable. On examination the patient wept throughout the interview and showed evidence of many hypochondriacal ideas. She firmly believed her symptoms were the result of some unknown disease. A diagnosis of a depressive reaction with hypochondriacal features was made, and she was started on supportive treatment as an out-patient. A poor prognosis made it likely that she would need treatment extending over a lengthy period, with observation and a possible future admission to

hospital. Her suicidal threats were not regarded seriously, and, in view of the hypochondriacal features, no attempt at educative psychotherapy was made.

The Neuroses

The second large group of patients comprises those with psychoneurotic disorders. Here again there is much ground for discussion, but it has been felt that the treatment of these patients is largely beyond the capacity of the general practitioner. Although many neurologists regard themselves as qualified to treat neurosis effectively, psychiatrists recognize that special techniques and facilities, and psychiatric training, are necessary. Again the main problem confronting the general practitioner is that of selection. Unlike the depressive illnesses, it is not essential to treat neurosis, and the number of neurotic patients is overwhelming. In a large practice selection must inevitably be made, and an emphasis has been placed on age, intelligence, and severity of symptoms. By no means all of the neurotic patients referred to the psychiatrist have been suitable for treatment, but even in those cases unsuited to intensive treatment an attempt has been made to help the general practitioner with some of his more "difficult" patients. And it is useless to deny that many neurotic patients are a source of exasperation to doctors, and even to psychiatrists.

The chronically dependent patients, living on their monthly bottle and their five minutes with the doctor, may wear out the best of us—and the psychiatrists may give much-needed relief to the general practitioner with this type of case. With the young, intelligent, and comparatively well-integrated neurotic, treatment may be extremely successful; and good results will convince the general practitioner that psychiatry can be of help to his patients. It has therefore been the policy of the psychiatrist to concentrate his efforts on such patients, and to build up an organization mainly devoted to psychiatric therapy. The briefer forms of psychotherapy have been used extensively, in the main aiming at symptomatic relief.

Marital Problems

The third group comprises the marital problems—the patients who consult their doctor, not on account of illness, but because they are finding some difficulty in their marriage. The majority can be dealt with satisfactorily by the general practitioner, but there are cases which can be dealt with only by a psychiatrist. This is not necessarily to say that much can be done to help such patients; indeed, it is most commonly a legal and not a psychiatric opinion indicated. However, when psychiatric symptoms have arisen as a result of marital disharmony it would be unwise to disregard them, and the general practitioner is best served when reinforced by a psychiatric opinion. Many of the irritations to the doctor caused by his becoming involved in legal affairs may then be avoided, for the psychiatrist should be more able to deal with such cases and to avoid legal entanglements.

Social Problems

This group comprises those in whom symptoms are related to social factors—loneliness, isolation, poverty, housing, unemployment. The use of the specially trained team of psychiatrist and psychiatric social worker may be of some value, their knowledge of social institutions providing a therapeutic link which the general practitioner cannot provide. Retraining for industry and the use of convalescent homes, of social clubs, and of the existing social services, can all be indicated in particular cases. The labour involved in steering the patient towards these services is often considerable, and can best be carried out by a psychiatric social worker, so relieving the general practitioner of a great deal of work.

From our experiences it is possible to give some indications as to the type of patient who will most benefit from the use of the psychiatric services. The frank psychotics and mental defectives who are in need of care and protection or are a danger to themselves or others present little difficulty

culty in disposal. However, we believe that it is well worth while to obtain a psychiatric opinion in all these cases, if possible, rather than to send them direct to an observation ward. The depressed patient will also require more special supervision than the family doctor can provide, and will need psychiatric treatment.

It is with the large group of neurotics that most difficulties will arise. On the whole we have devoted our main energies to young intelligent people who show good evidence of dealing with most facets of life on a realistic basis and whose neurotic symptoms are of recent origin. There is a great reservoir of chronic neurosis, as of chronic physical ill-health, and it is unrealistic to believe psychiatry can deal with such cases at present. The physician has usually no illusions about the patient with a "chronic medical disorder," but too many psychiatrists believe that almost every patient who comes to them can be helped. We have had no hesitation in rejecting for treatment cases which we have considered as falling into the category of chronic neurosis. These patients have been advised to regard themselves as partially disabled and to live their life accordingly. Such advice has, of course, come from the psychiatrist. If it came from the general practitioner it would not be welcome. Home truths are seldom appreciated, and a too-frank practitioner is not always successful. The aura of specialism, however, often predisposes the patient to listen favourably to the advice the specialist gives him, and some excellent results have been obtained. The following is an example.

Case 3.—A spinster aged 46 had been a constant frequenter of her doctor's surgery for many years. She had had "pneumonia" as an infant and at the ages of 3, 16, and 42; "measles three times as a child and once at 27"; influenza at 27; appendicectomy and left ovariectomy at 29; arthritis at 20 and 42; tonsillectomy at 30; haematemesis at 32; rubella at 35; chronic nasal discharge, left antrum drained, at 36; pleurisy at 43; otitis media at 45; painful feet since childhood, for which she had had special exercises and boots; and acrocyanosis. This formidable list of complaints was no less formidable than her personality, which was that of a chronically dependent and yet aggressive woman. The psychiatrist was called in when her demands on the doctor were becoming increasingly impossible to meet. She was taken into hospital and a firm line adopted, so that her wheedling childish tricks were exposed to her. In addition a sympathectomy was performed for the acrocyanosis, the result of which was very successful. She was then discharged after several frank and critical interviews with the psychiatrist. On follow-up a year later she was much better, had seldom consulted her doctor, and was working part-time. The general practitioner is delighted; her multiple ailments have vanished for the time being, and if she shows the slightest sign of a return of symptoms she will be referred to the psychiatrist again. The fact that she has not transferred herself to another general practitioner is a hopeful augury for the future.

Comment

Cases of marital disharmony have on the whole proved unsuitable for psychiatric treatment, and the less the psychiatrist or family doctor is involved in cases of "mental cruelty" the better. Many patients primarily needing a legal opinion are referred to a psychiatrist. From our experience there is little to be gained from this. However, there is more to be gained when social factors are of importance in the genesis of the psychiatric symptoms, but a careful selection of cases must be made on a realistic basis. It is little use expecting the psychiatrist to remedy social defects such as poverty or poor housing, for example. In this type of case the responsibility for the choice of treatment lies particularly with the general practitioner.

The results of all this activity are difficult to assess over a three-year period. As spontaneous recovery may occur in 60% of psychiatric patients, it is clear that a good deal of the psychiatrist's work consists in tiding a patient over a current difficulty more speedily than can be done by the non-psychiatrist. In Victorian times maidens swayed or had hysterics, and were treated with sal volatile or a bucket of water, according to their class. Nowadays a psychiatrist is called in, but it has not yet been proved that his

work is often more efficacious than the two remedies cited. However, the changed pattern of medical practice, which recognizes psychiatric disorder as within the province of the doctor, means that the general practitioner is called in to more and more psychiatric patients. He cannot handle a certain number of these, and if he is concerned for his patients he must hand them on to someone who can deal with them. We believe that the close liaison we have developed is a useful one, from the point of view of the patient, the general practitioner, and the psychiatrist.

Correspondence

Post-gastrectomy Syndrome

SIR,—I was much interested to read the article on post-gastrectomy syndrome by Mr. J. Ewart Schofield and Mr. P. St.G. Anderson (*Journal*, September 12, p. 598), and, whilst agreeing that they have made an important contribution to the cure of the persistent afferent loop syndrome following partial gastrectomy for duodenal ulcer, I feel strongly that they fail to lay sufficient emphasis on the type of operation performed in the genesis of this particular syndrome. In particular I find their explanation that "as all our anastomoses were anterior to the colon, we cannot agree with Ogilvie," who suggests anterior colic anastomosis as a possible cause of "dumping," somewhat ingenuous in view of any lack of comparison with the numbers of afferent loop syndromes occurring in retrocolic anastomoses.

The authors confirm the view that afferent loop stasis and reflux play a part in the "dumping syndrome" and regard the weight of the afferent loop as contributory—a view with which I am in agreement—but the point which seems to be missed by the authors is that these factors are bound to be increased in antecolic anastomosis (as opposed to retrocolic) in proportion to the greater length of the afferent loop. As one who was originally taught and brought up on the antecolic anastomosis and who has changed in the last four years to a routine retrocolic anastomosis, I have been impressed by the freedom of the latter operation from afferent loop complications. In the course of some 85 gastrectomies for duodenal ulcer performed over the last two years I have had no case of dumping syndrome severe enough to even contemplate further operative interference. It may be, of course, that complications may yet occur, but at worst I feel that these cases are better than two of the three quoted by Schofield and Anderson, whom, it should be noted, developed their syndrome within eight months of operation. I believe with Ogilvie that the antecolic anastomosis is a potent cause of the "dumping syndrome," and I am of the opinion that less numbers of this distressing complication would be seen if the retrocolic anastomosis were more commonly used.

Finally, may I make a plea for greater accuracy in terminology? The term Polya gastrectomy should be reserved for the retrocolic anastomosis; the antecolic anastomosis should be called the Balfour gastrectomy after the name of its originator.—I am, etc.,

I. LANGDALE GREGORY.

Dangers of Ethanolamine Oleate Injection Treatment for Varicose Veins

SIR,—Fostered by a first, and as yet only, allergic mishap with monethylolamine oleate, described in your columns some four years ago,¹ my interest in this matter has been reawakened by Mr. A. Lutton and Dr. G. H. Grant's letter (*Journal*, August 29, p. 510). In this litigious age where the published sayings of the not-so-great (a notable company of which I am happy to be a member) are apt to be quoted as evidence against some unfortunate defendant, one hesitates a while before expressing an opinion. Nevertheless, I feel that

there are by now certain rules governing sclerosant therapy which should find a prominent place in all varicose vein clinics.

First, I must reinforce Mr. Lutton and Dr. Grant's plea for withholding injection in asthmatic patients. This connexion has been brought out in almost all published cases, including my own. Secondly, adrenaline must always be to hand. Thirdly, *so must the patient*. (I always insist that cases should remain in the precincts for at least 10 minutes following an injection; after this period the risk of immediate and dangerous sequelae is past.) Fourthly, a test dose of 0.5 ml. should be given. Fifthly, the injection technique employed should encourage maximum obliteration with minimum dosage.

For this last purpose I cannot but commend a technique based upon the phlebographic investigations of Kinnmonth and Robertson.² I have described this in detail elsewhere,³ but briefly it is as follows. The patient stands, to distend the veins, whilst a venous tourniquet is placed upon the thigh. He then lies down flat whilst the needle is inserted into the vein. The tourniquet is loosened and 2 ml. of sclerosant injected, the patient remaining absolutely still both at this time and for five minutes following. During this period the ethanolamine spreads along the vein for at least 6 in. (15 cm.) on either side of the puncture, staying in concentrated contact with the endothelium. As soon as the slightest movement of toe or foot occurs the sclerosant is whisked away into some deep venous pool, there to be diluted to innocuous obscurity.

With this method there is no need to use more than 2 ml. at one visit; although of course, like all sclerosant manoeuvres, it is a waste of medical horse-power in the presence of untreated venous back-flow.—I am, etc.,

London, W.1.

STANLEY RIVLIN.

SIR,—With reference to the letter by Mr. A. Lutton and Dr. G. H. Grant (*Journal*, August 29, p. 510) I have never heard or read of the following addition to the technique. Let digital compression be applied to the vein both above and below the puncture, whatever agent be used. Be content to deal with a small length at a time, in which 2 ml. might well suffice. By this simple expedient one gets a maximum local effect and minimal systemic one. Let the pressure be maintained for several minutes.—I am, etc.,

Doncaster.

W. R. WILSON.

SIR,—We are indeed indebted to Mr. A. Lutton and Dr. G. H. Grant (*Journal*, August 29, p. 510) for reporting the death of a patient after an injection of ethanolamine oleate. As the injection of varicose veins is done so frequently, would you permit me to epitomize my experience of this therapy?

First, I find that only two types of veins will benefit by injection. They are the small clusters, aptly described as "trivial," "vanity," or "nylon" veins, which occur in young people. The others are outlying varices remaining after an adequate operation for varicose veins. No patient in whose varicosities there is an impulse on coughing or who gives a positive Trendelenburg test should be injected, for it is dangerous and useless. That varices may be a manifestation of a congenital arteriovenous fistula explains why a sclerosing injection can produce such sudden and serious systemic effects and yet give no result locally. A sluggish blood stream, which we have been taught is the invariable accompaniment of varicose veins, is indeed rarely the case. The circulation of blood in them is unduly brisk. Those who operate on them will testify to this characteristic.

Regarding the dose of a sclerosant, no matter what its nature I think the first trial injection should not exceed 1 ml. If it is tolerated, subsequent injections should never be more than 2 ml. Two to three groups of veins may be injected at a session with 1½–2 ml. in each, but there should be one minute between them—that is, the time needed to recharge the syringe. If a varicose vein fails to respond to an injection, then another sclerosant should be tried. The temptation to use a larger volume or stronger solution should be resisted. If the veins after several

treatments remain patent, then the diagnosis must be reconsidered; a ligation operation is almost certainly necessary.

There are several well proved and effective sclerosants, but I have decided that Riddoch's solution containing phenol 3%, glycerin 30%, in distilled water is the safest and most effective. I abandoned ethanolamine in 1943 because of the intense pain which followed its use and which often incapacitated patients, thereby encouraging a propagating thrombus and spread to the deeper veins. Collapses from sensitivity to it are also well known.

To sum up, therefore, I have found that injections up to 2 ml. in volume totalling two to three per session are effective and safe, and they are made only into trivial varices or those remaining after an efficient ligation and stripping operation. They are given to the sitting or horizontal patient.—I am, etc.,

London, W.1.

HAROLD DODD.

Hop Dermatitis

SIR,—Having picked hops, and having given first aid to hop-pickers, I feel that a likely cause of trouble has been left out of the discussion on dermatitis in hop-pickers by Drs. J. S. Cookson and Ann Lawton (*Journal*, August 15, p. 376) and Dr. F. Ray Bettley (*Journal*, August 29, p. 512). This is the very considerable abrasion of the skin that takes place in the process of removing the hop-cones from their stalks. The stalks are covered with fine spines which roughen the hardest skin. Matters are worse in wet or dewy weather, when the spines are firmer and skin is made soft by the moisture. The hands of most pickers become sore and scratched, and therefore presumably more susceptible to attack by specific sensitizing agents. Those who handle hops in oast-houses and breweries are not subjected to abrasion by the stalks. It is perhaps for this reason that they hardly ever become sensitized to hops.

My experience is confined to Kent, but, to judge from the figures kindly given to me by the Hop-pickers Medical Treatment Board (Kent), dermatitis is as common among hop-pickers there as in Herefordshire, where Drs. Cookson and Lawton made their observations.—I am, etc.,

London, N.W.3.

JOHN L. STRUTHERS.

Farm Accidents

SIR,—Two unusual farm accidents happening in the same week may be of interest. In the first, a young agricultural student was following a very common practice of oral suction to clear a blocked feed pipe in a tractor run on heavy vaporizing paraffin oil. The obstruction cleared suddenly and a gush of oil filled his mouth, came down his nose, and a quantity was unfortunately inhaled into the lungs. He momentarily lost consciousness, and, coming to, he described seeing objects clearly but at a great distance, as through the wrong end of a telescope. There was intense pain in the chest. A certificated first-aid worker treated him for shock, and gave a salt-and-water emetic which cleared the stomach. When seen, he was very restless, temperature 100° F. (37.8° C.), pulse 80, breathing rapidly, and complaining of severe pain all over the chest. During the night he deteriorated rapidly, temperature rising to 102° F. (38.9° C.), pulse rate rising, the expression anxious, and obviously developing an inhalation pneumonia. He was removed to hospital, where he was on the danger list for a week. A month later he is still in hospital, but making good progress. This case illustrates the dangers of oral suction so commonly practised by motorists.

The second case was that of a young girl who was in the habit of taking cod-liver oil capsules. The box was kept on a shelf in the farm kitchen. At 6 p.m. she took two capsules, and she remembered afterwards that they seemed larger than usual. About 11 p.m. she was violently sick, and complained of intense nausea and weakness. This was thought to be an ordinary gastric upset. Sickness continued all night, and it was only next day that another member of the family, becoming suspicious, looked on the shelf and

found a box of carbon tetrachloride capsules for sheep fluke near the cod-liver oil capsules, and it then dawned on them what had happened. The capsules each contained 1 ml. of carbon tetrachloride. When seen, sickness had stopped, but the intense nausea persisted. Pulse was 50, and the patient complained of feeling very weak. She was given mag. sulph. and heavy doses of calcium chloride, and all fats were forbidden. There was no jaundice or albuminuria. Nausea persisted in a lessening degree for over a week, but it was a fortnight before the pulse rate came up to normal. She has since remained well.—I am, etc.,

Aros, Isle of Mull.

FLORA MACDONALD.

Visual Aids to Education

SIR,—I was surprised that medical art was not considered at the meeting dealing with visual aids held during the First World Conference on Medical Education.

The quality of the diagrams accompanying the films showed clearly the need for artistic supervision. Also the special province of the artist in research work, reconstruction, and interpretation was ignored. The camera cannot think, the artist must; science as well as art goes to the making of a medical drawing. Because the artist is always seeking to show essentials clearly, and to elucidate difficult and obscure points, he is especially useful to students.

If an international committee on visual aids is formed, it is to be hoped that medical art will be represented by first-class artists, for without their help a large and most important field will be neglected, and without their trained artistic sense visual aids will lack much of the good taste and dignity which the medical profession merits.—I am, etc.,

Manchester.

DOROTHY DAVISON,
Medical Artist to Manchester University.

Control of Tachycardia by Quinine

SIR,—Seeing Dr. H. L. Maclure's interesting letter (*Journal*, August 29, p. 511) on the subject of paroxysmal tachycardia reminds me of a personal experience. About a year ago, at the age of 43, I began to have mild attacks of tachycardia. I suspected that they were caused by coffee, but continued to indulge in this beverage, as the attacks were trivial. One night, however, I was awakened by an attack which was decidedly unpleasant, so I decided to stop drinking both tea and coffee. The result was within a few days entirely satisfactory. The trouble disappeared. While on holiday this year, however, I decided to try the effect of drinking coffee again. Within a week I experienced a mild attack of tachycardia.

In the light of this experience I cannot help wondering if the improvement in Dr. Maclure's patient was due more to the omission of proguanil than to his taking of quinine.—I am, etc.,

Winfrith, Dorset.

P. R. BOUCHER.

Paroxysmal Myoglobinuria

SIR,—I was extremely interested in Dr. S. D. Elek and Mr. H. F. Anderson's article on paroxysmal myoglobinuria (*Journal*, September 5, p. 533). My own experience of this condition has been confined to the equine variety, but one or two observations I have made as to the aetiology of the condition may be of interest.

My "patients" were two thoroughbred racehorses, mother and daughter, which bears out the influence of heredity. The sire of the foal did not, so far as I could ascertain, suffer from the disease. The attacks which these animals suffered were completely typical. They were characterized by a sudden onset of swelling and marked stiffness of the muscles of hindquarters and back, with the excretion of very deep red, almost black, urine with a heavy deposit of phosphate crystals. Unfortunately no detailed analysis of the urine was carried out. This condition lasted 24–48 hours and was followed by wasting of the muscles involved and gradual disappearance of the stiffness. The wasting recovered rapidly and all was apparently normal after a week or ten days, even in the severest attacks.

The precipitating factor in all attacks in both animals, which incidentally were in strict training for racing, was fast exercise following a period of two to three days' rest with no reduction in the heavy carbohydrate feeding which racehorses usually get. The usual explanation for these attacks given by the veterinary surgeon was excessive formation of lactic acid in the muscles, which had become "overstocked" with glycogen during the rest period before the attacks. This rest period, which was usually due to some minor leg injury, is of great importance, apparently, because without it no attacks occurred. With regular work and exercise neither animal suffered any ill effects from the severest exertion. Both have won races without showing signs of the condition. Similarly, the heavy feeding is an important factor, as I have found that the attacks can be prevented by a severe reduction in the feeding of these animals during any enforced rest period.

A third member of this equine family, a yearling colt, will be going into training at the end of this year. It will be very interesting to see if he also inherits the disease.—I am, etc.,

Belfast.

D. H. CAMPBELL.

Endocarditis and Dental Extraction

SIR,—Mr. F. R. Coffin (*Journal*, September 5, p. 571) cannot understand why his medical friends do not insist on heavy doses of penicillin for several days before dental extraction in rheumatic subjects. He will find an answer in a paper by Professor R. V. Christie, Dr. J. E. Cates, and myself in this *Journal* (March 31, 1951, p. 653), giving the history of a patient in whom the effects of such treatment were disastrous. This man had been successfully treated with penicillin for subacute bacterial endocarditis five years previously, and, to protect him against recurrence, 2,000,000 units of penicillin was given daily for two and four days before as well as several days after two multiple dental extractions. He forthwith developed a bacterial endocarditis due to a *Str. viridans* requiring 4 units/ml. to inhibit its growth, whereas that causing his original attack had been normally sensitive.

Penicillin given in doses of more than 500,000 units daily is excreted in the saliva and eliminates sensitive organisms from the mouth, but their place is taken by resistant ones previously present in only small numbers, including coliform bacilli, *Candida albicans*, and any sufficiently resistant streptococci. As with other forms of penicillin prophylaxis continued for several days, the penalty for failure is thus an infection much more difficult to treat than any which is likely to have occurred had prophylaxis not been attempted at all. The object in connexion with dental extraction is not to sterilize the mouth but only to destroy such bacteria as enter the circulation. If procaine penicillin is used, the first dose may be given two hours before the operation; for sodium penicillin a more appropriate interval is five minutes. So far from this being an example of locking the stable door after the horse has bolted, what Mr. Coffin would have us do may be likened to opening the lion's cage instead of the jackal's.—I am, etc.,

London, E.C.1.

LAWRENCE P. GARROD.

A Doctors' Orchestra

SIR,—In various countries the music-loving members of the profession have formed orchestras, and it is intended to follow their example in London. Apart from the social and musical experience for those members of the profession who play orchestral instruments, such an orchestra may acquire high proficiency, be most useful for social functions of the profession and for charitable events, and in this way fulfil an important task. Would those medical and dental students, doctors, dentists, and members of their families who are interested in this venture and who play orchestral instruments or otherwise wish to help please write to the undersigned, giving particulars of their experience?—I am, etc.,

14, Upper Wimpole Street,
London, W.1.

H. UCKO.

Obituary

A. RENDLE SHORT, M.D., F.R.C.S.

Professor A. Rendle Short, emeritus professor of surgery in the University of Bristol, died suddenly at Hereford on September 14 at the age of 73.

Arthur Rendle Short was born at Bristol on January 6, 1880, the son of Mr. E. Rendle Short, a director of J. S. Fry and Sons Ltd. From University College, Bristol, he went on to University College, London, and first graduated in 1899 by taking the London B.Sc., with first-class honours in geology. Even as a boy he had

[Barratt's Photo Press, Ltd., London.]

thought of becoming a surgeon, and when he turned to the study of medicine he had an extraordinarily successful career as a medical student. He gained first-class honours in anatomy and won gold medals and exhibitions in physiology and materia medica. He passed the final M.B., B.S. examinations in 1903 with flying colours, winning a scholarship and a gold medal in medicine and obtaining first-class honours in obstetrics. A year later he

proceeded to the M.D., winning still another gold medal. After holding house appointments at the Bristol Royal Infirmary, including the post of senior resident officer, he obtained the diploma of F.R.C.S. in 1908 and became surgical registrar at the Infirmary and lecturer in physiology in the Bristol Medical School. Five years later he was appointed assistant surgeon at the Infirmary and soon afterwards became full surgeon. He was also surgeon to Clifton College for 28 years. A Hunterian professor of the Royal College of Surgeons of England in 1914, he was also an examiner for the Primary F.R.C.S. for a time. One of his many outside interests was the Association of Surgeons of Great Britain and Ireland, and he was a member of its council.

In 1933 Rendle Short was appointed professor of surgery in the University of Bristol, and he occupied the chair until 1946, when he retired and was appointed emeritus professor. A brilliant teacher, his dry humour and his tolerance and understanding of young people made him extremely popular with the students, and his ability to remain young in spirit lightened his task and theirs. A frequent contributor to the medical journals, Rendle Short was also the author of *The Causation of Appendicitis* and *The New Physiology in General and Surgical Practice*, a book which has reached its fifth edition. He was the editor of *Index of Prognosis* and co-editor of *The Medical Annual*.

Of strong religious convictions, Rendle Short belonged to the Plymouth Brethren, as did his father before him, and he founded the Inter-varsity Fellowship, a world-wide evangelical organization for undergraduates, and in this connexion, as well as as a surgeon, he paid many visits to the Continent. He was also a familiar figure in the pulpit, and his services as a preacher were in great demand. He never lost his early interest in geology and

seldom went for a country walk without a hammer in his pocket. Bird-watching, too, was a favourite pastime, and in the garden of his cottage in Cornwall he would spend many hours watching the flight of birds and listening to their calls, until in time he came to know the note of every bird. He married Miss Helen Case, and she survives him, together with his son, who is a doctor, and two daughters, one of whom is a doctor and the other a nurse.

We are indebted to Mr. A. WILFRID ADAMS for the following appreciation: It is a rude shock for our profession, especially felt by older members, when a figure so distinguished and long renowned as Professor A. Rendle Short suddenly falls. His surgical skill, backed by brilliance as a teacher and writer, had given him a national and indeed world reputation. He was gifted with an innate facility for absorbing knowledge, and from his youth up subjects of enduring import were his interest, as witness student days packed with gold medals not only in medical subjects but also in geology, at which he kept on "hammering" throughout life. One so talented and sure of his goal naturally achieved his boyish ambition, rose to the top of the tree in surgery, and very early in his career received the academic distinction of a Hunterian professorship in the Royal College of Surgeons. *Pari passu* with the acquisition of surgical experience, his professional lustre was soon enhanced by his bent for teaching and writing. He had a gift for the exposition of amassed facts in orderly array. Moreover, he had a flair for interspersing with his teaching mnemonics and anecdotes—prefaced with his "I well remember . . ."—whether at the bedside or while he swung the ruler to and fro coaching us students around his gas-fire. He was one of the pre-eminent surgeon-pedagogues of his day, a worthy representative of that class of general surgeon for which former generations were so famous, and crowds followed him. A sidelight on his kindly nature is afforded by the fact that Rendle's "firm" always fared well, despite wartime shortages, for the professor of surgery himself would buy and bring in the buns that brightened tea-time on operating days. A self-reliant man of strong convictions and simple tastes, he disliked ceremony of all kinds. He was a familiar sight on his bicycle long after the age when most of us cease such youthful pursuits. Coming to us from University College Hospital, London, he joined the Bristol Royal Infirmary in 1906 and soon became a much-wanted general surgeon in a practice ranging widely over the adjacent counties. He rose later to be senior surgeon, and inevitably followed Hey Groves in the chair of surgery. Since his retirement in 1946 he has been emeritus professor of surgery. His influence was of inestimable value to the sure foundation of a medical faculty in the early days of Bristol's university.

Medical publishers quickly realized Rendle Short's potentialities as an author. Messrs. John Wright & Sons selected him as a regular contributor to *The Medical Annual* in 1915 and as surgical co-editor in 1919, posts which he retained until his death. His output of new books included a monumental work, *The Index of Prognosis and Results of Treatment*, and textbooks on physiology and surgical subjects which went into many editions. A wealth of scientific knowledge was indicated by his presidential address to the Bristol Medico-Chirurgical Society in 1935, an address containing a spirited challenge against the orthodox views of the day on man's evolution. His able dialectic revealed extraordinary erudition in the fields of geology and zoology. The amazing compass of his brain was coupled with an unfaltering religious faith, and he has left with us the reflections of his lifetime in his latest book, *Wonderfully Made* (1951). He was an ardent advocate of public education on cancer, and was medical adviser to the South-Western Regional Cancer Bureau. Firmly convinced that the name "cancer" savoured to the public of incurability, he pressed that an alternative should be adopted.

There was the other side to his make-up. Rendle Short rose to the full stature of man: not only did the scientist

perceive the pattern of nature, but the seer early sensed divine direction behind the cosmos. In the realm of religion he had the whole situation clarified, definite, and—as some might see it—dogmatic. Inspired by this clear vision, he spent his life in the service of the Master he feared and loved seven days of the week. He wrote books on religious subjects and gave addresses all over the country. With his passing the student world is deprived of a powerful light which has for nearly two generations directed their thoughts upward. The Inter-varsity Fellowship is an enduring memorial to this side of his work.

We shall miss his strong personality. His service to the patients—and quite a host of beneficiaries were his professional colleagues—was vast and rendered with quiet method. My last glimpse of him this summer affords a tender and revealing farewell. He was quite absorbed—a manifest glow of gratification on his face—studying the display of plants at the local nurseryman's. Rendle not only mastered the science of natural history but revelled in the beauty of nature. His departure from our midst comes like a chilling shadow across life, and we offer our deep sympathy to his widow, latterly delicate and the object of his untiring devotion, and to his three children.

Mr. WILLIAM M. CAPPER writes: I should be grateful to be allowed to add a tribute to my old friend and chief, Professor Rendle Short. We who knew him more intimately in Bristol were always impressed by those high spiritual and moral qualities which some of us feel we so much lack. Rendle Short was essentially of a shy and retiring disposition, and a mere acquaintance sometimes left the impression of awkwardness, self-assurance, and even abruptness. But to those who really knew him this pose of self-defence was found to hide the most generous of hearts. We now know that very many people in all walks of life could recount stories of his generosity and timely practical help which virtually saved them, whether it was students who had fallen on evil days, young practitioners struggling with a financial burden, Christian missionaries overseas or crippled with illness at home, or the poor of numberless types. The missionaries and many Christian workers were never allowed to suspect the extent of the medical and nursing-home fees stealthily paid by this great Christian. He excelled as a diagnostician and a teacher of the basic facts of surgery. Perhaps it was his simplicity that gave him his greatness. I have heard few who could so pin down those he was teaching to the heart of the matter in order to get their principles correct. Former members of the Bristol medical school all over the world will continue to hear ringing in their ears some of the basic aphorisms of "The Rendle," as he was affectionately called. If heeded, they will keep them out of a lot of mischief. On behalf of many doctors in this country and overseas we must pay a deeply respectful tribute to his Christian influence upon us. No one of our seniors has more consistently impressed upon us the value of the Bible. No one has done more to show us how unnecessary it is to let the Bible lose its influence on our lives simply because of our supposed scientific outlook; and no one has more humbly and effectively impressed upon us the value of our Lord's atoning sacrifice. It is not too much to say that hundreds of medical students and qualified men through his wise words, clear writings, and consistent example have been prevented from allowing the anchor of their faith to drag amidst the storms of the last fifty years.

V. H. ELLIS, B.Chir., F.R.C.S.

Mr. V. H. Ellis died suddenly on September 15 at the early age of 52. He had collapsed from a cardiac attack after completing his usual morning's work in the fracture clinic at St. Mary's Hospital. His death has robbed orthopaedic surgeons of one of their wisest counsellors. Not only was he among the foremost orthopaedic surgeons of the day; he was also a scholar with an unusually broad knowledge and with interests that ranged

widely from finance to horticulture. His life was devoted to helping others, among whom his patients received first consideration.

Valentine Herbert Ellis was born in India on February 24, 1901, the son of Major-General P. M. Ellis, A.M.S. He was educated at Wellington College and Clare College, Cambridge. Thence he went to St. George's Hospital, qualifying M.R.C.S., L.R.C.P. in 1925. He became F.R.C.S. in 1928 and took the Cambridge B.Chir. three years later. After filling a number of junior appointments at his own hospital and elsewhere he decided on a career in orthopaedic surgery and went as surgical registrar to the Royal National Orthopaedic Hospital. There he came under the stimulating influence of some of the most prominent orthopaedic men of the time—Elmslie, Laming Evans, Bankart, Trethowan.

Appointed to the staff of St. Mary's Hospital in 1932, when he was only 30 years old, he was the first to hold the post of orthopaedic surgeon there. With tireless energy he set out to establish what has now become a leading orthopaedic and fracture department. He was soon appointed also to the staff of the Royal National Orthopaedic Hospital, and later he held additional appointments at Paddington Green Children's Hospital, the Lord Mayor Treloar Orthopaedic Hospital at Alton, and the Heatherwood Orthopaedic Hospital at Ascot. During the second world war he was in charge of the orthopaedic unit at the E.M.S. Hospital at Park Prewett, where many thousands of casualties flown direct from the battle fronts in Europe passed through his hands. Despite the number of hospitals that he served, such were his energy and capacity for work that he was able to do full justice to each of his responsibilities. Indeed, it is doubtful whether any man could have been more punctilious in his regular attendance or more conscientious.

In addition to these activities he found time also to make a considerable contribution, by his writings, to the advancement of orthopaedic surgery. He was joint author, with Mr. B. H. Burns, of *Recent Advances in Orthopaedic Surgery*, published in 1937, and he was a contributor to other authoritative books including Platt's *Modern Trends in Orthopaedics*, Handfield-Jones and Porritt's *Essentials of Modern Surgery*, and Fleming's *Penicillin*. He had a special interest in the shoulder-joint, and had undertaken research into the value and indications of arthrography in the diagnosis of shoulder lesions. Earlier he had made a study of injuries of the cervical spine, from which he concluded that internal fixation by bone grafts was advisable in unstable fracture-dislocations. A gifted teacher with clear ideas based on his own experience, he was nevertheless tolerant of the views of others, and he was seldom happier than when he was engaged in friendly discussion with his colleagues on some difficult problem.

Valentine Ellis will be remembered for his work on injuries of the neck and on disorders of the shoulder. But he will be remembered mainly, by those who knew him, for his sound common sense, his wise judgment, his kindly humanity, and his loyalty—qualities that commanded respect from all and endeared him to his colleagues and pupils.

He married, in 1937, Angela Peart Robinson, and his family life formed a happy background to his work. He leaves a widow with a son and a daughter.—J. C. A.

R. W. J. writes: After a preliminary warning some months ago we have lost Valentine Herbert Ellis, whom most of us knew as Gustav and some few as Val. He was not

always easy to know, but the more you did know of him the more you wanted to know him. It is to my own great regret that I did not know still more of this great individualist, this deep thinker, this man who behind the scenes exerted such influence on the British editorial board of the *Journal of Bone and Joint Surgery* and on the British Orthopaedic Association, of which he was quite certainly destined to be president within a few years.

He was a critic. He was always thoughtful. He had wide knowledge. His merits were best shown at quiet after-dinner meetings such as those of the W. Little Club, when the few select members presented their problems. He was always the dutiful secretary and recorder; his comments were earnest and faithful; and beneath the crust he was a very great friend indeed. We offer our deep sympathies to his wife Angela, and to his young son and daughter, Richard and Mary.

Universities and Colleges

NATIONAL UNIVERSITY OF IRELAND

The following medical degrees and diplomas were conferred at University College, Dublin, on July 11:

M.D.—V. Doyle, *J. Murphy, R. Towers.
M.Ch.—M. Ashe, B. Campbell, *C. Galvin.
M.B., B.Ch., B.A.O.—G. Crean, T. Poon King, M. Mulcahy, B. Achong, G. Gearty, M. Ali Shaw, M. Awon, Margaret Boylan, M. Browne, T. Casey, *F. Christian, A. Clery, P. Collins, J. Comerford, Marie Couacaud, R. Cullen, P. Curtis, P. Fitzpatrick, *J. Fleming, P. Fleming, Mary Frost, J. George, Khorsheed Ginwala, J. Goggin, W. Grant, J. Hassett, J. Hourihane, Elizabeth Hurley, W. Kanachowski, J. Kelly, Mary Kennedy, Mary Kent, F. Kirk, G. Lau, J. Leahy, P. Leddy, B. McCarthy, G. MacDonagh, Maev McGrath, E. Mackey, M. McNulty, J. Masterson, P. Moylan, J. Mozolowski, P. Mulligan, G. Murphy, M. Murphy, B. O'Duffy, T. O'Dwyer, M. Ongley, F. Roche Kelly, *B. Rooney, M. Shipsey, T. Staunton, E. Tempary, W. Verling, Ah-Yen Wong Shiu Leung, R. Znamirowski.

DIPLOMA IN PUBLIC HEALTH.—T. Simpson, *Hanora Forde, *Irene Finnegan, L. Delany, Mary Murphy, *Madeline Moran, J. Walsh, B. McCartie, W. Bushe, P. Carr, P. Daly, E. Desmond, Carmel Dooley, *Margaret Farrell, J. Heagney, A. Loftus, E. McArdle, *D. McCarthy, Ita MacMahon, *D. McNamara, S. Maurer, *P. Prestage, M. Reilly, Eva Roith, Mary Rynne, *P. Sweeney.

DIPLOMA IN CHILD HEALTH.—*D. Cantwell, J. Carroll, J. Cooney, Ellen Courtney, T. Gilroy, *K. Hickey, E. Killian, *M. O'Dwyer.

