The two patients with carcinoma of the head of the pancreas detailed below may be regarded as rather elderly to undergo pancreatrico-duodenectomy. They were aged 67 and 70 years, and their rapid recovery demonstrates that age alone is no bar to the performance of this operation in patients otherwise suitable. The second case has the additional interest that a subtotal gastric resection for haematemesis had been carried out six months earlier.

Case 1

A woman aged 67, with a four-weeks history of jaundice varying in intensity, had a dull pain deep in the right hypochondrium but no colic; no vomiting; anorexia. She enjoyed fatty food and had had no dyspepsia prior to the onset of jaundice. She had noticed that the stools were pale and the urine was dark in colour. There was no loss of weight. Appendicectomy had been performed in 1917.

On examination a moderately obese woman, deeply jaundiced but otherwise apparently well, was seen. Her blood pressure was 196/90, Hb 95%. Her heart was slightly enlarged; the respiratory system was normal. The abdomen was well covered; there was no tenderness or guarding. The liver was just palpable below the costal margin; the gall-bladder was tense and distended. A diagnosis of carcinoma of the head of the pancreas was made.

Operation.—On May 5, 1952, under general anaesthesia, the abdomen was explored through a right paramedian

incision. The liver was normal but the gall-bladder and bile ducts were distended. There was a hard inelastic nodule in the head of the pancreas. Nothing else abnormal was found. Mobilization of the duodenum and the head of the pancreas revealed that the growth was much larger than had at first been suspected. Further mobilization showed that the tumour was operable, and pancreatoduodenectomy was performed. Reconstruction was effected by bringing up a loop of proximal jejunum through the transverse mesocolon and anastomosing the apex of the loop to the common bile duct, end to side. The divided body of the pancreas was implanted into the side of the jejunum distal to the choledocho-jejunostomy and, distal to this again, intestinal continuity was restored by fashioning a gastro-jejunostomy. The abdomen was closed with drainage. The post-operative course was uneventful, neither a biliary nor a pancreatic fistula developing.

Pathological Report.—"The specimen shows a tumour in the head of the pancreas surrounding a major pancreatic duct and incompletely obstructing it. The common bile duct also shows some compression, but the mucosa is intact. A few adjacent lymph nodes contain deposits of tumour. Histological examination shows an adenocarcinoma of pancreas of mucus secretory type."

This patient lived an active and comfortable life for ten months.

Case 2

A woman aged 70 had undergone an emergency partial gastrectomy for haematemesis six months earlier; a retrocolic anastomosis, afferent loop of jejunum to lesser curve of stomach and incorporating a Hofmeister valve, was used. She made a good recovery and was discharged from hospital apparently fit and well. Two months after gastric resection the stools became loose, pale, offensive, and frequent. Three months later she became jaundiced; at the time of admission this was less deep. The urine was dark in colour. She lost weight. Her appetite was good and she had no aversion to fatty foods.

On examination, a thin woman, deeply jaundiced, was seen. The epigastric scar was soundly healed, the liver was not enlarged; the gall-bladder was not palpable. The stools were negative for occult blood; the Van den Bergh reaction was direct positive; serum bilirubin, 10 mg. per 100 ml.; alkaline phosphatase, 31 units; colloidal gold +. The jaundice got progressively deeper and the liver and gall-bladder became palpable. A diagnosis of carcinoma of the head of the pancreas was made.

Operation.—On May 5, 1953, under general anaesthesia, a right paramedian incision was made. The gall-bladder and bile ducts were distended and contained clean concentrated bile. The common bile duct was not involved in any reaction secondary to the manipulations of the partial gastrectomy; the duodenal stump was free and mobile. An indurated tumour in the head of the pancreas was thought to be a carcinoma and was found to be operable. The body of the pancreas was fibrosed and scarred where it had been involved by the gastric ulcer. Pancreatoduodenectomy was performed; the site of section of the pancreas coincided with the scarred area.

Reconstruction.—Intestinal continuity existed as a result of the gastrectomy. The short proximal loop of jejunum was anastomosed end to end with the common bile duct; as this left little room above the gastro-jejunostomy for implantation of the pancreas, that structure was oversewn and was not reimplanted. The peritoneal cavity was drained.

Pathological Report.—"The specimen shows a cellular tumour in the pancreas, microscopically a carcinoma. In some areas this shows acinar pattern and in others a pattern of duct carcinoma."

The patient made a rapid recovery. A biliary fistula did not develop, but from the fourth day there was a discharge of pancreatic ferments which was profuse for ten days and then rapidly dried up. The patient left hospital

four weeks after operation; her condition at the time of writing is discussed below.

In this case carcinoma of the pancreas was almost certainly present at the time of gastric resection. However, as this was an emergency operation undertaken to control haemorrhage, further exploration was not performed when the cause of bleeding, a large active gastric ulcer, had been found.

Discussion

The classical description of jaundice due to carcinoma of the head of the pancreas as progressive and painless is no longer accepted as invariable; each of the cases reported here showed variation. It is true, however, that marked fluctuation in depth of jaundice is more common with ampullary growths than with carcinoma of the head of the pancreas proper.

It is apparent that with fit patients age need not necessarily be a contraindication to operation. These patients, aged 67 and 70, were both remarkably well after operation. The first patient was not given more than sips of water by mouth for several days, and it is possible that her early post-operative course was conducted with excessive caution. For the second patient, on the other hand, it was possible to discontinue intravenous fluids after 24 hours, there being a satisfactory gastro-jejunostomy as a result of her previous operation. In this case it was pleasing to find that the partial gastrectomy did not increase the difficulty of the pancreatoduodenectomy; rather it simplified matters, as the mobilization was partly done and intestinal continuity already existed. The healed well-functioning anastomosis proved of great value, enabling the patient to take nourishment by mouth, without risk, at an early stage in the post-operative period, and excluded the necessity for the prolonged use of the potentially lethal form of therapy euphemistically termed intravenous alimentation.

So useful was the antecedent gastro-jejunostomy found to be that I would be inclined to follow Whipple, Parsons, and Mullins (1935) in employing it as part of the first stage in those cases considered to require a staged operation. All that is necessary is transection of the stomach followed by gastro-jejunostomy, employing an afferent loop of jejunum long enough to take, at the second operation, the pancreas and common bile duct. Apart from closure of its severed end, the distal segment of stomach need suffer no interference, thus leaving the operative field undisturbed for the second stage. However, a one-stage operation, where possible, is infinitely preferable.

Many forms of reconstruction have been described, and from them three principles have emerged: (1) the gastro-jejunostomy should be distal to the entrance of the common bile duct and the pancreas; (2) the common bile duct, not the gall-bladder, should be anastomosed to the jejunum; and (3) the pancreatic stump should be reimplanted. The third principle was not followed in Case 2, as, in the peculiar circumstances, there was little bowel readily available for reimplantation of both common bile duct and pancreas; also the body of the pancreas was so scarred at the site of section that its duct could not be identified. In this case the pancreatic fistula persisted for only two weeks, and it seems possible that the fortunately short period may be accounted for by the fact that the pancreas was already fibrosed at the site of transection.

Whitfield, Gourevitch, and Thomas (1952) investigated the metabolic effects of total pancreatectomy. They obtained 83% fat absorption when giving 11.5 g. of pancreatin a day, and thus demonstrated that, while reimplantation of the pancreas may be highly desirable, satisfactory fat digestion can be obtained by extraneous means. Brunschwig (1952) does not practise pancreatic reimplantation, and claims satisfactory function even without replacement therapy. Unfortunately my second case does not support this claim, as the patient continues to have frequent stools and has not regained weight. It is probable that the combination of pancreatoduodenectomy—without pancreatic reimplantation—and partial gastrectomy puts too great a strain on the

Medical Memoranda

A Case of Complete Aortic Atresia with a Dissecting Aneurysm

Coarctation of the aorta is a reasonably common form of congenital cardiac abnormality. Abbott (1928) found 142 in her classic series of 1,000 cases. Wood's (1950) series of 200 cases contained 16 coarctations of the aorta. Until recently the diagnosis was of academic interest only; now that surgery may in certain cases effect a cure it is important that the diagnosis should be made as soon as possible. The following case is of sufficient interest to merit publication.

CASE REPORT

The patient was a man aged 33. As a child it was noticed that his heart was abnormal. Unfortunately no details are available. He remained well and joined the regular Army, in which he served for 12 years, passing a special medical examination in the Royal Engineers as fit for diving operations. He had no symptoms until the last month of his life, when he noticed that he became very tired on exertion; two days before death he developed flatulence. On the day of his death he was cycling home from work when he was seized with a violent precordial pain which went through to his back. He managed to dismount and was brought to hospital in a passing car.

On admission he was cold, shocked, and still in great pain. His pulse was regular with a rate of 120, and his blood pressure was 70/50. A well-marked presystolic triple rhythm was heard at the cardiac apex; there were no murmurs. An E.C.G. showed nodal rhythm with bundle-branch block and raised ST segments in Lead I and the precordial leads. The tracing was a poor one owing to the patient's restlessness. His general condition precluded further examination.

He was given morphine, and in view of the profound shock a plasma infusion was started, but was stopped owing to a rigor after half a pint (285 ml.) had been given. He died a few hours later, the clinical diagnosis resting between a dissecting aneurysm and a cardiac infarct.

Post-mortem examination showed gross left ventricular hypertrophy. The aortic valve was bicuspid. There was complete aortic atresia at the usual site of the adult type of coarctation of the aorta. The intima showed a split just above the aortic valve, and the dissecting aneurysm had burst through the aorta, producing a large haematoma round the base of the great vessels (see Fig.). This could well have pressed on and obstructed the left coronary artery, but no myocardial infarct was seen. The collateral circulation was not dissected.

COMMENT

Coarctation of the aorta is of two types. The infantile type consists of narrowing of the whole isthmus of the aorta from the left subclavian artery to the ductus arteriosus; the

Photograph of the specimen.

remaining digestive function: it seems that the rapid passage of food through the small bowel due to the gastric resection does not allow enough time for the impaired digestion to achieve maximum results. Consequently, despite the fact that this patient has a very large appetite and takes a pancreatin compound by mouth, she hovers close to the verge of starvation. Her condition is worthy of note, as there has been some demand for extensive gastric resection to be incorporated with pancreatoduodenectomy in an attempt to eliminate the stomal ulcers which sometimes occur. This case indicates that such a course would not be without its own hazards.

Brintnall (1952) reported a series of cases in which he used a form of reconstruction essentially that described by Child (1944); this entails telescoping the pancreatic stump into the open end of the jejunum; below this the common bile duct is implanted end to side, and lower still the gastro-jejunostomy is formed. No fistulae developed and the method appears to be very satisfactory. Brintnall also advocates mobilization of the portion of the pancreas to be removed from left to right; this, he maintains, gives the greatest possible exposure of the portal vein.

Is there a place for pancreatoduodenectomy in the surgeon's repertory? There has recently been some suggestion that so extensive an operation is not worth while for carcinoma of the head of the pancreas, because the post-operative survival is generally short. This is a fallacious argument; palliation is at times the sole aim of surgery, and, though not so in this instance, it should be noted that effective palliation is obtained even when life is not greatly prolonged. Two patients have been observed following short-circuit operations; they became, within four months, impressively miserable from the pain of their growths. Suffering can be avoided by resection, and this operation should be done for all operable cases. Furthermore, Orr (1952) reports an average survival of 15 months with the radical operation, in contrast to 4.4 months following palliative procedures.

We must always seek to progress, and there is no doubt that dissatisfaction with results obtained is a greater stimulus to further endeavour than is the counsel of despair which labels a condition beyond the scope of surgery and incurable. Neither should it be overlooked that, in regard to carcinoma of the pancreas, Brunschwig, one of the pioneers in this field and an advocate of radical excision, reported a seven-year survival for carcinoma of the head of the pancreas proper.

Dodd wrote in 1949, "I make a plea that in cases in which painless jaundice has been present for a month the possibility of carcinoma of the pancreas should be considered and a surgical opinion sought." This statement merits repeating because it indicates the correct line to be followed if cases are to come to surgery early enough to allow a determined attack to be made on the growth with hope of success.

Summary

Two successful cases of pancreatoduodenectomy for carcinoma of the head of the pancreas, in patients over 65 years, are reported. One patient had recently undergone emergency gastric resection for haemorrhage.

The place of the operation in present-day surgery is discussed; it may require to be made more radical.

The importance of early laparotomy for patients with undiagnosed or painless jaundice is stressed.

I am grateful to Dr. J. McMurray for the pathological reports.

circulation depends on a patent ductus arteriosus, and is compatible only with a few weeks or months of life. The adult type consists of a localized narrowing about the level of the ductus arteriosus, and these patients may live for many years; in Abbott's series the ages of death varied from 3 to 92 years, with an average of 32. In 200 cases which came to necropsy the atresia was complete in 47, extreme (under 6 mm.) in 108, and moderate in 45. The figures of Reifenstein *et al.* (1947) are similar, the average age at death being 35. Both workers found that rupture of the aorta was a common cause of death, especially among younger patients. Abbott found it 40 times in her 200 cases examined at necropsy, and all Reifenstein's cases occurred between the ages of 10 and 30. The rupture generally occurred in the ascending aorta, but was sometimes seen at, or near the site of, the obliterated ductus. Here the aorta was often dilated at the emergence of the intercostal arteries, or kinked by the ligamentum arteriosum. Histological examination of the aorta nearly always showed medial degeneration. There was interruption and diminution of the elastica and muscle, with fatty and hyaline degeneration. The connective tissue was increased: Gore and Seiwert (1952) found this in 85 cases of dissecting aneurysm, not necessarily associated with coarctation; hypertension was present in only 58% of cases.

The recognition of coarctation of the aorta is not difficult if the diagnosis is kept in mind. Hypertension is present in most cases, but may be only slight in children. A systolic murmur is often heard over the front and back of the chest, where the enlarged collateral circulation may be seen and felt; the unusual site of the murmur is most suggestive of a coarctation. The femoral pulses are absent, or are feeble and delayed. Radiology may show notching of the lower borders of the ribs due to the hypertrophied intercostal arteries.

Surgical treatment of the condition is generally undertaken in children and young adults; therefore it is necessary to make the diagnosis early, generally before any symptoms arise.

If the femoral arteries are palpated as a routine during a medical examination cases of coarctation of the aorta will not be missed.

I wish to thank Dr. E. S. Duthie for the pathological examination and Mr. R. P. Welch for the photograph of the specimen.

Rupture of a Congenital Solitary Kidney

The disaster of severe trauma to a solitary kidney of congenital origin is fortunately rare. Orkin (1950) has collected seven examples. The following case is a reminder of this tragic possibility.

CASE REPORT

A man aged 63, returning from his work in a dockyard, tripped and fell across a heavy chain, injuring his left side. He walked home and, fearing he had injured his ribs, then walked to hospital. The casualty officer found severe tenderness over the left loin and left lower ribs, and took the wise precaution of inspecting his urine. Gross haematuria was found and the patient was admitted. Shortly after admission the pulse rose and the blood pressure fell. In half an hour an enormous tumour grew in the left loin and projected anteriorly, to be clearly delineated like a huge hydronephrosis. Blood transfusion failed to control the falling blood pressure, and there was every justification for a rapid transfer to the operating theatre.

Operation.—Through a left lumbar incision a huge perirenal haematoma was explored. In the midst of free fluid,

blood, and clot lay a lacerated kidney with its pedicle almost completely detached. The kidney was lifted out and the bleeding pedicle readily controlled. The cavity formed by the haematoma extended more than an inch (2.5 cm.) beyond the right margin of the vertebral column. Palpation to the right was thought to confirm the presence of a right kidney. With control of haemorrhage the general condition improved rapidly. In all, six pints (3.4 litres) of blood was given.

Post-operative Course.—As no urine was voided twenty-four hours after operation a catheter was passed and 1 oz. (28 ml.) of bloody urine withdrawn. The blood pressure was normal, and with no further secretion by the end of the second day it was noticed that the right testicle was not palpable in the scrotum or elsewhere. On the fourth day cystoscopy was performed and in a contracted bladder no right ureteric orifice could be found. The absence of a right kidney was now presumed. The patient died on the tenth post-operative day. A post-mortem examination confirmed the complete absence of the right kidney and ureter. The right adrenal gland was present. The bladder was small and thick-walled, with poor development of the right side of the trigone. There was a small but complete right intra-abdominal testicle. Examination of the left kidney confirmed that it was split transversely through the hilum and that the vascular pedicle was almost completely torn.

COMMENT

In this case the rapid deterioration from haemorrhage necessitated urgent operation. It was not justifiable to attempt intravenous pyelography, although it is agreed that this practice has an established place in the management of renal injury. Orkin (1950), amongst many others, has stressed how this investigation may determine the necessity or otherwise for immediate exploration of the damaged kidney, and how valuable it is in revealing a functioning kidney on the other side. It would have been possible to do a cystoscopy before nephrectomy in the above case, and had the absent testicle been noted suspicion of a solitary kidney might have been aroused. The fact that the injured kidney could not be saved does not forgive this inadequate pre-operative management. In other circumstances recognition of a solitary kidney might have encouraged an attempt at suture or even vascular repair.

Hamilton and Peyton (1950) reported a case in which by pyelography and cystoscopy it was recognized that an injured hydronephrotic kidney was solitary. Bleeding persisted and the kidney had to be explored: a 10-cm. laceration was sutured and the kidney saved. Orkin (1950) described the radiological and cystoscopic confirmation that an injured kidney was solitary. In this case operation was not required and conservative treatment was successful.

Congenital solitary kidney is not unduly rare. Collins (1932) collected 581 examples, and Longo and Thompson (1952) suggested that the necropsy rate is about 1 in 1,000 cases and the clinical incidence about 1 in 1,500 cases. If we add the possibilities of hypoplastic or maldeveloped kidneys, of kidneys destroyed by disease, and of kidneys removed by previous nephrectomy, injury to a solitary kidney is an accident worth consideration. The solitary kidney may be damaged rather more readily, as it is usually larger and therefore less protected than a normal kidney. Longo and Thompson (1952) have shown a high incidence of disease in the congenitally solitary kidney. This, too, may make it prone to injury—hydronephrosis being a common complication. Anomalies of the genital tract are common in females with solitary kidney; in males the association occurs in only 10% of cases. This is the second case I have seen in which an absent testicle was noted with a congenitally absent kidney.

Reviews

IN HONOUR OF CHARLES SINGER

Science, Medicine, and History: Essays on the Evolution of Scientific Thought and Medical Practice. Written in honour of Charles Singer. Collected and edited by E. Ashworth Underwood. Volumes I and II. (Vol. I: Pp. 563, illustrated. Vol. II: Pp. 646, illustrated. £11 11s. the set.) London: Geoffrey Cumberlege (for Oxford University Press). 1953.

The occasion of the presentation of these two volumes of *Essays* to Dr. Charles Singer has already been described in this *Journal*. To do justice to this splendid tribute to a great medical historian is no easy task. A brief biography of Dr. Singer with a bird's-eye view of his achievements, an introduction by Sir Arthur MacNalty, ninety learned essays, and finally a list of Dr. Singer's 412 contributions to the literature of medicine and medical history—all this can scarcely be treated adequately within the compass of an ordinary review.

Dr. Ashworth Underwood must have conceived the idea of these volumes and have started collecting the essays a good many years ago. Fourteen of his contributors have died without seeing the completed book, and the difficulties which oppress the editor of any composite volume are notorious. Dr. Underwood is therefore to be congratulated on bringing his heavily laden ship to harbour and to be thanked for the treasures it contains.

The essays in these two large volumes are as various in subject as the interests of Dr. Singer himself. They are divided into eight books, the first seven covering chronological periods, the eighth dealing with matters that could not be thus accommodated. The first book treats of the Ancient World, beginning with an illuminating essay by Professor Gordon Childe on "The Constitution of Archeology as a Science." Mr. Warren Dawson provides an authoritative account of "Egypt's Place in Medical History," in which he makes clear what were the original sources of medical and anatomical knowledge and how it was inextricably mixed with magic. The practice of mummification allowed the study of comparative as well as human anatomy and pathology, and so fostered the true beginnings of medical science in the Valley of the Nile. Another paper by Dr. Chauncey D. Leake and others reveals the fascinating contents of the Hearst Papyrus, from which it is clear that treatment of fractures by plaster casts was well established by 1500 B.C. An essay by the late Professor George Gask and the Rev. John Todd traces "The Origin of Hospitals," and from this it appears that no hospital in the true sense existed before Christian times and that probably they did not begin until the first half of the fourth century A.D. Dr. Wilfred Bonser's contribution on "General Medical Practice in Anglo-Saxon England" is remarkably interesting for its demonstration of how the curing of disease was virtually a monopoly of the Church. Saints and their relics were systematically exploited as the supernatural means of exorcising what was assumed to be a supernatural visitation. Christ had shown the way by His miracles, and the holiness of His saints was manifested by their power to do the same. Ignorance of the nature of disease was common to ecclesiastical and lay practitioners and their understanding of the remedies they used was correspondingly primitive. Blood-letting had been handed down from classical times, and, being connected with the doctrine of humours, was used indiscriminately and survived in medicine for more than another millennium. Dr. Henry Sigerist writes a characteristically interesting and important paper on the contents of the remarkable manuscript at Johns Hopkins University containing a gynaecological collection made by Johannes Hartlieb, a Bavarian court physician, in the middle of the sixteenth century. Dr. Castiglioni wrote not long before his death on Pliny's great book and the School of Ferrara, studying particularly the work and influence of Leoncenus. Mrs. Arber contributes a learned and interesting paper on

mediaeval herbalism and its progress to modern botany. Among the non-medical essays Professor F. J. Cole's history of Dürer's rhinoceros is particularly attractive. The animal passed through many pictorial transformations and in 1617 appeared as the crest of the Society of Apothecaries, its horn being then still of importance in the pharmacopoeia. Three papers on Vesalius—"Some Vesalius Studies" by Dr. Monteiro, of Oporto, "Vesalius and the Galenists" by Dr. Ashley Montagu, and "Vesalius: Imperial Physician" by Drs. O'Malley and Saunders—keep alive the subject of the great anatomist. Fernel's name is commemorated in Dr. Long's study of his ideas on tuberculosis. Dr. Galdston, of the New York Academy of Medicine, extracts much of interest regarding psychiatry in his survey of the writings of Paracelsus, who clearly used psychotherapy very much in the modern manner. Sir Arthur MacNalty pays his tribute to "Sir Thomas More as Student of Medicine and Public Health Reformer." Dr. Walter Pagel covers a wide field in seventeenth-century biological thought by consideration of the reaction of seven important writers to Aristotle. These include Glanvill, Charleton, Harvey, and Glisson. The importance of Glisson as a thinker in addition to his anatomical pre-eminence is well brought out.

The second volume covering the later seventeenth century, the eighteenth and nineteenth centuries, and the *Conspectus Generales* is perhaps less exciting than the first, but there is still plenty to attract the eye of a medical reader. Dr. Ashworth Underwood chooses for his own contribution an account of Gottfried von Berger and his textbook of physiology published in 1701. Mr. Johnston Abraham writes an all too short account of John Fothergill. Professor Cave draws attention to the fact that it was really Sir Richard Owen who first described the parathyroid glands, having dissected them in a rhinoceros in 1849. The credit is usually given to Sandström's monograph of 1880. Dr. Dorothy Turner examines the work of that extraordinary man, Sir Thomas Young, on the eye and vision. His dictum that "the longer a person lives the less he gains by reading" should not be a deterrent to the perusal of the volumes under review. The names of Professor K. J. Franklin, Dr. Major Greenwood, Dr. Douglas Guthrie, Professor J. F. Fulton, and Sir Charles Scott Sherrington among the writers of *Conspectus Generales* is sufficient evidence of their value.

Attention has here been directed chiefly to the contributions of medical interest, but this does not imply that those covering allied sciences are of any lesser significance. This splendid work is profusely illustrated, and, though the price seems high, the buyer may be assured that he is getting his money's worth. The full indexes provide an essential guide to the whole.

GEOFFREY KEYNES.

ANTIBIOTIC THERAPY

Recent Advances in Chemotherapy. Vol. III—Antibiotics. By F. C. O. Valentine, F.R.C.P., and R. A. Shooter, M.A., M.D. (Pp. 292, illustrated. 27s. 6d.) London: J. & A. Churchill. 1954.

The late Dr. G. M. Findlay had planned that the third edition of *Recent Advances in Chemotherapy* should be in four volumes, of which two had appeared before his death. The present authors have shouldered the main outstanding task, and the series now covers most of its immense subject, the chief hiatus being the absence of any section devoted to the sulphonamides.

Antibiotics do not belong exclusively to any one branch of medical science; clinicians, microbiologists, and pharmacologists are all entitled to write about them and have done so. Which of them can write the most useful book is a matter of opinion. The microbiologist starts with some advantages. Antibiotics are, after all, microbic products, and it is his business to understand them. Moreover, bacteria are his daily companions, and their behaviour in the presence of antibiotics is variously and vividly illustrated in cultures the examination of which now occupies much of his time. If at the same time he is in close touch with, and sometimes advising, numerous clinical colleagues,

perhaps in hospitals where new antibiotics are receiving their first trials in this country, his knowledge of the more difficult aspects even of clinical application may exceed that of the individual clinician.

This book is the product of such experience, and is the first satisfying one of its size on this subject to appear—at least to a reviewer who views these matters from the same standpoint. It is quite remarkably up-to-date: there is a reference to a paper which appeared in November, 1953—four months before publication. It deals thoroughly and soundly with all the specific infections in which antibiotic treatment is indicated and, regionally, with venereal diseases, infections of the lung, meninges, bowel, and urinary tract, but not with wound infections as such, or those of the eye, nose and sinuses, skin, or uterus. It is in these directions that expansion in further editions might enhance the value of the book, although it may well be argued that, since chemotherapy should be directed against the micro-organism rather than the particular type of disease, a regional approach is superfluous unless special techniques are involved. The index needs expansion, and more needs now to be said about reactions to penicillin: so-called anaphylactic shock, which has been fatal in many recently recorded cases, is not mentioned.

The table of sensitivities of 22 species to eight antibiotics and the chapter on the general principles of treatment in which it occurs are admirable features, and some of the best chapters are those on bacterial resistance, on staphylococcal infections, and on tuberculosis. The last in particular is the most informative and readable general account of this highly specialized branch of chemotherapy which has yet appeared. The book can be recommended confidently as a guide both to principles and to practical therapeutics.

L. P. GARROD.

FAVOURITE PRESCRIPTIONS

Favourite Prescriptions. Edited by Sir Heneage Ogilvie, K.B.E., D.M., M.Ch., F.R.C.S., and William A. R. Thomson, M.D. 2nd edition. (Pp. 88. 5s.) London: The Practitioner, 1954.

The second edition of this book contains a good new chapter by Dr. Philip Evans on paediatric prescriptions. It is doubtful, however, whether this justifies the perpetuation of a work so often advocating complex and irrational mixtures which are both unnecessary and uneconomic. The *National Formulary* fulfils most prescribers' requirements much more efficiently. The doses are expressed in imperial measures, and, except in Dr. Evans's chapter, the metric equivalents are clumsy and pedantically precise. Much of the treatment recommended is out of date and ill-advised. It is doubtful, for instance, whether 15 to 30 minims of oral nikethamide taken night and morning, or a mixture of strychnine hydrochloride and dilute hydrochloric acid, will help "the elderly suffering from arteriosclerosis and low blood pressure and/or vascular lesions in the brain"; and the addition of ammonium bromide to an iron mixture is likely to exacerbate rather than to relieve the "dull headaches and depression" met with in anaemia. It is a pity that the all-too-common belief that the neuritic pains commonly encountered in this country can be relieved by aneurine hydrochloride should be perpetuated, and that bromides should continue to be given pride of place in the treatment of epilepsy. Medical students would rightly be reprimanded for following the advice to use oily drops in nasal conditions, intravenous potassium (without qualification) for infective hepatitis, and topical sulphonamides for burns. Such examples could be multiplied many times. The advent of powerful and specific modern remedies should make us reconsider the advisability of using many of the preparations advocated in this book. There is a place for the use of placebos in medicine—though they are dangerous drugs for the doctor who prescribes them—but it is doubtful whether a book which gives them such a prominent place is necessary or desirable.

D. M. DUNLOP.

THE ACUTE ABDOMEN

Diagnosis of Acute Abdominal Pain. By William Requarth, M.D. Foreword by Warren H. Cole, M.D. (Pp. 243; illustrated. 38s. or \$5.) Chicago: Year Book Publishers, Inc. London: Interscience Publishers Ltd. 1953.

This is essentially a description of the surgery of the acute abdomen from the clinical standpoint. It is well illustrated by photographs, radiographs, and diagrams, and by clear descriptions of typical cases, and will reward careful study. Very full references to the literature will help those who want to make a special study of any one of the many different conditions described. To the student the elaborate laboratory tests described may be of interest, but we feel that they will be looked at a little askance by the practical surgeon—perhaps of the old and out-of-date school—who has dealt with many acute abdomens and often in the middle of the night.

To one who was taught by Henry Head and learnt at first hand his great work on visceral pain the book is a little disappointing, for it bears little relation to its title. There is no mention of the mechanism of abdominal pain or of what may be learnt from its study. Epigastric pain as an early symptom of appendicitis is mentioned, but not as indicating distension of the appendix; and the change in site and character of pain as infection reaches the lymphatics is not brought out. It is surely important to recognize the different characters and meaning of visceral pain, peritoneal pain, and referred pain, perhaps from the pleura, and to understand the mechanism of each. Apart from these small criticisms the book contains a large amount of useful information in small compass and is admirably produced, so that the excellent illustrations can be fully appreciated.

HENRY SOUTTAR.

MANAGEMENT OF PAIN

The Management of Pain: With Special Emphasis on the Use of Analgesic Block in Diagnosis, Prognosis, and Therapy. By John J. Bonica, M.D. (Pp. 1,533. 444 illustrations. £7 5s.) London: Henry Kimpton, 1953.

This book presents in one volume a complete discussion of the fundamental aspects of pain, the various diseases and disorders in which pain constitutes a major problem, and the methods employed in its management, with special emphasis on the use of analgesic block as an aid in diagnosis and treatment. The author is to be congratulated on the highly successful way in which he has covered this vast field. Numerous and detailed references are given at the end of each chapter, and these will prove of the greatest value to anyone seeking further information on a particular problem.

The book is composed of three parts: the first part includes a discussion of the fundamental aspects of pain, the author stressing that in order to manage pain properly its anatomical, physiological, and psychological bases must be understood. The second part is on the methods and techniques of managing pain, including not only analgesic block but also such subjects as the use of general analgesic methods, psychotherapy, physical therapy, and neurosurgery. Analgesic-block methods are discussed in great detail, and the account of them is one of the best yet published. The illustrations are excellent and the text is of remarkable clarity. Anaesthetists and others called upon to perform regional blocks for the management of painful conditions will find this section invaluable. In the third part the author presents the various diseases or disorders with painful syndromes which have been and can be managed with analgesic block with or without the aid of other methods.

Despite its size the subject-matter of this book is covered in a concise and readable fashion. The style of the text and layout of the book are most attractive; there are nearly 450 illustrations of excellent quality. This book is highly recommended to all interested in the management of conditions in which pain is prominent.

SATURDAY MAY 29 1954

PROLONGED TREATMENT WITH CORTISONE AND A.C.T.H.

Much experience has been gained in the use of cortisone and A.C.T.H. in the five years since Hench and his colleagues¹ reported the remarkable remissions which could be produced by Kendall's Compound E in rheumatoid arthritis. Clinicians in the U.S.A. have had access to larger supplies of these substances and for a longer period than workers in this country, where both have been sparingly distributed by the Ministry of Health. As a result much of the available material has been devoted here to relatively short courses of treatment or used in topical therapy, and most of the reports on the results of prolonged treatment have emanated from abroad. In the last two or three years, however, enough has been distributed to enable studies to be carried out on several series of patients. No one who has seen the immediate effects of cortisone or A.C.T.H. can doubt that they bring about profound and dramatic improvement in a variety of serious disorders. Apart from Addison's disease and hypopituitarism, where they are rationally used as a form of replacement therapy, it cannot be claimed that they do more than suppress symptoms. It is true that in some conditions they may tide a patient over an acute phase until a natural remission occurs, and they have been likened to an asbestos suit which enables the wearer to remain unscathed in the flames until the fire has burnt itself out. Unfortunately far too often the fire remains alight, and it seems as if the victim is doomed permanently to wear this uncomfortable apparel.

Rheumatoid arthritis is by far the commonest of the diseases relieved by cortisone and A.C.T.H., and it will be long before there is enough of these drugs to treat every case. The original hope that short courses of treatment would give lasting benefit has proved unfounded, and it is now realized that when treatment is discontinued many cases relapse. Interest is thus directed towards the benefit which may reasonably be expected from indefinitely prolonged administration. It is, moreover, necessary to weigh this benefit against the side-effects and complications that

may arise. Some of these are avoidable or reversible by manipulation of the dose, but others endanger life and have sometimes proved fatal. Opinions about the ultimate value of long-term therapy with cortisone in rheumatoid arthritis vary considerably. Most observers agree that it is often difficult to find a dose which will continue to relieve symptoms without giving rise to side-effects; all agree that advanced cases with ankylosed joints are unsuitable. But experience shows that in general patients are definitely better when they are receiving cortisone. It has, however, been claimed² that this improvement is no greater than can be achieved without the use of a potentially dangerous drug. This view receives strong support from a carefully planned and statistically controlled comparison of cortisone and aspirin in early cases of rheumatoid arthritis. This clinical trial, published in our opening pages this week, was sponsored by the Medical Research Council and the Nuffield Foundation; it was designed to answer a specific question: "Is it possible to maintain the well-being of a patient suffering from early and uncomplicated rheumatoid arthritis as well with aspirin as with cortisone?" Somewhat surprisingly the answer is unequivocally Yes.

In this series of sixty-one patients two comparable groups were treated and observed for a year. Great care was taken to ensure that the cases were matched with regard to sex, age, and duration of symptoms. The sheep-cell agglutination test gave confirmatory evidence of the accuracy of the diagnosis. Observations were made on the patients' general functional capacity and the activity of the disease. Measurements were carried out on strength of grip, on range of movement of the wrist, and on dexterity of hand and foot. Joint tenderness was assessed and the haemoglobin level and erythrocyte sedimentation rate determined. Standard doses of both drugs were used during the first fortnight, but later the quantities were adjusted for each patient so that a balance was maintained between benefit and side-effects. This dose was quite high, with a mean value of 76 mg. a day of cortisone (range 25–125 mg.) and 4.5 g. a day of aspirin (range 1.7 to 6.0 g.). The aspirin was camouflaged in brown tablets with a bitter flavour, and it seems unlikely that patients recognized the nature of these "Tabs. Rheumatic C." The results were statistically analysed by Dr. J. T. Boyd, of the Medical Research Council, but so similar was the progress of the two groups that simple inspection of the tables is convincing enough evidence of the validity of the deductions. The cortisone group had significantly higher haemoglobin levels and lower sedimentation rates than the aspirin group at the end of a year's treatment, but the differences were small. Perhaps the most important fact revealed by the investigation is that in 75% of the patients treated by aspirin

the disease was judged to be inactive at the end of a year and that 40% were capable of normal work and activity. It is by this standard that other forms of therapy must be assessed. It is interesting to speculate on the degree of improvement which might have been achieved if it had been possible to treat a similar group of patients with inert tablets or with some other analgesic such as phenacetin. Possibly what is being observed is the natural progress of the disease rather than the specific effect of a salicylate; nor can the element of suggestion be entirely excluded. Asher³ showed that inert tablets relieve pain in 50% of administrations, partly through suggestion and partly because they may be given at a time when pain is remitting spontaneously. Moreover, it cannot now be claimed that aspirin exerts its effects by stimulating the anterior lobe of the pituitary or the adrenal cortex, since salicylates do not increase the excretion of adrenocortical steroids⁴ or raise the plasma level of 17-hydroxycorticosteroids.⁵

Dr. W. S. C. Copeman and his collaborators,⁶ in a paper published in this *Journal* a fortnight ago, approached the problem of prolonged therapy of rheumatoid arthritis with cortisone from a rather different point of view. They reported the results of at least a year's treatment of twenty incapacitated patients, of whom seventeen had been able to return to their occupations. They were all severe cases of at least two and a half years' standing and described themselves as "crippled." They had received previous treatment with salicylates and gold salts, though no details of the extent of the courses were given. The average maintenance dose in this series was 69 mg. of cortisone a day. These observers believe the most suitable patients for cortisone treatment are those in whom functional disability exceeds the anatomical joint damage. Dr. F. Dudley Hart and his co-workers⁷ have also recorded the effects of cortisone treatment in doses of 25 to 75 mg. a day on twenty-two cases for six to eighteen months with "satisfactory" results in thirteen, "unsatisfactory" in four, and "unchanged" in five. They make the point that those showing a prompt reduction in soft tissue swelling benefit most, and conclude that cortisone therapy is a valuable addition to existing methods, even if it helps only a small proportion of sufferers.

In comparing these somewhat conflicting views it should be noted that the cases reported in this issue by the joint committee were all early and relatively mild. It may well be true that different results would have been obtained if long-standing and crippled cases had been included. But it will in future be necessary to determine the effects of full doses of aspirin before claiming that cortisone gives better results. It might be possible to devise some sort of cross-over test in which the individual patient could act as his own

control, and no doubt observations on these lines will be made. One important difference between cortisone and aspirin is the nature and severity of the toxic effects to which they give rise. Copeman and his colleagues divide them conveniently into those which are dangerous to life and the less important side-effects. Of their twenty patients, one developed psychological disturbance and one hypertension sufficiently severe to require withdrawal of the drug, and peptic ulceration was diagnosed in three and diabetes mellitus in one. In the joint committee's series side-effects were relatively mild and were equal in the early months of treatment with both aspirin and cortisone, but became less in the aspirin group as time passed. It must be admitted, however, that aspirin administration in full doses, though it may lead to unpleasant side-effects, is unlikely to endanger life and is greatly preferable to cortisone from this point of view.

If further experience confirms the view that most cases of rheumatoid arthritis can be treated as effectively and more safely with aspirin than with cortisone, larger quantities of cortisone will be available for the maintenance therapy of other conditions. The results of long-term steroid therapy over two and a half years at Guy's Hospital are therefore of special interest. Last week in this *Journal* Drs. E. H. McGehee and K. MacLean⁸ list the diagnoses of 185 cases treated with A.C.T.H. and cortisone and describe their experience of prolonged therapy of twenty-six cases of "collagen" diseases, skin disease, and eye conditions. In general the results they describe are more satisfactory than in most reported series. Many patients entered a phase of remission. Of special interest is their account of intermittent therapy with A.C.T.H. gel, which enables patients to attend hospital for review at only weekly or bi-weekly intervals. Complications which were encountered included three cases of gastro-intestinal perforation with two deaths, three psychotic episodes, and one case of diabetes.

Cortisone and A.C.T.H. are substances of outstanding physiological and pharmacological interest. At first, high hopes were held that we had in our hands the clue to the mechanism of many obscure diseases and that we could give sufferers from them permanent relief. This prospect is fading rapidly, and we can do little more than suppress symptoms and hope that the patient will undergo a natural remission and will not suffer a serious complication from the drugs he is receiving. Most of these diseases are in any event rare. It will be ironical if the major practical outcome of all the intensive work of the last few years is the discovery that aspirin given in maximum tolerated doses is the best and safest treatment for rheumatoid arthritis, the only common disorder for which cortisone is used.

VIRULENCE IN VIRUS DISEASE

What matters about viruses, so far as man is concerned, is their virulence; and to combat virulence an absolute understanding is needed of the complex set of factors which determine it. This is the basis of the experimental approach to the problem of virulence in virus disease—the subject of the Ciba Foundation Lecture recently given by Sir Macfarlane Burnet in London. Virulence is shown by the capacity of a virus to produce recognizable disease with lesions, symptoms, or death in a given host. The virologist attempts to show this when trying to establish a virus to grow in a new host; and it must be remembered that virulence will be determined not only by the virus but by the susceptibility of the host. In some cases several passages may be necessary before changes indicating cell damage of some magnitude are obtained. When this happens the virus concerned will be regarded as one of high virulence. Many viruses exist in nature as inapparent infections, multiplying probably at a slower rate and producing less obvious changes. Similarly in the laboratory there are many viruses, such as influenza and mumps, well adapted to growth in a particular medium, which produce little or no recognizable cell damage. Therefore, according to the particular virus-cell system being studied, marked variation in degree of virulence must be expected both in nature and in the laboratory.

The assessment of virulence in terms of quantity of virus is technically difficult. Direct counting of virus particles by electron microscopy is not yet a practical procedure. Similarly, histological examination is only of value in a virus-cell system where specific changes can be seen. The capacity of influenza and certain other viruses, including mumps and Newcastle disease virus, to agglutinate red cells affords a new approach to the quantitative estimation of virus. Under standard conditions haemagglutinin titrations present a simple and accurate *in vitro* test for estimating the concentration of virus in a given suspension, irrespective of its degree of virulence.

In the last few years Burnet and his team in Melbourne have been investigating the virulence of different strains of influenza virus, using the chick embryo for culture and the haemagglutinin test for titration. Most influenza A strains, which on primary isolation from a human case grow well in the chick embryo, produce little change in the mouse lung, apart from minor toxic effects; virus multiplication, however, occurs, and at about the eighth passage first signs of pulmonary consolidation develop. By the twentieth passage the mice succumb regularly with complete consolidation of the lungs. Examination of the original virus (which was avirulent for the mouse)

and the final virulent material in the neutral medium of the chick embryo shows that the only significant difference between the two is their relative virulence for the mouse lung. With the standard technique of limit dilutions employed in this work it seems clear that virulence is a genetically determined factor. Analysis of the bronchial washings taken from mice at different stages of the development of pulmonary consolidation and tested by the same method of limit dilutions strongly suggests that the increase in virulence is due to the selective survival of increasingly virulent mutants.

Under certain conditions, when two strains of influenza virus dissimilar in virulence are allowed to infect the same host, recombination of virus occurs, and the progeny of the double infection may have individual characteristics of the two parent strains.¹ In an extensive series of experiments Burnet and Lind² have shown that when a virulent and a non-virulent strain are crossed, strains of varying degree of virulence will emerge in the redistribution of virulence which results from genetic interaction. Burnet considers that in the same way the gradual development of virulence seen in the adaptation of influenza A strains to the mouse lung results from multiple genetic interaction and suggests that virulence genes exist as part of the virus make-up.

This work has a bearing on methods of controlling virulence in virus disease. Active immunization against yellow-fever, for instance, has been made possible by reducing the virulence of the live virus in the vaccine by a process of attenuation. The control of poliomyelitis by active immunization may well require in the long run the use of an attenuated virus vaccine: to achieve this will demand a very clear understanding of all the factors that govern virulence. Burnet's work with the influenza virus has been possible because of the ease with which the virus can be handled in the laboratory. It remains to be seen whether the study of other animal viruses can be approached in the same way. From the practical standpoint it will be difficult, but this important contribution from the Australian workers will undoubtedly arouse great interest and direct attention to the problem of virulence in virus disease as a whole.

AMERICAN SURGEONS IN LONDON

Apart from their purely professional value, international medical congresses can do much to promote sympathy and understanding between the nations. This function could nowhere be better exemplified than at the sectional meeting of the American College of Surgeons which was held in London for three days last week. A large number of American, British, and other surgeons gathered together on this

¹ Burnet, F. M., and Lind, P. E. (1950). *J. gen. Microbiol.*, 5, 60.
² ——— (1954). *Nature, Lond.*, 173, 627.

occasion. Before their arrival in London many of the Americans had already attended meetings in Glasgow and Edinburgh, as well as the annual meeting in Leeds of the Association of Surgeons of Great Britain and Ireland. As if this programme was not enough for them, some of our visitors went on immediately to meetings in France, Belgium, and Italy. In London the surgeons have chiefly forgathered at Lincoln's Inn Fields, and the occasion proved a fitting inauguration for the beautiful new Great Hall of the Royal College of Surgeons, completed only a few weeks ago. Although other parts of the College were also used for the various discussions, the huge hall, with its English chestnut panelling, gurney floor, and power-driven window-blinds, was the centre of attraction. Adjacent to this, and used for a number of social occasions during the meetings, is the new council chamber, which has oak veneer panelling—presented to the College by Ethicon Suture Laboratories Ltd—from a single tree planted at Lilford Park, Northamptonshire, in the reign of Elizabeth I.

The scientific programme was unusually full and varied. Each morning from 9 to 12 o'clock there was a marathon of papers, and many of these were presented in pairs, the opening speaker having twenty minutes and the second speaker ten. These paired papers were in each instance presented by an American and a British surgeon, and the time limit was strictly enforced. This intensive method of presentation of so many papers in the course of a morning was sometimes rather overpowering for the listener; but, after experience of so many British medical meetings, where time control is lax, those who were present could not but admire the way in which speakers were made to adhere to the timetable. Among such a large number of papers it would be invidious to single out individual contributions, most of which are referred to in this or in our last issue. But of particular note was Sir Gordon Gordon-Taylor's remark that he had performed his seventy-first hindquarter amputation on his 76th birthday. Enjoyable variations from the ordinary run of meetings were the two luncheon discussions at the Connaught Rooms. At each of these gatherings a panel of four speakers and a moderator dealt with the chosen subject in the space of one hour. Once again it was good to see the efficient organization, and the way in which the main speakers were encouraged to be brief, informative, and to the point. Supplementary questions, written out by members of the audience, were selected and presented by the moderator, this task being undertaken by Mr. Dickson Wright for a discussion on intestinal obstruction, and by Dr. Frank Glenn, acting president of the American College of Surgeons, for one on massive haemorrhage from the gastro-intestinal tract. Dr. Glenn's breezy, incisive, and expert cross-examination of the members of his

panel kept them all on their toes and enhanced the value of a lively and helpful discussion.

In addition to the formal papers and luncheon discussions, visits were made to a large number of London hospitals where a variety of interests was catered for in the clinical and operative demonstrations which had been arranged. The presentation of a Hunterian Lecture by a surgeon from the United States and of a Moynihan Lecture by a Canadian, further panel discussions on pre- and post-operative care and on hand surgery, as well as other meetings for those specially interested in gynaecology, ophthalmology, oto-rhino-laryngology, and urology, all served to emphasize the catholicity of this gathering. Apart from this intensive professional programme, the social side of the meeting was so full as to tax the endurance of the keenest socialite. Receptions were held at Lancaster House on behalf of Her Majesty's Government, at the House of Lords, the Society of Apothecaries, and the Ciba Foundation, as well as the Royal College of Surgeons. Suitable entertainments were arranged for the ladies, and on the second night there was a banquet at the Dorchester Hotel which was attended by 850 surgeons, their wives, and guests. Dr. Fred W. Rankin, president of the American College of Surgeons, the news of whose death on May 22 will have saddened his many friends in this country and elsewhere, was to have presided, and Dr. Frank Glenn took his place. The toast of the two Colleges was proposed by the Marquis of Salisbury and acknowledged by Dr. Glenn and Sir Cecil Wakeley, P.R.C.S. The whole meeting was widely adjudged a great success and a delightful example of international co-operation of the best possible kind. At the present level of medical incomes, drastic taxation, and sparse dollar allowances, probably not more than a handful of British surgeons could manage to travel to the United States for a similar congress. Perhaps better days will come, and meanwhile all will be grateful to our American friends for coming over here in such large numbers.

ROYAL SOCIETY CONVERSAZIONE

The song of cicadas buzzing at the Royal Society's conversazione last week may have reminded some of the Fellows of their less intellectual evenings by vineyard or beach, but it served here to reveal the physiology of its production under the guidance of Mr. J. W. S. Pringle, F.R.S., of Cambridge. Near by, that humbler insect the housefly was on show, strains resistant to insecticides being displayed in jars by Dr. R. Busvine, of the London School of Hygiene and Tropical Medicine. A few strains resistant to D.D.T. have now been found in England. Also from this school came another exhibit of insects: Dr. K. Mellanby showed how they can be rapidly acclimatized to normally lethal temperatures if they are first kept for a short time at an intermediate

temperature. Mr. A. F. Huxley, of Cambridge, showed an interference microscope, an instrument that has some advantages over the phase-contrast microscope, one being that it gives a more faithful image. Another ingenious piece of microscopy was being demonstrated by Sir Geoffrey Taylor, F.R.S., and Lord Rothschild, F.R.S., also from Cambridge. They had bulls' spermatozoa swimming in water and illuminated in the microscope field by a rapidly interrupted light. By adjusting the rate of interruption, the tail of any particular spermatozoon could be made to appear motionless even though it was flickering rapidly. The various types of oxygen equipment used in the climbing of Everest last year made an unusual exhibit. Inevitably rather heavy and cumbersome, their display served to remind visitors, albeit unwittingly, of the human will and muscle that were as necessary as inventive skill for living at those heights. Physiology of a kind more reminiscent of student days came from Mr. J. E. Pascoe, of the Physiology Department of University College, London, who showed how changes of temperature alter the transmission of impulses through an isolated nerve ganglion, and from Mr. A. C. Downing and others, of the same department, who showed how changes of pressure alter the contraction of an isolated frog muscle.

Once again the Marine Biological Association of the United Kingdom had dredged from the sea a variety of starfish, sea squirts, worms, and crustacea. Some of these animals, with their highly coloured integuments, owe their brilliant pigments to their ability to concentrate such rare metals as niobium and vanadium from the sea-water passing through them. That Nature still outstrips Man in inventiveness seemed to be the lesson that this exhibit bore for the radar experts in the next room.

CONFERENCE OF HONORARY SECRETARIES

In this week's *Supplement* (p. 283) we report the proceedings of this year's conference of Honorary Secretaries of Divisions and Branches, which took place at B.M.A. House on May 19, with Dr. D. M. Hughes in the chair. This annual event is an important one in the Association's calendar. It enables honorary secretaries from all over the United Kingdom to get together in a not too formal atmosphere and to pool the resources of their wide experience in furthering the smooth working of the organization. Not the least valuable part of the Conference is the opportunity which it gives for making personal acquaintances between the secretaries in the periphery and the Headquarters staff.

Mr. H. H. Langston, who is chairman of the Constitution Committee, recently set up by the Council to review the Association's organization, spoke in the morning on the question of "What is the most effective area as the basic unit of the Association?" and left no doubt that in his view it was the Division—a view which was supported in the discussion which followed. It emerged that the majority present felt that a small Division had more chance of fulfilling its function actively than a large one, and that the friendly spirit was more readily evoked among a small number. The afternoon

session brought suggestions from Dr. V. Cotton Cornwall on how the Association in its Divisions and Branches could help the newly qualified hospital resident, and Dr. Joan Chappell, who followed, thought that the Divisional meeting should be the Association's local shop-window and should show itself to the hospital resident as worthy of more than a glance. In the general discussion it was clear that honorary secretaries fully realized the need to attract and to help the young doctor, and many gave useful accounts of what they were already doing in this direction.

THE PRESIDENT'S TOUR

Last week the President, Mr. Tudor Thomas, gave a full report to the Overseas Committee on his recent tour on behalf of the Association of its Branches and Divisions in the Middle and Far East. The object of the tour was to carry greetings and good wishes from the Association in the United Kingdom to its members in these places, to express an interest in their welfare, and to help them in any way possible. It is not always realized that the B.M.A. has responsibilities towards some 4,000 members in Branches scattered over many countries outside the British Isles, not to mention the 11,000 in the Branches in Australia and New Zealand. The President was able to visit only five Branches, representing some 1,500 members, but they are perhaps among the most isolated by distance from contact with Headquarters in London, and barred by geographical obstacles from frequent meetings of members within their own bounds. The 150 members of the Middle East Branch, for instance, are spread over seven countries.

Mr. Tudor Thomas, accompanied by Mrs. Tudor Thomas, left London on March 9 and returned on April 24, having travelled in the interval some 22,500 miles by air and reaching as far east as Hong Kong. But this feat, formidable in itself, was, so to speak, only the connective tissue of a programme of some 30 addresses and lectures, a broadcast, 50 official dinners, lunches, and receptions, and visits to over 30 hospitals (where patients were often seen in consultation) and university departments. These figures speak for themselves of the amount of official business that was got through, but they do not record those numerous personal contacts which are the essence of such a tour, and to the value of which the President refers as follows: "Many of the doctors whom I met had never been in England and had never seen the workings of the Association in this country. I felt that they were pleased to realize that they formed part of the Association and that by my visit they were perhaps making a closer contact with the Association than they had ever done before." That the journey fulfilled its object in every way is clear from the President's modestly phrased report, and in thanking him for undertaking this strenuous task the Association will be conscious of its good fortune in having at its service so able an ambassador. All who know Mr. and Mrs. Tudor Thomas will be sure that, wherever they went, they left behind them a greater understanding of the functions and traditions of the B.M.A. and an enhancement of its prestige.

CLINICAL PATHOLOGY IN GENERAL PRACTICE

BIOPSIES

BY

RAYMOND WHITEHEAD, M.D., D.Sc.

Reader in Pathology, University of Manchester

A biopsy is an examination of tissue removed surgically. Since the term "biopsy" implies an examination, it is superfluous to speak of "biopsy examination." When the surgeon says he is "taking a biopsy," he is in fact "taking a specimen for biopsy" or "taking a biopsy specimen"; biopsies are performed by the pathologist, not by the surgeon, who simply obtains the material. Another name for this branch of pathological work is "surgical histology," which indicates clearly both the source of the material and the characteristic feature of the examination. The term "histopathology" has no advantage over "biopsy" and "surgical histology," and does not indicate whether the material was obtained from the living or the dead.

Biopsy may be performed before, during, or after treatment of the patient. When the lesion is both large and readily accessible—for example, on the surface of the body or in the mouth or rectum—the surgeon may remove a small piece of it and await the pathologist's report before deciding on the treatment. A lesion that is both small and readily accessible should be excised completely; there is no point in subjecting the patient to two operations; one, an excision of a minute fragment of the lesion for pathological diagnosis, and the other, excision of the rest of the lesion. Surgical excision of a lesion is preferable to therapeutic destruction of it *in situ*, since excision allows of a microscopical examination. When the diagnosis is reasonably certain on clinical grounds—for example, if the patient has the usual signs of a mammary scirrhus—the surgeon treats the patient radically without preliminary biopsy in the confident expectation that the diagnosis will be subsequently confirmed by the pathologist. When the lesion is internal, preliminary biopsy is often impracticable, and the biopsy can be made only on the specimen obtained after treatment on the strength of the clinical findings.

Value of Biopsy

All material removed surgically is worth examining, no matter how sure of his diagnosis the surgeon may feel. Although the clinical diagnosis is often confirmed, surprises are not rare, and the prognosis or treatment may be radically revised as the result of the pathologist's report. Malignancy may be simulated exactly by benign conditions; familiar examples are certain inflammations of the large intestine; and giant hypertrophic gastritis, though rare, may be clinically indistinguishable from gastric cancer. Conversely, lesions that the surgeon thinks benign—in the breast, for instance—may prove on microscopical examination to be malignant.

The certainty of pathological diagnosis varies as widely as that of clinical diagnosis. Many diseases are identifiable with certainty on examination of a section; these include most surgically removed cancers and tuberculosis and other well-known infections. Sometimes only the general nature of the disease is determinable; for example, a malignant growth may be so undifferentiated as to be unclassifiable even broadly as carcinoma or sarcoma, but the fact of malignancy is nevertheless an important item of informa-

tion. Sometimes the same histological picture is given by different diseases; in some cases of Hodgkin's disease the lesion is microscopically identical with that of mixed-cell sarcoma, and the two conditions have probably been confused. Similarly, early Hodgkin's disease in a lymph node may be microscopically indistinguishable from lymphatic leukaemia or lymphosarcoma. Some clinically malignant tumours may show little or no histological evidence of malignancy; these include certain "myxomas," "lipomas," and tumours of the thyroid; in such cases treatment must obviously be based on the clinical findings, supplemented when practicable by examinations other than biopsy.

The Specimen

The sooner a specimen is fixed, the better the section will be; the specimen should therefore be put in a fixing fluid immediately after its removal from the body; if the fresh specimen is put aside in a dish to be dealt with at the end of the day's operating, it may easily be thrown away or be left to dry until the hatching of maggots reminds someone of its presence.

The best practice is for the laboratory to keep the operating theatres supplied with vessels of various sizes already containing the fixative. The most convenient fixative is 10% formal saline; a litre of this consists of 100 ml. of commercial formalin, 900 ml. of tap-water, and 8.5 g. of sodium chloride. Since commercial formalin is a 40% solution of formaldehyde, the fixative contains 4% formaldehyde. Owing to the similarity of their names, formal saline and normal saline could be confused, with serious results; it would therefore be best if each container bore a large coloured label with the words "Pathological Fixative—Poison."

The whole of the tissue removed should be sent to the laboratory. This enables the pathologist to see the lesion as a whole, to note its relation to surrounding tissues, and to choose the best points for sampling. The whole of an amputated limb is not often sent, but if the condition is serious enough to require amputation the pathologist ought to have the whole limb so that he can study the extent of the tumour or the state of the blood vessels. To deal satisfactorily with large specimens such as limbs or massive tumours, the pathologist needs the help of the surgeon; by examining such specimens together, they can decide on the most suitable parts for microscopical examination, and so obviate the necessity for cutting many blocks. It is not unknown for the laboratory to receive only a minute fragment of a large excised tumour, or even only tissue adjoining an excised tumour, because the tumour itself was wanted for somebody's private collection. The commonest mistake of the surgeon is to send a part when he should send the whole.

When the specimen is more than a few inches in diameter, the surgeon should bisect it through the part containing the lesion. This gives the fixative immediate access to the lesion and incidentally allows the surgeon to see at once what he has removed. The worst fault is to make multiple incisions into such specimens as lymph nodes and small tumours of the breast; in such cases it may be impossible to get a satisfactory section for microscopical examination. Another good reason for not incising lymph nodes is that they may be heavily infected; they should be allowed to fix for some time before being opened.

Urgent Specimens and Dispatch

When a request form is marked "urgent" the time normally needed for reporting is reduced by (1) processing faster than usual if the specimen is small, (2) examining the section as soon as it is ready, and (3) telephoning the report. Abnormally rapid processing may result in poor sections, and consequently the diagnosis may be difficult or impossible; extra tissue may then have to be processed, the final result being a longer delay in reporting than if the request had not been marked "urgent." It is not desirable to process lymph nodes faster than normal, although time can be saved by immediate examination and telephoning the report.

There may be a variety of good reasons for "urgent" requests, but such requests should be made with discretion, and preferably with an explanation of the nature of the urgency. The laboratory has equal obligations to many surgeons, and every "urgent" request from one surgeon means delay in reporting for others. Most surgeons in fact make "urgent" requests only at long intervals, and the requests are accordingly accepted without question; when "urgent" requests come in large numbers from a single firm, the pathologist may well suspect that the word "urgent" is being used with insufficient discrimination.

A specimen for examination deserves at least the same care as a registered letter. There is little or no risk of loss once the specimen has been collected from the operating theatre by the messenger; but loss and delay are familiar enough in the theatre. The trouble is that usually no one is responsible for seeing that specimens are dispatched promptly and properly. The surgeon may ask the theatre sister to send them, but she may well pass on the instruction to another nurse or orderly—and either may have gone off duty when the messenger arrives to collect the day's specimens.

One person should be made responsible for the dispatch of specimens, and the most suitable person is the surgeon's assistant, who knows the importance of pathological examinations and what the requirements are; no member of the nursing staff is properly qualified for this function. The assistant in charge of specimens should never delegate his responsibility, but see to it personally that the specimens are collected by the messenger. There should be no difficulty in fixing regular times for the collection of specimens.

Data Needed by Pathologist

The meaning of a histological picture sometimes depends on the patient's age and the history of the lesion; if the pathologist is not informed of these, he can easily make a wrong diagnosis. A familiar example is the pigmented mole of the skin; this may look particularly malignant under the microscope and a report in this sense might result in an amputation. In childhood such moles are usually benign, however malignant they may look, and inquiry may show that the lesion has been present for years without any increase in size.

The accumulated experience of pathologists finds expression in the blank form commonly supplied to the surgeon who wants a specimen examined. This form requests such obvious particulars as the patient's name, sex, age, and ward; the site of the lesion; the duration of the illness; the clinical diagnosis; and the treatment given, especially if it is likely to affect the microscopical appearances, as in toxic goitre. This represents the bare minimum of information needed by the pathologist before he can form a sound opinion. All the information asked for by the laboratory should be supplied, preferably by the surgeon himself and not by an assistant or nurse.

The printed form cannot provide for all the information sometimes required by the pathologist. In specially difficult or interesting cases the surgeon may realize this and anticipate the need by sending unusually detailed information, but the pathologist often has to extract the information himself from the surgeon or his staff. When full information has

been supplied, it is sometimes possible for the pathologist to suggest a likely diagnosis from this alone.

Whenever there is doubt or difficulty on either side, surgeon and pathologist should meet for discussion. Such consultations usually result in complete agreement on the most probable diagnosis and the most suitable treatment and are of immense benefit to the patient; some surgeons are well aware of this and consult regularly. At the other extreme we have the surgeon who goes in for "penny-in-the-slot" pathology; consulting, usually with the reporter's superior, only when a mistake has been made through the surgeon's failure to supply essential information; or seeking a second opinion on a section without the knowledge of the reporter. A competent pathologist knows when he ought to consult a fellow-pathologist, and, the more able he is, the more often he sees the need and consults. Any query about a report should of course be raised with the reporter, not with a third party.

Paraffin and Frozen Sections

Paraffin sections are normally used for diagnostic purposes; the sections are stained with haemalum and eosin or some other routine combination of dyes. The introduction of automatic tissue processors has greatly reduced the minimum time interval between receipt of the specimen and issue of the report. The normal interval is now from two to three days, but very small specimens, such as those from a bronchus, can be processed and reported on within a day of receipt. These periods are attainable only if the section is of satisfactory quality and the microscopical diagnosis obvious. The chief cause of delay in reporting is difficulty in diagnosis; this may call for staining of further sections by special methods, the making of extra blocks, consultation with the surgeon or another pathologist, or work in the library. In such cases it may be possible to issue a provisional report.

The advantage of frozen sections is that they can be made within a few minutes of receiving the material, and where special arrangements exist the surgeon can interrupt the operation until he receives the report. The disadvantage is that frozen sections are much less satisfactory for diagnostic purposes than paraffin sections. When the surgeon is reasonably certain of the diagnosis on clinical grounds, he sends the specimen for examination by the paraffin method after the operation; it is when he is in serious doubt, having begun the operation, that he would most like a report before proceeding. But when the surgeon finds it difficult to make a diagnosis, the pathologist often does so too, and finds it more than ever necessary to study a paraffin section before expressing any opinion. When a biopsy is not feasible before operation, the surgeon should normally act solely on the clinical data, without interrupting the operation for a frozen section to be made, and send the specimen afterwards for study in a paraffin section. An exception to this rule may be made by the neurosurgeon, since frozen sections of tissue (or squashes of tissue) obtained by needling during an operation may enable the pathologist to say whether a lesion is in fact a tumour. Work of this kind presupposes both special arrangements and special training in neuropathology and is therefore outside the scope of the general pathologist.

Cytodiagnosis

This means diagnosis from the appearance of isolated cells in such material as sputum, gastric contents, or uterine smears. The method is used chiefly for the diagnosis of malignancy. Its use has been advocated enthusiastically and perhaps uncritically, with the result that experienced pathologists often refuse to use the method at all or use it with considerable reservations. It is true that no preparation can compare with a good paraffin section of a piece of tissue for quality and reliability for diagnostic purposes. The pathologist who decides to use only such material ought not to be labelled conservative or out of date; he is, after all, thinking only of the best interests of the patient, and if he himself were the patient he would wish to be examined in the same way.

The one field in which cytodiagnosis is of proved value is that of gynaecology. Smears critically studied may be helpful in detecting early cancers of the cervix. It is not so much isolated atypical cells that are significant as the occurrence of atypical cells in large numbers; the preparation can then be regarded almost as a teased tissue, and the method does not differ radically from the examination of a section.

Cytodiagnosis has also been much used for the detection of bronchial carcinoma. I have examined many specimens of sputum for this purpose but have never been able to make a confident diagnosis of malignancy. Since the thoracic surgeon can often obtain a piece of tissue without much difficulty, and since malignancy can often be diagnosed with certainty even in a minute fragment of material, it is uneconomic to consume the time of technicians and pathologists in innumerable sputum examinations yielding negative or inconclusive results. The average pathological laboratory is already fully occupied with ordinary biopsies; if a routine cytodiagnosis service is required in addition, the hospitals will have to provide extra facilities, technicians, and pathologists, and to pay for the special training required—expenses that are certainly not warranted by the results obtainable.

Grading of Tumours

The pathologist is sometimes asked to grade tumours numerically according to the degree of their structural difference from the corresponding normal tissue. There is undoubtedly an infinite series of gradations in appearance between a normal tissue—epithelial or connective—and the most undifferentiated tumour derived from it, but so many factors other than tumour pattern may affect prognosis that the value of such grading is limited. Another difficulty is that we can usually examine only a small part of a tumour; the more tissue we examine, the clearer it becomes that there are often wide variations in the appearance of a tumour from point to point, even transcending the limits of recognized types. For example, a bronchial carcinoma, if thoroughly examined, may show features of several distinct varieties of this growth; estimates of the frequency of different varieties may thus depend on the extent of the examination. These remarks are equally true of carcinomas of the breast, and malignant tumours in general may be justifiably classified only according to the predominant pattern. While formal grading is not worth doing, the information of interest to the surgeon can be conveyed by skilful description in the pathologist's report, and more usefully, since the meaning of the report will be clear to all who may read it, and not only to those acquainted with a particular classification. A description of a tumour implies an assessment of the degree of malignancy, so far as this can be judged histologically; in this sense, tumours always have been graded by all competent pathologists for generations past.

Biopsy Reports

The object of a report is to help the surgeon, a fact that cannot be too often remembered by the pathologist. The writing of reports is an art that can be acquired only by practice, but some general principles are worth stating. The surgeon is busy: therefore reports should be brief. With many reports about many patients converging on him, he is not going to read a technical dissertation, without a heading, filling a page with single-spaced type. Every report should be headed by the diagnosis in two or three underlined words, and the text should normally require only a few lines of type, which should be double-spaced. The three or four salient points about a section can be got into such a report. When the result of the examination bears on prognosis or treatment, the report should make this clear; in particular, the pathologist ought not to leave the surgeon guessing whether he should perform a radical or conservative operation or no operation at all. When the pathologist himself is doubtful, he should discuss the case with the surgeon before writing the report; a short conversa-

tion often solves such problems. While a report must be truthful, it should also be tactful, so that an intelligent patient would not be unduly alarmed.

A rare or interesting lesion may call for an unusually full description, but long reports issued as a routine on all cases mean that the pathologist is incapable of selecting the salient points or of writing concise English. The worst possible reports are those that wobble helplessly between "benign" and "malignant," or consist of academic descriptions of phenomena from which no practical conclusion can be drawn. Most of us have probably written reports of this kind, but we learn in time to resolve our difficulties beforehand by consulting a fellow-pathologist.

Refresher Course Book.—The first collection of articles in the Refresher Course for General Practitioners (fully revised) are available as a book containing 55 chapters, price 25s. Copies can be obtained either direct from the Publishing Manager, B.M.A. House, Tavistock Square, London, W.C.1, or from booksellers.

AMERICAN SURGEONS IN LONDON

CONCLUSION OF SECTIONAL MEETING

The sectional meeting in London of the American College of Surgeons concluded on May 19. The report of the first day's proceedings was published last week (p. 1203). During the three days of the meeting 64 papers were read, 32 by American and 32 by British authors. The meeting on May 18, presided over by Dr. F. A. COLLIER (Michigan), took the form of a symposium on cancer.

Cancer of the Lung and Cigarette Smoking

Professor E. A. GRAHAM (St. Louis) presented the results of a survey of 600 patients with cancer of the lung. A questionnaire was devised for the purpose of finding out how far cigarette smoking was implicated, and each patient was asked the questions at an interview. The results were nearly identical with those brought forward by Professor Bradford Hill and Dr. Richard Doll in this country. A remarkable relationship between excessive cigarette smoking and lung cancer was demonstrated, and the same was true of six additional studies carried out in the States. Atmospheric pollution had been advanced as an alternative cause, but this would not explain the sex incidence. The disease was five or six times as prevalent in men as in women. Any carcinogenic agent in the atmosphere would affect both sexes equally. On the other hand, it took 20 or 30 years of cigarette smoking to establish cancer, and large numbers of women had not been smoking for that length of time.

Mr. HOLMES SELLORS (London) described the results of surgical treatment of cancer of the lung. There were two methods of treatment available: the surgery of excision and radiotherapy. Results with the latter had been unfavourable, though the picture might be different with improved technique and apparatus. Age was not necessarily a contraindication to surgical excision; he had operated on many patients in their seventies, and his oldest patient was 84. He showed a table of results of 700 cases from three hospitals. At the end of two years after operation the proportion of survivors was 45%; after three years, 30%; after four years, 22%; and after five years, 20%. The most favourable type of cancer for operation was the medium-sized central squamous-celled carcinoma; 72% of the patients were alive after three years, whereas with "oat-celled" cancer the figure was 40%.

Cancer of the Thyroid

Mr. GEOFFREY KEYNES (London) opened the subject of cancer of the thyroid, giving the history of three patients. He discussed the value of radioactive isotopes. Professor WARREN COLE (Chicago) said that in the experience of his clinic the proportion of thyroid disease amongst patients admitted to the surgical wards was 15% in 1927. The figure had fallen to 10% in 1943, when thiouracil came into use, and was less than 5% in 1952. Non-toxic nodular goitre, however, had risen in incidence. The average age for the development of this condition was 44.5 years, and for carcinoma, 47.3 years.

Cancer of the Colon

Dr. ARTHUR W. ALLEN (Boston) spoke on the trend of treatment in carcinoma of the colon. Public health statistics in the United States showed in 1951 23,517 deaths from cancer of the colon (15.4% of all deaths from cancer), and 10,103 deaths from cancer of the rectum (6.6%). He discussed 316 cases on which he had operated from 1943 to 1954. In these, resection for cure was carried out in 256, and palliative resection in 49, accounting for 96.5% of the total; 11 (3.5%) were non-resectable. 182 of the patients had survived for five or more years. The operative mortality in these cases treated between 1943 to 1954 was only 4.3%, whereas in an earlier series, from 1925 to 1942, it had been 17.5%. With palliative resection the shortest survival time was one month (local spread from the sigmoid), and the longest 4.5 years (liver metastases from splenic flexure). The average survival time was nine months. With resections for cure the longest survival time was 14 years.

Mr. LAWRENCE ABEL (London), who said that cancer killed one person every six minutes in this country, and cancer of the colon one person every fifty minutes, described certain points in diagnostic technique. In assessing the main symptoms of the disease he stressed the importance of rapidly developing anaemia and loss of weight. He suggested that their radiological colleagues should use very weak solutions of barium, because more could be learned from the result in that way. Air replacement after barium was also sometimes helpful. With regard to operation, he advised against blind caecostomy or colostomy and felt it important to emphasize even in that gathering that the object of surgical manoeuvre was to ensure the removal of the widest possible area of lymphatic drainage, together with not only the tumour-bearing portion of the bowel but all the colon which was supplied by the vessels that had to be ligated. Removal of the extensive lymphatic field entailed ligation of the main arteries as closely as possible to their points of origin. Another point in technique was the placing of clamps on the bowel to prevent dissemination of cancer cells. The only solution which he believed effectually killed cancer cells in the lumen of the bowel was 1 in 500 perchloride of mercury. In spite of more radical operations and more frequent resections, thanks to modern anaesthesia and antibiotics and pre- and post-operative care the mortality rate had been halved. Propaganda directed to the public, and to their family-doctor colleagues, should ensure that these cases were referred early to a surgical team, and the results might then show still further improvement.

Mr. PHILIP R. ALLISON (Leeds) discussed cancer of the oesophagus. Negative x-ray examination of the oesophagus should not be taken as final evidence of the absence of carcinoma. Any patient with dysphagia, even if only for a day or two and passing off, should be investigated; it was no use waiting until the dysphagia recurred. Bronchoscopy should always be done, because the tendency of these conditions to spread was considerable. He praised Souttar's tube, which he regarded as a wonderful apparatus.

The topic was further discussed by Dr. R. H. SWEET (Boston); and cancer of the stomach was the subject of papers by Dr. S. F. MARSHALL (Boston) and Professor

DIGBY CHAMBERLAIN (Leeds), and cancer of the skin by Sir ARCHIBALD McINDOE (London) and Dr. W. G. HAMM (Atlanta).

Cardiovascular Disease

In a concurrent session the subject of cardiovascular surgery was taken. Dr. MICHAEL E. DEBAKEY discussed the surgical treatment of aneurysms of the aorta by resection; Mr. C. G. ROB, the reconstruction of the large arteries; Mr. R. C. BROCK, modern techniques in intracardiac surgery; Dr. F. L. GERBODE and Mr. DICKSON WRIGHT, cardiac arrest; and Mr. A. MICHAEL BOYD, the diagnosis and treatment of obliterative arteritis of the lower extremities.

Sir JAMES LEARMONTH discussed the principles of treatment of arteriovenous fistula. These principles were, he said, the preservation or restoration of adequate blood volume, maintenance of adequate blood pressure, preservation or restoration of normal haemoglobin, and restoration to normal of the diseased or injured tissue.

The session concluded with a film, preceded by a few words by Dr. ALFRED BLALOCK (Baltimore), illustrating the creation in a young child of an artificial ductus in the treatment of the tetralogy of Fallot. The film was first shown at the clinical congress of the American College of Surgeons last year.

Recent Advances in Surgical Procedures

On the last day of the meeting, May 19, many papers were presented on surgical procedures. Sir CLEMENT PRICE THOMAS (London) gave a review of the surgical treatment of pulmonary tuberculosis. He had had experience of 220 cases submitted to resection during the last five years. The deaths following operation had numbered 18 (13 early and 5 late). Both he and his partner in the discussion, Dr. J. C. JONES (Los Angeles), presented a mass of statistics. Dr. Jones spoke of 729 cases of major operation and 542 of minor, carried out in the period 1943-54, during which the proportion of major operations had steadily increased. The mortality after resection for pulmonary tuberculosis had been 8% in males and 5.4% in females, and 75% of the patients were still active and working.

Adrenalectomy in Advanced Cancer

Sir STANFORD CADE (London) discussed recent advances in surgery of the adrenals in advanced cancer, and presented what he called a modest series of adrenalectomies. This comprised some 40 patients on whom he had carried out the bilateral operation. It was dangerous, he said, to draw conclusions on the effect of any therapeutic procedure from so small a series, and even more dangerous to do so after a period of only eighteen months; yet he thought this method could be studied even in a small series, and he gave particulars of four cases of patients who had previously undergone the orthodox methods of treatment—surgical, radiotherapeutic, hormonal—and in all of whom the disease was widely disseminated. They had all failed to respond to other methods, and there seemed to be every justification for resorting to adrenalectomy. It could never be said in advance that bilateral adrenalectomy would be successful. He had not been able to find any relationship between the histological structure of the tumour and its response to the operation. If adrenalectomy was going to be a failure it would be an immediate and complete failure, and if successful it would be successful immediately, though not completely. His operative mortality among 40 patients, some of them in the last stages of disease, was 15%. In nine cases excellent results had been obtained. He considered that bilateral adrenalectomy in the control of cancer was well worth doing.

Professor J. GARROTT ALLEN (Chicago) discussed surgical treatment in Cushing's syndrome. The considerable surgical risks involved in attacking basophilic adenoma of the pituitary had encouraged a tendency to do bilateral adrenalectomy, which, however, failed to get at the primary

problem. He mentioned the value of cortisone during the pre-operative period and of cortisone plus A.C.T.H. for a brief time post-operatively.

Malignant Disease of the Hip-joint

Sir GORDON GORDON-TAYLOR (London) described the treatment of primary malignant tumours in the neighbourhood of the hip-joint (hindquarter amputation). His first operation of this kind was performed in 1922, and his latest was done on his 76th birthday a few weeks previously. At his hospital the operation had been performed 77 times. The operative mortality was some 14%, but several of the patients were in an almost hopeless condition. Of the 33 patients alive to-day, 30% had survived operation five years or more. The most favourable type of tumour from the operational point of view was chondrosarcoma; 25 operations for this type of tumour were done, and 75% of the patients were alive. He described the case of a woman who had a large tumour attached to the gluteus maximus region of the great trochanter and who was on the point of being sent to a home for the dying. He was reluctantly persuaded to operate. Six years later this woman was alive and well. Disappointments were of course to be expected, but postponement of the decision to operate only worsened the outlook, and in some cases the results exceeded the most sanguine expectations.

Professor BRADLEY COLEY (New York) discussed the general subject of malignant disease in the neighbourhood of the hip-joint. Professor R. H. SWEET (Boston) and Mr. A. L. D'ARREU (Birmingham) gave their experiences of surgical treatment of achalasia of the oesophagus; Dr. R. S. DINSMORE (Cleveland) spoke on the changing status of hyperthyroidism; and Dr. W. E. ADAMS (Chicago) brought the session to an end with a film showing pneumonectomy for carcinoma.

Massive Gastro-intestinal Haemorrhage

At a luncheon discussion presided over by Dr. FRANK GLENN (New York) massive gastro-intestinal tract haemorrhage was presented from different aspects. Professor W. WALTERS (Rochester, Minn.) said that massive haemorrhage was almost always due to the perforation or rupture of a large blood vessel, but he had seen it occur as a result of multiple small erosions of the gastric mucosa, so small that they could not be seen gastroscopically or demonstrated surgically, but were visible only under the microscope. Mr. NORMAN TANNER (London) spoke on massive haemorrhage from the oesophagus. The oesophagus, he said, was not a frequent site of massive bleeding. Bleeding was sometimes seen as a symptom of oesophagitis, but only rarely was it massive. Massive bleeding had been associated with oesophageal paralysis. In many cases bleeding was due to portal hypertension. The mortality of this condition was heavy, and a number of survivors died of recurrent bleeding within a year or two. He had seen no cases where gastroscopy precipitated bleeding. Bleeding from oesophageal varices was a matter for medical management at first. If bleeding recurred twice, and after a minimum of 48 hours, then surgical intervention was indicated.

Mr. C. G. W. ILLINGWORTH (Glasgow) spoke on massive bleeding from the stomach. Bleeding sometimes occurred without relation to gastric ulcer, presenting a minute pin-head bleeding-point which could be seen only with difficulty. Atrophy of the mucous membrane was a factor, and in a few cases carcinoma or indeed multiple carcinomas might be implicated. Finally Mr. IVOR LEWIS (Rhyll) dealt with massive haemorrhage from the duodenum. An acute ulcer, he said, could burrow right through the intestinal wall and similarly could open up one of the large vessels. Of 196 cases of massive gastro-intestinal haemorrhage on which he had operated personally, only 30 were due to duodenal ulcers.

Hand Surgery

The final session of the conference was occupied with a panel discussion on hand surgery. Professor MICHAEL

MASON (Chicago) acted as moderator, and the collaborators were Mr. PATRICK CLARKSON (London), Dr. G. E. CLOUTIER (Montreal), Mr. R. G. PULVERTAFT (Derby), and Mr. WILLIAM GISSANE (Birmingham). Mr. Gissane said that conservative treatment in the right case gave ideal results, but all too frequently this treatment was surprisingly disappointing. Every case must be considered on its merits. It was utterly wrong to resort to open methods only when closed methods had failed. By doing so, very often the opportunity was lost of getting functional repair. To get a good functional result required attention not only to the bone but to the soft tissues also.

During the day's proceedings Sir CECIL WAKELEY, P.R.C.S., gave a talk on the relationship of the Royal Family, from George III onwards, with the Royal College of Surgeons, and showed a motion picture illustrating the laying of the foundation stone of the new building by Queen Elizabeth II on May 5, 1953.

The thanks of the American visitors to their British hosts were voiced by Dr. PAUL HAWLEY, Director of the American College of Surgeons.

BRITISH ORTHOPAEDIC ASSOCIATION ANNUAL MEETING AT BUXTON

The annual meeting of the British Orthopaedic Association was held at the Devonshire Royal Hospital, Buxton, on May 6-8, under the presidency of Professor BRYAN MCFARLAND.

Syme's Amputation

Mr. J. H. SHELSWELL (Stanmore) spoke about Syme's amputation, an operation with a much better reputation in Canada than in this country. He had reviewed the Syme's amputees from the material available at Roehampton; of 534 cases, the 302 patients operated on before 1939 were chosen for assessment, and a follow-up on 66 of these was done. Two-thirds had had no significant trouble. Twenty-three per cent., including immediate failures, needed re-amputation, and, as Mr. LEON GILLIS pointed out in the subsequent discussion, this was no higher than the proportion of failures after the standard below-knee amputation. Syme's amputation had no place in the neuropathic limb or in those with vascular failure, and it was seldom indicated in women, who had no means of concealing the necessarily bulky and obvious ankle-joint in the prosthesis. But for the working man it was a most satisfactory operation, enabling him to stand and walk for long hours and even to play games. It was particularly advantageous for the double amputee, and Mr. Shelswell concluded that a properly done Syme's amputation was an excellent and long-lasting operation.

Review of 650 Arthroplasties of the Hip

Mrs. M. M. SHEPHERD (Birmingham), in an excellent and painstaking review of 650 arthroplasties of the hip, described how these cases had been followed up for a maximum of six years from operation, which were nearly all of either the vitallium cup or acrylic head type. They were assessed according to pain, range of movement, the patient's evaluation, and the objective estimate of function. Out of the great mass of figures available certain facts emerged. Excepting loss of pain, stability and satisfactory unconscious control of the hip were of greatest value to the patient, but the better the range the better on the whole was the result. Even so the mobility index (Gade) was not much worse in the poor than in the excellent results. The presence of slight residual fixed flexion seemed to give improvement, but transplantation of the trochanter delayed a good result. With regard to durability, cup arthroplasties went on improving up to four years, when 45% had good or excellent results; after five years 54% had poor results. The Judet arthroplasty was characterized by quicker recovery, but the patients deteriorated sooner and progres-

sively. Not all arthroplasties, however, deteriorated in later years, some with no apparent peculiarity retaining their excellence unchanged for many years. Mrs. Shepherd believed that arthroplasties with no inserted foreign material lasted best, then those with unfixed inserts—for example, cups—and lastly those with fixed prostheses. The percentage of good results was higher in unilateral than bilateral cases, and in the latter was higher when only one hip was operated on. The massive amount of material embodied in this impressive paper fell beyond the scope of a brief report.

Mr. K. H. PRIDIE (Bristol) expressed his dissatisfaction with the Judet arthroplasty, which he maintained should be reserved for those with a brief expectation of life. In his hands 5-10% would fracture their prostheses. Even at a year marked flattening and wear of the head was to be seen, and he thought that lack of this flattened facet was evidence that the prosthesis was rotating in the femoral neck. In his survey, 20% had loose prostheses, though a period of plaster fixation might fix them again. As an alternative to replacing the head when fracture or a poor result necessitated further operation, he considered the Girdlestone "pseudarthrosis" procedure satisfactory.

Kyphoscoliosis

Mr. J. I. P. JAMES (London) called attention to the lack of British work on the subject of kyphoscoliosis, although there was an extensive German literature about it. Apart from the deformities (usually mild) occasionally seen in Pott's or Scheuermann's disease, he classified his 27 cases into (1) congenital; (2) those associated with otherwise typical idiopathic scoliosis; and (3) those seen with neuro-fibromatosis. In the first group radiographs or operation displayed the malformation, but even early films of the second group showed no vertebral abnormality. Most congenital cases occurred in the lumbodorsal region, but there was a small group in the cervico-dorsal region. The deformity was progressive and severe, and might cause paraplegia. Early operation was indicated, but fusion was difficult to achieve.

Mr. R. ROAF (Liverpool) reported an operation of wedge excision of the vertebrae for scoliosis. In the past there had been general fear of direct operation emanating from the difficulties encountered in attempting excision of hemi-vertebrae. With his experience of antero-lateral decompression, combined with skilled anaesthesia and plaster work of the highest order, he could say that he had found no great difficulty in doing what was really a lateral osteotomy of the spine, and he described the technique. It was stressed that this was not an easy operation for routine use, but was suggested tentatively for those curves not responsive to other methods.

Pros and Cons of Hip Arthroplasty

A debate was held on the motion: "In the opinion of this house all methods of arthroplasty of the hip have failed to achieve their purpose." In spite of spirited arguments from the openers and the considerable number who finally voted in agreement with the motion, few could be found to speak wholeheartedly in its favour, and the motion was lost by a substantial majority.

Mr. K. I. NISSEN (London), proposing the motion, based his attack on hip arthroplasty on four counts: (1) the serious post-operative complications that could occur; (2) early deterioration; (3) the expense of the seemingly endless physiotherapy required; and (4) the faulty conception of the operations due to ignorance of the true pathology. One concept of vascular degeneration in the femoral head had been exploded by recent work at Oxford. Any pain-relieving operation reduces the blood supply of the hyperaemic head, but the arthroplasties interfered with it too extensively. The more British operations of McMurray's displacement osteotomy, Girdlestone's pseudarthrosis, or arthrodesis could be relied on to give equivalent or better results, and the reason they were not in favour with younger surgeons, was that the latter had little experience of them, the result being permanently good and not necessitating the

patient's return to the surgeon. In most arthroplasties of all types the head eventually disappeared to leave some form of pseudarthrosis.

Mr. W. A. LAW (London) opposed the motion. After saying that there was no universally applicable hip operation, he enumerated the essential requirements of a good arthroplasty: (1) a joint must be made; (2) the pain of the arthritic joint must be alleviated and that produced later from over-fatigue of the controlling muscles must be limited; (3) fixed deformity must be corrected; (4) the new joint must be stable; and (5) an adequate range of movement must be produced, though a stable joint with small range was greatly preferable to an over-free joint where muscle control was poor and fatigue-pain therefore marked. With these criteria he maintained that cup arthroplasty was a good operation, the beneficial results of which lasted better than Mrs. Shepherd's investigation suggested. Patients, asked him to do an arthroplasty on their second degenerating hip 5-10 years after one had been done on the first hip. But he stressed that careful selection of patients was essential. Obesity was not a contraindication, but the surgeon must be satisfied that the patients had the morale to pursue the necessarily arduous aftercare, and Mr. Law mentioned private patients favourably in this connexion. They must be warned of and understand the limitations of the result to be expected. The essential exercises could perfectly well be done at home, but circumstances often made prolonged supervision in the physiotherapy department essential. He did not look on cases needing revision as "failures," which was suggested by Mr. Nissen to be their proper description, but considered revision as an essential part of the treatment of the rheumatoid hip.

Mr. N. CAPENER (Exeter) seconded the motion. He said that we had not yet overcome the difficulties of certain essential mechanical conditions: (1) the new joint surfaces must have not only congruity but conformity of hardness; (2) there must be proper lubrication; and (3) the problems of leverage and adequate power must be solved. Present methods were incompatible with the above requirements. He estimated the cost to the nation of an arthroplasty at £200, which he looked on as very expensive for an operation doomed to failure. According to Mrs. Shepherd's figures deterioration set in five years after a cup arthroplasty and two years after an acrylic head, which, on the basis of the life-expectancy charts of insurance companies, should confine the former operation to the over-80's and the latter to the over-90's.

Mr. LLOYD GRIFFITHS (Manchester) seconded for the opposition. He denied that the traditional British operations relieved pain, and compared their results with those obtainable by taking the local waters. Arthroplasty was in a state of rapid evolution, and even the best of operations, like aeroplanes, were liable to temporary "grounding." He considered even the present results as well worth while, and pointed out that little progress would be made if surgeons must always await exact pathological elucidation of the problem.

In the subsequent debate, Mr. R. G. TAYLOR (Oxford) said that good results could be obtained in a properly done Girdlestone's pseudarthrosis. Mr. W. E. TUCKER (London) thought it advisable to make patients write down their pre-operative complaints as objective evidence for comparison with their later troubles, and Mr. H. OSMOND-CLARKE (London) said that arthroplasty had no place in the young patient.

Professor MERLE D'AUBIGNÉ (Paris) said he thought that all the failures of arthroplasty were due to technical errors. It took perhaps 200 arthroplasties to learn the art. He reported a much lower failure rate than the British figures, and stressed the importance of providing the correct length of neck and of correcting anteversion. He thought the results on the whole did not deteriorate in later years; indeed, some cases classed as only "fair" a year after operation became "good" with further passage of time. Mr. K. H. PRIDIE (Bristol) supported the advantages of the

d'Aubigné type of prosthesis. Sir REGINALD WATSON-JONES (London), while maintaining that arthrodesis was incomparably the better operation in the young, said he would vote against the motion as it was worded. Mr. JOHN CHARNLEY (Manchester) spoke of the advantages, essentially of principle rather than technique, of his operation of central dislocation of the hip, and thought that arthrodesis was a good operation even in the elderly, particularly those of wiry build.

Dr. ROBERT JUDET (Paris) gave figures to illustrate the good results of acrylic-head arthroplasty and recommended the new prosthesis with an oblique base. He pointed out that the crushed cancellous bone around the stem of any prosthesis was in a state comparable to a bone graft, and that therefore weight-bearing should be delayed two months, until revascularization of the trabeculae was advanced. Acetabular changes resulted from incongruity of the prosthesis, which should be of exactly the right size. Fractures of the prosthesis were now seldom seen in France, owing to a better acrylic resin. Mr. J. H. MAYER (Tunbridge Wells) thought the poor results were due to failures on the part either of the surgeon or of the material, and advocated the use of metal prostheses rather than acrylic resin.

Acrylic Prostheses in Fractures of the Femoral Neck

On May 8 the meeting was under the chairmanship of the vice-president, Mr. A. CHANCE.

Mr. C. M. M. MURRAY (Portsmouth) presented a review by Mr. G. N. GOLDEN (Guildford), Mr. A. G. ORD (Portsmouth), and himself of 60 cases of fractured necks of femur treated by primary replacement with Judet's acrylic prosthesis. There was no immediate operative mortality, but seven died while still in hospital. Later complications included two dislocations, two fatal cases of infected haematoma, one broken prosthesis, late ossification in the capsule, and late varus deformity. At 18 months over 80% had a satisfactory result, and he recommended the operation for the older age group, especially those with high or vertical fractures.

Mr. J. C. F. CREGAN (Manchester) gave a review of 65 cases of high fracture of the femoral neck similarly treated. In contrast to satisfactory immediate results, by the third year 85% suffered increasing pain and disability, and by the fourth year results were even worse. He thought that the integrity or otherwise of the region of the calcar femoralis had an important bearing on these results.

Mr. K. H. PAIDIE (Bristol) pointed out that with a Smith-Petersen nail 50% of patients at five years had a hip indistinguishable from normal, and deplored the use of an acrylic head as immediate treatment, a view supported by Professor d'AUBIGNÉ. Dr. ROBERT JUDET confirmed his recommendation of the operation in this connexion to the very elderly.

In further discussions Professor MICHAEL MASON (Chicago) and Mr. R. G. PULVERTAFT (Derby) spoke about wounds and injuries of the hand; and Mr. H. R. LUNT (Derby) gave a demonstration of the results of treating tuberculosis of the hip by a method aiming at shorter hospitalization, a greater range of movement, less epiphyseal dysplasia, and less shortening.

A rehabilitation workshop has been developed by British Railways (Western Region) at Swindon. It will provide productive work for convalescent patients and an occupation of therapeutic value by adapting machinery to give graduated work to a selected group of muscles or to increase movement in one or more joints. The medical officer visits the workshop daily and considers the work of the patients with the assistance of the workshop foreman. A time limit of eight weeks, with some exceptions, will be given to patients in the workshop. Admission is entirely voluntary. The men begin work ten minutes later and finish work ten minutes earlier than the normal factory hours to enable them to avoid the usual rush in the approaches to the works. The number at present employed is ten.

Reports of Societies

MASS MINIATURE RADIOGRAPHY

Who Should be Examined?

A joint meeting of the North-western and Midland Tuberculosis Societies took place at the Cheshire Joint Sanatorium, Market Drayton, on May 8. The chairman was Dr. T. W. LLOYD. In a discussion on "What is the place, if any, of mass radiography?" the opening speaker was Dr. E. SNELL, who believed that mass radiography had indeed a place in the early diagnosis of pulmonary tuberculosis and other chest diseases, and that the only reasonable argument against its use was that of financial stringency. Mass radiography units could be used in four ways: (1) as a mobile unit visiting factories, etc., in a district and x-raying all employees; (2) as a mobile unit visiting specially selected factories and industries which are known to carry a heavy hazard of tuberculosis; (3) as a static independent unit concentrating on selected cases—for example, referred by general practitioners, men called up for National Service, etc.; (4) as a static unit situated in and operated by the chest clinic, also concentrating on selected cases—for example, from general practitioners, school medical officers, ante-natal clinics, contacts, etc. Dr. Snell produced figures to show that the yield of tuberculous cases was much greater in selected groups. In 1953 nearly one-third of the new cases of tuberculosis in Liverpool were picked up by mass radiography. Apart from the number of cases found, they are discovered earlier, when they are more amenable to treatment. In Dr. Snell's opinion mass miniature radiography units should be operated from chest clinics and should devote their time to selected groups.

Pros and Cons

The next speaker, Dr. GEORGE LUNTZ, in an opening summary of the extent of mass miniature radiography in this country, said that up to the end of 1952 over 10½ million examinations had been done by 63 units, and that in 1952 18% of all cases of respiratory tuberculosis had been discovered by mass miniature radiography. In view of the fact that the present number of units allowed less than 10% of the population to be examined yearly it was important to consider whether any group of the population should have priority, and whether any group should be re-examined. There were three main ways of applying mass radiography: (1) True mass miniature radiography—that is, surveys of whole populations, the aim being to x-ray every individual in the community. Such surveys had been undertaken in Stockholm (80%), and in the Rhondda Fach (89%). A similar survey was in progress in Salford. (2) Group radiography, where the units concentrate on selected groups which are likely to yield the most cases. (3) Individual radiography, where members of the public can attend a mobile or static unit, either on their own initiative or because they have been sent by their doctor.

The problem, Dr. Luntz continued, was to decide which was the best method, and whether in fact mass radiography had any place at all. When used indiscriminately it was an expensive way of finding cases (£10 to £600 per case), and, even so, less than 20% of cases of tuberculosis were found by this method. Another point against it was that a normal x-ray finding might lull the subject and his doctor into a false sense of security, and subsequent symptoms might be ignored. Ideally radiography should be repeated annually, but this was impossible. Dual observer readings were necessary to prevent lesions being missed. Although mass miniature radiography was originally designed for tuberculous case finding, it detected many non-tuberculous abnormalities in heart and lungs, and with the rising mortality due to bronchial carcinoma mass radiography on the vulnerable age-groups might make a valuable contribution.

Dr. R. STALKER was convinced of the value of mass miniature radiography, but thought that there could be

improvements by reducing the amount of record keeping, thus freeing some of the clerical staff to assist the secretary in the canvassing of susceptible groups. He gave some figures from his own unit showing that the yield of new cases of tuberculosis fell from 4 per 1,000 in 1942 to 1.2 per 1,000 in 1953. He considered that in industry repeat protective surveys were of doubtful value, though they were justifiable in, for example, mental hospitals. Mass miniature radiography in schools where a case of active pulmonary tuberculosis had occurred was valuable, but it was doubtful whether routine surveys in schools were worth while. The 100% geographical survey was the ideal, but was impossible, and became increasingly difficult with the size of the town. It was agreed that there was a high proportion of tuberculosis in the non-attenders in a general population survey.

Larger Surveys

Dr. Stalker thought that mass miniature radiography should be kept mobile and should x-ray males or young females as individual members of the general public in preference to industrial workers. He described the Manchester Regional Hospital Board policy of "miniature" as well as "mass miniature" radiography, which was implemented by having 4 in. by 5 in. or 70 mm. units in major chest clinics for x-raying selected groups. He mentioned the Salford survey by six mass miniature radiography units working simultaneously on a population of 170,000: powerful though this was, it was small by American standards. He proposed that two or more regional boards in this country should combine for large surveys on the American plan, where they used 22 units for towns of over 100,000 and aimed to x-ray 80% of the population in four weeks. There was a case to be made for combining mass miniature radiography with B.C.G. injections in the 15 to 25 age groups.

The fourth speaker, Dr. L. A. McDOWELL, said that the function of mass miniature radiography was to assist in the eradication of pulmonary tuberculosis, which it could do by finding the infective, and especially the chronic infective, cases of tuberculosis. These cases usually had symptoms, and should be sent from the doctors' surgeries to the mass miniature radiography units. General practitioners and industrial medical officers should be persuaded to send all patients with symptoms for radiological examination. This did not mean that the mass miniature radiography service was setting up as a rival to the chest clinic. It was saving the chest physician from seeing large numbers of cases, of whom 9/10 had normal radiological findings. It also saved money and time, and the patients preferred it. He suggested that mass miniature radiography units should be withdrawn from industrial surveys and should go on a regular circuit of large centres of population, where they could examine people with symptoms and other groups such as contacts, school leavers, National Service recruits, etc. By this means each unit should be able to do 40,000 to 50,000 examinations yearly and provide the chest physicians with 400 new cases per year.

In the discussion which followed Dr. J. R. SINTON pointed out that most of the speakers had been advocating "miniature" and not "mass miniature" radiography, and that this was best undertaken by the chest clinic. He was against the principle of x-ray before clinical examination. Dr. J. ASPIN thought that the mobile factory survey would have to continue because the public expected it. In his opinion static units should be an integral part of the chest clinic service. Dr. D. MORRISON SMITH said that in finding infective cases of tuberculosis it would be cheaper to examine sputa than x-ray patients.

Dr. W. GRIFFEL thought that mass miniature radiography found too many cases which could not be treated. Dr. COTTON CORNWALL thought that some cases which were discovered did not have clinical tuberculosis and should not be "labelled." The opening speakers replied to many of the points raised and agreed that it was soul-destroying to do only mass radiography: it should be combined with chest clinic work.

THE PROBLEMS OF POLIOMYELITIS

Are there localities in this country which poliomyelitis specially tends to visit, or in which it particularly cares to linger? This was the question that Professor BRADFORD HILL, F.R.S., set out to answer in the presidential address delivered to the Section of Epidemiology of the Royal Society of Medicine on May 21.

The most striking features of the geographical distribution of poliomyelitis during 1919-46, he said, were the unexpectedly low numbers of cases in most of the counties in Wales and Northern England, and the unexpectedly high numbers in three groups of contiguous counties—one in the north-east Midlands, another including Shropshire, Hereford, and Radnor, and the third in the south stretching from Devon to Kent and Essex. There was an appreciable similarity between this pattern and that found in the years of higher incidence after 1946. There were reasons for believing that these geographical differences were not the result of differences in the accuracy of diagnosis or thoroughness of notification.

A detailed study of epidemics in the large towns showed that only twenty experienced a substantial epidemic between 1919 and 1946, and only twelve had more than one epidemic. But these twelve included nine in which poliomyelitis was epidemic three or four times during the quarter of a century—namely, Bristol, Oxford, Sheffield, Plymouth, Kingston-upon-Hull, Cardiff, Portsmouth, Manchester, and Birmingham. Why certain towns should have been picked out for visitation was a mystery, but Professor Hill drew attention to the fact that half of the twenty towns were ports, and of the nine towns with repeated epidemic experiences six were ports. If the epidemics were the result of imported infection, it was of interest to note that they did not spread widely. Nevertheless a study of incidence in administrative counties showed, for instance, that the epidemic years in Lincolnshire (Lindsey) were also those of the epidemics in Hull (1927), in Grimsby (1930), and in both of these ports (1938), and a similar coincidence was found in the timing of epidemics in Plymouth and Cornwall and in Portsmouth and Hampshire. Two months before the famous Broadstairs epidemic in 1926 there had been small but sharp outbreaks at Sheerness and Queenborough in the mouth of the Thames. The lack of epidemics in certain large towns between 1919 and 1946 might be expected to have made them vulnerable to later infection. The fact that some of them remained little affected during the widespread infection of 1947 was therefore very striking.

Change in Age Incidence

It has been shown¹ that in the years 1944-8 a significantly higher proportion of reported cases of poliomyelitis were over the age of 5 years than in the years 1912-19. Professor Hill, by reference to the reports of medical officers of health of towns where epidemics occurred in the intervening years, had come to the conclusion that there was little sign of change in age incidence until 1938, when the country experienced the sharpest epidemic up to that time, and when the change in age incidence became quite marked. It persisted until 1947, and had since become even more marked. Using the same source of information, he concluded that there had been no change in the ratio of arm to leg paralysis as a result of the great increase in inoculations since 1942.

One of the purposes of epidemiology is to define problems needing special investigation, and Professor Hill has indicated several here. If, as appears from the figures, fresh introductions of infection frequently took place through the ports, why was spread so limited? If the shift in age incidence to older people was the result of their not being immunized when young owing to improving standards of hygiene, what is the explanation of the comparatively abrupt change in 1938? Why do certain cities have repeated outbreaks, while others with similar environmental conditions escape? And why does the disease tend to reappear in certain localities?

Correspondence

Intravenous Ergometrine and the Undiagnosed Second Twin

SIR.—The value of intravenous ergometrine in the reduction of third-stage haemorrhage has been proved beyond doubt.¹ However, Drs. J. K. Russell, D. Tacchi, and Anne L. M. Graham (*Journal*, May 15, p. 1129) have drawn attention to the risk to an undiagnosed twin when intravenous ergometrine is given before the first child has been completely delivered. When ergometrine is given at the crowning of the baby's head or with the delivery of the shoulder, the rapid cessation of the placental circulation increases the risk of asphyxia neonatorum, especially by inhalation of mucus. This fear caused us, at Sorrento Maternity Hospital, to delay the injection until the baby has been born, when the uterus can be palpated abdominally before giving the ergometrine and all the risk of an undiagnosed twin avoided.

Out of 1,520 consecutive deliveries in this hospital, 130 cases were selected for intravenous ergometrine because they were considered liable to post-partum haemorrhage (grand multiparae, twin labour, inertia, previous post-partum haemorrhage, also after forceps and breech deliveries). In these cases 0.5 mg. ergometrine was given intravenously after the baby was born, and the loss of blood was no greater than that described by Drs. J. D. Martin and J. G. Dumoulin. In five cases where manual removal of the placenta became necessary, a slight contraction ring was found which relaxed readily when 3 min. (0.2 ml.) amyl nitrite was inhaled in addition to the general anaesthetic (nitrous oxide, oxygen, and ether). In no case was any difficulty encountered, although in all five cases part of the placenta was definitely adherent to the uterus. Surely this experience disproves the prevalent idea that it is necessary to administer ergometrine prior to the complete delivery of the baby when, in actual fact, there may be some danger?—I am, etc.,

Birmingham.

SIR.—In their article Drs. J. K. Russell, D. Tacchi, and Anne L. M. Graham (*Journal*, May 15, p. 1129) state that they had been fortunate in that none of their undiagnosed twins had been lying transversely, in which event a difficult intrauterine manipulation might be necessary, with risk to mother as well as child; nor do they appear to have experienced trouble from spasm of the cervix after administration of the drug. The following case illustrates both these complications.

An unbooked patient, a gravida-2, aged 28, was admitted to Queen Charlotte's Hospital as an emergency case on March 15, 1954. She was one of twins, but her pregnancy had been uneventful apart from a threatened abortion at two months. Labour commenced spontaneously at 33 weeks and the contractions became strong and frequent. She had two injections of pethidine, 100 mg., but the cervix did not dilate, and she was accordingly admitted to hospital after 44 hours in labour. Her general condition then was good; the uterus was not relaxing between frequent contractions, and it was not possible to determine per abdomen the presentation or position of the foetus, as the uterus was so hard. The fundal height was normal for 33 weeks, and a foetal heart was heard beating regularly at 170 per minute, thereafter remaining between 150 and 128 per minute. Vaginally, the presentation was found to be vertex with the head in mid-cavity in the R.O.A. position. The cervix was fully dilated and the membranes had ruptured. The head advanced very slowly, and, after 1½ hours in the second stage, an easy forceps delivery was performed under cyclopropane, gallamine triethiodide, nitrous oxide, oxygen, and trichlorethylene. The cord encircled the neck once, and was very tightly applied. The head and neck above this level were intensely cyanosed and swollen.

Although the heart was beating at birth, respiration was never established. The foetus weighed 3 lb. 8½ oz. (1.58 kg.).

Intravenous ergometrine, 0.5 mg., was given with the birth of the anterior shoulder. The uterus contracted firmly, but seemed rather large, and vaginal examination revealed the bag of waters of the undiagnosed second twin protruding into the vagina. The membranes ruptured during examination. The cervix now admitted only two fingers and the presentation of twin 2 was a shoulder. Time was allowed for the cervix to relax and an inhalation of amyl nitrite, 5 minims (0.3 ml.), was given, with some effect. As soon as a hand could be passed through the cervix, a difficult internal version was performed. A foot was brought down, followed by the other, and a breech extraction was performed. The extended arms were flexed and brought down. There was delay of 10 minutes in delivery of the head by the Mauriceau-Smellie-Viet manoeuvre, as the cervix was not completely dilated. A stillborn foetus weighing 3 lb. 8½ oz. (1.58 kg.) was delivered 70 minutes after the first twin. The placenta failed to separate and had to be removed manually. The uterus felt normal. The total blood loss was 14 oz. (0.4 l.) and the patient's condition was good throughout. She remained apyrexial and demanded to return home by ambulance on the third day of the puerperium.

Post-mortem Examination (Dr. Claireaux).—Twin 1: Intense engorgement and severe subcutaneous oedema of the head and neck above the level of the cricoid cartilage, the colour of the oesophagus changing abruptly at this level. Subpleural and thymic petechial haemorrhages. Subarachnoid and intraventricular haemorrhages. Twin 2: Subpleural and subepicardial haemorrhages. No intracranial lesion.

I am grateful to Miss K. M. Robinson for permission to record this case.—I am, etc.,

London, W.6.

ELLIS JONES.

Prolonged Cortisone Administration for Rheumatoid Arthritis

SIR.—The interesting article by Dr. W. S. C. Copeman and his colleagues on the management of rheumatoid arthritis with prolonged cortisone administration (*Journal*, May 15, p. 1109) once again raises the question not only of the criteria used for the evaluation of therapy, but also of our aims in treating this potentially crippling disease. In this well-observed and carefully followed up series of cases the authors, in their assessment, have correctly distinguished between the effects of therapy on functional capacity, joint involvement, and clinical and laboratory evidence of disease activity. The results were assessed largely on a practical functional basis, and the value of therapy appeared to rest chiefly on a definite functional improvement in 17 out of the 20 cases treated.

In spite of this, however, a number of cases showed radiological progression of damaged joints. In other words, although the treatment has been shown to be of practical value from the functional aspect, the disease has actually progressed from the point of view of joint damage. This may be the result of the natural course of the disease, but one cannot help but feel that increased use of damaged joints may be an important contributory factor. We may therefore ask ourselves whether, in treating rheumatoid disease over a prolonged period with a drug known to be non-curative, we should suppress symptoms and signs in order to encourage functional capacity. We may be justified in doing this with a short course of treatment in order to assist rehabilitation. On the other hand, in long-term treatment, encouragement of functional capacity may carry a danger of producing further joint damage. This applies particularly to the younger age group, where there is a greater opportunity for wear and tear of the joints over a period of many years. In such cases, our efforts should be directed chiefly to reducing rheumatoid activity. It is well known that the disease may undergo natural remission, and such remission is the best possible improvement short of a cure.

Having assessed and followed up many hundreds of patients treated with a variety of therapeutic agents, it is felt that, in rheumatoid disease, more emphasis should be laid on activity of the process than on functional capacity as a criterion in assessment. Although improved function

should be taken into account, reduction of rheumatoid activity must represent the major criterion for the effectiveness of any therapeutic agent.—I am, etc.,

Bath.

L. MANDEL.

Pleural Effusion in Young People

SIR.—The recent Ministry of Health memorandum on prevention of tuberculosis¹ (see *Supplement*, April 17, p. 174) urges an intensification of the war on this disease on many fronts simultaneously. To the various measures suggested we would make a plea for the proper assessment and treatment of cases of pleural effusion in young people, amongst whom it is a common condition. On the basis of recent work in England² and some Scandinavian investigations^{3,4} it can be calculated that, with the present rate of tuberculous infection in this country, at least 100 cases of pleural effusion will arise each year in schoolchildren alone per million total population. Most of these cases present with severe symptoms and are readily diagnosable. Indeed, the great majority are diagnosed, but the high probability of a tuberculous aetiology does not always seem to be sufficiently regarded. Many youngsters with pleural effusion receive no more treatment than a few weeks in bed followed by a few weeks more at a convalescent home. Too often the diagnosis of tuberculosis is not made because the doctor does not wish to cause anxiety to the parents.

Pleural effusion is a serious condition, being frequently followed by frank pulmonary tuberculosis. In our series² no fewer than 15% of girls who had what seemed to be a simple tuberculous pleural effusion between the ages of 10 and 16 developed obvious pulmonary tuberculosis during a follow-up period of six years. In young adults Thompson⁵ reports an even higher incidence. In addition, Sibley⁶ has shown that cases of pleural effusion run an appreciable risk of developing extra-pulmonary tuberculosis. These complications and sequelae are scattered over many years, and the short observation period often given to these cases is probably one reason why pleural effusion is too frequently said to be "benign." The seriousness of pleural effusion may be due, in a proportion of cases, to an underlying miliary tuberculosis which, for one reason or another, is not radiologically visible.

There seems good reason to advocate that pleural effusion in tuberculin-positive children and adolescents, in the absence of some definite alternative diagnosis, should be considered as tuberculous and should be thoroughly investigated and treated in special units where, of course, education can be continued. It appears likely that antibiotic therapy in selected cases, together with an adequate period of graduated rest and subsequent rehabilitation, will prevent the development of serious tuberculous trouble in many instances later in life, and will in consequence make a further contribution to the fight against this scourge, which, though retreating, still exacts too great a toll.—We are, etc.,

Psychiatry and General Medicine

SIR.—Perhaps it is unwise for one section of the profession to be over-critical of another. Most of us, after all, live in glass houses. Also, when Dr. Cyril Josephs (*Journal*, May 8, p. 1096) takes such pleasure in scoring off the psychiatrist, one wonders what is his unconscious motivation. Dr. Josephs is more than critical of psychiatric treatment and insists that psychiatry as a discipline must be measured by its success in curing patients. I do not think

this is altogether a logical argument, and heaven knows where it would leave, for example, brain surgery, dermatology, and much of general practice. It is true that advances in treatment are nowhere more necessary than in psychiatry. Illnesses like schizophrenia fill thousands of hospital beds, and neurotics are said to throng practitioners' waiting-rooms. Are we then to give up the practice of mental health until a benevolent Government opens its coffers to research and hastens the psychiatric millennium?

I suppose no one is more conscious of the limitations of therapy, both physical and psychotherapeutic, than the mental hospital psychiatrist administering it. After all, far from burying his failures, he often has to live among them. E.C.T. and insulin are useful therapies and can transform abject misery into optimistic well-being. Certainly they are empirical and sometimes fail. I venture to suggest that this is also true of much in general medicine, despite recent advances. Psychiatry, of course, has other weapons, and the doctor's use of them depends on his opinions, his qualities of personality, and his psychotherapeutic skill. Here again, however, he can expend his resources without success, and therefore he tries to apportion his time wisely. The chronic neurotic, pitiful though his situation may be, is not only a poor prospect for intensive treatment but also uneconomical. There are so many others for whom the psychiatrist can do more.

Admittedly psychiatry has overplayed its hand. Too many films and stories have moulded the psychiatrist into the likeness of God and given him powers he sometimes forgets he does not possess. Dr. Hunter Gillies¹ put it well when he said: "... The myriad patients against whom the dice were loaded from the moment of their conception rarely figure in such selected material, and then only in the productions of our heavier and gloomier writers. But it is these patients who daily confront us, and our support of these handicapped people, valuable and indeed indispensable as it is, appears pedestrian beside the miracles that the public have been led to applaud."

Perhaps Dr. Josephs will consider these few points and arrive at a more balanced and charitable conception of our specialty. There is needed on the part of the general public a more enlightened attitude towards psychiatry and mental hospitals, and this will come more speedily if doctors show it first.—I am, etc.,

Aberdeen.

Anthrax Protective Antigen

SIR.—In your annotation (*Journal*, May 8, p. 1083) on anthrax protective antigen, you state: "The Pasteurian method of producing active immunity against anthrax... has hitherto not been superseded in the 70 years since it was introduced." This is not quite accurate. Sterne¹ and Stamatin² independently isolated an avirulent spore vaccine in 1937 which, although used in a living state, differs from the old Pasteurian vaccine in an important way. Whereas the Pasteurian vaccines contain organisms that are potentially virulent, the Sterne vaccine lacks an essential factor for virulence—namely, the polyglutamic acid capsule. This makes it perfectly safe to use and avoids the failures and disasters that occasionally occurred with the Pasteurian vaccines, and is a very important advance on these older vaccines. It has in fact been used on a very wide scale, particularly in South Africa, where several million head of cattle have been immunized without a single accident. By its use, anthrax among cattle has been virtually wiped out in that country. This is the strain that the Porton workers used for the production of their soluble antigen and called by them "Weybridge." With more justice to its discoverer, who sent it to the Ministry of Agriculture's laboratories at Weybridge, it should be named the "Sterne" strain.

It has been clearly shown that these living vaccines immunize by a local proliferation at the site of injection, liberating soluble antigen *in vivo* in the same way that it is liberated by virulent organisms in anthrax infection; but,

whereas lesions of the latter are progressive, the local lesion of the former is invariably retrogressive. The production of the soluble antigen on a large scale *in vitro* is obviously an important advance, and the Porton workers are to be congratulated.—I am, etc.,

Oxford.

Mondor's Disease

SIR,—We read with interest Mr. G. M. Lunn and Mr. J. M. Potter's article on Mondor's disease (*Journal*, May 8, p. 1074). At that time we had a patient with this condition of one month's duration. Although less evident than when first seen, the lesion is still well shown in the photograph.

The patient, a married male aged 57, attended in April, 1954. His general health was excellent, with no recent illness apart from osteoarthritis of both first metatarsal-phalangeal joints. He had marked congenital clubbing of the fingers, and so had his son, while this was less prominent in his daughter and absent in his wife. A non-tender subcutaneous cord-like structure was palpable from the right

anterior axillary fold to the level of the fourth right intercostal interspace. Just above the right breast it bifurcated, the less prominent of the two limbs of the bifurcation passing across the areola. The lesion was brought into prominence by abduction and external rotation of the arm and then caused marked puckering of the skin. There was no discoloration, but the patient stated that it was "a pinkish colour" on the third day after he first noticed it, but that it was normal the following day. The breasts were normal, no glandular enlargement was noted, and many pigmented moles were present on the chest and abdomen. The disease did not affect the patient's general health. There was no history of trauma, but three weeks before the lesion appeared the patient changed all the wheels of his car and noticed definite strain in the forcible jerking movements to loosen the bolts.

Unfortunately, the patient was unwilling to have a biopsy taken. We have only seen one other example of this condition.—We are, etc.,

London, E.4.

Drinking Sea-water

SIR,—Air Commodore T. C. Macdonald's attempt (*Journal*, May 1, p. 1035) to discredit Dr. Alain Bombard's achievement in crossing the Atlantic in a rubber raft surely deserves some comment. He says dogmatically sea-water should not be drunk, and that Bombard's evidence for doing so is unsatisfactory. It is generally accepted that salt intake is necessary to replace that lost in the perspiration, which in a castaway may be excessive. The men in the Kon Tiki recognized this and took salt tablets with them; rather unnecessary, surely, when they were surrounded by salt. Then by accident they discovered that sea-water tasted very well in their gruel, and they continued to add it after this purpose. They also found that they felt better and their thirst was quenched more by adding between 20% and 40% of sea-water to their fresh water. For Air Commodore

Macdonald to ignore this aspect of salt replacement by a certain amount of sea-water and advise castaways to wait for rain water, as in Bombard's case, for 21 days, is remarkable, surely, and seems to require some explanation and qualification.—I am, etc.,

Belfast.

R. A. MCILRATH.

Anaemia

SIR,—May I make a few comments on Dr. R. O. Gillhespy's letter (*Journal*, April 24, p. 983) on the "Treatment of Pernicious Anaemia"? I would like to suggest that the case which he describes was not in fact suffering from Addisonian pernicious anaemia, but from a megaloblastic anaemia due to folic acid deficiency. Two factors should rule out a diagnosis of Addisonian pernicious anaemia, the first being that she had no absolute achlorhydria, and the second that she did not respond to vitamin B₁₂. As she responded to proteolysed liver she must have a folic acid deficiency—due either to malnutrition or to malabsorption, the second being much more likely, and a fat analysis of her stools might be helpful.—I am, etc.,

Edinburgh, 10.

R. P. GOULDEN.

Racial and Religious Tolerance

SIR,—Dr. C. P. Seager is certainly right in deploring racial and religious intolerance (*Journal*, May 15, p. 1156). As a matter of principle we should always be aware of the difference between reasonable and prejudiced conducts wherever we meet them. Our colleague seems, however, to ignore the psychodynamic function of various prejudiced sentiments. Compliance, to a certain extent, with such tendencies serves a role similar to the avoidance of phobic situations or the performance of compulsive actions by a large group of patients. Therefore, as long as not much immediate harm to others results, prejudices of some sorts have to be put up with, because of a corresponding need for them in the prejudiced subject.

Indubitably, some professional men will find co-operation easier with colleagues with whom they feel at ease, and this fact must be considered however irrational the prerequisites of such mental ease may be. The same applies to patients whose anticipatory confidence in a doctor may be much disturbed if they have to suppress their prevailing religious or racial prejudices towards him. May Dr. Seager and other readers be referred to a book *Co-operation, Tolerance and Prejudice*?¹ It is heavy going and not well written, but explains in detail the phenomena in question.

We may be glad ourselves not to be dominated by unfriendly prejudices of the kind Dr. Seager has in mind, just as we should not like to have to comply with phobias or compulsions. But I cannot imagine the life of certain personalities without such "unreasonable" attitudes impelling them to select and avoid groups of fellow-beings in their daily social contacts. Only some of these sentiments are based on ignorance and automatic acceptance, and therefore capable of being discarded. The main thing is that prejudice, and intolerance based on it, should never be rewarded by approval or power; but we must wisely tolerate much of such manifestations.—I am, etc.,

London, N.W.4.

S. LOWY.

REFERENCE

SIR,—When Dr. C. P. Seager (*Journal*, May 15, p. 1156) is a little older he may appreciate that the likes and dislikes of our colleagues and patients are to some extent to be respected. We choose our wives, our husbands, our food and drink, our friends, and our politicians as we will. This is freedom. We behave with courtesy to those persons we dislike, and allow them the freedom we ourselves enjoy. This is civilization. If the patient prefers a papist, a Jew, a negro, or even an Englishman or Scotsman, to anyone else, why should not his doctor? Likes and dislikes do not necessarily arise from faulty reasoning or "emotionally toned prejudice."—I am, etc.,

T. R. THOMSON.

Intravenous Iron

SIR,—I enjoyed reading the letter on intravenous iron by Drs. Frank Fletcher and E. London (*Journal*, April 24, p. 984). I am glad to see them admit that lethal factors in animals are not always related to factors producing reactions in man. I still cannot see, however, how increase of reticulo-endothelial activity *per se* can be invoked as the ultimate cause of reactions in man. Such abnormal activity is common in infections and reticuloses, yet no one invokes this as the ultimate cause of either. How can this evidence be marshalled? One method is surely to determine the presence of enlargement of liver, spleen, and lymph glands. These signs are commonly seen in the diseases mentioned, and also occur in serum allergy. It is strange, therefore, that no one has, to my knowledge, reported them so far to occur after injection of iron.

Their statement that reactions which follow the first administration of a dose of iron preclude an antigen-antibody response cannot go unchallenged. It is well known that severe anaphylactic reactions can occur in patients who have never had contact with the allergen before. I recall a patient of mine aged 16 years with no personal or familial allergic history who nearly died from anaphylactic shock following 100,000 units of intramuscular antidiabetic serum given for the first time. In the *Lancet* (April 24, p. 873) a case is reported in which a girl died following a small test injection of antitetanus serum. This is the so-called "phenomenon of natural supersensitivity." Some argue that such cases do not exist, in that unknown contact with a previously sensitizing substance always occurs. This may well happen if the complete antigen has not been introduced—that is, as I mentioned in a previous letter (*Journal*, March 6, p. 583) hapten activity occurs.