DIPLOMA IN PSYCHOLOGICAL MEDICINE.—*P. O'Connor.
*In absentia.

QUEEN'S UNIVERSITY, BELFAST

The following candidates have been approved at the examinations indicated:

M.D.—A. S. Clenaghan, Mary P. Cole.
M.B., B.Ch., B.A.O.—I. D. A. Johnston (with second-class honours), J. Alexander, F. E. Anderson, E. MacL. Ashenurst, J. A. C. Ball, J. B. Bridges, Beryl M. Bromham, D. Burrows, N. M'L. Campbell, G. C. R. Carey, Enid G. Carson, W. M. D. Clements, Florence M. Cousley, S. J. Cox, D. W. Davison, W. Essigman, Diana H. B. Gillies, A. G. Gordon, W. J. Gray, J. MacDougall, G. Harley, Claire D. Johnston, E. P. Jones, J. H. Jones, J. M. Kearney, Agnes M. T. Kelly, C. P. Kennedy, W. S. Kerr, W. C. Logan, R. J. Loughridge, A. D. M'Farland, J. J. E. M'Gartland, R. A. M'Keown, H. M'Laughlin, C. B. M'Shane, E. A. M'Williams, J. I. Maxwell, Renate M. Meyer, Shelagh M. Milligan, S. R. W. Moore, W. J. D. Murphy, Dallas M. J. Nixon, B. C. Onyeabo, T. A. Piggot, J. R. Purser, W. W. Ramsay, I. C. Roddie, A. C. Scott, E. G. N. Sinanan, G. D. L. Smyth, H. G. Smyth, M. M. Sundie, H. W. K. Thompson, P. M. Walsh, N. L. Wright.

CONJOINT BOARD IN SCOTLAND

The following candidates, having passed the final examinations, have been granted the diploma of L.R.C.P.Ed., L.R.C.S.Ed., L.R.F.P.S.Glasg.: R. B. Baluch, Cora Branker, Margaret P. Bruce, M. G. Cameron, C. Harris, Maureen E. Hillery, C. R. Johnson, I. Khosla, Eleanor M. Kneale, S. Lal, I. G. Macpherson, J. G. Noble, J. S. Walia, Mary H. Wallace.

INFECTIOUS DISEASES AND VITAL STATISTICS

Summary for British Isles for week ending September 5 (No. 35) and corresponding week 1952.

Figures of cases are for the countries shown and London administrative county. Figures of deaths and births are for the 160 great towns in England and Wales (London included), London administrative county, the 17 principal towns in Scotland, the 10 principal towns in Northern Ireland, and the 14 principal towns in Eire.

A blank space denotes disease not notifiable or no return available. The table is based on information supplied by the Registrars-General of England and Wales, Scotland, N. Ireland, and Eire, the Ministry of Health and Local Government of N. Ireland, and the Department of Health of Eire.

CASES In Countries and London	1953					1952

* Measles not notifiable in Scotland, whence returns are approximate.
† Includes primary and influenzal pneumonia.
§ Includes puerperal pyrexia.

Vital Statistics

Poliomyelitis

Poliomyelitis notifications (uncorrected) in the week ending September 12 (36th week of the year) were as follows: paralytic, 92 (123); non-paralytic, 81 (101); total, 173 (224). This is a decrease of 51 compared with the previous week, the figures for which are in parentheses. This is a fairly sharp fall, and suggests that the peak has been passed and that the expected seasonal recession has begun.

Graphs of Infectious Diseases

The graphs below show the uncorrected numbers of cases of certain diseases notified weekly in England and Wales. Highest and lowest figures reported in each week during the nine years 1944-52 are shown thus ———, the figures for 1953 thus ———. Except for the curves showing notifications in 1953, the graphs were prepared at the Department of Medical Statistics and Epidemiology, London School of Hygiene and Tropical Medicine.

Infectious Diseases

The largest variations in the number of notifications of infectious diseases in England and Wales during the week ending September 5 were falls of 247 for measles, from 1,049 to 802, and 112 for whooping-cough, from 4,170 to 4,058, and a rise of 40 for scarlet fever, from 443 to 483.

The incidence of measles is at the lowest level for the past four years. During the week reviewed a fall was recorded in all regions except the north-western, where a small rise occurred. The largest fluctuations in the returns of whooping-cough were a rise of 75 in Lancashire, from 262 to 337, and a fall of 48 in London, from 402 to 354. 20 cases of diphtheria were notified, being 4 more than in the preceding week. The chief features of the returns of diphtheria were a rise in London from 0 to 3, and in Plymouth C.B. from 1 to 4, and falls in Cheshire from 4 to 0, and in Durham from 3 to 0. Only small fluctuations occurred in the local returns of scarlet fever.

224 cases of acute poliomyelitis were notified during the week. These were 3 more for paralytic and 16 fewer for non-paralytic cases than in the preceding week. The largest returns were Warwickshire 22 (Birmingham C.B. 7, Coventry C.B. 10), Lancashire 20 (Blackpool C.B. 3, Liverpool C.B. 3), London 16, Dorsetshire 12 (Blandford R.D. 3), Surrey 11, Kent 10, Essex 10, Yorkshire West Riding 10 (Doncaster C.B. 3).

205 cases of dysentery were notified, being 1 fewer than in the preceding week. The largest centres of infection were London 43 (Chelsea 12), Lancashire 40 (Liverpool C.B. 10, Manchester C.B. 9), Yorkshire West Riding 21, Middlesex 16 (Willesden M.B. 6), Durham 12 (Stanley U.D. 6), Kent 10 (Chislehurst and Sidcup U.D. 8), and Essex 10.

Week Ending September 12

The notifications of infectious diseases in England and Wales during the week included scarlet fever 505, whooping-cough 3,708, diphtheria 19, measles 603, dysentery 204, paratyphoid fever 11, typhoid fever 6, and food-poisoning 244.

The Services

Surgeon Commander H. R. I. Wolfe, R.N.V.R., has been awarded the Royal Naval Volunteer Reserve decoration. Lieutenant D. A. Cahal, Royal Regiment of Artillery (now R.A.M.C., T.A.R.O.), has been awarded the Efficiency Medal (Territorial).

Air Commodore P. B. Lee-Potter, C.B.E., R.A.F., has been appointed Honorary Surgeon to the Queen in succession to Air Vice-Marshal W. E. Barnes, C.B.E., R.A.F., who has vacated the appointment on retirement from the R.A.F.

A Supplement to the *London Gazette* has announced the following awards:

Third Clasp to the Territorial Efficiency Decoration.—Colonel W. R. Ward, T.D., late R.A.M.C.

Second Clasp to the Territorial Efficiency Decoration.—Colonels H. Sissons, O.B.E., T.D., and W. R. Ward, T.D., late R.A.M.C., Lieutenant-Colonel (Honorary Colonel) E. J. G. Glass, T.D., and Major B. St. J. Steadman, T.D., R.A.M.C.

Medical News

Auditory Training of Deaf Children.—A hostel for young deaf children and their mothers was opened last week at Castle Bar Hill, Ealing, by the Minister of Health, Mr. Iain Macleod. It has been provided by the board of governors of the Royal National Throat, Nose, and Ear Hospital with the objects of allowing mothers to watch the auditory training of their children and of learning how to continue it at home. The hostel will also provide facilities for the trial of new training methods. After congratulating the governors on the imaginative use to which they had put most of their endowment funds, Mr. Macleod described the present supply position of the N.H.S. hearing-aids. Over 312,000 aids had been fitted and distributed, and the waiting-list would be only the end of the beginning; it would be possible then to spend more time on the auditory training of those who received the aids, amongst whom children had always had priority. A new light-weight aid for children was being developed, and pilot trials had to take place, but meanwhile the improved Mark III Medresco aid, which had batteries only half the weight and size of the earlier models, was coming into production, and children would again have priority.

Surgery of Peptic Ulcer.—In a Hunterian lecture at the College of Surgeons last March Mr. F. A. Henley described an operation for peptic ulcer, consisting in replacing the resected portion of stomach by a segment of jejunum, which it is claimed obviates the post-gastrectomy syndrome. Messrs. Allen & Hanburys Ltd. have selected this operation for the subject of the first of a series of medical teaching films. The film, made by Stanley Schofield Productions Ltd., was given a private showing last week. It is in colour, with a spoken commentary, and the operative details are extremely clear. One apparent advantage of the operation is that the normal processes of digestion are retained; there is the usual delay in the "stomach," and the food traverses the duodenum, where bile and pancreatic juice can mix with it. The operation is used routinely for cases of peptic ulcer needing surgery, to relieve severe post-gastrectomy symptoms, and for malignant disease of the stomach. Copies of the film may be obtained from Messrs. Allen & Hanburys Ltd., Bethnal Green, London, E.2.

NAPT Hunter Scholarships.—The National Association for the Prevention of Tuberculosis announces four scholarships for doctors and medical students, made possible through the generosity of a private donor, to be known as the Hunter Scholarships. The first is a postgraduate scholarship of £350 to enable a graduate of a British medical school, resident in the United Kingdom, to spend six months abroad studying the control of tuberculosis. The second, also of £350, is to enable a young graduate from any medical school in the British Commonwealth outside the United Kingdom to study tuberculosis in Britain. In addition, two scholarships of £150 each are offered to medical students, of either sex, who have been seriously handicapped through tuberculosis, to enable them to complete their training at any medical school in England or Wales. Inquiries about the scholarships should be sent to NAPT, Tavistock House North, Tavistock Square, London, W.C.1. The closing date for applications for the scholarships is March 31, 1954.

United States Research Fellowships.—In response to a request from the Organization for European Economic Co-operation, the United States Government has provided over \$1m. to enable 150 outstanding young scientists from Europe to travel to and live in the United States for up to two years in order to study in American research institutions. The National Academy of Sciences, Washington, is administering the scheme, and the Royal Society has been asked to

advise on the selection of candidates from the United Kingdom. About 25 fellowships will be open to candidates from the United Kingdom. No age limits are specified, but it is expected that most of the successful candidates will be between 26 and 32 years of age. Applications will be considered from candidates who propose to do research in the natural sciences and in the engineering, agricultural, and medical sciences, but excluding clinical medicine. Candidates must be in possession of a doctoral degree in science or have had equivalent experience. Applications, which may be made at any time, will be considered at regular intervals. For the first two sets of applications the closing dates are respectively October 1 and November 30, 1953. Forms of application and further information are obtainable from the assistant secretary, The Royal Society, Burlington House, London, W.1.

South African Medico-Legal Journal.—The Medico-Legal Society of Johannesburg is sponsoring a new medico-legal journal, the *Journal of Forensic Medicine*, under the editorship of Dr. H. A. Shapiro. The event is of more than national interest, as there is only one other similar journal written in English—the *Medico-Legal Journal*, which is published in Britain. The new journal will appear quarterly to begin with, and is intended for accounts of original research in forensic medicine and for case reports; it will also include reviews, abstracts, and medico-legal news. It is stated to be international in scope. The journal is published by Juta and Co., P.O. Box 30, Capetown, at an annual subscription of two guineas.

COMING EVENTS

Contraceptive Technique.—A lecture and demonstration on contraceptive technique will be given by Marie Stopes, Ph.D., at the Mothers' Clinic, 108, Whitfield Street, London, W.1, on Thursday, October 1, at 2.30 p.m. No fee is charged, but tickets must be obtained in advance as space is very limited.

King's College Hospital Medical School.—The inaugural address will be delivered by the Rt. Hon. Iain Macleod, M.P., at the Medical School, Denmark Hill, on October 2 at 2.30 p.m. Sir William Gilliatt will preside.

Royal Free Hospital School of Medicine.—The inaugural address will be delivered by Miss G. E. M. Jebb in the Beveridge Hall, Senate House, University of London, W.C.1, on October 2 at 3 p.m. Miss Jebb's subject will be "The University Student in the World To-day."

Faculty of Medicine, Sheffield University.—The opening sessional address will be delivered by Professor L. J. Wits in the Frith Hall of the University on October 8 at 5 p.m. Professor Wits will take as his subject "The Opportunities of Medicine."

SOCIETIES AND LECTURES

A fee is charged or a ticket is required for attending lectures marked ●. Applications should be made first to the institution concerned.

Monday, September 28
CENTRAL MIDDLESEX HOSPITAL, Park Royal, N.W.—5.30 p.m., Mr. Grayton Brown (Melbourne): Surgical Treatment of Duodenal Ulcer by Antro-duodenectomy.

Tuesday, September 29
SOCIETY OF INSTRUMENT TECHNOLOGY.—At 26, Portland Place, London, W.—6.30 for 7 p.m. Dr. C. N. Smyth: Electrical Techniques in Medicine with particular reference to the Measurement of Pressure and of Strain.

Wednesday, September 30
CAMBRIDGE MEDICAL SOCIETY.—At Addenbrooke's Hospital, 8.15 p.m. Clinical meeting.
MIDLAND MEDICAL SOCIETY.—At Birmingham Medical Institute, 8.15 p.m.—annual meeting. Valedictory Address by Dr. W. Watson Newton: Mesmer, Mind, and the Emotions.
ROYAL SANITARY INSTITUTE.—2.30 p.m., discussion: Future of B.C.G. Vaccination in Great Britain. To be opened by Dr. J. Lorber and Dr. K. N. Irvine.

Friday, October 2
INSTITUTE OF DERMATOLOGY.—5.30 p.m., Dr. Stephen Rothman (Chicago): Clinical Demonstration.
SOCIETY OF CHEMICAL INDUSTRY: CROP PROTECTION PANEL OF THE AGRICULTURE GROUP; ASSOCIATION OF APPLIED BIOLOGISTS; SOCIETY OF PUBLIC ANALYSTS; and PHARMACOLOGICAL SOCIETY.—At Imperial College, Imperial Institute Road, Kensington, S.W.—Joint Symposium: Organophosphorus Insecticides. Morning session, 10.30 a.m. to 12.45 p.m. Afternoon session, 2.15 p.m. to 5 p.m.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Scarlet Fever and Nephritis

Q.—Is it correct to treat scarlet fever cases, however mild, by rest in bed for at least two weeks in order to reduce the incidence of nephritis? If this is so, should not all cases of haemolytic streptococcal sore throat be treated in the same way for the same reason?

A.—Post-scarlatinal nephritis is regarded, probably correctly, as a toxic-allergic manifestation. There is no conclusive evidence that patients allowed up early are in greater danger of developing nephritis. When the disease was common, and dangerous, nephritis occurred even in the most carefully nursed cases, but only rarely in those efficiently treated with antitoxin. Nevertheless it is probably unwise to submit to strain and overactivity organs that have recently been subjected to a toxic or bacterial attack, and for this reason alone it is wiser to allow reasonable rest after the temperature has subsided.

Many authorities allow the discharge of patients from hospital about one week after onset of the disease; it is commonplace to release patients in from ten to twelve days. And this would not be practised if it were thought that a greater risk of nephritis would result.

Not all streptococcal throats are caused by scarlatinal strains, and some scarlatinal strains are poor toxin producers. The nephritic reaction is almost certainly linked with the specific toxin. Furthermore, the patient with a scarlatinal streptococcal tonsillitis may have a high immunity to the toxin. It is probable, therefore, that streptococcal throats without rash are even less likely than scarlet fever to end in nephritis.

Partial Impotence after Mumps

Q.—Three years ago a man of 57 had a bilateral mumps orchitis, and since then he has lost the full power of erection, although retaining his libido. This difficulty is overcome by giving 5 mg. testosterone daily. Are there any risks in continuing this treatment indefinitely? Is there a risk, for instance, of benign or malignant changes in the prostate?

A.—Mumps is more likely to attack the seminiferous tubules than the interstitial cells, but sometimes does destroy the latter and cause failure of testosterone secretion with resulting loss of potency. The small dose of testosterone that is given in this case—and I would conjecture that it is in the form of methyltestosterone—would be unlikely to influence such a loss of potency except by suggestion, so that one cannot rule out psychological impotency in this case. If, on the other hand, larger doses were required and the response was clear-cut, organic impotency responding to substitution therapy would be the correct diagnosis. There are no risks from small doses in regard to the effect on other endocrine organs or on the prostate. There is no clinical evidence that larger doses have a harmful effect on the prostate but conceivably such doses could produce a disturbing enlargement beyond the physiological. There is no evidence that malignant changes in the prostate would result. Methyltestosterone is not excreted as an androgen in the urine, and in this is unlike testosterone. It is inactivated by some process in the liver; it does not increase the urinary 17-ketosteroids, whereas testosterone does. However, probably because of these differences, methyltestosterone has been recorded as producing a form of jaundice with changes in the liver. This is a rare complication, and the present

writer has not met with it, although he uses methyltestosterone fairly extensively, but there would appear to be no doubt about its reality as a rare complication. This raises an important point as to whether methyltestosterone should ever be prescribed. At the present moment those who have met with the complication take the view that nevertheless methyltestosterone should be prescribed where it is indicated. The alternative method of giving androgens is to inject testosterone propionate, and if this is used in the form of testosterone-phenylpropionate the duration of action is some two weeks, which is a great improvement on daily injection. Another lasting method is the subcutaneous implantation of testosterone, the effect lasting some six or eight months. Testosterone cannot be given by mouth in the same way as methyltestosterone can, because it is largely inactivated. The same would apply to its absorption under the tongue, which method is used effectively for methyltestosterone.

Why Do Children Turn Their Toes In?

Q.—What is the cause of children walking with their feet turned inwards?

A.—During the early stages of walking most children develop bow-legs, knock-knees, or both. In the vast majority these deformities disappear spontaneously; they are in no way related to rickets. It is usually taught that these children turn their toes in because they are trying to improve their balance. With knock-knees there is necessarily eversion of the foot and usually also external rotation: by reversing this a steadier base is obtained; thus the child learns to internally rotate his legs to avoid falling. These cases seldom need any treatment.

Apart from this, there are causes of a more serious nature: congenital talipes equino-varus, or a metatarsal varus with actual deformities of the metatarsals and tarsal bones, is usually obvious; much less obvious is the internal rotation seen in a spastic child. Apart from these structural causes, there is unlikely to be anything else very wrong with a child that turns its toes in.

Faulty Absorption after Partial Gastrectomy

Q.—What are the likely causes of bulky, pale, offensive stools and low weight following a partial gastrectomy two years ago for duodenal ulcer? What treatment is suggested?

A.—Faulty absorption of fat and other food materials may follow partial gastrectomy. There are various causes of this defective absorption, and investigation of the gastrointestinal condition is required to establish the facts in each case.

A not uncommon finding is that the food passes rapidly out of the stomach remnant and thus tends to get ahead of the pancreatic and biliary juices, which cannot mix properly with it. This may result in delayed absorption and consequent bacterial changes in the lower part of the small intestine. Bacterial activity is likely to cause bulky, pale, and offensive stools. Defective absorption of water and possibly some food materials may account for loss of weight. Occasionally an error of technique at operation has led to the stomach being anastomosed to the lower jejunum or even the ileum, and in such cases proper digestion of the food is almost impossible. Apart from a full investigation of the stools it is clearly of importance to have a barium meal and follow-through examination to determine whether there is any gross anatomical abnormality. It also appears that excessive length of the afferent jejunal loop will contribute to this trouble, but to a lesser extent; in the same way an unduly radical gastrectomy, by encouraging too rapid emptying of the stomach, may also be a factor.

If investigation of the gut does not disclose some error of technique which can be remedied by further operation the treatment must be planned on the following lines: the taking of food should be spread over a reasonably long period to enable the pancreatic and biliary juices to mix with as much of the meal as possible. The meal may be

started with the ingestion of food which does not require pancreatic and biliary digestion, but which nevertheless stimulates the gastro-intestinal secretions in time for the arrival of the less easily digestible food. Alternatively, predigested foods or a potent pancreatic extract, intimately mixed with the food, may be taken at the start of each meal.

T.A.B. after Typhoid

Q.—Is it worth giving T.A.B. to a person who has recently had a severe attack of typhoid fever and is going to a country where both paratyphoid and typhoid are quite common? If inoculation is recommended, is the previous attack of typhoid likely to cause a particularly severe reaction?

A.—Second attacks of typhoid fever are rare, so that there is no indication for immunization against typhoid itself after an attack of the disease. Paratyphoid is a much milder infection and responds to chloramphenicol therapy. It must also be remembered that T.A.B. will not necessarily protect an individual against infection, particularly in countries where the risk of eating heavily contaminated food is considerable. The degree of reaction to T.A.B. vaccination is not likely to be affected by a previous attack of the disease but seems to depend more on individual idiosyncrasy. While, therefore, there is no great likelihood of severe reaction, there seems in this case to be no strong indication for prophylactic immunization.

Dermatitis Herpetiformis

Q.—What is the best treatment for dermatitis herpetiformis? Is autohaemotherapy any good? If so, how is it given? The patient in question is intolerant of arsenic, and neither chloramphenicol nor sulphonamides have been successful.

A.—Dermatitis herpetiformis proper is essentially an affection starting in early adult life and lasting very many years, but after the first few years the discomfort abates and ultimately active treatment is not necessary.

Arsenic, which is usually effective in controlling the affection, should not be employed in a chronic disease of this type, neither should chloramphenicol. Sulphonamides as such are of no value, but sulphapyridine, because of the pyridine ring, almost invariably controls the affection and appears to be safe in these patients, though the ordinary safeguards should naturally be employed. Other allied drugs, thiouracil, etc., are effective, but sulphapyridine is the best. 0.5 g. taken with meals three times a day rarely needs to be exceeded. Periodically the blood picture should be looked at. Autohaemotherapy has not proved of much value. It is conducted by taking 5 or 10 ml. of blood from a vein in the elbow and immediately injecting it into the muscles of the buttock.

It should be mentioned that, particularly in older patients, dermatitis herpetiformis, or an exactly similar eruption, may be dependent upon some organic disease, especially malignant disease internally.

Peeling Onions

Q.—Why do onions make the eyes water?

A.—The pungency of onions, and presumably their effect on the eyes, is attributed to volatile sulphur compounds. Allyl isothiocyanate, which is typical of this class of compound, is found in the horseradish and other plants.

Deafness on Board Ship

Q.—I have a slight nerve deafness for the higher tones. I always become quite deaf on board ship, with a tendency to excessive meatal secretion. Why is this?

A.—One possible reason for nerve deafness becoming more noticeable on board ship would be the constant noise of the ship's engines. Any person with high-tone deafness due to changes in the organ of hearing is likely to find that the hearing becomes less acute in the presence of any background noise. On the other hand, if there is naturally

some external otitis causing meatal secretion other than wax, then any increase in the secretion may block the meatus and so make the hearing defect worse. There is no particular reason why sea air should increase a tendency to excessive meatal secretion, though it might be caused by using salt water for washing purposes.

Vitamin B₁ and Parkinson's Disease

Q.—Does vitamin B₁ have any specific action in Parkinson's disease? A patient is greatly improved on 200 mg. weekly of the vitamin.

A.—Vitamin B₁ is not recognized to have any specific effect in Parkinson's disease.

NOTES AND COMMENTS

Immobilization in Spinal Tuberculosis.—Dr. K. W. TODD (Port Moresby, Papua) writes: In "Any Questions?" (*Journal*, April 25, p. 952) you were asked the best way of immobilizing cases of spinal tuberculosis. It would appear from the reply that Dr. Rollier's method, despite his experience and eminence, is little known. May I describe it? "Where is the fracture in Pott's disease?" said he. "In the body of the vertebra. Where is the sound structure to form a fulcrum? In the spinous processes and interspinous ligaments. How can you extend the fractured bone and separate the fragments? By nursing in the prone position, preferably with the chest and shoulders raised by the elbows." It was in this admirable position that Rollier's patients had heliotherapy. For greater ease, they had rings tied into the bed to prevent the elbows from slipping. This was just before streptomycin, and it may be that the period of bed immobilization is now shorter, and that a plaster is necessary for ambulant treatment.

OUR EXPERT writes: Rollier's methods are of course well known in this country, but his views are not entirely accepted, and in most hospitals in this country nursing supine with or without hyperextension is considered the preferable method, as only by it can adequate immobilization be achieved. Nursing prone with chest and shoulders raised is used in the early convalescent period to aid muscle recovery. The Rollier method's great disadvantage is that it does not provide adequate immobilization and needs constant supervision.

Filatov's Tissue Therapy.—Mr. E. GORDON MACKIE (Sheffield) writes: In "Any Questions?" (September 12, p. 634) an inquiry about Filatov's tissue therapy is answered—but it is incorrectly stated that "it is not a technique that has been studied elsewhere" (than in Russia). A paper "Placental Implantation for Retinitis Pigmentosa" was read by me at a joint meeting of the Royal Society of Medicine, Section of Ophthalmology, with the North of England Ophthalmological Society on April 20, 1951, in Sheffield. An abstract is to be found in *Proc. roy. Soc. Med.*, 1951, 44, 977. It compares the results reported by 20 workers (16 non-Russian) in this and certain other ophthalmic diseases and it cites (with references) certain parallel work in general surgery. Your inquirer might be interested in the information thus available.

Correction.—In a letter about neonatal asphyxia published in the *Journal* of September 19 (p. 675) Dr. David Morris discussed Akerren's method of resuscitation with intragastric oxygen. We should have made it clear that the hospital where he described it as being regularly used is the British Hospital for Mothers and Babies, Woolwich, London, S.E.18.

TREATMENT OF CANCER OF THE LARYNX BY INTERSTITIAL RADIUM NEEDLES

BY

W. DOUGLAS HARMER, M.C., F.R.C.S.

Consulting Surgeon to the Throat Department, St. Bartholomew's Hospital; Consulting Surgeon to Mount Vernon Hospital and the Radium Institute

The object of this investigation was to ascertain the value of interstitial radium needles in the treatment of cancer of the larynx and to compare it with other methods. This subject has not received as much attention as it deserves. Since 1924 120 patients have had operations with the help and advice of colleagues in the cancer departments of St. Bartholomew's Hospital, Mount Vernon Hospital, and the Radium Institute.

In so limited a space it is not possible to name all the "happy band of brothers," but I am especially indebted to Finzi for suggesting that the method should be tried, to Stanford Cade for his valuable advice and co-operation during at least 20 years, and to a number of distinguished physicists, particularly Gray and Neary, who have planned the method of delivering the best dose to the different parts of the larynx, and lastly to my son, who has helped me in the preparation of this paper.

All these patients have been followed up, with the exception of two who left the country within a few months of their treatment and who have been omitted: in one the growth had already disappeared, so that the outlook was favourable, and the other, with an advanced growth, has been assumed to have died of cancer.

Up-to-date reports of all these are recorded. A few that were lost after five years have been listed to the date of their last record.

Clinical Features

Before describing details of treatments some remarks about these cancers are advisable.

Aetiology.—Cancer of the larynx occurs chiefly in males (only 13% in females). Most of our patients were between the ages of 50 and 65. The oldest was 78; the youngest 20. During 55 years in practice I know of only one earlier case—that of a boy of 9½, seen recently in consultation with Mr. James Crooks, who performed a laryngo-fissure and who has since published this interesting case, which I have not included in my series. Nothing was discovered about causation, but a number of these patients stated that their symptoms started after influenza, and one young woman, who was apparently cured by radium needles for two years, had a rapid recurrence following a pregnancy and died in six months. Normally intrinsic cancer grows slowly, but the rate of growth is quite unpredictable. Thus, a

patient from India with hoarseness for about a month had a small localized lesion like a simple wart. As the section showed carcinoma he was treated by laryngo-fissure and the whole of his vocal cord was removed. His wife was assured that the outlook was excellent. In a short time, however, it became obvious that the disease had not been arrested, and he died six months later with large metastases in the cervical lymph nodes. The same may happen with growths elsewhere in the throat. A doctor had a small pedunculated wart the size of a pea on his tongue which looked like a simple papilloma. The biopsy report stated, "No evidence of carcinoma." Bilateral metastases were noted soon afterwards and grew rapidly, and when he died in six months they were as large as hens' eggs. Small pedunculated lesions in the upper air passages may be very malignant and incurable.

Symptoms.—It has long been accepted that the shorter the history of hoarseness the better the outlook, but, strangely enough, this statement is not always reliable. Table I gives the histories in 89 patients. It shows sur-

TABLE I.—Length of History

	Months				Years						
	<3	3	6	9	1	2	3	4	5	7	10 15
No. of cases	2	19	15	11	11	16	6	4	1	2	1
3-year survivals	0	11	6	5	5	7	2	2	0	0	1

prisingly little variation in survivals after three months. Although the numbers are small it is still not clear why this should be so. It seems that the outlook depends more on situation, type of lesion, and resistance to cancer. A man with a short history may be more difficult to cure than another who has had trouble for years. Incidentally, people who have lived in the Tropics for many years, who have led a sedentary life, or who have eaten and drunk too much seldom survive for long. On the other hand, another patient with 15 years' hoarseness and a very extensive growth involving the cartilages on both sides was needled and lived free of disease for 10 years. Presumably, a patient's resistance to cancer may be lower at the beginning of the disease than after a number of years. Whatever the explanation, some patients respond surprisingly well and others put up no fight at all.

Situation.—It is not known why cancer in one part of the larynx can be cured so easily whereas with a similar growth in another place a patient rarely survives for long. A good instance is cancer of the epiglottis; on the tip it may be so comparatively innocent that it can safely be treated with transoral diathermy excision, while on the base it is a dangerously malignant cancer which can seldom be cured even by wide laryngectomy. It is therefore enormously important to know how the disease behaves in different situations.

Biopsy.—This should always be made, and be repeated if necessary. The report may be negative. Several of our patients required three or more biopsies. If the disease is clinically malignant it should be treated as such. No patients had sarcoma, and personally I have seen only two cases. Generally speaking, the low-grade cancer has the best prognosis, but in the larynx the situation is more important than the histology. Most of our cases had biopsies. Many years after needling, Dr. Ruth Pearson examined the sections of 48 patients at my request and attempted to foretell the outcome according to Broders's grading. The results are expressed in Table II, which appears to show that, contrary to present-day opinion, grading is of considerable value.

TABLE II

Broders's stages 1 and 2	24	6	18	15	9
" " 3, " 4	24	5	19	9	15

Clinical Stages

There are three main stages:

I. Early Intrinsic

(37 patients—31% of total reported.) Here the lesion is strictly confined inside the cavity of the larynx. It is usually a small, slowly growing warty lesion localized to the anterior part of the vocal cord and occasionally spreading to the anterior commissure or to the opposite cord. It involves the mucous membrane only, and can often be stripped off without damaging the muscles of the cord (Fig. 1). In fact, when doing a biopsy it is important not to bite too deeply for fear of making a notch which may damage the voice permanently. In rare cases a growth may

FIG. 1.—Stage I. Early intrinsic.

be hard and ulcerated, which is a more serious condition. If the lesion extends below the cord it is no longer a stage I type. Early lesions often grow slowly and have long histories of hoarseness. They never invade the cervical lymph nodes. At least 80% are curable.

II. Advanced Intrinsic

(72 patients—62% of total reported.) When first examined these growths are nearly all very advanced, but without enlarged nodes. Incidentally, it is extremely difficult to decide how localized they are, particularly when the cord is immobile. Usually the whole vocal cord is involved and the lesion sometimes spreads to the anterior commissure, the base of the epiglottis, the arytenoid or subglottic space (Fig. 2). Sixty were unilateral, while twelve of them had bilateral lesions which had spread across the anterior or, rarely, the posterior commissures. Eight of these had

no tenderness or external swelling, but, when exposed, the growths had perforated the membranes and invaded or softened the cartilages, usually at the lower border of the thyroid cartilage or through the crico-thyroid membrane. Only one of them was cured for six years. Fig. 3 shows such a case in which a localized lesion which seemed superficial was found at operation to have penetrated the cartilage and so could not be included in stage II.

Clinically, there are two groups which help to decide the treatment. (a) The large, soft, cauliflower, non-ulcerated type, with a freely movable vocal cord and therefore no deep infiltration. Radium needling should be tried before laryngectomy. Thirty-three patients were treated, many with good results. (b) The hard, nodular, ulcerated type with a fixed cord, which signifies deep extension of the disease. Without operation it is impossible to determine how serious this is, but 39 were deliberately treated and some of them were cured. Nearly all these lesions were temporarily improved, and the ulceration usually disappeared.

The neck should always be examined to ascertain if there is any external swelling or thickening of the larynx. If on firm pressure the patient complains of tenderness or pain on the affected side, perichondritis should be suspected.

III. Extrinsic

(9 patients—7% of total reported.) Here the lesion is no longer confined inside the larynx. Two different types must be included.

(a) The growth which starts in the larynx and then spreads upwards to the base of the epiglottis or tongue or over the lateral fold to involve the pharynx or pyriform fossa, below the vocal cord to the subglottic space or trachea, posteriorly to the arytenoid cartilage or to the post-cricoid region (Fig. 4). All such cancers progress rapidly, and these patients seldom survive for more than a year if untreated.

(b) Here the cancer starts either on the margin of the larynx or on the neighbouring part of the pharynx, spreading later into the larynx.

FIG. 2.—Stage II. Advanced intrinsic.

FIG. 3.—Apparently intrinsic (stage II) found at operation to be perforating thyroid cartilage (stage III).

FIG. 4.—Extrinsic (stage III).

In the 1945 annual report of the B.E.C.C. dealing with extensive cancer of the larynx, the site of origin was given as follows:

Pyriform fossa	..	..	males 137	..	females 12
Post-cricoid space	..	..	22	..	68
Aryepiglottic fold	..	..	42	..	4
Vallecula and epiglottis	..	..	61	..	4

Such growths are always very malignant and progress rapidly, and the patients rarely live (untreated) for as much as a year. Involvement of the lymphatic nodes is common. The same report described: no nodes, 49; enlarged nodes, 81; nodes and adjacent tissues involved, 244; distant metastases, 9. To emphasize their virulence it was stated that, in spite of treatment, chiefly irradiation, only 15 cases survived for five years. With modern treatments much better results are now obtained.

Choice of Treatment

These can be considered historically. The first attempt to cure cancer was naturally by surgery.

Laryngectomy

In 1863 the first laryngectomy for papillomata was performed by Sands (Canada); in 1866 Patrick Watson (Edinburgh) removed a larynx for syphilis; and in 1873 Czerney and Billroth performed another laryngectomy for cancer. In 1887 the German Crown Prince contracted cancer, and von Bergmann advised this operation. When pressed, this great surgeon said that he had performed it seven times, with an average survival of 19 days. His advice was not accepted. But the prince's illness caused enormous controversy and Queen Victoria sent Morell Mackenzie to advise her son-in-law, greatly to the annoyance of the German surgeons, who walked out. The prince lived for just under a year, long enough to become emperor.

The years 1870 to 1900 can be described as the age of laryngectomy. During this period many larynges were removed, but nearly all the patients died of bronchopneumonia, sepsis, and heart failure. With antibiotics and modern anaesthesia laryngectomy can now be safely performed by surgeons who have sufficient experience of this operation. The mortality should be 2 to 3% provided the general health of the patient is good. It has always been a popular operation for all stages of the disease, and it is still regarded by many surgeons as preferable to other methods, particularly in Europe and America. But it is still a difficult operation for general surgeons, and for the patient is a great handicap. No patient should be told that it is the only safe treatment; nor can it be pretended that it will make no difference, for it often causes great depression. The patient should realize that only about 15% of them get good voices.

To-day there are simpler treatments which can safely be tried first. Without doubt laryngectomy is quite unnecessary for early lesions; before long it may even be found that radiotherapy in some form may cure a number of advanced cancers, and it will not be surprising if pre-operative ray treatments make laryngectomy more successful. For extensive cancer it is a very good treatment. Recently there have been improvements in technique and it has been found that the best results can be obtained only by very wide excisions, with removal of enlarged cervical lymph nodes in one block, preferably at the same operation. To be successful the sterno-mastoid muscles are usually removed. The internal jugular vein is tied on the affected side. Some surgeons now tie both veins. Even very extensive disease involving the pharynx, post-cricoid region, and nodes can now be treated successfully by laryngo-oesophago-pharyngectomy.

Laryngo-fissure

In 1900 Butlin and Semon published a paper showing that "thyrotomy" (as they called it) and local excision of early localized cancers of the vocal cord produced as many cures as laryngectomy, with far less mutilation. This

created a sensation and was vigorously contested. For many years it was unpopular in all other countries except England, but before long StClair Thomson, Chevalier Jackson, and the Mayo Clinic published a large series of cases with 75% of five-year survivals. It was always a good operation and still is the best surgical treatment for early lesions. It is a treatment which can be perfectly well carried out in any general hospital by an experienced surgeon. The mortality should be negligible. Nearly all patients have a useful voice afterwards, enabling them to carry on their occupations. A word of caution is necessary. Laryngo-fissure must be undertaken only for the removal of superficial growths which are absolutely localized to the anterior part of the cords. Even a growth which extends into the anterior commissure and affects only a small part of the opposite cord can be successfully removed, but any wide excision of both vocal cords is apt to cause stenosis and the voice may be seriously damaged. As has already been explained, it is sometimes difficult to be certain that the growth is entirely intrinsic, particularly if it is ulcerated and causing loss of movement of the cord. If the cord is completely immobile the disease is probably too advanced for local excision. Undoubtedly, early lesions can now be safely treated by laryngo-fissure.