Finally, I do feel that, although instability of the preparation used may be operating, yet the main factor in the rapid onset of such reactions is that of direct introduction of the substance into the blood stream, whether this be intravenous or intramuscular. This was one of the disadvantages stressed by protagonists of the administration of vaccine by mouth—for example, for treating dysentery.—I am, etc.,

Romford, Essex.

I. M. LIBRACH.

Nutrition and Experimental Malaria

SIR,—The recent renewal of interest in the effects of nutrition of the host on the development of malaria parasites makes it seem appropriate at this time to recall some of the earlier work and to emphasize the importance of the caution expressed in an annotation which appeared about a year ago in the *British Medical Journal*: "It does not necessarily follow that a substance is metabolized by parasites because it facilitates their growth when administered to the animal harbouring the parasites. . . ."

Passmore and Somerville¹ in 1940 published the first report of experimental work on the influence of nutrition on a malarial infection. They found no effect of a diet deficient in vitamins A and C on the course of infection with either *Plasmodium cynomolgi* or *P. knowlesi* in monkeys. Three years later² it was found that biotin deficiency specifically decreased the resistance of chickens and ducks to certain avian malaria parasites. The same year it was reported³ that pantothenic acid favoured the survival and development of one of these avian parasites, *P. lophurae*, when it was maintained *in vitro* in suspensions of erythrocytes. These two findings set a pattern which subsequent experiments have fully supported: growth factors, depending on their nature (and, as later work showed, on their concentration) can either favour or retard the development of a malarial infection. The results with pantothenic acid led to the successful experimental use of analogues of the vitamin as antimalarial agents⁴ and to the demonstration of the inability of *P. gallinaceus* to develop in chickens deficient in pantothenate.⁵ Much additional significant information has since accumulated. Deficiencies in the host's diet of folic acid,⁶ protein,⁷ or nicotinic acid,⁸ like biotin

deficiency, favoured the development of avian malaria parasites, whereas a deficiency in riboflavin retarded the development of avian parasites,¹⁰ and deficiencies in vitamin C,¹¹ methionine,¹² or para-aminobenzoic acid¹³ retarded the development of simian malaria parasites. The effects of a milk diet on certain mammalian malaria parasites,^{14 15} and their explanation in terms of para-aminobenzoic acid deficiency,¹⁶ are well known to readers of the *British Medical Journal*. Despite all these facts, it would be premature to draw any conclusions concerning the nutritional requirements of malaria parasites. We must remember that the experiments referred to above relate to parasites growing in erythrocytes within a host animal, or at best to parasites growing in erythrocytes maintained for a short period *in vitro*. Recent work with *P. lophurae* has shown that when this organism is maintained extracellularly *in vitro* it requires coenzyme A¹⁷ and not the pantothenic acid moiety of coenzyme A. It is likely that some of the other factors in the diet of the host which favour the development of the parasite do so only indirectly. They must be present in the diet of the host in order to permit the host to elaborate other substances which are the materials actually utilized by the parasite.—I am, etc.,

New York.

Important Anomaly of Long Saphenous Vein

SIR,—In your medical memoranda of April 17 (p. 918) you had an admirable account of "An Important Anomaly of the Long Saphenous Vein" by Dr. A. J. M. Cathro. I would welcome an opportunity to stress this abnormality. Trendelenburg's operation for varicose veins is common, and in the course of the last three years I have, unfortunately, treated three cases of amputation, two above the knee and one below the knee, for the erroneous ligation of the femoral artery. In each case it was difficult to ascertain why this had occurred, but undoubtedly the femoral artery had been ligated, and this was probably due to the fact that it was not recognized that the long saphenous vein may pass spirally round the lateral side of the femoral artery. In these days of litigation it would seem most important for surgeons to be aware of the existence of this anomaly.—I am, etc.,

London, S.W.15.

LEON GILLIS.

Infectious Mononucleosis

SIR,—Dr. S. Varadi (*Journal*, May 15, p. 1155), writing on infectious mononucleosis, states that whether one adopts the theory of one causal virus or of different closely related ones, the blood count is the most important test of infection and is most likely to reveal the diagnosis at an early stage: also that this diagnosis is not excluded by a negative Paul-Bunnell test. In my experience the blood count and the blood picture in cases of measles, mumps, and lymphocytic choriomeningitis may be indistinguishable from that of an infectious mononucleosis, which gives a positive Paul-Bunnell test. I have in the past seen an experienced haematologist report the presence of numerous Downey Type II cells in the blood of a patient whose Paul-Bunnell test was negative, and who subsequently developed a rising complement-fixation titre for lymphocytic choriomeningitis.

Should pathologists admit that the blood picture in the diseases mentioned above is indistinguishable from that of infectious mononucleosis, it is doubtful whether infectious mononucleosis with a negative Paul-Bunnell test can be regarded as a disease entity. I think it is closer to the truth to state that known and perhaps unknown diseases may have a blood picture identical with that of infectious mononucleosis. Therefore a disease giving this blood picture combined with a positive Paul-Bunnell test with the complete adsorption procedures could be called infectious mononucleosis. If the Paul-Bunnell test is negative, complement fixation tests for known virus diseases might give the diagnosis. If these tests are not done, or are negative, let us be honest and say the disease has not been diagnosed. As yet, I have not seen a positive complete Paul-Bunnell test in a case of measles, mumps, lymphocytic choriomeningitis, or other undiagnosed form of benign meningitis, although the blood picture in some of these cases was indistinguishable from that described by Downey for infectious mononucleosis.

London, N.12.

PETER WOLF.

Women in Medicine

SIR,—Your annotation (*Journal*, May 15, p. 1143) draws attention to the dual responsibility of married women in medicine. This difficulty is now enhanced for those who have been overtaken by the new regulation requiring a pre-registration year of internship. The compulsory living-in during this year raises serious problems in the home, particularly for those who have young families. Would it not be feasible to permit living-out, provided that duties were not interfered with, at least for those women who took up medicine and incurred family responsibilities before this regulation was announced?—I am, etc.,

London, N.W.3.

RUTH D'ARCY HART.

Renal Clearance of Creatinine and Urea

SIR,—In his article Dr. R. A. Kenney (*Journal*, May 15, p. 1130) has shown that in nine out of ten West Africans the (maximum) urea clearance was lower than the average normal value accepted in Great Britain and the United States (75 ml./min.): in eight of the ten, the value was less than 3/5 of the average normal. He has shown that the creatinine clearance is similar in West Africans and in Europeans, and states that other investigations not yet published have shown the identity of the glomerular filtration rate and the renal plasma flow rate in the two groups. From these results Dr. Kenney argues that the mechanism of excretion of urea in West Africans differs from that in Europeans. Such a conclusion is not justified by the evidence in his paper.

The table of urea clearances given by Dr. Kenney is meaningless, because we are not told how the six results from each subject are combined to give the values tabulated. If, as one suspects, the results were arbitrarily separated into those corresponding to urine flows over 2 ml./min. and those corresponding to urine flows under 2 ml./min., the grand means for all the West African subjects are differently weighted by individual results and no conclusions are possible. In any case no comparison is possible with the European subjects, because the number of these is not stated.

Dr. Kenney states that the African subject "fails to show the 'augmentation' phenomenon which is characteristic of urea excretion in the European subject." The "augmentation limit" which was introduced by Van Slyke and his colleagues¹ represents the rate of excretion of urea at which the rate of excretion of urea is maximal. However, inspection of the original data on which this conception was based suggests that every increase in the rate of excretion of urea is associated with some rise in the rate of excretion of urea, and it seems fair to say that later authors²⁻⁵ have abandoned the idea of an "augmentation limit": it is a simplification which has been convenient in the clinical application of the urea clearance test. Six results were obtained by Dr. Kenney on each of his subjects; the results in full would permit of comparisons with corresponding results obtained in Europeans.

It is, of course, important to consider how much significance should be attached to urea clearance obtained in a period of rapidly increasing diuresis. Finally, it is worth noting that Gokhale⁶ and Srikantha and Shamanna⁷ found low values for the urea clearance in Indians. Low results were also obtained by H. Fairfield Smith⁸ in British prisoners in Japanese hands.—I am, etc.,

Sheffield, 11.

Winter Vomiting Disease

SIR,—I welcome the letter of Dr. M. C. McKinnon (*Journal*, May 15, p. 1154) criticizing the use of the name "winter vomiting" for this disease. This unfortunate name suggests that climatic conditions have something to do with the matter, whereas, in fact, this disease is undoubtedly an air-borne virus infection. I have myself described an outbreak of over 313 cases,¹ and this occurred at the end of September and beginning of October, which even in this northern part of the country is not usually considered winter, and the weather conditions at the time were far from severe. Dr. McKinnon rightly draws attention to the short incubation period of this disease as compared with the much longer period for infective hepatitis. In my own outbreak, although I have had the opportunity of observing the children for more than three years since the event, I know of no case of jaundice. Another point is the abrupt onset of this disease as a contrast to hepatitis. I am, etc.,

Accrington.

Doctors and Technicians

SIR,—My friend Dr. J. F. Brailsford (*Journal*, May 15, p. 1152) sees the writing on the wall but misreads it. The trend of which he complains has nothing to do with the N.H.S. but must be studied against the background of social evolution. Hygeia, who, being the daughter of that respectable old G.P., Aesculapius, really ought to know better, now indulges in the most abandoned licentiousness, the latest offspring of her fecund womb being, apparently, the animal technician. The main cause of medical progress is the advance in technology. Consequently medicine itself must become more and more a technology, however deeply we may deplore the fact. Our mentors bleat *ad nauseam* that medicine is an art as well as a science, and that we must treat the whole man and not merely the diseased organ. The fact remains, however, that the fate of a patient is often decided by whether some backroom boy's burette reads 0.3 or 0.4. The backroom boy is not slow to realize his power.

The immense body of auxiliaries, the product of very efficient secondary education, is largely composed of those who, had Fate been kinder, could have entered medical schools and who would have made perfectly good doctors. These, urged by understandable ambition, and sometimes by resentment, are engaged in building parallel roads to a status equal to that which has been denied to them. Hence the claim that "the technologist has, or should have, equal status to the pathologist." Needless to say, this trend will become accentuated if the entry to medical schools is further restricted. At the same time these aspirants peck at every newcomer as savagely as barn-door fowls. This is what Messrs. A. E. Brown and F. Mather (*Journal*, April 24, p. 983) are now doing to the poor animal technician who is at the bottom rung of the ladder of diplomas, associateships, papers in journals, and annual congresses which they themselves are so successfully scaling.

Where will this end? I confidently predict that in 30 years all auxiliaries will have acquired consultant rank. The steps to this delectable consummation are not difficult to visualize. The training of auxiliaries in the last 20 years has made astonishing progress, while that of medical students has been comparatively static. Already there are some auxiliaries who hold the B.Sc. degree. Soon Ph.D.s will appear. They may, for all I know, be already with us. From this it will be but a short step to Doctors in Chiropody, Audiometry, Orthoptics, Speech Therapy, Radiography, Electro-encephalography, Medical Records, Operating Theatre Technique, and everything else. And if these, why not Doctors of Nursing? In the end the few who are not Doctors of some kind or other will hide their heads in shame. Never will so few have been so jealous of so many.

Some time ago I met a lady who had just been to a lecture given by a member of one of the auxiliary services. Her ecstasy knew no bounds. She might have been listening to the voice of God. I am afraid I could not conceal my amusement. "You shouldn't laugh," she said indignantly, "he's a great man. He talks to people at the Ministry."—I am, etc.,

Chesham.

FRRANCON ROBERTS.

SIR,—Dr. J. F. Brailsford draws attention (*Journal*, May 15, p. 1152) to a tendency in modern medicine on which others have also commented recently, and on which Dr. Ffrangcon Roberts dwells at length in *The Cost of Health*.¹ Dr. Brailsford suggests that the doctor who does little but stamp his signature on reports of work done by other people is in danger of losing both medical skill and status, and with this most would agree. It is also true that other workers now do for the doctor some tasks which he used to do for himself, but surely this is no cause for either alarm or despondency.

Modern developments in medical knowledge have resulted in the growth of aids to diagnosis and treatment, and in an abundance of specialized techniques so that no one person—however enthusiastic—could be expected to have an intimate grasp of them all. It seems to the impartial observer that the doctor or surgeon who makes wise and selective use of these various aids is benefiting himself and his patient, and is more likely to gain, not lose, clinical acumen and prestige. It is the non-use, or the indiscriminate use, of these subsidiary aids which is likely to harm both doctor and patient. The quotation made by Dr. Brailsford from the letters of two medical laboratory technicians ought not to be taken too seriously, especially out of their context. That context was a claim made in an annotation in the *Journal* of April 3 (p. 808) that "animal technicians" should be given equal status with medical laboratory technicians. When Mr. F. Mather's letter (admittedly ill-phrased) states (*Journal*, April 24, p. 984): "It would seem, therefore, to be more justifiable to state that in many respects the technologist has, or should have, equal status to the pathologist," I take him to mean "it would be as justifiable for the technologist to claim equal status with the pathologist as for animal technicians to claim equal status with the medical laboratory technologist," and no one would seriously support either claim. In any case the views of one or two medical laboratory technicians ought not to be taken as representing the views of the body of technicians nor that of the Institute of Medical Laboratory Technology. All professions, including the medical profession, have members who occasionally state views which would not be endorsed by the body corporate.

The approach to the problem posed by Dr. Brailsford is surely one of common sense. It is better that the physician or surgeon shall be free to concentrate his energies and training on the wider aspects of diagnosis and treatment than that he should dissipate his time and clinical specialty on the memorizing or performance of detailed technical procedures. He is not likely to have his status assailed because of the work performed by the various medical auxiliary professions: indeed, the effect of their work should be to increase it. Equally, it will profit nobody,

least of all the clinician, to undervalue the work which is daily being performed by the medical auxiliary professions.—I am, etc.,

Godalming.

W. H. VALENTINE.

Seven Generations

SIR,—In the museum here is an MS. pedigree of the family of Kinneir from which the following is taken.

Walter Kinneir, surgeon, of Highworth (1671–1746) was father of Richard Kinneir (1711–1784), surgeon, of Cricklade, who was father of Richard Kinneir (1749–1813), surgeon, of Cricklade, who was father of Richard Kinneir (1787–1874), surgeon, of Cricklade, who was father of Richard Kinneir (1813–1892), M.D., M.R.C.S., L.S.A., of Cirencester, Purton, Weston-super-Mare, and Sherborne, who was father of Francis William Edward Kinneir (1858–1939), who was father of Guy Kinneir (b. 1891), M.R.C.S., L.R.C.P., now in practice. Seven generations. Can any family beat this record?—I am, etc.,

N. M. G. CARTER,
Hon. Curator, Cricklade Museum.

Standard of Anaesthetics in Britain

SIR,—My attention has been drawn to an article in the *Daily Express* of Wednesday, May 19, entitled "The Danger of Machines." This purports to report remarks made on the previous morning by Mr. Dickson Wright to a meeting of the American College of Surgeons. The article imputes a deplorably low standard of behaviour to anaesthetists in general. Its final paragraph, which mentions my own name as President of the Association of Anaesthetists, might have given the impression that I was present at the time and that Mr. Wright's remarks had my tacit approval, neither of which is true. It would not be necessary for me to refute these remarks if they had reached only those of us who are familiar with Mr. Wright's form of jocularity and who would give them the weight they deserve, but the American visitors may not be so familiar. It will be a pity if they have been left with a wrong impression of the standard of anaesthetics in this country, which is generally considered to be as high as anywhere in the world.

The effect of the article is to undermine the confidence of patients about to undergo surgical operations and can only be deplored—it is, as always, too late to undo the harm. I feel some sympathy with Mr. Wright that his light-hearted comments have received wider publicity than he intended. For the future, I feel that we should all remember that exaggeration as a humorous device is not wisely used in what is meant to be serious discussion, and, probably, never when it involves the denigration of colleagues.—I am, etc.,

GEOFFREY ORGANE,
President, Association of Anaesthetists
of Great Britain and Ireland.

London, W.C.2.

Chloramphenicol for Athlete's Foot

SIR,—The only paper that has been published on the value of chloramphenicol in the treatment of fungus infections of the skin is by Robinson *et al.*¹ These investigators found a 1% or 2% ointment to be of value in controlling secondary infections in 17 cases of epidermophytosis. It may therefore be of interest to know that I have treated 25 cases of athlete's foot, and over a period of six months have had only two recurrences which have cleared up again after further treatment. The majority of these cases had suffered from the complaint for a number of years. The basis of my treatment was: (1) wash the feet with warm water only each night; (2) dry thoroughly and apply every alternate night a little chloramphenicol ("chloromycetin topical") with a small piece of cotton-wool and allow to dry; (3) no dusting powders or any other medication required; and (4) change socks daily. In most cases I have found three or four applications were sufficient to clear up the condition completely.—I am, etc.,

Glasgow.

Obituary

FRANK HOWITT, C.V.O., M.D., F.R.C.P.

The death of Dr. Frank Howitt on May 15 at the relatively early age of 59 removes a leading—indeed a pioneering—figure from the specialty of physical medicine and is a sad loss to a wide circle of professional colleagues and friends among whom he was held in unusual regard.

Frank Dutch Howitt was born on August 24, 1894, at Nottingham, and educated at Uppingham and Trinity College, Cambridge. In the first world war he served with the Royal Army Service Corps and later with the Royal Air Force. Returning to Cambridge, he took his M.A. in 1920, and graduated in medicine in 1923, proceeding M.D. two years later. He at once became attracted to physical medicine, and was appointed chief clinical assistant in the actinotherapeutic department at Guy's and physician in charge of physical medicine at the Royal Free Hospital and the Prince of Wales's General Hospital, Tottenham. Later he was appointed physician in charge of the large and

[Lafayette, Ltd.]

important department of physical medicine at the Middlesex, and in due course he became senior physician of the Arthur Stanley Institute for Rheumatic Diseases. Within five years of qualifying he was called in by Lord Dawson of Penn to administer certain physical treatments to George V during his serious illness in 1928, and he attended the King both in London and during his convalescence at Bognor.

Howitt was an active member of the British Medical Association, being honorary secretary to the Section of Dermatology at the Annual Meeting in 1927 and to the Section of Physical Medicine at the Centenary Meeting in 1932. In 1936 he was vice-president of the Section of Physical Medicine. He gave his services on several special committees of the Association. From 1932 onwards he was a member of the Practitioners of Physical Medicine Group Committee, and at the same period he took a prominent part in the consideration of proposals for the registration and training of physical treatment technicians and the training and recognition of balneological assistants. During the second world war he served in the R.A.M.C. with the rank of acting colonel in 1940 and the local rank of brigadier in 1942. He was placed in charge of the upgrading of recruits and of rehabilitation, and after the end of the war he continued to serve as senior consultant in physical medicine to the Army. He also became a director of Remploy Ltd. (the Disabled Persons Employment Corporation) and honorary adviser to the Ministry of Labour. When the Council of the B.M.A. set up a Rehabilitation Committee in 1945 Howitt served on it as a most valuable member for four years or more.

Industrial medicine and rheumatism were two of his great interests, and he was a member of the Nuffield Foundation committees on these subjects and chairman of the Research Board for the Correlation of Medical Science and Physical Education. He also served on the executives of the Empire Rheumatism Council and the Royal Institute of Public Health.

The illness which brought about his sudden end first manifested itself a year ago, but he faced the threat with splendid courage and patience, and his alert and eager mind continued at work. He might have looked forward to several more years of activity, but he could look back upon a career of high achievement, and also of great happiness, enhanced by his marriage in 1945 to Violet Norris, daughter of Alfred Leverton, to whom the sympathy of many friends will go out.

We are indebted to Dr. W. S. C. COPEMAN for the following appreciation: Frank Howitt, although popular in all of the numerous spheres of life in which, in addition to medical circles, he moved, was pre-eminently a man's man. He was gregarious, friendly, and easily approachable by his juniors. He entertained generously and elegantly, and was something of an authority on both food and wine. A dinner at his Harley Street home was always an experience. Although he became eminent in his chosen sphere of medicine, his real love was for the country life, and of recent years he spent all the time he could spare from practice at his farm in Gloucestershire. He was a first-rate tennis player and a fine shot throughout his life.

He came into prominence during the first illness of King George V, when he was invited by Lord Dawson to supervise the physical therapeutic measures which had become necessary. For this service he was appointed C.V.O. in 1929. It was characteristic of him that for several months subsequently he modestly avoided wearing the insignia, and later, if questioned about it, asserted humorously that he had been appointed "Mayor of Wigan, and was just showing the flag."

As a consultant in physical medicine during the second world war he was able to invest the subject with a far wider significance than had previously been attached to it. In this capacity he gathered round him a devoted band of juniors ("his boys") who carried his ideas into the various commands in which they later served. Much of what Howitt included under the heading of physical medicine has subsequently reverted to the provinces of social, preventive, and even general medicine, but he was successful in raising the subject from the status of a technique to that of a specialty. The conception, which he had inherited from Lord Dawson, that healthy living should be regarded as a powerful prophylactic against ill-health in later life led him to take a keen interest in the National Playing Fields Association and other similar movements.

In the Army he found great scope for the employment of his ideas in the upgrading of recruits and in the formation of rehabilitation centres where the concept of active convalescence was developed successfully. It was a considerable disappointment to him that these schemes proved to be less easy to apply in post-war civilian life. His friendship with the late Ernest Bevin while he was Minister of Labour, however, enabled him to exert considerable influence in the formation of industrial resettlement units, of which the chief is Egham, and other bodies such as Remploy Ltd., whose purpose is to return the defective worker to full-time productive employment.

He was an outstandingly successful Master of the Apothecaries Society, and he was at one time the vice-chairman of the Empire Rheumatism Council, in which he took a great interest.

Frank led a happy and useful life and we are all the poorer for his untimely passing.

ERIC POWELL, M.B., F.R.C.S.I., M.R.C.P.I.

The Kenya Branch of the British Medical Association has suffered a severe loss by the death while in office of its president, Mr. Eric Powell, on March 30 at the age of 36.

Willoughby Eric O'Connell Cole Powell was born in Yorkshire on May 12, 1917, the son of a doctor, but his early youth was spent with one of his uncles, Mr. George M. C. Powell, then a surgeon at Lusaka, in Northern Rhodesia. He returned to England to continue his education at Worksop College, Nottinghamshire, and from there he entered Trinity College, Dublin, where, with a grandfather, a father, and two uncles all members of the medical profession, it was hardly surprising that he should enrol as a medical student. A brilliant career at Trinity College was rewarded by the Daniel John Cunningham Medal in anatomy at the first medical examination, the John Mallet Purser Medal in physiology, biochemistry, and histology, the Professor's Prize in surgery, the Connolly Norman Medal in mental diseases, and the FitzPatrick Scholarship. He graduated in 1940 with second-class honours in the final M.B. and first-class honours in the final B.Ch. examinations. He had previously been awarded a gold medal as a moderator of exceptional merit. After graduation Powell held the appointment of house-surgeon at Sir Patrick Dun's Hospital, later becoming assistant in the ear, nose, and throat department, and for a time he was also assistant to the professor of pathology at Trinity College. Later he was appointed honorary consultant laryngologist to St. Patrick's Hospital, Dublin. He was elected F.R.C.S.I. in 1944 and M.R.C.P.I. in the following year. In 1947 he left Dublin to become ear, nose, and throat surgeon at King George VI Hospital, Nairobi. In addition, he established a private practice there and acted as surgeon to the British Military Hospital at Nairobi. As founder of the Nairobi Clinical Club he brought together once a month his colleagues in the profession, not only to discuss medical problems and to exchange views but to encourage the spirit of comradeship among them. His election as president of the Kenya Branch of the B.M.A. in January last was a tribute to the esteem with which he was regarded by his fellow members and to the ability they recognized in him. He had a variety of outside interests, being a city councillor, area commandant of the Kenya Police Reserve, and twice president of the Irish Society. As an after-dinner speaker and a performer on the piano accordion, his services were in great demand, while his love of children was particularly in evidence at the Christmas parties at the Children's Hospital. He was happy, too, in his well-equipped workshop, where the making and repairing of surgical instruments gave him great pleasure. He married Dr. Edna G. Merrick, daughter of Dr. William Merrick, of Castleknock, Co. Dublin, in 1941, the year after they both graduated in medicine at Dublin, and she survives him, together with the three children of the marriage.

F. W. RANKIN, M.D., LL.D., P.A.C.S., F.R.C.S.

Dr. F. W. Rankin, President of the American College of Surgeons, and a former President of the American Medical Association, died at Lexington, Kentucky, on May 22, aged 67. He was a son-in-law of Dr. Charles H. Mayo, one of the founders of the Mayo Clinic. His fatal illness prevented him from presiding at the meeting of the American College of Surgeons in London last week.

Fred Wharton Rankin was born at Mooresville, N.C., on December 20, 1886, and received his medical education at the University of Maryland, Baltimore. After graduating in 1909 he held a resident post in Baltimore until 1912 and served as assistant demonstrator in anatomy and as associate in surgery at his own university from 1913 to 1916. He then joined the Mayo Clinic as assistant surgeon until 1922, when he spent a year as professor of surgery in the University of Louisville. He returned to Rochester in 1926 as associate professor of surgery at the University of Minnesota Medical School and surgeon to the Mayo Clinic. He left these posts in 1933 to practise surgery at Lexington, Kentucky, where he was appointed surgeon to St. Joseph's Hospital, a position he held at the time of his death. Since 1941 he had been clinical professor of surgery at Louisville.

Rankin contributed much to the literature on clinical surgery, and was an internationally known authority on the surgery of the colon and rectum. His monograph on the *Surgery of the Colon* appeared in 1926, and he was also the joint author of *The Colon, Rectum and Anus* (1932), and *Cancer of the Colon and Rectum* (second ed., 1950).

During the last war he served as chief consultant to the Surgeon-General, U.S. Army, with the rank of brigadier-general. The American Medical Association in 1945 awarded him its Distinguished Service Medal for his meritorious services in this appointment. He was president of the Southern Surgical Association in 1937, the American Medical Association in 1942, the American Surgical Association in 1949, and the American College of Surgeons at the time of his death. In 1953 Rankin was awarded an honorary fellowship of the Royal College of Surgeons, and during the recent meeting of the Association of Surgeons of Great Britain and Ireland, attended by many distinguished members of the American College of Surgeons, the University of Leeds conferred upon him the honorary degree of LL.D.

Dr. E. WELLISCH died in hospital at Dartford, Kent, on March 11, after a short illness. Erich Wellisch was born in Vienna on January 21, 1898, the son of a high official of the municipality who made a name for himself by becoming an authority on blood groups after his retirement. To emulate his father's distinction was Erich Wellisch's fondest ambition. He graduated M.D. at the university of his native city in 1924. After a period of postgraduate study in neurology, he specialized in physical medicine and soon became an authority on light therapy. A monograph on this subject and a number of publications on the physiotherapy of neuritis and dermatitis bear witness to his great abilities as a clinical observer and to his therapeutic resourcefulness. Having had to leave Vienna in 1938, Dr. Wellisch started afresh in this country, taking the Conjoint Diploma in 1941. He took up psychiatry, and acquired the D.P.M. of the English Royal Colleges in 1945. With the seriousness and enthusiasm so characteristic of him, he specialized in child psychiatry, and from 1947 to his death was in charge of the Crayford Child Guidance Clinic at Bexleyheath, Kent.

Dr. E. STENGEL writes: Dr. Wellisch was a hard worker who did not spare himself. He succeeded in combining clinical and research work. He undertook a series of investigations into the application of projection tests in child guidance, and his papers on the Rorschach test were notable contributions in a field full of controversy. Other publications dealt with eye manifestations in maladjusted children, follow-up investigations in child guidance work, and dreamy states. Only a few months before his death he completed a book entitled *Isaac and Oedipus*, in which

he analysed the ancient Hebrew legend of the sacrifice of Isaac side by side with the Greek tragedy. Dr. Wellisch was deeply interested in the philosophical foundations of psychiatry. Had he lived he would undoubtedly have added to his achievements as a clinician and scholar. The sympathy of his friends and colleagues goes out to his widow and his two children.

Dr. V. E. BADCOCK, one of the best known and most respected medical practitioners in rural north Northumberland, died at his home near Cornhill-on-Tweed on April 6 at the age of 69. Vincent Edgar Badcock had a distinguished career as a student at Durham University, where he graduated M.B., B.S. in 1906, proceeding to the M.D. three years later, when he was awarded a gold medal for his thesis. After graduation he held resident appointments at the Royal Victoria Infirmary, Newcastle-upon-Tyne, and for a time he was assistant demonstrator in anatomy in the university. In 1909 he became assistant to the late Dr. Alexander Dey, of Wooler, and in the following year succeeded to the practice of Dr. W. H. Shand at Flodden Lodge, near Cornhill, and entered into partnership with Dr. Dey. In the first world war Dr. Badcock joined the R.A.M.C. and served with distinction in France as a regimental medical officer, being awarded the Military Cross for conspicuous gallantry in attending to the wounded when he himself was severely wounded in the foot. He would not have his wounds attended to until everyone else had been treated, and as a result his condition became worse. After numerous operations his leg was amputated below the knee. He returned to his extensive practice in a scattered rural district and was regarded in very high esteem by countrymen in all grades of society. He was beloved and trusted by his patients, and his colleagues in the profession found in him an honourable and delightful friend. In 1921 he was elected chairman of the North Northumberland Division of the B.M.A.; he was also a member of the executive and ethical committee for a number of years, and a regular attendant at divisional meetings as long as his health permitted. During the last war he was chairman of the local medical war committee and took a special interest in the protection of practices scheme and in the arrangements for the medical attention of evacuees in the area. Dr. Badcock was a keen cricketer and played regularly for the Tillside club, of which he became chairman. In his later years he rarely missed being present at a match on the delightful ground at Etal near his home. He was a bachelor and is survived by two brothers and several nieces and nephews. One of his nephews, Dr. Alan Bousfield, had been in partnership with him for some years, and will carry on the practice at Flodden Lodge.—D. T. McD.

Dr. R. S. DE BRUYN, who was on the surgical staff of the Stamford and Rutland Hospital, died at Capetown, South Africa, on May 6 at the age of 56. Robert Saunders de Bruyn, who was born on July 14, 1897, served in the Royal Flying Corps in the first world war and was awarded the D.F.C. in 1919. Soon after demobilization he enrolled as a medical student at Guy's Hospital, qualifying M.R.C.S., L.R.C.P. in 1927, taking the diploma of L.D.S. of the Royal College of Surgeons of England in the same year. After qualification he held a number of appointments at Guy's Hospital before settling in practice at Stamford in 1932, the year in which he was admitted F.R.C.S.

We are indebted to Dr. E. C. TILL for the following appreciation: The untimely death of Robert Saunders de Bruyn on May 6 is a grievous and irreplaceable loss both to his colleagues and to the community he served so ably for 20 years. His stature in general surgery was such that he was most unfortunate in not securing a staff appointment at Guy's. After a period spent as surgical registrar and some months in the U.S.A., he joined a firm of general practitioners at Stamford as a surgical partner, and in 1932 came on to the staff of the Stamford and Rutland General Infirmary. It was typical of his wide interests in medicine that, until the rapidly expanding volume of his surgical work

made it impossible, he undertook and enjoyed a fair amount of general practice. During the last war he laboured for six years, virtually without any holiday or respite, and achieved a truly remarkable volume of major surgery at his hospitals at Stamford and Holbeach. After the commencement of the National Health Service, he relinquished his partnership and continued consultant appointments with the East Anglian and Sheffield Regional Hospital Boards. In July, 1953, after some weeks of increasing unfitness, he submitted to lengthy investigations which terminated in an abdominal operation. His death at Capetown occurred as the result of a relapse while on convalescent holiday. Much of his professional success lay in his judgment, which was rarely at fault. Strongly individualistic and endowed with a fine memory for faces and events, he had that rare quality of so shouldering his patients' burdens that all worry and tension vanished with his advent. His rich personality did not suffer fools gladly, and his lambent wit flickered impartially upon all and sundry according to their deserts. Essentially a man of simple tastes, he enjoyed good music, literature, and the arts. He bore the considerable travail of his long illness with great fortitude, much aided by the devoted care and encouragement of his wife, to whom we offer all our sympathy in her great loss.

Mr. W. E. SPRINGFORD, consulting surgeon to the Charing Cross Hospital unit at Mount Vernon Hospital, Northwood, died at his home at Northwood on May 18 at the age of 41. William Edmund Springford was born on November 29, 1912, and received his medical training at Charing Cross Hospital, graduating M.B., B.S. from London University in 1936 and winning the Governor's Clinical Gold Medal at the hospital in the same year. He obtained the F.R.C.S. in 1941, and in the following year he was awarded the J. H. Morgan Surgical Prize at Charing Cross Hospital. After graduation he held the appointment of house-surgeon at his own teaching hospital, later becoming resident surgical officer at the Chesterfield and North Derbyshire Royal Hospital and at the Kent and Sussex Hospital, Tunbridge Wells. On the outbreak of war in 1939, Mr. Springford, who was then in practice at Snaresbrook, entered the Emergency Medical Service and worked at Ashridge Hospital, Berkhamsted, until 1944, when he joined the R.A.M.C. as a lieutenant. Ill-health, however, compelled him to relinquish his commission in 1947, by which time he had attained the rank of major as a surgical specialist. Soon after his return to civilian life, Mr. Springford was appointed surgical specialist at Northwood, later becoming consulting surgeon to the Royal Masonic Institute for Girls.

T. D. L. writes: Mr. W. E. Springford was without doubt one of the nicest consultants we in this area have ever known. He was ever ready with good advice and never let a practitioner down. His good humour and charm delighted our patients, and these qualities, with his sound surgery, made us happy to consult him. Those of us who were privileged to observe the remarkable courage shown by him and by Mrs. Springford towards the end have had an object lesson in dignity and fortitude. To Mrs. Springford we extend our deepest sympathy. We shall miss him much.

Dr. C. H. R. PENTREATH, who was 81 years of age, died in hospital in Nairobi on May 19, four days after he had been savagely and senselessly attacked by Mau Mau terrorists. He left his home on May 15 to buy some cigarettes at a near-by inn, when he was bludgeoned by a terrorist in a country road near Nairobi, and left in a semi-conscious state on the roadway. Charles Henry Reginald Pentreath was born at Exmouth, Devon, on October 1, 1872, and was educated privately and at Cambridge University, where he took the Natural Sciences Tripos in 1892. Four years later he obtained the degrees of M.B., B.Chir., having received his clinical training at St. Mary's Hospital. He spent much of his professional life abroad. In 1900 he was resident medical officer at the Auckland General Hospital in New Zealand, and from 1902 to 1905 resident

medical superintendent at the Government Sanatorium at Cambridge, New Zealand. In 1911 he returned to England, and at the outbreak of war in 1914 was in a partnership at Maidenhead, where he was also surgeon to the local cottage hospital. He served in the R.A.M.C. from 1914 to 1916, and then went to live in Devonshire, where he was oculist to the Devon County Council. From 1918 to 1920 he was a medical adviser to the Ministry of Pensions. Soon after the end of the first world war he went abroad again, this time to Nairobi, where he was in practice as an ophthalmic specialist until 1947, when he retired.

Medical Notes in Parliament

Prescribing Cortisone and A.C.T.H.

Mr. A. BLENKINSOP (Newcastle-upon-Tyne, East, Lab.) asked the Minister of Health whether, under his regulations, cortisone and A.C.T.H. could be prescribed by doctors to their private patients. Mr. IAIN MACLEOD stated on May 20 that there were no regulations governing the prescription of these or any other drugs for the use of private patients. In the public interest he had limited the distribution of cortisone and A.C.T.H. to selected hospitals, from which they might be obtained for the treatment of private patients suffering from certain serious conditions.

Mr. BLENKINSOP said it was undesirable that patients should feel that they could get these things as private patients but might not be able to get them, at any rate from general practitioners, under the Health Service. Would he urge on doctors generally that these drugs should not be prescribed except in hospitals? Mr. MACLEOD said that distribution was limited to about 100 selected hospitals. The supply position was rapidly becoming a great deal easier, and it was hoped to extend the distribution very considerably. Obviously cortisone could not be denied to a patient merely because he happened to be in a private room and not in a ward.

Mr. T. WILLIAMS (Don Valley, Lab.): Before a general distribution of cortisone is made, will the Medical Research Council be consulted on how, by whom, and in what quantities it shall be prescribed? Mr. MACLEOD: Certainly. As cortisone becomes increasingly available this sort of problem will arise. We shall move in step with the Medical Research Council.

Dr. EDITH SUMMERSKILL (Fulham, West, Lab.) asked the Minister to make it clear that if a hospital doctor thought a Health Service patient would benefit from the drug he would be able to prescribe it. Mr. MACLEOD replied that he was not certain that he could give precisely that assurance yet, but the time was rapidly approaching when supplies would be fully adequate to fulfil all such purposes.

Chloramphenicol Treatment

Mr. IAIN MACLEOD told Dr. BARNET STROSS (Stoke-on-Trent, Central, Lab.) on May 20 that information was not available about the number of deaths resulting from treatment by chloramphenicol. Dr. STROSS asked whether it was fair to say that this powerful and most useful drug should only be used for children if other drugs were not available or would not do the work. Mr. MACLEOD replied that that was not a matter on which a layman should pronounce. Certainly considerable dangers were involved in the use of the drug, and there had been a number of deaths—most of them due to an overdose being given.

Trichinosis from Sausage Meat

Mrs. E. BRADDOCK (Liverpool, Exchange, Lab.) asked the Minister of Health if his attention had been drawn to the recent outbreak of trichinosis in Liverpool; and what action he had taken to make it fully known that this infection was caused by eating raw pork sausage meat. Mr. IAIN MACLEOD replied on May 20 that the medical officer of health of Liverpool reported a localized outbreak of trichinosis there

last November, and at the time warned the public through the local and national press not to eat uncooked pork or pork sausage meat. Only three small outbreaks in England and Wales, of which this was one, had been reported in the past seven years. No further action on his part was called for. He did not dissent from Mrs. Braddock's further point that, although there had been only a few localized outbreaks, the danger existed and people should be made aware of it. The danger, he said, was in eating raw sausage meat as if it were meat paste.

Sale of Calomel

Mr. S. SWINGLER (Newcastle-under-Lyme, Lab.) asked the Home Secretary if, in view of public anxiety caused by the recent deaths of infants attributed to the presence of calomel in teething powders administered to them, he would state the grounds on which the Poisons Board had advised him against controlling the sale of calomel and request the Board to reconsider the matter. Sir DAVID MAXWELL FYFE, replying on May 20, declined, pointing out that the proceedings of the Poisons Board, the advisory committee set up by the Pharmacy and Poisons Act, 1933, were confidential.

Practice Loans in Scotland

Miss M. HERBISON (Lanarkshire, North, Lab.) asked the Secretary of State for Scotland on May 18 how many applications had been received from practitioners for an interest-free loan to establish group practices; and from which districts in Scotland they had originated. Commander T. D. GALBRAITH, Under Secretary, informed her that applications had been received from 18 groups of doctors in Edinburgh, Glasgow, Ayrshire, Fife, Lanarkshire, the Lothians, and Stirlingshire. Miss HERBISON asked how soon a decision would be given; and whether, as so many applications had been received in such a short time, "the miserable £100,000" would be sufficient to meet them. Commander GALBRAITH said the applications would have to be gone into before it could be decided which groups should get the first sums available. It might take some little time before a final decision was made.

Old People in Mental Hospitals

Mrs. JEAN MANN (Coatbridge and Airdrie, Lab.) asked how far it was the practice, when there is a shortage of beds in general hospitals, for old persons to be given accommodation in mental hospitals; and to what extent they were required to be certified, on refusing, in these circumstances, to enter voluntarily. Commander T. D. GALBRAITH said the Secretary of State was not aware of any such practice. Some forms of senile mental illness could be cared for properly only in a mental hospital; and where admission as a voluntary patient was not accepted, certification might be the only way of securing that the patient got the care and treatment needed. Mrs. MANN said there was widespread belief in industrial areas that old people were being put into mental hospitals because there were insufficient beds in general hospitals, and that when the old people protested and did not go voluntarily they were certified. Commander GALBRAITH said that if she would give him details he would look into them.

Mrs. MANN also asked if it was now permissible under regulations to certify elderly patients entering mental institutions as suffering from mental senility; and how far deviation from the words laid down by statute was permitted. Commander GALBRAITH stated that the conditions to be met before a person could be certified were laid down by statute, as also were the terms in which the relative certificates must be given. There was no power to permit any deviation, such as that suggested, from the terms and conditions laid down by statute.

Pay-beds in Scotland

Commander GALBRAITH stated in answer to Mr. W. HANNAN (Glasgow, Maryhill, Lab.) that during the year ended March 31, 1953, on an average less than a quarter of the pay-beds in Scottish Health Service hospitals were unoccupied. There were 913 such beds, or 1½% of all staffed

beds. The percentage occupancy of these beds was about 75, compared with 83½ for all the beds in hospitals. This was considered to be quite a high percentage.

Mau Mau Psychology

Mr. C. ALPORT (Colchester, Con.) asked the Secretary of State for the Colonies on May 19 whether the Government would appoint a technical group to inquire into the anthropological and psychological aspects of the Mau Mau outbreak. Mr. H. HOPKINSON, the Minister of State, replied that in February the Kenya Government invited Dr. J. C. Carothers, a psychiatrist with a number of years' experience in Kenya, to carry out a special investigation into the psychology of Mau Mau. He completed his report last month. Until this had been examined he could not say what further steps would be required.

M.P.'s Salaries

On May 24 Members of Parliament voted by 280 votes to 166 to raise their salary from £1,000 to £1,500 a year. This is two and a half times the 1939 salary of £600, and one and a half times the 1946 salary of £1,000.

Hospital Appointments Advertising.—Replying to Dr. A. D. D. BROUGHTON on the cost to the National Health Service for advertising to invite applications from medically qualified men and women for hospital appointments, Mr. IAIN MACLEOD said that complete information was not available, but the expenditure of all regional hospital boards and hospital management committees in England and Wales, and half the boards of governors, during the year ending March 31, 1953, was £191,000.

Birmingham Patients Waiting.—The Minister of Health has informed Mr. S. T. SWINGLER (Newcastle-under-Lyme, Lab.) that at the end of March there were 4,512 patients awaiting admission for gynaecological treatment at hospitals in the Birmingham region.

School Medical Service.—The Prime Minister, answering a question by Miss IRENE WARD (Tynemouth, Con.), said he was advised that it would not be desirable at present to transfer responsibility for the school medical service to the Minister of Health.

Stride Knee-joint Experiments.—Mr. IAIN MACLEOD has informed Lieutenant-Colonel M. LIPTON (Brixton, Lab.) that experimental tests of six Stride knee-joints were in progress, but no final decision had been reached. Experiments had been going on for just over a year.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

Dr. E. D. ADRIAN, O.M., P.R.S., Master of Trinity College, has been appointed a manager of the E. G. Fearnside Fund until December 31, 1956, and a governor of the Darwin Trust until July 30, 1958.

The following reappointments are announced: Dr. F. G. J. Hayhoe as University Lecturer in the Department of Medicine from March 1, 1954, to the retiring age; Dr. J. R. Robinson as an Assistant Director of Research in the Department of Experimental Medicine from October 1, 1954, for five years; Dr. W. A. Fell as an Associate Lecturer in Physical Medicine in the Department of Medicine from April 1, 1954, to the retiring age or for so long as he remains a consultant in physical medicine to the United Cambridge Hospitals, whichever period is the shorter.

Mr. J. H. Daggart has been appointed representative of the University at the seventeenth International Congress of Ophthalmology to be held at Montreal and New York in September, 1954.

Dr. G. H. Wright has been reappointed University Lecturer in the Department of Anatomy, and Dr. G. R. E. Naylor University Lecturer in the Department of Pathology, both with tenure from October 1, 1954, to the retiring age. Dr. P. A. G. Monro has been reappointed University Demonstrator in the Department of Anatomy, and Dr. T. S. L. Beswick University Demonstrator in the Department of Pathology, both with tenure from October 1, 1954, for two years.

Dr. Raymond Williamson has been appointed representative of the University at the International Congress on the History of Medicine to be held in Italy in September, 1954.

Dr. S. D. Elliott has been appointed an Assistant Director of Research in the Department of Animal Pathology with tenure from July 1, 1954, for five years.

Dr. J. A. Hislop has been elected to an Elmore Medical Research Studentship from January 1, 1954.

In Congregation on January 23 the following degrees were conferred:

M.D.—W. M. Keynes, O. H. Wolff, W. H. Simonds, B. Schofield.

M.B., B.CHIR.—H. H. Shawdon, *L. Wilkinson, D. E. Corlett, R. H. Morgan, H. J. Wood, R. D. France, *C. P. D. Tong, *H. Eaton, F. McP. Low, *Ee Keng Lee.

M.B.—*J. D. Avison, D. K. Robinson, *G. P. Vaughan, R. C. Benians, G. N. Penlington, *H. M. Buckland, C. W. M. Cooper, *I. M. Allison, *L. R. L. Burton, *J. G. Pritchard, *G. A. Reed, *G. McC. Grandsen, *B. I. F. Eminson, *S. R. Laing, M. J. Purves, *E. S. Reed, *F. S. Cozens, *J. L. Tasker, M. C. G. Mantell, R. E. Williams, Mrs. Jane F. Mackworth, *E. Moran, *L. Weiss.

In Congregation on February 5 the following degrees were conferred:

M.D.—J. F. P. Skrimshire.

M.B., B.CHIR.—*A. M. Hammerton-Fraser, *D. W. Bentinck, M.B.—*I. Oswald, J. R. T. Finlayson.

In Congregation on March 20 the following degrees were conferred:

M.CHIR.—*J. F. Bolton Carter, *A. G. Dingley, A. Standeven, M.B., B.CHIR.—*A. J. Danby.

M.B.—A. D. Thursz.

*By proxy.

The following candidates have been approved at the examinations indicated:

FINAL M.B.—Part II (*Principles and Practice of Physic, Surgery, Midwifery and Gynaecology*) (the figures indicate the section or sections passed): *I. M. Allison, *J. D. Avison, *S. G. Bayliss, *R. C. Benians, *G. F. B. Birdwood, *R. J. Blow, *J. A. D. Briggs, *L. F. Brunt, *H. M. Buckland, *G. L. Buntton, *D. C. L'E. Burges, *L. R. L. Burton, *D. J. Buttery, *W. H. Carling, *Mrs. A. Clarke, *D. M. T. Cones, *C. W. M. Cooper, *D. E. Corlett, *P. S. Cozens, *J. L. Crammer, *J. Crook, *Mrs. E. J. P. Davies, *M. W. L. Davis, *A. E. L. de Thierry, *J. P. Dickson, *D. G. Dingle, *P. M. Dunn, *H. Eaton, *Mrs. E. A. Eldon, *B. I. F. Eminson, *J. P. English, *J. Gibbs, *P. Gortval, *Mrs. M. H. P. Gregory, *A. M. Hammerton-Fraser, *J. W. Harding, *M. E. Hern, *F. Heyes, *G. H. Hilton, *B. Holt, *M. Horowitz, *L. H. Hurrell, *H. Jacobs, *P. O. Jones, *F. E. Kenyon, *R. J. Knight, *S. R. Laing, *R. C. Lawson, *E. K. Lee, *S. P. Lock, *F. M. Low, *C. M. McGregor, *R. F. McKnight, *Mrs. J. F. Mackworth, *J. R. McNeill, *M. C. G. Mantell, *H. C. Masheter, *G. F. Mayall, *J. S. Miller, *E. J. Mitchell, *M. T. Moore, *E. Moran, *R. H. Morgan, *N. H. Moynihan, *J. C. Newell Price, *I. Oswald, *C. J. Pattinson, *A. B. L. Peake, *J. G. Pritchard, *M. J. Purves, *E. S. Reed, *G. A. Reed, *D. K. Robinson, *J. O. Robinson, *Mrs. L. M. Rochelle, *J. D. Salmon, *J. R. Scott, *H. H. Shawdon, *P. T. Smith, *J. K. Snell, *G. P. Starck, *G. Tait, *J. L. Tasker, *A. D. Thursz, *S. A. Tillyard, *C. P. D. Tong, *D. E. Tunnadine, *G. P. Vaughan, *J. D. S. Vernon, *J. A. A. S. Webber, *J. H. H. Webster, *I. Weiss, *P. D. W. Wickenden, *L. Wilkinson, *R. E. Williams, *R. V. F. Williams, *W. D. W. Williams, *W. A. Williamson, *H. J. Wood, *J. R. Wood, *S. M. Worrall.

Part I (*Pathology and Pharmacology*): D. P. Addy, R. W. Ainsworth, I. R. Aldous, D. L. Almond, J. Anderson, P. C. Anderson, P. C. W. Anderson, W. Atherton, D. W. Atkinson, J. Bamforth, R. B. Bennet, D. W. Bentinck, G. D. Blackledge, J. R. Blatch, J. W. Blaxill, L. H. Blonstein, J. N. Bodger, A. Bracewell, J. P. Brady, P. Brine, M. E. Budleigh, G. L. Buntton, E. Burkinshaw, P. J. Burrows, N. R. Burt, J. R. Burwell, S. T. G. Butterworth, P. G. T. Bye, D. H. Cameron, W. H. Carling, G. G. Carmichael, R. A. Carpenter, R. A. Carter, S. B. Carter, T. D. Carter, J. D. Chard, E. B. Clayton, T. R. Clendon, J. R. Cobbett, W. L. Cordeaux, M. Cornelius, I. J. Cour-Palais, E. E. Denman, P. A. Dinkel, B. H. S. Dixon, W. D. Dolton, H. Dovey, P. A. Eckstein, J. D. Fitzsimons, R. D. France, A. M. Freeman, J. S. Garfield, F. E. Garrad, E. F. D. Gawne, A. E. Gibbs, A. E. R. Gibbs, R. K. Gilbert, G. McC. Grandsen, C. M. B. Grigson, J. N. Harcourt, B. Holt, J. H. C. Hunt, L. H. Hurrell, R. D. Hyde, R. B. Jenkins, F. L. Johnstone, D. H. Jones, P. J. D. Kirk, W. G. R. M.

Laurie, E. P. Lawrence, J. A. S. Lees, M. J. Littlewood, I. V. Longfield, R. D. Lowe, R. S. McKim, I. E. McLaren, S. M. Madeloff, R. Malley, J. W. Maltby, P. B. C. Matthews, K. L. G. Mills, C. J. Moore, C. B. Mortimer, J. F. Mowbray, M. T. C. Mower, M. A. Newland, W. S. Ogden, A. M. Parfitt, R. W. Payne, R. J. C. Pearson, G. N. Penlington, M. R. K. Plaxton, A. Pollard, D. J. H. Prosser, M. J. Purves, J. C. L. Rawes, J. N. Rea, E. Redfearn, S. E. Reed, D. J. Roberts, I. R. Robertson, A. Robinson, B. H. B. Robinson, I. Ross Russell, A. O. Russell, J. R. Scott, G. G. Scott-Brown, R. O. Selby, P. R. Shires, R. G. D. Small, G. C. Spackman, J. A. Stamford, L. M. Stauffer, R. M. Stirland, F. Summers, E. I. Tanner, G. J. M. Thompson, J. E. Trapnell, J. C. S. Turner, A. S. Valentine, I. H. M. Veitch, J. F. Walker, C. A. M. Walkley, R. S. Wardle, N. A. Waring, J. R. C. Weatherly, D. N. Whitmore, B. M. Wild, J. C. Willan, J. T. N. Williams, R. E. Williams, W. A. Williamson, J. F. Wood, B. Woods.

M.CHIR.—J. W. Bolton Carter, A. G. Dingley, A. Standeven, J. S. W. Whitehead.

The following degrees were conferred on February 20:

M.D.—D. Ainslie, R. J. Harrison, P. H. Mitchell, A. L. Furniss.

M.B.—P. T. Smith (by proxy), C. J. Pattinson, S. M. Worrall.

UNIVERSITY OF LONDON

Dr. J. P. Collard has been elected and Dr. A. Talbot Rogers re-elected as two of the representatives of the Faculty of Medicine on the Standing Committee of Convocation for three years from January 9, 1954.

Professor J. M. Mackintosh has been nominated for re-appointment as representative of the University on the governing body of the Slough Industrial Health Service.

Mr. J. M. Pullan has been recognized as a teacher of surgery in the University at St. Thomas's Hospital Medical School.

UNIVERSITY OF MANCHESTER

The Council of the University has approved the following changes in status of members of the staff, to take effect, except where otherwise indicated in parentheses, from September 30, 1954: *To be Reader in the subjects named:* Surgery, Mr. R. P. Jepson; *Social Medicine*, Dr. R. F. L. Logan (from March 1, 1954). *To be Senior Lecturer in the subject named:* Ophthalmology, Dr. Alan Stanworth (from a date to be approved). *To be Lecturers in the subjects named:* Pathology, Dr. J. C. Burne, Dr. G. E. Paget, Dr. J. P. Smith; *Neuropathology*, Dr. P. O. Yates (from October, 1953). *To be Assistant Lecturers in the subject named:* Pathology, Dr. H. de C. Baker, Dr. B. L. Williams.

The following candidates have been approved at the examination indicated:

DIPLOMA IN PSYCHOLOGICAL MEDICINE.—Part II: D. L. Fox, K. Rawnsley.

UNIVERSITY OF LIVERPOOL

The degree of Ph.D. in the Faculty of Medicine has been granted to T. G. Richards, M.D.

The following diplomas have been awarded:

D.M.R.(D).—Part I: H. J. J. Beyleveld, A. Bhattacharya, H. E. Jones, J. P. Murray, I. P. Smyth.

D.M.R.(T).—Part I: B. Roy.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW

At a meeting of the Faculty held on March 1, with Dr. Andrew Allison, President, in the chair, N. Radhakrishnan was admitted a Fellow of Faculty *qua* physician; on May 3 S. G. McAlpine was also admitted a fellow of Faculty *qua* Physician.

ROYAL COLLEGE OF SURGEONS IN IRELAND

On April 2 the Fellowship of the College was conferred on D. F. Doherty, J. Kyle, J. G. Maher.

The following diplomas have been awarded:

D.C.H.—B. P. K. Ryan, J. B. Shea.

D.O.M.S.—R. E. Tingey.

D.P.M.—E. Casement, A. C. Fleming, J. P. F. Fogarty, P. J. Meehan, D. C. Hutchison, K. A. McDaid, R. R. Steinert.

ROYAL COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS

At a meeting of the Council of the College held on January 30, with the President, Mr. Arthur A. Gemmell, in the

chair, the following were elected to the Membership: G. T. D. Barr, D. J. Cassidy, Vivienne A. Croxford, H. F. Daghistany, P. J. Dwyer, A. L. T. Easton, D. W. S. Gordon, T. P. Grant, J. Greenwell, K. Greig, R. W. Hughes, G. A. Humphreys, P. D. C. Jackson, K. B. Layton, C. V. Love, A. C. McNelis, P. Manolis, M. Mukerji, F. A. Murray, R. F. O'Donoghue, G. D. Pinker, D. E. Savage, S. G. Singh, H. J. Tighe, J. R. D. Tomlinson, A. C. Turnbull, R. Vaish, P. S. Watson, V. T. White.

CONJOINT BOARD IN SCOTLAND

The following candidates, having passed the final examinations, have been granted the diploma of L.C.R.P.Ed., L.R.C.S.Ed., L.R.F.P.&S.G.: H. C. Carver, T. K. Chetty, J. B. Collinson, P. T. Huppert, G. C. H. Knight, A. B. Masters, E. P. McKay, J. M. Nichols, A. I. Y. Orr, M. P. Pather, A. Pribyl, Katalin E. Schopflin, F. Shoucair, S. A. Singh, V. Vahala, J. Vitolsins.

FACULTY OF RADIOLOGISTS

At the examination for the Fellowship of the Faculty held in November, 1953, the following satisfied the examiners:—*Radiology*: F. M. Benton, D. M. T. Cones, G. M. King, W. D. Rider; *Radiodiagnosis*: K. E. Jefferson, K. A. Rowley, P. W. E. Sheldon.

Vital Statistics

Week Ending May 15

The notifications of infectious diseases in England and Wales during the week included pneumonia 463, scarlet fever 898, whooping-cough 2,660, diphtheria 9, measles 1,706, dysentery 1,031, acute poliomyelitis 19, paratyphoid fever 7, and typhoid fever 3.

Infectious Diseases

Increases in the number of notifications of infectious diseases in England and Wales during the week ending May 8 included 189 for dysentery, from 759 to 948, 148 for whooping-cough, from 2,233 to 2,381, and 96 for scarlet fever from 623 to 719, while the only decrease of any size was 236 for measles, from 1,970 to 1,734.

The 9 cases of diphtheria notified were 3 fewer than in the preceding week and the smallest number ever recorded. 4 of the 9 cases were notified in Liverpool C.B. The largest variation in the local trends of scarlet fever was a rise of 31 in Yorkshire West Riding, from 44 to 75. The largest fluctuations in the returns of whooping-cough were a rise of 53 in Kent, from 149 to 202, and a fall of 47 in Warwickshire, from 169 to 122. The only large decline in the incidence of measles was 144 in Norfolk, from 326 to 182. The number of notifications of paratyphoid fever rose from 3 to 13.

23 cases of acute poliomyelitis were notified during the week; these were the same for paralytic and 3 more for non-paralytic cases than in the preceding week. Two cases were notified in Leeds C.B., Sunderland C.B., and Lancaster M.B.

The largest rise in the notifications of dysentery was 119 in Lancashire. The largest returns were Lancashire 262 (Denton U.D. 54, Swinton and Pendlebury M.B. 31, Liverpool C.B. 23, Irlam U.D. 23, Manchester C.B. 19, Salford C.B. 13, Golborne U.D. 12, Blackpool C.B. 10, Bolton C.B. 10), Yorkshire West Riding 118 (Dewsbury C.B. 45, Bradford C.B. 13, Sheffield C.B. 10), London 107 (Islington 42, Lewisham 12, Hampstead 11), Middlesex 57 (Tottenham M.B. 22), Leicestershire 47 (Leicester C.B. 40), Kent 30 (Sevenoaks R.D. 25), Essex 29, Nottinghamshire 28 (Nottingham C.B. 21), Sussex 26 (Brighton C.B. 11), Cheshire 25 (Stalybridge M.B. 13), Warwickshire 25 (Birmingham C.B. 23), Glamorganshire 24 (Llchwyr U.D. 14), and Surrey 23.

In Scotland the number of notifications of dysentery increased by 31, from 280 to 311. The rise was due to the outbreak in Glasgow, where the cases rose from 178 to 220.

Graphs of Infectious Diseases

The graphs below show the uncorrected numbers of cases of certain diseases notified weekly in England and Wales. Highest and lowest figures reported in each week during the nine years 1945-53 are shown thus -----, the figures for 1954 thus ————. Except for the curves showing notifications in 1954, the graphs were prepared at the Department of Medical Statistics and Epidemiology, London School of Hygiene and Tropical Medicine.

INFECTIOUS DISEASES AND VITAL STATISTICS

Summary for British Isles for week ending May 8 (No. 18) and corresponding week 1953.

Figures of cases are for the countries shown and London administrative county. Figures of deaths and births are for the 160 great towns in England and Wales (London included), London administrative county, the 17 principal towns in Scotland, the 10 principal towns in Northern Ireland, and the 14 principal towns in Eire.

A blank space denotes disease not notifiable or no return available. The table is based on information supplied by the Registrars-General of England and Wales, Scotland, N. Ireland, and Eire, the Ministry of Health and Local Government of N. Ireland, and the Department of Health of Eire.

* Measles not notifiable in Scotland, whence returns are approximate.
† Includes primary and influenzal pneumonia.
‡ Includes puerperal pyrexia.

Medical News

Royal College of Surgeons.—At a meeting of the council on May 20, with Sir Cecil Wakeley, P.R.C.S., in the chair, Professor Arthur Steindler (Iowa City, U.S.A.) and Dr. G. Gavin Miller (Montreal) were admitted honorary Fellows, and Mr. J. W. H. Grice, Professor G. Hadfield, Professor J. Trueta, and Mr. W. A. Jackman were elected Fellows. The following prizes and awards were given: *Jacksonian Prize*: Mr. J. H. Peacock (Bristol). *John Tomes Prize*: Professor M. A. Rushton (Guy's). *Moynihan Lectureship*: Professor L. Deloyers (Brussels) and Professor Neils Dungal (Iceland). *Joseph Henry Lectureship*: Dr. R. A. M. Case (London). *Imperial Cancer Research Fund Lectureships*: Dr. J. Bamforth and Dr. E. F. Scowen (St. Bartholomew's). *Begley Prize*: Maurice A. Cowan (Sheffield). Mr. R. S. Handley (Middlesex) was elected and Mr. G. Qvist (Royal Free) re-elected members of the Court of Examiners for a period of three years.