Radiotherapy: 1. High-voltage X Rays

In 1898 Lewis Jones, using small tubes, began treating cancer with small doses for long periods, up to six months, at St. Bartholomew's Hospital. Since then an enormous amount of money has been invested in equipment which has been improved almost yearly. A colossal amount of research has been done by scientists, and accurate doses can now be given even to deep-seated lesions. More patients have been treated by x rays than by any other method. The medical profession and their patients have been told that it is safer than surgery and gives equally good results. As more powerful tubes have become available with an output of millions of volts, and of course costing more and more, the public have been assured that even better results will be obtained.

Unfortunately x-ray therapy has been disappointing. Cures are still reported only by special cancer clinics using the latest high potency equipments and by very experienced specialists. Radiotherapists should not treat cancer of the larynx with inferior equipment. They have no hope of good results.

To justify such an assertion it is necessary to analyse the evidence to support it. This can easily be obtained from the general hospitals. There can be little doubt that their x-ray treatments for cancer of the larynx have been a failure. It is extremely doubtful whether this bad habit will be cured for a long time: it has obtained such a hold on the public, in spite of its being a long harsh treatment lasting from six to eight weeks. The patient's health often suffers, severe reactions are common, hoarseness and pain persist, the tissues remain swollen, and it may be very difficult to decide whether the growth has been arrested. These signs may be due to perichondritis. Lastly, the skin and deep tissues may be damaged. After a time a new doctor may be consulted and the patient is told that he requires "a few more rays." Repeated ray treatments are often disastrous, and should rarely be given except for palliation of symptoms after recurrence. The following is a typical history:

A patient who complained of persistent hoarseness, probably due to perichondritis, was sent to the country to recuperate. The symptoms worried him, and he consulted a local radiotherapist, who, without a biopsy, advised "a few more x rays." A full course was started, but soon caused such inflammation that a tracheotomy became necessary. He suffered agonizing pain and died in six months.

It is only fairly recently that accurate localization of x rays has been possible. After a full course there may be severe reaction, and if the skin has been damaged healing may be affected.

A patient who had a recurrence two years after needling was treated with high-voltage x-rays and telerradium. Although the skin was scarred laryngectomy was risked. The flaps sloughed and when the wound had recovered a plastic repair with a large pedicle flap was performed, but this also failed to heal. Two further operations were necessary to close the fistula, but he died shortly afterwards of cancer.

Extrinsic cancer is hardly ever cured by x-rays alone, and never if the lymph nodes are diseased. But the treatment is of the greatest value for the relief of symptoms and for arresting the disease. Occasionally, dramatic results are obtained, and it is difficult to explain why this happens so rarely.

A woman aged 80 had an extensive carcinoma, which obstructed her larynx and required tracheotomy. A full course of deep x-rays was given by Finzi, and although the lesion did not shrink much it became inactive for four years, when she died of old age. Another cauliflower lesion almost filling the larynx in a man aged 79 entirely disappeared after x-ray therapy until his death. A still more remarkable cure should be mentioned. A man of 33 was treated by laryngo-fissure and remained perfectly well for 23 years. He then had a recurrence, and in a short time the growth fungated through the scar and tracheotomy became necessary. After x-ray therapy by Finzi in 1932 it disappeared and the patient is still living 20 years later, though a tracheotomy tube is necessary on account of stenosis.

2. Pre-operative Radiotherapy

It is known that even small doses of x-rays check mitosis temporarily and often shrink new growths to a large extent. In 1925 it was decided to give this treatment a trial: small doses totalling 1,000 to 1,500 r were given on three to five days and needles were inserted a day or two later. In all, 26 patients were treated as shown in Table III.

TABLE III

	Stage I (6 Cases)	Stage II (17 Cases)	Stage III (3 Cases)	Survival All Stages
3-year survivals ..	5	9	1	58%
5- " " "	5	7	0	46%

3. Telerradium

This seems to be a better treatment than high-voltage therapy for many deep-seated cancers in different parts of the body. For instance it is undoubtedly the best treatment for new growths in the tonsil and post-nasal space. This is fortunate, because surgery is useless. In the larynx it appears to be more successful than x-rays. It is less harsh, the reactions are milder, and the results are as good as any other treatment. Stanford Cade, to whom I am greatly indebted for advice for so long, has now abandoned other ray treatments, including radium needling, and uses the "bomb" for all stage I early lesions and for some intrinsic stage II growths. The Royal Cancer Hospital (London) has the largest series of laryngeal cancers in England. Lederer uses telerradium exclusively, and laryngectomy only for "failed bomb" cases.

To summarize, the drawback to both x-rays and telerradium is largely the cost. They require a house to live in, an apparatus which is more expensive each year, and which requires constant repairs—not to mention replacements—and a large and highly trained staff of specialists to run the ship. Obviously it will be impracticable for use in general hospitals, and it is unlikely that there can be more than a few of these units carefully placed in special cancer clinics throughout the country.

The Finzi-Harmer Operation

In 1924 Ledoux, of Brussels, described his "fenestration" operation, which consisted in removal of the cartilage from one side of the larynx and the insertion of short radium needles into the growth. After a visit to Brussels, where we saw some of his patients, it was decided to try the treatment. But to prevent disturbing the growth and risking

infection of the wound the needles were placed longitudinally outside the perichondrium covering the lesion. Our second patient, who had an extensive carcinoma and could only whisper owing to fixation of the vocal cord, had been advised to have his larynx removed, but when told that he could be treated by radium first he agreed to take the risk. He was cured by needling and remained well with a strong voice for six years, when he died, of all things, from psittacosis.

If the lesion is not causing severe obstruction to breathing and one vocal cord is moving, intratracheal anaesthesia is safe and preferable to local injections, but, to prevent troublesome bleeding, infiltration of the whole region with procaine and adrenaline is also advisable. The growth itself should not be infiltrated. Two incisions, 2½ in. (6.3 cm.) long, are made, one transversely above the thyroid cartilage with two-thirds of it on the affected side; the other vertically, over the side of the larynx to the upper rings of the trachea. Two skin flaps are turned laterally to expose the side of the larynx and the infrahyoid muscles. The latter are split from the hyoid bone to the trachea. Bleeding is arrested with coagulating diathermy or ligatures. A mastoid retractor is introduced to separate the muscles and to expose the lateral ala of the thyroid cartilage. The perichondrium is divided with cross cuts and reflected. The lateral ring of the cricoid cartilage is also exposed. With a small curved elevator the perichondrium under the lower margin of the thyroid is separated and a small piece of it is isolated and removed with cutting forceps. This is continued until nothing remains except a narrow frame along the upper and posterior borders. In front, the window should be carried almost to the middle line, leaving the centre keel intact. The upper edge of the cricoid ring is also stripped and notched so that the needles can be pushed under it (Fig. 5). The tissue beneath it is very thin and the dissection must be done with care. On no account must the growth or the larynx be punctured. As already stated, in advanced cases the growth may invade the perichondrium or even the cartilage. This is a serious complication, and unless the lesion is completely encapsulated it can seldom be cured by needling alone. Very rarely there may be upward extension of the growth to the base of the epiglottis, necessitating removal of the greater cornu of the hyoid bone (Fig. 6). The wound must be quite dry before the needles are inserted: each has two silk threads, and each one must be securely fixed with catgut sutures top and bottom.

Unfortunately, for six years it was not realized that the needles are apt to slip out of place and to bunch together: this happened to a distinguished physician who had an extensive bilateral growth for which seven specialists had

FIG. 5.—The fenestration operation.

FIG. 6.—The extended fenestration operation.

needles are apt to slip out of place and to bunch together: this happened to a distinguished physician who had an extensive bilateral growth for which seven specialists had

needles are apt to slip out of place and to bunch together: this happened to a distinguished physician who had an extensive bilateral growth for which seven specialists had

vised laryngectomy as the only safe treatment (Fig. 7). had just heard of radium, and, although at that time only 16 patients had been treated with it, he decided to try it. A bilateral fenestration was performed. Afterwards, had such violent vomiting that an x-ray film was ordered, and this showed that all the needles had slipped and were

FIG. 7

er 24 happy years. Because of the possibility of the needles becoming displaced every patient must have a diagram taken 24 hours after operation.

Bilateral Fenestration.—Lesions of both vocal cords are difficult to cure, and unless the patient is well and has a sonant voice in two or three months laryngectomy should be performed. Fourteen patients had bilateral needling: one had fairly early lesions of the cords and was cured for 19 years. He then had a recurrence, but died after laryngectomy. Eleven had extensive lesions which could have been treated only with laryngectomies. Seven died in the first two years. One died of old age in five years. Three were living, for 8, 19, and 24 years, the last the physician mentioned above.

Before closing the wound the cavity should be powdered thickly with sulphathiazole or soaked with 1:1,000 acriflavine solution. The threads are then tied together securely and cut short near the bases of the needles, but leaving one long thread which is fixed to the skin and acts as a guide when they are removed. The infrahyoid muscles are sutured together with catgut over the needles to keep them close to the growth. The transverse skin incision is closed accurately with fine interrupted sutures, which are removed when the wound has healed. In the lower incision, double breads of different colours are inserted, one group cut short to close the wound until the needles are removed, the others kept long for tying afterwards. No drainage is necessary.

Tracheotomy.—From 1924 to 1936 it was difficult to gauge the dose, and later researches showed that this probably varied from 3,000 to 13,000 r in different patients. It is not surprising, therefore, that many of them had severe reactions, with redness, filming, and oedema—particularly of the arytenoid cartilages. For fear of dyspnoea eleven tracheotomies were performed, the tubes being retained until the reaction subsided. Tracheotomy caused serious complications. All the wounds became infected and discharged pus for several weeks. The inflammation sometimes caused necrosis of the cartilages, and healing was naturally very slow. Five other patients required tracheotomy for recurrence. Since 1936 no tracheotomies have been performed after needling. It was found that if a growth was large enough to cause serious obstruction to breathing fenestration was not advisable unless one vocal cord was freely movable. Temporary dyspnoea after the operation can be relieved by retaining the intratracheal tube if necessary for a day or two. If, however, the difficulty of breathing is severe the trachea can be exposed, but not opened unless it is absolutely necessary: only two of the patients required this.

Removal of Needles.—If the wound is not inflamed and there is no swelling in the larynx the needles are usually retained for a week. For removal gas and oxygen or thiopentone can safely be given. The lower wound is opened and the needles are easily removed. Usually there is a small amount of blood-stained serum. The wound should be

washed out with acriflavine, 1:1,000, and sutured completely. "Mastisol" is painted on the skin, which is covered with a thin layer of gauze.

Wounds which become seriously infected may be very troublesome. Haemorrhage, sometimes severe, may occur. Extensive sloughing of the tissues may be caused. It is in this type of wound that perichondritis supervenes. Later on it may be followed by necrosis. The treatment of infected wounds is important. All stitches should be removed. The wound should be widely opened, if necessary under an anaesthetic. Debris and sloughs should be removed. The wound should then be packed with gauze soaked in penicillin and sulphathiazole. If the dressing is repeated frequently serious infection is usually controlled in a few days unless there is a communication with the interior of the larynx at the time of the operation which caused the infection. Such wounds may take weeks to heal.

The Dose

A colleague lecturing to students about certain cancers said, "Use radium—plenty of it." This delightful aphorism does not apply to the larynx, which is a difficult customer to please. Great care must be taken not to overdose the patient. From the physical standpoint the great advantage of the radium implant is that irradiation is highly localized, so that there is the minimum interference with unaffected tissues. On the other hand, it is virtually impossible to give a uniform dose to the whole vocal fold by this method. It is true generally, however, that when an irradiated volume is fairly small some non-uniformity in the dose distribution is tolerable provided that the lesion itself receives an adequate dose.

In first treatments, from 1924 to 1936, eight 1-mg. needles were placed touching each other in the window, their ends being tucked under the upper margin of the thyroid above and the cricoid below. It was soon realized, however, that in the middle the dose was too high, causing severe reaction or even necrosis, while at the ends it was inadequate. It varied from 13,000 to 3,000 r. In an ideal arrangement the dose in a week should be about 6,000 r to the anterior half of the cord, but there is a marked fall posteriorly to 3,000 r and also below the free margin of the cord with such short needles of only 16 mm. active length. In spite of this some surprisingly good results were obtained, although these patients must have been overdosed.

Since 1933, when the practice of removing part of the cricoid cartilage was adopted, longer needles have been used though the total amount of radium was approximately as before. As a result, a more uniform distribution of dose is obtained, particularly below the vocal fold. It has been found beneficial to add a transverse 1-mg. needle at the lower ends of the vertical needles in those cases in which the level of the vocal fold is much below the midpoint of the fenestrated area—for example, in many females or in lesions with subglottic extensions.

FIG. 8.—Dosage.

For stage I four 2-mg. needles of an active length of 32 mm. are inserted vertically and one or two 1-mg. needles transversely. The screenage of these needles is 0.8 mm. platinum, which is found to produce less local reaction than 0.5 mm.

For stage II rather larger doses are employed. Fig. 8 shows a transverse section of the larynx through the vocal fold for a typical implant of four 2-mg. and two 1-mg. needles (the second and fourth from the front) for a treatment time of one week. With this the anterior half of the vocal fold receives a dose of at least 6,000 r, and nearly all of the vocal fold at least 5,000 r. The fall-off in the dose towards the posterior end of the vocal fold may be partly counteracted by spacing the anterior needles, where the dose is high, rather more widely so that the posterior needles are closer together. In any event, the position of the needles in an implant should be checked the next day by a skiagram and the optimum treatment time for the required dose calculated. More detailed information about the dose distribution was given in 1944 in the *British Journal of Radiology* by Morton, Gray, and Neary, and there is also a good description of the operation in Ralston Paterson's *Treatment of Malignant Disease by Radium and X Rays*. An alternative method, using 1.5-mg. needles of 30 mm. active length, has been used for the vertical implant with a screenage of 0.6 mm., which appears to be nearly as satisfactory as 0.8 mm.

With a bilateral implant both sides contribute equally to the points exactly on the midline. But for a point which is not equidistant from the two implants the contribution from the implant further away is, of course, less than from the near implant. Thus the high local doses in the fenestrated area are not greatly increased by the presence of an implant on the other side. It is therefore difficult to decide, on physical grounds, how much radium is safe in a bilateral implant, since it is not enough to consider the dose at a single point, for no one point is representative for all. Except for very extensive lesions about 12 mg. seems enough.

The Voice

If treatment has been successful the growth soon begins to shrink and inflammation subsides in a few weeks; a fixed vocal cord becomes freely movable again and the resonance of the voice returns. If the disease is not arrested or if it recurs the voice does not improve. Persistent huskiness and swelling may be due to perichondritis or to growth or to both, and a biopsy should be made. Even when the growth is not arrested the report may be negative. In early stages it may be extremely difficult to distinguish these con-

ditions. If the symptoms do not improve within a month or two cancer must be suspected. It is a grave mistake to "wait and see."

Everyone knows that chemical sprays will kill weeds in a lawn and that the grass will recover. When radium is applied to a small localized growth the cancer cells die, the tissues recover, and the voice is normal. The majority of our successes have resulted in a perfect voice. When the voice remains husky it may be owing to damage when making a biopsy. A small notch may prevent perfect apposition of the cords, thus weakening the vibrations. But persistent hoarseness is a serious symptom. The treatment has probably failed, and a "spade"—laryngectomy—is advisable to dig out the weed.

To summarize, fenestration is a slight operation and can safely be performed by surgeons who have a good physicist to advise them about dosage. Not more than 12 needles are needed—a very small outlay. It is a short treatment which is completed in a week. For recurrence, if the lesion is still intrinsic, needling can be repeated. Since using well-filtered needles severe reactions have been rare. Redness, swelling, and filming are slight; oedema of the arytenoid cartilages is hardly ever troublesome. Perichondritis is uncommon and patients do not complain of dysphagia or dyspnoea. Without doubt, some of these patients could have been cured by early laryngectomies. With further experience, it will probably be found that a rule must be observed to remove the larynx unless it is normal in two months. In this series of patients very few laryngectomies were performed—and always too late.

Results

Of the 120 patients needled two went abroad and were lost sight of, as already mentioned. One was treated less than three years ago, so that 117 remain for follow-up analysis for varying periods, as follows:

Treated from 1924 to 1949, 3-year follow-up ..	117
" " " " 1947, 5- " " " "	111
" " " " 1942, 10- " " " "	92

Table IV expresses the results in terms of length of survival. The operative mortality must be regarded as high, but should be capable of improvement. Thus between 1924 and 1936 there were 6 deaths in 71 operations (8.5%), while between 1936 and 1951 there were 3 deaths in 49 operations (6.1%). Another feature of interest is that only five patients died of cancer after surviving for three years. There was no evidence, therefore, that metastases were common after needling. Cervical nodes were noted in only six patients, mediastinal deposits in five, and liver secondaries in only one.

Died of cancer or operation ..	3		1	4	1																						9
Survival at 3 years.—1 patient out of 9 treated = 11%																											
All stages:																										118	

Stage I: Early Intrinsic (37 patients).—Early lesions were confirmed by removal of the thyroid cartilage in every case. One patient died from the operation, three from cancer (one after 10 years), and sixteen from other causes. Seventeen are still living. Most of the survivors have strong resonant voices. The survival rates are shown in Table IV.

Stage II: Advanced Intrinsic (72 patients).—Usually these were unilateral, extensive, and apparently intrinsic with no enlarged lymph nodes. Twelve were bilateral. Soft tumours, if movable, responded better than the hard nodular ulcerated types. There were five operative deaths from chest infections, which were common when tracheotomies were performed, all of them before the introduction of antibiotics. Forty-two died of cancer, 31 in less than three years, six during the third year, but only five after this critical period. Among these 72 patients 26 survived with their larynges and excellent voices for periods ranging from five to twenty-four years. The survival rates are shown in Table IV.

Stage III: Extrinsic (9 patients).—These patients, who were found to have definite extrinsic lesions without obvious enlargement of cervical nodes, were needled and all of them died within three years. Needling alone has therefore been a failure. But, excepting for two who died of heart failure after operation, seven were temporarily improved for two to three years. Here again, laryngectomies should have been performed while the disease was arrested, and I regret that this was not done.

Summary

Lesions suitable for radium needling are therefore the following:

- (1) Early lesions (stage I). Even if the vocal cord is fixed. Lymph nodes are never affected in this group.
- (2) Localized lesions in the anterior commissure without involvement of the base of the epiglottis or of the tongue. In this region the dose is always a high one and needling usually succeeds in controlling the disease.
- (3) Extensive lesions that appear to be intrinsic (stage II).
- (4) Subglottic lesions (really stage III). In a few patients good results have been obtained and there is no risk in trying this treatment first, but laryngectomy should be performed early, in a month or two, if the swelling persists.
- (5) Lesions of the false cord and vestibule (stage III). These growths are unusually malignant and difficult to cure. Probably needling plus laryngectomy is the best treatment.

ENVOY

In putting on record the results of 30 years' work with this particular treatment for intrinsic carcinoma of the larynx it would seem to be reasonable to claim that the method has been unduly neglected. I am aware that as good figures have been published claiming that telerradium is superior to interstitial needling for early lesions. I have always maintained that cancer should be treated in special centres by the united efforts of a team of specialists in this disease. Yet there is still a place for simplicity in surgery, and no one can deny that the establishment and maintenance of a telerradium unit is extremely costly. Radiation techniques become increasingly complex and require more and more planning and space and time. The method which we have adopted (and which has been described, possibly a little grudgingly, as "a piece of brilliant empiricism") is relatively cheap and extremely simple in the hands of a competent surgeon. It gives really excellent results if used for the right patient. And it is here, of course, that the clinical experience gained in a long apprenticeship in laryngology counts.

The proof of the pudding is in the eating. I think that this has been a good pudding and that it would be a pity if the recipe were lost.

FOLIC-ACID-EXCRETION STUDIES IN THE INVESTIGATION OF MALIGNANT DISEASE

BY

RONALD H. GIRDWOOD, Ph.D., M.B., Ch.B.
F.R.C.P.Ed., M.R.C.P.

Senior Lecturer in Medicine, University of Edinburgh

When a test dose of 5 mg. of folic acid is injected in a normal individual a significant proportion is promptly excreted in the urine. Most of this excretion occurs within a few hours, but for metabolic studies it is advisable to collect the urine for twenty-four hours after the injection. It has been shown that the urinary excretion of folic acid is diminished in many cases of pernicious anaemia (Bethell *et al.*, 1947; Girdwood, 1951, 1953). In a short review of the subject (Girdwood, 1952a) it was suggested that the controls used in the studies of pernicious anaemia patients were unsatisfactory, and that patients with other forms of anaemia should be employed. Accordingly the present investigation was started as a study of folic acid excretion in various types of anaemia. At an early stage it was found (Girdwood, 1952b) that, of eight patients with iron deficiency anaemia, folic-acid excretion was diminished in four. All of these four suffered from carcinoma. It was decided, therefore, to investigate further the urinary folic-acid excretion in patients suffering from malignant disease and from various non-neoplastic conditions. About this time it was reported (Swendseid *et al.*, 1952) that folic-acid excretion was impaired in leukaemia. The patients in the present investigation were all given 5 mg. of folic acid subcutaneously.

Methods and Materials

The estimation of the urinary content of folic acid was carried out microbiologically. Under the conditions of the test the growth of *Streptococcus faecalis* in a suitable medium depends upon the amount of folic acid present in that medium. The growth of the test organism in tubes containing that medium and various dilutions of urine is compared with that in tubes containing the medium and dilutions of a standard solution of folic acid.

Estimations of folic acid were by the method of Teply and Elvehjem (1945), *Str. faecalis* R being used as the test organism. Estimations of citrovorum factor were by a modification of the method of Sauberlich and Baumann (1948) with *Leuconostoc citrovorum* as the test organism. In both instances turbidity readings were carried out in a Spekker photo-electric absorptiometer after incubation at 37° C. for 16 hours. The resting urinary content of folic acid is so small that no correction requires to be made for it in the folic-acid readings. The proportion of folic acid excreted as citrovorum factor is very small, as shown in the accompanying Tables, and the "folic acid" figures include any growth activity due to citrovorum factor. The citrovorum-factor readings have not been corrected for the resting urinary content of citrovorum factor, which on the average is of the order of 1 µg.

The folic acid was given by subcutaneous injection from a tuberculin syringe, and was taken from one or other of two batches of "folvite" that had been tested by us and found to contain 15 mg. of folic acid per ml. Several batches were rejected as they contained more than the stated amount. The volume injected was 0.33 ml.

Twenty-four-hour urine collections were put in brown bottles containing toluene and a phosphate buffer of pH 6.8. The greatest possible care was taken to ensure that the urines were total 24-hour specimens. The specimens were kept in a refrigerator at 4° C., and readings were usually

made within three days. All readings were at least in duplicate, usually triplicate. No antibiotics or sulphonamides were given to the patients during the period of the test.

Results

Folic-acid Excretion in Patients Not Suffering from Malignant Disease, Pernicious Anaemia, Intestinal Malabsorption, or Prolonged Infection

The results of the urinary excretion of folic acid in a number of patients with various non-malignant diseases are given in Table I. It will be seen that the only patient in whom the excretion was less than 30% of the dose administered (less than 1.5 mg.) was a man with severe congestive cardiac failure and oedema (Case 43). Two patients, one with a large pleural effusion and the other with massive ascites, are not included; in both instances folic-acid excretion was impaired, but it was possible to show that much of the vitamin was present in the effusion, and that urinary excretion took place over several days. These results suggest that in a patient with normal renal function and without oedema or a large effusion the 24-hour urinary excretion of a 5-mg. dose of folic acid should be greater than 1.5 mg.

It will be seen from Table I that anaemia in itself, even if severe, does not cause an abnormally low folic-acid excretion following a 5-mg. test dose. The same is true of hepatic cirrhosis.

Folic-acid Excretion in Patients Suffering from Malignant Disease and Allied Conditions

In Table II there are given the urinary folic-acid excretion results in a number of persons suspected of having malignant disease (including leukaemia and the reticuloses) or found as a result of hospital investigation to be so afflicted. The Table is constructed so as to include the provisional diagnosis when the patient was first seen in connexion with the present investigation. Thus in many instances it was not known whether or not malignancy was present, and it will be seen that in some cases it was fortunately possible to show that no neoplastic disease existed. In the cases included in this Table the final diagnosis had been definitely established, in many instances by biopsy or laparotomy. Most of the patients included in Table II had had no therapy, but a few had been treated by x rays or other means several months before the present investigation.

It will be seen from Table II that a normal folic-acid excretion (1.5 mg. or less after the subcutaneous injection of 5 mg.) is of no help in excluding the presence of malignancy. Fourteen patients with carcinoma, leukaemia, lymphadenoma, or some other form of reticulosis had a normal folic-acid excretion. It is true that in most of these cases the general condition was good and there was little evidence of spread, but this was not so in Cases 53, 64, 66, and 73. Case 63 suffered from weakness and pyrexia, but no abnormality was found on physical examination. The diagnosis of lymphadenoma at the time of the folic-acid test was made only by exclusion and treatment with nitrogen mustard was begun. Despite the satisfactory folic-acid test, the diagnosis of lymphadenoma was confirmed at necropsy only three months later. Case 51 felt so well despite the abnormal blood picture that no treatment was given.

Inspection of the records of cases in Table II who excreted less than 1.5 mg. of folic acid shows that all of them suffered from malignant disease. In some instances the folic-acid-excretion results were available some time before the presence of malignancy was established by x-ray films, biopsy, or laparotomy. Obvious weight loss was not invariably present in patients with a positive test. It will be seen, too, that there was no correlation between the sedimentation rate or the degree of anaemia and the result of the folic-acid-excretion test in either malignant or non-malignant cases.

Folic-acid Excretion in Chronic Infection

There are occasions on which it would be helpful to have a test to determine whether a patient suffers from chronic infection or from malignancy. For this reason a separate table (Table III) has been constructed to include untreated patients with chronic infections and collagen diseases. In all the cases of pulmonary tuberculosis the disease was extensive, but except in Cases 106 and 115 the general condition under a sanatorium regime was good.

Case 118 illustrates most clearly that prolonged generalized bacterial infection can give a diminished output of folic acid after a test dose. No treatment had been given for a year.

In Case 115 the possibility that amyloid tissue has an affinity for folic acid would require consideration.

It is possible that the diagnosis in Case 117 was incorrect, as there was an increase in plasma cells in the marrow, and the symptoms and fever did not respond to salicylates.

Case 114 is of interest in that the patient's general condition was good, and the only obvious abnormality was splenic enlargement. Nevertheless the test was positive.

Four patients with pyrexia, the cause of which is not yet certain, are included to show that prolonged fever will not itself necessarily lead to a diminished excretion of folic acid. In this respect Case 99 is of interest in that quite high fever—rising to 103° F. (39.4° C.)—has been present intermittently for 18 months without evidence of general deterioration. The diagnosis of Case 108 is uncertain, but,

although emaciation was severe, folic-acid excretion was normal. Case 116 (lupus erythematosus disseminatus) was also much wasted, and, although cortisone therapy led to marked clinical improvement, the folic-acid excretion remained abnormal in this patient.

Folic-acid Excretion in Megaloblastic Anaemia

This is the subject of other communications (Girdwood, 1951, 1953), and hence the only information required here is a summary of the findings in 20 cases of untreated pernicious anaemia, 2 cases of intestinal malabsorption that had

TABLE II.—Folic-acid Excretion in Patients Suspected of Having Malignant Disease

not received folic acid, vitamin B₁₂, or citrovorum factor, 7 cases of megaloblastic anaemia of pregnancy, and 1 case of idiopathic refractory megaloblastic anaemia.

TABLE IV.—Folic-acid Excretion in Megaloblastic Anaemia (Untreated)

	No. of Cases	Folic-acid Excretion (mg.) Following a 5-mg. Test Dose given Subcutaneously
Pernicious anaemia	20	0.066–3.08 (mean 1.55)
Intestinal malabsorption	2	0.126, 0.299
Pregnancy (megaloblasts, not transitional erythroblasts, present)	4	1.33, 1.50, 2.37, 2.64
Idiopathic refractory megaloblastic anaemia	3*	1.58, 1.75, 3.84
	1	1.92

* Received 15 mg. of folic acid by injection.

In all these patients the marrow was frankly megaloblastic: examples where transitional erythroblasts were found are recorded separately (Girdwood, 1953).

It will be noted from Table IV that in megaloblastic anaemia of pregnancy folic-acid excretion may be normal. Of the 20 pernicious-anaemia patients, 9 had an excretion of less than 1.5 mg.

Discussion

These results suggest that the folic-acid excretion test may have a limited place in the investigation of puzzling cases. Many more cases must be studied before we can say to what extent the test is of value in differentiating between such conditions as aplastic anaemia and aleukaemic leukaemia or simple iron-deficiency anaemia and iron-deficiency anaemia associated with advanced malignant disease. It is obvious that a "negative" test (normal excretion) is of no assistance to the clinician in the diagnosis of malignancy, since in 14 cases a normal excretion of folic acid was found. On the other hand, where there is no evidence of intestinal malabsorption, prolonged fever, megaloblastic anaemia, a large effusion or generalized oedema, and where renal function is not impaired, a "positive test" (an excretion of less than 30% of a 5-mg. test dose) would appear to suggest the presence of malignancy. Further investigations may show additional exceptions to this generalization. It is important that an exact dosage of folic acid should be given, and the urine collection must be complete. We have found that a

repetition of the test dose may give a less abnormal finding on the second occasion, possibly because the first 5 mg. of folic acid partially corrects the folic-acid deficiency in the tissues.

It is not certain what a diminished urinary excretion of folic acid indicates. In nutritional megaloblastic anaemia, and in untreated cases of intestinal malabsorption, the presence of megaloblasts in the marrow is taken to indicate deficiency of folic acid or of vitamin B₁₂. In untreated pernicious anaemia, in which the primary deficiency is believed to be of vitamin B₁₂, folic-acid excretion following a test dose is frequently low, but can be normal. Moreover, transitional erythroblasts rather than true megaloblasts may be found in association with either a normal or an abnormal output of folic acid. The excretion in megaloblastic anaemia of pregnancy may be normal or abnormal, and this is discussed elsewhere (Girdwood, 1953). In malignant disease the amount of the test dose of folic acid excreted may be much diminished, but megaloblasts are only very rarely found in the marrow. They were not seen in any of the cases reported here.

One possible explanation both of the absence of megaloblasts and of the low urinary excretion of folic acid would be that the tumour tissue competes with the host for folic acid or its derivatives, but not to the extent of depriving the red-cell precursors of enough folic acid for maturation along normoblastic lines. Such a possibility is understandable where there is widespread malignancy as in leukaemia (for example, Case 84, in which the illness had been of only three weeks' duration and there would hardly be time for any other mechanism to play a part). The occurrence of megaloblastosis cannot be related directly to the degree of impairment of urinary folic-acid excretion, since the mechanism of production of megaloblastic change in the marrow varies in different conditions. It is possible that where the primary fault is virtual absence of folic acid or associated substances from the diet, or malabsorption of the folic-acid group of vitamins, a greatly diminished urinary output of administered folic acid will be associated with megaloblastosis; but we have seen that where the primary fault is the absence of vitamin B₁₂, or where there seems to be mal-utilization of folic acid in the body (for example, pregnancy megaloblastic anaemia) this relationship does not necessarily hold.

THE PREVALENCE OF FOOT DEFECTS AMONG WARTIME RECRUITS

(Institute of Social Medicine, Oxford)

Other modes of production of the apparent folic-acid deficiency in cases of malignant disease that merit consideration are deficient intake due to anorexia with resulting primary malnutrition, and diminished absorption produced by widespread metastases or some other means.

It seems unlikely that either of these mechanisms could operate without significant weight loss occurring, and there was little or no weight loss in Cases 74, 76, 77, 81, 84, 88, 90, 95, and 114. Moreover, in Cases 77 and 114 there was no evidence at operation of any cause for intestinal malabsorption. This was true also at post-mortem examination in Cases 88 and 95.

In contrast, there was very severe primary malnutrition of many years' duration in Cases 40, 41, and 42, as established by a detailed dietetic investigation. An important source of calories for Case 40 was whisky. Case 41 weighed only 4 st. 12 lb. (30.8 kg.): a fat-balance test in this patient revealed normal fat absorption. A post-mortem examination of Case 42 revealed no abnormality other than generalized wasting.

Nevertheless these patients, while excreting less of the administered folic acid than did most of the other control cases, were able to excrete 1.5 mg. or more.

It is, of course, possible that several factors operate to give a diminished folic-acid excretion in some patients with malignant disease. Thus it would be reasonable to assume that intestinal malabsorption was an important cause in Case 79. Recently a folic-acid-absorption test has been devised for measurement of absorption of folic acid from the alimentary tract (Girdwood, 1953), and it may be that the application of this test to cases similar to those in Table II will be of value.

The data given do not indicate whether the result of the folic-acid-excretion test is of help in assessing the prognosis or of value in considering the best method of treatment to adopt, especially in patients with leukaemia or some form of reticulosis. Case 63 had a normal folic-acid excretion and died within three months. Case 87 had a very abnormal excretion, but is alive and well following x-ray therapy.

Summary

A test dose of 5 mg. of folic acid was given subcutaneously to 148 patients. The urinary excretion of folic acid usually exceeds 30% of the test dose, and an excretion of less than 1.5 mg. is recorded as a "positive" test.

The test may be positive in megaloblastic anaemia, but there is no evidence that anaemia in itself gives a diminished excretion.

Where renal function is good and the patient does not suffer from megaloblastic anaemia, intestinal malabsorption, generalized oedema, a large effusion, or severe infection of long duration, a positive test is likely to indicate the presence of advanced malignant disease. It is, however, possible to have advanced malignancy with a negative folic-acid test.

This work was made possible by the kind co-operation of many physicians, surgeons, and nursing sisters in numerous hospitals in Edinburgh and district. I wish to thank them, Mr. Robert Brown, for performing many of the assays, and Professor L. S. P. Davidson for helpful advice. Financial assistance was obtained from the John Risk Bequest. Dr. A. T. Mennie, of Lederle Laboratories Div., Cyanamid Products Ltd., kindly supplied the folvite.

There is a general, if unconfirmed, impression that foot defects are common, painful, and incapacitating enough to justify more attention than they have hitherto received from epidemiologists. A recent survey in Luton has indicated the number of persons who themselves complain of foot trouble (Dykes, Grundy, and Lee, 1952), but assessments of incidence based on clinical observations are mainly confined to children (Emslie, 1939; Wilkins, 1941), young women (Alford and Gorrie, 1952), and aged persons (Sheldon, 1948). In the present investigation the registers of Civilian Medical Boards, which are more fully described elsewhere (Martin, 1949; Clements and Pickett, 1952) have been used to obtain an estimate of the prevalence of foot defects in men of working age and, where possible, to identify predisposing factors.

The registers used in the present survey relate to men who were called up in 1941 and examined in Leicester. According to the official instructions circulated to the Medical Boards, "special attention should always be drawn to the defects which may cause a man to be classified in one of the lower grades of fitness for military service, or which may influence decision on possible claims for pension in the future: these should be described as in a clinical report." The instructions stress the importance of recording all types of foot defect and state that a detailed examination of the feet may be omitted only if a man is so severely disabled in other respects as to be totally unfit for military service. There were 358 such cases in the Leicester records. After the exclusion of these, and of a further 93 over 45 years of age, there remained 22,843 men between the ages of 17 and 44, of whom 3,287 (14.4%) shared 4,160 foot defects.

Age Distribution and Interrelation of Foot Defects

The distribution of foot defects by age and diagnosis is shown in Table I. The two categories of flat-foot distinguish cases in which the arch could be restored by standing on tip-toe (mobile, or A cases), and cases in which the

TABLE I.—Foot Defects Recorded at Specified Ages: Men Examined at Leicester in 1941

Defect	Cases per 1,000 Examinees Aged						Total No. of Cases
	17-19	20-24	25-29	30-34	35-39	40-44	
Of longitudinal arch:							
Flat-foot (A cases)	38.9	38.6	36.7	39.0	36.6	45.6	880
" (B " ")	8.5	11.6	20.4	24.6	34.8	38.2	502
Pes cavus	5.2	7.9	10.7	11.2	14.4	12.7	233
Of forefoot:							
Hammer-toe	20.5	32.5	44.1	48.4	61.9	67.1	1,003
Hallux valgus	13.9	15.1	26.0	33.5	40.0	46.9	640
" rigidus	2.3	1.8	7.4	7.3	8.4	6.0	126
Overlapping toes	12.0	12.7	17.2	21.1	22.7	20.1	405
Other:							
Callusities	5.0	5.5	10.7	21.1	25.8	26.2	356
Miscellaneous	0.8	0.5	0.9	1.0	0.4	0.0	15
No. of examinees	4,835	3,786	2,153	5,082	5,496	1,491	22,843

longitudinal arch had permanently disappeared (rigid, or B cases).^{*} The category "miscellaneous" includes deformed nails (5), extra toes (3), skin pedicles (2), webbed toes (1), and four undiagnosed cases.