The monthly dinner of the Royal College of Surgeons on May 19 was the first to be held in the new Great Hall, a graceful room in the building risen from the debris of war ruins. Many of the College's Fellows have given the chairs that furnish the hall. Their names appear on the backs of them, and as the President, Sir Cecil Wakeley, said, all the great names in British surgery are inscribed there. Sir Cecil welcomed the guests, and in particular Sir Bernard and Lady Dawson from New Zealand. In reply Sir Bernard said he had often wondered what were the components of the force that pulled them back to London from overseas, and he found part of the answer in this kind of occasion, in the opportunity it gave of meeting their colleagues again. Mr. Geoffrey Keynes, recently appointed the first honorary curator of the College's pictures, then gave a short discourse on them illustrated by lantern slides. Chiefly portraits, they were intimately bound up with the history of the College. The most famous of them, ascribed to Holbein, showed Henry VIII giving the Act of Union to the barbers and surgeons. The College had paid 50 guineas for it in 1786. The portrait of John Hunter in old age, by Reynolds, was now said to be a sombre ghost of what it had been, owing to Reynolds's practice of mixing bitumen with his paint. It had yet been declared by Sir Gerald Kelly, P.R.A., to be the best portrait in England. Mr. Keynes ended by showing some slides of paintings from the Hunter collection depicting abnormal human beings and exotic animals.

Mosquito Control.—A full account is given of the habits and distribution of British species of mosquitoes and of the best measures of controlling them in the revised *Memorandum on Measures for the Control of Mosquito Nuisances in Great Britain* (H.M.S.O., 1s. 3d.). The revision is by Sir Gordon Covell and Mr. P. G. Shute. *Anopheles atroparvus* is believed to be the only species responsible in Britain for indigenous malaria. It is largely confined to the coastal areas in east and south-east England, whence nearly all indigenous cases have been reported.

Parke, Davis & Co.'s new research and administration building at Hounslow was opened on May 20 by the Mayor of Heston and Isleworth in the presence of many distinguished guests representing the medical profession, the pharmaceutical industry, and the Ministry of Health.

"Family Doctor."—The June issue of *Family Doctor* presents its readers with a separate "Summer Beauty Book" as well as articles on such diverse topics as the psychology of war (by Dr. J. R. Rees), diabetes (by Dr. R. D. Lawrence), and travel sickness (by Dr. Alan Porter). Some of the many problems that mothers experience in rearing their children are also discussed and neatly solved.

Changing Trends in the Chest Service.—In a lecture recently given at the Royal Institute of Public Health and Hygiene Dr. Philip Ellman gave some interesting figures

showing how the work of tuberculosis dispensaries had changed over the course of the past 20 years or so. As long ago as 1929 he had succeeded in changing the title of the East Ham Tuberculosis Dispensary to "Chest Clinic" because of the opprobrium connected with the former term in the mind of the public. The total attendances had risen from 2,398 in 1928 to 27,521 in 1953, while the proportion of those found tuberculous had fallen from 28.5% in the former year to 5.8% in the latter. The majority of the other 94.2% of the patients were found to be free from disease, and among the remainder were cases of almost every other disease in general medicine, including every type of acute or chronic inflammatory lung disorder, new growths, especially carcinoma of the lung in males, and heart disease. Dr. Ellman's figures underlined his warning against any tendency to develop the tuberculosis service on narrow lines of specialization: prevention, diagnosis, treatment, and after-care must be considered as a continuous process. The chest clinic, situated within the parent hospital, should be itself one department of a whole chest service.

Oxford Graduates' Medical Club.—Founded in 1884 with the object of maintaining associations with the University and promoting good fellowship among members, the club has now extended membership to lady graduates. The life subscription is one guinea. The club dines twice a year, and the summer dinner will be held on July 2 at 7 p.m. in Oriel College, Oxford, with Mr. Ogier Ward in the chair. Guests may be invited. Tickets at 32s. 6d. may be obtained before June 26 from Mr. Selwyn Taylor, 3, Roedean Crescent, Roehampton, London, S.W.15.

B.M.A. Scholarships.—The following research scholarships have been awarded by the B.M.A. for 1954-5: Ernest Hart Memorial Scholarship (£250) to Dr. R. M. Acheson for research into radiological methods in tuberculous meningitis, to be carried out at the Radcliffe Infirmary, Oxford. Walter Dixon Memorial Scholarship (£250) to Mr. G. W. Taylor for research into lymphoedema, at St. Bartholomew's Hospital. Ordinary Research Scholarship (£200) to Dr. I. J. MacQueen, of Sheffield University, for research into radiological methods in tuberculous progressive resistance exercise.

Leverhulme Award.—A Leverhulme research grant has been made to Mr. S. G. Browne, a medical missionary in the Belgian Congo, for the training of medical auxiliaries there.

R.A.M.C. Dinner.—The medical officers of the 56 (London) Armoured Division (T.A.) held their first annual dinner at the Naval and Military Club on May 18. The A.D.M.S., Colonel J. A. Dudgeon, was in the chair, and Brigadier A. L. Crockford, honorary colonel, was also present. Among the principal guests who attended were Major-General D. Dawnay, Major-General B. C. H. Kimmins, Major-General A. Sachs, Colonel Walter Mourmand, Jr. (American Medical Services), Dr. S. Morley, Master of the Apothecaries, and Mr. Ronald Champness, of the Worshipful Company of Spectacle Makers.

Sheffield University.—Mr. R. P. Jepson has been appointed to the chair of surgery in succession to Professor R. St. Leger Brockman. Dr. J. M. Thoday is appointed from October 1 head of a new department of genetics.

Royal College of Obstetricians and Gynaecologists.—At a meeting of the council on May 22, with Mr. A. A. Gemmell, P.R.C.O.G., in the chair, the following were elected to the council:—*Representatives of Fellows*: Professor H. H. Evers, Newcastle-upon-Tyne; Professor C. H. G. Macafee, Belfast; Mr. T. N. MacGregor, Edinburgh; Professor W. C. W. Nixon, London. *Representative of Members*: Mr. I. McG. Jackson, London; Mr. R. Murdoch, Glasgow; Dr. J. Walker, Aberdeen.

Welsh Anaesthetists.—The Society of Anaesthetists of South Wales on April 9 elected the following officers for the year:—*President*: Dr. D. S. Jones. *Vice-president*: Mr. F. Y. Pearson. *Treasurer*: Dr. D. K. W. Picken. *Secretary*: Dr. H. G. Middleton.

Royal Sanitary Institute.—At the annual general meeting on May 18 Dr. A. Scott, M.O.H. of London County Council, and Dr. J. W. Starkey, M.O.H. of Kingston-on-Thames, were re-elected to the council of the Institute.

COMING EVENTS

Contraceptive Technique.—A lecture and demonstration will be given by Dr. Marie Stopes at the Mothers' Clinic, 108, Whitfield Street, London, W.1, on June 3, at 2.30 p.m. Tickets must be obtained in advance.

Leprosy.—An exhibition on leprosy by Dr. R. G. Cochrane will be shown at the Institute of Dermatology on June 7-26.

Brussels Meeting.—A medical conference will be held in Brussels on June 11-15 under the presidency of Professor Pol Gérard. Themes to be discussed include the treatment of pulmonary tuberculosis, liver diseases, and virus diseases. Excursions and other entertainments are offered. Full details from Secrétariat Général, Rue Belliard, 141, Brussels.

Industrial Health.—Dr. M. W. Goldblatt will give the Mackenzie Industrial Health Lecture, entitled "Research in Industrial Health in the Chemical Industry," on July 19 at 2.30 p.m. in the library theatre, Manchester, with Dr. J. A. L. Vaughan Jones in the chair. This is a biennial lecture, organized by the B.M.A. in memory of Mr. James Mackenzie, the founder of the Industrial Health Education Society.

NEW ISSUES

Journal of Neurology, Neurosurgery, and Psychiatry.—The new issue (Vol. 17, No. 2) will be available in a week's time. The contents include:

MENINGIOMAS WITHIN THE LATERAL VENTRICLE. A. E. Wall.
ISCHAEMIC SENSORY LOSS IN PATIENTS WITH PERIPHERAL NERVE LESIONS. R. W. Gilliat and T. Graham Wilson.
MEMORY DISTURBANCES IN THIRD VENTRICLE TUMOURS. Moyra Williams and Joe Pennybacker.
VARIATIONS IN THE NUMBER OF ACTIVE PALMAR DIGITAL SWEAT GLANDS WITH AGE. Pamela C. B. MacKinnon.
PHOSPHATE ESTERS IN MYOTONIC HUMAN MUSCLE. P. C. Caldwell and T. A. J. Frankard.
A RARE PRE-SENILE DEMENTIA ASSOCIATED WITH CORTICAL BLINDNESS (HEIDENHAIN'S SYNDROME). A. Meyer, Denis Leigh, and C. E. Bagg.
TWO CASES OF CONGENITAL ATRESIA OF THE FORAMINA OF MAGENDIE AND LUSCHKA. A. F. J. Maloney.
AUTONOMIC CHANGES FOLLOWING UNILATERAL LEUCOTOMY. Alick Elithorn, Malcolm F. Percy, and Margaret A. Crosskey.
A COMPARISON OF ISONIAZID WITH MODIFIED INSULIN THERAPY IN NEUROTIC STATES. Maurice Silverman.
RAPIDLY PROGRESSIVE CEREBRAL DEGENERATION WITH MENTAL DISORDER, FOCAL DISTURBANCES, AND MYOCLONIC EPILEPSY. D. P. Jones and S. Nevill.
BOOK REVIEWS.

Issued quarterly; annual subscription £2 2s.; single copy 12s. 6d.; obtainable from the Publishing Manager, B.M.A. House, Tavistock Square, London, W.C.1.

Journal of Clinical Pathology.—The new issue (Vol. 7, No. 2) is now available. The contents include:

THE USE AND LIMITATIONS OF FILTER-PAPER ELECTROPHORESIS. N. H. Martin and G. T. Franglen.
THE ESTIMATION OF γ -GLOBULIN. George Discombe, Raymond F. Jones, and D. P. Winstanley.
SIMPLIFIED ESTIMATION OF CALCIUM IN BIOLOGICAL MATERIALS BY FLAME PHOTOMETRY. J. G. Liawado.
A STUDY OF THE BLOOD PYRUVIC ACID LEVEL IN PATIENTS WITH CONGESTIVE HEART FAILURE. J. Kleeberg and S. Gitelson.
MALIGNANT CELLS IN CEREBROSPINAL FLUID. Arthur I. Spriggs.
A CASE OF ANOREXIA NERVOSA WITH NECKROPSY FINDINGS AND A DISCUSSION OF SECONDARY HYPOPITUITARISM. R. R. Wilson.
THE STRUCTURAL FEATURES OF EPILEPSIA WITH SPECIAL REFERENCE TO ENDOCARDIAL FIBROELASTOSIS. L. Crome.
CEREBRAL MUCORMYCOSIS. F. Kuttel.
FURTHER EXPERIENCE WITH THE MALE-TOAD PREGNANCY TEST USING EUROPEAN SPECIES. Magnus Haines, H. P. Ferreira, J. W. Law, and Audrey May.
A STRAIN OF STAPHYLOCOCCUS RESISTANT TO FIVE ANTIBIOTICS. Kevin Anderson.
A NOTE ON THE SEROLOGY OF SARCOSPORIDIOSIS AND TOXOPLASMOSIS. F. I. Awad and R. Lainson.
STREPTOMYCIN-DEPENDENT VARIANTS OF BACT. COLI ISOLATED FROM PATIENTS DURING TREATMENT WITH STREPTOMYCIN. Aksel Stenderup.
THE USE OF A BILE-ASCULIN MEDIUM AND OF MAXTED'S TECHNIQUE OF LANCEFIELD GROUPING IN THE IDENTIFICATION OF ENTEROCOCCI (GROUP D STREPTOCOCCI). Alexander Swan.
THE ERYTHROCYTE SEDIMENTATION RATE AND THE PLASMA VISCOSITY. Robert D. Eastham.
ASSOCIATION OF CLINICAL PATHOLOGISTS: 52ND GENERAL MEETING.

Issued quarterly; annual subscription £2 2s.; single copy 12s. 6d.; obtainable from the Publishing Manager, B.M.A. House, Tavistock Square, London, W.C.1.

SOCIETIES AND LECTURES

A fee is charged or a ticket is required for attending lectures marked ●. Applications should be made first to the institution concerned.

Monday, May 31

EDINBURGH UNIVERSITY.—At Physiology Class Room, University New Buildings, 5 p.m., Dr. D. J. Guthrie: Primitive Medicine and its Influence.

EDINBURGH UNIVERSITY: FACULTY OF MEDICINE.—At Obstetrics Lecture Theatre, 60, George Square, 5 p.m., MacArthur Postgraduate Lecture by Professor Bruce Mayes (Sydney): Experiences in the Management of Pregnancy Toxaemia in Sydney.

INSTITUTE OF CARDIOLOGY.—9.30 a.m., Sir John Parkinson: Palpitation.

●INSTITUTE OF OBSTETRICS AND GYNAECOLOGY.—At Hammersmith Hospital, 3 p.m., Professor J. Louw (Capetown): Eclampsia.

INSTITUTE OF PSYCHIATRY.—5.30 p.m., lecture-demonstration by Dr. E. Stengel.

POSTGRADUATE MEDICAL SCHOOL OF LONDON.—4 p.m., Dr. O. G. Edholm: Effects of Environment in Man.

ROYAL EYE HOSPITAL.—5.45 p.m., Miss J. M. Dollar: Films on Operative Surgery (2).

Tuesday, June 1

EDINBURGH UNIVERSITY: FACULTY OF MEDICINE.—At Anatomy Lecture Theatre, University New Buildings, 5 p.m., MacArthur Postgraduate Lecture by Dr. J. W. Clegg: Surgical Pathology of Pulmonary Tuberculosis.

INSTITUTE OF DERMATOLOGY.—5.30 p.m., Dr. P. D. Samman: Reticuloses.

●INSTITUTE OF NEUROLOGY.—5.30 p.m., Dr. R. N. Ironside: Arteritis.

ORPINGTON HOSPITAL.—4 p.m., Dr. P. L. Mollison: Blood Transfusion: Indications and Contraindications.

WRIGHT-FLEMING INSTITUTE OF MICROBIOLOGY.—5 p.m., Almoth Wright Lecture by Professor H. B. Maitland: Histamine-sensitizing Property of *E. pertussis*.

Wednesday, June 2

INSTITUTE OF DERMATOLOGY.—5.30 p.m., Dr. H. Haber: Necrobioses and Erythema Elevatum Diutinum.

●INSTITUTE OF OBSTETRICS AND GYNAECOLOGY.—At Queen Charlotte's Hospital, 12 noon, Professor J. Louw (Capetown): Rupture of the Uterus.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m., Arvik and Gale Lecture by Professor David Slome: Physiological Studies on the Nasal Circulation.

Thursday, June 3

EDINBURGH UNIVERSITY.—At Physiology Class Room, University New Buildings, 5 p.m., Dr. D. J. Guthrie: The Hippocratic School: The Apprenticeship Idea.

●FOOD EDUCATION SOCIETY.—At 16, Berkeley Street, W., 3 p.m., meeting on Milk and Health. Speakers, Professor H. D. Kay, D.Sc., F.R.S., Dr. J. G. Davis, D.Sc., and Mr. W. R. Trehan, M.Sc.

HONYMAN GILLESPIE LECTURE.—At University New Buildings, Edinburgh, 5 p.m., Dr. F. S. Fiddes: Alcohol and Road Safety: The Role of the Doctor in Examining Suspected Car Drivers.

●INSTITUTE OF NEUROLOGY.—5.30 p.m., Mr. Valentine Logue: Injuries to Cranial Nerves.

●INSTITUTE OF OBSTETRICS AND GYNAECOLOGY.—At Chelsea Hospital for Women, 3 p.m., Professor J. Louw (Capetown): Urethral Pathology as it Affects the Gynaecologist.

ST. ANDREW'S UNIVERSITY.—At Physiology Department, Dundee, 5 p.m., Professor U. S. von Euler (Stockholm): Functional Relationship Between the Suprarenal Medulla and the Adrenergic System.

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL.—5 p.m., neurology demonstration by Dr. J. H. Paterson.

ST. JOHN'S HOSPITAL DERMATOLOGICAL SOCIETY.—4.30 p.m., (1) Demonstration and discussion of clinical cases. (2) Annual general meeting.

Friday, June 4

●INSTITUTE OF DERMATOLOGY.—5.30 p.m., clinical demonstration by Dr. G. B. Dowling: Scleroderma.

POSTGRADUATE MEDICAL SCHOOL OF LONDON.—2 p.m., Mr. E. F. Chin: Surgery of Acquired and Congenital Defects of the Diaphragm.

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL.—4 p.m., Holme Lecture by Professor H. K. Beecher (Harvard, Mass.): Drug Induced Changes in Sensation.

WHIPPS CROSS HOSPITAL MEDICAL SOCIETY.—8.30 p.m., Dr. W. Burridge: Excitation and Inhibition.

APPOINTMENTS

EAST ANGLIAN REGIONAL HOSPITAL BOARD.—J. M. Salmon, M.B., B.Ch., Assistant Chest Physician, Great Yarmouth and Lowestoft Chest Clinic.

Area: Mrs. Heather J. Lopert, L.R.C.P.&S.Ed., Anaesthetic Registrar, Peterborough Memorial Hospital; R. I. H. Welsh, M.B., B.Ch., Surgical Registrar, Peterborough Memorial Hospital; R. C. MacGillivray, M.B., Ch.B., F.R.F.P.S., D.P.M., Consultant Psychiatrist, Little Plumstead and Norwich Hospital; J. H. Jennings, M.B., B.Ch., Surgical Registrar, Stamford and Rutland Hospital; T. J. K. Merritt, M.B., B.S., Registrar in Psychiatry, St. Andrew's Mental Hospital; M. E. York-Moore, M.B., B.S., D.Obst.R.C.O.G., Registrar in Psychiatry, Hillesdon Mental Hospital.

HAGAN, J. G., M.B., B.Ch., D.P.H., Deputy Medical Officer of Health and Deputy Principal School Medical Officer, Northampton County Borough.

LAURIE, ALEXANDER, M.B., Ch.B., D.P.H., Assistant County Medical Officer of Health for the Derbyshire County Council and Medical Officer of Health for the Borough of Ilkeston and the Urban Districts of Alfreton and Ripley.

LIVERPOOL REGIONAL HOSPITAL BOARD.—A. R. Carrado, M.D., T.D.D., Whole-time Medical Director of No. 2 Mass Mobile Radiography Unit.

E. H. Strach, M.D., M.Ch.Orth., F.R.C.S., Whole-time Assistant Orthopaedic Surgeon to Clatterbridge General Hospital; J. R. Bryson, M.B., Ch.B., F.F.A.R.C.S., Consultant Anaesthetist to Clatterbridge General Hospital; Edith M. Thorp, M.B., Ch.B., D.P.M., Whole-time Assistant

Any Questions?

What is Fibrositis?

Q.—(1) What is fibrositis? What are the nodules which clinicians feel, or profess to feel, in the affected tissues? What are the so-called trigger zones? (2) What is the relationship between fibrositis and emotional stress and osteoarthritis of the spine?

A.—(1) Fibrositis is in large measure a medical myth. It is loosely applied to pain felt in the musculo-skeletal system for which a more exact nomenclature cannot be found. One of the most common types is pain associated with an anxiety neurosis (the so-called "psychogenic rheumatism" of the Americans). As commonly used, the term includes also pain due to subacromial bursitis, pain arising in tendons and ligaments as the result of chronic or acute trauma, postural pain, pain arising from disk lesions, and pain arising through pressure on sensitive structures such as nerves in the thoracic inlet. The nodules which are to be felt in this condition are usually normal fatty lobules; like any other structure, they may be the site of referred pain and tenderness. They are palpable in certain areas of the back in many people without fibrositis. There is no histological proof of any specific lesion in the muscles or connective tissue that justifies the name of "fibrositis." Trigger areas are those areas in which pressure produces radiating or referred pain.

(2) The relationship between fibrositis and emotional stress or strain is often a direct one. People in a disordered psychological state are often more aware of the ordinary aches and pains of everyday life and particularly more aware of any pain due, for instance, to postural disorders. Osteoarthritis of the spine is something that occurs in everyone with increasing age. However, when this is discovered radiologically it is frequently blamed for pain in the back. It may sometimes be the cause of it if the abnormal bony proliferation interferes with movement and the function of the spinous ligaments.

Storage of Oxygen Cylinders

Q.—In this district we propose to have oxygen for emergency cases kept by the local pharmacist. Can you kindly tell me what are the dangers of explosion? Can an oxygen cylinder be left stored in a room with a gas or open fire? We propose to use a B.L.B. mask. Can this be used in a room with a gas, electric, or coal fire?

A.—The risk of stored oxygen cylinders exploding is practically negligible. Where there is no alternative, an oxygen cylinder may be left in a room with an open fire, so long as the cylinder is placed as far from the fire as possible and shielded so that it does not become unduly hot. It is better, however, that cylinders should be stored under proper conditions, as outlined in British Standard 1319, 1946. It is dangerous to use oxygen therapy near an open fire because in the presence of oxygen inflammable objects catch fire more easily and burn more vigorously. If the use of oxygen with a B.L.B. mask is imperative in these circumstances, the patient and cylinder should be placed as far from the fire as possible and good ventilation of the room ensured. An oxygen tent is never permissible in the vicinity of an open fire.

Rosehip Syrup

Q.—Can you provide a recipe for making rosehip syrup so that it retains a high content of vitamin C?

A.—A good recipe may be found in the leaflet "Hedge-row Harvest," which was issued by the Ministry of Food. Two pounds (0.9 kg.) of hips are put through a coarse mincer, and at once placed in three pints (1.7 litres) of water which has been kept briskly boiling in readiness. The water is again brought to the boil, and the saucepan is then

Psychiatrist to Winwick Hospital; D. M. Prinsley, M.D., Senior Resident Medical Officer to Barrowmore Hospital.

MURRAY, FRANCIS J. A., L.R.C.P.&S.I., D.P.H., Medical Officer of Health, Stone Rural District Council, Staffordshire; became medical officer of health for Stone Urban District Council in February, 1953.

NORTH-WEST METROPOLITAN REGIONAL HOSPITAL BOARD.—R. E. Kelly, M.D., M.R.C.P., Consultant Neurologist, Mount Vernon Hospital, Northwood, Middlesex. G. Osborne, M.D., M.R.C.P., D.M.R.D., Consultant Diagnostic Radiologist, Whittington and New End Hospitals. S. H. Harrison, F.R.C.S.Ed., L.D.S.R.C.S.Ed., Consultant Assistant Plastic Surgeon, Mount Vernon Centre for Plastic Surgery and Jaw Injuries. H. W. A. Baron, M.Chir., F.R.C.S., Consultant Surgeon, Hoxsey Central Hospital. J. Rubie, M.D., M.R.C.P., D.C.H., Consultant Paediatrician at Hospitals in Windsor Group and at King Edward Memorial Hospital, Ealing. Dorcen Nightingale, M.S., F.R.C.S., Consultant Surgeon, National Temperance Hospital. T. M. Moylett, M.B., B.Ch., D.P.M., Assistant Psychiatrist (S.H.M.O.), Three Counties Hospital.

SOUTH-WESTERN REGIONAL HOSPITAL BOARD.—D. I. Rees, B.M., B.Ch., D.L.O., D.A., General-practitioner Anaesthetist (two sessions) at Stroud General Hospital, Gloucester; Joan R. Collins, M.B., Ch.B., General-practitioner Anaesthetist (two sessions) at Newquay and District Hospital; H. J. Doran, M.B., B.Ch., D.L.O., Clinical Assistant in Ear, Nose, and Throat Surgery (two sessions) in the Exeter Clinical Area; W. L. Burrows, M.D., M.R.C.P.I., Clinical Assistant in General Medicine (one session) at Royal United Hospital, Bath; Irene P. Rowlands, F.R.F.P.S., M.R.C.P., M.R.C.P.Ed., Geriatrician (S.H.M.O.) to North Gloucestershire Clinical Area; D. R. Little, M.R.C.S., L.R.C.P., F.F.A.R.C.S., D.A., Consultant Anaesthetist in Bristol Clinical Area (Weston-super-Mare); G. F. Trobridge, M.B., Ch.B., Registrar in Diseases of the Chest at Hawkmoor Chest Hospital, Bovey Tracey, Devon; L. G. Tulloch, M.D., Senior Registrar in Dermatology in Bristol Clinical Area; D. E. Truscott, M.B., B.S., D.M.R.D., Consultant Radiologist to West Cornwall Clinical Area based at West Cornwall Hospital, Penzance; C. D'Arcy Laidlaw, F.R.C.S., Surgical Registrar, Southmead Hospital, Bristol; Rhona E. Morgan, M.B., B.Ch., D.Obst.R.C.O.G., D.C.H., Medical Registrar at Cheltenham General Hospital; J. H. Fox, M.B., Ch.B., D.P.H., Registrar in Diseases of the Chest, Bristol Clinical Area; M. J. Catton, M.B., B.S., Registrar in Pathology at Southmead Hospital, Bristol.

WESTON, JOSEPH W., M.R.C.S., L.R.C.P., D.T.M.&H., Whole-time Assistant Pathologist (S.H.M.O.), Halifax Group, Leeds Regional Hospital Board. (Corrected announcement.)

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Ansell.—On May 19, 1954, at the Liverpool Maternity Hospital, to Beatrice (formerly Dubow), B.Sc., wife of Abraham Ansell, M.D., D.M.R.D., a daughter.

Baker.—On May 13, 1954, to Dr. Hazel Baker (formerly Hill), wife of Mr. J. A. C. Baker, M.A., of Wednesbury, Staffs, a third son—Francis William.

Eastcott.—On May 16, 1954, at Iver, Bucks, to Bobby, wife of Mr. H. H. G. Eastcott, M.S., F.R.C.S., a daughter.

Garrets.—On May 10, 1954, at the British Military Hospital, Iserlohn, B.A.O.R., 24, to Sheila Ruth (formerly Hirschfeld), wife of Captain Maurice Garrets, M.B., M.R.C.P., R.A.M.C., a daughter—Angela Edelle.

Hewitt.—On May 18, 1954, at Bristol Maternity Hospital, to Yvonne, wife of Dr. Keith M. Hewitt, a son.

O'Sullivan.—On May 13, 1954, at Doris Court Nursing Home, Manchester, to Una, wife of Dr. J. G. O'Sullivan, a son—Timothy Francis.

MARRIAGES

King-Watts.—On April 10, 1954, at the Cathedral of the Highlands, Nairobi, Kenya, Anthony John King, B.Sc., F.G.S., of Wallasey, Cheshire, to Anne Wendy Watts, M.B., B.S., of Newcastle-upon-Tyne.

DEATHS

Bradlaw.—On April 19, 1954, at 8, Hatherley Court, Baywater, London, W., David Barnett Bradlaw, L.R.C.P.&S.I.&L.M., aged 79.

Collins.—On April 14, 1954, at Virginia Water, Surrey, Michael Abdy Collins, O.B.E., M.D., of Saxmundham, Suffolk, aged 75.

Elliott.—On April 20, 1954, at 82, Stepney Road, Scarborough, John Lewis Elliott, L.M.S.S.A., late of Cudworth, Yorks, aged 81.

Fardon.—On April 19, 1954, at 23, Rose Hill, Dorking, Surrey, Albert Henry Fardon, M.D., D.P.H., aged 76.

Glicksht.—On April 9, 1954, at the North Staffordshire Royal Infirmary, Stoke-on-Trent, Adam Glicksht, M.B., Ch.B., of Bleak Hill House, Burslem, Stoke-on-Trent, aged 68.

Glynn.—On March 28, 1954, at his daughter's home, 76, Hawthorne Crescent, Stoke Poges Lane, Slough, Bucks, John Joseph Glynn, L.R.C.P.&S.I. & L.M., late of 159, Old Street, London, E.C.

Hammond.—On April 20, 1954, at the Royal Hospital, Wolverhampton, John Hammond, M.B., Ch.B., of Fantaile, Albert Road, Wolverhampton.

Heath.—On April 6, 1954, Thomas Lowthian Heath, M.R.C.S., L.R.C.P., of Thornton Heath, Surrey, aged 62.

Henderson.—On April 8, 1954, in hospital, David Henderson, M.D., late of Cheddleton, near Leek, Staffs.

Hoyten.—On April 4, 1954, William James Hoyten, M.D., D.P.H., aged 86.

Jones.—On April 7, 1954, at Camberley, Surrey, David Elgan Eiddig Jones, M.B., F.R.C.S.

Lowson.—On April 6, 1954, at Wendover, Bucks, James Prain Lowson, M.D.

Marcus.—On November 28, 1953, in Trinidad, British West Indies, Emil W. Marcus, M.D.

Mayberry.—On April 2, 1954, at 92, Holden Road, Finchley, London, N., Robert John Mayberry, M.B., Ch.B.

Mills.—On April 10, 1954, at Orpington Hospital, Frederick André Mills, M.B., B.Ch., late of 20, The Drive, Sevenoaks, Kent, aged 84.

Nickerson.—On April 10, 1954, at Court Kintyre, Argyll, William Henry Snyder Nickerson, V.C., C.B., C.M.G., M.B., Ch.B., D.P.H., Major-General, late R.A.M.C., retired, aged 79.

Peel.—On April 12, 1954, at Glenhorne, Staircase Lane, Bramhope, Yorks, John Percival Peel, M.B., B.S., aged 53.

Stanley.—On April 8, 1954, at St. Leonards-on-Sea, Sussex, Hubert Stanley, M.B., B.Ch., aged 90.

Sturrock.—On April 4, 1954, Herbert Monieriff Sturrock, L.R.C.P.&S.Ed., L.R.F.P.S., F.D.S.R.C.S.Ed., of 28, Melville Street, Edinburgh.

Vivian.—On April 4, 1954, at Westaway Drive, Bexhill-on-Sea, Sussex, Harold Sugden Vivian, M.B., B.S., D.O.M.S.

put aside to cool for 15 minutes. The water and hips are next poured into a jelly-bag made of flannel or linen, crushed, and allowed to drip until most of the fluid has come through. If the first drippings from the jelly-bag contain hairs from the insides of the hips they are put back into the bag. When the flow of fluid has ceased the hips are returned to the saucepan and are stirred up with another $\frac{1}{2}$ pints of boiling water. After standing for 10 minutes they are put back into the jelly-bag and more fluid is collected. The combined extracts are boiled down to a volume of $\frac{1}{2}$ pints, and a final boiling of five minutes is given after the addition of $\frac{1}{4}$ lb. of sugar. While still hot the syrup is poured into small bottles, which must be hot and sterile. If they are sealed with corks these should be boiled for a quarter of an hour just before use, and should be covered with melted paraffin wax.

About two teaspoonfuls of the extract should supply a daily dose of vitamin C. The syrup should be stable if kept in full bottles in a cool darkened cupboard, but the vitamin deteriorates in a few weeks after the bottles have been opened and air admitted. Cooking utensils made of copper or uncovered iron should not be used for making the syrup, since these metals accelerate the destruction of vitamin C.

Intraperitoneal Transfusion of Infants

Q.—When anaemic infants who are in no immediate danger from anoxia need blood transfusions, I have found the following technique useful in tropical practice. The freshly collected blood is injected into the peritoneum. If no sodium citrate or heparin should be available, fresh blood may be used, clotting being prevented by contact with the peritoneum. A 50- or 20-ml. syringe is satisfactory, provided one works quickly and leaves the needles in situ during the proceedings. The blood haemoglobin rises within a few days, and the procedure may be repeated at short intervals. Do you commend this technique? During the first few minutes of life, is it safe to use the mother's blood for this purpose without grouping?

A.—There is plenty of evidence that when red cells are injected intraperitoneally the majority eventually find their way into the blood stream. However, the process is relatively slow, and may not be complete one week after the injection. In practice the procedure appears to be fairly safe, since some authors have given quite large numbers of intraperitoneal blood injections to children without observing any ill-effects. Nevertheless, it cannot be considered as safe as an ordinary transfusion nor can it be considered so efficient.

During the first two or three months of life the only antibodies present in the infant's serum are those derived from the mother by placental transfer. Thus, at this time, the mother's red cells can be injected into the infant without any risk of a haemolytic reaction. However, it has to be remembered that the mother may be Rh-positive and the infant Rh-negative, so that there is a possibility of sensitizing the infant to the Rh antigen. In the case of female infants this is a serious matter, since sensitization to the Rh antigen, once established, persists indefinitely; therefore tests must always be made to ensure that Rh-positive blood is not given to an Rh-negative recipient.

Carbon Dioxide Bubbles on Acidifying Urine

Q.—When clearing phosphatic urine with acid is there a production of visible bubbly carbon dioxide?

A.—When a urine is very alkaline, as in alkalosis produced by taking excess of alkali-forming salts, there will be sufficient carbonate present to give rise to visible carbon dioxide formation on the addition of acid. The usual cause of evolution of carbon dioxide on acidifying is that the urine is stale and bacterial decomposition of the urea has formed a considerable amount of ammonium carbonate which gives a marked evolution of gas on acidifying.

Can a Doctor Practise as a Vet?

Q.—Can a doctor legally practise veterinary surgery for payment without a veterinary qualification?

A.—No person may practise veterinary surgery, whether for payment or otherwise, unless his name is entered in the Register of Veterinary Surgeons or the Supplementary Veterinary Register. The only exceptions to this rule are: (1) Treatment given to an animal by its owner or a member of his household or his employee; (2) anything done otherwise than for reward by a person engaged in agriculture to an animal owned for the purpose of agriculture; (3) the rendering in emergency of first aid for the purpose of saving life or relieving pain; (4) the destruction of any animal by painless methods; and (5) the castration of certain young animals, the tailing of a lamb, the docking of a dog's tail, or the amputation of its dew claws before its eyes are open.

Bleary Eyes

Q.—A young man of 26 in otherwise excellent health and with perfect eyesight complains that his eyes are persistently rather bleary and bloodshot, especially in the morning, i.e. which time he finds it difficult to face bright light without his eyes watering. On examination, his eyes are slightly bloodshot (although not nearly so markedly, he states, as in the morning). What is the likely cause and what treatment is recommended?

A.—The most likely explanation is that he is suffering from slight conjunctivitis together with a greater than average sensitiveness to bright light. Another possible factor is that his lacrimal glands secrete excessive tears on relatively slight provocation. It should be remembered that the visibility of the superficial vessels of the conjunctiva varies from person to person, even in the absence of inflammatory changes. Exposure to dust and to irritating vapours, including tobacco smoke, is a frequent cause of conjunctival injection. If this young man's eyes are actually inflamed, an attempt should be made to find out whether he is exposed to any avoidable irritant, and then treat the conjunctivitis on general principles if it should persist after elimination of the probable source of irritation.

NOTES AND COMMENTS

Infection from the Chalice.—Dr. JULIAN M. JEFFRIES (Hove) writes: In your issue of May 8 (p. 1107) under "Any Questions?" is a full and useful reply on infection from the chalice, but it states that "in fact no instance of transmission by this means has ever been substantiated." The following incident is within my recollection. It occurred in the Christian village church of Clarkabad in the Punjab, India, about 30 years ago. The English head of the C.M.S. mission, who was on a visit there, was the celebrant. One of the congregation developed hydrophobia shortly after communicating, and died. Later, one or possibly two others were also affected. The celebrant was severely infected and died. No doubt these facts are recorded and could be verified in the Church Missionary Society's records.

"Any Questions?" Book.—The second book of selected "Any Questions?" is available, price 7s. 6d. (postage 6d.). Copies may be obtained either direct from the Publishing Manager, B.M.A. House, Tavistock Square, London, W.C.1, or from booksellers.

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 4499. TELEGRAMS: Attilology Western, London. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the British Medical Journal alone unless the contrary be stated. Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors overseas should indicate on MSS. if reprints are required, as proofs are not sent abroad. ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. House, Tavistock Square, W.C.1 (hours 9 a.m. to 5 p.m.). TELEPHONE: EUSTON 4499. TELEGRAMS: Britmedad, Western, London. MEMBERS' SUBSCRIPTIONS should be sent to the SECRETARY of the Association, TELEPHONE: EUSTON 4499. TELEGRAMS: Medicaea, Western, London. B.M.A. SCOTTISH OFFICE: 7, Drumshannach Gardens, Edinburgh.

THE DYNAMICS OF HAEMOPOIESIS*

BY

Sir LIONEL WHITBY, C.V.O., M.D., D.Sc., F.R.C.P.

Regius Professor of Physic in the University of Cambridge

Even the most casual survey of the activities of the haemopoietic system, which has to maintain a constant population of erythrocytes, leucocytes, platelets, and other factors in the face of losses caused by daily wear and tear, can leave no doubt that the system is highly dynamic. It is perhaps not inappropriate that I should have chosen this title for the Thomas Huxley Lecture, since Huxley himself, who qualified from this great school in 1845, was a most dynamic personality. I propose to present, in a necessarily most limited survey, a few of the active features of the haemopoietic system in the light of my experiences and work, as well as my considered opinion of the work of others; and I shall try to make some estimate of the nature and magnitude of the task of providing and renewing a normal population of blood cells. This will necessarily call for some survey of the physiological processes of blood formation.

It is fortunate, perhaps, so far as dynamic studies are concerned, that the many mobile cells of the haemopoietic system have an unmistakable appearance or a unique composition which enables something of their life histories to be accurately followed by cytochemical, serological, and radioactive techniques, and by these means some estimate has been made of what is required in everyday life, as well as in times of stress.

The active bone marrow in the average adult is estimated to weigh some 3,000 g. (3.5–6% of body weight, or 1,500–3,500 g.); it roughly equals the weight of the liver; its volume is large, being some 70 ml. at birth and about 4,000 ml. when the subject is full-grown. In the adult, however, only about half the marrow is in an active state, but it has an enormous reserve of functional capacity, as well as considerable room for expansion. The parent cells of the marrow can produce many times their own volume of mature cells in a relatively short time.

The Erythron

So far as the erythron (Fig. 1) is concerned the 3,000 g. of bone marrow makes use of the amino-acids derived from the protein pool and of iron derived from the catabolism of effete red cells, as well as some of the that which is absorbed from the intestine, and a little of that which is contained in the iron stores, in order to maintain a circulating erythrocyte population of some 25 million millions (25×10^{12}).

There is good evidence that in a normal person the life-span of the red corpuscle is some 120 days.

The task of maintaining the erythrocyte population, the replacement of $1/120$ each day, amounts, therefore, to approximately 2.1×10^{11} corpuscles a day, or about

*Thomas Huxley Lecture delivered at Charing Cross Hospital Medical School on March 18.

9,000 millions in an hour. This involves the incorporation of 6.5 g. of haemoglobin (each gramme containing 3.34 mg. of iron) a day on the production side, whilst the daily destruction of cells leads to the liberation of about 20–26 mg. of iron, together with porphyrin and globin.

The process of red-cell destruction is carried out by the reticulo-endothelial system, itself being about half the weight of the marrow, from whence the iron and globin are used again, whereas the porphyrin pigments, appearing in the bile, are excreted mainly in the faeces as some 250 mg. of faecal urobilinogen a day. Excretion, however, is very variable, and it is difficult to obtain correlation between corpuscular destruction and pigment excretion.

FIG. 1.—The erythron (after Wintrobe).

On the other hand, the amount of iron which is excreted is minimal, and is fairly precisely known, being a daily amount of from 0.6–0.8 mg. in the bile (Hawkins and Hahn, 1944) and 0.4–0.6 mg. in the urine (Barer and Fowler, 1937) according to sex. In all estimations, however, the fact that women suffer an iron loss of 10–40 mg. at each menstrual period, or about 1 mg. a day over the whole menstrual cycle, has to be borne in mind, since it means that women lose about twice as much iron as men.

Pregnancy, a physiological process, almost doubles the figure, but lactation adds no more than 1.5 mg. to the normal daily loss, unless menstruation becomes re-established, whereupon the total iron loss becomes almost as great as in pregnancy.

In effect, some nine-tenths of the dry weight of the red cell consists of haemoglobin, and this is contained in a complex stroma, itself a unique combination of

protein and lipids together with such specific factors as blood-group substance as well as enzymes, minerals, and other substances. The whole comprises a cell which is one of the most specialized structures in the mammalian organism, a cell whose functional activity is carried on for months after its nucleus has been lost, and with such efficiency that it consumes practically none of the oxygen which it transports.

This simplified and elementary summary of the everyday dynamics of erythropoiesis underlies the basic pathology of all anaemias, for when the pace is not maintained then anaemia occurs—that is, when blood loss or blood destruction outstrips the daily production (Whitby, 1937). And the principle is the same whether the blood loss is obviously direct, as with haemorrhage or a violent haemolytic process, or whether it is no more than the physiological hourly blood loss of some 9,000 million cells, to which I have already referred.

Failure to keep pace with the physiological blood loss may be due to very many causes. Some of these are trivial, some are serious, some curable, others incurable, and they may operate with different intensities, and singly or in combination, to reduce the efficiency of the process of blood formation to various degrees; these causes include everything in the vast field of what used to be called secondary anaemias. A proper understanding of these different stresses demands some knowledge of the processes involved in haemoglobin synthesis, iron balance and metabolism, red-cell production, and red-cell maturation.

Haemoglobin Synthesis

The synthesis of haemoglobin requires supplies for the formation of the sub-units and the building up from these of the main components of haemoglobin; in this process enzymes, hormones, vitamins, and other substances play a large part. Globin is synthesized from natural amino-acids; its availability is not usually impaired except by gross dietary deficiency of one or more of the ten essential amino-acids. Moreover, the deficiency has to be sustained and severe before globin formation is reduced, because the body preferentially breaks down even its own proteins to provide amino-acids for haemoglobin formation, rather than that there should be a globin deficiency. Tissue respiration is indeed a primary vital function.

The synthesis of haem requires adequate supplies of porphyrin precursors and of iron. Two porphyrins (I and II) are found in nature and in the animal body. In the human subject these porphyrins are synthesized and are not, as in some animals, derived from preformed pyrroles such as chlorophyll.

When haemoglobin is catabolized the porphyrins are not used again as such, but the iron which they contain is mainly conserved and, indeed, forms the major part of the iron used for the daily requirements of haemoglobin, since it appears to be preferentially used before either the iron which is absorbed from the intestine or that which is contained within the body stores. Nevertheless, as a protection against stress, the iron reserves of the body are very considerable, a fact which becomes obvious when one realizes the speed with which a patient who has suffered a moderate haemorrhage can regenerate his blood without supplementary iron treatment.

Iron Stores

Hynes (1949) found that the iron stores in a normal man probably amounted to some 600 mg., which is sufficient to replace about one-quarter of the circulating haemoglobin in times of need. This estimate agrees with the clinical observation that a haemorrhage of roughly this order is the

largest amount from which recovery is readily possible without supplementary iron treatment.

We have made a fairly close study of children in my department in order to arrive at some estimate of the amount of iron required by growing children to furnish an adequate tissue store. Because the blood volume increases with growth and because the tissue stores likewise enlarge, the growing child requires considerably more iron than the adult. We have estimated that infants, during the first year of life, need to lay down an additional store of some 200 mg. of iron, the amount falling to 100 mg. annually in the third year, and remaining at this figure until about the ninth year, when growth begins to increase rapidly. The amount of iron then laid down rises to about 350 mg. at the age of 17, and thereafter declines to zero at 21, when growth ceases.

The building up of iron stores is, however, by no means a straightforward process, since the manner in which iron is absorbed from the intestine and the form in which that which is derived from the catabolism of red cells or from intestinal absorption is transported to the various stores within the body, or, from the stores, to be incorporated in the haem molecule, is one of the processes in iron metabolism which are by no means simple.

Transport of Iron

At any one time the total serum iron of a normal man is about 4 mg., whilst every day some 20–26 mg. of iron leaves the blood stream, and of this about four-fifths is taken up by the marrow. This is used for the immediate daily requirement in haemoglobin synthesis, whilst the excess is stored primarily and mainly in the liver. In order to transport the amount of iron required for normal daily haemoglobin synthesis the iron in the plasma must therefore be turned over some five times a day.

The marrow is very active in removing serum iron from the blood. Theoretical calculations suggest that during increased haemopoietic activity more than 10% of the plasma iron passing through the bone marrow may be retained (Laurell, 1952), and since this iron in process of transport—so-called Fe-transferrin, a plasma-globulin—is mainly derived from the catabolism of red cells, and is rapidly used again, it follows that the iron stores of the body are turned over relatively slowly. The main cycle of iron turnover is from the plasma to the newly formed cells and from the old catabolized cells back to the plasma.

Thus the level of plasma iron in the blood represents an equilibrium among a number of dynamic processes which include the rate of haemoglobin breakdown and the release of iron therefrom, the rate of uptake of iron by the marrow for the synthesis of haemoglobin, the rate of removal of iron from the blood stream for storage in the tissues, the rate of formation and decomposition of transferrin itself, as well as the degree to which it is saturated with iron. This last point enters into the field of practical clinical medicine, since the level of plasma iron and the degree of iron saturation are considered to be sensitive and reliable indices of iron deficiency or iron excess.

For example, it is generally found that transferrin is saturated with iron in diseases, such as haemochromatosis, in which iron is in excess; or when haemoglobin catabolism is active, as with the haemolytic anaemias; or when the marrow needs iron but cannot use it properly, as with pernicious anaemia.

On the other hand, transferrin remains very unsaturated with iron when the bone marrow is highly active in a physiological manner, as with acute haemorrhage and iron-deficiency anaemia.

Absorption of Iron

From the aspect of physiology, as well as practical therapeutics, the control of iron absorption represents one of the key points in iron balance and iron metabolism. This likewise is not simple. A single guiding principle determines

the maintenance of iron balance—namely, that to the human body iron is a precious metal which is carefully conserved. Excretion is minimal.

Iron balance is maintained by a regulation of absorption according to the needs of the body, rather than by the excretion of unwanted excess. If this were not so, then every aged person would suffer from haemochromatosis. Sufficient iron to balance the small daily excretion is ordinarily derived from everyday foodstuffs, some of which contain reasonable quantities of the metal and others a negligible amount, and there is abundant evidence (Moore *et al.*, 1944) that ferrous iron is absorbed twice as effectively as ferric.

Without entering into detail, one may say that in certain foods iron is more available than in others, that valency and reaction, such as the difference between achlorhydria and normochlorhydria, affect absorption, and that an iron-free protein in the intestinal mucosa—apoferritin—can become appropriately and variously saturated with iron to form ferritin, according to body needs, until no more can be absorbed. This enters the plasma to contribute to the transferrin therein, and to be deposited therefrom in the tissue depots as ferritin once again.

It is instructive to note that, in experimental iron-deficiency anaemias, neither ferritin nor apoferritin can be detected in the cells of the intestinal mucosa, but that both quickly appear when iron feeding is instituted. This leads to the attractive theory that apoferritin is specifically formed in response to the stimulus supplied by the presence of ionized iron in the gut.

It would seem that ionic iron in the mucosal cell is in equilibrium with the plasma iron and this, in turn, with the iron in ferritin in the store depots. Thus, when the ionic iron in the mucosa attains a certain level, a state of mucosal block occurs and continues until the level of ionic iron in the cells falls low enough to allow more iron to be absorbed.

Utilization of Iron

Because of all the factors which govern the movement and utilization of iron, it is not easy to translate practical therapeutic principles into simple mathematical expressions, since the theoretical requirements are greatly influenced by such matters as absorption, route of administration, the nature of the preparation, and the extent to which its iron content is utilized.

An adult with 100% of haemoglobin has from 750–900 g. of circulating haemoglobin containing from 2.5–3 g. of iron. In order to replenish each 1% of haemoglobin deficiency, the body must absorb and utilize some 25 mg. of iron. Ferrous salts, the best preparations, are used only to the extent of about 15%. One gramme of anhydrous ferrous sulphate contains 360 mg. of iron, and if 10% of this is utilized the administration should cause a rise of about 2% in the circulating haemoglobin.

Practical experience has shown that there is no advantage in giving more than 2 g. of ferrous sulphate a day, which ought to ensure a rise of 4%. It is not justifiable, however, to assume that iron given to anaemic patients in optimal doses will be absorbed in accordance with the theoretically expected utilization; in that, with iron deficiency, it is often absorption which is at fault.

Many patients also do not respond to ingested iron, and it is quite useless to increase the dose beyond the optimum. On the other hand, with intravenous iron, the whole is absorbed and is rapidly available for utilization provided the pathological process is not such as to inhibit it.

In some circumstances the utilization may amount to as much as 80% (Whitby, 1949), causing an apparent increase in haemoglobin of threefold or more. I have deliberately said “apparent” since every now and again we become aware of the fact that figures obtained from samples of the peripheral blood are relative rather than absolute, and that they may be fallacious unless they are converted into total figures by means of a blood-volume determination.

Table I (a case of gross iron deficiency) is a simple illustration of this point, since it reveals the fallacy of estimating iron utilization by the peripheral blood figure alone without

TABLE I.—*Absorption and Utilization of Iron in Patient Weighing 50 kg. (Ferrous Sulphate=600 mg. Iron Daily)*

Day of Treatment:	0	9	23	49
Hb (g. per 100 ml.)	6.7	8.3	10.5	13.3
Increase Hb	—	24%	5.7%	100%
Plasma vol. (ml.)	2,120	2,250	2,410	2,180
Corpuscular vol. (ml.)	710	1,060	1,290	1,590
Total blood vol. (ml.)	2,830	3,310	3,700	3,690
Total Hb (g.)	190	280	390	490
Increase in total Hb	—	47%	105%	160%

reference to the total haemoglobin as determined by the blood volume. Whereas the former shows an increase of the order of 100% (from 6.7 to 13.3 g. per 100 ml.), the latter shows the true increase to be 160% (from 190 g. to 490 g.).

In theory, a patient with pernicious anaemia should have no need for iron, in that the haemoglobin was once normal and almost all the iron derived from the cells during the course of destruction is retained in the body. But we (Whitby and Britton, 1953) have found that some 40% of patients with pernicious anaemia require iron as judged by the mean corpuscular haemoglobin concentration, and, so far as women are concerned, a great number are iron-deficient before they contract pernicious anaemia.

Table II shows the very large amount of iron that is utilized during the cure of pernicious anaemia, as well as the adjustments in corpuscular and plasma volumes which

TABLE II.—*Iron Requirements in Pernicious Anaemia. Female Weighing 45 kg.*

Day of Treatment:	0	50
Haemoglobin (g. per 100 ml.)	3.9	14.0
Plasma vol. (ml.)	3,070	2,300
Corpuscular vol. (ml.)	400	1,500
Total blood vol. (ml.)	3,470	3,800
Total haemoglobin (g.)	150	550
Total iron (mg.)	434	1,770

occur at the same time; the patient, a small woman of some 45 kg., used as much as 1.34 g. of iron with a four-fold increase in total haemoglobin, and at the same time an initial high plasma volume became readjusted to a lower figure coinciding with an increase in corpuscular volume, though the total blood volume remained virtually the same.

It is unfortunate that there is no simple method, indeed no method entirely free from fallacies and objections, for the determination of blood volume, since an accurate appreciation of the movements and alterations in cells and plasma would be of great value in clinical medicine.

Erythropoiesis under Stress

The examples which I have given illustrate some of the features associated with the utilization of iron, but they also serve to show that even under apparently straightforward conditions the mathematics of iron balance may be complex.

Numerous factors may indeed intrude to upset a simple calculation, and even though as a basic principle it can be accepted that many anaemias are due to the fact that production fails to keep pace with the physiological but negative side of the iron-balance equation, it is axiomatic that a gross negative imbalance could not endure for long, otherwise the subject would soon have no red cells at all. This can be well illustrated by the dynamic activity that lies behind the clinical syndrome of haemolytic anaemia.

If the volume of the circulating cells is to remain constant, then production and destruction must be equal, even though the organism may need to adapt itself to a diminished population or to a population of cells ill-equipped to perform their proper function, assuming that both such

populations are composed of cells having a normal survival time.

When the negative side is rapidly increased, as with blood loss or violent haemolysis, balance can be maintained only by compensatory hypertrophy. When, therefore, as is usual in many of the haemolytic anaemias, the average red cell survives for a significantly, sometimes very considerably, less time than the normal average of 120 days, the degree of compensatory hypertrophy needs to be great, and may, indeed, be more than the latent reactive powers of the marrow can accomplish.

Crosby (1954) has given some instructive figures illustrating this point. Thus the function of the red marrow is to maintain a constant level of circulating red cells, and for this purpose, to quote Crosby, "Ten red cells that survive twelve days are equivalent to one red cell that survives 120 days, so that, to maintain a normal level with short-lived twelve-day erythrocytes the marrow would have to produce each day ten times the normal number."

FIG. 2.—The maintenance of a normal level of circulating leucocytes.

In certain circumstances, both factors—red-cell survival and marrow function—may contribute to the production and maintenance of a severely anaemic state—namely, cells which have a short survival time, which are destroyed by random selection rather than by virtue of age, and a marrow which is incapable of an adequate response.

Another example is pernicious anaemia, when the life-span of the red cells is about 30 days (about one-quarter of the normal period), and it is perhaps difficult to appreciate that even though the bone marrow utilizes as much as 17 g. of haemoglobin a day, or two and a half times normal, the hypertrophy is insufficient to maintain the red-cell count at a normal level.

In congenital haemolytic icterus the utilization of haemoglobin by the hyperplastic marrow is even greater. This is because the spherocytes have the short survival time of some 12 days only, and because at times of an aregenerative (sometimes called aplastic) crisis the marrow cannot keep pace with the demands. The degree of anaemia may then rapidly become severe.

The Leucocyte

Leucopoiesis is also highly dynamic. The number of leucocytes needed to replace daily losses and maintain the circulating cells within the normal range has been studied frequently and by many methods, but the estimates made of the normal life-span of the different leucocytes vary widely. Studies in parabiotic rats (van Dyke and Huff, 1951) gave times as short as 23 minutes for the average neutrophil and 170 minutes for a lymphocyte. White (1954), however, estimated the intravascular life-span of transfused neutrophil leucocytes, tagged with mepacrine, to be from 30 to 90 minutes.

At the other end of the scale, when using radioactive phosphorus, the average survival time of the neutrophil polymorphonuclear in a normal subject was estimated (Kline and Clifton, 1952) to be thirteen days. Many other intermediate values have been obtained by different methods, and it is not possible in the present stage of knowledge to make more than a rough estimate of daily leuco-

cyte loss. The lowest figure must be of the order of 1,000 million leucocytes, and the highest may be as much as a million million. But as an approximate compromise, if it be accepted that the life of the neutrophil polymorphonuclear does not exceed five days, it is necessary for the marrow to replace at least some 5,000 million neutrophils each day, and if lymphocytes have a life-span of less than one day then the daily replacement figure needs to be some 3,000 millions.

With leucocytosis and leukaemia, in which the circulating leucocytes are greatly increased in number, the task of production is probably more exacting, though there is some evidence (Kline and Clifton, 1952; White, 1954) that the life-span of leukaemic leucocytes is several times that of the normal cell.

Leucocytic production, whether physiological or pathological, demands the synthesis and new formation of the basic fundamental substances comprising the cell. Cytochemical studies have shown that multiplication is associated with an intensive production of protein within the cells.

Granular leucocytes also contain considerable amounts of phospholipids and glycogen, as well as numerous enzymes, including trypsin, lipase, amylase, catalase, alkaline phosphatase, esterase, and oxidase.

Some of the factors concerned with and the processes involved in maintaining a normal leucocyte count are shown in Fig. 2. In general, there is a balance between production by the marrow and reticulo-endothelial system; sequestration in the lungs, lymph nodes, and spleen; and destruction in these same sites as well as in the circulation itself.

Nutritional Factors in Leucopoiesis

Nutritional deficiencies of various kinds have been found to cause defective formation of leucocytes under experimental conditions.

Several investigators (Daft, 1947; Guggenheim and Buechler, 1949) found that a protein-free diet would produce severe leucopenia in experimental animals which could be corrected with a diet containing optimum amounts of protein or amino-acids. The effectiveness of different proteins for regenerating leucocytes under such experimental conditions appears to bear some relation to efficiency in growth promotion, suggesting that the same amino-acids are necessary for growth as for leucopoiesis. Deficiencies of tryptophan (Cartwright *et al.*, 1945), pantothenic acid (Ashburn *et al.*, 1947), and riboflavin (Endicott *et al.*, 1947) will cause leucopenia which can be corrected with folic acid. Presumably the leucopenia of pernicious anaemia is due to a nutritional deficiency, since it responds to treatment of the disease with folic acid, citrovorum factor, or vitamin B₁₂.

Control of Leucopoiesis

The mechanism for the physiological control of leucopoiesis is unknown. Nervous and hormonal factors have been surmised, but there is little experimental or clinical evidence in support of such views. Corticotrophin and adrenal corticoids appear to influence the peripheral leucocytes in some way, but Rosenthal *et al.* (1951) found no alteration in bone-marrow cellularity or differential cytology as the result of treating human subjects with these steroids. Nevertheless, both corticotrophin and cortisone sometimes have a stimulating action on the marrow in cases of agranulocytosis.

The question of the existence of a splenic hormone is of interest, but the available evidence, such as the large leucocytosis which immediately follows splenectomy, suggests that any splenic controlling effect is on release of cells into the circulation rather than directly upon production and maturation.

For the past fifteen years Menkin (1940, 1949) has consistently studied certain substances present in inflammatory exudates, which affect not only the maturation of leucocytes but also their release into the circulation. These leucocytosis-producing and leucopenia-producing agents have, in Menkin's hands, caused hyperplasia and hypoplasia of myeloid marrow elements when injected into experimental animals. No physiological counterparts are known.

The mechanism controlling the release of leucocytes into the circulation is little understood, but it would appear to be intact, if not overactive, in the aleukaemic forms of leukaemia (Whitby, 1951) and in the refractory anaemias associated with a paradoxically hyperplastic bone marrow (Whitby, 1952). The concept of hypersplenism and the rationale of its treatment with splenectomy implies, in fact, that the spleen has the power of regulating the release of all types of cells. Splenectomy, for any reason, may cause a considerable leucocytosis which may persist for years, but a leucocytosis does not occur in parabiotic animals unless the spleen is also removed from the second partner (Palmer *et al.*, 1951).

The interpretation of such results is, however, not always straightforward, as, for example, with the increase in circulating leucocytes which follows upon the injection of adrenaline. A critical examination of the cells in adrenaline leucocytosis shows no shift to the left in the Arneith count, and it would seem that the increase in cells is due to release of white cells from various sites of sequestration (Fig. 2) rather than to direct stimulation of or release from primary sites (Smith and Hayhoe, 1951). It may well be that the leucocytosis and leucopenia-producing factors of Menkin act also by controlling release of cells, as well as by stimulating a change in marrow activity.

Nucleic Acid Metabolism

Most, if not all, of the cells of the haemopoietic system have developmental processes in common, involving the synthesis and incorporation of substances less specific than the iron which is the essential constituent of haemoglobin, and which provides such an excellent marker for radioactive studies. Nevertheless, many of the highly differentiated cells have a unique composition, and all have intricate enzyme systems. A considerable speed in cell multiplication is obviously essential in order to replace daily wear and tear.

The vital chemistry of both red cells and leucocytes is concerned with nucleic acid metabolism. The nuclei and the cytoplasm of the young actively growing cells contain nucleic acids in high concentrations which are attached to proteins as nucleoproteins. These, in general, fall into two groups—the ribonucleic acids with a sugar component of the pentose series, and deoxyribonucleic acids with a sugar component of the deoxypentose series.

Cellular growth and active multiplication obviously depend upon the new formation of these fundamental substances within the cell, the nucleoproteins being the controlling factors, in that the energy necessary for synthesis is available within the molecular structure of nucleic acid.

Mitosis of marrow cells can proceed very rapidly when required, but it is not known whether a demand causes an increase in the number of cells undergoing mitosis, or shortens the time interval, or accelerates the process. Bone-marrow activity can be observed directly and the histological changes accurately described, and these in turn can be expressed roughly in terms of basic chemistry by cytochemical methods of staining.

The nucleoli and cytoplasm of blood cells contain ribonucleic acids, and in the cytoplasm the ribonucleic acids are found especially in the mitochondria, which are the site of enzymatic activities and probably serve as centres for protein synthesis.

The ribonucleic acids of the nucleoli and cytoplasm appear to be concerned not only with the proliferation of young marrow cells but also with the synthesis of their

characteristic cytoplasmic contents—namely, haemoglobin in the red-cell series, and complex enzyme systems in the specific granules of the leucocytes (White, 1947); ribonucleic acid diminishes as these specific substances appear (Thorelli, 1947b).

The Feulgen reaction shows that the nuclei of early cells, particularly the chromatin and chromosomes, are rich in desoxyribonucleic acid, especially during the period of active division of the cells, when it may well provide the energy necessary for the protein synthesis which takes place at this time.

The widely distributed enzyme alkaline phosphatase, which is found in normoblastic nuclei, is formed in large amount around the nucleus during active blood regeneration. The nucleus becomes infiltrated with the enzyme, after which pyknosis, fragmentation, or extrusion occurs. It is believed that alkaline phosphatase is intimately concerned with nuclear destruction. During active haemopoiesis, also, the magnesium content of the red cell is increased (Dahl, 1950), which is of interest since magnesium is a potent activator of the phosphatases.

A balanced production of the cells of the bone marrow clearly depends upon a carefully regulated chemical system, and since nucleic acids appear to govern cell division the differences in their concentration or availability may even determine the proportions of red and white cells in the blood. In certain pathological conditions there may be competition within a cell or between cells for substances which are essential for maintaining normal equilibrium.

The importance of these basic facts in practical haematology becomes clear as advances are made in knowledge concerning the factors essential for blood formation, as well as the manner in which these factors act. It is significant, for example, that thymine and thymidine have a haematological therapeutic action, whilst folic acid, citrovorum factor, and vitamin B₁₂ may exert their essential activity as coenzymes for certain stages in the synthesis of nucleic acid from simple substances (Fig. 3).

FIG. 3.—Scheme for the synthesis of nucleic acids from simpler substances, with suggested points of action of certain haemopoietic substances.

Abnormal Haemopoiesis

In some pathological processes the deviations from normal may be explained, or at least expressed, in terms of alteration in the normal rhythm. In other conditions the mode of action of an apparently specific material such as vitamin B₁₂ or folic acid may be thought of as being due to the part it plays in the synthesis of essential cellular constituents from simpler substances, and especially in relation to nucleic acid metabolism (Fig. 3).

For example, Japa (1945) suggested that the essential abnormality in megaloblastic erythropoiesis was one involving nucleic acid metabolism preventing the proper development of nucleoli, thereby inhibiting the capacity for cell division and leading to a prolonged duration of mitosis, decreased frequency of division, earlier cessation of division, and consequent differentiation at an earlier genealogical stage.

In the marrow cells in pernicious anaemia the ribonucleic acids of the cytoplasm and nucleolar apparatus do not disappear even when haemoglobin formation occurs (Thorelli, 1947a). This is in contrast to what happens in

the normal subject, as well as in the haemorrhagic anaemias, even though haemoglobin synthesis in the latter is retarded by lack of iron. In leukaemia, leucocytes accumulate a high concentration of ribonucleic acids in the cytoplasm and nucleoli which does not rapidly decline, as in the case of normal cells.

Desoxyribonucleic acids are an important constituent of chromosomes, being apparently attached at specific loci in the polypeptide chain which goes to make up the chromosome fibre; the amount differs at the different phases of chromosome division, and is noticeably abnormal in certain pathological states.

Under normal conditions there is more desoxyribonucleic acid in the chromosomes of the proerythroblast than the promyelocyte at the metaphase. In pernicious anaemia, however, the promyelocyte chromosomes contain very little desoxyribonucleic acid, and this leads to incomplete spiralization; the proerythroblasts and early megaloblasts, on the other hand, show an excess which consequently leads to over-spiralization. Over-spiralized chromosomes are associated with irregular division, multipolar spindles, and chromatoid bridges at the anaphase. In short, it would seem that mitotic abnormalities are closely associated with different distributions of desoxyribonucleic acid.

Conclusion

In this limited survey of some of the dynamic aspects of haemopoiesis I have naturally laid most emphasis on basic principles, some of which are now well established owing to the specific characteristics which the cells of the haemopoietic system possess. I have also paid some attention to the quantitative aspects of the subject and to some of the fallacies which may so easily intrude with hasty interpretation.

Simple quantitative aspects of haemopoiesis are indeed of such everyday application in clinical medicine that they are all too often accepted without critical analysis, without thought of possible alternative interpretation, or from a superficial viewpoint, to the neglect of fundamental principles.

Quantitative deductions cannot be accurate unless made upon unequivocal facts entirely free from ambiguity.

Leonard Huxley (1900) quotes Thomas Huxley, when writing to Charles Kingsley, as saying, "My business is to teach my aspirations to conform themselves to fact, not to try to make facts harmonize with my aspirations. Sit down before fact as a little child, be prepared to give up every preconceived notion, follow humbly to wherever and to whatever abysses nature leads or you will learn nothing."

In no field of medicine is this more true than in haematology, which in its daily clinical application to the dynamics of haemopoiesis is largely quantitative and in which precise results require the most critical appraisal if they are to be properly and accurately assessed.

ASSISTED CIRCULATION BY PUMP-OXYGENATOR DURING OPERATIVE DILATATION OF THE AORTIC VALVE IN MAN

BY

IAN AIRD, Ch.M., F.R.C.S.

Professor of Surgery

D. G. MELROSE, B.M.

Assistant Lecturer in Surgery

W. P. CLELAND, F.R.C.S.

Lecturer in Thoracic Surgery

AND

R. B. LYNN, M.D., F.R.C.S.

Assistant Lecturer in Surgery

Postgraduate Medical School of London, Hammersmith Hospital

Interest in the clinical application of the various forms of pump-oxygenator (extracorporeal circulation or artificial heart-lung machine) is growing so rapidly, and the use of this type of apparatus in man has so seldom been followed by recovery, that it is customary for isolated examples of its use to be reported (Dennis *et al.*, 1951; Dogliotti, 1952; Gibbon, 1953; Dodrill *et al.*, 1953; Helmsworth *et al.*, 1953).

Three authors, Dogliotti (1952) in Turin, Gibbon (1953) in Philadelphia, and Dodrill *et al.* (1953) in Detroit, report survivors, and Helmsworth *et al.* (1952) have used an oxygenator for vein-to-vein perfusion in a case of fibrosis of the lung. The pump-oxygenator employed in the case here reported was that designed and developed by Melrose in the department of surgery of the Postgraduate Medical School. Melrose (1953a) has described the machine and Melrose *et al.* (1953b) have reported the animal experiments performed in the Buckston Browne Laboratories of the Royal College of Surgeons, which seemed to prove that the machine might be used with safety in man. The machine consists essentially of a rotating oxygenator and two rotary pumps. Its chief advantages are a high degree of efficiency in oxygenation (100 ml. of oxygen per litre of blood) and a low initial charge of blood.

The circumstances in which the machine might be used with profit in a clinical way have also been discussed (Aird, 1953), and the opinion was then expressed that the use of such a machine to by-pass heart and lung totally and to provide safely a dry heart for surgery was an aim not then immediately obtainable. We

now have evidence that with a machine of this kind the surgical approach to the interior of the heart and even to the mitral valve under vision may well be possible. We hope to approach this aim by using the pump-oxygenator as a form of assisted circulation during operation, gradually increasing the proportion of the total circulation for which it is responsible.

There are certain standard procedures in cardiac surgery whose performance at present carries the risk of a dangerous fall in the rate of flow in the coronary arteries and the development of a ventricular fibrillation or cessation of heart-beat which is sometimes irreversible. The maintenance of flow in the coronary arteries during such a procedure seems to lessen the risk of ventricular fibrillation, and its severity if it occurs. Notable among these procedures is an attempt to deal surgically with severe degrees of aortic stenosis. When a thoracic surgeon is faced during operation with a seriously low aortic pressure, decreased coronary flow, and loss of cardiac efficiency, he normally has recourse to cardiac massage, occlusion of the thoracic aorta, and gravity or pump transfusion of blood directly into the aorta above the clamp to maintain coronary and carotid flow, at least in part.

We decided that a more effective method of maintaining the mean aortic pressure at a level sufficient for an adequate coronary and carotid flow would be to apply the pump-oxygenator throughout operation in parallel with the patient's own heart and lungs as a form of assisted circulation which could function in emergency as a total replacement for heart and lungs if cardiac function should give rise to serious anxiety. The indication for its use should be, we feel, a patient seriously incapacitated by a form of cardiac disease amenable to surgery who would, without some form of assisted circulation, be refused operation as too great a risk. When a new apparatus is used in such cases and the patient does not survive it is extremely difficult to exonerate the apparatus from blame and to apportion responsibility fairly between the severity of the operation and the danger of the ancillary apparatus. Similarly, if the patient survives, it is difficult to say to what extent the machine was of benefit, and to disprove that the operation might perhaps have been performed without its use. Recovery does show, however, in what manner the apparatus may be used without doing the patient detectable harm.

Clinical Features

The patient with whom this report was concerned was 32 years of age. She had contracted rheumatic fever first at 13 years, with chorea thereafter, a second attack of rheumatic fever at 23 years, and progressive dyspnoea from 1948. Since 1949 there had been attacks of winter bronchitis, and in July, 1952, an attack of carditis with congestive heart failure. Consequent upon this there was anginal pain on the slightest exertion, and when the patient presented she had been bedridden for six to eight months. Before operation the heart was fibrillating slowly, the pulse was small and slow-rising, and there were clear signs of mitral incompetence and aortic stenosis.

The pre-operative electrocardiogram, the patient being on digitalis, showed slow auricular fibrillation. There was no evidence of ventricular hypertrophy or infarction.

It is perhaps clear even from so abridged a clinical description that an operative attempt to dilate the aortic valve would carry an extremely heavy risk of serious coronary inadequacy developing during operation unless some artificial method of maintaining a satisfactory aortic pressure were available. Before it was available, operation

had in fact been refused on grounds of risk to life, and an attack of acute appendicitis had been treated conservatively (July, 1953) because of the high risk even of appendicectomy.

Operative Details

Operation (W. P. C.) was undertaken on December 9, 1953. After premedication with promethazine hydrochloride and pethidine, anaesthesia (Dr. John Beard) was induced at 2 p.m. with thiopentone and maintained with nitrous oxide, oxygen, and relaxants.

At 2.20 p.m. the superficial femoral artery and saphenous vein were exposed in the upper part of the right thigh. Seventy mg. (1 mg. per kg.) of heparin was then injected slowly. A 4-mm. (internal diameter) "polythene" catheter with multiple perforations was passed up the saphenous vein for a distance of 30 cm. so that its tip should lie in the inferior vena cava just above the diaphragm. On insertion of this catheter quite rapid bleeding occurred, through the perforations, before all the perforations lay within the vein. An obturator has now been devised for this catheter to prevent bleeding during its insertion and to be withdrawn when the venous catheter is in place. The venous catheter was held in place by a ligature around the vein, the distal vein being ligated. The artery was then controlled by two tapes and opened by a transverse incision. The arterial catheter, 2.5 mm. in internal diameter, was then passed up the femoral artery to a distance of 45 cm. so that its tip should lie within the arch of the aorta. A tape around the proximal artery and catheter was kept tight as a temporary ligature by an artery forceps. The distal artery was controlled by a bulldog clamp. Both catheters were in place at 2.40 p.m. and at 2.43 the pump was started at a rate of 500 ml. a minute; the pulse was not palpable at the wrist at this time. The chest was entered through a postero-lateral incision in the fifth intercostal space. Bleeding was not excessive, though the clotting-time was 30 minutes. At 3.10 the pericardium was opened to reveal a moderate excess of pericardial fluid and a very large tense left ventricle. The left atrium was aneurysmal and exhibited well-marked systolic pulsation. A systolic thrill was felt on the atrial wall below the inferior pulmonary vein, a coarse systolic thrill on the ascending aorta. Aortic valve closure was not palpable. The heart rate was now 84 and the radial pulse was just palpable and irregular. The pump rate was increased to 600 ml. a minute.

At 3.16 p.m. the heart was opened through the auricular appendage to reveal free mitral incompetence through a circular valve opening approximately 3 cm. in diameter. There was no stenosis of the mitral valve.

At 3.23 p.m. left ventricular cardiomy was performed, using a purse-string suture and Rumel's tourniquet. A guide wire was inserted through the ventricle and aortic valve into the aorta. The valve was fully dilated on three separate occasions with the triradiate Bailey dilator. No noticeable disturbance of heart rate or rhythm or any alteration in the force of the beat was detectable during these manoeuvres. The heart rate was 50-60 with periodic extra beats. The pump rate throughout this manoeuvre was maintained at 800 ml. a minute. At 3.30, after the dilatation, the aortic systolic thrill was noticeably less. Re-examination of the mitral valve did not reveal any noticeable alteration in the regurgitant flow of blood through the valve. At 4 p.m. both cardiomy wounds were closed with interrupted sutures and the pericardium was loosely stitched. The blood pressure in the arm was now 100 mm. Hg and the radial pulse was palpable. The rate of extracorporeal circulation was slowed progressively from 800 ml. to 500 ml. during closure of the cardiomy incision and was decreased still further to reach 300 ml. a minute at 4.20, when it was discontinued, after the pump had been in operation for 97 minutes.

The chest was kept open for three-quarters of an hour after completion of the cardiomy until the rather persistent oozing, noticed towards the end of the operation,

had ceased. At 5 p.m. the catheters were removed from the saphenous vein, which was ligated, and from the femoral artery, which was repaired with 00000 arterial silk. The groin incision was closed in layers, and 70 mg. of protamine sulphate was given intravenously as a 0.01% solution in isotonic saline. The clotting-time after operation was 6-8 minutes. The estimated blood loss during operation was 6 pints (3.4 litres); and $7\frac{1}{2}$ pints (4.3 litres) of blood, 4 pints (2.3 litres) of them freshly drawn, were given by transfusion. The pharyngeal temperature was 36.4° C. at the end of operation.

The mixed venous blood during the running of the machine showed an oxygen saturation of 78 to 76%, and a carbon dioxide content of 47-45 volumes %.

The serum potassium arose from a pre-operative level of 3.7 mEq/l. to a maximum of 6 mEq/l. during operation, falling again to 4 mEq/l. on the evening of operation.

At 6 p.m. the patient was returned to the ward already conscious; at 6.5 she asked what time it was.

Electrocardiographic Studies During Operation

A continuous E.C.G. tracing was run during the operation, and some 40 feet (12 metres) of this was recorded. We are indebted to Dr. J. F. Goodwin and Dr. L. G. Davies for its interpretation. At the beginning of the operation the electrocardiogram showed, as it did before operation, slow auricular fibrillation. This continued until 3.16 p.m., when during exploration of the left atrium the E.C.G. showed occasional ventricular ectopic beats from multiple foci, and auricular fibrillation. At 3.23, during dilatation of the aortic valve, there were various multifocal ventricular ectopic beats, some T-wave inversion following normal QRS complexes, and auricular fibrillation. At 3.30, following aortic-valve dilatation, occasional ectopic beats were seen. The QRS complex lost its Q and developed a deep S wave, with T still upright and taller than before. This was thought to be due either to a clockwise rotation around the long axis of the heart or perhaps to a diminution of left ventricular strain. Auricular fibrillation was still present. At 4 p.m. auricular fibrillation was still present, but there were no ectopic beats and the T waves had increased in height. No further change in the E.C.G. occurred while the chest was closed. At 10 p.m. slow auricular fibrillation was present as before operation, and the QRST complex had returned to normal.

Post-operative Course

On the evening of operation there was slight cyanosis of the lips, but the patient was fully conscious and in possession of all faculties two hours after operation. Cyanosis faded within four hours of the end of the operation.

Subsequent progress was uneventful, only 26 oz. (740 ml.) draining from the chest, but there was extensive ecchymosis of the chest wall round the thoracotomy incision and around the stab drain. Clinically the aortic systolic murmur is now softer and the patient has not experienced anginal pain such as was her chief complaint before operation. Convalescence has proceeded satisfactorily apart from a thrombophlebitis of the catheterized saphenous vein. Pulses did not return in the ankle of the limb whose femoral artery had been catheterized, but the limb remained warm and identical in appearance and temperature with its fellow of the opposite side. An improvement in exercise tolerance permits the climbing of 48 steps without undue distress. Previously completely bedridden, the patient can now walk many hundreds of yards. She has returned home and her exercise tolerance still improves daily.

Bleeding

Dr. S. J. Baker, of the department of haematology, has been our adviser on this subject, and has provided this report.

All workers in the field of extracorporeal circulation experience trouble with haemorrhage, both in experimental

animals and in human subjects. In this patient excessive bleeding occurred especially towards the end of the operation, even after the administration of adequate amounts of protamine to neutralize the heparin. This bleeding is explicable, at least in part, by the development of a thrombocytopenia. The platelet count (direct method) fell from a pre-operative level of 217,000 to 44,000 per c.mm. in the first half-hour after application of the machine. It remained at this level until several hours after the completion of the operation. Over the next eight days it gradually returned to the pre-operative level.

Immediately after operation the one-stage "prothrombin time" was normal, so factors V and VII were apparently still present in adequate amounts. Antihæmophilic globulin and Christmas factor were not tested for in this case, and it is possible that these may have been reduced.

There are three factors which may produce a deficiency of coagulation components: (1) the operation itself—coagulation factors, especially platelets, are sometimes reduced during major surgical procedures; (2) the "dilution" effect of replacing a considerable proportion of the patient's blood by stored "bank" blood, which contains no platelets and will probably be deficient in antihæmophilic globulin and factor V, to an extent depending on the length of storage; and (3) the machine, which, although lined throughout by silicone, causes marked loss of platelets presumably by adhesion to foreign surfaces and/or by mechanical destruction.

The most effective available method of correcting the thrombocytopenia in a patient at the end of a procedure such as this would appear to be the transfusion, or replacement transfusion, of a substantial quantity of platelet-rich blood freshly drawn into siliconed apparatus, or the use of a direct platelet transfusion. Bell and others (Bell, 1953; 1954) in Gibbon's unit have made an extensive survey of coagulation disorders arising after massive simple transfusion, and also during the course of extracorporeal circulation. Their work suggests that, apart from the thrombocytopenia, the "dilution" effects could be prevented by the use of blood not more than 48-72 hours old; but this may be difficult to achieve.

Conclusions

The pump-oxygenator previously described has been shown at least not to be productive of serious immediate toxic effects, and no delayed effects can be predicted on theoretical grounds.

It is our impression that the machine has been helpful when used to assist the circulation of a human patient throughout a severe cardiac operation which would not have been attempted without some kind of artificial help. Throughout the operation no anxiety was felt concerning the coronary circulation, as measured by the visible contraction of the ventricle and the electrocardiogram. Previous experience without the use of the machine has shown that even less severe aortic dilatations performed in patients less debilitated have been accompanied sometimes by irreversible disturbances of cardiac rhythm. There was never any threat in this case of cardiac cessation or ventricular fibrillation during two explorations of the left atrium and mitral valve, and three separate forcible dilatations of the aortic valve.

We have previously stated that the chief therapeutic use we saw immediately for this machine was its application to extreme cardiologic emergencies, and we propose to apply it to this purpose, for it is capable not only of increasing oxygenation but of reducing the blood carbon dioxide to any desired level, so avoiding the dangers of present methods of oxygen therapy in heart failure. We consider now, however, that this machine may also be used to open the way gradually towards the ultimate aim of a pump-oxygenator for routine total replacement at surgical operations. Rare congenital defects in infants are susceptible to open repair under vision with the assistance of cooling. In adults, selected cases of aortic stenosis may be treated

with every chance of improvement without the use either of cooling or of the extracorporeal circulation, but the most important aim of modern surgery is the direct correction under vision of the adult mitral valve, and this can be attained only by some form of assisted circulation.

It may be that one way of progressing towards this aim of a dry adult heart for the routine performance of surgery on its interior may be the use of an assisted circulation to take over in successive cases more and more of the circulation.

Experience will show what amount of aortic flow per minute is required for the maintenance of an adequate coronary and carotid circulation, but previous experience with pressure perfusion of the clamped aorta in emergency, by quantities of blood per minute small in proportion to the output of the pump, suggests that the necessary flow may not in fact be particularly high. On this occasion a flow of 500 to 800 ml. was maintained for a total period of 97 minutes, and it might be estimated that in that time there was a total flow of 70 litres through the machine. Alternatively, it might be said that the patient's total volume of circulating blood passed through the machine about 15 times, or that, for 97 minutes, the machine was responsible for 20 to 30% of the total cardiac output.

Bleeding during and after the operation is the most serious problem which we have to face, but we prefer the risk of bleeding as we experienced it in this patient to the still greater risk of clotting around the tubes of the machine at some critical stage of operation during which the patient's life might depend upon the efficiency of the artificial circulation. It seems reasonably certain that the bleeding we experienced was due in the main to platelet loss, though the effect of operation, transfusion of foreign blood, and the machine on clotting function is highly complex, and other factors certainly operate too. Methods are being developed for the collection of fresh blood rich in platelets; even fresh blood, drawn by routine methods, loses a high proportion of platelets in collection.

All the data collected concerning the effect of the machine have not been presented here—much of the material cannot be fully analysed until a series of cases is available for study. The management of collecting devices and the drill for the timing of samples require a large team of medical and technical staff, and the arrangements and control of apparatus, especially collecting apparatus in an operating-room already occupied by a complex surgical team, have been the subject of prolonged study and experiment.

We wish to acknowledge our indebtedness to many colleagues and assistants who have been concerned in this work and in the management of the case here reported. To the cardiologists at Hammersmith Hospital, including Dr. J. F. Goodwin and Dr. R. I. S. Bayliss, we owe a great deal of day-to-day advice and the pre-operative investigation and management of patients who are considered for this and other forms of surgery. We are indebted for help and advice in our electrocardiographic studies to Dr. J. F. Goodwin and Dr. L. G. Davies. Dr. S. J. Baker, of the department of haematology, has given much time and thought to our problems of coagulation and haemorrhage. Dr. John Beard, anaesthetist for thoracic surgery in the Postgraduate Medical School and Hammersmith Hospital, has been a most important member of the operative team, and has collaborated most helpfully. Mr. Ralph Shackman and the staff of the Surgical Research Laboratories have given us constant help, and Mr. Gerald Rainbow and Miss Eva Bottoms particularly have been unwearied in the maintenance of the machine. With New Electrical Products Ltd. we have explored now for a long period, and very happily, the technique of liaison between surgical and technological research; and Mr. J. Brown of that company has not only devoted endless time and skill to the original construction of the machine but has attended and studied its performance in the operating theatre. A second phase of this prototype apparatus embodying improvements which the function of this machine has suggested is now under construction; the cost of its development is being borne by a grant from the Nuffield Foundation. We have had assistance from the National Research Development Corporation in our plans for the machine's development.

INSULIN RESISTANCE FOLLOWING HYPOTHALAMIC LESIONS AND REMOVAL OF THE ADRENAL MEDULLA

BY

J. BEATTIE, M.D.

Strangeways Research Laboratory, Cambridge

It has long been thought that insulin-resistant diabetes might be associated with the presence of an insulin antagonist (Himsworth and Kerr, 1940). Resistance to insulin has been shown to develop in intact animals after the injection of purified growth hormone (Young, 1950) and of cortisone (Campbell et al., 1950) over periods of some days. The work of Bornstein and Park (1953) has shown that neither of these hormones is an insulin antagonist, but that both are necessary for the development in the intact animal of the insulin antagonism found in alloxan-diabetic rats. Bornstein (1953) found that the insulin antagonism was confined to a specific lipoprotein fraction of the serum of such rats. The serum from a human subject rendered hypoglycaemic by a large dose of insulin also exhibited insulin antagonism, while that from a normal human subject and from normal rats possessed no such activity.

Section of those pathways from the hypothalamus to the brain stem which mediate autonomic function produced no change in insulin sensitivity (Beattie and Chambers, 1953a), but when the adrenal medulla was removed from these rats they developed marked resistance to insulin. These experiments are described below.

Material and Methods

Male albino rats of a single strain and weighing between 200 and 250 g. at the start of the experiment were used. For five weeks before the experiments began they were kept at a constant environmental temperature of 29.5° C. Rats of the series 1 experiments were kept at this temperature throughout the experimental period. Rats of the series 2 experiments were kept at 29.5° C. until day 12 of the experiment, when they were transferred to a cooler environment with a mean temperature of 18° C.

The rats of each series were divided into four groups. Group A rats were unoperated controls. Group B rats had brain lesions inflicted on day 0. The adrenal medullary tissue was removed from the group C rats on day 7. Group D rats had brain lesions made on day 0 and the adrenal medullary tissue was removed on day 7. All rats were killed on day 21.

Each group of rats in series 1 was divided into four subgroups. The first subgroup was used to obtain resting blood-glucose and resting liver-glycogen values. The second subgroup was given an intraperitoneal (I.P.) injection of insulin (1 unit per kg. body weight) on day 21. Blood-

glucose concentrations were determined on blood samples taken before and 30 minutes after the injection. The third subgroup received an I.P. injection of glucose (1 mg. per g. body weight) on day 21. Blood-glucose concentrations were determined as in the previous group. Samples of muscle were taken before and 30 minutes after the injection, and a sample of liver also 30 minutes after the injection. These tissue samples were used to determine the glycogen content. The fourth subgroup received an injection of glucose and insulin at the above dose levels and by the same route. Samples of blood, muscle, and liver were taken as in the third subgroup. The rats of series 2 were used only to determine resting blood-glucose and liver-glycogen values and the response of the blood glucose to an injection of insulin. The insulin used in all the experiments came from the same batch and had been assayed for glucagon content.

The site of the brain lesions and the method of producing them have been described already (Beattie and Chambers, 1953b). The adrenal medulla was removed by incising the cortex and expressing the medulla by gentle pressure on the cortex. At the end of the experiment the glands were fixed and sectioned to confirm that no remnant of medullary tissue had been left within the gland.

The procedures at the end of the experiment were:

1. Food was withdrawn at 5 p.m. on day 20 but ample water provided.

2. Between 10 a.m. and 12 noon on day 21 the rats were anaesthetized by an I.P. injection of pentobarbitone sodium (40 mg. per kg. body weight).

3. When anaesthetized a blood sample (0.2 ml.) was withdrawn from the heart. The left gastrocnemius muscle was exposed, ligated near its origin, and a sample (approximately 0.4 g.) removed, avoiding any obvious tendinous tissue. After weighing on a torsion balance, the sample was dropped into 4 ml. of a hot (100° C.) solution of potassium hydroxide (30% w/v).

4. Immediately after removal of the muscle sample the injection of insulin, glucose, or glucose with insulin was given. The total volume of fluid injected did not exceed 0.6 ml. per 100 g. body weight.

5. Precisely 30 minutes after the injection a second blood sample was taken from the heart, and after its removal a sample of muscle was removed from the right gastrocnemius muscle and treated as before.

6. The abdominal cavity was opened and a sample of liver (approximately 0.4 g.) taken from the left lateral lobe and treated in the same way as the muscle samples.

Blood samples were deproteinized by the barium-zinc procedure and the glucose content was determined by the method of Nelson (1944). After the samples of muscle and liver had dissolved, the tubes were cooled and the glycogen precipitated by adding 7.2 ml. of absolute alcohol. After centrifuging, the supernatant fluid was discarded, and the precipitate dried and then dissolved in 10 ml. of distilled water. Glycogen was determined (as glucose) by the anthrone method of Seifter *et al.* (1950). The glycogen content of liver and muscle was expressed as grammes of glucose per 100 g. wet tissue.

Results

Effect of Insulin on Blood-glucose Level.—The mean resting blood-glucose concentrations were considerably lower in group D rats of both series than those of the other groups. Rats of group D in both series failed to show a hypoglycaemic response after the injection of insulin (Table I).

Muscle-glycogen Content.—The glycogen content of muscle was determined only on series 1 rats. Rats with brain lesions only (group B) had a resting content of glycogen which was not significantly different from that in the control group. After removal of the adrenal medulla (group C) the resting level of glycogen was lower in one set of experiments and equal to that of the control rats in another set. Group D rats had a resting content significantly lower than that of the control group (Tables II and III). After the injection of glucose the glycogen con-

Dose of glucose, 1 mg. per g. body weight. Dose of insulin 1 unit per kg. body weight. Values in parentheses under the mean glycogen content of liver are mean resting values from Table IV.

tent of muscle rose by almost the same amount in groups A, B, and C, but that of group D remained unchanged (Table II). When insulin and glucose were given the glycogen content rose again in groups A, B, and C, but not in group D. The blood-glucose levels fell in groups A, B, and C, but rose in group D by the same amount as it had when glucose alone was given (Table III).

Liver Glycogen.—The resting glycogen content of the liver in series 1 rats was not significantly different in groups A and B. The mean content in group C was significantly lower than that of groups A and B. Rats of group D had

a very low content equal to about 15% of that in the control group. After exposure to cold conditions for nine days all liver glycogen values were markedly reduced. Group C rats again had a lower mean content than the control group and those of group D an extremely small amount (Table IV).

TABLE IV.—Resting Glycogen Content of the Liver and Blood-glucose Levels

Group	Operation	No. of Rats	Series 1 Environmental Temp. 29.5° C.		Series 2 Environmental Temp. 18° C.	
			Blood Glucose Mean ± S.E. mg./100 ml.		Liver Glycogen Mean ± S.E. g./100 g.	
A	Control	8	111 ± 5.3	0.962 ± 0.042	96 ± 5.9	0.073 ± 0.010
B	Lesions	8	103 ± 4.7	1.178 ± 0.061	98 ± 4.0	0.073 ± 0.008
C	Adrenal medulla removed	8	106 ± 5.7	0.658 ± 0.037	115 ± 5.8	0.045 ± 0.005
D	Lesions and adrenal medulla removed	8	78 ± 4.9	0.120 ± 0.008	73 ± 4.1	0.011 ± 0.004

All determinations were made on day 21 of the experiment. Series 2 rats had been exposed for 9 days to an environmental temperature of 18° C. from day 12 to day 21.

Body-weight Changes.—The differences between the mean weight at the start of the experiment and that on day 21 are given in Table V. Series 1 rats all showed an increase in weight which was not significantly different between

TABLE V.—Changes in Body Weight During the Experimental Period

		No. of Rats	Mean Change of Weight ± S.E. g.	No. of Rats	Mean Change of Weight ± S.E. g.
A	Control	28	+24 ± 7.6	16	+20 ± 5.2
B	Lesions	21	+20 ± 5.8	19	1 ± 4.2
C	Adrenal medulla removed	25	+22 ± 8.6	18	+5 ± 9.6
D	Lesions and adrenal medulla removed	23	+13 ± 11.7	15	7 ± 10.1

The change in body weight is the difference between the weights of rats on day 0 and those on day 21.

groups. The control rats of series 2 had the same overall weight increase as the corresponding group in series 1. Rats of groups B and C maintained their starting weight, and those of group D showed a slight fall below the weight at the beginning of the experiment.

Discussion

Rats of series 1 (kept at 29.5° C.), which had brain lesions and were without any adrenal medullary tissue, showed no hypoglycaemic response after the injection of insulin and were unable to increase the glycogen content of muscle either in the presence of a slight hyperglycaemia following the injection of glucose or when insulin was given with glucose. Rats with either no adrenal medullary tissue or with brain lesions responded to these various injections of insulin, glucose, and insulin with glucose in the same way and to the same degree as the control rats. The glycogen content of the liver in rats on whom both operations had been done was much reduced. These findings suggest that an insulin antagonist was present in the rats with brain lesions and without adrenal medullary tissue, and that this antagonist was probably inhibiting the hexokinase system.

Bornstein and Park (1953) found that the insulin antagonism shown by the serum of alloxan-diabetic rats was

reversible by insulin in a concentration of 0.1 unit per ml. in the medium in which the isolated diaphragm from a normal rat was suspended. If the test muscle was taken from an alloxan-diabetic rat and suspended in serum from such a rat then insulin in this concentration failed to produce complete reversal of the insulin antagonism. Krahl (1951) had already pointed out that reversal of insulin antagonism was possible, provided there was enough insulin available. In the present experiments insulin was given in a dose of 1 unit per kg. body weight. Assuming that all the insulin was distributed over the extracellular fluid of the rat, and that this space forms about 28% of the weight of the rat, then the maximum concentration of insulin in the fluid bathing the muscle cells could not have exceeded 0.1 unit per 28 ml. if the insulin were evenly distributed throughout the space. It was probably much less. Rats of groups A, B, and C responded to this low concentration of insulin by increasing the muscle glycogen content, but the rats of group D did not. It would appear, therefore, that the insulin resistance exhibited by rats of group D would require an extremely high concentration of insulin for its reversal.

Bornstein and Park (1953) demonstrated that the presence of both growth hormone and cortisone was essential for the development of insulin antagonism in the serum of the hypophysectomized and alloxan-diabetic rat. If either or both hormones were added to normal serum no insulin antagonism was developed in that serum. If the insulin antagonism found in the rats of group D was of the same type as that found by Bornstein and Park, it would require both hormones for its development. The data in Table V leave no doubt that rats kept at 29.5° C. with brain lesions and with no adrenal medulla were able to increase their weights over a period of 21 days. It may be presumed, therefore, that these rats produced growth hormone at a rate at least as great as that of normal rats. These rats, too, showed no evidence of adrenal cortical deficiency, and normal cortical tissue was found in all the adrenal glands examined. It is reasonable to infer that these rats were producing, in quantities at least sufficient for normal existence, both corticotrophin (A.C.T.H.) and adrenal cortical steroids. Thus there is reason to believe that the two hormones necessary for the production of insulin antagonist of the Bornstein and Park type were present in rats of group D.

The mere differences in body weights recorded on day 0 and on day 21 do not give a true picture of the pattern of weight change. When brain lesions of the type inflicted in the present experiments are made there is a loss in body weight of about 20 g. during the first four days after the operation. This loss is made good by the end of the ninth day (Beattie and Chambers, 1953b). Removal of the adrenal medulla is followed by weight loss of about the same amount and is repaired in about the same time. Rats in group D thus repaired a total post-operative weight loss of about 40 g., and in addition increased their body weight by 13 g. above that on day 0. The true increment of weight in group D rats during 21 days was thus about 53 g., as compared with a weight increase in control rats of about 24 g.

Rats exposed to cool conditions (18° C.) react to these conditions by increasing heat production. Normal rats increased their oxygen consumption by 8%, those with brain lesions by 13.5%, rats without adrenal medulla by 15%, and rats without adrenal medulla and with brain lesions by 22% (Beattie and Chambers, 1953c). Thus after single operations (groups B and C) a weight loss of about 20 g. was repaired in spite of an increased oxygen consumption of 13.5–15%. The rats of group D regained almost all the weight loss after the two operations in spite of a rise in oxygen consumption of 22%. It would therefore not be unreasonable to presume that the rate of growth-hormone production, and probably also that of adrenal cortical steroids in the group D rats, was greater than that in normal rats under the same environmental conditions.

The exact role of the hypothalamus in the control of production of growth hormone and of corticotrophin (A.C.T.H.) is still obscure. Information derived from the effects of lesions in experimental animals and from the effects of tumours in man is equivocal. For example, Spiros (1954) found that moderate-sized lesions of the hypothalamus (area unspecified) were followed by increased insulin sensitivity which could be countered by injections of growth hormone. Paton and Petch (1954) reported hyperglycaemia, a diabetic type of glucose-tolerance curve, and reduced sensitivity to insulin in a human subject in whom a brain tumour involving the hypothalamus (area unspecified) was discovered at necropsy. It would be valueless to attempt to explain the present findings in terms of hypothalamic function when such a conflict of evidence exists.

The interest of the present experiments lies in the fact that insulin resistance was produced in rats without destruction of pancreatic islet tissue and without the continued injection of hormones. Moreover, no direct damage was caused to the cell masses of the hypothalamus by the division of the fibre tracts leading from the hypothalamus to the brain stem. Late chromatolytic changes were seen in certain cell masses which could with certainty be attributed to the section of the efferent fibres from them. Neither of the two operative procedures used in the production of insulin resistance had any demonstrable effect on insulin sensitivity. The insulin resistance which followed when both operations were done on the same rats was present 21 days after infliction of the brain lesions and 14 days after removal of the adrenal medulla. It is therefore improbable that the insulin resistance could be due to some irritative action set up by the operative procedures.

If the insulin resistance induced in these rats were due to the presence of an insulin antagonist—and the evidence is consistent with this assumption—then the possibility that insulin-resistant diabetes might arise from a cause or causes which do not involve primarily either the pancreas or the pituitary gland must receive serious consideration.

Summary

After section of the pathways from the hypothalamus to the brain stem and removal of the adrenal medulla, rats kept at an environmental temperature of 29.5° C. showed no fall in the blood-glucose level 30 minutes after the injection of insulin in a dose of 1 unit per kg. body weight. Removal of the adrenal medulla alone or section of the hypothalamic pathways produced no change in insulin sensitivity.

The resting content of glycogen in muscle (gastrocnemius) was significantly lower than normal in rats with the hypothalamic lesions and without adrenal medullary tissue. The glycogen content did not rise after the injection of glucose (1 mg. per g. body weight) or after the simultaneous injection of glucose and insulin. The glycogen content of the liver was markedly reduced (15% of normal) in the resting state. When such rats were exposed to cold for nine days they still displayed no hypoglycaemic response to the injection of insulin. The glycogen content of the liver in the resting state was reduced to 11 mg. per 100 g. of liver.

The experimental data suggest that the insulin resistance found in these rats was due to the presence of an insulin antagonist.

It is a pleasure to thank those who have made this work possible. Dr. Honor B. Fell placed laboratory facilities at my disposal, Mr. F. G. Moore and Mr. H. N. Smith made it possible to acquire most of the necessary equipment, and the Medical Research Council met part of the cost of technical assistance. I am indebted to Mr. R. D. Chambers for carrying out the major portion of the technical work.

THE OCCURRENCE OF ELECTROCORTIN IN HUMAN URINE

BY

C. L. COPE, D.M., F.R.C.P.

AND

J. GARCIA-LLAURADO, M.D.

British Council Scholar

(From the Department of Medicine, Postgraduate Medical School of London, W.12)

The discovery by Grundy, Simpson, and Tait (1952) of a new hormone, called electrocortin,* which has the ability to increase both sodium retention and potassium excretion by the kidney, must inevitably give a new impetus to the study of the many conditions associated with sodium retention in man.

In recent years several workers have found evidence of the occurrence in certain human urines of a substance having the power to increase sodium retention by the kidney; but careful analysis of extracts of such urines by modern chromatographic methods has failed to reveal any evidence of the presence of deoxycortone, the only steroid hitherto known to possess such sodium-retaining properties in marked degree. It now seems likely that the sodium-retaining effects observed by earlier investigators were due to the presence in the extracts of this new hormone, electrocortin.

Most of the original observations suggesting the presence of a sodium-retaining principle in urine were made by Deming and Luetscher (1950). Using a method of bioassay on young adrenalectomized rats, they found that chloroform extracts of some human urines had the power, when injected, of reducing sodium excretion by the kidney. Under the conditions of their test deoxycortone acetate in doses of 5 to 25 µg. per rat had a similar effect, but larger doses of extract did not give greater sodium retention. In their earlier experiments evidence for the existence of a sodium-retaining substance in normal urine was equivocal, but a significant degree of activity was found in extracts of the urine of five out of eight patients with cardiac failure. In one patient with nephrosis a high titre of activity was also found. An extension of these observations was reported by Luetscher *et al.* (1952), who then found that the titre of sodium-retaining substance was high in the oedematous stage but fell to normal levels after diuresis with elimination of the oedema.

In 1953 Singer and Venning also found some evidence of sodium-retaining activity in extracts of nephrotic urine, and McCall and Singer (1953) found a sodium-retaining substance in eight out of nine nephrotic chil-

*The chemical formula of electrocortin has just been published by Simpson, Tait, Wettstein, *et al.* (*Experientia*, 1954, **10**, 132). It proves to be a steroid similar to corticosterone, but with an aldehyde grouping on C 18.

dren when they were gaining weight, though it was present in only one out of six when weight was stationary and the patients were no longer retaining sodium.

Chart and Shipley (1953) have claimed to detect a sodium-retaining factor excreted by normal adult males, the daily amount being equivalent in activity to 40 to 80 µg. of deoxycortone. They found that patients with hepatic cirrhosis and ascites showed a high excretion equivalent to as much as 3,162 µg. daily, although when ascites was absent excretion was normal. These workers also obtained some evidence that the active principle differed from deoxycortone itself, for they noted that it entered the aqueous phase when partitioned between benzene and water, whereas deoxycortone itself tends to enter the benzene phase freely. They suggested that it is probably associated with the so-called amorphous fraction of the adrenal cortical extract.

In 1951 Zaffaroni and Burton made a careful analysis of the steroids in adrenal cortical extract, employing their own particularly suitable and sensitive methods of paper-partition chromatography. They were able to find small amounts of deoxycortone in aqueous extracts of adrenal cortex, but could not find any trace of the hormone in chloroform extracts of human urine made at pH 1. Since a large part of the cortisone and hydrocortisone (compound F) content of such urines is extracted by chloroform at this pH it seems likely that any deoxycortone present would also be extracted in this way.

In 1952 Grundy *et al.* first published their evidence for the existence of a hitherto unrecognized hormone in the adrenal cortex causing sodium retention by the kidney. They were able to show that the new hormone was quite distinct from deoxycortone, for there was a great difference in the rates at which the two substances ran on paper chromatograms. In the toluene/propylene-glycol system of Burton, Zaffaroni, and Keutmann (1951) it ran at a rate almost exactly the same as cortisone, whereas deoxycortone ran very much faster. The activity in the cortisone zone was much greater than could be accounted for by the activity of the small amount of cortisone actually present there.

Simpson and Tait (1953) have reviewed the further intensive work they have done on this new hormone. They find that it is a reducing steroid having from 50 to 90 times the activity of deoxycortone on an equimolecular basis. The culmination of this work has been the isolation of the new hormone in the form of crystals by Simpson, Tait, Wettstein *et al.* (1953). Desaulles *et al.* (1953) have tested this purified preparation and found it to be 25 times as potent as deoxycortone on sodium retention and five times as active in increasing potassium excretion. An independent account of the properties and isolation of this hormone has been published by Mattox *et al.* (1953).

In the work presented here we have employed the assay procedure developed by Simpson and Tait for electrocortin activity to look for this hormone in human urine extracts. Our results suggest the presence of a small amount in normal urines. In addition a patient has been found who was shown on several occasions to be excreting large quantities of a substance having the special properties of electrocortin but who showed no evidence of sodium retention.

Methods

The rats used in these experiments were young of an albino strain bred in the department and weighing 60 to

80 g. Bilateral adrenalectomy was performed by the dorsal approach under ether anaesthesia. Only animals whose adrenals were removed unbroken were used. After operation the animals were fed a stock diet of "research" rat cubes and drank unrestricted 1% saline solution. Assays were carried out on the fourth day after operation. Each group of test animals consisted of five to seven rats and a control group of the same size was used on each day of testing. In preliminary experiments it was observed that variations between control groups from one week to another were greater than the differences between males and females. For this reason both male and female rats have been used in these experiments, though all animals in any one assay were of the same sex. Control and test animals were mixed in the cages to avoid variations due to the order in which the animals were handled.

In the earlier experiments survival time after withdrawal of saline was determined as evidence of completeness of adrenalectomy, but survival, implying an incomplete adrenalectomy, was so rarely observed that this was finally abandoned as a routine. The rats were allowed to continue drinking saline until the morning of the test day.

For each test four groups of five to seven rats were taken. The first group served as controls, the second group all received 10 µg. of deoxycortone, and the third and fourth groups were injected with different quantities of the extract to be tested. All injections were made up to a volume of 0.1 ml., the solvent being 20% ethanol in water. The control group received solvent alone. The injections were made at about 10 a.m. on the morning of the test. One hour later the bladders of all rats were emptied by suprapubic pressure combined with a light inhalation of ether. After this, a subcutaneous injection of 1 ml. of a mixture containing 73 µg. of Na²⁴ and 295 µg. of K⁴² was made, the total radioactivity of the injected dose at the time of assay being about 60 µC. Immediately after injection each rat was placed in a separate 500-ml. beaker fitted with a raised wire mesh. All beakers had previously been cleaned with chromic acid and distilled water.

Three hours after the injection the rats were made to urinate by the method described above, all urine being collected in the beaker. Although every effort was made to get complete emptying of the bladder, this was not essential to the accuracy of the test. The beakers and wire meshes were carefully rinsed with 5 ml. of distilled water projected against the walls by means of a syringe and needle. The washing fluid was collected in a small bottle. The ratio between Na²⁴ and K⁴² concentration was determined in each sample by a method essentially similar to that of Tait and Williams (1952) and Simpson and Tait (1952) which involves measurement of the intensity of radiation with and without a thin aluminium screen.

Some modifications of the detail of the method were made. Only 0.2 ml. of the diluted urine sample was used for the radioactivity measurement, since this gave a sufficient number of counts a minute, from 5,000 to 10,000. This 0.2-ml. sample was placed on a disk of thin filter paper fitted into a nickel planchette 25 mm. in diameter. With the uniform distribution of this fluid thus obtained the radioactivity count could be made without drying the sample. Direct comparison showed that there was no significant difference between this wet method of counting and the method with dried samples used by Simpson and Tait. Counts were made on each sample, both with and without a filter screen composed of six sheets of 5/1000 in. (0.13 mm.) aluminium, and using a Geiger-Müller tube, G.E.C. type Z B 7, v.v. 1400.

From the ratio of unfiltered to filtered counts the relative proportions of Na²⁴ and of K⁴² in the sample could be derived by reference to a calibration curve constructed from mixtures of the two isotopes in known proportions. The degree of activity of the sodium-retaining factor in the extract under test was indicated by the fall in the ratio of Na²⁴ to K⁴² in the urine sample excreted after the injection,

this ratio being expressed as a percentage of the mean figure obtained for the control group on the same day.

The principle of measuring the Na/K ratio rather than the actual excretion rate of either sodium or potassium alone was introduced by Simpson and Tait, and has several important advantages. It eliminates the need to collect and measure accurately the whole urine sample excreted by each rat. To achieve this reliably Singer and Venning had to ligate the urethras of all their rats and sacrifice them to obtain the bladder urine. When only the ratio is required completeness of collection is much less important. The rats were not sacrificed in our assays, but were used again two days later for similar assays, using another method with Na^{24} and K^{42} with subsequent estimation of the Na/K ratio by means of the flame photometer. In this paper only the results obtained by the isotope method are considered. A comparative study of the results obtained by the isotope and two other methods will be published elsewhere.

Preparation of Urinary Extracts

Owing to our uncertainty about the stability of the sodium-retaining principle, the extraction procedure was deliberately made as simple as possible to minimize the risk of destruction. Twenty-four-hour samples of urine were collected without preservative. These were extracted by manual shaking with 15 volumes per 100 ml. of urine, repeated four times with fresh lots of chloroform. No acidification of the urine was done before extraction, the pH usually being between 6 and 7. The chloroform extract was evaporated to dryness under reduced pressure, using a water bath at 50° C. Suitable aliquots were obtained by dissolving the residue in a small known volume of fresh chloroform, dividing this into small tubes, and blowing off the chloroform with a stream of nitrogen. For injection into rats the residue was dissolved in 20% ethanol in water, the volume being so chosen that the dose to be injected into each rat was contained in 0.1 ml. solution.

All extracts were stored dry until the day of assay.

Results

Under the conditions of our experiments a linear relationship was found between the $\text{Na}^{24}/\text{K}^{42}$ ratio, expressed as a percentage of the mean figure for the control group, and the logarithm of the dose of deoxycortone injected. This relationship was found over the range of dose from 5 to

Fig. 1.—Effect of deoxycortone acetate. Linear relation between log. dose and percentage drop in $\text{Na}^{24}/\text{K}^{42}$ ratio.

5 μg . per rat, and is shown in Fig. 1. Below 5 μg . per rat a linear relationship was not found, the ratio rising above the control level. In this respect our observations confirm the finding of Forsyth (1953) that very small doses of deoxycortone may actually have a sodium-excreting effect. Because of this excreting effect activities equivalent to amounts of deoxycortone less than 5 μg . could not be detected. It was considered desirable, therefore, to test all extracts at two dosages in order to increase the likelihood of obtaining an optimum content of the sodium-retaining substance. In this regard it is of interest that previous workers have usually failed to establish any quantitative relationship between size of dose and degree of response. Thus Luetscher *et al.* (1952) had found that

increases in dose much above the equivalent of 20 minutes' urine output by the patient did not regularly yield a proportionate increase in response. Singer and Venning have also found sodium-retaining activity in the urine from some patients with nephrosis but had failed to get a bigger response with a larger dose of extract.

Five normal subjects have therefore been studied by injection of half-hour equivalent and of three-hour equivalent of urine extract into separate groups of six test rats. A sixth normal subject was also studied at the half-hour dose only. In four of the six subjects tested at the half-hour dose the ratio was depressed to 80% or less of the control level. An elevation of the ratio occurred in the other two (Fig. 2). This rise could have been due to a sodium-

Fig. 2.—Extracts of normal urine. Mild depression of $\text{Na}^{24}/\text{K}^{42}$ ratio.

excreting effect of a very small dose of the active principle present in the extracts and comparable to the sodium-excreting effect of small doses of deoxycortone observed both by Forsyth and by ourselves. Support for this interpretation is found in the fact that both these extracts produced effective and significant depression of the ratio when given in the three-hour dose. With the other three extracts tested at both dose levels no significantly greater activity was observed at the higher dose than at the lower. Our experience of these extracts is thus the same as that of Luetscher *et al.* (1952) and of Singer and Venning (1953).

Since the $\text{Na}^{24}/\text{K}^{42}$ ratio can readily be depressed to a much lower figure by a sufficient dose of deoxycortone it would seem that the active principle whose effect is being observed in normal urine has very different pharmacological properties from deoxycortone itself. The results thus indicate the frequent presence of a sodium-retaining factor in chloroform extracts of normal urine, but they do not provide enough evidence on which to base an estimate of the amount present in terms of deoxycortone activity. Thus by reference to the deoxycortone calibration curve in Fig. 1, extracts C and E have respectively 4.5 and 6.5 μg . equivalents per half-hour sample. These figures correspond to 24-hour outputs of 216 and 312 μg . of activity expressed in terms of deoxycortone. On the basis of the three-hour assay, however, the same extracts showed activity indicating a daily output of active substance equivalent to only 40 and 35 μg . of deoxycortone respectively. Under such circumstances the assays are of little more than qualitative value.

They do serve, however, to show that such urinary extracts contain a principle which qualitatively alters the electrolyte excretion by the kidney. Methods of assay hitherto used have measured the effect on the rate of excretion of sodium only. Any factor in the extracts which may be toxic to the kidney and may cause a temporary impairment of renal function is likely to give a reduction in sodium excretion and thus, by a non-specific reaction, to suggest the presence of a specific sodium-

retaining factor. Any temporary impairment of renal function which may result from injection of the extracts is much less likely to affect the ratio of sodium to potassium. Changes in this ratio may be regarded, therefore, as a more reliable indication of the presence of a specific factor than will reduction in the rate of sodium excretion alone.

These results on normal urines may be contrasted with comparable assays on four patients suffering from rheumatoid arthritis. Extracts of the urine from these patients gave no indication of the presence of a sodium-retaining factor at either the half-hour or the three-hour dose. In Fig. 3 each column represents the mean effect on batches of five rats for each extract as compared with control groups of the same size.

Fig. 3.—Extracts of urine from patients with rheumatoid arthritis. Failure to influence $\text{Na}^{24}/\text{K}^{42}$ ratio.

In three patients suffering from congestive cardiac failure with gross oedema, results were less consistent. Subject P, with recurring ascites associated with severe tricuspid incompetence, showed no activity at two- or three-hour dosage. Subject F, losing oedema under mersalyl therapy, showed no activity at either half-hour or three-hour dose. On the other hand, subject M, with chronic congestive failure not improving under treatment, showed considerable sodium-retaining activity at the three-hour dose on two occasions.

These results on cardiac subjects merely confirm the findings of earlier workers that a sodium-retaining factor is present in human urine at certain times, but they do not assist in the prediction of the conditions under which it is likely to appear. Under such circumstances it is difficult to define more closely the properties of this elusive principle and to determine whether these properties coincide with those of electrocortin.

We have made several attempts to increase the output of this principle in urine to more manageable levels. The

Fig. 4.—Effect of various extracts on $\text{Na}^{24}/\text{K}^{42}$ ratio (see text). Electroecortin in "eucortone."

maintenance of a normal subject for a week on a diet containing less than 0.5 g. of sodium daily did not result in any detectable amount of the sodium-retaining factor in a subsequent urine extract. Similarly, the urine of a patient maintained on large doses of A.C.T.H., which was shown to have provoked a large increase in hydrocortisone output, did not show any significant activity. Thus neither of these procedures seems to lead to an increased output of the sodium-retaining factor (Fig. 4).

Detection of Electrocortin

Electrocortin can be distinguished clearly from deoxycortone by the rate of its flow on paper chromatograms. When the toluene/propylene-glycol solvent system is used electrocortin flows at almost the same rate as cortisone. While several other steroids have similar rates of flow in the chromatogram, it is very improbable that any other will combine a similar rate of flow on paper with a high degree of sodium-retaining activity. The demonstration of both these properties in an extract will thus establish the presence of electrocortin with a high degree of probability.

The most easily available source of electrocortin at present is commercial adrenal cortical extract. Using the Burroughs Wellcome preparation "eucortone," we were readily able to show that it contained strong sodium-retaining activity. When eucortone was added to urine samples and chloroform extracts were then made in the usual manner, these extracts also had strong sodium-retaining activity in our test. This activity ran in the cortisone zone. Though quantitative conclusions could not be reached it was clear that when electrocortin was added to urine a large proportion was recovered by the extraction procedure we were using (Fig. 4).

The chance discovery of a patient who proved to be excreting continually large amounts of the sodium-retaining substance in her urine has luckily enabled us to establish the approximate rate of flow of the principle on paper chromatograms and to show that this is the same as electrocortin.

The subject, Mrs. A, was a West African negress, aged 41, who was under investigation by Dr. M. D. Milne because of recurrent attacks of severe muscle weakness, which were found to be due to low serum potassium. Balance experiments conducted by Dr. Milne showed that she suffered from a very severe potassium-losing condition, apparently due to a renal tubular anomaly which was associated with a chronic pyelonephritis. Blood urea and pyelogram were normal; albuminuria varied between 1 and 3 g. per litre. At no time was there any oedema or other clinical evidence of sodium retention. Careful balance experiments showed that she was neither retaining nor losing sodium at the time of study. The full clinical history of this case with extensive electrolyte investigations is being published (Milne, 1954).

Three separate urine collections from this patient were tested and all showed strong sodium-retaining activity—much greater than we had encountered in any other subject. Depressions of the $\text{Na}^{24}/\text{K}^{42}$ ratio with both half-hour and three-hour doses of extract are shown in Fig. 5. One of these highly active extracts, analysed for cortisone and hydrocortisone content by the chromatographic method described by Cope and Hurlock (1953), was found to contain 57 μg . of cortisone and 11 μg . of hydrocortisone a day. Thus a three-hour aliquot of this extract contained about 8 μg . of the combined hormones, a quantity much too small to influence the $\text{Na}^{24}/\text{K}^{42}$ ratio in the tests. As may be seen from Fig. 5, an injection of 30 μg . of cortisone acetate per rat produced no detectable alteration in the ratio.

A sample of this extract equivalent to 48 hours' urine output was submitted to paper partition chromatography, using the toluene/propylene-glycol system. After a run of 72 hours most components of the extract had run off the bottom of the chromatogram, there being retained on the paper only those as polar as, or more polar than,

cortisone. Two zones were cut out from the chromatogram, one corresponding to the cortisone level (E) and the other to that of hydrocortisone (F). Both were separately eluted from the paper with methyl alcohol. The eluted fractions after evaporation of the methyl alcohol were then tested in the usual manner. The cortisone fraction showed a strong sodium-retaining activity, whereas no activity

FIG. 5.—Strong electrocortin-like effect of urine extracts from Mrs. A. Activity confined to cortisone zone in the paper chromatogram.

was found in the hydrocortisone zone (Fig. 5). Thus the activity could be regarded as being due to electrocortin with a high degree of probability, the likelihood of any other substance combining a similar biological action with the same rate of flow on the chromatogram being extremely small.

Conclusions

The results obtained on normal urine extracts suggest the presence of small quantities of a substance having electrocortin-like properties, but they do not provide enough evidence on which to base any reliable estimate of the quantity present.

In contrast four urines from patients with rheumatoid arthritis all failed to show the presence of such a substance. It would be unwise to draw any conclusions from these relatively few cases, but, in view of the suggestions of Selye (1950) that disturbance of mineral corticoid production may play a part in the aetiology of rheumatoid arthritis, it is clearly of importance to determine whether such an absence of electrocortin from the urine is a regular feature of rheumatoid arthritis.

From the finding of activity in one of three patients with congestive cardiac failure examined no conclusions can be drawn. Although a high and maintained output of electrocortin by Mrs. A was demonstrated, it cannot be claimed that this throws any light on the nature of the peculiar renal and metabolic defect she was found to have. It is of great interest that in this patient there was ample proof that no sodium retention was taking place, and it must be concluded, therefore, that a high titre of electrocortin may occur in the urine in the absence of any sodium retention. Previous workers have claimed to find evidence of a sodium-retaining substance most readily in patients who were actively retaining sodium at the time. The fact that this patient was losing large amounts of potassium may, however, be of significance. It is at present quite unknown what are the relations between the level of steroid in the blood and the rate of excretion in the urine. Indirect evidence from the behaviour of hydrocortisone and allied steroids suggests that a rise in blood concentration is followed by a prompt increase in excretion. It is natural to assume, therefore, that a high output of electrocortin in the urine indicates a high concentration of this hormone in the blood, since it also is probably a very similar steroid. It is possible, however, that electrocortin may be bound

to protein or even to potassium salts, so that its excretion rate is determined more by permeability changes in the kidney or by potassium output than it is by the concentration in the blood. In the present state of our knowledge of this hormone, however, any such suggestion must be purely speculative.

While this work was being prepared for publication a report appeared stating that Luetscher and Johnson (1954) have also been able to show that the sodium-retaining substance they find in the urine of nephrotic subjects runs on the paper chromatogram at a rate similar to that of cortisone. This substance also is therefore presumably electrocortin. Much work remains to be done before the significance of a high excretion of this new hormone by the human subject can be properly judged.

Summary

A substance having the power to increase sodium retention by the kidney has been found in large amount in the urine of a woman suffering from a severe potassium-losing condition. Other properties of this substance suggest that it is the adrenal hormone electrocortin.

Indications of the presence of a similar active substance in small amount in normal human urine have been found. No such active principle could be detected in four patients suffering from rheumatoid arthritis.

Our thanks are due to Dr. J. E. F. Bradley and D. G. Arnott for advice on the handling of isotopes, and to Miss Mary Standing for much technical aid.

A medical school will form part of the Rhodesia University College at Salisbury, Southern Rhodesia, plans for which are now rapidly maturing. Last autumn the college's inaugural board visited London and discussed the college's foundation and constitution with H.M. Government, the Inter-University Council, and London University. As a result a capital grant of £1,250,000 towards the cost of its building and equipment has been promised from Colonial Development and Welfare funds, subject to the balance of the total capital cost (estimated at £2,000,000) and the annual maintenance costs (over £250,000) being found locally. The city of Salisbury has provided 458 acres as a site for the college. Land will be available near the new Salisbury Native Hospital for a medical school, and about 1,000 acres for an experimental farm. The first faculties to be established will be those of arts and science, and after that faculties of agriculture and medicine. The college will provide education for London University degrees and will be open to students of all races without discrimination. It is hoped that the college will be ready for teaching to begin early in 1956.

A DANGER OF PEPTIC ULCERATION

A SURVEY OF EIGHT CASES COMPLICATING SURGERY AND TRAUMA

BY

P. A. LANE ROBERTS, M.Ch., F.R.C.S.

Senior Surgical Registrar, Guy's Hospital

In the last seven years eight patients have been observed whose convalescence from surgery and trauma had been interrupted by the appearance or the recrudescence of peptic ulceration. Of these eight patients five died, four as a direct result of their ulcers. It is therefore a complication to be feared, whether the preceding trauma be strictly causal or not. A connexion between trauma and ulceration has long been known, and has been recorded in the literature.