According to Table I the A cases of flat-foot showed a fairly level age incidence, but the B cases increased steadily with age to become four times as common in the early forties as in the late teens. In theory this discrepancy can be accounted for in several ways, but the most likely explanation (which assumes that the A cases represent a stage between normality and total extinction of the longitudinal arch) is that new cases were occurring between the ages of 17 and 44 at roughly the same rate as established cases were progressing to an irreversible stage. If, however, the A and B cases of flat-foot are two distinct clinical entities then the figures in Table I can be explained only by assuming that (1) mobile as well as rigid flat-foot is an irreversible condition; (2) regularly throughout the age group 17 to 44 years new cases of rigid flat-foot continued to develop *de novo*; and (3) virtually all the cases of mobile flat-foot were manifested before the age of 17.

Table I also shows the incidence of metatarsal and related defects at various ages. The two most common conditions in this group show a rising age incidence, and by the early forties nearly 7% of men had hammer-toes, and nearly 5% had hallux valgus. A similar though less noticeable increase with age is seen in the case of callosities and overlapping toes, but the incidence of hallux rigidus shows little variation within the age range 17-44. There was also a distinct tendency for foot defects, especially when severe, to occur together. A measure of this tendency is shown in Table II.

TABLE II.—Frequency of Multiple Foot Defects

r	No. of Men with r Defects	Expected No. of Men with r Defects, on the Assumption that Defects Occur Independently
0	19,564	18,970
1	2,554	3,594
2	584	267
3	129	
4	11	12
More than 4	1	
All	22,843	22,843

which gives the actual number of men having 0, 1, 2, 3, 4, and more than 4 defects and the numbers to have been expected if each defect had occurred independently.

The expected figures were obtained by multiplying the appropriate proportions and summing when necessary. For example, the expected proportion with exactly one defect

was $\sum_i \left\{ \frac{p_i}{1 - p_i} \left[1 - (1 - p_i) \right] \right\}$ in which p_i stands for the

proportion of men with the i th defect. In this calculation both categories of flat-foot are, of course, treated as one defect, since by definition they cannot occur together.

It will be seen that isolated defects occurred with less than three-quarters, pairs of defects with over twice, and three or more defects with nearly twelve times their expected frequency. The following list shows the extent to which particular defects tended to be associated, the figure beside each defect being the ratio of the number of times it was found in conjunction with other defects to the expected number, in the sense defined above: callosities, 4.75; flat-foot (B cases), 3.59; hallux valgus, 3.54; hallux rigidus, 3.10; overlapping toes, 3.05; hammer-toe, 2.80; pes cavus, 2.76; flat-foot (A cases), 0.64. The position of callosities at

^{*}According to the official instructions, all A cases were automatically placed in the top fitness category (Medical Grade I) and B cases in Medical Grade IIa (feet), but in the presence of more disabling conditions the medical grade no longer serves to distinguish the two groups. These cases had to be "placed" at the time of coding and the convention was adopted that, in the absence of fuller clinical descriptions, all cases of "mild" or "slight" flat-foot should be coded A and all cases of "severe" or "disabling" flat-foot coded B.

the head of the list reminds us that these painful skin lesions are apt to accompany every variety of bony displacement. The list also shows that mobile flat-foot is rarely and rigid flat-foot commonly found in association with other deformities. This suggests that by the time other lesions have developed in flat-footed persons the longitudinal arch has usually disappeared.

The analysis of multiple defects was carried one stage further by calculating "association" ratios for specific pairings of defects. The two most frequent pairings were hammer-toe and callosities (121 times) and hallux valgus and hammer-toe (104 times), but for several other well-known combinations the excess relative to the "expected" number of cases was even greater. Thus hallux valgus and overlapping toes were eight times, hallux rigidus and flat-foot seven times, and pes cavus and hammer-toe four times, as common as they would have been if they were independent lesions.

The tendency for bony deformities of the foot to be found in association with diseases which affect other parts of the skeleton was also studied and foot defects were found to be especially common in persons who had had the paralytic form of poliomyelitis. There were also significant associations for lower limb injuries, curvature of the spine, rheumatoid arthritis, and for a mixed group of skeletal conditions mainly composed of operations on the lower limb and undiagnosed wasting of leg muscles.

Relation of Foot Defects to Body Size and Build

According to Lake (1943) the human foot is still imperfectly adapted to the extra strain imposed upon it by the upright posture. Since this strain is related to body build it was thought worth while to examine the association between overt foot defects and certain measurements recorded at the time of the medical board.

In Table III the number of men ($\times 100$) with foot defects who fall into eight weight groups has been compared with the number to have been expected if the risk of foot troubles were independent of weight. The corresponding analysis for height is shown in Table IV. In both tables the age distribution of the different groups has been taken into consideration. The numbers on which the ratios are based have also been subjected to a statistical test which measures the likelihood of obtaining so large a departure from expectation as a result of chance fluctuations only. The results of these χ^2 tests are shown in the right-hand column of the table.

For foot defects as a whole (bottom line of Table III) there was no perceptible association with body weight, but a few specific conditions revealed statistically significant departures from expectation. The most definite of these associations were the exceptionally high ratios for rigid flat-foot, pes cavus, and overlapping toes in men weighing less than 110 lb. (49.9 kg.). The findings for A cases of flat-foot were inconclusive, but the highest ratio was at the heavy end of the weight scale, whereas for B cases it was at the lowest end.

For all types of foot defect taken together the association with height was much stronger than that with weight, and there were also significant associations for several individual lesions (see Table IV). Once again, however, the findings were not straightforward. Thus, overlapping toes were less common among medium-sized men than among either tall or short men; both categories of flat-foot had a maximum incidence in short men, and all the metatarsal deformities gave high ratios at or near the top of the height scale. In the extreme case of hammer-toe the risk for men of 70 in. (178 cm.) or taller was over twice as great as for men of 64 in. (162.5 cm.) or shorter. There are no measurements of foot length in civilian medical board records, but Morant and Gilson (1945), who studied men in the Royal Air Force, found that the coefficients of correlation between foot length and height, and foot length and weight, were +0.700 and +0.557 respectively. This may account for the departures from level incidence associated with variations in height being greater than those associated with weight.

TABLE III.—Relation Between Body Weight and Incidence of Foot Defects. Standardized for Age (Standard Incidence=100)

Foot Defect	Weight (lb.)										Probability (P) that the Observed Departures from Standard Incidence could have Arisen by Chance
	< 100	< 110	< 120	< 130	< 140	< 150	< 160	< 170	< 190	190 +

Callosities ..			94	87	115		144	0.01 > P > 0.001
One or more of the above	106	96	94	95	102	118	121	0.01 > P > 0.001

Considering the close association between weight and height (the coefficient of correlation for the present set of records was +0.725) there were remarkably few examples of contrasts between light and heavy men appearing again as contrasts between short and tall men. On the other hand, there were several examples of the same risks for short men and heavy men—for example, flat-foot—and for tall men and light men—for example, hammer-toe. It is clear, therefore, that certain foot defects are as closely related to general build as to absolute size.

An attempt was made to measure the relationship between foot defects and body shape, but only three measurements were available for the purpose—namely, height, weight, and chest circumference.

Chart showing relation between body shape and incidence of foot defects, standardized for age. (Standard incidence=100.) Probability that observed departures from standard incidence could have arisen by chance: Flat-foot (broken line), 0.01 > P > 0.001; forefoot defects (continuous line), P < 0.001.

root of the weight in pounds) has a minimum value for a perfectly spherical body, and increases with increasing linearity of build. In adult males the normal range of variation of this index is from 11½ to 14½. Since the index tends to fall with age, the incidence ratios plotted in the Chart have been standardized for age in the same way as the separate ratios for height and weight. The diagram traces the relationship between the body-build index and the incidence of two groups of foot defect—namely, tarsal (that is, both grades of flat-foot) and metatarsal (that is, hallux valgus, hallux rigidus, overlapping toes, and hammer-toe, either alone or in combination). The

figure shows that for stocky men, with low values of the body-build index, flat-foot occurred in excess. It is possible, therefore, that overweight, or some associated condition, predisposes to this type of foot defect. The incidence of metatarsal defects, however, rose continuously with increasing linearity of build, and the risk appeared to double within the observed range of the index. For these cases, therefore, it is more reasonable to look for causes associated with underweight or slender build.

Relation of Foot Ailments to Economic Circumstances and Occupation

According to the Foot Health Educational Bureau (1949) "Exact figures are hard to come by, but, though as yet we have no unselected random sample of foot conditions among adult groups in Great Britain, it is probably correct to say that ailments of the feet . . . are distributed irrespective of income level." From an analysis of the civilian medical board records, however, it appears that this statement is almost certainly incorrect (see Table V).

TABLE V.—Relation Between Social Class and Incidence of Foot Defects. Standardized for Age (Standard Incidence=100)

Foot Defect	Social Class (according to Registrar-Gen.)					Probability (P) that the Observed Departures from Standard Incidence could have Arisen by Chance
	I	II	III	IV	V	
Flat-foot (A cases)	70	104	110	94		0.02 > P > 0.01
" (B cases)	79	96	107	139		0.01 > P > 0.001
" (total)	73	101	109	111		0.01 > P > 0.001
Pes cavus	101	98	119			0.70 > P > 0.50
Hammer-toe	82	99	115	106		0.10 > P > 0.05
Hallux valgus	68	98	108	132		0.01 > P > 0.001
" rigidus	149	91	103			0.20 > P > 0.10
Overlapping toes	68	98	122	118		0.05 > P > 0.02
Callosities	74	96	110	139		0.05 > P > 0.02
One or more of the above	60	80	100	108	112	0.001 > P

The age-standardized ratios for all foot defects except hallux rigidus showed a marked social class gradient, with the highest incidence among unskilled and semi-skilled workers. But a separate analysis of the two varieties of flat-foot showed that it was only the B cases which tended to concentrate in the lower-income groups. A possible explanation of this difference is that economic factors are more potent to aggravate pre-existing conditions than to initiate new lesions.

The relatively level social class and age distributions of hallux rigidus are in marked contrast with the corresponding gradients for hallux valgus and rigid flat-foot. The contrast between hallux rigidus and hallux valgus corresponds to known differences between the aetiology of these two conditions, but that between hallux rigidus and rigid flat-foot is at first sight difficult to reconcile with the orthodox view that a flat-footed gait predisposes to osteoarthritis of the first metatarso-phalangeal joint. Provided, however, a majority of cases of hallux rigidus are due to causes other than flat-foot, there is no contradiction between the findings of the present investigation and accepted clinical opinion.

Table VI summarizes the results of an attempt to relate the risk of foot defects to strictly occupational influences, as distinct from risks associated with low economic status. Table VI abounds with examples of significant departures from standard incidence, but it is clear that many of these only reflect the earlier analysis by social class. There are, however, a few findings which cannot be accounted for on this score and suggest the possibility of more specific occupational influences. For instance, (1) shoe operatives had an exceptionally low incidence of hammer-toe but a high incidence of overlapping toes; (2) the group of lathe operators and testers had a high incidence of flat-foot and an unusually low incidence of hammer-toe; (3) transport workers had a high incidence of foot defects in general, and of flat-foot in particular; and (4) workers in farming and building had a large excess of pes cavus. With the data available it was not possible to explore these relationships further, but they offer promise that survey of footwear and "foot work" in selected industries would yield some interesting results.

Discussion

In the case of a disease, such as tuberculosis, which has been intensively studied from the statistical angle, even the minutiae of survey findings can usually be seen in their proper perspective. When, however, an epidemiologist attempts to use survey data for a study of foot defects he soon discovers that there is no ready-made context for his findings. The present study has resulted in a collection of miscellaneous facts which, like the pieces of a jigsaw puzzle, are tantalizingly rich in detail but lacking in general coherence. Nevertheless a start must be made some time, and, though the present investigation has left nothing fully proved, it does suggest some new lines of inquiry.

It is possible, for instance, that the variations in incidence of foot defects which have been found to be associated with variations in body build and social class reflect the fact that there is not, in this country, a wide enough range of shoe shapes and sizes to cope with the general need. Or that, if there is, the need remains unsatisfied because the public does not realize the dangers of ill-fitting shoes. This

theory rests on two basic assumptions. The first is that the relationship between foot shape and body shape is such that persons of stocky build have feet which are disproportionately broad, and persons of slender build have feet which are disproportionately narrow. If this is so, then the fact that stocky men have emerged as bad risks in respect of flat-foot, and slender men as bad risks in respect of pes cavus and metatarsal deformities, may be due to the former being forced to wear shoes which are too long for the necessary width and the latter shoes which are too short.

The second assumption, which is introduced to explain the contrasts between tall and short men, is that the feet of tall men grow faster (as well as longer) than the feet of short men. The argument runs as follows: parents of children whose feet grow exceptionally slowly or exceptionally fast tend to misjudge the time taken to outgrow a new pair of shoes. As a result the slow growers (who are destined to be short men) spend most of their youth in shoes which are too big, and the fast growers in shoes which are too small. Finally, the social class gradient is accounted for by supposing that cheap shoes do more harm than expensive shoes, and that working-class parents find it particularly difficult to keep pace with the needs of growing children.

This is a highly speculative theory, and it is doubtful whether it would ever be possible to test it at all points, even if it proved acceptable to orthopaedic specialists. It will, however, have served its purpose if it shows how valuable it would be to know more about the relationship of body build to foot shape and the relationship of shoe habits to foot defects.

Summary

In a sample of 22,843 men aged 17 to 44 who were examined at Leicester in 1941, it was found that:

1. There was an increase with age in the incidence of rigid flat-foot, hammer-toe, hallux valgus, callosities, overlapping toes, and pes cavus. Hallux rigidus and mobile flat-foot showed a relatively even age incidence.
2. There was a real tendency for foot defects to occur in association with one another and with certain other skeletal defects.
3. Tall men suffered more often than short men from metatarsal defects (hallux rigidus excepted), but flat-foot more commonly affected short than tall men.
4. The risk of metatarsal defects increased continuously with increasing "linearity" of body build (as measured by the index $Ht \div \sqrt{Wt}$). Flat-foot, on the other hand, was more common among men of stocky build.

INCIDENCE, ORIGIN, AND PREVENTION OF CERTAIN FOOT DEFECTS*

BY

DORIS A. CRAIGMILE, M.D., C.P.H., D.R.C.O.G.
Assistant Area Medical Officer, Middlesex County Council
(Area 7)

As the public know well, and hospitals' and chiropodists' reports confirm, many otherwise healthy adults suffer from foot trouble. A preliminary investigation in schools in Ealing (Craigmile, 1950) showed that many of the causes of adult foot disability were already present in the older schoolchildren. As a result of this, a routine foot inspection was begun in all maintained schools in the area. Until recently (Dykes *et al.*, 1952) there was no published report of the foot health of a normal population, and a survey of a factory in the area was made to determine the extent and chief causes of foot trouble in a normal working population. The results of this survey are in many respects confirmatory of the report of this survey at Luton, although undertaken on a different population and by different methods.

It soon became apparent that many foot troubles, while not present in the infant, began early in life and were due to stresses and strains imposed on an otherwise normal foot by modern conditions. Many of these

Survey II: Schoolchildren

The area under review covers both closely populated and semirural districts. About half the total school population was examined and all types of school were represented. The same two observers saw the children, and particular attention was paid to conditions likely to be precursors of adult foot trouble. Advice and treatment were given, where necessary at special sessions, and proved a valuable method of health education.

The results of the inspection of the 12,765 children are summarized in Table III.

TABLE III.—Percentage of Certain Defects Found in Schoolchildren on Routine Foot Inspection

Age Group	No. of Children	Proximal Hallux Valgus	Varus 1st Metatarsal	Cramped Toes	Valgus Ankles	Pes Cavus	Verrucae	Tinea	Unsatisfactory Footwear	Treatment Required

Hallux Valgus

This deformity is of two distinct types. The distal or interphalangeal type does not give rise to pain in adult life, and, while it appears to be congenital in some children, occurs with generalized cramping in association with short footwear (see Table IV). The proximal type is an important cause of pain in adult life, occurring most often in

TABLE IV.—Percentage of Cases of Proximal and Distal Hallux Valgus in Boys and Girls in Relation to Age and Suitability of Shoes Worn

Age Group	Good Shoes			Bad Shoes		
	No. of Children	Proximal Hallux Valgus %	Distal Hallux Valgus %	No. of Children	Proximal Hallux Valgus %	Distal Hallux Valgus %

TABLE V.—Percentage of Cases of Proximal Hallux Valgus Found, and the Angle of Deflection, at Different Ages

Age Group	% of Proximal Hallux Valgus	Mean Deviation of Hallux	Range of Deviation
Infants, 5-7 years	0.1	5.0 degrees	3-18 degrees
Juniors, 8-11 "	2.0	8.5 "	5-16 "
Senior boys, 12-15 years	2.4	10.7 "	5-28 "
Senior girls, 12-15 "	8.7	16.5 "	7-35 "

women. In schoolchildren this end-result can be seen in process of development (see Table V). A comparison of junior and senior children shows that three times as many girls had hallux valgus and with a greater mean angle of deflection. This implies that factors which result in many women suffering from bunions start to operate in the middle years of childhood and become fully active before the union of the metatarsal epiphyses.

In an attempt to assess the causes of this deformity various possibilities were considered: the intrinsic action of a short or a varus first metatarsal bone, or a pronated forefoot, and the action of extrinsic factors.

A short first metatarsal bone occurred in 39.4% of children and showed no age or sex differentiation; its presence was not closely related to hallux valgus. The intermetatarsal angle decreases with age (Keith, 1931) but a wider angle appears more common in females (Hardy and Clapham, 1952). Children with this variation from normal have difficulty in finding shoes broad enough for their feet, and, in order to eliminate this extrinsic factor, the combination of metatarsus primus varus and hallux valgus in children who wore good shoes was examined. These figures (Table VI) show no significant correlation. In other words, this suggests that metatarsus primus varus is not in itself an exciting cause of hallux valgus. It may, however, be a predisposing cause.

The pronated forefoot appears to be related to hallux valgus of both proximal and distal types. In children who wore good shoes the probability of association was 0.01, and therefore unlikely to have arisen by chance.

There is an increase in the number of children wearing badly fitting shoes with age, the senior girls being far the worst group. A study of Table IV shows that there is a great increase in both types of hallux valgus with bad footwear. This increases with age, and is maximal among senior girls. Examination of the shoes showed two patterns which appeared particularly detrimental: the first type had sharply pointed toes, and the second was the "flatie" or "casual," which gives no support to the instep and therefore increases any tendency to pronation as well as cramping the toes.

TABLE VI.—Relationship Between Metatarsus Primus Varus and Hallux Valgus in Children Wearing Good Shoes

Sex	No. Examined	No. of Cases Metatarsus Primus Varus Alone	No. of Cases Hallux Valgus Alone	No. of Cases Combined Defect	χ^2	Probability
Boys	1,875	445	85	34	0.611	0.80 (Not significant)
Girls	1,962	411	122	49	0.518	0.90 (Not significant)

Deformed Toes and Flat Foot

Hammer-toes and mallet-toes showed a constant percentage of 1.7 for all ages. While about 99% of the children over 10 years of age have some twisting of the fifth toe, this was symptomless in many cases. Cramping of all toes associated with signs of pressure was found in about 10% of the children and was closely associated with tight shoes.

Of the main types of flat-foot, the stable low-arched foot was very common and, as in the adult, it was symptomless. Pronation of the forefoot is, however, important as a potential cause of future pain. It is very common in the pre-school group, but only about 5% of cases persist into school life. Pronated forefeet are also closely associated with hallux valgus.

Pes Cavus

Pes cavus may be congenital or acquired, and of the latter type, as well as those secondary to neuromuscular causes, there are many idiopathic cases. These latter are of interest in that they, alone of all structural foot defects, are more common in boys than in girls. This pes cavus was not related to heel-height, but was associated with short shoes. (B.B.S.A.T.R.A. Research Report No. 107).

Survey III: Ealing Contributory Shoe Scheme

This scheme was open to all children attending one welfare centre and one school in the area. It was designed to be financially self-supporting. For a lump sum, payable in instalments before entry, the child was able to obtain three pairs of walking-shoes and one pair of sandals each year. Careful medical supervision of the feet was undertaken at intervals of ten weeks throughout the year, and a general physical examination was made on entry to the scheme.

The scheme was made possible by the co-operation and interest of Messrs. James Southall & Co., who supplied the shoes, and of their two agents in the area.

At the first examination it was decided whether the standard shoes should be worn or if any modifications were required; this was noted on the voucher with which the shoes were purchased. In special cases joint consultations were made with the shop managers or the technical adviser to Messrs. Southall. Assistants who had special training in children's fittings supplied the shoes from a full range of four fittings to each half-size.

The scheme ran for two years, fresh entrants being accepted for the second year, and 164 children were studied (Table VII). The information obtained may be divided into non-medical data and facts of more direct medical value. As had been estimated, three pairs of strong shoes were just enough for the needs of most children. The amount of repairs varied widely, and rubber composition appeared to be the most hard-wearing material. A

TABLE VII.—Number of Children who Joined the Shoe Scheme, the Cost of the Scheme, and the Annual Expenditure on Shoes of a Sample of Children in the Borough, in the Previous Year

Age in Years	No. of Children	Annual Cost of Scheme	Yearly Expenditure of "Average" Child

Total	250	117	69

FIG. 1.—Graph showing the average angulation of the great toe at the metatarso-phalangeal joint at various ages.

record of the fittings required showed that at least three fittings to each half-size were necessary to obtain an accurate fit.

Pedograph Records.—A pedograph was made on entry to the scheme and after one year; it proved a useful measure for demonstrating decreasing pronation of the forefoot and the redistribution of weight in the foot.

Defects and Deformities

Table VIII shows the decrease in number of defects during one year and illustrates the rapid decline in foot troubles when expert advice is available. Certain conditions showed a spontaneous recovery without treatment other than well-fitting shoes and socks. The younger the

FIG. 2.—Histogram showing the mean annual increase in length and width of the foot for each year of age.

child the quicker was the return to normal. These defects were corns, callosities, cramped toes, and proximal hallux valgus. The angle of the hallux was studied, and 48 children showed a deviation of more than 2 degrees in either direction. There was a marked decrease in the angles of deviation after one year (see Fig. 1).

Growth Rates

Measurements were made of the rate and periodicity of growth, and the results in 107 children who attended regularly for at least one year are shown in Fig. 2. The rate

FIG. 3.—Graph showing two types of growth in length of children's feet. The shaded background shows the range of measurements found in the shoe-scheme children of the same age.

in girls and boys was fairly close, the average increase in length being just under $\frac{1}{2}$ in. (1.3 cm.) a year; this corresponds to one whole size in shoes. The periodicity of growth is interesting, and Fig. 3 shows the types which occur. The commonest type was a curve showing alternating periods of growth and quiescence. This may be an annual or a biannual spurt. Child A shows both types over the two years; a regular slow growth, illustrated by Child B, was less common. The period of the year at which most growth occurred was the summer (June–August), while the autumn (September–November) was the usual quiescent period.

Discussion of the Three Surveys

Many adults suffer from pain in their feet. This is borne out by the demand for chiropody treatment in private practice and by the first survey on adult factory workers. Such discomfort must have an appreciable effect on the general health, temper, and work of the sufferer, while the final result on the country's economics is an interesting imponderable. This survey also suggests that the principal causes of pain are hallux valgus and bunions, pain in the long and transverse arches, and corns. The first-named occurs chiefly in women.

The results of the school survey show that these defects begin to develop during the years of childhood and increase progressively with age. While no single cause for the predominance of hallux valgus in girls is apparent, the figures shown suggest that both valgus ankles and bad footwear, which are more common in girls than in boys, play a part in producing this deformity, but the preponderance of valgus ankles is not in itself sufficient to account for the greater number of cases of hallux valgus in girls. That idiopathic clawed foot is more common in boys than in girls is probably related to the predominance of metatarsalgia in men. One theory of development may be suggested: that the rounder shape of a boy's shoe, when short, exerts equal pressure on all toes, causing retraction and dorsiflexion, while a girl's more pointed shoe presses mainly on the fifth and first toes.

The experimental contributory shoe scheme has shown that it is both possible and practicable to run such a scheme for supervising the care of children's feet and, by so doing, to diminish the amount of foot trouble in children. While its inherent principles are sound, the scheme has certain disadvantages. First, that while prices are unstable it may be impossible for manufacturers to budget accurately for a year ahead; secondly, it is a pity to limit the scheme to one firm only; and, thirdly, comparatively few parents have taken advantage of it, as many felt that the prices were beyond their reach. This assumption was not entirely reasonable, for the prices in the scheme compared very closely with the average amount spent on footwear in the preceding year in the same district (Mayers, 1950). Nevertheless a modification of this scheme suggests a line of approach to the problem of the great number of painful and defective feet in the adult population.

Conclusions

A survey to study the main causes of foot trouble in the adult suggests that bunions and hallux valgus, metatarsalgia, long-arch pain, and corns are the chief types of foot disability in healthy adults. An examination of schoolchildren has shown that these defects begin in the later years of childhood. An attempt to maintain foot health by providing children with good footwear and by supervising their feet during the growing period showed that it is possible to prevent deformities and that certain early defects will correct spontaneously, given freedom for normal growth.

It is my pleasure to thank the Health Department of Middlesex County Council for facilities to carry out this research; in particular, Dr. W. G. Booth, area medical officer, Area 7, Middlesex County Council, to whom the Ealing Contributory Shoe Scheme owes its origin; also the British Boot, Shoe, and Allied Trades Research Association for loan of instruments; the Managing Director and Technical Adviser of "start-rite" shoes; to Mrs. Murton, S.R.N., for help in examination of the subjects.

"It is regrettable that the position in relation to the institutional care of mental defectives has steadily worsened over the past four years. There is now a waiting-list of more than 420 patients for admission to institutions, as compared with 170 in 1948. The county council provides domiciliary supervision for all mental defectives in the county, and there are eight occupation centres where defectives may go daily for training and occupation, but this is no adequate substitute for institutional accommodation in many cases. There are numerous households where the defective child or adolescent is an intolerable burden and where only segregation in an institution will meet the case. The need for additional institutional beds for such patients is most urgent and should have a high priority in planning the use of available resources in manpower and money."—From the Report for 1952 of the Essex County Medical Officer of Health, Dr. H. K. Cowan.

THE 17-HYDROXYCORTICOSTERONE CONTENT OF HUMAN ASCITIC FLUID

BY

C. L. COPE, D.M., F.R.C.P.

AND

B. HURLOCK

(From the Postgraduate Medical School of London, W.12)

In spite of many investigations uncertainty still exists about the quantity of adrenal cortical hormone present in human blood and other human body fluids. Most work in this field has been done on animals, and particular attention has been paid to the blood leaving the adrenal gland by the adrenal vein, since the highest concentrations of adrenal hormones may be expected in such blood. Both chemical and biological methods of assay have been applied, but neither has been entirely satisfactory, since chemical methods have not in general been sufficiently specific, and the biological methods have not been sensitive enough to respond to the very small quantities of active hormone present in circulating blood.

The Literature

One of the earliest estimates was that of Hemphill and Reiss (1947), who used a chemical extraction of blood and subsequent estimation of the reducing power of the steroid fraction. They worked mainly on rats, but found 0.21 to 0.43 mg. per 100 ml. in human blood. This early estimate must now be regarded as much too high.

Paschkis, Cantarow, and Boyle (1949) reported the detection of small amounts of adrenal hormone in arterial plasma of the dog. They used the method of glycogen deposition in the liver of the adrenalectomized mouse which had been developed by Venning, Kazmin, and Bell (1946). In the following year Paschkis, Cantarow, Walkling, and Boyle (1950) reported finding values of 14 to 50 μ g. per ml. of dog adrenal-vein blood, the activity being expressed in terms of 11-hydroxycorticosterone (compound A) acetate. They could also demonstrate biological activity in the peripheral blood of the dog.

In 1950 also, Nelson, Reich, and Samuels succeeded in isolating and identifying compound F of Kendall (17-hydroxycorticosterone; hydrocortisone) in the blood of the adrenal vein. Brownell, Hartman, and Liu (1951), who used the Venning glycogen deposition method, reported finding biological activity in dog adrenal-vein blood, but they were unable to detect any activity in the peripheral blood. Thus the earlier work of Paschkis and his colleagues on peripheral blood was not confirmed.

The relatively higher concentrations of hormone in adrenal-vein blood enabled more rapid progress to be made than was possible with peripheral blood, and Pincus, Hechter, and Zaffaroni (1951) were able to extract adrenal steroids from dog adrenal-vein blood in amount sufficient to allow of analysis by paper chromatography. In the dog the steroids identified were mainly 17-hydroxycorticosterone and corticosterone. The concentration of these after adrenal stimulation by A.C.T.H. rose as high as 55 μ g. of each per 100 ml. Cortisone was present in a concentration less than 10 μ g. per 100 ml., and was regarded as a metabolite, 17-hydroxycorticosterone and corticosterone being the main products.

Following up their identification of 17-hydroxycorticosterone in dog adrenal-vein blood, Nelson, Samuels, and Reich (1951) developed a chemical method based on the purification of the extracted adrenal steroids on a chromatographic column and subsequent measurement of the eluted adrenal steroids by means of a colour reaction with phenyl-

hydrazine and sulphuric acid. This colour reaction had been developed by Porter and Silber (1950) and had been shown by them to be specific for steroids having a 17-21-dihydroxy, 20-keto grouping. Both cortisone and 17-hydroxycorticosterone give the typical reaction, but it is given only weakly by corticosterone. Compounds giving this reaction are often called 17-hydroxycorticosteroids. The reaction cannot be regarded as entirely specific for active hormones, since some other products of adrenal steroid metabolism, notably tetrahydrocortisone, also give a strong reaction with the reagent but are biologically inert. Using the reaction on a micro-scale, Nelson and Samuels (1952), and Nelson, Willardson, Tyler, and Samuels (1951) found 4 to 6 μ g. of 17-hydroxycorticosteroid per 100 ml. of human venous blood and 9 to 11 μ g. in human arterial blood. Both figures rose after A.C.T.H. While some of this was probably 17-hydroxycorticosterone an unknown proportion may have been tetrahydrocortisone. This latter metabolite presumably occurs in blood, since it is present in large amount in urine, and has been identified in a peritoneal dialysate by Savard, Kolff, and Corcoran (1952).

Complication rather than simplification has ensued more recently. Thus Bush (1953) showed that the adrenal steroids differed in nature in different species of animal, some having much 17-hydroxycorticosterone and little corticosterone, and other species more of the latter than the former. Sweat and Farrell (1952), using a microchromatographic technique and subsequent detection of the steroids by fluorescence, developed a method sensitive to 0.25 μ g. They found 4 to 8 μ g. of adrenal steroid in the adrenal-vein plasma of stressed rats, but were unable to find any in peripheral blood of adrenalectomized rats. In the adrenal-vein plasma of dogs under stress they found 3 μ g. of a steroid resembling 17-hydroxycorticosterone and 1 μ g. of a corticosterone-like steroid.

At the same time Pincus, Romanoff, and Romanoff (1953) were producing data indicating the complexity of the problems involved in this and allied aspects of adrenal metabolism, for they were able to detect 35 different neutral lipoids in hydrolysed human urine, and similar compounds were found in human peripheral blood. Among the most important of these were corticosterone (compound B), 17-hydroxycorticosterone, cortisone, pregnane 3-11-17-21 tetrol 20-one, and pregnane 3-17-21 triol 11-20 dione (tetrahydrocortisone).

Zaffaroni and Burton (1953) have analysed a large volume of dog adrenal-vein blood from an animal stimulated by A.C.T.H. They found 130 μ g. of 17-dehydroxycorticosterone and 95 μ g. of corticosterone per 100 ml. of blood. Only traces of other compounds were found, but the method they used would not have detected some of the important inert metabolites such as tetrahydrocortisone.

The present position may therefore be summarized as follows.

Both corticosterone and 17-hydroxycorticosterone are present in appreciable quantity in adrenal-vein blood of experimental animals. Cortisone is not usually found. The most refined chemical methods indicate the normal presence of 4 to 6 μ g. of 17-hydroxycorticosteroid in 100 ml. of peripheral venous blood and 9 to 11 μ g. per 100 ml. of arterial blood. A considerable part of this seems to be 17-hydroxycorticosterone, but an uncertain fraction is metabolites which give the same colour reaction but are biologically inert—for example, tetrahydrocortisone. Biological assay indicates the presence of some active adrenal steroid in dog adrenal-vein blood, but no certain activity has been established in peripheral blood in either animals or man.

It seemed to us that useful light might be thrown on the problem by analysis of human ascitic fluid. Although ascitic fluid is not a normal body product it can be obtained in relatively large quantities, sufficient to make a biological assay feasible if the content in active hormones is 1.5 μ g. or more per 100 ml. We have found activity in excess of this figure in five out of ten ascitic fluid samples tested.

Methods

Samples of ascitic fluid have been obtained from suitable patients in volumes of 3 to 7 litres. These samples were extracted and the steroids concentrated into a volume small enough for injection into mice by a method employed by Bush (1952) for blood. The ascitic fluid was extracted by shaking four times with separate lots of chloroform, each representing 15% of the volume of the sample. The four extracts were combined and evaporated under reduced pressure at a temperature below 50° C. to small volume. To the residue of 5 to 10 ml. was added 200 to 400 ml. of acetone and a few drops of saturated magnesium chloride. The mixture was cooled overnight in the refrigerator. After filtration the acetone solution was distilled down to a small volume (3 to 5 ml.). This residue was taken up into 100 ml. of 70% aqueous ethanol and washed three times with 10-ml. portions of light petroleum to remove excess fats. The ethanol solution was evaporated under reduced pressure to dryness, dissolved in a small volume of chloroform, and transferred to a small tube in which it was evaporated to dryness by a stream of nitrogen to await injection.

For bio-assay the method described by Cope, Boysen, and McCrae (1951) has been used. This method makes use of the fact that cortisone-like hormones lower the number of eosinophil cells in the blood of adrenalectomized mice. An extract equivalent to 1,500 ml. of ascitic fluid was injected subcutaneously into each adrenalectomized mouse. For injection the extract was dissolved in propylene glycol, using 0.1 ml. for each 1,500 ml. of ascitic fluid represented. Four volumes of saline were then added, so that the final volume was such that each mouse received a 0.5-ml. injection of this 20% propylene glycol solution.

The eosinophil cell drop in the injected adrenalectomized mice was measured at four and six hours, the greater drop being taken as the significant one. The equivalent activity of cortisone was read off from a calibration curve prepared by injecting cortisone acetate in similar and constant volume of 20% propylene glycol, but in varying dosage into adrenalectomized mice.

Results

The results obtained with these extracts are summarized in the accompanying Table. Ten samples of human ascitic fluid have been separately extracted and tested, most of

Patient	Disease	Vol. per Mouse (ml.)	No. of Mice	Toxicity	Mean Drop Eosinophils	Equivalent Cortisone Content (µg. per 100 ml.)
1 Fr	Cirrhosis	1,500	3	++	No drop	Nil
2 Fr	"	1,500	3	+	"77"	4.4
3 Re	"	1,700	2	+	"77"	4.4
4 Pe	Carcinoma of peritoneum	1,600	3	++	62%	3.1
5 Pe	"	1,500	2	+	11%	<1.5
6 Du	Tricuspid incompetence	1,560	2	0	68%	3.8
7 Du	"	1,500	3	0	77%	5.0
8 Ha	Cirrhosis	1,560	3	0	74%	4.5
9 Du	Tricuspid incompetence	1,500	2	+	15%	<1.5
10 Du	"	1,500	3	+	20%	<1.5

+ toxicity = Well-marked sedation without loss of consciousness. ++ toxicity = A light coma from which the animals recovered in a few hours.

these being of sufficient volume to provide material for three mice. Five of these extracts showed unequivocal evidence of eosinopenic activity. Two extracts, both from the same patient, showed no trace of biological activity, and in the remaining three the presence of activity was equivocal.

Some of these extracts were rather toxic to the mice, producing lethargy and sometimes light narcosis. This effect was at first thought to be due to traces of the magnesium chloride used in the preparation of the extract being carried into the final residue, but efforts to remove this magnesium did not remove the toxicity. There was no relation between this toxicity and the magnitude of the eosinopenic response. Long-acting anaesthetics such as pentobarbitone sodium do not influence the eosinophil response to cortisone in the

adrenalectomized mouse. The degree of toxicity of the extracts is indicated in the Table.

It will be noted that although both ascitic fluid samples obtained from patient Fr were completely devoid of activity, yet in patients Pe and Du eosinopenic activity varied in samples of ascitic fluid removed from the same patient at different times. No explanation can be offered for this apparent variation, since the method of making the extracts was the same in all.

Discussion

The data obtained indicate that, although the amount of biologically active adrenal hormone extractable from human ascitic fluid appears to be variable, it does not usually exceed 5 µg. per 100 ml. In half the extracts examined it was much less than this, being below the level necessary for reliable detection by the methods used. Our previous experience with this bio-assay technique indicates that the variations in activity observed are much greater than could be due to errors in the method of assay.

Some information has been obtained on the nature of the hormone responsible for this biological activity. Extensive search by many investigators has failed to reveal any hormones other than cortisone and 17-hydroxycorticosterone, which lower the eosinophil count in the blood of adrenalectomized mice. Portions of four of the ascitic fluid extracts used in the present study have been submitted to analysis by paper chromatography, using the solvent systems developed by Burton, Zaffaroni, and Keutmann (1951). Whereas a substance behaving like 17-hydroxycorticosterone could be demonstrated in all of the extracts examined, cortisone was usually absent completely. It was indeed detected only in faint trace in a single extract. Urine, in contrast, usually contains both 17-hydroxycorticosterone and cortisone. Actual paper chromatograms of both urine and ascitic fluid extracts are compared in the accompanying illustration. The 17-hydroxycorticosterone found in these extracts was identified by the following points: (1) Its rate of flow in the chromatogram was identical with that of an authentic sample of free 17-hydroxycorticosterone. (2) It reduced the blue tetrazolium reagent like the authentic compound. (3) It absorbed ultra-violet light at 240 mµ. (4) The compound behaving identically with this which is present in urine has been injected into mice and shown to have strong eosinopenic activity.

Sufficient of one extract (No. 10) was available to permit a chemical estimate of the quantity of 17-hydroxycorticosterone present by measurement of the amount of tetrazolium reagent reduced at the appropriate point on the chromatogram. The estimate of 1.8 µg. per 100 ml. agrees well with the traces of activity found in the biological test, for larger quantities in the extract would have given an unequivocal biological response.

As corticosterone itself has been identified in the blood of many mammals, it is possible that this compound also is present in human ascitic fluid. No search for this substance was made in the present work, because no sample of

Comparison of paper chromatograms of both urine and ascitic fluid extracts.

PIPERAZINE IN THE TREATMENT OF
THREADWORMS IN CHILDREN

REPORT ON A CLINICAL TRIAL

AND

O. D. STANDEN, M.Sc.

Wellcome Laboratories of Tropical Medicine, London

authentic corticosterone was available for comparison. Corticosterone, however, is reported to have only a slight eosinopenic effect, which would not contribute appreciably to the biological activity detected in these ascitic fluid extracts.

It may be concluded, therefore, that almost all of the biological activity observed is due to the content of 17-hydroxycorticosterone, and that this varies in different samples of ascitic fluid from zero to about 5 µg. per 100 ml. Cortisone itself does not contribute to the biological activity in significant degree.

It is, of course, clear that one cannot assume that the hormone content of ascitic fluid is necessarily the same as that of circulating blood. Ascitic fluid may, however, be regarded as representing a form of extracellular fluid. Its hormone content may be indicative of the adrenal hormone content of extracellular fluid in general, a content which must be of more direct importance to living cells than is the hormone content of the blood. Our inability to demonstrate any hormonal activity in the two samples from patient Fr raises the possibility that conditions may sometimes exist in which adrenal cortical hormone diffuses with difficulty from the blood into the extracellular fluid. Such a state could account for the fact that rheumatoid arthritic tissues and joints respond promptly to cortisone or 17-hydroxycorticosterone therapy, although all the evidence suggests that adrenal cortical function is normal in this disease. While this suggestion is purely speculative at the present time, further investigation of the hormonal content of human ascitic fluid should prove of considerable interest, in so far as it is representative of an extracellular fluid.

Summary

The adrenal cortical hormone content of human ascitic fluid has been measured biologically, using the power of such hormones to lower the level of circulating eosinophil cells in adrenalectomized mice.

Of ten samples of ascitic fluid tested, five showed activity equivalent to between 3 and 5 µg. of cortisone per 100 ml. In two samples from one patient no activity at all could be detected. In the remaining three activity was equivocal and less than 1.5 µg. per 100 ml.

17-Hydroxycorticosterone (compound F) was detected by chromatographic analysis in all four samples in which it was sought, but cortisone was found only as a faint trace in a single extract. The biological activity is apparently due almost entirely to the 17-hydroxycorticosterone, only a negligible part being due to cortisone.

Grateful acknowledgments are due to the Medical Research Council for a grant for Miss B. Hurlock; to Professor Schuman (Ciba) for a generous gift of 17-hydroxycorticosterone, and of free cortisone; and to Miss Mary Standring for much technical assistance.

The successful use of piperazine in the treatment of threadworms was first recorded by Mouriquand, Roman, and Coisnard (1951) and later by Turpin, Cavier, and Savaton-Pillet (1952). Mouriquand *et al.* used piperazine hydrate in solution, while Turpin *et al.* chose piperazine diphenylacetate in the form of glutenized granules. In most instances oral dosage was supplemented by the use of piperazine suppositories. The clinical trials carried out by both groups of workers were preceded by successful preliminary experiments upon the mouse *Aspicularis* or *Syphacea*. In the clinical trials Mouriquand *et al.* reported a high proportion of cures in 18 patients, while Turpin *et al.* recorded one definite failure out of 41 patients.

We ourselves decided to carry out clinical trials following successful experiments with piperazine hydrate against *Aspicularis* in the mouse (Standen, 1953). As a comparative standard, gentian violet was also included, and, in addition, diphenan, which has achieved considerable popularity on account of its lack of toxic side-effects. Laboratory tests had failed to demonstrate oxyuricidal properties in diphenan. These results were in keeping with the clinical findings of Miller and Choquette (1950), Beaver and Young (1950), Dowsett and Brown (1953), Jung and Beaver (1953). In contrast, Killingsworth *et al.* (1952), using diphenan in conjunction with hexylresorcinol enemas, reported 77% cures, while Bumbalo *et al.* (1953) reported 30% cures with diphenan alone. Killingsworth *et al.* and Van Someren (1939) both quote Schulemann (1920) as stating that diphenan breaks down in the small intestine to form para-benzylphenol, and that this kills oxyurids in 5–10 minutes at 1:4,000 dilution. In fact, Schulemann was working with "Strudelwürmen," which are free-living turbellarians and not in any way related to oxyurids in particular nor to nematodes in general. It is considered that this mistranslation of Schulemann's work should be recorded, since it appears to be in danger of perpetuation in the literature.

Clinical Tests

The material used in the tests consisted chiefly of children admitted to hospital for medical or surgical reasons, and these were identified as cases of *Enterobius infection* by microscopical examination of adhesive "cellophane" swabs of the perianal area. Swabbing was carried out in the morning before the children were bathed or used the toilet, and was repeated for seven days unless a positive result was obtained earlier. In addition, previously established cases of oxyuriasis were included. For purposes of comparative drug effect the children were treated in four groups, each group receiving piperazine, gentian violet, diphenan, or a lactose placebo.

Treatment

(a) *Piperazine*.—Used in the form of piperazine hexahydrate embodied in a flavoured syrup. The children receiving piperazine were divided into two groups, one receiving 100 mg. and the other 250 mg. per day per year of life, the drug being given in divided doses, morning and evening. Treatment continued for seven days, and a second similar course was given after seven days' rest.

(b) *Gentian Violet*.—Given as sugar-coated pills at a dose level of approximately $\frac{1}{4}$ gr. (11 mg.) daily per year of life in divided dosage for seven days and repeated after seven days.

(c) *Diphenan*.—Given as whole or fractions of plain 500-mg. tablets. Owing to difficulty in subdivision of tablets to suit each year of age, the children were arranged in broad age groups. Inevitably this meant a range in dosage from approximately 100–300 mg. t.d.s. per year of life in the lower dosage group and approximately 200–600 mg. t.d.s. for those at higher dosage. The course of treatment was for seven days, and was repeated after seven days' rest.

(d) *Lactose Placebo*.—A control group was considered highly desirable in order to determine the degree of spontaneous cure. The placebo was given morning and evening in two courses of seven days as with the other drugs.

Follow-up

Swabbing of the perianal area with adhesive cellophane was begun 14 days after completion of the second treatment period, and was continued each morning for seven successive days. Any single swab showing one or more ova indicated failure to cure, while seven successive negative swabs formed the criterion for cure.

Hygienic Precautions

In most instances the children received treatment as outpatients, and it was considered unrealistic to expect parents to adhere uniformly to strict hygienic precautions. Consequently, beyond instruction concerning general cleanliness, no special precautions were imposed. Thus the trials were carried out under conditions that would normally prevail in an average household.

Toxicity and Side-effects

(a) *Piperazine*.—During the first quarter of the century piperazine was widely used in the treatment of gout and allied conditions, but it has fallen into disuse because of ineffectiveness in these complaints. Consequently many reports have been published concerning its use in this respect and no important toxic effects have been recorded. Absence of toxicity has been reported by numerous authors, notably Frankel (1921), Gadamer (1924), Fayard (1949),

Mouriquand *et al.* (1951), and Cavier (1953). Recent pharmacology and toxicity studies in laboratory animals (De Beer, unpublished) failed to elicit any significant toxic effects. In our experience during clinical trials only one case showed intolerance. At a dose level of 58 mg./kg. per day, this child complained of loose stools. When treatment was discontinued the diarrhoea ceased immediately. The drug was, in fact, found to be extremely well tolerated even up to dose levels of 150 mg./kg. daily. This higher dose relates to treatments of ascariasis, which will form the subject of a further communication.

(b) *Gentian Violet*.—Out of 20 cases treated two complained of abdominal pain and one experienced nausea and vomiting during the first week of treatment. Otherwise no side-effects were reported.

(c) *Diphenan*.—Treatment with diphenan produced no toxic side-effects.

Results

Comparative Results.—At 100 mg. per day per year of life piperazine hydrate gave a lower cure rate than gentian violet at $\frac{1}{4}$ gr. (11 mg.) daily per year of life (see Table)—that is, 54% and 70% respectively. At the higher dose level of 250 mg. per day per year of life the cure rate for piperazine hydrate was much enhanced, giving 83% cures out of 42 cases treated. The efficiency of diphenan at both dose levels (see Table) closely resembled that of the lactose placebo—that is, 17% out of 23 cases and 19% out of 16 cases respectively.

Analysis of Piperazine Results.—It was appreciated that considerable weight variation occurred within each age group tested, and analysis of the total results of piperazine hydrate tests at both dose levels (see Fig.) shows that on a weight/dose/cure ratio a cure rate of 97% was obtained where the daily dose exceeded 50 mg./kg. body weight.

Conclusions

The results obtained from the clinical trial of piperazine hydrate, gentian violet, diphenan, and a lactose placebo as control showed that while gentian violet had a marked oxyuricidal effect (70% cures) at a dose level of $\frac{1}{4}$ gr. (11 mg.) daily per year of life, this was well surpassed by piperazine hydrate syrup when the dose level was in excess of 50 mg./kg. per day, and the cure rate reached 97%. Though diphenan gave a cure rate of 17% at a dosage of 100–600 mg. daily per year of life, this apparent oxyuricidal effect was discounted by the fact that 19% cure was obtained with a lactose placebo control. The latter indicated that a spontaneous clearance of threadworms may be expected in approximately 19% of infections. Thus piperazine hydrate syrup proved to be the most effective, while producing negligible side-effects; gentian violet was less effective, and was also undesirable on account of its nauseating effects and staining properties; diphenan was ineffective. It is concluded that piperazine hydrate, at a dose level of 50–75 mg./kg. per day, is the drug of choice for the treatment of oxyuriasis in children.

Chart showing relationship of dose of piperazine hydrate in mg./kg. per day to cure in 69 cases of oxyuriasis.

Summary

In clinical trials of piperazine hydrate, gentian violet, and diphenan against oxyuriasis in 136 children, piperazine hydrate syrup and gentian violet showed marked oxyuricidal properties, while diphenan was inactive.

Owing to lack of toxicity and side-effects, to ease of administration, and to its excellent therapeutic properties, piperazine hydrate syrup at a dose level of 50–75 mg./kg. per day is considered to be the drug of choice for oxyuriasis in children. Of 31 children treated at levels greater than 50 mg./kg. daily 97% were cured.

The use of suppositories is unnecessary.

Spontaneous cure may be expected in 19% of cases of oxyuriasis.

The facilities provided by Dr. Philip R. Evans in the Department of Child Health at Guy's Hospital and the Evelina Hospital, London, are gratefully acknowledged. The guidance and advice of Dr. R. C. MacKeith, Guy's Hospital, are deeply appreciated. Without the co-operation of the medical and nursing staffs at these two hospitals this work could not have been completed, and to them our greatest thanks are extended.

The piperazine hydrate used in these trials was provided by Messrs. Burroughs Wellcome and Co. as "antepar" elixir.

EXPERIMENTAL CHEMOTHERAPY
OF OXYURIASIS

BY

O. D. STANDEN, M.Sc.

From the Wellcome Laboratories of Tropical Medicine,
London

The two drugs most commonly used in the treatment of oxyuriasis are gentian violet and diphenan. From time to time claims of efficacy in clearing threadworms have been made for other substances, notably aluminium 8-hydroxyquinoline ("nyxolan"), N-isoamylcarbaminic acid-3-methyl-6-isopropyl phenyl ester ("egressin"), and garlic preparations. Owing to the length of the life cycle and the possibilities of auto-infection, properly controlled clinical trials against *Enterobius (Oxyuris) vermicularis* are extremely complicated. The eight weeks or so required for diagnosis, treatment, and follow-up is longer than children usually remain in hospital, and any trials started under the control and supervision of the medical and nursing staff must be continued with the co-operation of the parents. The difficulties inherent in such an arrangement probably account for the relatively few occasions upon which adequate clinical trials have been made with potential oxyuricides. Obviously some

laboratory method of screening drugs of this kind is desirable, so that these cumbersome clinical trials may be initiated only when justified by experimental evidence.

As no laboratory animal has been found that will act as host to *E. vermicularis* the oxyurids of rodents have been employed for chemotherapeutic trials. The laboratory evaluation of egressin was carried out using *Passalurus ambiguus* in the rabbit (Eichholtz and Hotovy, 1950); *Aspicularis tetraptera*, oxyurid of the mouse, was used for study of the oxyuricidal properties of antibiotics (Wells, 1951a, 1951b, 1952a, 1952b); *Syphacia obvelata* in the mouse was used by Chan (1952) for screening a number of potentially active substances, while Turpin *et al.* (1952) tested piperazine against both *Aspicularis* and *Syphacia*. Mouriquand *et al.* (1951) used piperazine hydrate against *A. tetraptera* in the mouse.

A. tetraptera occurs naturally in the caecum and rectum in many laboratory strains of white mice. For the experimental work here described it was decided to use such natural infections with this parasite and to carry out a series of tests on substances of reputed activity against human threadworms. Tests on certain closely related substances were also to be included. By this means it was hoped to determine whether tests against *A. tetraptera* in the mouse would provide valid indications of activity against *E. vermicularis* in man and to demonstrate substances worthy of clinical trials.

Material and Method

White mice 11–12 weeks old showing ova of *Aspicularis* in the faeces were segregated and used for drug-testing. Necropsy of untreated mice showed a range of 2–120 worms per mouse. Because of the relatively small number (10–20) of mice that could be used in each test it was considered that this range in numbers of worms was too large to warrant valid statistical deductions to be drawn on the basis of reduction in worm numbers following treatment. Therefore the degree of activity of a drug was estimated in relation to the dose required to clear the worms from all or a proportion of the mice treated. The drugs were given orally by stomach tube as a solution or suspension in water or liquid paraffin. The animals were dosed either once or twice daily for five consecutive days. According to the availability of infected mice, 10–20 animals were used for each test. Faecal examinations were made at six days and necropsy at 12 days after completion of treatment. In some instances necropsy was carried out at six days after treatment without prior faecal examination.

To facilitate worm counts the rectum and caecum of each mouse were removed at necropsy and placed in Bouin's fixative. Material fixed in this way could be stored and examined when convenient. At examination this portion of the gut was slit open under water and the contents were removed gently with a camel-hair brush. The inside of the examination dish was painted black, and the worms, now stained bright yellow, were easily seen and counted against this background.

Results

Table I shows the relative efficiency of a number of reputed oxyuricides in clearing mice of *Aspicularis*. None of the drugs used, except perhaps oil of garlic, was particularly toxic* at the dosages employed, and only two, gentian violet and piperazine hydrate, produced any marked worm clearance. In seven other instances partial clearances were obtained, but four of these (Nos. 4, 6, 10, and 13)

* All mice on test had been exposed to infection with *Schistosoma mansoni*. A proportion of the mouse mortality would result from this.

Table showing the Comparative Effectiveness of Drugs Used in Clinical Trials Against *Enterobius vermicularis* Infections in 136 Children

Drug	Daily Dose per Year of Life	Age Range	Total No. Treated	Cases Followed Up			
				Total No.	No. of Cures	No. of Failures	% Cures
Piperazine hydrate	100 mg.	1½–11 3 adults	44	35	19	16	54
	250 mg.	1½–13 2 adults	64	42	35	7	83
Gentian violet	1/6 gr. (11 mg.)	2½–12	38	20	14	6	70

TABLE II.—Showing the Graded Dosage Effect of Gentian Violet and Piperazine Hydrate in Clearance of *Aspiculuris tetraptera* from Naturally Infected Mice

Drug	Oral Dose (mg./kg.)	No. Doses Daily	Total Dose (mg./kg.)	Mice Surviving at Necropsy	Days After Treatment	% Mice Cleared of Worms	Average No. of Worms per Mouse	Range in No. of Worms	Drug Efficiency Rating
Gentian violet	100	1	500	5/10	12	100	0	—	++++
	90	1	450	16/20	12	80	7.0	2-11	+++
	50	1	250	10/10	12	100	0	—	++++
	25	1	125	10/10	12	0	31.0	2-61	—
Piperazine hydrate	400	1	2,000	13/13	12	100	0	—	++++
	200	1	1,000	10/13	12	90	0.1	0-1	+++
	100	1	500	13/13	12	62	3.0	1-8	++
	50	1	250	12/13	12	31	40.0	2-212	+

were of 10% or less, and can be ignored. Other clearances—hexylresorcinol (40%), mepacrine (25%), and santonin (20%)—were not convincing. In the case of hexylresorcinol the 40% clearance was obtained with 10 mg./kg. unit dose, but no clearance resulted when the dose was doubled. Obviously some spontaneous clearance may occur, and unless reasonably uniform results are produced in repeated tests isolated successes must be disregarded.

The clearance rates obtained with gentian violet and piperazine were further investigated. The results of these further tests, together with the original ones, are given in Table II. It will be seen that gentian violet gave a ++++ rate at 50 mg./kg. unit dose, but failed to clear at 25 mg./kg. Piperazine hydrate gave a good response at 400 and 200 mg./kg. unit dose, and at most dose levels the numbers of worms left were very small. In the piperazine 50 mg./kg. group one mouse had 212 worms, whilst the average for the remaining seven positives was only 15. At the 200 mg./kg. level only one mouse remained infected, and this had only one worm, whilst the scanty worm burden remaining at the 100 mg./kg. dose level is perhaps additional evidence of drug activity.

It may be concluded that, in terms of dose/weight ratio, gentian violet is rather more efficient in clearing mice of *A. tetraptera* than is piperazine hydrate, but, nevertheless, piperazine is highly promising and is worthy of clinical trial. The rate at which the intestinal contents move in the mouse is very high compared with that in man, and it is conceivable that in the human subject the piperazine may be absorbed or destroyed before it reaches the worms.

Since this work was completed, clinical trials of piperazine hydrate, gentian violet, and diphenan have been concluded (White and Standen, 1953). The activity of piperazine hydrate and gentian violet against *Aspiculuris* in the mouse is confirmed against *Enterobius vermicularis* in children,

whilst diphenan, inactive against *Aspiculuris*, was similarly shown to be of no value in the treatment of human oxyuriasis. The comparative evidence so obtained justifies the use of *Aspiculuris* in a laboratory screen against threadworm infestation.

Summary

Aspiculuris tetraptera, threadworm of the mouse, was used to test the efficacy of reputed oxyuricides. Of these, only gentian violet and piperazine hydrate cleared the mice of worms.

Drug-testing against *Aspiculuris tetraptera* in the mouse is of considerable value in establishing the efficiency of oxyuricides prior to clinical trial.

Regulations which came into effect on September 1 control the manufacture of aureomycin. When it is intended for parenteral injection it may not be manufactured for sale except under licence and in conformity with prescribed conditions as to strength, quality, and purity. The regulations are entitled the Therapeutic Substances Amendment Regulations, 1953.

VAGINAL ULCERATION DUE TO POTASSIUM PERMANGANATE

BY

E. A. J. ALMENT, M.R.C.O.G.

Late Registrar, Department of Obstetrics and Gynaecology, London Hospital; late Junior Registrar, Department of Obstetrics and Gynaecology, St. Bartholomew's Hospital

AND

C. S. NICOL, M.D., M.R.C.P.

Medical Officer in Charge, Special Treatment Centre, St. Bartholomew's Hospital; Assistant Physician to the Whitechapel Clinic, London Hospital

Over 100 cases of vaginal ulceration following the insertion of potassium permanganate tablets for the purpose of procuring an abortion have been described since the first account of this condition by Lacassagne and Friess in 1932. Voron, Rochet, and Contamin (1935) reported a case in which severe arterial bleeding resulted from the ulceration in the vagina. Shull (1941), among 17 patients with a similar condition, followed up four in whom pregnancy was confirmed; only one patient miscarried. The largest series has so far been described by McDonough (1945). Of 65 patients, 34 required packing of the vagina to control the bleeding and 12 needed transfusion. In 40 patients pregnancy was confirmed; six miscarried, and one was delivered by caesarean section on account of scarring following the vaginal ulceration. Blondin, Benassy, and Masse (1948) added two more cases. Jetter and Hunter (1949) described the case of a woman who died after using a douche of saturated permanganate solution containing a total of over 7 g.

The first account in the British literature was reported by Miller (1951), who described 10 cases. In some of these he found ligation of arterial bleeding points in the base of the ulcer necessary, and formed the opinion that pregnancy remained undisturbed unless the tablets were introduced into the region of the cervix. Henderson and Watt (1951) reported that they had seen cases for many years, and caesarean section had been necessary in three on account of scarring of the vagina.

The following four cases seen at St. Bartholomew's and the London Hospitals are described to draw further attention to the widespread practice of using potassium permanganate, especially in tablet form, as an "abortifacient," and to deprecate the method as an effective means of terminating pregnancy. In the first case, seen in the gynaecological department at St. Bartholomew's Hospital, although typical vaginal ulceration was present the use of potassium permanganate tablets inserted direct into the vagina was not established. One of the other three cases was seen in the gynaecological department of the London Hospital, and a history of using tablets followed by vaginal bleeding was obtained, but no vaginal ulceration was seen. The remaining two patients first attended at the Whitechapel Clinic of the London Hospital. In both these cases the diagnosis was fully established and photographic records were made.

Case 1

A 3-para aged 38 attended St. Bartholomew's Hospital on November 25, 1950, with vaginal bleeding in pregnancy. Her last regular period had begun 23 weeks before attending. Vaginal bleeding, she stated, had occurred two weeks

later, and had continued intermittently until a heavy loss a week previously, after which it had ceased. She admitted using a douche made up with potassium permanganate tablets, but denied inserting any of these tablets directly into the vagina.

Examination showed a healthy woman; the uterus was enlarged to the size of 24 weeks' gestation, and the foetal heart was audible. In the vagina were two apposition ulcers, one in the anterior and one in the posterior wall, about 5 cm. from the introitus. A grey slough was present in the base of each, and both bled readily to the touch. Routine investigations in the special treatment centre, including dark-ground examinations, all proved negative. During the next two weeks healing of the ulcers took place with no scarring, and arrangements for antenatal care were made, but the patient subsequently defaulted.

Case 2

A single nulliparous girl aged 16 was admitted to the London Hospital on January 19, 1952, on account of vaginal bleeding in pregnancy. Her last regular period had begun 22 weeks previously. Twenty-four hours before admission, she stated, she had inserted two tablets of potassium permanganate into the vagina. A few hours later she experienced slight pain in the lower abdomen associated with bright vaginal bleeding.

Examination showed a healthy girl with the uterus enlarged to the size of 22 weeks' gestation. No vaginal ulceration was seen on examination with a speculum. Pregnancy was confirmed by an Aschheim-Zondek test, and the patient gave birth to a live premature infant 12 weeks later.

Case 3

A single nulliparous woman aged 22 attended the London Hospital on February 14, 1952, with a history of pain and swelling of the vulva for two days associated with dysuria. Her last regular period had begun five weeks previously; the normal cycle was 28 days.

Examination showed two shallow apposition ulcers with greyish bases 1.5 cm. in diameter on the inner aspect of the labia minora. Black debris which was scattered elsewhere over the vulva consisted of manganese dioxide produced by the breakdown of potassium permanganate. On passing a speculum another two apposition ulcers, circular and deeper than those on the vulva, were seen in the anterior and posterior vaginal walls just below the level of the cervix, with a disintegrating tablet *in situ*, and further brownish-black debris was scattered over the vaginal wall. All routine investigations, including dark-ground examination of the ulcers, proved negative.

It was only on further questioning that the patient gave the following details. Eight days before attending, fearing she might have conceived, she had inserted tablets into the vagina just before her next period was due. She had worn a sanitary pad to retain them. Heavy vaginal bleeding had ensued. It is assumed that the vulval ulceration had been caused by one of the tablets slipping down between the labia shortly after insertion. On her next attendance the patient brought for inspection a tablet similar to those she had inserted. This was analysed and found to be a compressed tablet of 5 gr. (325 mg.) of potassium permanganate.

During the next four weeks the ulcers healed completely without residual scarring. The cervix became softened and the uterus enlarged; three weeks after the patient first attended an Aschheim-Zondek test confirmed that she was pregnant.

Case 4

A single nulliparous woman aged 28 attended the London Hospital on May 13, 1952, with a history of brown vaginal discharge. The last menstrual period had been nine weeks previously. Her normal menstrual cycle was 28 days, and, believing herself to be pregnant, she had inserted three tablets of potassium permanganate into the vagina three days before

attending. Slight bleeding began the following day. She produced a bottle of 100 2-gr. (130-mg.) tablets of potassium permanganate which she had obtained from a chemist.

Examination of the vagina with a speculum revealed a deep circular ulcer 1.5 cm. in diameter on the portio vaginalis of the cervix to the right of the external os. A similar ulcer lay in apposition on the right vaginal wall (see accompanying photograph). Much black debris was present in the vagina. The cervix was soft, and the uterus enlarged to correspond with the period of amenorrhoea. Routine investigations, including dark-ground examinations of the ulcers, were negative. The Aschheim-Zondek test was positive. Analysis of one of the tablets confirmed that it was potassium permanganate.

Photograph showing appearance of cervix and posterior vaginal fornix in Case 4.

At subsequent attendances the ulcers were seen to heal slowly and spontaneously, and after three weeks' observation no trace of them, and no scarring, remained. The patient miscarried one month later as a result of interference of a different kind.

Discussion

Of the four cases described, three were found to have the characteristic apposition ulcers produced by potassium permanganate in high local concentration. Three patients gave a history of inserting tablets to achieve abortion; the remaining one admitted only using a solution of tablets in a douche, although typical circular vaginal ulcers were found. Bleeding occurred in all four cases, although in none was it enough to warrant the measures described by other writers. Abortion did not occur as a result of the use of tablets in any of the patients. This conforms to the experience of others that the agent is not usually an effective abortifacient. It should be noted that two patients first attended at a gynaecological out-patient department, and two at a special treatment centre. A history of pregnancy may not be forthcoming, the irregular bleeding being the only complaint. The use of tablets may not be admitted initially by the patient. Therefore correct diagnosis of the condition may rest upon finding the characteristic circular apposition ulcers in the lower genital tract, with the remains of a tablet or the brownish-black debris of manganese dioxide still *in situ*.

The similarity of these ulcers to primary chancres in the male was pointed out by Blondin *et al.*, who described the practice of certain legionaries who lingered by inserting a tablet of potassium permanganate under the prepuce. A provisional diagnosis of primary syphilis in women with lesions suggesting contact chancres is therefore likely to be made until full investigations, including dark-ground examination and serological tests, fail to confirm the diagnosis. It is then that further questioning may reveal the true history of the use of potassium permanganate tablets as an abortifacient.

2-gr. and 5-gr. (130-mg. and 325-mg.) tablets of potassium permanganate are readily obtainable at chemists. There is no restriction on their sale.

Summary

Four cases of bleeding following the insertion of potassium permanganate into the vagina in pregnancy are described.

The use of this chemical in tablet form was confirmed in three cases.

The typical ulceration produced is illustrated by a photograph.

The tablets used in two cases were subjected to chemical analysis.

The possible confusion of the lesion with primary chancres, especially in patients who conceal the true history and first attend at special treatment centres, is pointed out.

The common use by women of potassium permanganate in tablet form for procuring abortion and the ease with which it may be obtained for this purpose are stressed. It does not appear to be an effective abortifacient.

ADDENDUM.—Since preparing this report one of us (E. A. J. A.) has seen a fifth patient, in whom very heavy bleeding was caused by the vaginal ulceration. A single girl aged 19, who subsequently admitted inserting tablets of potassium permanganate into the vagina for fear of pregnancy, was admitted on account of a sudden profuse haemorrhage. After half a pint (285 ml.) of fresh blood clot had been removed from the vagina, ulcers were seen on the anterior and posterior walls. The anterior ulcer had eroded the wall of a large artery, which was bleeding freely. Ligation of the vessel was necessary.

Our thanks are due to Dr. Ambrose King, senior physician at the Whitechapel Clinic of the London Hospital; to Dr. Eva Gallagher, who assisted in the follow-up of cases in the Whitechapel Clinic; and to the photographic department of the London Hospital. Permission to describe their cases is gratefully acknowledged to Mr. Wilfred Shaw and Mr. Donald Fraser at St. Bartholomew's Hospital, and to Mr. Alan Brews at the London Hospital.

Launching the autumn recruiting campaign for the National Hospital Service Reserve last month, the Minister of Health, Mr. Iain Macleod, said that in order to be ready to meet the demands of war the Reserve must increase its present strength of 30,000 volunteers to 100,000. He hoped that the new drive for recruits would carry the total well on its way to this target. The Reserve had its role in peacetime too, in dealing with the emergencies of everyday life. "We have had some pretty grim reminders of this in Lynmouth and the East Coast floods and two terrible railway disasters within the last twelve months," he said. "It may not be generally realized," he continued, "that each year there are over one million serious accidents in our homes—serious enough, that is, to require treatment in hospital—and that another 200,000 injuries occur on the roads. With these facts in mind I ask myself: Should not every man and woman have some training in first-aid and simple home-nursing, and would not women gain in confidence and competence if they added practical knowledge of first-aid and petence to their many other accomplishments? The simple nursing to their many other accomplishments? The chances are that each one of us some time in our lives will be confronted with a serious accident or injury in our homes, at work, on holiday, or on the roads. We all dread the possibility, but knowledge and training would take the dread out of such occasions, substituting confidence and competence for fear and futility."

PREGNANCY AND GAUCHER'S DISEASE

BY

Y. M. BROMBERG, M.D.

R. TOAFF, M.D.

AND

D. DIENGOTT, M.D.

(From the Obstetric-Gynaecologic Department and Medical Department "A," Hadassah University Hospital, Jerusalem, Israel)

Gaucher's disease is a rare condition affecting the reticulo-endothelial system, which is loaded with a complex lipo-protein (kerasin, a cerebroside) not normally found in the body. Clinically this condition is known to be characterized by an enlargement of the spleen, sometimes reaching to enormous dimensions, a much less marked hepatomegaly, moderate anaemia, leucopenia, and thrombocytopenia, with a tendency to bleeding, skeletal changes, a brownish pigmentation of the skin, and frequently a peculiar yellowish thickening of the conjunctiva (pinguicula). Most of the above manifestations are due to an invasion of the spleen, liver, and bone marrow by large histiocytic elements with a foamy cytoplasm charged with kersin, which are termed Gaucher's cells and are pathognomonic of the disease.

The condition has a familial tendency and may appear in infancy and childhood, but diagnosis is usually arrived at in the adult. Females are more often affected than males, and the disease has a predilection for the Jewish race.

We were repeatedly confronted with the problem of management of pregnancy in Jewish patients affected by Gaucher's disease, and, surprisingly enough, could find no data in the available literature on this subject. Indeed, the only reference to the influence of the disease on the female genital functions concerns the frequent occurrence of menorrhagia (Brill and Mandlebaum, 1913). The haemorrhagic tendencies, the anaemia, the splenomegaly, the destructive changes in the bones, and the poor general condition of these patients may lead obstetricians to consider the interruption of pregnancy. We felt, therefore, that a report of our experience of Gaucher's disease complicated by pregnancy might be helpful for an evaluation of the risks involved.

Material

The present study is that of a group of seven Jewish women of Eastern European extraction affected by Gaucher's disease in whom the course of 13 pregnancies was recorded (Table I). Nine were deliveries at

TABLE I.—Data on Pregnancies in Seven Women Affected by Gaucher's Disease, in Relation to Establishment of the Diagnosis

7	12	12	16	20	1	21	—	—	—	1	1	—

* Twins. † One was a stillbirth (cerebral haemorrhage).

term, resulting in nine living offspring, and four pregnancies were interrupted. One of the patients had a twin pregnancy, and on delivery bore one living child, the other being stillborn. The pregnancies occurred between the ages of 21 and 36 years. The first pregnancies were preceded by a marriage interval of 0.5–1.5 years in four cases (Cases 2, 3, 5, and 7), whilst in three cases conception was preceded by a period of sterility, involuntary in one case (Case 6) and voluntary in two cases (Cases 1 and 4).

Parity.—Four out of seven patients had only one pregnancy, which ended with a full-term delivery (Cases 3, 4, 5, and 7), while three others had respectively three, two, and four pregnancies (Cases 1, 2, and 6). Case 1 had two full-term deliveries and one artificially induced abortion. Case 2 had one full-term pregnancy and one artificially induced abortion. Case 6 had two full-term pregnancies and two induced abortions (the abortions in all cases having been performed because of Gaucher's disease). The patients who conceived only once had been discouraged by their medical advisers from venturing upon further pregnancies. It should be mentioned that the current medical opinion among the physicians of Israel is that pregnancy involves increased risks for the patient affected by Gaucher's disease, and that the majority of full-term pregnancies reported in the present paper occurred, therefore, before the diagnosis of the disease was established.

In all cases reported (Table I) the diagnosis was based on the absolute criterion of finding Gaucher's cells in the bone marrow or spleen. The clinical manifestations and relevant laboratory findings are given in Table II.

Menstrual History.—In three of the seven cases periods of menorrhagia were recorded (Table II). In none was the increased blood loss during the menstrual periods severe enough to require special treatment. Menstruation occurred regularly during the observation periods of two to seven years. In Case 4 a short period of amenorrhoea occurred, lasting three months. Cases 2 and 6 became pregnant while suffering from menorrhagia, indicating that this increased menstrual flow was not associated with failure to ovulate.

Influence of Gaucher's Disease on Course of Pregnancy

In this series there was no case of spontaneous abortion or premature labour. The course of pregnancy was not complicated by the toxæmias or by haemorrhagic accidents. It should be noted that the enormous spleen typical of the disease does not interfere with the normal increase in size of the gravid uterus. This was our experience with two cases (Nos. 1 and 6) in which no distress resulted from the pressure of the uterus on the enlarged spleen and liver. All the babies delivered at full term were normally developed and their birth weights within normal range. No case of foetal death *in utero* occurred. In Case 3, a twin pregnancy, one foetus died during delivery, and post-mortem examination revealed a cerebral haemorrhage. The course of labour in all cases was uneventful. The third stage was not complicated by haemorrhage of more than an average amount, in spite of the known tendency to bleeding found in these patients. Lactation was normal in all but one case.

Influence of Pregnancy on Gaucher's Disease

It was our experience that pregnancy did not adversely affect the course of Gaucher's disease. On the contrary, in at least two patients there was an increased feeling of well-being during pregnancy (Cases 4 and 6). That in these two cases the diagnosis of Gaucher's disease was made during pregnancy was not due to any deterioration in the condition of the patient but to the finding of splenomegaly on

* Some impairment of movements and muscular atrophy.

routine abdominal examination. The major manifestations of Gaucher's disease did not appear to be aggravated during pregnancy. No changes were noted in the size of the spleen or liver. Despite considerable thrombocytopenia (in Case 4 and in the first and second pregnancies in Case 6) no aggravation of the haemorrhagic tendency was observed. In Case 1 severe bleeding from the anorectal mucosa, a condition antedating the third pregnancy, continued during the first two months and went on unabated after the pregnancy had been interrupted. Severe skeletal changes, accompanied by impairment of function in the lower extremities, preceded pregnancy in Case 3. No further anatomical or functional damage was wrought by the pregnancy. The general impression received during the relatively short period of observation was that pregnancy or repeated pregnancies have no adverse effect upon the disease.