Curling (1842), inspired by the observations of Cooper (1839) and Long (1840), collected 11 cases of ulceration following burns, four of which he had treated in person in the wards of St. George's Hospital. Billroth (1867) first reported ulceration following operation, citing a case of death from gastro-intestinal haemorrhage on the sixth day after an operation to decompress a large retrosternal goitre. Von Eiselsberg (1899) described eight cases of ulceration, five fatal, mainly after operations for strangulated hernia. Busse (1905) and von Winiwarter (1911), from the same clinic, developed the theme; the latter collected 30 cases of gastro-intestinal haemorrhage after operations other than on the bowel, 17 of which were fatal.

Cushing (1932) described ulceration and necrotic mucosal lesions following intracranial operations and disease. He believed these to be due directly to lesions in the hypothalamus, and he instigated animal experiments, such as those of Hoff and Sheehan (1935), to corroborate this belief.

Penner and Bernheim (1939), in their study of the pathological changes in "shock," disputed Cushing's conclusions, and ascribed the ulcerating lesions to the non-specific stimulus of the shock. Herbut (1945) and McDonnell and McCloskey (1953) investigated the frequency of acute peptic ulcers in necropsies on patients dying within two months of operation, and found an incidence greater than could be explained by chance.

There have been sporadic reports of cases following trauma, such as those by Griffiths (1922), Ramond and Chêne (1932), and Gray (1945). There can be little doubt, therefore, that there is a relationship between peptic ulceration and the trauma both of accident and of operation. The cases here reported show that peptic ulceration may follow or be reactivated by injury and operation; that it may present as bleeding, penetration, or perforation; and that it may cause death, or be an incidental finding after death. A knowledge of this complication will result in its more frequent recognition and in the undertaking of the early and energetic treatment which it demands.

Case 1

A wizened man of 68 was admitted to Guy's Hospital on November 30, 1946, with a four-years history of indigestion and epigastric pain. Operation had been advised in June, as radiography had revealed a large gastric ulcer, which was probably malignant, but he had refused it. Later his symptoms had compelled him to change his decision.

On December 19 Mr. Grant Massie performed a high subtotal gastrectomy for a large carcinomatous gastric ulcer involving the pancreas. Progress was satisfactory until the evening of the fourth day, when there was a sudden onset of upper abdominal pain and rigidity, and the patient became shocked. In view of his poor general condition and the bad prognosis of the disease, it was decided to treat him conservatively. He sank steadily, became jaundiced, and died on the fifth post-operative day.

Necropsy showed an intact suture line and revealed no cause of the jaundice. At the oesophago-gastric junction and extending 3 cm. up the oesophagus there was an ulcer, triangular in shape, with its base 2 cm. in length. The floor was covered with purulent exudate and there was a perforation in the lower part into the peritoneal cavity, which was generally inflamed.

Case 2

A man aged 73 was admitted to the Radcliffe Infirmary under Mr. D. C. Corry on May 26, 1948, complaining of retention of urine for three days. He had been relieved by catheter daily, and his nearest hospital had been unable to admit him after he had travelled some twenty miles to its casualty department. His blood pressure was 220/110, and he complained of some giddiness on stooping. Apart from occasional "flatulence," he was well.

On the day of admission cystoscopy under general anaesthesia confirmed the presence of a large prostate and a trabeculated bladder. Vaso-ligation and retropubic prostatectomy were performed. Progress was good, and urine was draining freely through a urethral catheter until May 31, when he complained of nausea and melaena occurred. Blood was taken for cross-matching, morphine was given, and he was placed in recumbency, being allowed sips of water by mouth. His blood pressure remained at the post-operative level of around 160 mm. Hg systolic, his pulse was steady at 80 a minute, and he was comfortable. The next evening, however, the sixth after the operation, he suddenly complained of nausea again, vomited a large quantity of coffee-ground material, and collapsed. A transfusion of plasma was started immediately, and while the first pint of blood was being run into an arm vein he died.

Necropsy showed a healthy site of operation, and hypertrophy of the left ventricle. In the duodenum, 2.5 cm. from the pylorus, there was an ulcer just over 1 cm. in diameter with a little puckering of the surrounding mucosa and some fibrous thickening. Microscopy showed fibrotic and necrotic pancreas in the base of the ulcer, and polymorph infiltration of the mucosa. At one end of the ulcer there was a small arteriosclerotic vessel, the lumen of which was patent and completely eroded. The jejunum and large bowel were filled with some altered and some dark red semi-clotted blood.

Case 3

A man aged 51 was admitted to the Putney Hospital on November 11, 1949, having been concussed in a crash while on duty in a police car. He had been unconscious for about five minutes, but was then suffering from lacerations of his forehead, chin, and hands, which required a few sutures only. He had a tender right second costo-chondral junction with some bruising, but there was no radiological evidence of bone injury or any clinical evidence of trauma to the abdominal viscera. He was kept in bed under observation and was about to be discharged, when, on November 19, he complained of faintness and dizziness and passed a large tarry motion; at the same time he vomited a small amount of "coffee-grounds." There were no physical signs other than those of haemorrhage, and inquiry elicited no previous history of indigestion. He was treated by rest, sedatives, and two-hourly milk feeds; his haemoglobin dropped to 66%, but there was no further bleeding. On December 7 radiography showed that the duodenal cap was a narrow channel which did not relax, and in it there was a barium-filled crater. There was no local tenderness.

After this he was under observation as an out-patient with very few gastric symptoms. Radiography on March 3, 1950, showed a healed ulcer; and on June 2 there was scarring and spasm, but no tenderness. He was finally discharged on November 24, a year after the original injury, with no symptoms other than occasional indigestion relieved by medicine and diet.

Case 4

A man aged 76 was admitted to the Putney Hospital on December 31, 1949, having been knocked down by a car while wandering across a road; he had not been rendered unconscious, but had sustained various lacerations and bruises about the right eye, the right side of the chest, and the crest of the left ilium, which was fractured. His main injuries were bilateral compound and comminuted fractures of the tibia and fibula. There was very little clinical evidence of shock and after resuscitation he withstood very well toilet of his wounds, suture of the skin, and the application of plaster-of-Paris to both legs, which were then suspended from a Balkan beam.

In spite of his severe injuries he gave no cause for concern until January 13, 1950, at 9.15 p.m., when he complained of a sudden onset of severe abdominal pain and breathlessness. On examination he was sweating, was very restless, and was increasingly pale; his blood pressure was 120/80 and his pulse rate 100 a minute. There was no cyanosis or any abdominal physical signs, but rectal examination revealed tarry stools. There was a smell of blood, and while being examined he vomited a large amount of dark altered blood. Morphine was given intravenously and a blood transfusion was started as soon as possible, but he died at 10.15 p.m.

Post-mortem examination revealed recent bleeding from a chronic duodenal ulcer and further blood throughout the intestines. There was no evidence of abdominal injury, and no other gross lesion was found.

Case 5

A man aged 57 was admitted to Guy's Hospital on November 19, 1952, with an acute on chronic intestinal obstruction due to faecal impaction and a volvulus of the splenic flexure of a long redundant colon. He gave a history of a duodenal ulcer which had perforated seven years before, but which had given him no trouble for six years; his left kidney had been removed for stone eighteen years before this admission. The strangulated loop of colon was resected by the Paul-Mikulicz method on the same day, and on December 12 an attempt was made to close his double-barrelled colostomy extraperitoneally. After two small bowel actions the wound broke down and all his faeces discharged through the wound and continued to do so.

As there was an area of dermatitis round the fistula and as the abdominal wall was weak and scarred it was felt that further operation should be postponed. He was therefore discharged on February 1, 1953, rather against his will. It was hoped that repeated rectal wash-outs might remove the faeces that kept impacting in the distal bowel, and that his fistula might close spontaneously.

His domestic arrangements were ill suited to this regime, and the dermatitis round the fistula became worse. Shortly after discharge he complained of fullness after meals and epigastric pain going through to the back. On March 9 he was readmitted as an emergency because for the last two days he had passed profuse, tarry, ill-smelling motions, and had become faint and giddy. He was pale, his pulse rate was 106, and his blood pressure 120/75. Rest, morphine, and two-hourly milk feeds were prescribed, and during the next few days five pints (2.7 litres) of blood was transfused. Frank melaena was present on only two more occasions, but occult blood was repeatedly present in his stools; a fractional test meal showed blood in all specimens and a high total acidity. At laparotomy on April 7 Mr. Wass found a duodenal ulcer with signs of recent activity and some fibrosis extending into the pancreas. A

partial gastrectomy was done with a retrocolic valvular gastro-jejunostomy. Finally on June 4, after repeated evacuations of faecal masses in the sigmoid colon, the fistula was successfully resected and the remaining colon anastomosed. On June 27 he went away for convalescence. He has since been seen, well and free from symptoms.

Case 6

A man aged 71 was admitted to Guy's Hospital on March 30, 1953, with symptoms due to an anal neoplasm of two months' duration. Biopsy the next day showed this to be an epithelioma of the anus infiltrating the sphincters. On April 14 a synchronous combined abdomino-perineal excision of the rectum and anus was done by Mr. Wass and myself; recovery was uneventful, apart from some sepsis in the abdominal wound. On April 27 he began to complain of epigastric pain and fullness; on April 29 he vomited 12 oz. (340 ml.) of dark material in which were seen "coffee-grounds." On questioning he admitted to having been treated two years before by his own doctor for ulcer symptoms. He had been put on a diet, to which his symptoms had responded, but no radiography had been performed. A diagnosis of duodenal ulcer was made, and he was treated with alkaline powder and atropine, his symptoms soon resolving. On May 14 a barium-meal examination showed that the stomach and duodenum were much displaced and distorted by an enlarged and tender head of the pancreas; further radiography on May 21 showed that this distortion was no longer present, but that there was a trefoil deformity of the duodenum with ulceration. On May 5 he was transferred for treatment of his anal neoplasm by radiotherapy; 2,500 r was administered to both groin fields, and no further digestive upset occurred.

Case 7

A spinster aged 68 was admitted to Guy's Hospital under Mr. Wass on May 31, 1953, complaining of "piles" for one year, malaise for six months, and constant watery diarrhoea for six weeks. She was a retired lady almoner who had lost 14 lb. (6.4 kg.) in weight in the last eight weeks. On examination she was pyrexial and looked ill; she had lower abdominal distension, especially marked in both iliac fossae. Rectal examination revealed at the fingertip a hard mass filling the upper pelvis. On June 9 at laparotomy the large bowel was found to be grossly distended and hypertrophied as far as the lower sigmoid, where there was a mass, the size of a foetal head, stuck to the left wall of the pelvis and to the bladder. A left iliac colostomy was fashioned to relieve the obstruction. For a week she did well, apart from an inability to pass urine unaided by catheter. Her colostomy worked well at first, but she then began to get colicky abdominal pain and her temperature rose. Attempts to break up hard faecal masses in her proximal colostomy loop were only partially successful, and she died on June 19, ten days after operation, in coma, with a temperature rising to 106° F. (41.1° C.).

At necropsy some smooth-walled cysts and two cavernous haemangiomas were found in her liver; the main cause of death was a peritonitis from two perforated stercoral ulcers of the colon proximal to the colostomy. The primary lesion was found to be a necrotic adenocarcinoma of the upper rectum, involving bladder and perirectal tissue, 10 cm. in diameter. In the first part of the duodenum there were five ulcers 0.5 to 1.5 cm. in diameter; from the floor of the largest projected a pedunculated blood clot which formed a cast of the duodenum. This ulcer had also penetrated the posterior wall of the duodenum, and a haematoma had formed between this and the pancreas. Microscopy showed an acute deeply penetrating ulcer.

Case 8

A man aged 74 was admitted to Guy's Hospital on September 15, 1953, under Mr. Law, complaining of increasing dimness of vision from his right eye for nine months. He had had a gastro-jejunostomy performed in

1912 for duodenal ulcer, since which time he had been troubled little by indigestion, save for a haematemesis in 1947, for which he had refused hospital treatment. On September 16 his right eye was removed for a malignant melanoma, with no local complications.

On September 22 he vomited altered blood on two occasions and passed a melaena. His general condition responded initially to blood transfusion and morphine, but he failed to maintain progress, dying on September 25.

Necropsy seven hours after death showed clean wounds and no local tumour cells, but microscopy of the liver revealed a minute melanotic deposit in one hepatic portal duct. His abdomen showed gross distension of the stomach and upper jejunum with thin grumous fluid. There was a retrograde ante-mortem intussusception of mid-jejunum, with the distal small intestine empty of contents and contracted to the size of a lead pencil. The large bowel was full of concentrated altered blood of various ages.

A retrocolic gastro-jejunostomy and four peptic ulcers were seen. Two were apparently of long standing—one on the lesser curve of the stomach and one on the jejunal side of the suture line. Two were recent—one in the fundus of the stomach and one in the jejunum about 2 cm. from the suture line.

Microscopy of the lesser-curve gastric ulcer showed a fibrous-tissue floor with two vessels filled with organizing thrombus; the mucosa showed some recent necrosis and infiltration with round cells and plasma cells, which suggested recent ulceration on the site of a long-standing ulcer. Microscopy of the distal jejunal ulcer showed the vertical edge characteristic of acute ulceration with the histological picture of acute mucosal destruction.

Discussion

Eight cases of proved peptic ulceration arising after trauma are presented. All the patients (seven male and one female) were over 50 years of age, the average being 67; four died as a direct result of the ulceration; in two cases the ulcers were multiple and in one they were an incidental finding at necropsy. The time interval from the original trauma to the first symptom varied from four days to ten weeks, but in seven of them it was from four to thirteen days. The original trauma varied widely.

The mechanism whereby this ulceration arises is a matter for conjecture. In Case 1 it may have been due to the pressure of the intragastric Ryle tube, but this was in place for only three days and the ulcer was much bigger than any such area of pressure. The direct trauma of the operation might be blamed, but the lower oesophagus and upper stomach share a blood supply, and the ulcer, which had the appearance of a typical peptic ulcer, stopped abruptly at the cardia. The vascular disease responsible for the hypertension in Case 2 might have been contributory, but the coronary arteries were only moderately atheromatous and the kidneys were normal. A direct injury to the abdomen might have originated the ulcer in Case 3, but there was no haematemesis at the time or any bruising of the epigastrium.

Physical disturbance in the form of severe shock was a feature in only one patient (Case 4), who had compound comminuted fracture of both lower limbs. None of the operations were minor, but none of the patients were unduly affected by them.

Mental disturbance may have been a factor in some. Case 1 evidently lay in dread of operation, having refused one previously; Case 2 had had the distressing experience of transport several miles to a hospital which had refused admission and sent him home again; Case 5 desperately wanted his faecal fistula closed, as his home conditions were quite unsuited to its care. On the other hand, no one could have seemed more placid than Case 3, who was quite unruffled by his illness.

An attractive hypothesis would be that the ulceration is the result of the excess secretion of adrenocorticotrophic hormone or cortisone during the adrenergic-corticoic phase of Moore (1953). The effects on the gastric secretion of these hormones have been well described by Gray *et al.* (1951).

A previous history of indigestion was given by two patients: Case 2 admitted to occasional flatulence and Case 6 had been treated with diet for ulcer symptoms for two years previously. In two there was a history of ulcer: Case 5 had suffered from a perforated duodenal ulcer seven years before his admission, and Case 7 had had a gastro-jejunostomy performed 41 years before for duodenal ulcer. But neither of the two with a history of ulcer had been troubled with symptoms for six years.

Summary of Cases

Case No.	Sex and Age	Operation	Presenting Symptom	Ulcer	Result	Interval to Symptoms	Interval to Death (days)	Comment
1	M 68	Subtotal gastrectomy for carcinoma of stomach	Perforation	Oesophageal (juxta-cardiac)	Died	4 days	5	Had refused operation for carcinoma 4 months previously
2	M 73	Prostatectomy for urinary retention	Melaena	Duodenal	"	5 "	6	Had been admitted after 3 days' catheterization and after being refused admission by another hospital. History of occasional "flatulence" No epigastric injury
3	M 51	Road traffic accident, concussion and minor lacerations	"	"	Survived	8 "	—	
4	M 76	Road traffic accident, compound fractures both tibiae and fibulae	Pain and melaena	"	Died	13 "	13 plus 1 hour	No epigastric injury. Sudden pain and collapse with death during transfusion
5	M 57	Volvulus of large bowel, attempted closure of faecal fistula	"	"	Survived	10 weeks	—	Perforated D.U. 7 years before; no symptoms for 6 years. Sore skin round fistula and desperately eager for closure
6	M 71	Abdomino-perineal resection for epithelioma of anus	Pain, fullness, and coffee-ground vomit	"	"	13 days	—	Two years ago "ulcer" symptoms treated by own doctor by diet with success
7	F 68	Colostomy for massive infiltrating carcinoma of upper rectum	None	Duodenal (multiple)	Died	—	—	Incidental finding at death from perforation of stercoral ulcers in bowel proximal to colostomy
8	M 74	Enucleation of right eye for malignant melanoma	Melaena and haematemesis	Gastric and jejunal	"	6 days	9	Gastro-jejunostomy 41 years previously. Haematemesis 7 years previously

In those cases in which microscopy of the lesion was carried out the results have been reported. That it was not done in every case is no great defect: microscopical evidence of chronicity is probably unreliable (Tanner, 1953). Clinical differentiation of acute from chronic ulceration is also arbitrary. At one end of the scale is the patient with severe symptoms for many years, who at laparotomy is found to have a minimal lesion; at the other is the patient—often elderly—who has no symptoms until haemorrhage or stricture ensues, and who is found to have a gross chronic ulcer. However, from a consideration of these cases it would appear that the earlier a patient dies the more acute the appearances (Case 1); and the longer he survives the more chronic these are (Case 4).

More important from a clinical aspect would seem to be the anatomical site of the ulcer (see Fig.) and whether its

base is formed by peritoneum (Case 1), pancreas (Case 6), or blood vessel (Case 4). Perforation or haemorrhage brings a grave prognosis to elderly patients who are convalescing from accident or surgery, and in six of these patients the main symptom was haemorrhage.

It is apparent from a study of these cases that there may be some warning that ulceration is taking place. There was none in Cases 1, 4, and 7 (all of whom died); but there was warning with Cases 2, 3, 5, and 6 (of whom one died), and it is possible that early treatment might have saved life.

Conclusions

Peptic ulceration after trauma may be regarded as the abnormal reaction of an ulcer-prone patient to a physiological stimulus. Until such a time as the physiological reaction to stress and trauma can be measured and safely regulated, the best way to deal with this complication would be by prophylaxis and by early recognition and treatment. Prophylaxis is difficult, as the ulcer-prone patient does not declare himself. It is not the practice of surgeons to ask patients awaiting consultation to fill in "pro formas" on personal habits and previous and family history; were it so, however, it would be worth asking, "Have you suffered much from indigestion?" or, "Do you take stomach powders, tablets, or mixtures?" and if the patient be over the age of 50 and a man particular heed should be paid to such an admission. A careful general history is as important in surgery as it is in medicine.

If such a history is elicited the regime after operation should not be too active, and inquiry should be made into upper abdominal symptoms. In addition to the daily examination of the calves, a hand might well be applied to the epigastrium. If relevant symptoms appear, antacids and atropine should be given, and if tarry stools are passed the matter should be reported immediately, a serious view taken, and arrangements made at once to collect serum for cross-matching in preparation for a transfusion of blood that may be needed with great urgency.

Summary

Eight cases are presented of ulceration arising as a complication of operation or injury.

This ulceration may arise *de novo* or may be an exacerbation of previous ulceration.

A watchful outlook should be maintained for epigastric postprandial pain; particularly in the early convalescent phase. Melaena and coffee-ground vomit must be recognized as alarm signals, and immediate steps should be taken to arrange for rapid blood transfusion if necessary.

Energetic medical treatment may well avert death from a complication which has a high mortality rate.

I express my gratitude to Mr. H. J. B. Atkins for his great help in the preparation of this paper; to Mr. D. C. Corry, Mr. Grant Massie, Mr. S. H. Wass, Dr. C. Hardwick, and Mr. F. W. Law for permission to publish the details of their cases; and to Dr. R. B. Hervey Wyatt, H.M. Coroner for Battersea, for allowing me access to the post-mortem records of Case 4.

RECENT EXPERIENCE OF ENCEPHALITIS IN CHILDHOOD

BY

E. G. BREWIS, M.D., F.R.C.P., D.P.H.

Associate Physician, Children's Department, Royal Victoria Infirmary, Newcastle-upon-Tyne; Physician, Walkergate Hospital, Newcastle-upon-Tyne

This communication is based on a clinical study of 93 children with encephalitis seen since 1946 in the children's wards of three hospitals associated with the Department of Child Health in the University of Durham. This experience has been so varied that it invites an attempt to analyse it.

The term "encephalitis" is used without attempting to indicate any particular aetiological factor, whether of virus, allergic, or toxic origin. What is meant, therefore, is the occurrence, in a previously healthy child, of the classical symptoms or signs of disturbed cerebral function, which, after the exclusion of bacterial and vascular conditions and of chemical poisonings, are presumed to be the result of non-suppurative disorder of the brain.

The patients fall into two groups: (1) those associated or following on a recognized infective condition (measles, 12; pertussis, 8; varicella, 3; rubella, 1; mumps, 1; herpes simplex, 1; acute rheumatic fever, 1; infectious mononucleosis, 1), of which there are 28; and (2) those of unknown aetiology with no obvious causative factor, of which there are 65.

In attempting to define the clinical pictures of these diseases, this material could have been dealt with in two

ways. First, the cases associated with known infections might have been analysed to see if each had a distinctive clinical picture, and those of unknown aetiology could then be related to or compared with them. Bearing in mind that encephalitis may be the only manifestation of infections such as mumps, measles, and rubella, studies such as those of Greenfield (1950) have been of immense value in indicating the variety of conditions which can give rise to encephalitis, but they have been concerned solely with fatal cases and, even so, have shown quite clearly that there has been no uniformity of the clinical pattern in the various pathological groups. Second, all the cases might have been analysed according to the pattern of the clinical illness, regardless of aetiology or pathology, to ascertain whether any types were discernible. It is realized that in the absence of virus and histological studies, cases of encephalitis lethargica, subacute inclusion encephalitis (Dawson, 1933, 1934), haemorrhagic encephalitis (Baker, 1935), acute haemorrhagic leuco-encephalitis (Weston Hurst, 1941), and poliomyelitis (McAlpine *et al.*, 1947; Brewis and Neubauer, 1948; Jennings *et al.*, 1949; Kelleher *et al.*, 1949; Barrett *et al.*, 1952) may be grouped together in this way. This second method of analysis was chosen because it reveals clinical patterns of illness, irrespective of aetiology, which offer guidance to the practitioner in giving a prognosis.

Four main patterns of illness have been distinguished, although in this attempt at classification it has not been possible to insist on rigid criteria, and many of the signs and symptoms of impaired function of the nervous system have been common to all. Only the more obvious differences in onset, course, and duration have been used, and in some minor respects overlap between the types has occurred; in addition to which many cases could not be classified and have been described as a heterogeneous group.

Type 1.—Cases presenting as a sudden cerebral calamity in a previously healthy child or following an indefinite prodromal phase. Convulsions were prolonged or repeated, and unconsciousness lasted several hours or even two to three days. The duration of the acute phase was short, death or returning consciousness occurring in two to three days.

Type 2.—Cases beginning usually with a non-specific and meningitic illness with pleocytosis in the C.S.F. and followed by the acute onset of unconsciousness, stupor, or somnolence of a few days' duration, from which a rapid or sudden recovery frequently occurred. Cranial nerve paralysis and lower motor weakness were often encountered and recovery was the rule.

Type 3.—Cases often with a prolonged and insidious prodromal phase of indefinite symptoms or occasional convulsions, with periods of well-being followed by gradual unsteadiness developing into gross ataxia, tremors, and continuous choreiform movements of the whole body, particularly of the eyes. The illness was long, and was associated with emotional instability. Usually these cases had been diagnosed as chorea or cerebral tumour.

Type 4.—Cases which resembled encephalitis lethargica, with a short prodromal phase, and a slowly developing somnolence or coma. This lasted several days and was followed by cranial nerve involvement and a slow return to consciousness, interrupted by mental and emotional instability.

Type 1. Sudden Onset with Convulsions and Unconsciousness

Illustrative Case.—A. G., aged 10. On previous day, shivering, restlessness, and vomiting; no headache. Later

unable to speak; convulsion with bilateral clonic movements lasting 1½ hours. Temperature 107.8° F. (42.1° C.) reduced to 101° F. (38.3° C.) by sponging. On admission gravely ill, unconscious and vomiting; limbs immobile and flaccid. Face constantly twitching; eyes deviated, coarse nystagmus. No meningeal signs; C.S.F., 22 lymphocytes. Reflexes absent; W.B.C., 32,300. Remained unresponsive, with sporadic twitching of right hand, fingers, and toes; later, tonic neck reflexes present; head and eyes deviated to right, with facial weakness and hemiparesis. Constant variation in physical signs. Rapid deterioration, death 33 hours after first convulsion. Necropsy revealed small perivascular haemorrhages and cuffing in right basal ganglia, frontal cortex, brain stem, and spinal cord, and also perivascular collections of round cells in areas of the occipital and parietal cortex. No neuronal changes.

There were 19 cases of unknown aetiology in this category, 13 of them being below the age of 2 years. In nine there had been prodromal symptoms of malaise, listlessness, slight cold, and restlessness for one to five days. Eleven patients had vomited, six had loose offensive motions, and two had abdominal pain, although the bowel disturbance did not usually continue into the illness. In addition there were three cases of measles, four of pertussis, one of mononucleosis, and one of mumps which were similar in type.

Convulsions, generalized in 21 cases and limited to twitching or spasms of the face or limbs in 7, varied in number from 2 to 50 before admission. They had been continuous in 17 patients, and after admission were still continuous in 13, of whom 7 died. All patients were unconscious or stuporous from the onset of the fits. The temperature was raised in all but five, a high rising temperature being associated with a bad prognosis. Meningeal signs were present in only four cases due to measles or where the aetiology was uncertain, but were present in five of the other six cases of known infection. The C.S.F., examined in 26 cases, was normal in 18, while there was a mild pleocytosis of 12 to 56 cells in the remaining eight, one of which was blood-stained. Of these latter cases five were fatal.

The subsequent course of the illness in the survivors was very variable. Convulsions recurred in six cases and lasted for a few hours; drowsiness or coma for a day or two, accompanied by retardation, aphasia, slurring of speech, spasticity, choreo-athetosis, and ataxia were seen. Often recovery was quick, the illness lasting a week or less in nine cases, one to two weeks in four, two to four weeks in five, and two months in one case. The longer the illness the more likely were sequelae to develop; two cases were left hemiplegic with fits, three mentally retarded, and one with fits. Hemiplegia occurred in three other cases, one a fatal case and the others recovered completely.

Nine patients died, usually after short illnesses—six of 48 hours, two of three days, and one of 16 days. The last-mentioned case was that of a baby who continued to have convulsions for 10 days after admission and died a few hours after ventriculography. At necropsy, infiltration and old haemorrhages into the arachnoid were the only findings. Perivascular demyelination and haemorrhage were found in the mid-brain of one patient and the cortical areas of another; while perivascular cuffing and neuronophagia of polioclastic type, petechial haematomata, and capillary thrombi with infiltration were the appearances respectively in the other three patients on whom necropsies were done.

Type 2. Acute Onset with Short Somnolent Phase and Paralysis

Illustrative Case.—D. D., aged 10. Headache, sore throat, and fever lasting one day; then well for five days. Relapsed with pain in neck, headache, and sleepiness. Vomited continuously next day, but rational and co-operative. Marked meningeal signs, nystagmus, and right facial weakness, diminished tendon reflexes. Temperature 101° F. (38.3° C.); C.S.F., 45 cells, mainly polymorphs. Subsequent deterioration with deepening coma lasting five days, bilateral facial palsy, weakness of left arm and right shoulder, and diffi-

culty in swallowing. Slow improvement; becoming rational, though incontinent, excitable, and difficult to control. Went home 18 days after admission with paralysis of right face, deltoid, and left thigh, and emotionally labile. Went through a difficult phase, being bad-tempered, excitable, and nervous; often rude and vulgar. Speech staccato; appetite voracious; thin and restless. Eighteen months later had steadied down was doing well at school, and had recovered neurologically.

There were 15 cases in this category, all of unknown aetiology, all children in their early years, and most were encountered during outbreaks of poliomyelitis. Thirteen had some form of prodromal illness lasting two to eight days and consisting of headache, vomiting, fever, transient diplopia, disturbance of micturition, drowsiness, aphasia, and dysphagia. Fits were present in three cases, and in two cases siblings had a febrile meningitic illness about the same time. All but three were febrile. Meningeal signs were present in 12 cases, but in all there was a pleocytosis in the C.S.F.

The mental state on admission was variably described as: unconscious (2), stuporous (3), persistently asleep (3), retarded but rousable with difficulty (4), uncontrollable following three days' somnolence (1), conscious but aphasic (1), rational, becoming semicomatose for a week later (1).

Recovery of mental clarity occurred early: nine patients became conscious on or before the fourth day, four during the next three days, and only one took longer than a week. Sometimes this return of consciousness was very dramatic and sudden; a child having been deeply asleep or semicomatose for some days would waken in a few hours and become quite alert, would be found wandering round the cubicle, or, in one case, drinking out of the cubicle tap. Similarly, the return of speech followed the same pattern, and so striking was this apparent transformation from lethargy and sleep that the condition became known as the "Snow White syndrome."

The cranial nerves were not infrequently involved; strabismus (1), ptosis (1), facial palsy (3), aphasia (4), dysphagia (3). Paralysis of an arm or a leg occurred once each, and only five cases failed to show some form of lower motor weakness at some stage of the illness. Pyramidal signs were seen in six patients.

Only one death occurred: that of a 14-year-old child who was stuporous but responding on admission, and who became progressively comatose and died on the fourth day. At necropsy the lumbar cord was congested and showed punctate haemorrhages anteriorly, and perivascular cuffing was seen in the cervical cord and the thalamic region.

In only three cases did permanent sequelae persist: two cases of unilateral facial palsy and one of foot-drop; although temporary emotional instability was occasionally encountered.

Type 3. Insidious Onset with Continuous Choreiform Movements and Ataxia

Illustrative Case.—E. R., a male child aged 18 months. Previously well; then off his feet slowly; began to shake, and eyes moved from side to side. Very miserable; no temperature; C.S.F. normal. Seen again in one month; no progress and still very ataxic. A month after this, although bright and friendly, he had difficulty in balancing even when sitting still. His head was moving up and down regularly, and he was making mouthing movements. Unable to crawl, but could roll over. Reflexes, fundi, and C.S.F. normal. W.R. negative. E.E.G. indefinite. Developed basal ganglion tremor, particularly in arms. Excessive salivatory movements almost disappeared. Three weeks later he had again deteriorated, and the tremors were as bad as before, affecting head, eyelids, mouth, and to a less extent the limbs, and being continuous in sleep. These movements gradually became worse; arms, legs, and head jerked about uncontrollably; the eyes were never still, and

rolled upwards. He became uncooperative and resented interference. His condition was unchanged a year later.

There were nine cases similar in type to this, all of unknown aetiology, and all except one were under 5 years. There was an insidious onset from two weeks to three months, and occasionally isolated fits occurred two to three weeks beforehand, followed by a period of well-being before the characteristic signs developed. Sometimes a gradual unsteadiness of the limbs was the first manifestation, followed by stumbling and ataxia with tremors, squints and continuous eye movements or oculogyric crises, or a typical chorea-like illness. In four cases irritability, hysterical behaviour, or personality changes were also present, and frequently these patients were thought to be suffering from an intracranial tumour. The temperature was normal in all except one case.

The patients might be co-operative, lying quietly and slightly drowsy, or irritable, wildly excited and restless, violently choreiform and ataxic, with gross nystagmoid movements of the eyes. Coarse tremor on voluntary movement, nodding of the head, jerky speech, and salivation were present in some cases. Meningeal signs were seen in only one case, the C.S.F. contained a few cells in four cases, and the Lange curve carried out in five was normal. The subsequent course was usually slow improvement, often punctuated by relapses, emotional lability, staccato speech, outbursts of temper or excessive cheerfulness, and with slowly improving ataxia. The illness was usually long—between two and three months from the onset although in two cases it was only two to three weeks.

Two patients died: one with continuous writhing and twitching, upward deviation of the eyes, slow deterioration, and finally opisthotonos with death in the eighth week; the brain showed occasional microscopic haemorrhages and signs of neuronal degeneration. The other case showed a progressive increase of the choreiform movements, alternating with phases of quiescence, when the temperature subsided for a time, but, following mental degeneration and blindness, the illness terminated in a convulsion in the seventeenth week. Minor changes with neuronal degeneration were seen in the mid-brain and cervical cord.

Sequelae were not infrequent: only three cases left hospital apparently normal; one was unchanged and had gross tremor and ataxia, myoclonus, and eye movements more than two years later; one was abnormally restless; one was irritable and domineering; and another was attending a psychiatric clinic.

The cases of this type were very similar in description to those of subacute inclusion encephalitis, although the normal Lange curves in four cases and the subsequent course did not conform to the usual fatal result or complete disablement reported by most observers (Campbell *et al.*, 1952; Foley and Williams, 1953), and at necropsy in two cases no inclusions were found.

Contrasted with the prolonged illness and very marked disturbance of cerebral function, the pathological changes were surprisingly scanty.

Type 4. Somnolent and Lethargic Illness with Spasticity and Retardation

Illustrative Case.—B. H., a boy aged 4½. Illness began two days before admission, with abdominal pain, repeated vomiting, and large offensive stools; drowsy; temperature 101° F. (38.3° C.), but no abnormal signs. On morning of admission he was found in a state of coma, with slight muscular rigidity and bilateral extensor responses; mild meningeal signs; C.S.F. normal. If undisturbed he lay as though peacefully asleep, but he resented interference, grimacing and crying, but otherwise aphasic. The face had an "ironed-out" appearance, and, although occasionally his attention was attracted, lethargy and sleep rapidly returned. Breathing was shallow and periodic, with deep sighing; inability to swallow necessitated tube-feeding almost continuously for six weeks. State of consciousness varied;

flexibilitas cerea developed and increasing spasticity—in the arms, of "cogwheel" type. Illness complicated by hypostatic pneumonia, generalized rigidity, double incontinence, and thrombosis of the inferior vena cava, the last-named being compensated by large venous anastomoses over the abdominal wall. Slow improvement occurred, and emotional responses returned, together with ability to swallow and a decrease in spasticity. Further progress was relatively rapid, rigidity of the left side of the body being slower to recover than the right. Euphoria and emotional lability were seen for a long time and walking was ataxic. He left hospital in three months, and when seen one year later was happy but somewhat backward, and still had slight spasticity of the left arm.

Five cases of unknown aetiology showed this type of illness—an infant and four young children. Prodromal symptoms were present in all, lasting from two to three days to one week. They consisted of headache, vomiting, abdominal pain, screaming and staring, occasionally twitching or a definite fit. In addition in this group there were seven cases of measles, three of pertussis, one of acute rheumatic fever, and one of rubella.

Meningeal signs were present in nine cases and a pleocytosis up to 150 cells in eight—not always the same cases. When first seen these patients were comatose or apparently deeply asleep. The cranial nerves were often affected, squints (9), ptosis (3), facial paralysis (9), pharyngeal paralysis (7), and a mask-like face or "dead-pan" appearance (5) being seen.

The course of the disease varied in duration up to two and a half months, five cases due to the acute infections had illnesses lasting one to two weeks only. Usually the drowsiness or coma increased for a few days, then improved gradually, being followed by variable periods of stupor, aphasia, dysphagia (two cases required tube feeding for three to six weeks), wild tremor and ataxia, twitchings and occasional unilateral or bilateral fits, spasticity with extensor responses, flexibilitas cerea, irritability, screaming, salivation, and yawning. There was no sudden awakening from the lethargy such as occurred in the Type 2 cases.

There were two deaths, both in measles cases; 10 cases recovered completely; two were much improved but were mentally reduced; and one was apparently of normal intelligence but excessively noisy. One of the measles cases was backward, with infantile speech; another, who left hospital in a hopeless state and was little better a year later, when seen five years after the illness was second in his class at school, though his temper was uncertain. One pertussis patient was also left mentally retarded.

Cases with a Varied Clinical Picture not Resembling Other Types

There were 24 cases, 17 of unknown aetiology, which could not easily be placed in any of the other categories, although they showed certain similarities to them, often to more than one type. In many there were bizarre features; one child attacked another in the next bed and had alternating phases of aggression and docility; eventually he was transferred to a psychiatric ward, where he had several fits followed by stupor for three weeks. He made a complete recovery.

Three cases were thought to be associated with sensitivity reactions, sulphadimidine and "sulphatriad" probably being the responsible agents in two instances. The rashes were all urticarial and of mixed type, showing morbilliform, scarlatiniform, and petechial elements. There was sudden onset of drowsiness and slurred speech or aphasia. All had extensor responses, two were pyrexial, and initially the C.S.F. was normal in all, though later one showed a pleocytosis of 24 cells. Recovery was rapid, within two to three days, and with fading of the rash. One has a persistently abnormal E.E.G. and violent bursts of temper.

Four cases had illnesses resembling cerebellar tumour in which a variable period of dysphagia, dysarthria, disorientation, and fits preceded nystagmus, cerebellar ataxia, and

sometimes indefinite pyramidal signs. So marked were these signs that air encephalography was carried out in one case, with negative results. A diagnosis of tumour was originally suggested in many cases in the whole series, but exploration was carried out in only three other cases.

There were three cases following varicella which had a not dissimilar appearance to those just mentioned, but the diagnosis was never in doubt, and they all recovered quickly.

In two cases there was an illness progressing over five and sixteen days respectively, consisting of headache, vomiting, drowsiness, and apathy, and in one a fit, followed by a slowly developing hemiplegia. The temperature was normal and meningeal signs were absent; the C.S.F. in one case contained 22 cells, the other fluid being normal. On admission the patients were apathetic or fretful, becoming increasingly drowsy for a few days. One recovered from the hemiplegia in three weeks; the other was left with a spastic hemiplegia and an impulsive temperament. These cases were not unlike those described by Weston Hurst (1941), except that neither was fatal.

The remainder of this group were made up of two cases of measles, one of pertussis, and one of herpes simplex which could not be classified elsewhere.

The fatal case was that of a child of 3 months who was taken ill suddenly with continuous loud screaming and extreme restlessness. The temperature was only 99.3° F. (37.4° C.), and vomiting was absent. Apart from a depressed fontanelle, there were initially no abnormal signs. The screaming continued for five days, and was followed by unconsciousness and generalized spasticity. The C.S.F. was repeatedly blood-stained, was under normal pressure, and later became xanthochromic. The child lay completely unresponsive, developing nystagmus and intermittent squints and bilateral optic atrophy, apparently being blind and deaf. The limbs remained spastic, with occasional tremulous movements. The fontanelle later became tense, but otherwise the condition remained unchanged for three months, when, following a short period of continual spasms affecting the limbs, and hyperthermia, the child died. Different diagnoses had been entertained at different times, among them Schilder's encephalopathy, cerebral venous thrombosis, and cerebral sclerosis of Krabbe; but at necropsy the changes, though not gross, were compatible with haemorrhagic leuco-encephalitis.

Four other cases had sequelae, one was mentally defective and a severe epileptic, another was difficult to manage and had fits, a third had a slight hemiparesis, and a fourth was affected by sudden attacks of falling or stumbling.

The following Table shows the results according to type of case:

Type	Cases	Deaths	Complete Recovery	Survivors with Severe Disability
1	28	9 (32%)	13 (46.4%)	6 (31.6%)
2	15	1 (6.6%)	11 (73.4%)	—
3	9	2 (22.2%)	3 (33.3%)	1 (14%)
4	17	2 (11.6%)	10 (58.8%)	3 (20%)
Others	24	1 (4.1%)	18 (75%)	5 (21.7%)
Total	93	15 (16%)	55 (59%)	15 (19%)

Summary

A study of 93 cases of encephalitis is presented; 65 (12 deaths) were of unknown aetiology and 28 (3 deaths) followed definite infections.

Sequelae were encountered in 23 of the 78 survivors, an incidence of almost 29%. They were severe or disabling (fits, mental reduction, or hemiplegia) in 15 cases, or 19% of the survivors.

An attempt has been made to group many of the cases according to the type of the clinical illness, and it has been found that there appears to be no constant relationship between the clinical picture and the aetiology or pathology. The histological changes in the brain have

often been surprisingly mild and have been disproportionate to the degree of cerebral disturbance seen during life.

It is suggested that, to some extent, the severity of the illness may be assessed by observing the mode of onset, the depth and duration of unconsciousness, the frequency of convulsions, and the persistence of signs indicating focal damage of the brain.

I am indebted to Professor Sir James Spence for much help and criticism in preparing this paper, and for allowing me to use many of the cases under his care. My thanks are due also to Dr. George Davison, Dr. F. J. W. Miller, Dr. S. D. M. Court, and Dr. C. E. Cooper for inviting me to see and to use the records of their cases.

EXTRAMEDULLARY PLASMOCYTOMA

BY

BRYAN ROWLANDS, F.R.C.S.

Chief Assistant

AND

NORMAN SHAW, M.B., Ch.B.

House-Surgeon

Professorial Surgical Unit, the Royal Infirmary, Sheffield

Plasma-cell tumours may occur in bone and in soft tissues. Multiple myeloma is the most common manifestation, and its clinical and pathological features are well known. The solitary plasmacytoma of bone and extramedullary plasma-cell tumours are less common, while the interrelationship of the three conditions is still not finally proved. This case of extramedullary plasmacytoma is recorded because of its rarity, its unusual clinical presentation, and its interest as a case for differential diagnosis.

Case History

A man aged 55, who had lived in Jamaica all his life, was admitted to the Royal Infirmary, Sheffield, in August, 1952. In March, 1950, he had noticed a swelling on the left side of his neck. The following day he had a pyrexia of 102° F. (38.9° C.), and was treated by his doctor with penicillin injections. After a week the temperature subsided, but the swelling in his neck remained. The temperature rose again for several days in May, 1950. A radiograph of his chest and a full blood count at this time revealed only a "slight anaemia." His doctor diagnosed tuberculous glands of the neck. Thereafter, at intervals of six weeks, he had pyrexia, occasionally as high as 104° F. (40° C.), which persisted for several days before subsiding. In April, 1952, a lymph-node biopsy was reported on as Hodgkin's disease.

On examination three enlarged lymph nodes were present in the left anterior triangle of the neck. The largest of the three was approximately 2 cm. in diameter. They were freely mobile and painless. Examination of the oral cavity was normal and there was no evidence of dental caries.

The nose, nasopharynx, pharynx, and larynx were examined by an otolaryngologist and pronounced normal. A complete clinical examination revealed no other abnormality.

Investigations.—X-ray examination of the chest, skull, lumbar spine, long bones, and accessory air sinuses revealed nothing abnormal. The Wassermann and Kahn reactions were negative. Agglutination reactions: *Brucella abortus* and *Brucella melitensis* less than 1/10. The urine was examined on many occasions: albumin was constantly present, but tests for Bence Jones proteose were repeatedly negative. Plasma protein: serum protein, 8.3 g. per 100 ml. (albumin 4 g., globulin 4.3 g.). Haematology: haemoglobin, 82%; red cells, 4,000,000; leucocytes, 7,000 (band cells 3%, lymphocytes 24%, polymorphs 64%, monocytes 6%, eosinophils 3%). The white-cell morphology appeared to be within normal limits. Platelets 620,000 per c.mm. (Lempert). Bone marrow (left ilium): The abnormal features included the presence of some macronormoblasts and an occasional megaloid cell. Abnormal nests of plasmocytes and their precursors were seen—in all, 5.6% of 500 cells. There was megakaryocytic hyperplasia.

Biopsy of the cervical lymph node on August 29 was reported on by Professor Willis as follows: "The extremely heavy infiltration of this lymph node by plasma cells is, I think, rather more than might be accounted for by any inflammatory disease, and my diagnosis is plasmacytoma. Whether this may be due to a primary growth in the upper respiratory passages or to skeletal myelomatosis can only be decided by other investigations, especially x-ray studies of the bone. The high plasma protein level favours myelomatosis. Bence Jones proteosuria should be carefully watched for."

The patient's general condition remained good and no further pyrexia occurred. As the radiological examination of the bones, the clinical state of the patient, and the other investigations were against a diagnosis of multiple myeloma, the lesion in the neck was treated with x-irradiation as a case of primary extramedullary plasmacytoma. Satisfactory regression of the remaining enlarged glands took place.

Since his return to Jamaica he has remained in good health. No Bence Jones proteosuria has been demonstrated. Radiological findings (skull, thorax, vertebral column, pelvis, long bones of upper and lower extremities) were normal in May, 1953.

Discussion

Solitary plasmacytoma is an established clinical condition. Although any part of the skeleton may be the site of such a lesion there appears to be a special predilection for the innominate bone and the long bones of the lower limbs. Amongst recorded cases are those of Rogers (1930), Chesterman (1936, 1948), Leedham-Green *et al.* (1938), Willis (1941), and Lumb (1948).

Willis (1941) considers that in order to establish a diagnosis of solitary plasmacytoma the following criteria must be fulfilled: microscopical proof that the tumour is of plasma-cell nature; exclusion of the possibility that the lesion is the first evidence of generalized myelomatosis; there must be radiological proof that no skeletal lesions are present, both at the time of examination and at subsequent examinations at repeated intervals; and Bence Jones proteosuria shall be absent on repeated examinations.

The validity of this last criterion is questioned by Lumb (1948), who found Bence Jones proteose in the urine of a case proved at necropsy to be one of solitary plasmacytoma of the sacrum. He concludes that the proteosuria is consequent on actual tumour volume—namely, the amount of bone-marrow involvement.

Plasmacytomas of soft tissue are much less often encountered. Hellwig (1943) found 127 published cases in the literature reviewed between 1905 and 1942, to which he added a case of his own. The lesions in most cases are situated in the upper air passages, especially the nasopharynx, maxillary antrum, and oral cavity. Cases have

also occurred in the conjunctivae, while odd sites recorded include the testis and uterus (Andersen, 1949) and pancreas (Hefferman, 1947).

The occurrence of extramedullary plasmacytoma in cervical lymph nodes unassociated with other lesions is referred to by Hellwig (1943) and by Andersen (1949). Andersen quotes a personal case, occurring in a submaxillary lymph node. Hellwig was able to find four cases, of which three subsequently developed lesions elsewhere. McNamara and Rogers (1943) recorded a case of extramedullary plasma-cell tumour of a tonsil with metastasis in a cervical lymph node, the interval between the removal of the primary lesion and the appearance of the metastasis being six years. In our case the lesion appears to be localized to a group of glands. A gland had previously been removed for biopsy elsewhere, and at the more recent biopsy a further complete gland was removed.

The possibility of a metastasis from a primary growth in the nasopharynx, antra, tonsils, etc., was considered. Radiological examination of the antra was negative, as was a complete clinical examination by an oto-laryngologist.

The late development of multiple myeloma in some cases of solitary plasmacytoma has led to certain conjectures regarding the pathogenesis of the two conditions. Some thought that the multiple lesions were due to a form of metastasis (Cutler *et al.*, 1936). Geschickter and Copeland (1928) found myeloma cells in marrow blood vessels, interpreting this finding as evidence of that possibility. Other authors, however, consider that the disease is multifocal in origin. The various forms of the disease, they say, should not be regarded as separate entities but as different manifestations of the same process (Lumb and Prosser, 1948; Lumb, 1948; Snapper, 1949). If this theory be accepted a solitary plasmacytoma must be regarded as a single focus of disease, which more usually presents in a multifocal form (Lumb, 1948). It is suggested by Willis, however, that as a plasmacytoma of the bone may remain solitary for years, and that, as a generalization, when it occurs it usually does so early, it is more probable that there are two separate types of the disease. He is of the opinion that "if thorough radiographic examination one year from the date of tentative diagnosis is unequivocally negative and proteosuria has been regularly absent, it is improbable that signs of generalized myelomatosis will appear later, and the tumour may be diagnosed with reasonable certainty as a solitary one."

Many cases of extra osseous deposits occurring in multiple myeloma have been recorded (Churg and Gordon, 1950; Hayes *et al.*, 1952). Any organ may be so implicated, but most commonly those of the extraosseous haemopoietic system—namely, spleen, lymph nodes, and liver. Churg and Gordon state that in their experience the more lymph nodes taken for section the more commonly is myelomatous infiltration found. The retroperitoneal nodes are involved most commonly, the hilar glands less frequently, superficial adenopathy being rare. In our case multiple myeloma was regarded as probably eliminated in view of the negative radiological findings and the absence of Bence Jones proteose. The marrow pictures were equivocal.

The history of attacks of high pyrexia was difficult to associate with a diagnosis of solitary or multiple myeloma. No abnormal pyrexia was noted during the patient's stay in hospital. Bailey and Haines (1951) found fever significant in only 1 to 3% of cases of multiple myeloma, and seldom was the temperature in excess of 100° F. (37.2° C.). Unfortunately, it was not possible to obtain the sections of the lymph-node biopsy reported on as Hodgkin's disease in April, 1952. The histological picture of Hodgkin's disease may be simulated by various kinds of chronic lymphadenitis, notably brucellosis, glandular fever, and torulosis. In view of the febrile history, it is possible that this biopsy may have shown a picture different from the latter one. Agglutination tests for brucellosis were negative.

The fact that albuminuria was present but Bence Jones proteose absent calls for cautious comment. Magnus-Levy (1932) (quoted by Bailey and Haines, 1951) thought that

where these findings occurred the albuminuria was largely due to the Bence Jones fraction and that negative reports of its absence were erroneous. In Bailey and Haines's series of cases, 29 out of 32 patients suffering from multiple myeloma had albuminuria. This was equal to 90% of their cases, and was the most frequently observed positive laboratory investigation in their series.

More than a year has elapsed since the first biopsy was made in our case, and in view of the normal findings on recent radiological examination it is most likely that the lesion was a primary extramedullary plasmacytoma. Diffuse plasma-cell myelomatosis with little or no radiographic evidence of bone lesions does occur, and this is still a possibility in view of the equivocality of the marrow picture. The continued absence of Bence Jones proteosuria is, however, a strong point in favour of the former diagnosis.

Summary

A case of extramedullary plasmacytoma is reported. The differential diagnosis, the interrelationship of the three main types of plasma-cell tumours, and the significance of the main findings are discussed.

We thank Professor R. A. Willis for his helpful advice and criticism in the preparation of this paper. We also thank Dr. E. K. Blackburn for help with the haematology, Professor R. St. Leger Brockman for permission to publish the case report, and Dr. R. G. F. Lampart, of Chapeltown, Jamaica, for giving us details of the patient's present condition.

The Tobacco Industry Research Committee in the U.S.A. has invited university, hospital, and other medical research organizations to submit proposals for specific cancer research projects for consideration by the committee's scientific advisory board. The board is said to be now reviewing 60 applications and inquiries already received. An initial fund of \$500,000 has been appropriated for research. The Tobacco Industry Research Committee is composed of the large cigarette-manufacturers, tobacco-growers, and warehousemen. The scientific advisory board is guiding the development of long-term research to be conducted in institutions outside the tobacco industry. The industry will not set up any research facilities. No industry funds will be given to tobacco company laboratories. All projects will be in addition to research carried on by companies. The members of the advisory board are: Dr. CLARENCE C. LITTLE, director of the Roscoe B. Jackson Laboratory; Professor MCKEEN CATTELL, head of the department of pharmacology at Cornell University Medical College; Dr. LEON JACOBSON, professor of medicine at the University of Chicago; Dr. PAUL KOTIN, assistant professor of pathology at the University of Southern California Medical School; Dr. KENNETH LYNCH, professor of pathology at the Medical College of South Carolina; Dr. STANLEY P. REIMANN, scientific director of the Institute for Cancer Research, Philadelphia; and Dr. WILLIAM F. RIENHOFF, Jr., associate professor of surgery at the Johns Hopkins School of Medicine, Baltimore.

ISONIAZID AND WEIGHT GAIN

A PILOT INVESTIGATION

BY

I. S. MUDIE, M.B., D.T.M.&H.

N. W. HORNE, M.B., M.R.C.P.Ed.

AND

J. W. CROFTON, M.D., F.R.C.P.

(From the Department of Tuberculosis and Diseases of the Chest, University of Edinburgh)

In groups of patients with pulmonary tuberculosis treated with isoniazid a remarkable gain in weight has been one of the principal effects reported (Medical Research Council, 1952, 1953). Compared with other treatments, weight gain has been so marked as to lead to a suspicion that a non-specific effect on metabolism was involved as well as a direct effect on the disease. There have also been reports of a great increase in appetite, undue sleepiness or wakefulness, and alterations in emotional tone, although none of these has been so frequent as the gain in weight. In order to determine whether it was worth while undertaking detailed metabolic investigations or a large-scale trial in normal subjects it was decided to carry out a controlled pilot trial on a small scale.

Methods

The subjects were eight male medical members of this department aged between 25 and 40. None had had tuberculosis, and in all a normal radiograph of the chest was obtained immediately before the start of the trial. They were divided by random allocation into a treatment group and a control group, each of four subjects. No subject knew to which group he had been allotted. The total period of the trial was fourteen weeks, including an initial observation period of two weeks before administration of any drugs and a final two-weeks period after administration had stopped. The control group received capsules containing lactose, and the treatment group was given isoniazid 100 mg. twice a day in identical capsules. The control group received lactose for the whole ten weeks. During the ten weeks of administration the treatment group received isoniazid for eight weeks and lactose for two weeks. By this plan each subject given isoniazid had control periods on lactose and on observation alone. In addition the whole treated group was compared with a control group, randomly selected, which received only lactose.

The subjects were weighed weekly to the nearest quarter-pound (0.1 kg.). In order to avoid suggestion or alteration in food intake they were weighed with their backs to the scale and were not informed of the readings. At the end of every week's treatment each subject filled in a questionnaire recording his impressions with regard to appetite, sleep, emotional tone, or any other possible effects of the drug.

Results

The weight changes are given in the Table. The individual gains or losses of weight over the two-weeks initial and two-weeks final observation periods are listed for both treatment and control groups. For the control group the weight change over the ten weeks on lactose is recorded, but for the treated group the changes during the two weeks on lactose and the eight weeks on isoniazid are given separately. The average weight change per man per week is calculated for each period. It will be seen that the average weight gain per man per week when the treated subjects were on isoniazid was 0.13 lb. (59 g.), compared with 0.12 lb. (54 g.) when on lactose and 0.53 lb. (240 g.)

Weight Changes in Normal Males Given Isoniazid and in a Control Group

Subject	Loss or Gain in Weight (lb.)				Net Change in 4 Weeks
	2 Weeks' Initial Observation	2 Weeks on Lactose	8 Weeks on Isoniazid	2 Weeks' Final Observation	
Treatment group:					
T1	+1	-1	-3	+1	1
T2	+1	+1	+3	-2	+4
T3	+1	+1	+4	-1	+4
T4	0	-1	-1	-1	-2
Total	+4	+1	+4	-1	+7
Average weight change per man per week (lb.)	+0.53	+0.12	+0.13	-0.17	+0.14
Control group:		10 Weeks on Lactose			
C1	-1	-1	-1	+5	+4
C2	-1	-1	-1	+1	+4
C3	+2	+1	+1	-1	+1
C4	+1	+1	+1	0	+2
Total	+1	+10	+1	+2	+14
Average weight change per man per week (lb.)	+0.22	+0.25	+0.36	+0.25	

* This subject stopped isoniazid after 64 weeks because of Raynaud's phenomenon. The next weighing was at 7 weeks, so he is included in the calculations as if he had had 7 weeks' isoniazid and 3 weeks' subsequent observation.

† Weight for final observation week not recorded; calculations based on a single final observation week and 13 weeks' total observation.

during the initial two-weeks observation period when no drug was administered. An average loss of 0.17 lb. (77 g.) occurred during the final two-weeks observation period, suggesting that there was no delayed effect of isoniazid in increasing weight. The control group averaged 0.25 lb. (110 g.) gain per man per week when on lactose and 0.22 (100 g.) and 0.36 lb. (160 g.) during the initial and final observation periods. The individual fluctuations in the two groups do not suggest that there was any difference between them attributable to the drug. It will be noted that both groups on average gained weight. This may be because the trial was started in January and continued to the early spring, or possibly because the trial itself had some psychological effect.

Appetite.—Of the four subjects in the control group, two noted no change; the other two recorded fluctuations at varying periods. In the treatment group, only one recorded an unchanged appetite; fluctuations occurred in the other three, but without any consistent pattern which suggested an effect of the drug.

Sleep.—In the control group two observed no change, whereas two recorded variations in their sleep requirements from week to week. They were the same subjects who had shown some variations in their appetite. In the treatment group three recorded no change, but the fourth said that he was definitely more sleepy in the evenings during the last three weeks of the course, and during the last two weeks had been having more frequent nightmares. It is, to say the least, doubtful whether these changes should be attributed to isoniazid.

Emotional Tone.—One of the control group stated that he had become more cheerful, but in the treatment group no changes were recorded.

Other Possible Side-effects.—The only other effect which might be of significance was an experience of one subject to whom isoniazid was being administered. After four and a half weeks of continuous isoniazid treatment he experienced Raynaud's phenomenon in both hands, with stiffness, blanching, and coldness. This became steadily worse during the ensuing two weeks, and the drug was stopped. There was steady improvement thereafter. This subject had never experienced Raynaud's phenomenon before, but its relation to isoniazid must remain in doubt.

Discussion

The results of this study in man, although its scale was limited, are consistent with experiments in animals. Normal rats treated with isoniazid showed no significant gain in weight (Benson *et al.*, 1952; Rubin *et al.*, 1952), and in dogs there was no change in metabolic rate (Rubin and Burke, 1953). In man, Faloon (1953) found no change in nitrogen balance, appetite, or food intake in three patients with non-tuberculous disease given isoniazid for six to eight days. The observations here presented provide no evidence that isoniazid has any effect in causing gain in weight in the normal human male. In view of the negative results, we do not contemplate engaging in a trial on a larger scale. It seems doubtful whether the minor side-effects noted above were attributable to isoniazid.

Summary

The average weekly weight gain in four healthy males receiving isoniazid for eight weeks was similar to the gain in the same group treated for two weeks with control capsules containing lactose and to the gain during four weeks on observation alone. The average weekly gain was less than that of a similar group of four males treated for 10 weeks with control capsules containing lactose. We have therefore obtained no evidence to suggest that isoniazid in tuberculous patients has an effect on weight gain other than that due to its effect on the disease. No side-effects were recorded which could be attributed with certainty to isoniazid. One member of the treated group became unduly sleepy; another experienced Raynaud's phenomenon for the first time. One of the control group experienced an unexpected increase in cheerfulness, but no change in emotional tone was recorded by any member of the treated group.

We are most grateful to our colleagues who cheerfully put up with the inconveniences of the trial. We also record our gratitude to Messrs. E. R. Squibb and Sons for a generous gift of the isoniazid and control capsules. This investigation is one of a series supported by a grant from the Royal Victoria Hospital Tuberculosis Trust.

The annual report of the Fountain Hospital, the 600-bedded hospital at Tooting Grove for mentally defective children from London and Surrey, draws attention to Section 3 of the Mental Deficiency Act, which allows a child to be placed in hospital by the parents without the need of a magistrate's order. Of the 84 certified direct admissions to the Fountain Hospital during 1953, over 80% were admitted under this procedure. The admission of young children without any legal formalities, the report continues, would go a long way towards improving the public's attitude to mental deficiency in young children. Indeed, a plea is made that this should be tried out experimentally. "If the Fountain Hospital, owing to its special circumstances, could be exempted for a temporary period from the normal working of the Mental Deficiency Acts experience would be gained in the voluntary care of defective children, comparable to that made possible by the Mental Treatment Act of 1930. This evidence might be of considerable value to the Royal Commission inquiring into the certification and detention of mental patients."

BLOOD GROUPS
AND GYNAECOLOGICAL CANCER

BY

ERIK KROKFORS, Med.lie.

AND

OLAVI KINNUNEN

Lecturer in Gynaecology, Assistant Physician-in-Chief
 (From the Women's Clinic I and II, Helsinki, Finland)

Stocks showed in 1950 that the standardized mortality of cancer of the stomach tended to be greater in northern than in southern towns in England. He assumed this to be connected with the fact that gastric cancer depends on an irritant. In an attempt to explain the variations in mortality, Aird, Bentall, and Roberts (1953) demonstrated that the frequency of blood group A was greater in patients suffering from gastric cancer than in the general population of the same locality. They collected their series from a number of hospitals in England and Scotland, using as controls an equal number of patients chosen at random from the same hospital or, where this was difficult, estimating an equal control number from the blood-group frequencies in large numbers of the local population. In most cases diagnosis was confirmed by a histological report; in only a few cases were the authors dependent on radiological findings or on the clinical picture alone.