Discussion

The course of Gaucher's disease is a chronic one interrupted by infrequent exacerbations characterized by haemorrhagic episodes, bone pains, and a general deterioration in the patient's condition. Thannhauser (1950) states that "in the interval (between individual flare-ups), which often lasts 10 years or more, there are no complaints and no disturbances of important functions. The patient may lead a normal life and even perform hard work. . . ." Life expectancy of these patients seems to be only slightly affected, especially when symptoms become manifest during or later than the third decade (Thannhauser, 1950).

In our opinion, women affected by the disease should not be deprived of the chance of becoming mothers if a negative answer can be given to the following two questions. (1) Does pregnancy endanger the life of the woman? (2) Does the disease affect the offspring?

This study of nine full-term pregnancies in seven patients leads us to believe that childbirth does not exert any deleteri-

ous effect, either immediate or remote, upon the woman suffering from Gaucher's disease. In fact, in every case in this series there was a comfortable pregnancy, followed by a successful normal full-term delivery. It is especially important to observe that haemorrhagic complications, which could be expected in Gaucher's disease, did not in fact occur. In Case 6 we had the opportunity of studying the patient over a period of seven years, throughout the course of four pregnancies, and no deterioration in her condition was observed.

Concerning the fate of the offspring, our short period of observation allows only limited conclusions. All infants born in our series were normal at birth and subsequently showed normal development. None showed any manifestation of Gaucher's disease. No absolute evidence that the disease is hereditary has been claimed in the literature on the subject, and the chances of the child becoming affected by the same condition are negligible.

It seems justifiable to draw the conclusion that women affected by Gaucher's disease should not be denied motherhood. No justification for the interruption of pregnancy in patients affected by the disease was found in the present study.

Summary

The course of 13 pregnancies in seven patients affected by Gaucher's disease has been studied. Nine pregnancies proceeded to full-term deliveries and four were interrupted during the first trimester.

The course of the nine pregnancies which continued to term was uneventful, and they terminated in normal deliveries of apparently healthy babies.

Four pregnancies were interrupted because of the prevalent opinion that pregnancy involves serious risks for the woman affected by Gaucher's disease.

The effects upon each other of pregnancy and Gaucher's disease are discussed and the conclusions drawn that conception in women affected by the disease should not be discouraged, and that interruption of pregnancy in this condition is not justified.

USE OF THE ELECTRODERMATOME, WITH SPECIAL REFERENCE TO ITS VALUE IN SERIOUS BURNS

BY

PATRICK CLARKSON, F.R.C.S.

Senior Plastic Surgeon, Plastic Centre, Basingstoke;
Casualty Surgeon, Guy's Hospital

AND

D. A. CAMPBELL REID, F.R.C.S.

Senior Registrar, Plastic Centre, Basingstoke

This article is based on experience with the electrodermatome during the past year at the Basingstoke Plastic Centre. Our experience in plastic and general surgery confirms the view widely held in America that the ease and reliability of cutting grafts of varying sizes and depth the electrodermatome presents an advance over other graft-cutting instruments. The graft-cutting instruments hitherto available have been the Thiersch razor, the Blair blade, the Humby knife, and the Paget dermatome. Of these the Humby knife has the widest range of general usefulness and needs the least experience for reliable results. The razor is, of course, in all respects inferior to the Blair blade, but even with the Blair blade in the most expert hands it is not possible with certainty to cut areas of graft from the thigh (the most common donor site) of more than 8 to 10 by 3 to 4 in. (20 to 25 by 7.5 to 10 cm.); the graft can be cut of uniform thickness only if it is very thin. Irregularities in thickness leading to poor donor-site scars are common. With the Humby knife grafts of 10 by 4 in. (25 by 10 cm.) can be cut with some practice. It has the added advantage of making possible grafts of medium thickness in depth; but again thickness of graft tends to vary. The Paget dermatome cuts an area of up to 8 by 4 in. (20 by 10 cm.). This instrument has been of great value in certain definitive repairs of the hand and elsewhere, but the donor-site scars are liable to keloid formation; it is a time-consuming method, and there is often trouble with the dermatome cement. Furthermore, in addition to the limitation of length it is not possible to cut thin split-skin grafts reliably with it.

There are many repairs which properly belong to the field of general surgery but which are still often referred to plastic centres simply because of the technical difficulty which current grafting instruments present to surgeons. Early experience in watching the use of the electrodermatome in a general surgical service (at the Brooke Army Hospital, San Antonio, Texas) convinced one of us that the electrodermatome could be of value in this way, as well as being an advance on other grafting instruments in the ease, speed, and reliability with

which extensive reasonably thin split-skin grafts could be cut from a variety of donor sites in patients with serious deep burns.

The Instrument

The electrodermatome was introduced in the United States after the last war. It is an electrically powered instrument in which a rapidly oscillating blade placed horizontally cuts against a lower fixed bar. The thickness of the graft can be regulated by adjusting the two micrometer screws which carry a vertically adjustable bar immediately above the knife edge. Grafts from 0.015 to 0.055 in. (0.038 to 0.138 cm.) can be cut. The maximum width of graft, which is 3 in. (7.5 cm.), can be reduced as required by a third screw which operates a pair of width guides against which the blade cuts. The length of graft is limited only by the extent of the donor area. The small electric motor is encased in metal to ensure its being spark-proof. It is connected to the instrument by means of a flexible drive shaft, and is operated on 10 volts A.C. or D.C. by a foot switch controlled by the surgeon. The knife blade is slotted into the instrument much as a razor blade into a razor, and is held there by three screws which are tightened by a spanner. We have found it possible to get good use out of blades which have been sharpened two or three times, although this is contrary to the manufacturers' experience. One blade will remain sharp during the cutting of skin from most of a thigh.

For sterilization, the dermatome, flexible shaft, and spanner are autoclaved; the blades are cold-sterilized. The motor, which does not enter the sterile field, must not be autoclaved. It is simply cleaned with a damp cloth.

Operation of the Electrodermatome

An adequate or the best available site is selected; it may be thighs, buttocks, legs, arms, chest, abdomen, or back—that is, any area except head, neck, hands, and feet. The skin of the donor site is covered with a thin coating of mineral oil such as sterile liquid paraffin. It is put on a slight stretch by the surgeon's free hand, placed behind the area from which the graft is to be cut. The dermatome is then placed with its undersurface flat against the skin. While firm pressure is maintained on it the instrument is moved slowly and steadily forward. An assistant grasps the cut edge of the skin graft with a pair of haemostats placed on each corner as the graft presents above the cutting blade, and slight tension is maintained by him on the graft. When the necessary length of graft has been cut the front of the instrument is directed upwards to sever the attachment of graft to the donor site.

Applications of the Electrodermatome

1. In Burns.—Graft cutting:—The special value of the instrument is the ease and speed with which extensive areas of graft can be cut even by those with little experience in its use. This saving of time can be of great importance during an operation in the second week in cases of serious

FIG. 1.—Early excision of sloughs with the electrodermatome. The instrument is run once or twice rapidly over the burnt area (in this case on the fifth day).

FIG. 2.—Grafting of extensive varicose ulcers. The pre-operative photograph of an elderly patient who had been in hospital for two years on account of circumferential bilateral extensive ulcers.

burns. An additional advantage is the thinness of the skin. There need therefore be less blood loss during the operation, and these donor sites can be soon "milked" again when necessary. Nor are they likely to give rise to hypertrophic and unsightly scars so often caused by the Paget dermatome. The instrument is also of value in definitive repairs for burn deformities, when medium or thicker-quality skin may be needed. **Slough removal:**—The electrodermatome is also in our experience the quickest and least haemorrhagic of methods for the early removal of some sloughs (Fig. 1). In a matter of a few minutes very extensive areas can be cleared. The dermatome can be run over the same area more than once until an unquestionably viable bed is exposed. In some

FIG. 3.—Post-operative photograph of the same case as Fig. 2. Four months after radical excision of ulcer, scarred epithelium, and fibrous tissue. Areas covered with thin split-skin grafts cut by the electrodermatome from the thighs.

tion the superficial layer of epidermis could be easily and quickly removed as thin grafts from those areas of the flaps whose future viability was suspect. These grafts could be stored at 4° C. for subsequent use (leaving the flap to declare itself) or applied at primary operation after excision of the flaps.

3. Other Soft-tissue Injuries and Surgical Problems.

The instrument is of most value where extensive uniform-depth grafts are needed, and especially when it is desirable to save time and limit blood loss. It has therefore a role in any major soft-tissue loss. Its value in the reparative stage of radical mastectomy operation is the ease with which the adjacent trunk skin can be cut to cover residual defects.

4. **Varicose Ulcers.**—Certain extensive varicose and gravitational ulcers, such as the circumferential ulcers depicted in Fig. 2, need a repair by very extensive grafts (Fig. 3) of a skin of reasonable quality. Many of these patients are elderly, for whom it is undesirable to prolong the time of operation. We have used the electrodermatome to provide extensive grafts quickly and of a quality which holds a suture securely.

5. **Lymphoedema.**—In cases chosen for treatment by circumferential excision of skin and fat down to fascia and muscle, the electrodermatome is the most efficient method of first removing skin grafts from the skin of affected areas to be discarded. These grafts can be used to cover the raw areas established by the excision.

6. **Tattoo Marks and Facial Acne.**—The electrodermatome will rapidly efface the design of a tattoo mark (Fig. 4). It may not remove the staining completely if the tattoo is deep, but the result is generally a very effective obscuration of a design which has often long since ceased to please the patient. The instrument has also been used to remove severe and extensive acne of the face.

Summary

Attention is drawn to the value of the electrodermatome, both in general and in plastic surgery.

It is suggested that the expense of this rather costly instrument would be justified for any large surgical service. Our reasons for this belief are the greatly increased ease and speed with which extensive grafts of any thickness may be cut by it with little experience. We believe the instrument represents a further stage in the simplification of graft-cutting techniques, and one that is likely to increase the scope of the reparative work which can be retained in general surgical services.

We have found it of special value in cutting extensive grafts for severe burns, especially when the usual donor sites are not available.

It has also proved a most efficient agent for the removal of burn sloughs from the trunk and limbs.

As a graft-cutting instrument it has a number of other valuable uses, especially in the surgery of trauma.

A new low record for accidents in the mines was established in 1951, according to the annual report of H.M. Chief Inspector of Mines. Persons killed totalled 487, and 1,942 were seriously injured. In comparison with 1950 these were 6 fewer killed and 78 fewer injured. These record figures were attained in spite of the serious disaster at Easington Colliery, in Durham, which caused the death, directly or indirectly, of 83 people.

Medical Memorandum

Prolapse of the Urethra in Young Girls

Prolapse of the urethral mucosa in the adult woman is well recognized, but it is not so well appreciated that the condition occurs in young girls. Keefe (1917), in a study of the recorded cases, found that 60% of the patients were children, 28% were women over 40 years of age, and the remaining 12% were between 15 and 40 years of age.

CASE REPORT

A 7-year-old girl was brought to hospital in January, 1952, on account of a blood-stained discharge which soiled her clothes. This "spotting" was of three days' duration and was accompanied by some pain in the urethral region on micturition.

On examination an inflamed ring of tissue surrounding the urethral opening was seen. No other abnormality was found. She was admitted to hospital a few days later. Under general anaesthesia the vulva was more carefully examined. The

Photograph showing inflamed oedematous urethral meatus.

interrupted catgut stitches. Convalescence was uneventful, and the patient was discharged well and free from symptoms on the eleventh day.

Section of the excised tissue showed a covering of transitional epithelium, which was shed in places, over an engorged submucosa containing round-cell infiltration.

AETIOLOGY

The condition may occur at any age. It is reported that the youngest patient was 5 days and the oldest 92 years (Epstein and Strauss, 1937). Hepburn (1920) believes that the supporting structures around the bladder neck are poor in these cases, and that straining produces a partial herniation of the bladder (and urethral mucosa with it) through these poor supporting structures. Certainly the condition has been observed following severe coughing and straining at stool. Keefe (1917) suggests that excessive force by the detrusor muscle of the bladder causes prolapse of a loose mucosa of the urethra. Chute (1925) reported three cases of partial prolapse of the urethral mucosa associated with malignant disease of the bladder and vesical tenesmus. It would appear that, provided the urethral mucosa is only loosely supported, an increased downward pressure, whether supplied by the vesical detrusor muscle or by a raised intra-abdominal pressure, will tend to cause prolapse of the urethral mucosa.

CLINICAL FINDINGS

The chief complaint in these cases is "spotting" of blood on the patient's garments. This results from trauma of the prolapsed mucosa. This may be accompanied by dysuria, which may be severe when the prolapsed mucosa is strangulated, and even give rise to retention of urine. The prolapse

involves the entire circumference of the urethra. The lumen of the urethra is thus completely surrounded by an oedematous and bruised ring of tissue. It is therefore distinguished from the urethral caruncle which involves only a portion of the meatus, usually the posterior lip. A urethral polyp protrudes from the centre of the urethral lumen. A urethrocele produces a swelling through the vagino-urethral septum and is covered by vaginal epithelium. Carcinoma of the urethra may have to be distinguished from the urethral prolapse in the older patient. The carcinoma is indurated and friable, and bleeds easily on examination. In some cases biopsy may be needed to distinguish the one from the other.

TREATMENT

Since vesical tenesmus may be an aetiological factor in the production of the urethral prolapse it would seem to be a wise precaution to exclude any lesion in the bladder by cystoscopic examination. Further, since the prolapsed mucosa is often inflamed (especially when there is strangulation), it follows that the area should be cleaned with sitz baths to reduce infection to a minimum before any cutting operation is carried out.

Simple digital replacement of the mucosa has been advocated, but the chances of recurrence are great. Berry and Greene (1938) record the case of a patient of 10 years who, one year before being seen, had a swelling of the urethral orifice following a fit of coughing. This had been treated by the patient's mother by rest in bed and local applications with apparently a good result. Recurrence occurred with another fit of coughing, when she was seen and treated surgically.

Livermore (1921) favours four-point fulguration of the mass to induce submucosal fibrosis and so bring about reduction of the prolapse. Hepburn (1927) is more radical in his treatment. Since he maintains that there is a partial hernia of the bladder through poor supporting structures around the bladder neck, he pulls up the bladder through a suprapubic approach and attaches it to the back of the pubic bones and anterior abdominal wall. Keefe (1917) is in favour of replacing the prolapsed mucosa and then, through a vaginal incision, shortening the constrictor muscles around the lower end of the urethra.

The remaining methods of treatment involve removing the prolapsed portion of urethra. A catheter has been placed in the urethra and a ligature tied around it and the prolapsed mucosa. This is left until the prolapsed ring of mucosa sloughs off. The ring of mucosa has been amputated with the electric cautery without any suturing, as suggested by Moffett and Banks (1951), or it may be cleanly amputated with the knife and the cut end of the urethra sutured to the cut edge of the meatus as done in the case described above.

The Heating Appliances (Fireguards) Act came into force on October 1, 1953. The Act makes it an offence for any person to sell or hire (except in certain specified circumstances) an electric or gas fire or an oil-burning heater which is not fitted with a guard conforming to prescribed safety regulations. There are, however, about 4,500,000 such fires, and a further 12,000,000 open solid-fuel fires, already in use in people's homes, to which the Act does not apply, and a large proportion of these are not equipped with adequate guards. Unless their owners provide guards many preventable accidents will still occur. Cotton fabrics and artificial silks are most often involved in burning accidents, and it may soon prove possible to render these materials less inflammable.

Reviews

CONQUESTS OF MEDICINE

Fifty Years of Medicine. By Lord Horder, G.C.V.O., M.D., F.R.C.P. (Pp. 70. 5s.) London: G. Duckworth and Co., Ltd. 1953.

Goethe in *Kunst und Altherthum* wrote of Sir Walter Scott's *Life of Napoleon*:

"What could be more delightful to me, than leisurely and calmly to sit down and listen to the discourse of such a man, while clearly, truly, and with all the skill of a great artist, he recalls to me the incidents on which through life I have meditated, and the influence of which is still daily in operation."

Those members of our profession who have had the privilege of working with Lord Horder or of being his pupils can re-echo these words of Goethe as they open this slim volume, an expanded version of the Harben Lectures which the author delivered at the Royal Institute of Public Health and Hygiene in December, 1952. The book will be equally appreciated and valued by the younger medical men and women who now enjoy the fruits of the conquests in the realm of scientific medicine which Lord Horder and his contemporaries throughout fifty years have achieved.

Lord Horder, like Tennyson's Ulysses, is not only a part of all that he has met, but is also "honoured by cities of men and manners, climates, councils, governments," and "has drunk delight of battle with his peers." Even those who differed from him could not help but recognize the courage with which he has urged his convictions.

Succinctly, and in good English prose, he indirectly narrates his Odyssey in these pages. The first lecture describes "The Birth of Scientific Medicine," and recalls how the lecturer "took the bench to the bedside"—that is, he introduced clinical pathology to the wards. The second lecture, "Medicine Enlarges its Boundaries," treats of the important advances in knowledge of nutrition and food, physical medicine and rehabilitation, industrial medicine, and nursing. In the third lecture, "The Present and the Future" are briefly surveyed, and certain constructive criticisms are made of the National Health Service.

This is a book to keep and treasure for its wisdom and historical value. *Magna est admiratio copiose sapienterque dicentis.*

ARTHUR S. MACNALT.

CIVILIAN HEALTH IN WAR

Medical History of the Second World War: Civilian Health and Medical Services. Edited by Sir Arthur Salusbury MacNalty, K.C.B., M.D., F.R.C.P., F.R.C.S. Volume I: The Ministry of Health Services; Other Civilian Health and Medical Services. (Pp. 441. £2 5s.) London: H.M. Stationery Office. 1953.

This is the sixth volume published so far of the Medical History of the Second World War. Sir Arthur MacNalty, who is the editor-in-chief of the complete work, has edited this volume himself. It deals mainly with England and Wales and the Channel Islands. Volume II of "The Civilian Health and Medical Services" will deal with Scotland, Northern Ireland, and the Colonies, and with the medical services of the Ministry of Pensions.

It is only when the material is presented in one book that the far-reaching effect of the impact of war on a well-organized community can be realized. Established services are disrupted; staff disappear; buildings are requisitioned; new problems arise, and new machinery, devised to meet them, must be produced. The book not only describes the state of the various fields of public health activity at the beginning of the war and what happened to them during the war, but also the steps taken at the end to revive them. Full information is given of the action taken to distribute food. "The rationing provision for children and the priority classes went beyond maintaining pre-war diet and aimed at providing an optimum diet." Credit is given to the British Medical Association for its foresight in compiling in 1937 a

register of doctors so that, when the blow struck, the selection of those to be recruited could be made with least disturbance to civilian needs.

Air-raid shelter problems and the provision made for the welfare of evacuees, refugees, and the homeless are described in detail. No definite conclusion is reached on why we escaped devastating epidemics, though several suggestions are made. At the beginning of the war cerebrospinal fever became more prevalent; there was an increase in the mortality from tuberculosis and in the incidence of scabies; epidemic jaundice became a problem; but venereal disease was kept in check, and the steps to prevent the spread of malaria, typhus fever, and smallpox were successful. Influenza was feared, but never attained epidemic proportions. There was "considerable reduction in the amount of mental disorder during the first two and a half years of the war." There were 151,936 confinements in emergency maternity homes, with a maternal mortality of 0.8 per 1,000, a stillbirth mortality of 19.3, and a neonatal mortality of 9.6 per 1,000. The general conclusion is: "There was little evidence of a lowering of the standard of health during six years of war, and for this no little credit is due to the skill and devotion of insurance medical practitioners."

War tends to stimulate the development of health services. During this war the Public Health Laboratory Service, mass radiography, and special allowances for the tuberculous were started. The diphtheria immunization scheme was pressed, with highly satisfactory results. Authentic information about venereal disease was, for the first time, published in newspapers, and talks were given in the B.B.C. programmes. The Radio Doctor made his debut. The W.V.S. was born.

The invaluable work of the voluntary agencies is described, including that of the American Red Cross Harvard Field Hospital Unit. Mention is made of the Civilian Medical Recruiting Boards, who examined 7,100,409 persons, and the medical work of the Ministries of Health, Education, Labour and National Service, Supply, and War Transport is well described. There is a special chapter on Wales and another on the Channel Islands. The heavy tribulations of the latter are discussed by the medical officers of health of Jersey and Guernsey.

The book is written without any attempt to play on emotion. It is a simple, well-written, and well-documented account of an epic story where everyone did what was expected of him or her, and more.

ALLEN DALEY.

RADIOISOTOPES IN MEDICINE

Radioisotope Techniques: Proceedings of the Isotope Techniques Conference, Oxford, July, 1951, sponsored by the Atomic Energy Research Establishment. Volume I: Medical and Physiological Applications. Ministry of Supply. (Pp. 466; illustrated. £2 10s.) London: H.M. Stationery Office. 1953.

In July, 1951, a conference took place in Oxford on radioisotope techniques as applied to various fields of work. The report of the industrial applications appeared earlier this year, and that of the medical and physiological applications has now been published. This report consists of the full texts of the 70-odd papers that were presented in these sections, together with a note of the discussion on each; and even now, two years after the conference, it is a useful survey of this field of work. This is perhaps explained by the international, yet very informal, nature of the conference, where the preliminary results of a large number of laboratories were fully described and discussed.

The papers are about equally divided between medical diagnostic and therapeutic applications of the radioisotopes, and work on intermediary metabolism and the distribution of materials within the tissues. On these subjects the report is as valuable as the conference was, for it collates work from many different centres, yet with surprisingly little overlap between the various papers on similar subjects. Inevitably, the long interval between the conference and publication of its proceedings robs the book of some of its value, but it remains a most important record of a fertile

conference and a representative "cross-section" of the biological investigations to which radioisotopes are applicable. Even now there are few books on this rather forbidding subject that offer such a mine of important information as does this one. Its editing and preparation by unnamed members of the Harwell staff are as excellent, and must have been as laborious, as their preparations for the conference itself. That is saying a great deal, and it as much deserves our gratitude.

E. ERIC POCHIN.

FOOD HYGIENE

Food Hygiene Handbook. By W. Clunie Harvey, M.D., D.P.H., F.R.San.I., and H. A. Perry, F.R.San.I., M.S.I.A. Foreword by Sir William Savage, M.D. (Pp. 159; 34 illustrations. 15s.) London: Heywood and Co. 1953.

A century of strenuous effort in relation to environmental conditions has eliminated most of the serious dangers to the public health. One of the major defects remaining in this field is faulty food-handling, which is rife in Britain. Hygiene in the manufacture, storage, sale, and serving of food is far too often appallingly poor. The number and severity of food-poisoning outbreaks and the high incidence of the dysenteries are cogent evidence of the existence of conditions apt to be ignored because they are largely hidden. This book deals most effectively with the problems and gives the answers. It is intended as a practical guide for the keepers of shops, restaurants, and hotels and for canteen supervisors and housewives. But general practitioners, medical officers of health, and sanitary inspectors will find here much to interest and stimulate them.

The authors carefully and succinctly summarize the law relating to food hygiene and succeed in making legal reading much less painful than usual. Food-poisoning and the provision and equipment of food premises are subjects adequately considered, and people concerned with individual food trades will find their peculiar difficulties discussed, together with guidance for their solution. The food trade and local authorities have still much to do, but so also has the housewife. The results of care before delivery can easily be undone by carelessness in the home. The authors have laid down clearly and shortly a series of rules which the housewife would be well advised to follow in the interests of her family. There is a valuable section on the infestation of food premises and how to destroy the insects concerned. Many of the excellent illustrations are devoted to these creatures and will help in their identification. At the back of the book there are advertisements of food equipment and materials used in food control. They are relevant to the subject-matter, but I feel that, much as I like this publication, I should have liked it more without them.

This book is commended to everyone concerned directly or remotely with the control of food; and the more widely it is read the greater will be the improvement in food hygiene.

C. METCALFE BROWN.

NEUROSYPHILIS

Clinique et Pathologie de la Neurosyphilis. By Professor J. Alves Garcia. (Pp. 160; 36 figures. No price given.) Paris: Masson et Cie. 1953.

The modern treatment of syphilis has so profoundly transmuted its characteristics that the florid manifestations of the disease are becoming less common and the signs of neurosyphilis less obvious. Nowadays cases seldom correspond to the classical descriptions, and the forms of neurosyphilis, which twenty or thirty years ago were so rich and varied, have been considerably modified by modern therapy. During this transitional period in the history of syphilis the author has had the advantage of observing this metamorphosis as professor of psychiatry and physician to the Hospital for Neurosyphilis at Rio de Janeiro, where extensive clinical material has been at his disposal for some twenty years. His readable monograph on the clinical and pathological aspects of neurosyphilis records the results of his accumulated clinical

experiences and histopathological investigations, which he hopes will stimulate further research into the newer pathological concepts.

Without being exhaustive or so statistical as to be monotonous, the earlier chapters are complete essays on the various clinical types of neurosyphilis and their pathology. Later chapters are on the pathology and histopathology of parenchymatous syphilis, some original researches on malarial therapy and the irreversibility of its vascular lesions, optic atrophy, congenital neurosyphilis, and a final chapter on treatment.

The many divergencies of opinion on the possibility of dualistic strains of *Treponema pallidum* are fully discussed. The supporters quote the rarity of cerebral syphilis among the American negroes, the Chinese, the Persians, and the natives of Central Africa. But other provocative factors must be recognized such as fatigue, intellectual strain, and alcoholism. Possibly when the virus is not sterilized by energetic treatment it acquires new characteristics and becomes neurotropic. Moreover, modern treatment may have provoked biological alterations in the spirochaete to render it neurotropic rather than dermatotropic. Meanwhile, modern research seems to have discarded the thesis of a neurotropic strain of spirochaete.

The author says that malaria therapy for G.P.I. has not been surpassed by any other method of treatment, and penicillin has not had the success which might have been expected. He considers penicillin insufficient treatment for the pure forms of parenchymatous syphilis and would administer it only as an adjuvant in those cases showing intense cellular reaction in the cerebrospinal fluid. He is an advocate of malaria therapy, preferably with malignant tertian in Brazil, for both tabes and G.P.I., and follows it immediately with arsenic and liposoluble bismuth. But he would absolutely forbid the use of all quinquivalent arsenicals in the presence of optic atrophy. These are strong words, coming as they do from a hospital where, during the ten years 1942-52, most of the admissions (62%) were cases of G.P.I.

The author stimulatingly declares that there are no mental symptoms which are specific of syphilis, not even in G.P.I., and provokingly asks why this same condition provides such a variety of symptoms when the anatomical lesions are so invariably the same. And, since they are so uniform, why are the clinical symptoms not equally so? Again, although G.P.I. is generally considered to be non-infectious, he remarks that the blood from such a patient can cause typical granulomatous lesions when inoculated into a laboratory animal. Such numerous incidental observations scattered throughout the book make it well worth reading, for they are the plums from a unique experience and the personal hallmarks of a master of his subject.

T. ANWYL-DAVIES.

A Catalogue of Engraved Portraits in the Royal College of Physicians of London, by A. H. Driver, has been published by the College, price £2. In the preface reference is made to previous work by the late Dr. Arnold Chaplin. He devoted many years to the task of building up and describing the collection, and his catalogue forms the basis of the work now published. The biographical data included in the present catalogue show evidence of considerable knowledge of medical history and bibliography, and it would have been more accurate to concede its authorship to Dr. Chaplin and its revision to Mr. Driver. The College now possesses some 4,500 prints, including the large collection given by Chaplin in 1934, and this printed catalogue marks an important step forward in the documentation of such material. Besides dates and brief biographical notes of the subjects, information given on each portrait includes size, painter, and engraver. There is also an alphabetical list of engravers. We must now look forward to the time when catalogues of the comparable collections at the Royal College of Surgeons and the Royal Society of Medicine and the much larger collection in the Wellcome Historical Medical Museum can be published. Equally valuable would be a printed version of the magnificent catalogue of all known engraved portraits of British medical men, compiled some years ago by Chaplin, Herbert Bruen, and W. J. Bishop, which at present exists only in typescript copies at the Royal College of Physicians, the Royal College of Surgeons, the Royal Society of Medicine, and the Print Room at the British Museum.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY OCTOBER 3 1953

RESPONSIBILITY FOR MURDER

The most far-reaching of the conclusions suggested by the Royal Commission on Capital Punishment¹ will probably prove to be those on the M'Naghten Rules, for of the Commission's leading recommendations, summarized at page 775 of the *Journal*, these are the most likely to be accepted in something like their present form. They are largely in accord with the medical evidence presented by the B.M.A. and by the Institute of Psycho-analysis, as well as with that of some, though by no means all, individual medical men who gave evidence. They will have, too, some legal support, and public opinion is unlikely to cavil at them.

In brief, the Commission (with some dissentients) concludes that the Rules should be either amended or abrogated. If amended, they should be enlarged with some such phrase as that suggested by the B.M.A.,² so that there would be added to them the test whether the accused was labouring, as a result of disease of the mind, under "a disorder of emotion such that, while appreciating the nature and quality of the act, and that it was wrong, he did not possess sufficient power to prevent himself from committing it." If the Rules are to be abrogated—and the Commission would prefer that—then the jury would have no formula put before it, but would determine, in view of all the evidence, whether at the time of the act the accused was suffering from disease of the mind to such a degree that he ought not to be held responsible. In either case mental deficiency no less than disease of the mind is held to be a possible cause of irresponsibility.

The chief reason why the Commission would have the M'Naghten Rules altered is because they take into account only the cognitive faculties, which is the main criticism the medical profession has made of them—and began making almost as soon as they were formulated over 100 years ago. But the phrase "irresistible impulse" which was so often on the lips of reformers is open to objections also. In the first place, its critics would ask, how is an irresistible impulse to be distinguished from one that is unresisted? An objection perhaps more telling to the medical mind is that

it gives a false picture of the mentality of some people arraigned before the courts. Often it was not some overwhelming wave of passion, with an implication of transience, that guided a criminal's conduct so much as a long-continued mental state. Commonly such a condition could be classified as paranoia. This and other mental disorders are often enough accompanied by sufficient clarity of intellect to enable the accused person to know the nature and quality of his act and that it was legally wrong, yet it may be questioned whether any accused thus afflicted has been hanged in recent years. Some have been reprieved by the Home Secretary after a medical investigation, while others have been found "Guilty but insane" under the M'Naghten Rules. This has been possible only because of the considerable latitude with which they have been interpreted. As that great lawyer, Viscount Simon, expressed it in an address published in the *Journal* recently³: "Judges and juries are impressed by really strong medical evidence of irresponsibility, and the legal formula is not of cast-iron, but allows of elastic application." It is this elasticity of interpretation that has been invoked both by those who would retain the Rules and by those who would replace them; for, argue the first, rules of some kind are necessary, and a humane application of them has made them work in practice; while the second contend that rules with which such liberties have to be taken to conform to public opinion of the day are better scrapped altogether. The Commission has taken the second view, and there is much to be said for it. Whether it would prove workable in practice is another matter. An extension of the Rules may be preferred, and in that case medical opinion would seem to be well met by the Commission's suggestion of adding to the formula a phrase to the effect that the accused, as a result of disease of the mind (or mental deficiency), "was incapable of preventing himself from committing" the act.

But whatever of the suggested modifications is made to the M'Naghten Rules the formula is bound, so long as it is retained, to have the defect of any formula applied to the infinite variety of human experience. In attempting to distinguish between the responsible and the irresponsible, judges and juries are likely to be harassed by those puzzling cases in the borderland where reason glows dimly but is not extinct. With this in mind the B.M.A. included in its evidence a recommendation that a verdict of "guilty with diminished responsibility" should be returnable in suitable cases in the English courts as it is in the Scottish. The Commission was unable to agree. Its main objection is against trying to take a doctrine that has grown up gradually in the common law of Scotland and inject it in one dose into

the English law; but, recognizing that some alteration in the present state of things may be necessary, the Commission embarks on the highly controversial argument that the jury should have the power of deciding whether the prisoner should hang or whether mitigating circumstances demand a lesser sentence. We pass here beyond the borders of medicine into those many other problems that the Commission sets before us on which a doctor's opinion will owe less to his medical training than to his private judgment.

Among the recommendations of special interest to medical men is one that has achieved some considerable publicity—namely, that on execution by injection of a lethal drug. While the Committee does not recommend lethal injection "in present circumstances," it does recommend, "unanimously and emphatically," that it should be considered periodically. Here most medical men will feel that the Commission has gone rather astray. Whatever may be said for or against various procedures for causing death speedily and humanely, the Commission does not touch on what to practising doctors must be one of the strongest arguments against lethal injections. It is that the injection of a drug is a procedure that was invented and has always been used wholly for beneficial purposes, and it is so regarded in the public mind. To execute criminals by the same procedure as brings ease and sleep to sufferers from pain must surely arouse, even if unconsciously, feelings of abhorrence in many people. No emphasis is needed to the evidence put before the Commission by the B.M.A. that no medical man would be associated with the giving of lethal injections or the training of other people to give them.

ANTIBIOTICS IN WHOOPING-COUGH

The unusually high number of whooping-cough cases being reported in England and Wales each week is illustrated graphically in our epidemiological columns. It remains a serious disease, especially in very young children, and unfortunately antibiotics offer no dramatic benefits. *Haemophilus pertussis* is highly susceptible *in vitro* to the action of the newer antibiotics, yet their efficacy in the treatment of the disease is still uncertain. This is perhaps not surprising in view of the fact that, in the untreated disease, *H. pertussis* disappears early from the clinical picture, though symptoms persist and often increase for several weeks after it can no longer be detected. Perhaps *H. pertussis* induces an altered state of the tissues which is responsible for the symptoms, and once this state is induced the presence or absence of the organism is of little account. A drug whose only action is to inhibit *H. pertussis* could

not be expected to alter the course of the disease unless it were applied before the tissue reaction had been induced. While this is no more than conjecture, something of the sort may explain the discrepancy between clinical and laboratory results.

A report¹ published by the Whooping-Cough Subcommittee of the Antibiotics Clinical Trials Committee of the Medical Research Council analysed the results of treatment with chloramphenicol, aureomycin, and an inert control preparation in 294 patients. Children aged 0–11 months were given 1 g. daily in two doses, children aged 12–35 months 1.5 g. daily, and children aged 36–59 months 2 g. daily, in each case for seven days. The effect of the treatment was judged by the frequency and severity of the spasms and by the culturing of per-nasal swabs. The bacteriological evidence was clear: treated cases cleared more rapidly than controls. Clinical effects were much less striking, and it was mainly in cases treated within eight days of the onset of the earliest symptoms that any significant difference was found. The report emphasizes that these earliest symptoms are cough or coryza, not the development of a paroxysmal cough, which for this purpose must be regarded as appearing at a relatively late stage of the disease. It is also clear from the report that even in the early group results of treatment were not dramatic: indeed, most of the children were still having typical spasms three weeks after the start of treatment. The drugs appeared to diminish the severity of the paroxysms to a greater degree than their number. But in cases treated later than eight days after the onset of symptoms the difference in number and severity of paroxysms between treated and control groups was very slight, though always in favour of the treated group. As the report states, if attention had been directed to a comparison between the whole of the treated and of the control groups, it would have been concluded that chemotherapy failed to produce a clear-cut clinical cure.

Gray,² commenting on the report, criticized a dosage scheme based on age rather than tissue mass. He worked out the equivalent doses per kg. body weight: these range from 50 mg. to 75 mg. per kg. It is quite possible that such doses are not high enough, but they are not unreasonably low. Gray then quoted some figures of chloramphenicol concentrations in post-mortem lung and brain tissues showing that concentrations of the drug vary from tissue to tissue, that vascular obstruction coincides with low concentration, and that in uninflamed human

¹ *Lancet*, 1953, 1, 1109.² Gray, J. D., *ibid.*, 1953, 1, 1257.³ *ibid.*, 1950, 2, 800.⁴ LaBocchetta, A. C., and Dawson, K. E., *Amer. J. Dis. Child.*, 1952, 84, 184.⁵ Lassen, H. C. A., and Grandjean, L. C., *Lancet*, 1951, 1, 763.⁶ Hazen, L. N., *et al.*, *J. Pediatr.*, 1951, 39, 1.⁷ Booher, C. E., *et al.*, *ibid.*, 1951, 38, 411.⁸ Bogdan, A., *Lancet*, 1951, 1, 764.⁹ *British Medical Journal*, 1952, 2, 136.¹ Report of Royal Commission on Capital Punishment, 1949–53. 1953. H.M.S.O. 12s. 6d.² *British Medical Journal*, 1950, 1, 365.³ *Ibid.*, 1953, 2, 1.

lung chloramphenicol is rapidly removed. These are points of considerable importance, suggesting that different dosage may be required at different stages of the disease, but whether they can be translated into a practical dosage scheme is another matter. In an earlier paper Gray³ investigated the use of aureomycin and chloramphenicol in the treatment of whooping-cough: for aureomycin the dosage was 50 mg. per kg. per day in four doses, for chloramphenicol 100 mg. per kg. per day in one dose, in both cases for a total of five days. He found that both drugs reduced the number of coughs, but that chloramphenicol also lessened the whooping and vomiting and loosened the cough. His results showed no dramatic change in the course of the disease: children were still having paroxysms three weeks after the onset of the disease, but the number of paroxysms was less than in the controls. He suggested a higher dosage scheme.

Other workers have had similar experiences. La-Bocchetta,⁴ using aureomycin in a dosage of 50 mg. per kg. body weight for ten days, concluded that, except in cases treated in the first week of the disease, there was no marked apparent effect from the use of the drug. Lassen⁵ treated 93 cases with chloramphenicol, given as rectal suppositories for three to five days, and claimed that the frequency of the paroxysms fell sharply. No untreated controls are reported for comparison, and patients were still having paroxysms at the end of the period of observation, though fewer in number. Hazen⁶ and Booher⁷ used terramycin as well as the other two drugs, and it appears to have a similar degree of efficacy. Bogdan⁸ used chloramphenicol to treat contacts, and his results are striking: in 10 out of 13 cases the disease was arrested in the pre-paroxysmal stage. The treated contacts must be isolated from infectious cases to avoid reinfection.

It is clear that no drug has yet been discovered which will rapidly control an attack of whooping-cough. Aureomycin, chloramphenicol, and terramycin probably all have some effect if given in the earliest stages, but the effect is far from dramatic. When given later in the disease they have very little effect. These drugs have toxic effects—most notably chloramphenicol⁹—and it is inadvisable to prescribe them in every case. The minimal dosage is 50 mg. per kg. body weight per day, and 75 or 100 mg. per kg. may be better given in three or four doses per 24 hours for seven days. Because babies under 1 year suffer most severely from the disease, it is justifiable to treat all patients of that age. All cases diagnosed within a week of the first symptom—not the first spasm—might also be treated. Even in these cases dramatic results should not be expected. Probably the most rational use of the drugs is in the treatment of contacts before they develop the typical symptoms of the disease.

SEVERE REACTIONS TO PENICILLIN

It has long been recognized that sensitivity to penicillin may develop, certainly in consequence of treatment and possibly in other ways. Some of the penicillin in the blood is bound to plasma proteins, and it therefore evidently behaves as a haptene. As long ago as 1945 A. Rostenberg and H. Welch¹ found 5% of subjects to be sensitive as determined by intradermal tests. S. M. Peck and his colleagues² found this condition in 5.4% of 499 subjects, and in a higher proportion of those who had been treated with penicillin. These authors and R. Schuppli,³ who observed a marked increase in the frequency of sensitivity between 1947 and 1951, also consider that skin mycoses predispose to it; whether antigenic relationships or simply an allergic diathesis are responsible for this seems uncertain. The usual effects of giving penicillin to such a patient in these earlier times were fever and urticaria.

More recently much more alarming and even fatal reactions have been described. Following the paper by F. J. Pick and J. F. Patterson⁴ recently published in this *Journal* describing a fatal reaction to a penicillin injection, and the report in our medico-legal columns⁵ of an inquest on a similar case, we have had several letters, some which appear in our correspondence columns this week, describing similarly alarming but fortunately non-fatal reactions. Experiences of this kind, although apparently new, are by no means unique: Bayer and five colleagues,⁶ writing from Illinois, describe six such occurrences, one being fatal, and are puzzled that so little has been written on this subject "in view of the ease with which this series was collected in a short period." Since there appears to have been nothing unusual in their methods of giving the drug, such reactions cannot be very uncommon, and it is important to know how to prevent them.

In the first place, suction before injection should always be practised in order to ensure that what is intended to be an intramuscular injection is not in fact intravenous. The subcutaneous route is perhaps preferable on this account, since the likelihood of entering a vein is then remote. Intravenous sodium penicillin is harmless in a normal subject, but penicillin in some of its present forms is not. If the preparation contains oil, or procaine penicillin crystals in suspension, these are at least liable to obstruct lung capillaries, while some of the more complex penicillin compounds, including that used by Pick and Patterson, are suspected of exerting an actually toxic effect when accidentally injected intravenously.

This is certainly not the explanation of every such reaction, since one in the series of Bayer and his colleagues resulted from nothing more than the intradermal injection of 10 units of crystalline penicillin as a test of sensitivity. The other factor is unquestionably sensitization: such patients always give a history of previous penicillin treatment, and often of previous reactions of some kind. The fact that they have been sensitized can

⁷ *Arch. Derm. Syph. (Chicago)*, 1950, **62**, 314.

be proved by the intradermal injection of a small dose, the usual result of which is immediate wheal formation. The time has apparently come when at least some cursory inquiry about previous reactions should be made before giving any patient penicillin: a test for sensitivity should follow if the history is suspicious. Patients having asthma or other allergic conditions should evidently be treated with caution. The administration of an antihistamine compound with the penicillin itself, according to S. W. Simon and M. D. Feldman,⁷ serves to prevent the ordinary type of hypersensitivity reaction, and would presumably have a similar effect on the more severe. Drugs of this type are also apparently at least as useful as adrenaline for the treatment of the established reaction.

It would be most unfortunate if, as one of our correspondents seems to suggest, this development tempts doctors to abandon penicillin for one of the newer antibiotics. Penicillin has properties possessed by no other drug, and what is chiefly required is greater discrimination in its use.

CULTIVATION OF THE COMMON COLD VIRUS

At the end of the last war the Harvard Hospital at Salisbury, originally designed and shipped to the United Kingdom for the study of infectious disease arising in the European theatre of operations, was most generously handed over by Harvard University to the British Government for the study of problems in preventive medicine. For the last seven years it has been the centre of research into that most common of all human afflictions, the common cold. The starting line for this enterprising project was acceptance of the belief that the primary aetiological agent of the common cold was a virus. Dochez¹ had shown this to be so more than twenty years ago, and it has since been confirmed on numerous occasions by Andrewes and his colleagues at Salisbury.² Having accepted this fact, research workers had as their first and main objective to catch the virus and study it under laboratory conditions. It may seem strange that a virus which is capable of causing such universal and indiscriminate disease in man should be so difficult to adapt to laboratory life. But so it has been. Despite innumerable attempts, aided by all the tricks of the trade, the common cold virus has, with the exception of Dochez's success with chimpanzees, resisted all the efforts made to cultivate it outside the human host.³ How then could this objective be reached? The successful adaptation of poliomyelitis viruses to tissue culture of human embryonic material pointed to a new line of attack on other viruses pathogenic to man.⁴

Earlier experiments with the common cold suggested that the virus at least survived in human embryonic tissues. Now with improved technique Andrewes and his team present evidence that actual virus multiplication has taken place.⁵ Using the roller-tube technique with explants of human embryonic lung and a single strain

of virus, they have brought on colds in human volunteers by intranasal inoculation with material up to and including the tenth serial passage. Some intermediate passages have been negative, but colds artificially induced do not always "take." Controls, however, have been clearly negative. The repeated dilution that has necessarily taken place on passage suggests that the colds produced at the tenth passage have been caused by fresh virus rather than by any virus remaining from the original inoculum.

Human volunteers have so far played an indispensable part in this work as indicators of the presence of virus in test material. The second objective will therefore be to find some method of identifying the presence of virus without recourse to human beings. Cytopathogenic effects, a noticeable feature in poliomyelitis tissue cultures, have so far not been observed in the case of the common cold. More detailed microscopical examination and immunological tests may provide a way of overcoming this obstacle. It seems clear that further calls will be made for human embryonic material in modern virology. For understandable reasons, supplies of such material in this country will fall short of demand, and so it is important that the fullest possible use is made of any material that is available until such time as a more convenient medium can be found.

OCCUPATIONAL FERTILITY

The last part of the Registrar-General's 1931 Decennial Supplement¹ has just appeared; it is mainly on occupational fertility. The crude birth rate per 1,000 married males aged under 55 in 1931 was, for all classes combined, 95.9. The crude birth rates of social classes I to V expressed as percentages of that for all classes were, respectively, 75.1, 67.6, 99.4, 110.4, and 127.4. There were fluctuations within the social classes, and the most remarkable for occupational groups with 1,000 married men or more was that of company directors (so returned) in finance and insurance in social class I, who had a ratio of 277.9. This ratio was much the largest recorded. After that the other ranks of the Services had the highest birth rates, the percentage ratios of their birth rates to the rate for all classes being 228.2 for the Royal Air Force, 213.7 for the Army, and 194.9 for the Royal Navy and Marines. The ratios for the Merchant Navy were much the same, being 204.5 for petty officers, seamen, and deck hands, 203.6 for pursers, stewards, and domestic staff, and 202.6 for firemen, trimmers, greasers, and donkeymen. The largest ratios among civilian occupations were greengrocery salesmen and shop assistants 190.6, other assistants to furnacemen and rollers 190.0, builders' labourers 184.7, haulage and cartage contractors, managers, and master carmen 174.2, slaters and tilers 166.5, tube drawers and welders 161.4, motor mechanics (so returned) 159.0, constructional engineers (not professional) 152.0, other dock workers 149.5, miners, other workers below ground 148.6, miners, hewers, and getters 147.2. The lowest ratios were those of metal workers, foremen, and overlookers in machine shops 12.7, and heads or managers of commercial

¹ *J. exp. Med.*, 1930, **52**, 701.

² *Lancet*, 1949, **1**, 71.

³ Andrewes, C. H., *New Engl. J. Med.*, 1950, **242**, 235.

⁴ *British Medical Journal*, 1953, **1**, 826.

⁵ *Lancet*, 1953, **2**, 546.

offices 17.0. Generally the group of foremen and over-lookers had a very low ratio, and in nineteen types of occupations with 1,000 or more married men aged under 55 the ratios varied between 20 and 40. Other very low ratios were lodging- and boarding-house keepers 19.8 and chief constables, inspectors, and superintendents of police 22.1.

Most of these differences are not so much occupational as due to age, for a parent has commonly founded and perhaps reared his family before attaining a position of responsibility. The difference between the younger and older men can be readily demonstrated with railway workers. In the period round 1931 the locomotive engine fireman had to serve several years before promotion to engine driver, and during his spell of firing he married and started a family. In 1931 the ratio of the crude birth rate to that of all occupations was 143.9 for firemen and only 44.2 for engine drivers.

A comparison has been made between the relative fertilities of married men aged under 55 and their wives aged under 45. The index for each sex was found by expressing the birth rate for each population group as a percentage of the rate for all classes combined. The index for each sex was in very close agreement, and generally differences of 5 or less were recorded. But fishermen were an exception, for the married men had a birth rate in 1931 of 79.0% of all males, while the married women had a rate of 139.7% of all married women.

Some data for 1939 included in this volume were analysed by thirteen occupational groups. The wives of miners had the lowest average age at marriage of 23.3 years, the lowest at first maternity of 25.1 years, and the shortest average duration between marriage and first maternity of 1.8 years. On the average the wives of professional and administrative workers married at 25.9 years, and had their first child at age 28.6 after a marriage duration of 2.7 years. The wives of miners had the highest stillbirth rate, while the professional classes had the lowest.

Twenty-two and a half years have passed between the 1931 Census and the publication of this volume, though the inclusion of information collected in 1939 is some compensation. Doctors and others who are interested in such information as the Registrar-General publishes here would be better served if it concerned contemporary rather than historical events, and many will hope that the results of the 1951 Census will not be so delayed.

PREVENTION OF FOOT DEFECTS

In an ageing population there is bound to be a steady rise in the incidence of disabilities due primarily to wear and tear. This applies especially to foot defects, which have become a serious medical problem. It is economically impracticable, even if it were possible, to provide effective treatment for all those with established foot defects, and under the National Health Service it has been considered an economic impossibility to provide chiropodial treatment for all, because the demand would be so great. A close analogy may be drawn between the foot and the motor-car. Although cars of varying

quality are produced, they are all capable of giving good service provided that they receive careful maintenance. The need for specially equipped repair shops is in inverse proportion to the care with which cars are serviced. The same applies to the human foot, but so far we have concentrated on providing expensive specialist services and elaborate equipment for the repair of broken-down feet, when what is required is an organization for their care and maintenance, especially during the running-in period—that is to say, during childhood. One factor that has delayed the development of such services is the lack of factual information about the incidence, aetiology, and mode of development of the various types of foot defects. As a result of recent surveys, however, the general picture is becoming much clearer. The information afforded by the survey¹ conducted in the borough of Luton on the incidence of foot ailments at all ages among the general population has now been reinforced by two further surveys whose results are published in this issue of the *Journal* (pp. 745 and 749). The conclusions that may be drawn from these and other investigations should be of assistance in the planning of preventive measures.

Perhaps the most important point brought out by all investigations is the fact that the majority of those defects which are responsible for the more serious disabilities of later life are already well established by late adolescence. A second fact of almost equal significance is that, although a foot may have a congenital weakness rendering it liable to develop some particular defect, whether it does so or not depends primarily upon the care it receives during childhood and adolescence, with special emphasis on footwear. An obstacle to the comprehensive organization of preventive measures lies in the multiplicity of the various interests involved, from the public health and school authorities on the one hand—with their teams of workers comprising doctors, health visitors, school nurses, physiotherapists, and chiropodists—to the shoe manufacturers and retailers on the other. Finally, there is the fact that the foot is a complicated piece of mechanism demanding knowledge and understanding for its proper care. Before real progress can be made much closer co-operation is needed between the diverse interests concerned, and a better and more general understanding of the problems. The Boot and Shoe and Allied Trades Research Association and the Foot Health Educational Bureau have already done much good work on these lines. Now that the latter has been taken under the wing of the Central Council for Health Education it is to be hoped that it will have the opportunity for increasing the scope of its work still further. The fruits of co-operation are already evident in the plans for a "foot health week" to be held in Birmingham later this month under the aegis of the Foot Health Educational Bureau and the Birmingham health and education departments.

Further knowledge could now best be gained by conducting pilot experiments in foot care in various parts of the country. A provisional pattern for such experiments has already been worked out, the essential features comprising the regular inspection of the feet of school-

¹ Dykes, R. M., Grundy, F., and Lee, H. E., *Med. Offr.*, 1952, **87**, 223 and 235.

children, the assessment of the significance of any defects noticed by those with the requisite training and experience, advice and regular supervision in the matter of footwear, and arrangements for special treatment in selected cases. Fortunately, for once, the requirements do not entail great expense on elaborate equipment, buildings, or staff. Although local health and education authorities already have their hands full with other urgent tasks, it is very much to be hoped that more of them will take the initiative in helping with this important aspect of preventive medicine.

QUALITY IN GENERAL PRACTICE

It might be thought that a good postgraduate grounding in clinical medicine would be apt to make a man pre-eminently suited to general practice. But the difficulties experienced by many holders of higher qualifications, and especially the M.R.C.P., in entering general practice suggest that there are at least some established doctors who do not share this view. Another aspect of this problem was discussed in the General Medical Services Committee of the B.M.A. last year,¹ when Mr. R. M. Forrester, chairman of the Registrars Group Council, put before the committee the anxieties and needs of registrars for whom no consultant openings would be made. He received the sympathetic hearing that his case deserved. But while the problem was rather a different one with its own special urgency then, its discussion served to throw light on the more general question whether postgraduate study is in fact the asset it is sometimes claimed on paper to be when a doctor seeks an entry into general practice. Several speakers expressed the view—and no one can cavil at it—that a doctor, however well qualified in medicine, must begin at the beginning when he starts in general practice, and not expect to become immediately a principal in a large practice ready-made for him. Nor, indeed, is he likely to get far if he enters general practice with an air of doing so as a last resort and with an expectation of obtaining part-time hospital work straight away. Those responsible for his appointment to a vacancy, whether as assistant or principal, may well take care to assure themselves that he intends to devote his whole energy to general practice. But when allowance is made for those few registrars who take no heed of such criteria as these, there remain many who believe that they have been turned down for no other reason than that they have done several years of postgraduate medical work in hospital and achieved a higher qualification. In a letter at page 161 of the *Supplement* this week a correspondent draws attention to the plight of some of these people. Whatever may be said for or against his specific cases, there is more than a grain of truth in the jocular remark—which came from a good source—that to the applicant for a general-practice vacancy the possession of a car is more important than the possession of an M.R.C.O.G., F.R.C.S., or—most dangerous encumbrance—M.R.C.P.

While there is an obvious truth in the assertion—and it has needed emphasis recently—that general practice is

a special branch of medicine, there is the danger too that the hypnotic reiteration of a catch-phrase may obscure the fact that the greater part of general practice is still clinical medicine. It may gather tributaries from other springs of knowledge, but surely a thorough foundation in ordinary general medicine to the M.R.C.P. standard can be nothing but an asset. And so it is held to be for even the much more restricted medical specialties, such as, for instance, anaesthesia or dermatology, many of whose consultants have a higher postgraduate qualification in general medicine. There are already far too many barriers to free and easy movement in the Health Service. Most of them are inherent in its administrative structure, and doctors have rightly condemned them many times. It would be deplorable if a few but influential people in our own profession should heap up more barriers, and ones peculiarly harmful to that lively spirit now to be seen animating general practice in many quarters.

CLINICAL PATHOLOGY IN GENERAL PRACTICE

One of the facilities general practitioners have been seeking for some time is easier access to pathological investigations, though one may note as a corrective to this that in the G.P. Review Committee's report¹ some 50% of general practitioners did not think their practices suffered from the absence of such facilities. Nevertheless it is difficult to see how general practitioners can do what one witness in the inquiry¹ described as "good medicine" unless he has at his disposal the exact information and guidance a clinical pathologist can give him. General practitioners will want to know just what facilities are available, how they may make use of them, and how they may interpret the findings of the laboratory so as to use them for the benefit of their patients. It is for this reason that we are publishing over the next few months a series of articles on "Clinical Pathology in General Practice," the first of which, by Professor S. P. Bedson on "Facilities under the National Health Service," appears at page 774. Future articles will be on such subjects as the method of collecting specimens, technique of venepuncture and lumbar puncture, taking specimens for medico-legal purposes, and on the value of various tests and investigations in the diagnosis of disease. Throughout it is hoped to give the normal values of various bodily constituents so that the practitioner may constantly have these by him; and the writers in this series will discuss the significance to be attached to variations from the normal. As Professor Bedson puts it: "The important thing is that the general practitioner should consult with the pathologist about his case, for only in that way will he get full value from this service." Such a consultation should be of the highest interest to both, for it will bring the pathologist into more direct contact with the everyday problems of practical medicine and give the practitioner a more exact idea of the help the science can give the art. And the patient will benefit. It is hoped that the present series will make such co-operation fruitful.

CLINICAL PATHOLOGY IN GENERAL PRACTICE

FACILITIES UNDER THE NATIONAL HEALTH SERVICE

BY

S. P. BEDSON, M.D., D.Sc., F.R.C.P., F.R.S.

Consultant Adviser in Pathology to the Ministry of Health

This century has seen enormous progress in the application of pathology to the elucidation of clinical problems. Fifty years ago the pursuit of pathology was largely academic. It was, of course, recognized as being fundamental to the science of medicine, and morbid anatomy and histology were used to a limited extent for the purpose of solving clinical problems in retrospect. But a diagnostic service of hospital pathology such as we have to-day, in which microbiology, biochemistry, and haematology take their place with the more ancient discipline of histopathology, had hardly been conceived. By the outbreak of the second world war the teaching hospitals and the larger voluntary hospitals had built up departments of pathology which not only provided a diagnostic service but served also in many instances, and particularly in the case of the teaching hospitals, as active centres of research. But this was not the case in many municipal or small voluntary hospitals which at that time either lacked completely, or were ill supplied with, such an essential aid in the treatment of their patients. And nothing had been done to supply the wants of the general practitioner in this respect, if one excludes one or two commercial or local authority ventures which in the main provided a limited postal pathology service of a most undesirable kind.

The consequences of war are not invariably evil, and one of the good things achieved by the recent war was the raising of the standard of medicine in the more isolated and less advanced hospitals of this country. This was the outcome of the Emergency Medical Service with its transfer of staff, equipment, and ideas from the efficient hospitals of our large cities to the more lowly and sometimes rather primitive institutions in the less congested parts of the country. Upgrading these hospitals was not merely a question of implanting in them a leaven of good clinicians; all the other services had to be installed or improved, and that meant setting up adequate departments of pathology, because, as all are agreed, a good service in pathology is essential to a high standard of achievement in medicine. And when in 1948 the National Health Service came into being it was very largely on the pattern evolved during the war that the service was fashioned, at any rate so far as pathology was concerned. There was, however, this difference, and a very important one at that: the pathology service envisaged by the designers of the health service was to be just as readily available to general practitioners as to the clinical staff of the hospitals.

One ought, perhaps, to say that the general practitioners did at times make use of the Emergency Laboratory Service, and in this they were not discouraged either by the local authorities or by the Ministry—in fact, in some parts of the country the service was thrown open to them. For example, the county laboratory service with which I was associated in the

war was made freely available to the practitioners, and very popular it proved. But this is a different matter from the nation-wide service in pathology which, in theory at any rate, became available to the general practitioner with the passing of the National Health Service Act. There can be no two opinions about the value of such a consultant service to those engaged in general practice, but it should be clearly understood that what one has in mind in saying this is a consultant service and not just the provision of laboratory aids for general practitioners.

Scope of the Service

One knows, of course, that general practice can be carried on without any help from the laboratory at all, and Duncan (1952), who practises in Portsmouth and who, incidentally, is an enthusiastic advocate of a general-practitioner service in pathology, reckons that about three-quarters of his patients can be satisfactorily treated without recourse to laboratory aid. There is little help, for instance, which the laboratory can give in the diagnosis of the exanthemata, with the exception of smallpox, of mumps, or of the common cold, and, as Duncan rightly says, there is no need to seek the aid of the pathologist in connexion with the diagnosis of influenza when this condition is epidemic. The sporadic case would, however, present an entirely different problem, for without the context of similar cases it might be difficult to distinguish it from pyrexias of undetermined origin, and in the investigation of such febrile states the help of the laboratory can be invaluable. And there are many other conditions in the diagnosis and the treatment of which the general practitioner will find consultation with the pathologist and the resources of the laboratory an advantage and sometimes a necessity: urinary tract infections, disturbances of renal function, renal failure, the many forms of anaemia, hepatitis, the virus pneumonias, and the control of the therapeutic use of such preparations as liver, vitamin B₁₂, thiouracil, and the antibiotics are some of these.

In addition to these investigations of a more or less routine type there are certain special ones which should be mentioned. Selective weed-killers of the dinitro-ortho-cresol (D.N.O.C.) type are much used these days for the various corn crops. They are applied to the growing crops in the late spring, and, although they are highly toxic for man, their continued use is widespread because of the greatly increased yield per acre which they make possible. The wearing of masks and protective clothing reduces the risk of poisoning to negligible proportions, but cases of poisoning have occurred and knowledge of the level of D.N.O.C. in the blood is helpful diagnostically, and also as a warning of impending intoxication. Hospital laboratories situated in strategic positions throughout the country undertake this investigation.

Another agricultural hazard comes from the use of organic phosphorus insecticides, such as diethyl-para-nitrophenyl-thiophosphate ("parathion"), by the fruit growers. Poisoning by these preparations results in destruction of cholinesterase, and the estimation of the blood level of this enzyme is useful to the doctor both in the diagnosis of parathion poisoning and in its prevention. Four laboratories undertake this particular investigation; they are

situated in Worcester, Peterborough, South-east London, and Portsmouth, near to the important fruit-growing districts where these particular insecticides are most used.

A third special investigation concerns the diagnosis of pregnancy. There are several tests available for this purpose, and of these the Hogben test, which makes use of the *Xenopus* toad, is probably the most satisfactory. Not infrequently it is necessary for medical reasons to know at the earliest possible time whether or not a woman is pregnant, and pregnancy-test centres have been established, at Watford and at Sheffield, to investigate these cases.

A Consultant Service

The description of the pathological service available to the general practitioner has been made in very general terms; specific mention of what to send, and when or how and to whom, has been avoided. This has been done deliberately. For one thing this article is to be followed by others dealing in a more detailed way with particular aspects of the general-practitioner laboratory service, and the answers to some of these questions will be found in them. But it has been done for a much more important and fundamental reason: to emphasize that this service in pathology offered by the National Health Service to the general practitioner is by the National Health Service to the general practitioner; for a consultant service and not a penny-in-the-slot business; for that would be no better than the postal services of the past. If a general practitioner wishes to make use of the service he should get in touch with the nearest pathologist and tell him what his problem is. It may be that it will suffice to send a specimen to the laboratory, or possibly it may require sending the patient, in which case an appointment can be made. If the patient cannot be moved it may necessitate a domiciliary visit, or, of course, it may be one of those cases in which the pathologist cannot be of help. The important thing is that the general practitioner should consult with the pathologist about his case, for only in that way will he get full value from this service.

There is another aspect to this. The general-practitioner service and the hospital service are both parts of the National Health Service equal in importance with the third component, the public health service, and, as Sir Allen Daley (1953) has pointed out in his Croonian Lectures, these three parts of the Service will make a more effective contribution to the health of the nation if they work together as closely as possible. There is a definite risk of the general practitioners and the hospitals drifting apart, so that any contacts between the two should be fostered. And here is a natural link, between the practitioner and the pathologist; it could only be to the mutual benefit of the two and of the Health Service that this link should be forged and strengthened.

Will the Pathologist be Overwhelmed?

It is common knowledge that the extent to which the pathology service is being used by the general practitioner varies greatly in different parts of the country. In some areas it flourishes, whereas in others it has hardly made a beginning; this has been attributed to the reluctance of the pathologist to encourage the practitioners to use his service for fear of being overwhelmed with a flood of work beyond the resources of his laboratory. Those of us who have had experience of this form of service would agree with Sir Allen Daley (1953) that these fears have usually proved unfounded. In defence of the pathologist who has been hesitant to undertake this work it should, however, be pointed out that when the Health Service was formed, since the practitioner work was probably an unknown quantity, the pathologist worked out the establishment of his laboratory on the basis of the hospital work it would have to undertake. He no doubt thought that he could proceed cautiously and increase his staff as the service developed; he was probably not allowed to do otherwise. Now for various reasons, economic as well as the difficulty of getting staff, he could not expand the work of his laboratory very much if he wished, and he is faced with trying to fit a quart

measure into a pint pot. So it makes it all the more important for the general practitioners to get in touch with the pathologists in their districts to find out how they are situated and what they can reasonably undertake. When this service is brought to maturity not only will it lighten the load on the hospitals by making it possible to treat more ill people in their homes, but it will bring an added interest to the work of the pathologist and make general practice an even more worth-while career.

CAPITAL PUNISHMENT FOR MURDER

THE ROYAL COMMISSION'S REPORT

"... to consider and report whether liability under the criminal law in Great Britain to suffer capital punishment for murder should be limited or modified."

Such was the Royal Warrant for the Commission which has been sitting under the chairmanship of Sir Ernest Gowers for more than four years and has now issued its report. Evidence was taken from 117 witnesses in Great Britain—and many more in other countries—from the Archbishop of Canterbury to the Chief Executioner. In its 500 pages the report discusses proposed amendments to the law, the exercise of the royal prerogative, and alternatives to capital punishment. The sections which will be of chief interest to medical readers are those concerning the M'Naghten Rules and concerning methods of execution. This latter subject was added to the terms of reference at the request of the then Prime Minister (Mr. Attlee).

Murder is, in peacetime, the only offence for which the sentence of death is imposed, and the only offence for which the court has no discretion to alter the sentence. The crime may be human and understandable or brutal and callous to an unbelievable degree; it may have been committed in a fit of passion or as the result of premeditation; motives may range from cupidity or lust to pity or despair, but there remains the one penalty.

Categories of Murder

During the last 50 years, in England and Wales, 1,210 persons have been convicted of murder and sentenced to death. Recommendations to mercy were made in 468 cases and reprieves were granted in 555. Murder in this country is slowly declining. The number of murders known to the police has almost consistently fallen since 1900. The years of highest incidence in England and Wales were 1903 (5.14 per million of population) and 1945 (5.11); the incidence was highest also in Scotland in the last year of the second world war. A rising figure since 1941 is for murders in connexion with sexual assault.

The Commission discusses certain categories of murder. It makes no recommendation with regard to infanticide. It is not considered right to provide by law that a mother who kills her child should in no circumstances be adjudged guilty

¹ Royal Commission on Capital Punishment, 1949-53. Report. Cmd. 8932. London: H.M. Stationery Office. 12s. 6d. net.

of murder. Nor does it advise that in suicide pacts the cases which merit sympathy should be taken out of the category of murder; it is a matter for the Home Secretary to consider advising the exercise of the royal prerogative. The same is true of "mercy killings." The plea that women should be exempted is not accepted; it is based on emotion rather than on logic. By a narrow majority the Commission recommends that the statutory age limit below which a person may not be sentenced to death should be raised from 18 to 21.

The M'Naghten Rules

Out of 3,130 persons committed for trial at assizes on the charge of murder during the present century, 1,275 were certified as insane before trial or insane on arraignment, or were found "guilty but insane," and 48 were certified insane on a medical inquiry held after the trial.

The test of responsibility which a jury must apply was laid down in the replies of the judges to the questions of the House of Lords in the M'Naghten case (1843). The M'Naghten Rules have been closely followed by judges where evidence of insanity was disputed, but have been more freely interpreted or even disregarded where insanity was accepted by the prison medical officer and not disputed by the prosecution. Nevertheless, rare cases arise in which the effect of applying the rules is that sentence of death has to be pronounced on a person whom it would be clearly wrong to regard as responsible.

Among the witnesses heard by the Commission the principal exponent of the inadequacy of the M'Naghten Rules was the British Medical Association,² which recommended the adoption of a formula for their enlargement, and this was supported by other witnesses, notably by Lord Justice Denning. In the Commission's view the test of criminal responsibility contained in the rules cannot be defended in the light of modern medical knowledge, and it adopts a British Medical Association formula, but expressed rather more shortly as follows:

"The jury must be satisfied that, at the time of committing the act, the accused as a result of disease of the mind (or mental deficiency) (a) did not know the nature and quality of the act or (b) did not know that it was wrong or (c) was incapable of preventing himself from committing it."

The Commission holds that it would be better to amend the rules in this way than to leave them as they are, but (with three dissentients) that it would be preferable to abrogate the rules altogether and leave the jury to determine whether at the time of the act the accused was suffering from disease of the mind or mental deficiency to such a degree that he ought not to be held responsible.

Medical Inquiries

Another recommendation is that, following more or less the Scottish practice, every person in England and Wales awaiting trial on a charge of murder should be specially examined by two doctors, of whom one at least should be a psychiatrist of standing, not a member of the prison medical service. The prosecution at present relies on the prison medical officer. The Commission does not recommend the appointment of medical witnesses by the courts instead of by the prosecution or defence; such a procedure would have many repercussions beyond murder trials.

The Commission is of opinion that there will continue to be cases where the accused is insane, though the issue was not raised at the trial either by the defence or by the judge, and therefore that the statutory machinery for medical inquiry after conviction should be retained. It is pointed out that these inquiries are not the same as trial by jury: the jury would consider the state of mind of the accused at the time of the offence, but the medical inquiry is directed primarily to his state of mind at the time of examination.

² Witnesses on behalf of the British Medical Association were Mr. Neville Faulkes, the late Dr. R. G. Gordon, Dr. T. Rowland Hill, and Dr. E. B. Strauss.

Methods of Execution

In the western world there are four main methods of execution in addition to hanging: electrocution (in 23 States of the U.S.A.); the guillotine (in France and Belgium); lethal gas (in 8 States of the U.S.A.); and shooting (in almost every country for those sentenced to death for offences against the military code). It is curious that hanging, which was originally adopted because it was so degrading, exhibiting the criminal in the most ignominious and abject of postures, and so thought to have a strong deterrent value, should now be defended on the score of being uniquely humane. Prison chaplains say that hanging is to be preferred "to, say, a shot from the hypodermic. . . . If a man is to die let him walk to his death cleanly." Mr. Pierrepont, the executioner, told the Commission that in his long experience he had known only one instance of struggle. It is easier for a man to show courage and composure in his last moments if the final act required of him is a positive one, such as walking, than if it is a passive one, like awaiting the prick of a needle.

The time elapsing between the entrance of the executioner into the condemned cell and the fall of the lever is normally between 9 and 12 seconds, provided the cell adjoins the execution chamber, as it usually does. In a series of 58 executions at Wandsworth and Pentonville the cause of death was shown to be fracture dislocation of the cervical vertebrae with laceration or crushing of the cord. Such dislocation causes immediate unconsciousness, though the heart may continue to beat for 20 minutes.

Lethal Gas-chamber and Injection Methods

Accounts are given of the procedure of electrocution and of the lethal gas-chamber. With electrocution the interval between leaving the condemned cell and death is two to four minutes. In the gas chamber the prisoner is apparently unconscious within four seconds of entry; certainly unconscious within five, and respiration and heartbeat have stopped within six. The Commission is in no doubt that in respect of the time taken over preliminaries hanging is superior to either of the other methods.

The Commission was impressed by the opinion of the British Medical Association that if an alternative to hanging had to be found (though it did not advocate any change) gassing by carbon monoxide would be best. There are certain objections to this, chiefly on the ground that the prisoner would not become unconscious for at least one minute after the first inhalation. Lethal injection from a hypodermic syringe is an alternative which suggests itself on the ground of humanity, certainty, and decency, though, apparently, it is not adopted in any country. The drug, probably a barbiturate, would be injected into a vein; in about 20 or 30 seconds it would reach the brain, and the prisoner would become unconscious and die a minute or two later. Expert witnesses, however, questioned the practicability of it. It is impossible to give intravenous injection to a person with certain physical abnormalities, and it is never easy to give it except with the co-operation of the subject. It also demands professional skill, and, says the British Medical Association, "no medical practitioner should be asked to take part in bringing about the death of a convicted murderer." The Commission says:

"We of course respect the attitude of the British Medical Association, but we think they may have magnified its probable consequences. A later medical witness thought the profession would treat the question as one of individual conscience, and not all doctors would feel debarred from giving instruction for such a purpose. Moreover, it is not only within the profession that the necessary skill is to be found."

The difficulty of getting executioners, if it were the only obstacle, would not prove insuperable. The Commission recommends that the question of lethal injection as a substitute for hanging be examined periodically, especially in the light of the progress made in the science of anaesthetics.

The report contains a vast amount of information about the law of murder in many countries, a historical survey of the M'Naghten Rules, and summaries of notable cases.

SCIENTIFIC FILM CONGRESS IN LONDON

[BY A SPECIAL CORRESPONDENT]

The cinematograph film as a source of amusement has for many years been one of the most popular forms of entertainment, but there is still some doubt as to the exact position it will ultimately take as a means of scientific education. Experiments have been made in many countries to advance technique, and the International Scientific Film Association has done excellent work in collating and co-ordinating the results from all over the world. The seventh International Congress, which was organized for the International Association by the Scientific Film Association of Great Britain, was held in London from September 18 to 27 under the presidency of Mr. John Maddison, and was attended by representatives or observers from 40 countries. At the same time the Royal Photographic Society's International Conference was being held and was attended by many of those interested in scientific films. Sir Arthur Elton, President of the British Scientific Film Association, played an important part in the organization of the Congress.

There was a daily continuous showing of scientific films in several different places, and on two evenings there was a gala performance at the National Film Theatre at which representative films from many countries were shown, and very remarkable some of them were. We recall with particular interest one which showed the life history of the locust, how plagues of locusts arise, and how they can be controlled; and another beautiful film which showed the flight of birds in migration. Official notice of the Congress was shown by a formal reception of the delegates by Lord Woolton at Lancaster House, and by short addresses given at the gala performances by Sir Walter Monckton and Sir Stephen Tallents.

Medical Section

There was a special medical section, of which the chairman was Professor H. M. Dekking (Holland) and the vice-chairman Dr. Ronald MacKeith (London). This section held several meetings to discuss technical points, to consider how the moving film might be applied to endoscopy, to examine its application to biology and the problems of forensic medicine, and to determine its value in medical diagnosis. The last-mentioned was perhaps of most use to the medical members. Dr. MacKeith opened the discussion by a general account of the uses of films in medicine, and he was followed by Professor Dekking, who emphasized the limitations of the film in diagnosis. Then came Mr. Denis Browne (London), who gave examples of the proper use of the film in surgical diagnosis but pointed out that films were only of use as a means of investigation leading up to the final mental process of diagnosis. Dr. P. N. Cardew (London) then stressed the importance of a knowledge of the technique of film-production if the best results in teaching were to be obtained, and finally Dr. P. J. Collard (London) gave evidence of the actual value of films in teaching. The general opinion emerged that films can be used with great advantage in teaching medicine and surgery, but they must be regarded only as animated illustrations and reminders; they can never be a substitute for the routine and time-honoured methods of medical education.