Table I shows the results of Aird, Bentall, and Roberts. It indicates that in different parts of England and Scotland the frequency of blood group A was

TABLE I

	Cancer Cases				Controls			
	O	A	B	AB	O	A	B	AB
Newcastle (101 cases)	43.6	43.6	11.9	1.0	52.5	37.4	7.6	2.5
Leeds (217 cases)	42.4	47.9	7.4	2.3	46.5	40.3	7.1	6.2
Manchester (771 cases)	44.7	44.5	6.4	3.8	52.1	38.4	7.0	2.5
Liverpool (217 ca. es)	39.2	44.7	12.4	3.7	49.7	39.6	7.8	2.7
Birmingham (100 cases)	37.0	57.0	3.0	3.0	49.6	44.4	3.0	3.0
Total of Northern England (1,406 cases)	42.9	46.4	7.6	3.1	50.7	39.3	6.8	3.2
London (1,340 cases)	43.1	46.0	7.9	2.9	45.8	42.2	8.9	3.1
Scotland (478 cases)	51.2	36.4	9.6	2.7	52.6	32.5	11.7	3.1
Overall figures (3,632 cases)	44.5	44.8	7.8	2.9	48.6	39.8	8.3	3.2

greater and that of blood group O correspondingly less in patients with cancer of the stomach than in the general population.

Our Own Investigations

It seemed of interest to make a corresponding study of the distribution of the blood groups in patients suffering from gynaecological cancer. Our series consists of 300 patients with uterine or other gynaecological cancer whose blood groups had been determined; they were treated at the Women's Clinic of the University of Helsinki during the period 1948–53. Diagnosis was confirmed in all cases by a histological report. Owing to the centralization of hospital conditions in Finland, the majority of all cases of gynaecological carcinoma, both operative cases and those given radiation, are treated at the Women's Clinic in Helsinki. This being so, the patients no doubt represent a cross-section of the population as regards distribution of blood groups. The control series was therefore selected on a similar basis.

All such acute cases of gynaecological disease as are predominantly from Helsinki or its immediate vicinity—for example, abortions and extrauterine pregnancies—were excluded. We also used for control purposes the data published by Streng and Ryti (1927) regarding blood-group distribution in the general population of Finland.

Table II compares our results with the data obtained by Streng and Ryti.

TABLE II

	Gynaecological Cancer				Controls			
	O	A	B	AB	O	A	B	AB
Krokfors and Kinnunen	113 37.7%	110 36.7%	57 19%	20 6.7%	98 31.6%	139 44.8%	48 15.5%	25 8.1%
Streng and Ryti					33.5%	42.7%	16.8%	7.0%

Comparison of the control data in Tables I and II shows, first, that the frequency of blood group O is considerably less and that of groups B and AB correspondingly greater in the general population of Finland than in that of England and Scotland. Group A is about equally frequent in both countries. But when we compare the distribution of blood groups in our carcinoma patients and in our controls we find that blood group O seems to predominate clearly in the cancer group, blood group A having a correspondingly lower frequency.

We subclassified our cancer group into cancer of the uterus and other gynaecological cancer, and this seemed to cause no appreciable changes in the distribution of the blood groups (Table III).

TABLE III

	O	A	B	AB
Cancer of the uterus	37.9%	37.1%	18.5%	6.5%
Other gynaecological cancer	36.5%	36.5%	20.0%	7.0%

It occurred to us that there might be a correlation between the blood group and the age of the patient at the onset of gynaecological cancer. We therefore studied separately 100 patients, the youngest in the series. Their upper age limit was 45 years. The blood groups were as follows: O, 42%; A, 33%; B, 17%; and AB, 8%. The relatively greater frequency of blood group O thus seemed to increase further when this subdivision was made.

Conclusion

On the basis of our own studies we can only state briefly that, in contrast to the English series of cancer of the stomach, a Finnish series of gynaecological cancer showed a clearly lower frequency of blood group A than the corresponding controls. It seemed, on the contrary, that the incidence of blood group O was particularly high in our series of gynaecological cancer; this appeared most distinctly in the youngest patients studied.

From May 16 margarine must contain between 760 and 940 international units of vitamin A per ounce and between 80 and 100 international units of vitamin D per ounce. This vitamin-A content is roughly equivalent to that of butter. This Order applies to all home-produced and imported margarine sold by retail, including margarine sold as such by a caterer but not margarine used by him in made-up foods or in cooking. It does not apply to sales of margarine to a caterer.

Medical Memoranda

Extreme Sensitivity to Insulin

Since its introduction by Sakel in 1935, treatment by insulin has been widely used in various forms of mental illness. Considerable variations have been experienced in the reaction of patients to insulin, and it is generally agreed that there is marked individual sensitivity to the drug (Tennent, 1944). Success in the induction of coma has been reported with doses of 15 units (James *et al.*, 1938) and of 18 units (Parfitt, 1937). A case is described in which coma was induced with a dose of 2 units, and a method of desensitization is given. I have been unable to trace any record in the literature of coma being induced with such a small amount of insulin.

CASE REPORT

An unmarried woman aged 19 suffering from anorexia nervosa was referred to Fulbourn Hospital, Cambridge, for a course of modified insulin on July 20, 1953. Her weight at this time was 5 st. 7½ lb. (35 kg.).

The initial dose (see Table I) was 15 units, given intramuscularly at 7.15 a.m. At 9.30 a.m. she was in sopor and showed loss of a normal response to speech and

TABLE I

Days	Units of Insulin Given at 7.15 a.m.	Time of Sopor	Time of Coma
1	15	9.30 a.m.	10.5 a.m.
2	10	9.50 "	10.0 "
3	1	No reaction	No reaction
4	3	10.15 a.m.	10.25 a.m.
5	Sterile water	No reaction	No reaction
6	2	10.0 a.m.	10.30 a.m.

impairment of orientation. At 10.5 a.m. she was in coma: she showed loss of all purposive responses, none being elicited from visual, auditory, or tactile stimuli. The next day the dose was reduced to 10 units, and sopor was produced at 9.50 a.m. and coma at 10 a.m. Because of this marked sensitivity, the following morning she received only 1 unit. This produced no effect. The next day the amount of insulin was raised to 3 units, and sopor came on at 10.15 a.m. and coma at 10.25 a.m.

To ensure that it was in fact the insulin which was causing these reactions, on the succeeding morning an intramuscular injection of sterile water was given at 7.15 a.m., but this had no effect whatever on the patient. At the same time a specimen of blood was taken in order to ascertain the fasting blood sugar. This was 0.72 g. per 100 ml. The next morning 2 units of insulin was given, and this time sopor was induced at 10 a.m. and coma at 10.30 a.m.

It was decided to attempt to desensitize the patient by starting at a dose of 0.2 unit and increasing this by 0.2 unit daily. This proved successful, and by December 18 she was having 17 units daily, which was enough to induce drowsiness but not to produce sopor or coma. Her weight was then 6 st. 2 lb. (39 kg.).

COMMENT

It is known that insulin hypersensitivity is present in clinical cases of hypopituitarism—for example, Simmonds's disease (Wright, 1952). As the physical picture of this disease may closely resemble the classical "anorexia nervosa" and as there may be a secondary disturbance of pituitary function in the later and more severe stages of anorexia nervosa, the patient was investigated to discover if any pituitary dysfunction was present. The following factors were in favour of anorexia nervosa: she was a young unmarried woman of a neurotic obsessional personality, there was no loss of hair, and, in spite of emaciation, restless overactivity was very obvious.

Fraser and Smith (1941) have sought to differentiate between organic pan-hypopituitarism and "functional" anorexia nervosa by estimation of 17-ketosteroids and an insulin-tolerance test. In the organic disorder they found

extremely low or no excretion of 17-ketosteroids, and after injection of insulin under controlled conditions delay of blood sugar in returning to normal. The 17-ketosteroid output was often low in anorexia nervosa, but in no case entirely absent. Although neither test is specific, they believe that the combination of both enables a diagnosis of pan-hypopituitarism to be made with fair accuracy (Hemphill, 1944). In the above case the 17-ketosteroid excretion was 5.8 mg. a day (normal range, 4–20 mg. a day). The insulin-tolerance test showed no delay in the return of the blood sugar to normal after 120 minutes (see Table II). It would therefore seem that the pituitary was functioning normally.

TABLE II.—Insulin-tolerance Test (0.3 Unit per kg. Body Weight Given Intravenously at 7.15 a.m.)

Blood Taken	Result (g./100 ml.)
Before insulin given	0.077
20 minutes after giving insulin	0.056
30 "	0.047
45 "	0.059
60 "	0.057
90 "	0.065
120 "	0.077

I would like to thank Dr. D. H. Clark, medical superintendent of Fulbourn Hospital, for his valuable criticism of this report.

Poliomyelitis in Mother and Child in Trieste

In recent years we have begun to recognize that poliomyelitis in infancy is not a rare occurrence. Reports by earlier observers, including Mouton, Smillie, and Bowers (1950), have stressed the rarity of infection in young children, but in recent reports such as that of Logan (1952) a different story is told. He records that in the outbreak in England and Wales of 1950 there were, for example, 82 reported cases in children under 6 months of age.

Infection in the neonatal period, however, although well known, is an event of some interest. Thus there are reports of five cases in 1950 in England and Wales in such an age group, of which four were fatal. In 1952 an outbreak occurred in a private nursing-home (Sims-Roberts and Thomson, 1953), and of the four babies affected three died. Wright and Owen (1952) record a further case of neonatal infection in which both mother and child died of the disease. This therefore brings the total of neonatal cases in England and Wales in 1952 to five, with four fatalities. Obviously the incidence is much greater than these figures would suggest, as subclinical and non-paralytic cases are more common than paralytic and more difficult to detect in the very young child. Indeed, it is usually the onset of paralysis which is the first indication that infection has taken place, and the pre-paralytic stages are very often silent. Thus in two outbreaks in England in 1950 and 1952 affecting many thousands of people there are reports of only 10 neonatal cases, of which 8 were fatal.

In Trieste there is an Italian-Slav population of approximately 300,000, and a British military population of 5,500, including troops and families. Only 14 cases of clinical poliomyelitis were reported here last year, and in the British military population only two. These two cases were in a mother and her newborn child, and are of interest because of the rarity of such an event, considering the total number of cases involved. No cases have been recorded by the American forces in Trieste.

Neonatal infection is rare and often fatal, but for some obscure reason infection in both mother and young child seems to be even less frequent. In Logan's figures for 1950 there were, according to Geffen and Tracy (1953), only six instances of infection in mother and child, and of these

only two of the babies were in the neonatal period when affected. The ages of the other children in whom there was this "mother-child" infection varied from 9 to 17 weeks.

Thus in 1950 there were only two cases in which clinical or subclinical poliomyelitis was recognized in both mother and newborn child. In 1952 only one case was recorded—that of Wright and Owen, in which both mother and child were affected—although in one case reported from the nursing-home outbreak poliomyelitis virus type III was isolated from the stools of one healthy mother. There are examples of only three cases of double infection in these two years, and it is of note that in all three cases the mother died, and in two the child died also. The remaining child was said to have suffered from a severe attack of the disease. The following cases are therefore of interest in that they record the occurrence of a "mother-child" infection in a very small poliomyelitis outbreak affecting a British population overseas. Further, both mother and child have survived and at the time of writing this report were improving.

CASE HISTORIES

1. The wife of a British Army sergeant was admitted to the B.M.H., Trieste, on September 13, 1953. Thirteen days previously she had been delivered of a healthy female infant in the same institution. When seen on September 12 she had complained of two days' headache and fever, and on the morning of admission she noticed weakness of both legs and inability to pass urine. On examination she was pyrexial, temperature 103° F. (39.4° C.), and there were signs of complete flaccid paralysis of the lower limbs without sensory changes, together with bladder and bowel paresis. Lumbar puncture on September 14 showed 234 cells per c.mm., 87% of which were polymorphs; and 75 mg. of protein per 100 ml.

2. The daughter of the above patient was admitted at the same time as her mother and isolated from her. She was then 13 days old, and it was noted that her rectal temperature was 101° F. (38.3° C.). One day later the child was still pyrexial, and suddenly developed a complete and flaccid paralysis of the right arm with minimal involvement of the muscles of the left shoulder girdle also. The general hypotonicity and drowsiness of the child were significant features during and immediately after the development of paralysis. These characteristics have been stressed by Shelokov and Weinstein (1951), the classical signs and symptoms of poliomyelitis in its early stages often being absent at this age. Lumbar puncture on September 16 showed 69 cells per c.mm. (17% polymorphs, 72% lymphocytes), and 110 mg. of protein per 100 ml.

After four weeks' observation both of these patients were transferred to another centre for further treatment. At this time their clinical condition had improved and some movement was beginning to return in the lower limbs of the mother.

SUMMARY AND CONCLUSION

Two cases of poliomyelitis are reported in the Army population in Trieste, where a very small outbreak occurred. These two cases consisted of a mother and her 13-days-old child, both of whom sustained paralysis and had typical cerebrospinal fluid.

The reported combination of clinical infection in mother and newborn child is rare, and that of poliomyelitis in the neonatal period is also of sufficient rarity to record.

Both of these patients have survived, which is of interest in that poliomyelitis in the neonatal period is often fatal to the infant and, indeed, to the mother when affected.

My thanks are due to Lieutenant-Colonel R. H. Hunt for permission to publish these cases.

Reviews

THE SCIENCE OF PATHOLOGY

Lectures on General Pathology. Edited by Sir Howard Florey, M.D., F.R.C.P., F.R.S. (Pp. 733; 343 illustrations and 4 coloured plates. 63s.) London: Lloyd-Luke (Medical Books) Ltd. 1954.

This volume, edited by Sir Howard Florey, is a collection of 37 lectures delivered at the Sir William Dunn School of Pathology, University of Oxford. They form part of a 16-weeks course in general pathology taken by students who have spent the previous year reading Honour School of Physiology and are about to begin their clinical training. Each lecture occupies between 10 and 20 pages of text and there are 10 contributors. The volume is profusely illustrated by original photomicrographs, many of which are taken from the published research work of the authors.

The editor is responsible for 10 lectures; Professor G. R. Cameron, of University College, London, for four and part of another, and Dr. G. P. Gladstone, the University Reader in Bacteriology, for five and part of three others. Each contributor deals with subjects in which he has a special interest. Dr. A. H. T. Robb-Smith, the Nuffield Reader in Pathology, discusses collagen; Dr. R. G. Macfarlane, the University Lecturer in Haematology, the reaction of the blood and blood-forming organs to injury; and Dr. F. K. Saunders, a member of the external staff of the Medical Research Council, the cellular and tissue reactions to viruses. Equally fundamental problems are reviewed in the form of reported lectures given as part of the course by Drs. E. P. Abraham and W. E. van Heyningen, who are senior research officers, and Drs. K. B. Roberts and H. Harris, who are scholars in the Sir William Dunn School. It is quite clear from the high standard of these lectures that the Oxford medical undergraduate is given an exceptionally good opportunity in the seclusion of his University to get a firm grasp of the general principles of pathology before he enters the strange and confusing atmosphere of his hospital.

It is surprising that British pathologists have been so reluctant to provide the serious student with a full and authoritative account of the general principles of pathology. This may be partly responsible for the fact that the educational value placed upon this subject shows such wide variations from one university to another, yet no one would deny that general pathology ranks as an experimental science in its own right and deals with a branch of biological knowledge which is an essential prerequisite for the proper understanding of clinical subjects. It is certainly difficult to teach general pathology during the clinical years, for there are too many legitimate distractions in the clinical atmosphere for teacher as well as student. This, however, does not account for the wide variation in the scope and quality of its teaching. The fact is that this fundamental science is in great danger of becoming eclipsed by the enormous accumulations of knowledge which deal with the practical application of its principles to clinical diagnosis, and it is to be hoped that Sir Howard Florey's book will check this ominous threat to one of the most basic of the medical sciences.

The last British treatise confined to general pathology and written by a panel of experts was published in 1913 under the editorship of M. S. Pembrey and James Ritchie. It was greatly treasured by a former generation of pathologists, but is now outmoded and out of print. It is therefore most gratifying to find, after a gap of 40 years, that Pembrey and Ritchie now has, in this product of the Oxford school, a modern equivalent and a worthy successor which preaches the same sound doctrine and is based upon the deep conviction that "the student must try to grasp what is known of the general principles underlying the pathological changes that he will be called upon to diagnose and treat."

As one might have predicted before reading the book, the editor is a strong and convincing advocate for the use

of the experimental method, not only in pathology but with greater force in its clinical applications. He expresses the hope that "some students will find sufficient stimulus from the lectures to carry an experimental outlook into clinical medicine and surgery, for these subjects have suffered and continue to suffer in this country from an approach which pays too little attention to experimental science. At the present day nearly all significant advances in diagnosis, treatment, and prevention of disease depend upon the application of experimental methods."

For the most part the lectures deal with the various aspects of the "reaction to injury," using this word in its widest connotation. Inflammation, phagocytosis, haemostasis, fever, the tissue reaction to infective agents and to injuries inflicted by irradiation occupy over 40% of the text, while the general principles of immunity, the pathogenesis and virulence of micro-organisms, anaphylaxis, and specific hypersensitivity take up another 30%. Shock, haemorrhage, and oedema absorb 6%; healing and regeneration about 12%.

In a book devoting nine-tenths of its text to the reaction to injury it may be regarded as an unfortunate omission that the profound general metabolic response to injury receives so little consideration; but any criticism based on omission carries little weight, as the book was not planned to cover the whole subject, and in full compensation for its incompleteness it has two outstanding merits: first, that every lecture covers its subject in a commendably comprehensive manner which would be impossible in a textbook; second, that in almost all the lectures the author is dealing with a subject to the experimental study of which he has devoted a part of his life. One therefore finds, in dealing with such subjects as the participation of the lymphatics in inflammation, the secretion of mucus and inflammation in mucous membranes, blood coagulation and haemostasis, shock, regeneration, and the pathogenic action of bacteria, that the lectures have the indelible stamp of authority and are far more satisfying and infinitely more stimulating than the chapters of the average textbook. Almost every lecture is a model of the way in which scientific evidence should be handled and evaluated.

The inclusion of such general subjects as the pathology of growth and tumour formation, the functional failure of vital organs, the consequences of arterial ischaemia, and a number of other similar topics would have increased the bulk of the volume to unwieldy proportions. Having successfully but only partially filled so large a gap in British pathological literature, Sir Howard Florey and his colleagues, it is to be hoped, will regard it as a public duty to publish another volume of lectures—and the sooner the better.

GEOFFREY HADFIELD.

ADVANCES IN PAEDIATRICS

Advances in Pediatrics. Edited by S. Z. Levine. Associate Editors: John A. Anderson, Margaret Dann, L. Emmett, jun., A. Ashley Weech, Myron E. Wegman. Volume 6. (Pp. 323; illustrated. 58s.) Chicago: The Year Book Publishers Inc. London: Interscience Publishers Ltd. 1953.

This book, comprising seven monographs by recognized authorities, is well up to the high standard set by previous volumes in the series. Each article presents an up-to-date review of the subject and ends with a valuable list of references. Neonatal problems are very much to the fore at present, and this is reflected in the four monographs on, respectively, preventive prenatal paediatrics, intestinal obstruction in the neonatal period, haemolytic disease of the newborn, and pulmonary pathology in the newborn. Of these, perhaps the most stimulating is the first, by T. H. Ingalls, because he indicates the methods to be adopted if fresh light is to be thrown on the subject. As he points out, each approach—clinical, experimental, and epidemiological—presents its own difficulties, and the author's pen-picture of the clinician's feeling of frustration is worth quoting: "The nearly insurmountable obstacle to clinical study of prenatal sickness arises in the fact that the patient voices no complaint, remembers nothing about

his illness, hides himself from view, and puts off his visit to the doctor until the last possible moment."

S. van Crefeld's monograph on the lipoidoses is an excellent survey of a difficult subject; and the chapter by H. W. Dargeon on lymphosarcoma in childhood will be welcomed not only for its detailed information about a relatively uncommon growth but because the prognosis is viewed somewhat more hopefully than in the past.

The final monograph—on megaloblastic anaemia of infancy—is a comprehensive review of some 55 pages and with 122 references. The authors (W. W. Zuelzer and J. Rutzky) cover all aspects of this curious disorder and discuss their own cases in some detail. Prevention and treatment are carefully considered, and, as might be expected, the paper is a happy combination of the experimental and clinical viewpoints.

Each new volume of *Advances in Pediatrics* adds emphasis to the wisdom of having this series available in medical libraries.

NORMAN B. CAPON.

MYOCARDIAL CONTRACTION

On the Nature of the Myocardial Contraction: A Study of the Electrolytes. By F. Lenzi and A. Caniggia. Preface by Professor G. Izar. (Pp. 112; 19 figures. No price.) Basle and New York: S. Karger. 1953.

This little book describes the clinical application of the work of one of the authors on the electrolytes in the heart. The English is good and the book is most readable; even if the technical nature of the subject sometimes makes the expression rather hard to follow, there is really no great difficulty, for clarity and brevity are qualities to be found throughout. This subject is becoming of considerable importance to the cardiologist. The question of sodium metabolism is much to the fore. It seems likely that study of the electrolytes and the part they play in the contraction of the heart may provide the next big step forward in understanding what happens when the heart fails. The relative importance of the electrolytes and of adenosine triphosphoric acid is carefully discussed. It is with the former that most of the authors' work has been done. By using the terms of electrocardiography the authors have now sought to explain what goes on at the cell membrane. This gives some information about the variations of the concentration of ions inside and outside the cell. The opposition of the ions of sodium and potassium, the one mainly outside and the other mainly inside, affects the muscular contraction. They point out how particularly important is the "gradient" or actual differences in the levels of concentration of the ions across the cell membrane. How far the authors' theories are correct the clinician cannot judge, but it has been most interesting and stimulating to read about them. This book will certainly appeal to cardiologists as a good discussion of a fascinating subject which deserves careful study.

TERENCE EAST.

CANCER RESEARCH

Advances in Cancer Research. Volume 1. Edited by Jesse P. Greenstein and Alexander Haddow. (Pp. 590. \$12.) London and New York: Academic Press Inc. 1953.

The post-war years have been noted for a series of excellent summaries on various subjects in biochemistry. These have appeared on both sides of the Atlantic, and in the case of the volume at present under review many have been prepared on both sides of the ocean. *Advances in Cancer Research* is edited by Professor J. P. Greenstein and Professor A. Haddow, both well-known names in the field. This volume is the first of a series which will be produced from time to time, and the object is to provide an up-to-date account of various aspects of cancer research. That this has been done can very readily be verified by turning to the references, and one will see that there are a number of papers quoted in late 1952.

The book begins with a very able summary of the present position in relation to electronic configuration in carcinogenesis by C. A. Coulson. The second part deals with

epidermal carcinogenesis by E. V. Cowdry, and it is interesting in that the section is devoted to the question of epidermal carcinogenesis in the human subject. The milk agent is given a special section by Dmochowski, in which he gives a clear account of the rather complicated relationship of the milk agent and the hormonal production of cancer of the breast. W. U. Gardner gives a very full account of hormones in relation to the development of tumours in experimental animals, whilst R. J. C. Harris deals with the question of the Rous agent. This section concludes with an interesting speculative account on the origin of the Rous agent. Radioisotopes in relation to experimental cancer research are dealt with by C. Heidelberger, and a full summary of the present position of the carcinogenic aminoazo dyes has been written by J. A. Miller and E. C. Miller. The cytotoxic agents are discussed by W. C. J. Ross, and there is a most interesting account on nutrition in relation to malignant disease by A. Tannenbaum and H. Silverstone. There are some interesting observations recorded on cancer in man in relation to nutritional states. The volume concludes with a paper on plasma proteins by R. J. Winzler.

It is not possible to do more than mention the sections in this brief review, but in general it may be said that the standard of the whole book is very high indeed, and no cancer research laboratory can afford to be without it.

E. C. DODDS.

AGE AND ACHIEVEMENT

Age and Achievement. By Harvey C. Lehman. Memoirs of the American Philosophical Society held at Philadelphia for promoting useful knowledge. Volume 33. Foreword by Lewis M. Terman. (Pp. 359; 170 figures. 60s. or \$7.50.) Princeton, U.S.A.: Princeton University Press. London: Geoffrey Cumberlege. 1953.

Osler's severe judgment that the world could do without men over 40 and would be well rid of men over 60 is unlikely to appeal to a generation more concerned with raising the pensionable age than with lowering the age at death. Nevertheless, for anyone above or near the age of 40 it will be comforting to learn that the contemporary viewpoint is supported by something more than humanitarian considerations. This comfort is provided in a book by an American professor of psychology who has attempted to identify the "great works" (in science, medicine, philosophy, music, art, and literature), and to establish the ages at which they were produced. His data indicate that although the age of greatest output is undoubtedly below 40, and is surprisingly constant over a wide range of subjects, there is no age at which men cease to make important contributions. Chloroform at 60 (the newspapers' interpretation of Osler's remark) or even at 80 would remove some useful as well as many useless people.

After inspecting the 61 tables and 170 figures in *Age and Achievement* the reader may ask himself whether it was necessary for the author to put himself to quite so much trouble to make his points. It is an unfortunate practice among social scientists to expand to book length material which in other fields would be communicated in a modest paper in a research journal, and one feels that Mr. Lehman might have had a greater reward for less effort if instead of examining age of achievement so exhaustively he had taken up one or more of the numerous problems raised by his fascinating subject. Nevertheless some of his data are interesting, although those who doubt the relevance of statistics to the human situation are unlikely to be reassured by the statement that "appropriate computations suggest that if an author is destined to produce a book of such unusual merit as to be chosen by 8 or more compilers of best book lists, the chances are much less than one to a thousand that the author will publish that book when he is beyond 80 years of age." And they may feel that one place of decimals would have been sufficient to convey the information that at the time he published the second part of *Faust* Goethe was 3.56 standard deviations above the mean age of 101 authors of 224 best books.

THOMAS MCKEOWN.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY JUNE 5 1954

CARDIAC SURGERY AND THE ARTIFICIAL HEART

Many successful experiments have now been performed at various centres throughout the world in which a mechanical device is substituted for, or assists, the heart and lungs of an animal. A temporary artificial circulation of this sort has now been used in several human patients. Elsewhere in this issue of the *Journal* Professor Ian Aird and his colleagues describe the use of a pump-oxygenator during an operation for the relief of aortic stenosis. The apparatus used was the one described last year in this *Journal* by Melrose,¹ who with his colleagues reported experiments on dogs.² F. G. Dodrill, of Detroit,³ has recently reported four operations, using a mechanical heart.

The potential usefulness of such machines lies not only in cardiac surgery but also in the emergency treatment of acute cardio-respiratory failure. The apparatus consists essentially of a pump or pumps and of an oxygenator; the latter need not be used if the subject's lungs continue to function. Its purpose is to assist the heart, or to replace it entirely, or to replace one or other side of the heart. In reversible acute cardiac failure, as sometimes occurs with myocardial infarction, it should be possible to aid the enfeebled heart by withdrawing blood from the great veins, pumping it through the oxygenator, and returning it to the systemic circulation. The necessary cannulation of a major artery may mean its subsequent ligation is unavoidable. For cardiac operations a by-pass of one side alone will often suffice.

Since no efficient cardioscope has been devised, all operations on the heart valves must at present be done blindly, and guidance by the surgeon's sense of touch may often only be indirect, through instruments. The prospects of a dry heart offer attrac-

tive possibilities of operating under direct vision. To by-pass the right side of the heart blood must be withdrawn from the right atrium and returned to the pulmonary artery. Alternatively blood can be taken from the venae cavae, which are then clamped near the heart; but this manoeuvre allows the considerable blood flow from the coronary sinus and Thebesian veins to enter the heart, which is then by no means dry. The cannula returning the blood to the circulation can conveniently be inserted in the lower branch of the right pulmonary artery pointing upwards, so that the left lung is also supplied. There are not many conditions for which the right by-pass is needed: perhaps the most important is congenital pulmonary stenosis; the septum must of course be intact and the main pulmonary artery clamped just below its bifurcation. It has been shown in animals, and the finding probably applies to man, that reflexes arise from the right side of the heart which pass by the vagus nerve and help to control the systemic blood pressure; as the atrium empties, the pressure falls. This effect is increased in the presence of anoxia, which underlines the importance of good oxygenation.

The left side of the heart can be by-passed by extracting blood from the pulmonary veins—four cannulae being used—and returning it to the aorta via the subclavian artery. This enables the mitral valve to be exposed under direct vision. The aortic valve must be competent or reflux of blood will flood the field. There are good prospects here for advance on the crude surgery now possible, and hope that an effective technique for the relief of mitral incompetence may be devised. The left side can also be by-passed by extracting blood from the left atrium; if this is done the atrium must not be left open, since air embolism will occur. This prevents exposure of the mitral valve, but prolonged blind manipulations can be done. By a combination of the methods described above both sides of the heart can be completely by-passed without using an artificial oxygenator—an arrangement probably of most value in the treatment of congenital defects with a patent septum. Professor Aird and his colleagues used the pump-oxygenator to assist the whole circulation, extracting blood from the inferior vena cava via the femoral vein and returning it to the aorta via the femoral artery after it had been oxygenated. The patient, with aortic stenosis, severe angina, and congestive failure, would not have been fit for operation without assistance, especially as the necessary manipulation would have reduced the coronary blood flow below the tolerable level, resulting in irreversible ventricular fibrillation. A successful dilatation was carried out. To prevent blood clot-

ting in the apparatus heparin was added; in spite of neutralization by protamine, troublesome but not serious haemorrhage occurred towards the end of the operation. It was thought that this was mainly due to loss of platelets. The patient's angina was relieved, and her exercise tolerance greatly increased.

Dodrill and his colleagues^{3,4} by-passed the right heart in a young man for twenty-five minutes, and performed a pulmonary valvuloplasty under direct vision: the patient made a complete recovery. In another case, a left by-pass enabled an open operation to be successfully performed on the mitral valve. A left by-pass for a closed mitral operation lasting seventeen minutes had previously been reported.⁵

Dodrill also describes an operation for congenital pulmonary stenosis on a girl who had both sides of her heart by-passed: she survived four days. The use of a mechanical heart during operation for the repair of cardiac defects has also been reported by Dennis and his colleagues⁶ (successful repair of an atrial septal defect), by Helmsworth and his colleagues⁷ (repair of ventricular septal defect, with death sixteen hours later), and by Dogliotti.⁸ Operations have also been reported⁹ to have been carried out successfully on the hearts of patients with the aid of a compatible donor's lungs instead of an oxygenator. The subjects' venous and arterial circulations are connected to those of the donor by polythene tubing; a pump assists the cross-circulation.

Hypothermia, or artificial lowering of the body temperature, by reducing the demands for oxygen allows a greatly reduced circulation and provides another means of obtaining a dry heart for the surgeon—perhaps by a less complicated method than the mechanical heart. It may be found that a combination of the two techniques will be valuable.

ALDOSTERONE, THE NEW ADRENAL STEROID

Some months ago we referred¹ to a new and highly potent adrenal steroid, provisionally termed electrocortin, which was isolated in crystalline form from the adrenal glands by British and Swiss investigators working in collaboration—Simpson and Tait, of the Middlesex Hospital, London, Reichstein and von Euw, of Basle University, and Wettstein and Neher, of the Ciba research laboratories, Basle.² These same workers³ have now succeeded in establishing the chemical structure of the hormone, which chemically is closely related to cortisone and deoxycortone but differs in containing an aldehyde group. In view of this the new hormone has been named "aldosterone"

instead of "electrocortin." Drs. C. L. Cope and J. Garcia-Llaurado draw attention in this issue of the *Journal* to reports of the occurrence of a sodium-retaining substance in normal human urine and of an increased amount of this principle in the urine in conditions such as congestive heart failure, nephrosis, and hepatic cirrhosis with ascites. It is of interest that Cope and Llaurado think it likely that the sodium-retaining effects observed by these earlier investigators were due to the presence in the extracts of aldosterone, for by means of paper chromatography they have identified what appears to be this hormone in certain urinary extracts which they found to have sodium-retaining activity.

So far detailed investigation of the physiological activity of aldosterone has been difficult because of the very small quantities that are obtained by extraction of the adrenal glands. In a recent paper Gross and Gysel,⁴ of the Ciba laboratories, have reported experiments on the action of aldosterone in the adrenalectomized dog, the tests used being the survival test and the effect on the electrolyte and water metabolism. They found that the daily dose of aldosterone necessary for the maintenance of life in the adrenalectomized dog is 1.5 to 2.0 µg./kg. injected subcutaneously in two divided doses in oily solution, whereas the maintenance dose of deoxycortone acetate (D.C.A.) for animals weighing 13 to 16 kg. is 0.7 to 1.0 mg. injected subcutaneously daily. Aldosterone is thus 25 to 30 times more active than D.C.A. in this test. After changing over from D.C.A. to aldosterone, which owing to limited supplies could not be administered for more than ten days, the excretion of urine was increased and the urinary sodium and chloride showed a transient rise, while the concentrations of chloride, sodium, and potassium in the plasma showed no clear-cut changes. The authors suggest that the increased excretion was probably due to excretion of depots of sodium, chloride, and water which had been retained under D.C.A. therapy. These changes were accompanied by an increase in the haemoglobin concentration and in the blood non-protein-nitrogen, representing the disappearance of the hydraemia which develops in the adrenalectomized dog treated with D.C.A. In water-load experiments Gross and Gysel found that with aldosterone the excretion is delayed in about the same manner as with D.C.A., whereas, in contrast to D.C.A., overdosage with aldosterone for several days does not produce any marked retention of water, sodium, and chloride.

Amer. med. Ass.*, 1952, 150, 642.⁶ *Ann. Surg.*, 1951, 134, 709.⁷ *J. thorac. Surg.*, 1953, 26, 617.⁸ *Bull. Johns Hopk. Hosp.*, 1952, 90, 131.⁹ *New York Times*, May 1, 1954.

On the clinical side Mach and his colleagues¹ have given aldosterone to two patients with Addison's disease and obtained results similar to those described above in the adrenalectomized dog. The effective dosage lay between 150 and 200 μ g. per day (2.5–3.3 μ g./kg.), aldosterone thus proving in man to be 20 to 30 times more potent than D.C.A. Within several hours of the beginning of treatment the clinical symptoms of the disease disappeared and within a few days skin pigmentation regressed and the blood pressure rose to normal. Like D.C.A., aldosterone caused sodium and chloride retention and increased the excretion of potassium, and unlike D.C.A. it converted the hypoglycaemic glucose tolerance curves to normal. In one of the patients who had arthralgia of the knees this symptom disappeared during treatment with aldosterone. The new hormone thus seems to combine the effects of deoxycortone with certain properties of cortisone. We now await its synthesis on an economical basis, for if supplies become generally available aldosterone will probably supplant deoxycortone and cortisone in the treatment of adrenal insufficiency.

ENCEPHALITIS IN CHILDHOOD

Twenty-five years ago the term encephalitis was almost synonymous with encephalitis lethargica (von Economo's disease). Since then many other varieties have been described, and encephalitis lethargica is no longer seen. The association of encephalitis with smallpox vaccination caused great concern about twenty years ago, but this complication has become exceedingly rare of late. It is almost never seen when primary vaccination is undertaken in the first year of life. Encephalitis may be due to the direct action of neurotropic viruses and may occur both epidemically and sporadically, or it may be due to poisons or to the toxic or allergenic effects of bacteria. It is known to follow some of the commoner infectious fevers, especially whooping-cough, measles and mumps, and occasionally german measles and chicken-pox, and is one of the very rare, but unpleasant, complications of whooping-cough vaccination. It may also occur in glandular fever and sometimes it accompanies poliomyelitis. Apart from these clear-cut causes there are various infections of unknown aetiology causing encephalomyelitis. The initial diagnosis is usually "influenza" until neurological signs of different kinds appear. Other forms also occur, but are rare. For example, Wernicke's haemorrhagic encephalitis, occurring in

¹ Arch. Neurol. Psychiat. (Chicago), 1934, 31, 685.

infantile beriberi, and the hereditary and familial degenerative diseases such as Schilder's disease have been known for many years. Some authorities would include chorea as a rheumatic encephalitis, citing the not infrequent hemichorea as supporting evidence, but there is scant convincing pathological proof of their association. Dawson¹ has described an encephalitis in childhood which runs a subacute course progressively downwards to dementia and death. The distinguishing feature is the finding of intranuclear eosinophilic inclusion bodies in the neurones, particularly in the cortical grey matter and the basal nuclei. Lead encephalopathy still occurs sporadically, usually in children suffering from pica, and is a serious condition. It should not be forgotten as a possible explanation for convulsions and tremors suddenly afflicting a child known to be given to sucking lead toys or the paint off his cot.

There is as yet no satisfactory classification of encephalitis, though attempts have been made to provide one related to the epidemiology, the aetiology, or the clinical pattern. Children seem to be more prone than adults to encephalitis, and in the last eight years Dr. E. G. Brewis, as he reports at page 1298 of the *Journal* this week, has collected no fewer than 93 cases from the children's wards in three hospitals. Of these 93 cases of encephalitis, nearly one-third followed recognized infections and the rest were of unknown aetiology. No constant relationship was found, either clinically, aetiological, or pathologically, in the 65 unclassified cases, but Brewis was able to distinguish four main clinical patterns among them. In the first group, consisting of 19 children, of whom 13 were less than 2 years old, the onset was sudden with convulsions and unconsciousness; recovery was rapid or death occurred in a few days. In the second group the disease began with meningeal symptoms, in the third with gradual ataxia and choreiform movements (eight children under 5 years of age), and in the fourth group with somnolence and disorders of the cranial nerves. Despite these fairly typical and clinically different pictures, nearly a quarter of the cases could not be fitted into any one because they overlapped or presented bizarre features.

The comparative frequency of encephalitis in childhood and the mortality (16%), together with the high incidence of severe sequelae in the survivors (19%), combine to make this disease of some importance. There is no effective treatment, but it may present the general practitioner with a problem in diagnosis. In any doubtful case a lumbar puncture should be performed; for this reason, and because of the special nursing that is essential to full recovery,

admission to hospital is advisable for all children in whom this diagnosis is likely. While the association of encephalomyelitis with the specific fevers is fairly well known, in the various unclassified forms the diagnosis may be in doubt until the cerebrospinal fluid is examined or neurological signs have become evident. Examination of the cerebrospinal fluid is the key to the diagnosis in most cases. The various forms may present signs and symptoms suggesting meningitis, chorea, cerebral tumour, or an infectious fever with convulsions. The cerebrospinal fluid is usually clear, with a mononuclear pleocytosis and increased protein, but may occasionally be normal, particularly at the outset. The withdrawal of a clear fluid by lumbar puncture excludes meningitis (except tuberculous meningitis and choriolymphocytic meningitis, which have, however, other characteristic findings) and thus is a contraindication to prescribing intensive chemotherapy, which is of no value in encephalitis. The prognosis may be difficult to determine, both of the immediate outcome and of the ultimate mental and physical state after recovery. In general, Brewis found that the mode of onset, the depth of unconsciousness, and the frequency of fits were the immediate guides to the severity of the condition. Viruses, and especially neurotropic viruses, seem to be on the increase. More forms, and more cases, of encephalitis are therefore likely to be seen among infants and children.

INSULIN-RESISTANT DIABETES

Most middle-aged, obese diabetics are strikingly resistant to insulin. The same phenomenon is seen temporarily in severe ketosis, and is a feature of the diabetes associated with acromegaly and Cushing's disease. A.C.T.H. and cortisone may increase insulin requirements if given to patients with diabetes, and Bornstein and Park¹ have recently shown that growth hormone and cortisone in combination are necessary for the development of insulin resistance in diabetic animals. Insulin resistance has also been recorded in patients developing diabetes in association with cerebral tumours affecting the hypothalamus,² though no consistent change has been demonstrated in animals with hypothalamic lesions.³ In the *Journal* this week Dr. J. Beattie reports at page 1287 the production of insulin resistance in rats by interruption of the hypothalamic nerve tracts and removal of the adrenal medulla. Rather surprisingly, neither hypothalamic lesions nor adrenal medullectomy alone caused any upset in carbohydrate metabolism, whereas the combined procedures resulted in hypoglycaemia, with depletion of liver and muscle glycogen and complete un-

¹ Bornstein, J., and Park, C. R., *J. Biol. Chem.*, 1953, 205, 303.

³ Long, C. N. H., *Res. Publ. Ass. nerv. ment. Dis.*, 1940, 20, 486.

⁴ Himsworth, H. P., and Kerr, R. B., *Clin. Sci.*, 1940, 4, 287.

responsiveness to insulin. Moreover, when glucose was given, with or without insulin, the blood sugar rose to the same extent. The finding that insulin did not lower the blood sugar in these animals is a remarkable one and suggests the presence of one or more insulin antagonists. This has been a popular theory to explain insulin resistance since the experiments of Himsworth and Kerr,⁴ and both growth hormone and cortisone may well be insulin antagonists. Evidence from the present experiments suggests that both these substances were present in considerable quantities. Thus adrenal medullectomized animals with hypothalamic lesions put on more weight than the controls, and there was no reason to suppose that there was adrenal cortical insufficiency since normal cortical tissue was found when the animals were sacrificed. Moreover, rats exposed to cool conditions not only increased their oxygen consumption, but managed to regain their pre-operative weight. As the author points out, the interest of these results lies in the possibility that insulin-resistant diabetes may arise from causes which do not primarily involve the pancreas or the pituitary. Nevertheless many problems remain to be solved. Why adrenal medullectomy should result in insulin resistance in the presence of hypothalamic lesions is difficult to understand. It is a well-known clinical observation that patients with Addison's disease are particularly sensitive to insulin, and it is generally thought that the ability to recover from insulin hypoglycaemia is due in part at least to the production of adrenaline. The present study suggests that the presence of insulin antagonists may be more important than the role of adrenaline in the body's response to insulin.

COLOURED DRIVING-GLASSES

Road travellers returning on Monday night from the Whitsun holiday will experience severe and even dangerous discomfort from the dazzle of on-coming headlights, even though many devices against glare have been put on the market. The dipping of headlights and such-like mechanical measures have done much, but recently some drivers have taken to wearing yellow-tinted glasses in the belief that they absorb selectively that part of a beam of light which produces glare, whether in the more severe form of dazzling or in the lesser form of mere discomfort.

Subjectively such glasses give some drivers the impression that the visual field is brighter, and this has helped to increase their popularity—a popularity spuriously enhanced by the belief that the penetrating yellow light of fog-lamps is useful. There is, however, nothing to be said in favour of yellow-tinted lenses for driving. A clear-glass windscreen transmits 92% of light falling on it, and the lightest yellow filter passes about 88%. A combination of both will pass only 81% under ideal conditions, and considerably less in the presence of dirt and scratches. As might be expected, yellow-tinted driving glasses adversely affect the visual efficiency of drivers, especially at night, when the level of illumina-

tion is low. Richards^{1,2} and others have shown that visual acuity falls when using these lenses, and Miles³ found a reduction not only in visual acuity but also in resolving power and stereoscopic acuity, and, perhaps most striking of all, a slight but definite fall in visual acuity in the presence of glare, itself likely to increase with any scratches on the lenses. Davey and Sheridan⁴ have shown that under night-driving conditions the eye is adapted to a much lower level of illumination than is generally assumed, and that the wearing of yellow-tinted lenses is an impediment to detecting faint peripheral stimuli. Yellow-tinted lenses are particularly disadvantageous to colour defectives; Miles³ has stressed that such people (who are likely to seize upon any device which may help them) have a reduced sensitivity to light, so that even the palest filter will have a marked effect on their night vision. The subjective improvement experienced with yellow lenses may be the result of their sharp cut-off in the blue region of the spectrum. Blue light is scattered more than red, and the eye is myopic for blue light—an effect heightened by "twilight myopia." The beam from a motor-car headlight, however, contains very little blue light.

The use of tinted lenses is not so widespread in Britain as in the U.S.A., where both pink lenses and green wind-screens are used, sometimes simultaneously. Green glass is used there to absorb some of the sun's heat which floods through the wide curved sheets of glass at present fashionable in American cars. The fact that some States have banned the use of this green glass is a recognition of its potential danger. There do not appear to be any restrictions on the use of coloured driving-glasses either in Britain or in the U.S.A., but it may be questioned whether the use of coloured screens and coloured driving-glasses do not contravene the requirements of the Road Traffic Act,⁵ which lays down that all glass or other transparent material fitted to motor vehicles shall be maintained in such condition that it does not obscure the vision of the driver.

NUMBERING OFF

It might be said of many doctors, especially those who qualified before the last war, that they passed in medicine and failed in mathematics. They are apt to regard statistics with dislike and statisticians with that uneasy respect which King Arthur's knights must have accorded to Merlin. Perhaps this is because statistics often deals harshly with cherished conclusions, as Dr. R. A. J. Asher suggested when opening a debate held last week by the Study Circle on Medical Statistics of the Royal Statistical Society. Proposing that the house should welcome the growing influence of statistics in all branches of medicine, Dr. Asher listed the conventionally accepted applications of statistical analysis in medical research—for example, in assessing the probability that an event occurs by chance; in studying results which might be

influenced by several factors; in assessing the significance of apparent correlations, and in revealing those which are not so evident; and in the planning of clinical trials of drugs, when to the clinicians taking part it must sometimes seem that the statistician acts as a kind of *agent provocateur* by including in the trial inert substances indistinguishable in appearance from that under test. But it was in the moral field that Dr. Asher concluded statistics exerted their most beneficial influence. Their salutary discipline could but engender in doctors the twin flowers of modesty and admiration for the works of Nature. Common sense, he said, was not enough, and obvious conclusions could be fallacious.

Mr. R. S. Murley opposed the motion. He found it impossible to disagree entirely with Dr. Asher, but pointed out that the motion referred to *all* branches of medicine. Medicine was an art, statistics a science; he conceded that the latter had its uses, but when it came to mixing science and art statistics was as out of place as a skillet in a Crown Derby tea-service. Doctors and laymen alike read too much into the results of statistical analysis, he thought, which in any case could not give the answer to such human imponderables as the value to the patient of increased survival conferred by a particular line of treatment which left the sufferer a life of chronic invalidism at best or misery at worst.

This aspect of statistical analysis was criticized from the floor by a later speaker, who deprecated the application of statistics to the psychological assessment of personality structure. Another speaker referred darkly to the deliberate misuse of statistics, fostered for what sinister purpose?—by statisticians themselves. Statistical publications, he said, could be recognized by the prolixity of their tables. In his view no papers should contain any tables at all. The statisticians present coldly ignored this challenge, though the one who framed the motion affirmed that his profession were the champions of common sense, and he urged the house to welcome the growing influence of statistics in all branches not only of medicine but of life itself. Another statistician, supporting the motion, thought that statistical techniques available at any one time might not be of use in medicine, and went on to give a tantalizing glimpse of the technical world of becoming in which statisticians work. Summing up, Dr. Asher said that everyone should be his own statistician, while Mr. Murley struck an undemocratic note in concluding that statistics might be all very well for the elite but were a menace to the mob. On a show of hands the motion was carried by a narrow majority.

The freedom from bias of the opening speakers was emphasized by the revelation that the terms of the motion had been withheld from them until shortly before the meeting. Both had, with an impartiality admirable in two members of a conservative profession, expressed their willingness to speak for or against the motion, whatever it should turn out to be. With such a margin for the operation of chance, the significance of the result of the debate remains obscure. Even if it were not so, can one say, as one speaker did, that significant results are true?

CLINICAL PATHOLOGY IN GENERAL PRACTICE TESTS OF GASTRIC FUNCTION

BY

F. AVERY JONES, M.D., F.R.C.P.
Physician, Central Middlesex Hospital

Tests of gastric function have a limited role in clinical medicine. Sometimes simple inspection and analysis of a sample of the gastric contents may contribute towards the diagnosis. A fractional test meal will demonstrate the response of the stomach to various secretagogues, and the varying curves may be associated with different clinical conditions.

Passing of a Stomach Tube

There is considerable individual variation in the ease with which a tube may be passed, but if carefully done a minimum of discomfort is caused. For most patients it is more comfortable to pass the tube through the nose than over the back of the throat. The nose may feel sensitive to the touch of the tube, but this is rarely uncomfortable, and once the tube is down the gullet there is little discomfort in the throat. Pharyngeal irritation may be uncomfortable when the tube has been swallowed over the back of the tongue and is constantly touching the soft palate. For performing fractional test meals the nasal route is preferable, but if a brief aspiration of the gastric contents is to be undertaken a small but fairly rigid oesophageal tube may be quickly passed through the mouth into the stomach. For performing a fractional test meal, a soft rubber Ryle tube, 42 in. (107 cm.) long, No. 12 French, is probably the most useful one to use. It has a small metal olive at the tip, with four holes between 1 and 5 in. (2.5 and 12.7 cm.) from the olive. Alternatively a Levine tube may be used. This is a round-tipped tube size 14 or 16 F. with four openings in the terminal 3 in. (7.6 cm.). The average distance from the teeth through the cardia is 18 in. (46 cm.), and from the cardia through the pylorus another 11 in. (28 cm.). The nasal route is 2 in. (5 cm.) longer than the oral route.

The tube is well lubricated with water and passed gently into the nostril. As soon as the tube reaches the nasopharynx the patient is encouraged to swallow continuously until the first ring has reached his nostril. He is then allowed a pause and told to breathe through his mouth, while the tube is slid gently down until the tip is well below the pool of gastric juice; in most patients this is about the level of the third ring marked on the tube. Gentle suction is then applied with a syringe. If no gastric contents are obtained, the position is adjusted and a little air is injected. For any research work it is important that the position of the tube should be checked radiologically, but this is seldom necessary in routine clinical studies. It should be appreciated that the tube may curl up in the fundus of the stomach and prevent proper samples being obtained.

Performance of a Gastric-function Test

The purpose of this test should be explained to the patient. He is instructed to have neither food nor drink after 10 p.m. the previous day, the test being carried out early on the following morning. It is best to have the patient sitting upright with his back well supported by a pillow. His nose is inspected to see which nostril is larger, and the tube, well wetted, is then inserted and gently passed as already described. The stomach is emptied and the volume of the residual fluid measured. The free end of the tube is then spigoted and firmly attached to the patient's cheek by strapping.

When the necessary stimulus has been given, samples of about 10 ml. are withdrawn every 30 minutes for two and a half hours. After each aspiration the syringe is

washed out with water and a little air is injected down the tube, then the spigot is replaced. One and half hours later gastric juice is tested with Töpfer's reagent, which turns red with acid, or with Congo-red paper, which turns blue if free acid is present. If no free acid is present then an injection of histamine, 0.5 mg., is given subcutaneously. The patient is warned that this will make him feel flushed and may give him a headache, and that there will be redness and irritation at the site of the injection. When the test is completed he is asked to depress his chin on his chest while the tube is withdrawn. Throughout the test he is instructed not to swallow saliva. He should be provided with a receptacle in which to spit. The following are the commonly used tests.

Gruel Test Meal.—This provides evidence of the response of the stomach to a normal food stimulus. Gruel has the advantage of being practically colourless and of such a consistence as not to block the tube. It is prepared by bringing to the boil four tablespoonfuls of breakfast oatmeal with a quart (one litre) of water and then simmering down to a pint (half a litre) and straining through muslin. It is advisable not to add sugar or salt, and on no account must milk be used, as it may effectively neutralize the acid secretion.

Alcohol and Histamine Test Meal.—This is used to demonstrate the presence or absence of achlorhydria. Fifty millilitres of 7% alcohol is given and specimens are taken every fifteen minutes for one hour. Histamine, 0.5 mg., is then given and two further specimens are obtained.

Histamine Test.—By repeated aspiration or by continuous suction it is possible to determine the volume of juice secreted in response to histamine injection; this provides a quantitative estimate of gastric secretory function. With the *lhre* technique* a secretion volume at the rate of 180 ml. an hour is taken as indicating hypersecretion. This test is carried out by injecting 0.1 mg. of histamine per 10 kg. body weight and using continuous suction for one hour after the injection. The maximum acid secretory response† may be estimated by injecting four times the normal body-weight dose of histamine. An antihistamine, such as mepyramine hydrogen maleate (100 mg.), should be injected intramuscularly 30 minutes before the histamine is given. This is to protect the patient against the systemic effects of histamine. Continuous suction is applied, and the secretion collected from one-quarter to three-quarters of an hour after the histamine injection is taken as the maximum secretory response. More than 600 mg. of hydrochloric acid an hour suggests hypersecretion.

Indications for Examination of the Gastric Contents

In problem cases with symptoms referable to the upper abdomen—for example, patients with epigastric pain, loss of weight, but with a normal barium meal report—an examination of the gastric contents may help to establish the diagnosis. Examination of fasting juice alone may reveal gross blood-staining from a carcinoma of the fundus, which is easily overlooked radiologically. Gross blood-staining of all specimens in a test meal, together with an offensive smell and a big difference between "free" and total acidity, is strong evidence of a neoplasm, whether or not there is achlorhydria, and a gastroscopy is indicated. If only a blood-staining resting juice is found, it is worth repeating the observation, for a carcinoma of the ampulla of Vater or head of the pancreas can cause bleeding which

*Acta med. scand., 1947, Suppl. 196, 322.

² Highway Research Abstracts, 1953, 23, 32.

³ Arch. Ophthalmol. (Chicago), 1954, 51, 15.

⁴ Optician, 1953, 126, 33.

⁵ The Motor Vehicles (Construction and Use) Regulations, 1951, para. 74.

can be regurgitated back into the stomach. Again an excessive amount of fasting juice, together with a high-climbing curve, is suggestive of a duodenal ulcer which has been missed radiologically—a further x-ray examination is indicated. The odour of the gastric juice must always be noted. The normal pungent odour is lost with a fungating or ulcerating neoplasm, and also with a gastrocolic fistula, and the odour may be very unpleasant.

Another type of problem case is the patient with an anxiety state and abdominal symptoms, in whom it is necessary to exclude organic disease. A patient with a physical lesion suffering pain will usually accept a test meal when this is suggested, but a functional dyspeptic commonly reacts vigorously against the suggestion; indeed, the reaction of the patient may be another piece of evidence for or against a physical lesion.

Carcinoma of the Stomach.—It is important to appreciate that a normal acid curve and sometimes a high-climbing curve may be found in patients with carcinoma, particularly in those with small pyloric tumours. At least one-third of the patients with carcinoma ventriculi diagnosed radiologically will have free acid present, but, as mentioned above, there may be a bigger difference than usual between the total and free acid levels. The others will have achlorhydria with a high total acidity but no free acid. If there is a radiological diagnosis of gastric neoplasm but the clinical picture does not fit the diagnosis, it is certainly worth arranging both a test meal and a gastroscopy. Sometimes an unnecessary laparotomy may be avoided.

Gastric Ulcer.—A test meal does not contribute usefully to the management of a patient with a gastric ulcer. If there is any doubt about the benign nature of the ulcer, a gastroscopy is required. Gastric ulcer patients may have high acid curves, but more usually they are normal or low. Absolute achlorhydria does not occur with active gastric ulceration, but it may need additional tests, such as a 24-hourly pH test or Kay's special histamine test to demonstrate this (see above).

Duodenal Ulcer.—A test meal is not indicated in the routine management of duodenal ulcer, but may reasonably be done if operation is indicated. A high basal secretion, together with a high level of acidity, may encourage the surgeon to undertake a full 70% resection. Alternatively, a low level of secretion which may sometimes be found may encourage a gastro-enterostomy and vagotomy in a poor-risk subject, and particularly in women, in whom this is still a reasonable surgical procedure.

Chronic Gastritis.—A test meal does not provide conclusive evidence of chronic gastritis, but a low acid curve will be found with an atrophic gastric mucosa. The gastric biopsy technique introduced by Wood and Doig* is a simple method of providing definite histological evidence of the state of the mucosa and gives better information than gastroscopy.

Addisonian Anaemia.—A histamine-fast achlorhydria is a reasonable requirement for clinching the diagnosis, but it is very likely that a "tubeless" test meal will eventually suffice. This depends on the release of quinine by acid from a quinonium resin and measurement of its excretion in the urine.†

Factors Influencing Gastric Secretion

Gastric secretion may be divided conveniently into two phases—the period of digestive secretion and the inter-digestive phase. The period of digestive secretion is that in response to meals, and this may be further divided into three phases; the psychic, the gastric, and the intestinal.

The *psychic secretion* is provoked by sight, smell, taste, and even the thought of food, and the secretion evoked is highly acid and rich in pepsin. Vagal section or large doses of atropine will abolish this phase, but it is difficult to measure this secretion in man. In practice, using gruel test meals, this mechanism plays a small and unimportant part.

*Med. J. Aust., 1952, 1, 593.

†Harkness, J., and Durant, J. A. (1953). *J. clin. Path.*, 6, 178.

In the *gastric phase* are three types of stimulating agents which provoke gastric secretory responses. Simple mechanical distension is one mechanism, and it has been shown conclusively that distension of the pyloric part of the stomach stimulates the secretion of hydrochloric acid by the parietal cells of the body and fundus of the stomach. How much of this plays a part in man is still open to question. This secretion can be produced even in a denervated pouch and provides proof of the existence of a hormone for gastric secretion, which is called "gastrin." The second mechanism for acid secretion is the chemical stimulation of the stomach by the products of digestion of food or by food substances themselves. These secretagogues are present in many foods, such as milk, meat, and meat extracts, and in the breakdown products of digestion of proteins. The normal gastric phase of secretion is partly dependent on an intact vagus innervation, and a marked decrease in response to secretory stimulants, such as food, alcohol, and histamine, occurs after a successful vagotomy. It has been suggested that the response of a secretagogue depends upon the basal level of acetylcholine production in the gastric mucosa and thus upon vagal activity. A third mechanism of secretion may depend on actual chemical irritation of the mucosa with liberation of histamine, and this may be the way in which alcohol stimulates gastric secretion.

The *intestinal stimulatory phase* of secretion does not appear to play a significant part in man. More important is the inhibitory effect on secretion and motility that arises from the presence of fat in the intestine, which stimulates the formation of an inhibitory hormone, enterogastrone.

Interpretation of Tests

At one time there was a tendency to relate dyspepsia either to an increased or to a decreased peptic secretion, and a diagnosis of hyperacidity or hypoacidity was regarded as conclusive. Unfortunately this is not so, for both high and low levels of acidity can be found in individuals who are free from digestive disorders. The terminology has been most misleading. Test meals measure a concentration of acidity and not the total output of acid secretion, so that hyperacidity is not necessarily synonymous with hypersecretion. The concentration of acid in the gastric contents depends on two variables—the amount of acid secreted and the rate of emptying of the stomach. With rapid emptying there may be little fluid left to dilute newly secreted acid, and the concentration may therefore be far higher than if the stomach had emptied more slowly but secreted at the same rate.

At the other end of the scale, the term "achlorhydria" can also be misleading. The limit of free acid is reached when Töpfer's reagent turns from red to yellow. This colour change occurs at pH 3.5, which is well above neutrality point at pH 7, and there is, in fact, a small amount of free acid left at pH 3.5. Normally, however, it is perfectly adequate to take pH 3.5 as indicating achlorhydria.

The secretory response to a test meal depends on the quantity and chemical nature of the food, and to a smaller extent on the enjoyment with which it is eaten. The products of digestion of protein, or even their watery extracts, are good stimulants. Starches, on the other hand, are poor secretagogues and their secretory effect is mainly due to distension of the stomach. Nevertheless, the starch test meal has a considerable advantage over a meat-extract meal. The stomach may give an average response to a gruel meal but a hyperresponse to meat extract or alcohol, and the latter would therefore fail to differentiate between a normally secreting stomach and the hypersecretory response associated with a duodenal ulcer. The gruel test meal is commonly used, but the alcohol and caffeine tests are sometimes used instead. Alternatively, the quantitative response to histamine may be measured.

When a gruel test meal is given and samples of gastric juice are taken every 15 minutes, there is an initial fall in acidity followed by a steady increase, with a gradual

fall after about one and a half to two hours. The initial fall is due to the dilution of the small initial secretion by the bulk of the meal. The increase in acid is often due to the mechanical stimulation of the gruel, which unlike many foods, such as milk, eggs, or meats, does not have any intrinsic secretagogue action.