The first session of the World Health Organization's newly appointed committee on rheumatism was held in Geneva last month under the chairmanship of Dr. W. S. C. Copeman. The committee deprecated the indiscriminate use of the new hormone remedies and advised that they should be reserved for use by specialists attached to hospital departments and for clinics. They recommended that practitioners should be instructed in modern methods of early diagnosis and treatment of rheumatic diseases, and that in under-developed countries young doctors be encouraged to specialize in them.

Correspondence

Because of the present high cost of producing the Journal, and the great pressure on our space, correspondents are asked to keep their letters short.

Christmas Gifts Fund Appeal

SIR,—I shall be most grateful if you will spare space in your columns for me to appeal for donations to the Royal Medical Benevolent Fund to enable us to distribute Christmas gifts to beneficiaries of the fund.

I hope that all members of the profession will contribute towards this extra help at Christmas time, for it is enormously appreciated by doctors and their dependants who have fallen on hard times. The fact that they are remembered by their more fortunate colleagues gives the recipients of gifts even greater pleasure than the gifts themselves, which, however, provide extra comforts or small luxuries for which they have been longing.

I ask subscribers to the fund to spare a little more for this special purpose, and I beg others to become subscribers at the same time as they respond to my present appeal.

Donations and subscriptions should be sent to the secretary of the Royal Medical Benevolent Fund, 1, Balliol House, Manor Fields, Putney, London, S.W.15, and marked "Christmas Gifts."—I am, etc.,

WEBB-JOHNSON,
President,
Royal Medical Benevolent Fund.

Danger of Penicillin Injection

SIR,—At the suggestion of the manufacturers I am reporting a case of severe anaphylaxis to crystalline penicillin.

The day following my reading in the *Journal* about a case of fatal anaphylaxis to penicillin (September 12, p. 605), I had occasion to give 500,000 units crystalline sodium penicillin to a patient with a large boil on the nose. After about five minutes she was walking home and felt ill. The first symptom was swelling of the tongue and gums followed by intolerable itching of the skin in all areas. She managed to reach home, where she collapsed and became unconscious. I was called after about 15 minutes. She was still unconscious but scratching her skin persistently. Her face was swollen almost beyond recognition, and her skin showed a generalized "flare" response. She was cold, clammy, and almost pulseless. Her airway was not obstructed, however, and there was no cyanosis. She gradually regained consciousness after 1 ml. adrenaline hypodermically, but did not fully recover for another 24 hours.

This same lady, some months ago, had 300,000 units procaine penicillin, and afterwards complained of slight facial swelling and faintness. She said on questioning that she usually swelled unduly after cocaine at the dentist. I therefore assumed that she was sensitive to the procaine, and this was supported by the fact that she had three injections afterwards without any reaction at all. This last injection which was followed by such alarming results was the first for some months, though in the past two years she has had three courses of the drug.

I am happy to say that the bacteria responsible for the boil were equally sensitive to the penicillin, and the lesion had completely subsided by the next day.—I am, etc.,

Anglesey.

KATHLEEN MORGAN.

SIR,—I have read with interest the paper by Drs. Frank J. Pick and James F. Patterson (*Journal*, September 12, p. 605) and the letter from Dr. E. J. Masters (p. 629), both of which draw attention to the dangers of penicillin injection. I have personally observed two alarming reactions to injected penicillin in my own small practice.

The first was in a woman aged 30, to whom I had given 500,000 units of pure crystalline penicillin G by intramuscular injection. A few minutes afterwards her face became red and visibly swollen and there was severe difficulty in breathing. She was acutely agitated, but gave no indication of a sense of impending death such as occurred in the cases reported by Batchelor *et al.*¹ Fortunately, intravenous diphenhydramine hydrochloride ("benadryl") was immediately available, and 1 ml. was injected into an arm vein without difficulty. Recovery was rapid and was more or less complete in about 10 minutes.

The second case, also in a woman, occurred after intramuscular injection of 600,000 units of a suspension of procaine penicillin. Within one minute she became acutely ill and on the verge of collapse, but did not lose consciousness. She remained calm mentally, but repeated on several occasions that she was about to die, even going so far as to tell me where her next-of-kin could be reached. Neither intravenous diphenhydramine hydrochloride nor adrenaline was immediately available, and she was placed on a couch until she felt able to go home—a matter of about one hour later. In neither of the above cases could a history of previous asthma be obtained.

It would appear that an increasing percentage of the population is becoming hypersensitive to penicillin, and it may be that the number of near-disasters is greater than is commonly supposed. I would therefore suggest with all earnestness that the time is now ripe for urging the powers that be to agree to the release of aureomycin for general use by doctors.—I am, etc.,

Belfast.

H. J. CRONHELM.

REFERENCE

¹ *Lancet*, 1951, 2, 195.

SIR,—The great variation in form from case to case in the published reports of severe anaphylactic reactions to penicillin prompts me to report the following case which presented rather bizarre symptoms.

A woman, aged 34, had a course of penicillin injections for puerperal pyrexia $3\frac{1}{2}$ years ago, and a further course one year ago for a carbuncle on the face, without incident. There is no personal or family history of allergy. She was seen late on September 2, 1953, with acute otitis media, and was given an intramuscular injection of 1 mega unit crystalline penicillin with the usual precautions against injection into a vein. One minute later she suddenly collapsed. She remained unconscious for half a minute, then gradually came round, repeatedly expressing her conviction that she was dying. Her pulse, which was almost palpable during the phase of unconsciousness, became stronger, rate 100/min. with multiple dropped beats. She continued to feel very ill and weak, and after 15 minutes in this state she suddenly developed a very severe low abdominal colic, exacerbations and remissions each occupying about 10 seconds, and each spasm causing her to writhe. It was "like labour pains, not a bellyache." Pulse still 100/min. with multiple dropped beats. This colic continued for half an hour, then ceased suddenly. A few minutes later she seemed normal, with pulse 80/min. and regular. At no time was there any respiratory embarrassment or cyanosis. A syringe containing 1 in 1,000 adrenaline was held in readiness, but was not used.

Twenty-four hours later she commenced to menstruate, ten days before she was due. She has never before had any menstrual irregularity and has never had dysmenorrhoea. Fifteen days later an intracutaneous injection of 4,000 units crystalline penicillin in 0.2 ml. produced no reaction.

I have used penicillin on a considerable scale in doses of this order for five years, often in allergic individuals and several times in acute attacks of asthma precipitated by respiratory infection, without previously encountering a severe reaction.—I am, etc.,

Leeds, 7.

The Diploma in Public Health

SIR,—The course for the D.P.H. is at present under examination by the Society of Medical Officers of Health. Having recently taken the course and engaged in public health work, I was struck by how little the D.P.H. training assisted me in my duties, particularly as so much weight was given to this diploma in advertisements for assistant medical officers of health. I hope that this letter will give rise to helpful, constructive discussion.

A considerable number of meetings were devoted to clinical instruction in infectious fevers. At present, senior medical officers of health are still in many cases in charge of fever hospitals, but it seems likely that as they retire these hospitals will come under the control of consultants appointed by the regional boards, although apparently the Ministry of Health is not yet committed on this subject. Clinical instruction in fevers would appear to be unnecessary if this assumption is correct, since epidemiology is otherwise dealt with.

A major criticism is that the teachers seemed to overlook that we were all graduates, and a great deal of time was spent in studying matter that had been already learned in our undergraduate days. A whole term was given over to visits with sanitary inspectors and health visitors, and to various departments of local authority work, but many of these had already been done in my youth, and a good many others, such as water-works, were not worth a visit. Six visits were made to a venereal disease clinic and only two to a child welfare clinic. One had the impression that much of the work had been inserted to fill out the course to a year, and indeed one of the lecturers was of opinion that the work could be done in one term. Parasitology was covered in four lectures. One of these described the life of the fly in detail, and was completely useless, since all that can be said about the fly in relation to public health can be said in a few words. Other lectures dealt with amoebic dysentery and tapeworms and were identical in content with undergraduate lectures and valueless. These lectures are a relic of past methods of instruction and their retention is unwarranted and probably due to inertia.

A committee has been appointed by the General Medical Council to examine the C.P.H. diploma, which is a necessary preliminary to the D.P.H. This involves the attendance of external examiners, as well as the payment of an examination fee, after only one term's work, and it appears that only in Bristol University do any candidates fail to proceed to the D.P.H.

The average assistant medical officer of health spends most of his time in antenatal, child welfare, and school health work, and if the dead wood was cut out of the present course there would be ample time to deal with these. The physiology of the normal child should be included in the curriculum, and extended clinical instruction should be held at child welfare centres and antenatal clinics. In fact, much of the material treated in the D.C.H. should be included. Medical officers must be trained in London before they are qualified to test intelligence quotients under the Act, but there seems no reason why instruction of this kind should not be carried out in any university and included in the course. It must be added that, although regulations are laid down by the General Medical Council as to subjects which should be included, there is some latitude in the subjects at different universities, and it may be that some of these suggestions are already practised elsewhere. At the university at which I studied there were courses of instruction in economics and insurance theory, and some time was devoted to the problems of rehabilitation, which are all extra subjects and could well give way to more relevant matter.—I am, etc.,

Gateshead.

Breast-feeding in Oxford

SIR,—May we comment briefly on a few of the points raised in the correspondence following our article? Professor R. S. Illingworth (*Journal*, August 22, p. 441) has suggested that the involuntary exclusion from the Oxford Child Health Survey of babies who had been seriously ill

during the first two months of life may have led to our obtaining an unduly favourable impression of the results of bottle-feeding. If there had been in Oxford a large number of babies who, as a direct consequence of early weaning, fell ill before the age of 2 months and either died or continued to have manifest signs of their illness after this age, then such a bias could have been introduced. We have, however, no reason to suppose that such a group of babies existed, nor do we agree that even in such a hypothetical case "the entire results would be invalidated."

We fully agree that breast-feeding, while it lasts, is a valuable protection against enteric, and possibly other, bacterial infections. Other things being equal, therefore, the amount of illness experienced during infancy should vary inversely with the duration of breast-feeding. But if it is argued that breast-feeding diminishes the incidence of illness in the post-weaning period, then clearly evidence must be produced which distinguishes between illnesses occurring before weaning and those occurring later. Unfortunately, the figures cited by Dr. Elenora Simpson (*Journal*, September 12, p. 628) fail to make this distinction. In the Oxford Survey it so happened that the babies who had been breast-fed for longest had above-average illness rates in the post-weaning period. We do not accept this finding at its face value, but we remain, for the present, sceptical of any allegedly superior resistance on the part of formerly breast-fed babies. On the other hand, the psychological advantages of breast-feeding mentioned by Dr. Duncan Leys (*Journal*, August 29, p. 508) fall right outside the scope of our observations and we do not presume to question their existence or importance.

We agree with Dr. F. Charlotte Naish (*Journal*, September 19, p. 674) that a morbidity index which takes into account the severity and length of illness provides a more precise measure of ill-health than one which merely counts cases. But we do not think that such an index would invariably result in greater differentiation of bottle- from breast-fed babies. Records of duration are available for about 70% of the illnesses covered by our study. These incomplete records show that, on average, a baby receiving breast milk recovered from an attack of bronchitis in about two-thirds of the time taken by a baby who was entirely bottle-fed. For gastro-enteritis, however, which occurred more than twice as frequently during bottle-feeding as during breast-feeding, the mean difference in duration only amounted to a decimal part of a day.—We are, etc.,

Inflamed Appendices in Femoral Sacs

SIR,—In view of the letter by Dr. T. E. Winckworth (*Journal*, September 5, p. 567), the following two cases of inflamed appendices in femoral sacs may be of interest.

A housewife, aged 50 years, suddenly noticed a painful lump in the right groin. It appeared to be partly reducible.

It remained tender and of the same size for a week, after which she was admitted to hospital. She was operated on by Mr. G. Myers on November 25, 1948, and a femoral hernia was found, containing a partly strangulated distal half of appendix. The appendix was returned to the abdomen, the sac excised, and the hernia repaired. Laparotomy was performed and a long appendix was removed. It measured 5 in. (13 cm.) in length (see photograph). About its middle was an impression left by the neck of the hernial sac and below this it was red, oedematous, and inflamed.

The patient made a good recovery, but 18 months later a large recurrent hernia appeared and a further repair was performed.

A housewife, aged 57 years, had an attack of abdominal pain and distension associated with a lump in the right groin two weeks before admission. During the next few days the lump became red and painful and then subsided, leaving a firm swelling 2 in. (5 cm.) in diameter and only slightly tender. At operation on November 17, 1952, a femoral hernia was found to be present. It contained pus and the distal half of an acutely inflamed and adherent appendix, the tip of which had perforated. The sac was excised, and appendicectomy performed through the inguinal incision. The hernial orifice was also repaired and the wound closed with drainage. Recovery was good.

Both these cases were seen within a space of four years. The specimens of both cases are now in the hospital museum.—We are, etc.,

Reciprocity of Qualifications

SIR,—In any future meeting of medical teachers there is one subject which could well be considered which does not seem to have been touched upon during the first World Conference on Medical Education. It is the lack of a uniform system to indicate that a person is fit to practise generally or specially in medicine in any particular country. Unfortunately, different standards are still required in various countries. However, the present multiplicity of recognized qualifications, registrable and otherwise, within countries is confusing and discourages any reciprocity. In the United Kingdom, especially, the innumerable abbreviations affixed to medical practitioners' names appear senseless, particularly to lay and foreign people.

National diplomas or degrees like those recently begun in agriculture and forestry may be the solution, provided county licensure is avoided—otherwise complex conditions similar to those in North America would arise.—I am, etc.,

HAROLD T. DAVENPORT.

Chester.

Cancer and the Public

SIR,—What value can cancer propaganda bring other than that fear which would drive many that have not got it to the doctor? In the recent inquiry by the British Empire Cancer Campaign as to whether doctors considered it a good thing, the majority were against it (see Lord Horder's letter, *Journal*, July 18, p. 148), and it is as well to realize that those against it were not doctors who were likely to "profit" by the opinion; they prefer to be free from the fear-directed patients. One might think from the propaganda enthusiasts that there was a cure for cancer, and that neither general practitioners nor patients had the sense to recognize cancer; that it needed a specialist to do this. Whereas the truth is that we have no cure, and the patient (including the doctor-patient) recognizes its possibility before any specialist can. Unless the patient goes to the doctor and is able to indicate either local signs or symptoms the specialist cannot find it, even in the sick patient, until the patient is nearly or completely dead. This can be illustrated by the histories of patients who when ill consulted the most renowned specialists and submitted themselves to all the latest forms of treatment. Even when the patient goes to the specialist with the earliest recognizable lesion, though localized surgery is then easier, he cannot truthfully say he can cure, as I know full well. And he ought not to add untruth to the anguish of the patient with advanced lesions by chiding the patient that had she come to him earlier he could have cured her, or by writing to the doctor and suggesting that he had neglected the patient by failing to send her before.

I have seen patients who have knowingly had cancer 7–10 years but have failed to consult the doctor because they

feared the fate of relatives and friends who had sought such aid, and, as Shakespeare recognized, "like the owner of some foul disease, to keep it from divulging, let it feed on the pith of life." Find a cure and there will be no need for propaganda. The major manifestations of syphilis have been abolished even though secrecy and not propaganda has dominated treatment. Neither general practitioners nor patients are the fools our propaganda enthusiasts appear to think them. The death rate from cancer is advancing in spite of all the propaganda and the use of every treatment regarded as efficacious. It is just as prevalent in those cities and countries who use these as in the areas which are "spared" these facilities. It seems to me that cellular pathology as applied to cancer has been responsible for much meddlesome interference and little advance in our knowledge. As long as treatment is based on localized lesions, instead of recognizing localized lesions as manifestations of general disease, we shall not advance. Syphilis was not cured by amputation of gummatous organs or limbs. As with any other antisocial affliction, localized shootings or amputations merely drive the growth underground. And what is this propaganda? Since it is implied that general practitioners do not understand it, is it some rare knowledge to be imparted by the most learned? No, the truth is that the truthful element in it is simple common sense which the ordinary school-leaver could readily grasp and the average person already knows, for the propagandists have not spared the public press for many years.

A well-known surgeon was recently quoted in the public press as saying: "I advise the man who smokes heavily, especially if he is over 40, to have a chest x-ray every six months—or preferably every three months—so that the physician can find the cancer, if one develops, while surgery can cure it." Apart from the truth that no one has a right to claim a cure, would it not be wise, if it can be proved that smoking is the certain cause, to prohibit smoking? I say this though the radiologist, the physician, and the surgeon with all their army of specialists and technicians would be deprived of work. If it is admitted that smoking can cause cancer once, surely it can cause it again in the same patient if, and it is a big if, surgery could cure the first lesion. John Hunter recognized the truth when he told us: "To amputate is to mutilate a patient you cannot cure." No advance has yet been made on this knowledge.—I am, etc.,

Birmingham.

JAMES F. BRAILSFORD.

The Tutorial System

SIR,—We have heard a good deal lately about the increasingly overcrowded medical curriculum, and of the difficulties of deciding what to include and what to omit.

After second M.B., the difficulties, I venture to suggest, do not arise so much from the growing amount of information as from the curious belief that unless much material is packed into courses of compulsory lectures it will not be learned. The maturing student, normally conscientious and ever aware of the forthcoming examinations, is thus placed in the position of an unwilling and irresponsible school-boy. Getting "signed-up" for such courses is a regular student preoccupation, for, besides being time-consuming, they rob him of chances of attending extra out-patients, visiting the wards, etc.

Rather than attempting to teach increasing amounts in the classroom, the student could be encouraged to learn for himself and, in addition, be given more time in which to do this. Courageous pruning of lecture courses might be coupled with the introduction of the tutorials urged by Sir Lionel Whitby (*Journal*, August 29, p. 451). Most students, I think, would welcome not only this opportunity for discussion but the directives given to their reading by the selection of given topics for these. Lecture courses, on the other hand, would be the more valuable if allotted a supplementary role to ward teaching and private reading, to fill in an ever-broadening and sometimes bewildering theoretical background.—I am, etc.,

Hull.

M. K. STRELLING.

Obituary

S. W. JEGER, M.P., M.R.C.S., L.R.C.P.

A Member of Parliament since 1945, Dr. S. W. Jeger died on September 24 at the age of 55.

Santo Wayburn Jeger was born in London on May 20, 1898, and was educated at University College, Cardiff, and at the London and St. Mary's hospitals, qualifying M.R.C.S., L.R.C.P. in 1923. After qualification he settled in general practice in London. Outside his professional work Jeger was keenly interested in politics, and he played an active part in local government. He was elected to the Shoreditch Borough Council in 1925, subsequently becoming chairman of the public health committee, and in 1930 he was elected mayor of the borough. From 1931 to 1946 he was a member of the London County Council and served on its hospitals and public health committees. In 1937 he paid two visits to Spain during the civil war to advise the republicans on medical aid work. During the last war he was medical officer in charge of a mobile ambulance unit and a first-aid post. He was one of the founders of the Socialist Medical Association.

Jeger was first returned to Parliament at the General Election in 1945, when he was elected Labour Member for St. Pancras South-east, a constituency he had unsuccessfully contested in 1935. At the General Elections in 1950 and 1951 he retained his seat in Parliament as the representative of Holborn and St. Pancras South.

W. LANGMUIR WATT, C.M.G., M.D.

Colonel Langmuir Watt, who was at one time surgeon to the radiotherapy department at Guy's Hospital, died at his home at Victoria, British Columbia, on August 14 at the age of 77.

Walter Langmuir Watt was born at Walkerton, Ontario, on July 12, 1876, and was educated at Manitoba University, where he was a medallist in arts and medicine. After graduating M.D., C.M. in 1898, he continued his medical studies at Dublin, where he obtained the diploma of L.M. at the Rotunda Hospital in 1901, and at Edinburgh, taking the Scottish triple qualification in 1907. For some time before the outbreak of war in 1914 he was in charge of the x-ray and electrotherapeutics department of Winnipeg General Hospital, but in August of that year he was mobilized with the Canadian Army Medical Corps, which he first entered in 1902, being commanding officer of the 16th Cavalry field ambulance for many years. Serving throughout the first world war, he attained the rank of colonel, was mentioned in dispatches, and was appointed C.M.G. in 1918.

After the war he settled in practice in London, and in 1923 was appointed assistant surgeon to the actino-

therapy department at Guy's Hospital, where the high-voltage x-ray treatment unit for research work, provided at his own expense, demonstrated in a most striking manner its enormous powers for the relief and possible cure of cancer and of serious diseases of the blood. Later the unit was incorporated in the radiotherapy department, to which he became consulting surgeon. He retired from the active staff of the hospital, under the age limit, in 1937, but continued to practise in London until after the end of the second world war, when he returned to Canada. He married Miss Violet Clarke in 1916, and she survives him, together with the son and daughter of the marriage.

Professor MAXIME LAIGNEL-LAVASTINE, the distinguished French psychiatrist and medical historian, died in Paris on September 5. Born at Evreux on September 12, 1875, he received his medical education in Paris, where he qualified in 1903. At the Hôpital Laennec he was chef de clinique médicale from 1904 to 1907, and in 1919 was appointed chef de service. His early interests lay in neurology and psychiatry, and his many publications in this field include *La Méthode Concentrique dans l'Etude des Psychonévroses* (1928), which was translated into English in 1931. He later turned to the study of medical history and was appointed professor of the history of medicine at Paris in 1931. He was co-author of *Les Maladies de l'Esprit et leurs Médecins du XVII au XIX Siècle* (1930), and with Molinier he wrote a short history of French medicine, which in 1934 appeared in translation in the *Clio Medica* series. He edited the superbly produced three-volume *Histoire Générale de la Médecine* (1934-49). Laignel-Lavastine was elected a member of the Académie de Médecine in 1936, and was made an officer of the Legion of Honour in 1939. He was president of the Société Internationale d'Histoire de la Médecine and of the Ligue de Défense de l'Homme contre le Crime. He was on his way from Paris to preside over the Second International Congress of Hippocratic Medicine at Evian when he had a fatal coronary thrombosis.

Medico-Legal

ANAESTHETIST'S RESPONSIBILITY

The administration of a general dental anaesthetic is ruled to be the responsibility of the anaesthetist and not the dentist. The London Executive Council has had before it a case in which a dentist extracted the wrong tooth from a patient who was given a general anaesthetic by an anaesthetist. The dentist, while very much regretting the occurrence, said that in his opinion it was due to the unaccountable nervousness of the anaesthetist. The Dental Services Committee, after hearing the case, expressed its opinion in the following terms:

"There was an unavoidable breach of the Terms of Service in connexion with the administration of the general anaesthetic, and, although the fault lay primarily with the anaesthetist, the responsibility for the treatment of the patient nevertheless rests with the respondent [dental] practitioner."

The executive council communicated this to the Ministry of Health, and the Ministry responded with this contrary opinion:

"The Minister has noted and agrees with the recommendation of the council, except with regard to the findings that there was a breach of the Terms of Service. In this connexion . . . the Minister is advised by his lawyers that under the regulations the dentist is not responsible for the acts and omissions of the anaesthetist and that any person who suffers injury at the hands of the anaesthetist should be left to his civil rights for a remedy."

The Services

Colonel W. R. Ward, T.D., Q.H.S., late R.A.M.C., T.A., has been appointed Honorary Colonel of a T.A. unit in succession to Major-General R. E. Barnsley, C.B., M.C., late R.A.M.C., whose tenure has expired.

A Supplement to the *London Gazette* has announced the following awards:

First Clasp to the Territorial Efficiency Decoration.—Colonel W. R. Ward, T.D., late R.A.M.C., Lieutenant-Colonel (Honorary Colonel) E. J. G. Glass, T.D., Lieutenant-Colonel and Brevet Colonel O. G. Prosser, M.C., T.D., Lieutenant-Colonel A. E. K. Price, T.D., Major (Acting Lieutenant-Colonel) R. R. Davies, T.D., Majors J. O. McCarter, F. C. Mayo, T. R. W. Millar, T.D., J. H. Pattison, T.D., H. R. Shields, B. St. J. Steadman, T.D., and Captain (now Temporary Major, S.S.R.C.) D. R. Hood, R.A.M.C.

Territorial Efficiency Decoration.—Majors (Honorary Lieutenant-Colonels) D. A. Hunt and A. J. Moffett, Majors J. O. McCarter, F. C. Mayo, H. R. Shields, W. J. Street, Captains (Honorary Majors) H. L. Cohen (retired) and W. H. Stephen, Captain (now Temporary Major, S.S.R.C.) D. R. Hood, and Captains H. C. W. Baker and S. S. B. Gilder, R.A.M.C.

Universities and Colleges

ROYAL COLLEGE OF SURGEONS OF EDINBURGH

At a meeting of the College held on July 15, with Professor Walter Mercer, President, in the chair, the following were admitted Fellows of the College without examination: Professor Harold Robert Dew, F.R.C.S., F.R.A.C.S., Professor Robert Walmsley, M.D.

At the same meeting the following candidates, having passed the requisite examinations, were admitted Fellows: I. A. Agjee, A. M. Akram, M. A. Uddin, V. Benatar, A. C. Boonzaier, H. D. Bulos, Anne M. Calder, B. M. Chatterjee, S. Chinnatamby, B. H. Colman, D. J. Currie, D. S. Desai, R. B. Duthie, E. C. Eadie, Stella P. Eadie, H. H. Francis, R. Ger, V. N. Larsen, C. W. Law, K. H. Macdonald, J. M. Moore, A. Moselhi, W. J. Oram, J. R. S. Paterson, R. E. Peasegood, J. K. M. Quartey, W. L. Robinson, S. Schwartz, M. Shaffi, S. Sher, K. Y. Shrikhande, H. B. Torrance, H. T. V. Reddi, P. Vulfsons, R. le S. van der Riet.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND

The following candidates were duly admitted licentiates in medicine and midwifery on July 3, having passed the final examination in medicine, surgery, and midwifery of the Conjoint Board of Ireland: B. D. Amarasingham, J. J. Biezenski, P. J. Bofin, Eleanor R. Comyn, M. G. Connell, T. A. I. Cunningham, F. T. Daly, R. K. Doyle, H. W. Eldemire, I. J. Fibersima, P. W. Ford, C. W. Gale, T. U. Glasspole, A. J. Grehan, T. Kirkwood-Hackett, B. P. Harkin, P. J. G. Henry, T. E. C. Jarrett, Zofia Jedliczka, R. Kachan, H. Levison, Barbara Lipowska, D. Lynch, R. B. Macaulay, G. C. Martin, M. J. Murphy, A. Mutchnik, Joan McGill, E. H. Noble, G. A. Obiora, L. O'Brien, C. L. O'Connell, N. O'Connor, T. O'Keeffe, K. N. Oji, K. Ramouthar, D. Stachiewicz, M. O. Thomas, Madeline G. P. Thomson, O. A. Tomlinson, S. W. Wajdenfeld, F. H. Walter.

ROYAL AUSTRALASIAN COLLEGE OF PHYSICIANS

At the annual meeting of the College held at Hobart in March, with Dr. Alex Murphy, the President, in the chair, the following were elected to the Fellowship: Dr. Ruthven Blackburn, Dr. J. T. Cahill, Dr. M. V. Clarke, Dr. R. G. de Crespigny, Dr. E. B. Durie, Dr. T. H. Steel, Dr. I. M. Wartski, Dr. S. W. Williams, and Dr. F. Hales Wilson.

The following, having satisfied the Board of Censors in New Zealand, were admitted to the Membership: Dr. K. E. Eyre, Dr. L. G. Hannah, Dr. M. J. Murray, Dr. J. L. Newman, and Dr. G. H. Robertson.

At a meeting of the Council held at Melbourne on May 30, the following, having satisfied the Board of Censors in Australia, were admitted to Membership by the President: Dr. D. E. Anderson, Dr. Peter Bull, Dr. F. Harding Burns, Dr. Eugene G. Galea, Dr. Bryan Gandevia, Dr. R. A. Joske, Dr. J. B. Hickie, Dr. D. A. Hicks, Dr. W. M. Moore, Dr. J. L. Stubbe, Dr. H. P. B. Harvey, Dr. J. D. McDonald, Dr. J. A. W. Kelly, Dr. J. S. Calder, Dr. S. C. Milazzo.

INFECTIOUS DISEASES AND VITAL STATISTICS

Summary for British Isles for week ending September 12 (No. 36) and corresponding week 1952.

Figures of cases are for the countries shown and London administrative county. Figures of deaths and births are for the 160 great towns in England and Wales (London included), London administrative county, the 17 principal towns in Scotland, the 10 principal towns in Northern Ireland, and the 14 principal towns in Eire.

A blank space denotes disease not notifiable or no return available. The table is based on information supplied by the Registrars-General of England and Wales, Scotland, N. Ireland, and Eire, the Ministry of Health and Local Government of N. Ireland, and the Department of Health of Eire.

Vital Statistics

Poliomyelitis

Poliomyelitis notifications (uncorrected) in the week ending September 19 (37th week of the year) were as follows: paralytic, 123 (92); non-paralytic, 104 (81); total, 227 (173). This is an increase of 54 compared with the previous week, the figures for which are in parentheses. The increase is largely accounted for by cases in Coventry C.B. and Kettering M.B., in both of which places there has been an abnormally high incidence of the disease. There is little reason to believe that the rise is more than temporary or that the seasonal recession will not be resumed shortly.

Poliomyelitis at Coventry

The incidence of poliomyelitis at Coventry is higher than previously recorded, and the form of the disease is the most severe known there. We are indebted to Dr. T. Morrison Clayton for the following information. In 1950 and 1951 the incidence was rather high in Coventry, with 82 cases in the first year and 98 in the second, of which 21 and 9 cases respectively were paralytic. In 1952 there were 21 cases, 4 of them paralytic. In the present year up to September 26 there have been 152 cases, 91 of them paralytic. There has so far been only one death. The age incidence of the cases notified from June 13 to September 26 is shown in the Table below.

Age	Paralytic	Non-paralytic	Total
0-4 ..	17	19	36
5-9 ..	22	24	46
10-14 ..	8	5	13
15-19 ..	6	3	9
20-29 ..	18	6	24
30+ ..	20	4	24
Total ..	91	61	152

Industrial Accidents and Diseases

The number of workpeople (other than seamen) in the United Kingdom whose deaths from accidents in the course of their employment were reported in August was 114, compared with 117 in the previous month and 81 in August, 1952. The number of cases of industrial disease reported was 23, including lead poisoning 1, anthrax 3, epitheliomatous ulceration 11, and chrome ulceration 5. There were no deaths.—*Ministry of Labour Gazette*, September, 1953.

Infectious Diseases

The largest fluctuations in the trends of infectious diseases in England and Wales during the week ending September 12 were decreases in the number of notifications of 350 for whooping-cough, from 4,058 to 3,708, and 199 for measles, from 802 to 603.

The incidence of measles after reaching the highest level ever recorded in the beginning of this year has now declined to the lowest for almost eight years. During the week reviewed the only large variation in the returns of measles was a fall of 83 in the number of notifications in Lancashire, from 187 to 104. The largest falls in the notifications of whooping-cough were 82 in Lancashire, from 337 to 255, 74 in London, from 354 to 280, and 61 in Yorkshire West Riding, from 321 to 260. The number of notifications of scarlet fever were 505, being 22 more than in the preceding week, and no changes of any size were reported in the local trends. 19 cases of diphtheria were notified, 1 fewer than in the preceding week. The chief features of the returns of diphtheria were a rise in Cheshire from 0 to 3 and a fall in Devonshire from 4 to 1.

173 cases of acute poliomyelitis were notified during the week. These cases were 31 fewer for paralytic and 20 fewer for non-paralytic cases than in the preceding week. The largest centres of infection were Warwickshire 14 (Coventry

C.B. 6), Dorsetshire 13 (Poole M.B. 4), Yorkshire East Riding 11 (Kingston-upon-Hull C.B. 4, Beverley M.B. 4), London 10 (St. Pancras 6), Southampton County 10 (Bournemouth C.B. 3), Yorkshire West Riding 9 (Leeds C.B. 3), Lancashire 9, and Northamptonshire 9 (Kettering M.B. 8).

204 cases of dysentery were notified during the week, 1 fewer than in the preceding week. The largest returns were Lancashire 33 (Manchester C.B. 7), Nottinghamshire 30 (Southwell R.D. 26), London 24 (Chelsea 8), Yorkshire West Riding 22 (Bradford C.B. 12), Middlesex 19 (Ealing M.B. 5), and Cheshire 17 (Birkenhead C.B. 17).

Graphs of Infectious Diseases

The graphs below show the uncorrected numbers of cases of certain diseases notified weekly in England and Wales. Highest and lowest figures reported in each week during the nine years 1944-52 are shown thus -----, the figures for 1953 thus ———. Except for the curves showing notifications in 1953, the graphs were prepared at the Department of Medical Statistics and Epidemiology, London School of Hygiene and Tropical Medicine.

Quarterly Returns for Scotland

The birth rate during the second quarter of 1953 in Scotland was 18.6 per 1,000, and was 0.8 below the average of the five preceding June quarters. The infant mortality rate was 29 per 1,000 registered live births; this rate was 5 below that for the corresponding quarter of 1952 and 8 below the five years' average, and was the lowest rate ever recorded for any quarter in Scotland. The general death rate was 11.2 per 1,000, being the same as the rate in the preceding June quarter but 0.4 below the five years' average. 278 deaths were ascribed to respiratory and 34 to other forms of tuberculosis, giving rates of 22 and 3 per 100,000 of the population. These rates were respectively 25 and 5 below the average of the five preceding second quarters. 84 deaths were attributed to the principal infectious diseases, being 13 fewer than in the June quarter of 1952. The deaths included in this heading were 50 from influenza, 14 from measles, 13 from whooping-cough, and 7 from meningococcal infections. The death rate from malignant neoplasms was 194 per 100,000, and was 9 above the five years' average.

Week Ending September 19

The notifications of infectious diseases in England and Wales during the week included scarlet fever 633, whooping-cough 3,555, diphtheria 25, measles 608, dysentery 202, paratyphoid fever 8, typhoid fever 6, and food-poisoning 280.

Medical News

Cancer Education.—The Standing Advisory Committee on Cancer and Radiotherapy and the Central Health Services Council have advised the Minister of Health that he should encourage local authorities and voluntary bodies to carry out exploratory schemes of cancer education to enlarge the knowledge of what can be done in this field. Accordingly the Minister of Health has sent a circular (18/53) to local health authorities suggesting that they should consider initiating cancer-education schemes through the medical officer of health, and he draws attention to the model scheme prepared by the Central Council for Health Education. Any authority considering such a scheme must first secure the co-operation of the general-practitioner and hospital services of the area, and the circular states: "Early contact with general practitioners is of particular importance and an invitation should be given to general practitioners to be represented on any committee formed in carrying out work on cancer education." The Minister considers it important that the results of exploratory schemes of cancer education should be carefully and accurately assessed, and the circular enumerates some points on which information would be especially valuable. Regional hospital boards have been asked to assist local authorities with their schemes and to do what they can to achieve the proper registration and follow-up of all cases.

No Change of Name.—At an extraordinary general meeting on September 17 the Society of Medical Officers of Health debated a special resolution to change the name of the society to "The Society of Preventive Medicine."

Dr. Andrew Topping, the retiring president, who was in the chair, said that this question had been before the society for many years, but no satisfactory alternative name had suggested itself until last year, when a joint meeting of the county and county borough groups had declared itself in favour of bringing the phrase "preventive medicine" into the title. To make this change would require a two-thirds majority at an extraordinary general meeting. A postal vote had already been taken, with 937 votes in favour of the change and 160 against it. One reason for the change was the alteration in the composition of the society during the last twenty years. There was not now a preponderance of statutory medical officers of health. After a short discussion, in which Dr. G. W. Fleming (Gosport) urged a combined name, Dr. T. Ruddock-West (Norwich), Dr. Tudor Lewis (Wandsworth), and Professor Leslie Banks (Cambridge) spoke against the change, and Dr. John Yule (Stockport) and Dr. K. Cowan (Chelmsford) supported the change of name, the proposal was defeated by 78 votes to 31. Following the extraordinary general meeting, Dr. C. Metcalfe Brown, medical officer of health for Manchester, was installed as president of the society. He delivered his presidential address on "The National Public Health Service."

W.H.O. European Regional Office.—The Regional Committee for Europe has recommended that the European Regional Office should move to premises in Geneva outside the Palais des Nations, where it has been temporarily housed for the last two years. The World Headquarters of W.H.O. are in the Palais des Nations.

Inquiry into Health Visiting.—The Ministers of Health and Education and the Secretary of State for Scotland have appointed a working party to advise on the proper field of work and the recruitment and training of health visitors in the National Health Service and school health service. The chairman of the working party is Sir Wilson Jameson. The members are Dr. A. Beauchamp, Alderman Mrs. K. Chambers, Miss E. G. Himsworth (nursing supervisor for Midlothian and Peebles), Miss E. Stephenson (chief nursing officer, Newcastle-upon-Tyne), and Dr. J. F. Warin. The inquiry will start this month.