Gastric secretion consists of two components: the parietal cell component—that is, hydrochloric acid—and an alkaline secretion from the pyloric glands which, together with mucus, lowers the final level of acidity. The fall in acidity commonly found at the end of a test meal is mainly due to this "non-parietal" secretion; regurgitation of bile and pancreatic juice plays a minor part. The exact mechanism of co-ordination between the acid and alkaline components of the gastric juice is not yet fully understood. There seems to be a normal "brake" mechanism which operates through the duodenum; when the pH reaches a certain level an inhibitory mechanism begins to come into action and depresses gastric acidity either by increasing the alkaline component or by decreasing the acid secretion, or both. With duodenal ulcer this "brake" mechanism may be lost, hence the high rising curve sometimes found.

The standard gruel test meal provides a number of points for consideration: first, the amount and appearance of the resting secretion; and, secondly, the shape of the curve, the level of acidity attained, and the approximate rate of emptying of the stomach. The curve is commonly plotted on a printed sheet which gives the limits of the so-called normal responses in a shaded area. It must be remembered that this so-called normal response merely represents the limits which account for 80% of symptom-free subjects. The remaining 20% of normals had either well-marked "hyperchlorhydria" or hypoacidity.

In a standard test meal it is customary to give histamine, 0.5 mg., after one and a half hours if there is no acid present in the stomach by then. Histamine is a powerful stimulus to acid production, but if there is no response to histamine it is still not conclusive evidence of the complete inability of the stomach to secrete acid. For example, in a patient with a histamine-fast achlorhydria and a gastric ulcer, it is possible to get copious free acid for many hours during the day when hourly samples are taken round the clock, yet the histamine response may have been repeatedly negative. The ordinary dose of histamine does not get all the parietal cells into action, and about four times the usual dose is required to do this, but a dose of this size can be given only when covered by an antihistamine drug. This technique does enable one to assess the "total secretory mass" of the gastric mucosa.

Conclusion

The standard test meal is, in practice, full of pitfalls and fallacies, and unless done with care by an interested observer will not justify the discomfort caused to the patient or the time taken in the laboratory. It has been said that the test meal is a much better test of the patient's endurance than of his gastric function. Gagging and retching may cause secretory inhibition and produce an apparent achlorhydria. Achlorhydria, with increased difference between the free and total acid, may be due to the gruel being made with milk or to the patient having had a meal before the test was started. The presence of flecks of blood is sometimes misinterpreted and may be merely due to the trauma of suction on the mucosa. A chemical test for blood is too sensitive and it is better to rely on naked-eye appearance. Appreciable blood-staining is usually significant. The end of the tube may sometimes slip back into the gullet or pass through into the duodenum. Nevertheless, when the test is done by someone with experience and sympathy, particularly if the nasal rather than the oral route is used, it can be made reasonably comfortable and the major difficulties can be avoided.

A SURVEY OF ST. ALFEGE'S HOSPITAL 'GERIATRIC UNIT FOR 1952

BY

A. J. MESTER, M.D.

Geriatrician, Greenwich and Deptford Hospital Group

This geriatric unit is known as St. Alfege's Hospital II. It is situated in two separate blocks, each of three stories. Each floor consists of one ward divided into two—one for the bedridden, and the other for patients who are up and about. These arrangements have been made for the comfort of the patients and, more especially, to facilitate the work of the staff, particularly at night. The present bed establishment is 268—164 for women and 104 for men. As a considerable number of women patients are under 60 one ward is allotted to them together with diabetic patients. The same need does not arise in the case of male patients, but, on the other hand, there are more surgical and post-surgical cases, mainly due to urinary tract conditions (prostatic hypertrophy, cancer of the prostate, urinary retention, cystostomy), and therefore one ward is allotted to them. Male diabetics have a special ward.

Population Served

The area served by this hospital covers the boroughs of Greenwich and Deptford. According to the latest available figures the population is 170,000 (and therefore the present number of beds represents 1.6 per 1,000). If we regard 14% as being the geriatric group—that is, persons of pensionable age—this would amount to approximately 24,000, and therefore there are available 1.1 beds per 100 for the group.

It is well known that the social structure of the population is of great importance when assessing the number of beds required for elderly people. For instance, it is likely that a hospital situated in an upper-class residential area might require fewer beds than one in a working-class district. The population in our area consists almost entirely of weekly wage earners; most members of the family go out to work, and neighbourly help is therefore seldom readily available. Housing conditions are sometimes poor, with overcrowding. As a result of these circumstances there is often a heavy demand for hospital beds for old people. A large proportion of the population, mostly women, live alone, and the additional burdens which accompany winter may well bring their slender resources, already stretched to the utmost, to breaking-point, and compel them to seek hospital admission.

Admissions

During the year under review 300 women and 246 men were admitted. Requests for admission come from the following sources: General practitioners, acute wards of St. Alfege's and Miller Hospitals, the Emergency Bed Service, the medical officer of health, receiving-room, and other hospitals (teaching, cancer hospitals, etc.).

The procedure for the admission of patients put on the waiting-list by general practitioners is as follows.

In the late spring and through the summer, when the number of applications is not large, patients are admitted solely on their doctors' recommendations, because it is thought that even those patients who need residential rather than hospital accommodation will benefit from a stay in hospital before moving on to a local authority home.

Patients who are mentally deranged often benefit in the same way, but if after a period of observation their mental condition does not improve the advice of the consultant psychiatrist is sought. On his recommendation suitable patients can be transferred to Tooting Bec Mental Hospital.

where those over 70 are received for observation and treatment without being certified. Only occasionally do we find any reluctance on the part of the family to such an arrangement; when there is any reluctance it can usually be overcome by explaining the position. In very rare circumstances does a patient have to be certified, and, in fact, this was necessary only once during the year.

During the autumn and winter, when there is a heavy demand for hospital beds, the procedure for admission is different. Each patient who is put on the waiting-list by a general practitioner is visited and examined at home in order to assess his priority, which is based roughly on these grounds: (a) recent cerebrovascular accidents; (b) medical cases which should respond to treatment and be made fit for discharge in a short time; (c) medical cases which will require a longer time to be made fit for discharge; (d) patients requiring admission on social grounds not referred by the medical officer of health (the medical officer of health's patients have priority); (e) mentally deranged patients who may be put on the waiting-list for Tooting Bec Hospital; and (f) mental patients who cannot be kept or certified at home.

Stay in Hospital

After admission to hospital patients receive the necessary medical treatment, including physiotherapy and occupational therapy, both remedial and diversional. During their stay the lady almoner greatly assists by relieving their worries and, when necessary, putting their home affairs in order. Later, when the time for discharge has come, she supplies information on whether the home conditions are suitable for the patient's return. She may arrange for the district nurse to call or a home help to be supplied, or for such other assistance as is given by the Red Cross, St. John Ambulance Brigade, Women's Voluntary Service, Old People's Welfare Committee, and so on. Should the patient not have a suitable home, application is made to the local authority for accommodation. These transfers are arranged smoothly on an exchange basis, thus enabling patients in Part III homes to receive hospital treatment.

A high percentage of elderly people are mentally deranged as a result of arteriosclerotic processes of the brain, chronic softening of the brain, and so on. Such patients will be considered for transfer to Tooting Bec Hospital.

We have noticed a striking increase in the number of readmissions, and we regard this as a welcome and salutary phenomenon. As in the case of younger rheumatic heart patients who spend their lives between periods of some activity and periods for repair in hospital, it is a good policy to give old people periods of treatment and rest prophylactically, and thus prevent or delay deterioration where further recovery is not possible.

Discharges

Discharges for the year under review numbered 321. Seventy-two patients (23%) were transferred to local authority homes and Tooting Bec Hospital, or, if in need of specialized treatment such as neurosurgery, to other hospitals. The other 249 (77%) discharged patients returned to their own homes: this does great credit to the patients' relatives, who showed themselves willing to accept the task of caring for an invalid, often infirm and frail.

On discharge the patient is told to inform his doctor that he is at home again. By this time the general practitioner has received a summary of his patient's diagnosis, treatment, and other pathological and radiographical information. The patient is also visited by a health visitor from the London County Council Health Department, who sends a report to the lady almoner for the information of the doctor in whose charge the patient has been during his stay in hospital.

Patients are seen and followed up in a geriatric outpatient clinic and, when necessary, readmitted or provided with further amenities at home.

Long-stay Cases

The problem of long-stay hospital patients is one of great importance, for these reduce the turnover in hospital beds. The recognition of the factors which necessitate a long period in hospital may help to solve the problem. Those who remain in hospital longer than a year fall into three main groups:

(1) *Chronic Joint Conditions*.—There were 64 cases: 11 had rheumatoid arthritis; one had Charcot's syphilitic osteoarthropathy of hip, knee, and ankle-joints; and 52 had osteoarthritis of different localization, but chiefly of hip- and knee-joints. It is easy to fall into controversy on the problem of osteoarthritis in elderly patients. It is well known that all people over 60 have osteoarthritis, but not all are sufferers. The condition may be more or less marked or more or less dispersed. The discomfort and apperception vary from nil to 100%. Very many patients with thickened phalanges suffer psychologically without sustaining pain or impairment of movement. On the other hand, some patients are completely crippled by osteoarthritis of the hips. To suggest that osteoarthritis in these patients is the primary cause of admission to a geriatric hospital or of incapacitation would be incorrect. Many patients are admitted for other reasons, such as cerebrovascular or cardiovascular diseases, and even a marked osteoarthritis may be an accidental finding. There are, of course, many patients who seek admission only on account of osteoarthritis, particularly of the hip-joints. Their history often reveals that for months or even years their treatment has consisted in resting in bed, which frequently results in severe contractures. The 11 patients with burnt-out rheumatoid arthritis, in addition to being over a year in this hospital, spent several years in other hospitals during the active stage. The problem of rheumatoid arthritis in active and non-active stages is beyond discussion here.

(2) *Disseminated Sclerosis and Other Nervous Disorders*.—One man and five women suffered from this disease; three of the women were paraplegic.

(3) *Arteriosclerosis*.—Patients suffering from this illness form the bulk of long-stay cases, and they are discussed below.

Deaths

During the year 238 patients (124 men and 114 women) died. There were 12 coroner's post-mortem cases, 9 of which were held because death occurred within 24 hours of admission, two on account of fractures sustained at home before admission, and one sustained in the ward. Fifty patients died of cancer (34 men and 16 women), the distribution being as follows:

Men	
Alimentary tract (pharynx 1, stomach 9, pancreas 1, rectum 6, colon (ascending) 1)	18
Urinary tract (bladder 1, prostate 5)	6
Lung	9
Sarcoma of muscle (patient aged 54)	1
Women	
Alimentary tract (stomach 1, liver 2 (primary), gall-bladder 1, colon (ascending and transverse) 3, rectum 1)	8
Metastases in abdomen (primary not found)	1
Urinary tract (bladder 1, uterus 2—1 corpus, 1 cervix)	3
Breast	2
Lung	1
Cerebellar tumour	1

The causes of death in the remaining cases were chiefly of cardiovascular origin—primary, or secondary to chronic pulmonary disease such as emphysema and chronic bronchitis with chronic pulmonary heart.

Deaths during the year were as follows: January to March, 52; April to June, 44; July to September, 58; October to December, 84. The increased number during the last period can be largely attributed to the fog.

Conclusions

It is evident that an allocation of 1.1 beds per 100 of the geriatric population should be enough under normal circumstances, and only in the event of an exceptionally severe winter or epidemics of serious upper respiratory infections might a temporary shortage of beds arise. To

ensure that a high rate of turnover is maintained it is essential that such patients as those suffering from osteoarthritis should be treated in the early stages and encouraged by persuasion and physiotherapy to be mobile. Further improvement in the position could be effected by the development of clinics for rheumatic out-patients. These, if the patients were encouraged to attend conscientiously at the onset of illness, would prevent or delay immobility, thereby easing one of the burdens on the geriatric hospital.

The bulk of long-stay cases are those suffering from arteriosclerosis, especially of the brain, with consequent inability to walk, incontinence, and mental deterioration. Such patients need special accommodation, as they require little more than nursing supervision. We are convinced that it is of the utmost importance to create intermediate accommodation between Part I (hospital) and Part III (local authority), which should offer to suitable patients the attention and nursing which they require.

These "nursing annexes" would accommodate bedfast patients incapacitated through cerebrovascular accidents; disseminated sclerotics if they are paraplegic; incontinent; burnt-out rheumatoid arthritis; and those beyond the reach of active medical treatment, such as persons immobilized through severe osteoarthritis and advanced arterio-cerebral sclerosis. These "nursing annexes" would require only a small trained nursing staff, as the patients' chief needs—care and attention—could be provided by orderlies working under trained supervision. Medical supervision would be in the hands of the geriatrician, and such day-to-day care as was necessary could be given by the house-physician of the geriatric unit.

I should like to express my appreciation of the co-operation extended by the general practitioners in Greenwich and Deptford, who are carefully selecting their patients for admission, thus enabling us to admit really needy patients with little or no waiting.

Preparations and Appliances

SIMPLE THYROID RETRACTORS

Sir HENRIE OGILOVE writes: In 1953 the surgeons of Wellington, New Zealand, gave me the privilege of taking part in a three-weeks postgraduate course in surgery as a member of the staff of the Wellington Hospital. I was

allowed the use of 25 beds, allotted a very able house-surgeon and ward sister, and given two operating days a week.

For a thyroidectomy I was provided with a pair of retractors of a type new to me,

and better than anything I had seen in England. I was unable in the time to buy some for myself, but on my return I drew what I wanted and asked Down Bros. to make them for me. The idea comes from the Wellington Hospital, but I cannot say who designed them, nor can I claim that mine are a true copy of the originals.

As will be seen from the figure, the retractors might be described as a pair of large opened hairpins made of spring

wire, with the points bent down. After the skin flaps have been turned up and down, towels are laid over them, and a retractor, closed by compression, is put under the edge of the towel and skin on each side of the midline and allowed to spring open. The points of the retractors should be about an inch (2.5 cm.) apart above and about 2 inches (5 cm.) apart below. Towel forceps are used to clip the towels at the ends of the incision, and as they drop back they hold the elbows of the retractors back as well. These retractors give adequate exposure, stay in all the time, are never in the way, damage nothing, are cheap, and need no repairs. *O si sic omnia.*

Nova et Vetera

SWEDISH PIONEERS OF MEDICINE GO TRAVELLING

In a "Docent" lecture published in the organ of the Swedish Medical Association, *Svenska Läkartidningen*, for September 4, 1953, Dr. Wolfram Kock, of Stockholm, shows how, in the past, if you wished to end up as a pioneer of medicine you had to travel far and see much in your youth. Not a bad thesis even now. His material consists of two distinguished quartets. The first was composed of Olaus Rudbeck, Petrus Hoffvenius, Urban Hiärne, and Johan von Hoorn, who made their mark in the seventeenth century.

A Seventeenth-century Quartet

Olaus Rudbeck was the discoverer in 1650 of the thoracic duct—a discovery made independently of the Frenchman Jean Pecquets, whose identification of this duct dates back three years to 1647. In 1652 Rudbeck's discovery of the lymphatic glands and lymphatic system earned him renown and an invitation to demonstrate this system to Queen Kristina of Sweden. When he finally settled in Sweden he founded the botanical garden in Upsala, having taken seeds and plants from Holland wherewith to stock it.

Hoffvenius, who died in 1682, had already successfully defended two theses, entitled respectively "De Oculo" and "De Symptomatibus," when he set off in 1658 for Leyden on a royal scholarship. After studying anatomy there he returned to Sweden in 1661, and was appointed professor of medicine "et Physices" in Upsala. His gifts as a physician earned him the title of the "father of Swedish medicine," but for want of hospital accommodation he taught his students by taking them with him on his rounds to his patients—a system he had learnt in Leyden.

Hiärne was only 25 years old when he set out on his travels as personal physician to a high Swedish official appointed Governor of Riga. From there he travelled to Germany, Holland, England, and France, and he spent three years studying chemistry in Paris under Christopher Glaser, apothecary to Louis XIV. On his way home from Paris in 1673, Hiärne picked up a useful tip from the famous Dutch doctor Helvetius, who told him that ipecacuanha was a cure for dysentery. The Polish campaign by Charles XII of Sweden was at this time seriously complicated by dysentery, for which the new drug proved a godsend under Hiärne. As well as being a popular physician in Stockholm, he was instrumental in founding Collegium Medicum, an organization for the control of the practice of medicine in Sweden.

Johan von Hoorn, the "father of Swedish obstetrics," earned this title by his prolonged studies in Leyden and Paris. By September, 1687, when he reached Paris, he had already mastered the literature of his subject, but still felt in need of some practical experience. He would have liked to acquire it at the old hospital, Hôtel Dieu, where a whole ward was set aside for obstetrics. But foreigners were not welcome here at this time, so Hoorn had to learn his trade by joining forces with a Madame Allegrain, known

to be a "wise and very quick" midwife. She had a large practice among the poor of Paris, and by tipping her patients judiciously Hoorn was allowed to be present at their confinements. There was only one snag: Madame Allegrain was not allowed to operate. So Hoorn got into contact with a Monsieur Le Frad, a duly accredited "accoucheur" who had mastered the technique, for what it was worth at that time, of the treatment of "partus praeternaturalis." Obstetric forceps had been discovered by this time, but were a strictly guarded and secret monopoly into whose cult Hoorn was never admitted. On his return to Sweden he took an active part in converting the "unscrupulous drunkards" practising as midwives at that time into a semblance of well-trained midwives.

An Eighteenth-century Quartet

The next quartet of Swedish pioneers of medicine was composed of Nils von Rosenstein, the botanist Carolus Linnaeus (raised to the nobility with the title of von Linné), Abraham Bäck, and Olof Acrel, the "father of Swedish surgery."

Rosenstein is perhaps best known to the vulgar world of to-day on account of his chest drops (vinum glycyrrhizae opiatum), still an infallible remedy. The son of a clergyman, Rosenstein was originally destined for the Church, and he had already pursued theological studies when he switched to medicine. In order to become a university teacher he studied abroad, first at Halle and later at Turin, Montpellier, and Paris. At the small university town of Harderwijk he graduated in medicine in 1730 with a thesis entitled "De Historiis Morborum Conscribendis," which in plain terms means the art of keeping case records. In 1740 he was appointed professor of natural history, with the task of teaching anatomy, physiology, pathology, and practical medicine. He also became the author of the first Swedish textbook of anatomy.

Linnaeus is so famous as a botanist and zoologist that his possession of a medical degree is often overlooked. His travels abroad between 1735 and 1738 brought him to Denmark, Germany, Holland, England, and France. At Harderwijk he graduated as doctor of medicine on a thesis written in Swedish and entitled "Hypothesis Nova de Febrium Intermittentium Causa." Here he showed that the clay content of drinking-water was the cause of intermittent fever or ague. He is said to have defended this thesis with "presence of mind and great ingenuity." At Leyden Linnaeus was anxious to meet the intellectual giant of his day, Boerhaave, old and rich and much sought after by his patients. To get Boerhaave's ear you had to tip his servants properly, and it took the penniless Linnaeus a week to secure an audience, for which he had applied in writing. But in due course he and Boerhaave became the best of friends, and the grateful Swede called his Dutch teacher "my father in medicine." Clinical medicine as well as botany was discussed by the two, and in 1737 Boerhaave suggested to Linnaeus that he should take part in a botanical expedition to Dutch Guiana. As a bait for this undertaking, Linnaeus was informed that a predecessor holding the same appointment for five years had secured some barrels of gold in a salubrious climate producing beautiful plants. But Linnaeus seems to have been more impressed by Boerhaave as a scientist than as a promoter of gilt-edged expeditions to the Tropics.

Abraham Bäck was disappointed in his youth over some academic appointment, so he undertook foreign studies wherewith to equip himself for later promotion. Setting forth in 1741, he spent four years abroad, studying anatomy and botany in Leyden. Later he proceeded to England, where, with introductions from Linnaeus, he visited Oxford, the botanical gardens in Chelsea, and the naval hospital at Greenwich. Going to Paris in December, 1742, Bäck spent two years studying anatomy, surgery, pathological anatomy, internal medicine, botany, and zoology. He learnt how to make anatomical preparations by injections and other methods, and he studied pharmaceutical chemistry at the Jardin des Plantes. He was also diligent in going the

rounds of the Hôtel Dieu. On his return to Stockholm in 1745 he became a teacher of anatomy and soon afterwards Court physician. He took an active part in founding a hospital for the combined care of the sick and the training of physicians. With his Paris background, Bäck was naturally inclined to think in terms of the Hôtel Dieu. But he was shrewd enough not to swallow Hôtel Dieu standards wholesale, with each bed shared by two or three bed-fellows and in the maternity ward by four bed-fellows at a time. For in Bäck's plan for a new hospital in Stockholm he referred specifically to "hospital wards with beds in two rows and only one person in each bed." One of his arguments in favour of a hospital for Stockholm was that "a well-equipped hospital should also render costly studies abroad superfluous." When the Serafimer Hospital was opened Bäck became as a matter of course its first medical superintendent.

Olof Acrel, also one of the founders of the Serafimer Hospital, learnt much of his surgery abroad under stormy conditions. Travelling through Denmark to Germany, he studied anatomy and physiology under Albrecht von Haller and surgery under Richter. However, he soon moved on, as there were only four corpses for dissection each year. In London he studied operations for stone under William Cheselden at St. Thomas's Hospital. War having broken out on the Continent, Acrel fitted himself out with surgical instruments at Strasbourg and joined the French Army as a surgeon. In the autumn and winter of 1743-4 he was a senior surgeon in the fortress of Lauterburg, where he had some 1,200 patients and 24 assistant surgeons under his care. When the fortress was taken in 1744, Acrel became a prisoner of war, but he was allowed to return to Sweden in the autumn of the same year. On the initiative of the Swedish Academy of Sciences, he published a study of hospital administration in connexion with the new Serafimer Hospital, to which he was attached as senior surgeon for 54 years, with the title of professor and general director.

CLAUDE LILLINGSTON.

Opening a hostel for rheumatic sufferers at Bracken Hill House, Northwood, Middlesex, last week, Miss PAT HORNSBY-SMITH, Parliamentary Secretary to the Ministry of Health, referred to the "unremitting research" that is going on. Since the war, she said, the financial support given to research on rheumatism both by voluntary and by governmental agencies had substantially increased. Research centres up and down the country now received steadily increasing support from the Medical Research Council, from the regional hospital boards, from many university departments of medicine, as well as from voluntary organizations such as the Nuffield Foundation. The Ministry would watch with great interest the present venture at Bracken Hill House, the fundamental idea of which was to enable patients to be temporarily resident near a hospital which possessed specially experienced medical staff as well as adequate treatment facilities. The British Rheumatic Association rightly regarded this as a pioneer effort, and it was, of course, a field of experiment for which voluntary effort was pre-eminently suited. Such pioneer ventures were always difficult for a Ministry to promote, but experiments by voluntary organizations often provided a useful guide to later official action. She welcomed the financial support which industry had given ventures such as this, for to them rheumatism presented a grave manpower and production problem. She said she was also glad to know that a two-years financial guarantee had most generously been given by LORD NUFFIELD of £1,000 a year against loss in operation. It was of particular interest that patients for the 25 beds with which the hostel was starting would initially be mainly drawn and selected from industry. The interests of the British Rheumatic Association were, of course, national in scope, and she understood that the association was exploring the possibility of similar hostels in other areas. She said the Ministry welcomed such experiments and would watch keenly and be ready to learn from the results.

FACIAL PARALYSIS

The first of what is hoped will become a series of informal discussions on clinical problems was held by the Ciba Foundation on May 10, the subject being the treatment of facial palsy. Dr. BASIL KIERNANDER was in the chair.

Miss JOSEPHINE COLLIER spoke first and stressed that it was important to differentiate between the pre-degenerative phase of the nerve lesion and the phase of established degeneration. Treatment should begin in the pre-degenerative stage and should be designed to prevent actual degeneration. Mr. TERENCE CAWTHORNE said he performed decompression two to three months after the onset of symptoms if there was still no voluntary or faradic response. One-third of these cases showed signs of recovery one week later. He believed local ischaemia to be an important factor in these cases. Wing-Commander P. F. KING gave the results of 160 cases treated in the R.A.F. Of these, three-quarters were Bell's palsy. The treatment was stimulation of the facial muscles by interrupted galvanism until voluntary mobility returned; thereafter active exercises were practised in front of a mirror. Fifty-eight per cent. of his cases had some form of splint. The rate of recovery was as follows: by two months 56% had recovered, by three months 70%, by six months 84%, by twelve months 90%, and over one year 94%. Of these, a total of three had to have fascial slings.

Dr. RITCHIE RUSSELL said the peripheral nerve lesions behaved as pressure palsies which either recovered rapidly or showed degeneration. A nerve could conduct impulses for 24 hours without a blood supply, and he suggested that the logical times for decompression would be in the first few hours of symptoms, or as soon as the reaction of degeneration occurred, or at eight or nine months. The treatment of paralysed muscles should not consist in keeping them permanently relaxed, and they should be put through a full range of movements daily. Mechanical support was necessary only with sagging. Dr. A. T. RICHARDSON said that the main points to decide were whether there was a nerve block or whether degeneration had occurred. He stressed the importance of testing for nerve conduction, stimulating the facial nerve as it emerged from the stylomastoid foramen. If nerve conduction was present at the fifth day there was a fair prognosis, if at the seventh day a good prognosis, and at the twenty-first day a very good prognosis, for no further degeneration usually occurred after twenty-one days. For treatment he agreed that short-wave diathermy or anodal galvanism applied to the stylomastoid foramen were of no value, and he used interrupted galvanism as previously described. Mr. D. N. MATTHEWS described his operation of fascial sling where the mouth was motored by the masseter muscle and the eye by the temporalis. Mr. C. R. McLAUGHLIN said there were three ways in which plastic surgery could help. The first was static support of the corner of the mouth and cheek; the second was reanimation with rounding of the cheek and corner of the mouth; and the third was the relief of epiphora. His indications for operation were complete failure to recover or partial recovery after five years.

The meeting closed with a vote of thanks to Dr. Wolstenholme and the Ciba Foundation.

A convention on social insurance, dealing with benefit for old age, widowhood, orphanhood, and industrial injuries, has been signed with Switzerland. It provides, among other things, that a national of either country who has qualified for benefit in one of the two countries shall receive that benefit while he is resident in the other country. It also relaxes the nationality conditions of the Swiss scheme in favour of citizens of the United Kingdom and Colonies; insured persons who have not paid enough contributions in one country to qualify for a pension under that country's scheme are enabled to receive a supplement to the pension payable by the other country. Any person in Great Britain who may be affected by the convention should get in touch with his local Pensions and National Insurance Office.

Correspondence

Undergraduate Education

SIR,—The Report of the Undergraduate Education Committee of the Council of the College of General Practitioners (*Journal*, May 15, p. 1146) emphasizes what have been the opinions of many of us for years, and adds some useful new recommendations in the form of answers to a questionnaire, rather than as a statement of the opinion of the Committee and Council based upon a summation of the individual opinions of general practitioners represented on the fifteen regional faculty boards.

It is indeed good to read that the great majority of doctors urge that the boy and girl while still at school should continue to receive a "broad general education" in the humanities before bending his or her entire thought to specialize in the materialism of the natural sciences. It is amazing that some universities should have so far forgotten their true function by insisting that the first premedical examination should be passed before leaving school.

The Report also repeats the criticisms, which have been voiced for years, of the undue time wasted in learning the unessential minutiae of anatomy, and those of more recent date, of the professorial type of teaching of medicine. For the student medicine now is little more than biochemistry, physical mechanical methods, and a mass of various diagnostic tests. Here is an illustration. Some three years ago, while walking through a maternity ward with a group of students, I stopped before a pregnant woman propped up in bed with glaring exophthalmos and a large lump in her neck. I asked one young man—who had "done his medicine"—"What is her trouble?" He looked at her for half a minute and then said, "I should first like to know her blood-cholesterol." Perhaps a knowledge of her blood-rhubarb would have been equally helpful in making a diagnosis!

The Report also stresses the necessity for instruction in the common disorders of daily general practice. Again, this has been urged on the schools for years, but still the teaching is deficient. How often does the student hear a talk on the man who tells us that he feels "run down," or the other who complains of increasing fatigue? I am surprised, however, to find no specific mention of the importance of teaching of so-called functional disease or symptoms without discoverable physical signs. This is a group of disorders which comprise, perhaps, three-quarters of all the patients we see, primarily based nearly if not always on disturbances of the mind and emotions. Psychiatry is mentioned along with three or four other incompletely taught subjects, but psychiatric patients are apart from those suffering from the many neuroses which belong to all the branches of medicine.

That no reference is made to the teaching of psychology, "the motives and mechanisms of the mind," as expounded some years ago by Graham Howe, is a reflection on the choice of questions submitted to the faculties and on those who answered the questionnaire, inasmuch as they neglected one of the most important of all the omissions in clinical teaching. By all means let the student be taught more about the common things—"run down," fatigue, insomnia, obesity, food, loss of weight, leucorrhoea, swollen ankles, "wind," constipation, and many others—but also give him much more emphasis on the protean manifestations of neurosis and functional disorders.

I wrote to you, Sir, in December, 1932,¹ on the urgent necessity for including some teaching on psychology in the curriculum, but even in 22 years there has been so little progress that still the student regards the neuroses as "clinical rubbish" to be passed from one out-patient department to another.—I am, etc.,

it in headlines. Nobody suggests that particular individuals should not do all the research they want to do into anything which takes their fancy. It is the premature presentation to the public, and method of presentation of unproved results, which is the cause of the matter. How a statement about "smoking and cancer of the mouth" at this stage could help to allay "apprehension, ignorance, and uncertainty" I really fail to see.

We cannot put the clock back, I agree, but there is no need deliberately to put it forward. There has obviously been a failure somewhere, on our part, in allowing this "cancerphobia" to develop in "nearly 100% of the population," so let's think again, examine our own fears, and find out what has gone so badly wrong in our methods, which has produced this modern mental disease. Make no mistake, we are responsible for it. It isn't the patient's attitude which needs changing. It is our own, which places the accent on organic disease to the exclusion of mental. For the greater part of the population it is the latter which is the more important, and the patient "dies a thousand deaths" instead of one. In conclusion, "Knowledge is the antidote to fear," but Emerson did not mean "knowledge" culled from kidney pill advertisements and press stunts.—I am, etc.,

PAUL R. SAVILLE.

Pethidine for Pain and Insomnia

SIR.—The preference shown by Drs. R. G. B. Wigoder and H. Jeffs (*Journal*, May 15, p. 1156) for using pethidine instead of morphine in the symptomatic treatment of pneumonia deserves extensive trial. This is justified by the adequate reasons given. Since we have no memory for pain, however, the following case outline is submitted, as it may add weight (if indirectly) to their thesis.

An otherwise fit labourer first attended hospital in the early morning, bitterly complaining of the pain in his right thumb. He had no sleep during the night because of this. On examination there was an extremely tender, fully developed distal pulp infection, for which immediate surgery was imperative. A general anaesthetic was, of course, recommended to the patient. This he firmly refused to have. Still, he was anxious to have his thumb "lanced." Pethidine 100 mg. was given intramuscularly, then the part was suitably prepared for incision and an ethyl chloride spray was applied to it. Deep bilateral incisions of the affected volar pad were greeted with no more protest than a gush of pus. There was no pain.

Obviously, treatment would have been impossible had not pethidine first been given. In the circumstances more could not have been required if morphine had been administered alternatively.—I am, etc.,

DUNCAN D. MACDONALD.

Single Incision for Bilateral Orchidectomy

SIR.—Mr. C. J. Cellan-Jones (*Journal*, May 1, p. 1039) looks on my recommendation of the scrotal approach to the testis as humorous. He should know from our meetings in the Middle East that I am a Scotsman, and therefore humourless. The phrase he underlines to make his point, "trim or enucleate," was used to summarize all these procedures (short of removal, in which case it is not replaced in the scrotum) to which a testis may be subjected. Enucleation through a scrotal incision is the best method of castration in the treatment of prostatic cancer.

The inguinal approach to the testis is, in my view, an example of muddled post-Listerian thinking, which looked on the avoidance of "germs" as more important than the preservation of tissue resistance. This attitude was knocked out by the experience of the first world war. The tendency of surgery to-day is to favour direct approaches where they are not traumatic, and to avoid the unnecessary dislocation of areolar planes implied in such incisions as the infra-umbilical paramedian rectus-retracting approach to the appendix.

I do not seek to convince anyone. I would only say: "Don't think; try the experiment." If Mr. Cellan-Jones was unlucky with the scrotal approach 25 years ago, he might be luckier to-day. Most of the surgeons with whom I have conversed during the recent meetings of the Association of Surgeons and the American College prefer the direct to the indirect operation.—I am, etc.,

London, N.W.8.

HENEAGE OGILVIE.

Tuberculin Testing

SIR.—In regard to Dr. P. D. Mulkern's letter on the "false positive" jelly test (*Journal*, May 1, p. 1039), may I make the following observations? From experience in the general B.C.G. contact clinic, and in routine tuberculin jelly testing in residential nurseries, it was found necessary to assess the reliability of the jelly test. In a sample test the children at two residential nurseries had jelly and Mantoux tests (1/1,000 old tuberculin) at the same time. Thirty-nine children were tested, and thirty had positive jelly tests. All had negative Mantoux tests and normal chest x rays. At the one nursery, control jelly tests were done, and there was no suggestion of any reaction; it was also noted that the results were almost identical with two different makes of jelly used simultaneously on each child. The cause of positive jelly reactions in children who were Mantoux-negative (1/1,000) was not found, but the practical significance is clear. There is general acceptance that the jelly test is equivalent to the ten units Mantoux test.

It has been the practice at the B.C.G. contact clinic for suitability for vaccination of infants under 6 months old to be decided on by jelly testing. If the occurrence of these anomalous positive jelly tests is not realized, there will be failure to vaccinate these infants. It appears that vaccination of contact children may be the most effective application of B.C.G. vaccination in the reduction of childhood tuberculosis in this country. It is most important that false positive jelly tests do not result in failure to vaccinate tuberculin-negative contact children. Experience in the general clinic substantiates the occurrence of these anomalous positive jelly reactions. In this work there was no appreciable association of a positive jelly test with a stereotyped catarrhal syndrome. A report is in preparation on the suitability of the jelly test for routine use by health visitors, and on B.C.G. vaccination of anomalous jelly-positive Mantoux-negative cases.—I am, etc.,

Domiciliary Obstetrics

SIR.—Your own kindly criticism (*Journal*, April 10, p. 861) of my essay on domiciliary obstetrics (p. 841) doubted whether the family doctor with consultant support but no postgraduate experience could give adequate intranatal care, but you were in no doubt about his ability to do so antenatally. Mr. C. J. Dewhurst (*Journal*, May 1, p. 1037) does not agree, for, he suggests, the newly qualified practitioner will forget to take a history, will forget that previous postpartum haemorrhage is an indication for hospital delivery, will agree to the delivery of twins at home, will be uncertain of his findings on abdominal examination, cannot diagnose a breech, and will examine cases of antepartum haemorrhage vaginally. He will attempt forceps delivery although he cannot estimate cervical help. To this, Mr. D. S. Greig (p. 1038) adds that general practitioners are not alert to note the onset of pre-eclampsia, and have little regard for the presence of anaemia in pregnancy.

Some would call this exaggeration. If it is not, then it is a terrible indictment of the teaching of the future general practitioner in the obstetrical departments of our medical schools. I find it difficult to agree with Mr. Dewhurst that these simple things cannot be taught, or to believe that it

is impossible to train the future family doctor to be adequate in domiciliary obstetrics; and, as the average practice produces about 30 normal cases a year, he would have a sufficient volume of work to remain adequate if all these cases remained under his care, including those now delivered in hospital for social reasons.

If it is demanded that the general-practitioner obstetrician must have postgraduate experience, the number of cases per doctor will be high enough to perpetuate the present state in which a large part of antenatal and intranatal care has to be delegated to the midwife. This may have been good enough in the past, but improvement in the future is likely to depend on close co-operation between the midwife and a doctor. If it is not with the family doctor, then it is likely to be, eventually, with a house-surgeon when general-practitioner midwifery disappears completely. Mr. Greig's figures, showing that 80% of maternal deaths in his area followed home delivery, tend, as he says, to increase the demand for hospital delivery, and serve to stampede normal primiparae into hospital beds. He does not say whether the patients who died were suitable for home delivery, and it may be, as Jameson and Handfield-Jones¹ have suggested, that too many normal cases are delivered in specialist hospitals, and too many abnormals outside them.—I am, etc.,

Gloucester.

IVOR COOKSON.

Herpes Zoster and Chicken-pox

SIR.—Coexistence of herpes zoster and chicken-pox in the same patient, a further example of which was recorded by Dr. C. Spencer Whitehouse (*Journal*, May 8, p. 1097), cannot be considered excessively rare. Indeed, a search of the records of this hospital for the five years 1949-53 shows that 31 patients suffering from herpes zoster were admitted during that period, and that four patients admitted for the treatment of other diseases developed zoster at some time after admission. Of these 35 cases, 11 also developed chicken-pox, usually about 3 days, but in one case 9 days, and in another case 12 days, after the herpetic eruption. Cases of trigeminal herpes were found to be complicated by chicken-pox about twice as frequently as cases of herpes of either cervical or thoracic roots; while the ophthalmic nerve was the site of the infection in four out of five cases of trigeminal herpes complicated by chicken-pox.

Most patients in whom zoster and chicken-pox coexist are, of course, elderly persons whose immunity to chicken-pox, developed in response to infection in childhood, might be presumed to have waned with the passage of time. A precise explanation of all the well-known phenomena which seem to suggest identity, or a very close relationship between the two diseases is, one feels, most likely to be supplied by further virological studies.—I am, etc.,

C. F. L. HILL.

Animal Technicians

SIR.—I do not wish to introduce any note of acrimony into a correspondence that has already included two rather ungracious letters (*Journal*, April 24, p. 983), and I was glad to read a considered statement from the Chairman of the Institute of Medical Laboratory Technology (*Journal*, May 22, p. 1207) repudiating the extravagance of some of the views of these correspondents. However, Mr. Norman himself invites a like rebuke to that which he offers your annotator, whose ignorance of the knowledge required by present-day technicians in hospital laboratories he deplores. Might not the same be said of Mr. Norman in regard to the work of animal technicians in a research department, who are expected to handle and understand several different species of experimental animals? Hospital laboratories deal mostly with guinea-pigs on routine diagnostic tests, although small numbers of mice, rabbits, amphibians, and other species may sometimes be used; but

outside this restricted field—restricted from the point of view of animal work—the animal technician may find himself with responsibilities different from, but no less exacting than, those of the medical laboratory technician.

Comparisons are odious, and your annotator should perhaps have kept off a discussion of differential status among workers in complementary fields; but he has been justified retrospectively by the resentment apparently caused by his comparisons. Respect of one for the other's job is more useful than quibbles about status. Dog does not eat dog.—I am, etc.,

London, N.W.3.

W. LANE-PETTER.

Folic Acid and Pernicious Anaemia

SIR.—I was interested to see Dr. C. P. Lowther's report (*Journal*, March 6, p. 564) of a case illustrating the dangers of polypharmaceutical preparations containing folic acid, and your annotation (p. 573) on the wrong use of folic acid in pernicious anaemia.

I desire to draw your attention to the following case of mine. A girl of 18 was diagnosed in 1943 to be suffering from tropical nutritional megaloblastic anaemia on adequate grounds, including bone-marrow studies. She was doing very well for the next six years on a proper diet and maintenance therapy with liver extract. During this period she bore two children. Then someone told her that there was no need to have the periodic pricks with the advent of the new remedy, folic acid, which could be taken as tablets. Six months after she gave up the liver extract and took to folic acid alone, she was admitted in my wards with well-marked subacute combined degeneration and gross sepsis in the bladder, to which she succumbed within a week of her admission.

This case would show that the danger of precipitating neurological signs exists not only in true Addisonian pernicious anaemia but also in other megaloblastic anaemias in younger persons.—I am, etc.,

Madras.

K. S. SANJIVI.

Racial and Religious Tolerance

SIR.—While sympathizing with the sentiments expressed by Dr. C. P. Seager (*Journal*, May 15, p. 1156) I can't help thinking that he does less than justice to those who imply a preference for assistants of a particular race or religion. Preference for some is different from intolerance to others. By now we all know the type of person we are likely to get on with best, and if we happen to be Badmanians with a green skin is it unreasonable that we should prefer to work with similar beings?—I am, etc.,

London, W.1.

R. G. ISAAC.

Mitral Stenosis

SIR.—Dr. Paul Wood's treatise "An Appreciation of Mitral Stenosis" (*Journal*, May 8 (p. 1051) and May 15 (p. 1113)) will long be read as a Bible by all those interested in the subject. It is not an exaggeration to say that no similar work has been done in the world. On reading the paper one becomes aware of the fact that the mass of information at the author's disposal is so large that only part of it could have been published. More time will be needed for the proper digestion of that which is still to come. In the interest of the future work I would like to submit an objection and then a comment.

It is stated that there was no single instance in which primary myocardial fault was responsible for failure in mitral stenosis, but it is not disclosed how the myocardial failure was excluded—perhaps by E.C.G. It is emphatically stated that in cases of predominantly mitral stenosis the cause of heart failure is high pulmonary resistance. A table is produced in evidence, which shows that all cases of mitral stenosis with failure did have high pulmonary resistance although mitral incompetence could go into failure without the latter. The fact that high pulmonary

resistance was present does not prove that it was the cause of failure, because it could have been a concomitant phenomenon.

My comment is on pregnancy. Dr. Wood states: "Pregnancy aggravates the symptoms and usually [my italics] causes some permanent deterioration." This statement is contradicted by Dr. Paul Wood himself, because he says that in 83 mothers 140 pregnancies were recorded (probably not personal observation) and no symptoms developed in 97 pregnancies, while symptoms appeared in 43, which gives a ratio of 2.2:1 in favour of "no symptoms," or one could say that symptoms developed only in one-third of pregnancies. Moreover, Dr. Wood says that only 17% of pregnancies precipitated permanent disabilities, and 17% cannot be called usual. The statement then should be as follows: permanent disabilities usually do not develop.

This is so if we accept all Dr. Wood's figures, but in the leading article (p. 1138) we are rightly reminded that Dr. Paul Wood's cases were selected from the rather severe groups: he then obtained probably the worst results in pregnancy. It would be interesting to know how much even of this deterioration is due to the natural progress of the disease for a period of nine months without pregnancy. The table of life history (Table III) shows that once the symptoms appeared—average age 31 years—the deterioration from one severity grade to the next can be very short, from 0 months till 6 as a minimum (without pregnancy). This would apply to pregnancies after the appearance of symptoms only.—I am, etc.,

London, S.E.11.

J. KOHARI.

Standard of Anaesthetics in Britain

SIR.—As the author of the *Daily Express* article referred to by Dr. Geoffrey Organe (*Journal*, May 29, p. 1267), I should like to say how much I regret any trouble which my report has caused, either to Mr. Dickson Wright or to the anaesthetists. I must point out, however, that I attended the meeting by invitation along with several other newspaper reporters, including at least one representative of the *American Press*, and that in my account Mr. Dickson Wright was accurately reported.

It seemed to me and to some of my colleagues that Mr. Dickson Wright's statements were not mere light-hearted asides but that he was airing a serious grievance. This was also the view of two surgeons with whom I discussed Mr. Dickson Wright's speech. I have since learned from Mr. Dickson Wright that his comments were not intended to be taken so seriously, and that he was unaware that reporters were present.

I went to much trouble to give Dr. Organe the opportunity of commenting on the speech so that his views on behalf of the Association of Anaesthetists could be given similar prominence to those of Mr. Dickson Wright. Dr. Organe could not be contacted, but I left messages for him. My statement that Dr. Organe and other anaesthetists demonstrated their machines to the visiting American surgeons was not intended to suggest that Dr. Organe was present when Mr. Dickson Wright made his remarks. I do not believe that it did, in fact, give this impression to our readers.—I am, etc.,

Lopdon, E.C.4.

CHAPMAN PINCHER.

Homosexuality

SIR.—Recently I was rung up by a daily newspaper, asking my views on the Home Secretary's proposed committee on sexual crime and prostitution. Had I not been debarred from stating them, this would have been my answer: I am in favour of the Home Secretary's proposed committee, provided that, in the considerable time before it reports, the fact of its being called into existence is not taken in the slightest degree to condone homosexuality between adult males in private. It must be remembered that the word "homosexuality" has become a euphemism

for the practice of mutual masturbation, intra-crural and intra-anal intercourse, and other less easily stated practices between males.

I am confident that the committee will report against any legalizing or tolerating of adult male homosexuality in private. Otherwise it will be faced with the prospect in any or every city of the churches, the schools, the youth movements, the university, the Services in barracks and in the nearby aerodrome, and every parent, all trying to turn out clean and decent citizens, all holding that these unnatural practices are immoral or evil or deadly sin, and filthy and just as foul by whatever name they are called, while in the midst of them there might flourish two exclusive clubs—let us call them "The Wilde" and "The Gomorrah"—legally in being, open to men "above the age of consent only," with their many private rooms, corrupting men so that each has his character changed, a corruption that has a considerable degree of permanence and is passed on to others, so that chains of homosexuality are formed which may persist for generations. No responsible body of men and women could for a moment consider the possibility of creating such a state of affairs. Non-medical speakers and writers seem to have no difficulty in finding opportunities to express their views on this important and partially medical subject in the press, in B.B.C. "Any Questions?" and in so-called "brains trusts." Surely, in fairness, I should be allowed to state mine in a medical paper.—I am, etc.,

Beckley, Rye.

C. G. LEAROYD.

Mondor's Disease

SIR.—Following on the article by Mr. G. M. Lunn and Mr. J. M. Potter on Mondor's disease (*Journal*, May 8, p. 1074) and on the letters of Mr. John Hosford and Dr. F. Harwood Stevenson (*Journal*, May 22, p. 1207), I would like to describe a similar case which came under my care very recently.

The patient, a married man aged 39, attended surgical out-patients on April 27, 1954, complaining of pain in the right pectoral area, most marked when reaching for an object above his head. The pain had been present for two months. There was no history of infection in the area, but he stated that in December (four months before) he had been using a brace and bit for several hours, drilling some very hard wood, and in order to get firm pressure he had pressed the butt of the drill on to his chest. He was not used to this sort of work, his own occupation being clerical. On examination, there was an ill-defined area of induration in the lower lateral quadrant of the right breast, some 1 in. (2.5 cm.) in diameter, and a plexiform mass of hard cords extending from the right axilla to the right costal margin.

Two weeks later he again came to the out-patients, and the area of induration had nearly gone. The mass of cords was still present. A biopsy of one of these cords was taken, and the report on the section is as follows: "A section of this portion of tissue showed that it was lined by a normal stratified squamous epithelium and the subcutaneous tissues were entirely normal apart from a deeply placed mass of tissue which suggested fibrous tissue. No lumen of a vessel or other evidence of an obliterated vessel was seen."

My thanks are due to Mr. C. F. Critchley for his permission to publish this case, and to Dr. J. Keall for his help with the pathology.—I am, etc.,

London, S.W.11.

D. M. PAUL.

A Genetic Investigation

SIR.—We are anxious to extend a genetic investigation which is at present in progress into the rare syndrome which includes hypoplastic patellae and finger-nails. One recent description of this condition is that of Hawkins and Smith.¹ If any case is known to your readers we should be most grateful for the opportunity to do further family and linkage studies.—We are, etc.,

Obituary

Sir JAMES SPENCE, M.C., M.D., F.R.C.P.

Paediatrics has lost a leading figure and the nation a wise counsellor in the death of Sir James Spence on May 26 at the age of 62. His reputation was international, and he had made it so by hard work, clear thinking, and a happy gift of exposition which often sounded more like a fireside chat than a set lecture.

James Calvert Spence was born on March 19, 1892, the son of Magnus Spence and Isabella Turnbull, and was educated at Elmfield, York, and at the University of Durham. He graduated M.B., B.S., with honours, in 1914, just in time to enter the R.A.M.C. and serve with distinction throughout the war of 1914-18, being awarded the Military Cross and bar. An appointment at the Hospital for Sick Children, Great Ormond Street, London, followed, and this probably determined in some measure the pattern of his life, for it has been said that those who are privileged to work at this hospital are influenced by it for the rest of their lives. He then moved to St. Thomas's Hospital during 1920-2, where he held the John and Temple Research Fellowship. After this Spence went north again to become clinical pathologist and medical registrar at the Royal Victoria Infirmary, Newcastle-upon-Tyne. Biochemistry as applied to medicine was just beginning to grow, stimulated in part by Professor Hugh Maclean at St. Thomas's, under whose influence Spence had come. The scientific

discipline thereby obtained was to shape his thoughts on medical education in the years to come. Next followed a year in the U.S.A. as a Rockefeller Fellow in 1926-7, mostly spent at the Johns Hopkins Hospital, Baltimore, and a return to the staff at Newcastle as a general physician. Local controversies kept him out of special paediatric work for several years, and to some extent the Babies' Hospital there was a reply to a policy which kept a man, already gaining an international reputation, off the staff of the children's hospital. Meanwhile Spence had proceeded M.D. in 1921 and had obtained the M.R.C.P. in the same year. He was elected F.R.C.P. in 1930.

As his ideas matured Spence managed to achieve a remarkable synthesis between a scientific approach and a deeply humanistic outlook, the latter no doubt influenced by his Quaker origins. At meetings of such bodies as the Association of Physicians and of the

British Paediatric Association, of which he was an original member and in 1950-1 president, his earliest contributions on scientific work gave place later in the case of paediatrics to a more social approach. During his chairmanship of the Social and Preventive Medicine Committee of the Royal College of Physicians of London in its early days—in the second war period under Lord Moran's presidency—there developed a growing interest in social paediatrics. His election to the Chair of Child Health in the University of Durham in 1942 was in keeping with the development of ideas in children's medicine and in tune with his own position. This was the second chair in the British Isles of this kind and the forerunner of others with similar titles in almost all the medical faculties in the United Kingdom. His choice as a medical member of the Curtis Committee was welcomed, and a great deal of the report of that

committee and the subsequent legislation owed much to Spence's inspiration. He was also at this time or later a member of the medical advisory committee of the Nuffield Provincial Hospitals Trust, the Medical Research Council, the University Grants Committee, and the Central Health Services Council. In 1953 he was appointed a member of the Clinical Research Board by the Medical Research Council. The establishment of the board was one of the principal recommendations in the White Paper on "Clinical Research in Relation to the National Health Service." All this entailed much travelling, and the strain undoubtedly contributed to an illness in 1952 which necessitated a slowing down of the pace. He was greatly in demand as a lecturer, and the list of official lectureships is long, including the Bradshaw Lecture

(1940), the Charles West Lecture (1946) at the Royal College of Physicians of London, the Dawson Williams Prize and Lectureship of the British Medical Association (1949), and the Linacre Lecture at St. John's College, Cambridge (1951). Abroad equally he fulfilled his role as ambassador and lecturer. He was the Inter-State Postgraduate Lecturer in Australia in 1948, and he gave the Cutter Lecture at Harvard in 1949 and the Blackader Lectures before the Canadian Medical Association in the same year. By now he was physician to the Royal Victoria Infirmary, Newcastle-upon-Tyne, with his child health department in the grounds of the hospital, to the General Hospital, and to the Babies' Hospital in that city. There he began to experiment with the admission of mothers with their babies, and so successful was this that many visitors sought out "Sir Spence," as overseas friends called him, to see exactly what was done. His knighthood had come in

[Elliott & Fry, Ltd., London]

1950 and was a culmination of many other honours, including an honorary D.Sc. from the University of Western Australia in 1948 and an honorary LL.D. of Cincinnati. He was a member of the American Academy of Pediatrics and of the Canadian Society for Study of Diseases of Children.

James Spence—"Jim" to his intimates—had an attractive personality. His twinkling blue eyes and uncontrolled lock of hair gave him a faintly puckish appearance, which was reflected also in his talk. "Whimsical" is the adjective that was often used. It was often uncertain what way he was thinking, and indeed he was often a jump or two ahead of current thought and practice. A faint but friendly exasperation would sometimes develop among those associated with him, easily dissipated by the next conversation. He married in 1920 Kathleen, youngest daughter of Robert Downie-Leslie, of Aberdeen, and had one son and four daughters. His home life was friendly and charming for those privileged to share it. The holiday house in Grasmere among the mountains he loved to climb was a popular trip for those visiting Windermere for the British Paediatric Association, in the founding of which he played a notable part; and to him largely was due the happy choice of Windermere as a meeting-place. He moulded the development of the B.P.A., especially in its orientation towards social paediatrics in the war years, and was a wise elder statesman long after he had held office on its committees. His work for university education revealed a mind which was deeply steeped in tradition and humanitarianism. Whatever it was—the development of some medical department, the securing of adequate remuneration for junior lecturers in all the faculties—he was equally keen and well briefed by his personal investigations of the problem which over and over again demanded a scientific analysis and a solution which involved a deep concern for personal problems. Spence was an international figure as well as a national one, and he has left the whole community in his debt.

We are indebted to Sir HAROLD HIMSWORTH for the following appreciation: The death of James Spence has deprived British medicine of an influence that it could ill afford to lose; but it was an influence which was so largely personal that it is difficult to pay tribute to it so that future generations will understand the esteem in which he was held by his contemporaries. There are some men—the majority—who achieve eminence by building some part of the factual structure of knowledge. There are others—the architects of knowledge—who give shape to particular concepts. Both leave contributions which are evident not only to their contemporaries but to their successors. But there are yet others—a few—whose contributions lie in appreciating needs and creating the climate of opinion in which these can be translated into realizable concepts. Their influence is to be measured not in terms of the factual contributions which survive them but in the value that was placed on their advice during their lifetime. To a certain extent no man can achieve eminence in his profession without contributing in each of these ways. James Spence made his own contributions to factual knowledge. In his work for child health he developed his concept of the particular field of medicine in which he was interested. But it is probable that it was in his contribution to professional thought, of the form and shape which medicine should take to meet the needs of its own development and the society which it serves, that his influence was most pervasive and profound.

At the time of his death James Spence was serving for a second period on the Medical Research Council. That in itself was an indication of the regard in which his advice was held. He attended his last Council meeting on April 23.

His advice on detail was as valuable as ever; but it was typical of him that, ill as he was, his main concern was to ventilate a problem broader even than medicine itself. He was concerned with the whole question of the relationship of scientific knowledge to the intellectual development of our society, not in any vague or sentimental sense, but as it expressed itself in the concrete problem of integrating the effort of the scientific organizations of government with that of the universities. It was this ability to appreciate the larger significance of the drift of events, and to arrest the attention of those who might influence them, that gave his advice its peculiar value. Not that he was proved always to be right. No man who attempted to foresee distant developments could hope to be. But his opinions were never negligible and, more often than not, showed a grasp that seemed almost inspired.

Foresight of this range is a talent which, in general, men appreciate only in retrospect. At the time it is seldom welcome. Perhaps the greatest tribute that can be paid to Spence as a man is that his contemporaries were prepared to heed him and yet still held him in affection. If his character had been different, he might so easily have followed the commoner lot of the imaginative and become a mere rebel. He had, however, a fundamental generosity of temperament which conditioned his attitude to others and their response to him. This, combined with a very characteristic whimsical charm, endeared him even to those with whom he was in most disagreement. To juniors he was an inspiration. His curiosity was ever alive, and he retained the capacity to see the fascination of the ordinary. But he never forgot the man behind the work; and there must be many who remember the appreciative aside which showed that the true measure of their achievement had not been overlooked. To both contemporaries and juniors alike, he was a very stimulating, very human, and most engaging colleague.

C. W. FORSYTH, M.D.

Dr. C. W. Forsyth, formerly medical superintendent of Winson Green Hospital, Birmingham, died suddenly at Capetown on May 16 while on a visit to his son. He was 77 years of age.

Charles Wesley Forsyth was born on June 28, 1876, and was educated at Owens College, Manchester, and at University College Hospital, London, where he had a distinguished career as a student. He graduated M.B., with first-class honours in anatomy, from London University in 1903, having taken the diplomas of M.R.C.S., L.R.C.P. in the previous year.

His early years were devoted to general practice, but he eventually became interested in psychiatry, and after serving in various hospitals of the London County Council proceeded to the M.D. (in mental diseases) in 1919. In the same year he was appointed deputy medical superintendent of Hollymoor Hospital, Northfield, Birmingham, and in that post was able to develop his undoubted clinical ability to the full. These qualities led to his promotion to the position of medical superintendent of Winson Green Hospital, an appointment he held until his retirement through ill-health in 1938.

On the academic side, too, Dr. Forsyth had a distinguished career, being lecturer, clinical lecturer, and examiner in psychological medicine at Birmingham University from 1932 until his retirement. The years covered by his tenure of office at Winson Green saw a steady development of the active treatment of mental illness, and alongside this, and indeed arising from it, an extensive programme of modernization of the hospital. In the inception of that programme Dr. Forsyth was personally responsible, and it constitutes a memorial to his energy and enthusiasm.

Aside from his purely medical interests his principal hobbies were gardening and cricket. Evidence of the former is to be seen in the layout of the hospital grounds, which are in striking contrast to the industrial surroundings; while as a keen cricketer he was responsible for the recruitment to the hospital staff of many sportsmen who later, under his guidance and tuition, became equally competent male nurses. Dr. Forsyth leaves a widow and a son, to whom we extend our sympathy in their loss.—J. J. O'R.

W. J. WILSON, M.D., D.Sc., LL.D., D.P.H.

By the death on May 6 of Professor W. J. Wilson, emeritus professor of public health in Queen's University, the Belfast Medical School has lost one of those who played an important part in its growth and development. He was 74 years of age.

Born at Straid Mills, Co. Antrim, on August 23, 1879, William James Wilson was educated at the Royal Belfast Academical Institution and at Queen's College, Belfast, then a constituent college of the former Royal University of Ireland, and there he had a brilliant career. He won the Henry Hutchinson Stewart Scholarship in anatomy and physiology of the University for 1901–2, graduating B.A. with first-class honours in the latter year. He secured first place in the final M.B., B.Ch. examination in 1905, again passing with honours, and two years later he proceeded to the M.D., gaining a gold medal for his thesis. In 1906 he obtained the Cambridge D.P.H. and won the studentship in pathology and bacteriology of the Royal University of Ireland, and four years later he took the degree of D.Sc. of Queen's University. Earlier, while at Queen's College, he won the senior scholarship in chemistry in 1902 and the Dunville Studentship in the following year.

After a period of postgraduate study in Berlin, Wilson returned to Queen's as Riddell demonstrator in pathology and joint lecturer in sanitary science, and it was in the latter subject that he made his greatest contribution to the University and to medicine in general. Under his guidance his joint lectureship grew into an independent department of public health, and in 1921 he was appointed to a chair in the subject. He retired from the chair in 1948 and was appointed emeritus professor; later, the honorary degree of LL.D. of Queen's University was conferred upon him.

Wilson early became interested in the improvement of bacteriological culture media, and before the first world war he made several contributions in that field. In this period, too, he described the presence of antibodies in the blood of patients with typhus fever, which had the power to agglutinate some coliform organisms, and thus paved the way for the development of the Weil-Felix reaction. After the war he continued his search for selective culture media, and with Dr. E. M. McV. Blair eventually developed the Wilson-Blair glucose-sulphite-iron-bismuth-brilliant green medium in the examination of sewage for the presence of *Salm. typhi*, a method which has proved itself of such value in public health bacteriology. In the first world war he served with the R.A.M.C. with the rank of major and continued his bacteriological studies. From 1914 to 1917 he was specialist sanitary officer and inspector of tetanus for the Belfast military district. He was one of the first to describe Zenker's hyaline degeneration in the muscles in the influenza epidemic of 1918. On returning to civilian life he was

appointed bacteriologist to several public authorities and took over the care of the water supply of Belfast, in addition to his university duties. Through such appointments he gave much service to the community at large.

Busy as he was on routine work, Wilson continued his interest in research. He also gave freely of his time to administrative matters. From 1928 to 1943 he was Dean of the Faculty of Medicine, and in that position was concerned with the welfare of the medical school in the early years of the last war. Many graduates and students owe him a deep debt of gratitude for his wise guidance in time of trouble and for his amiable interpretation of rules and regulations. A member of the British Medical Association for 48 years, he acted as one of the honorary secretaries of the Section of Pathology when the Association held its Annual Meeting at Belfast in 1909; at the Nottingham Meeting in 1926 he served as a vice-president of the Section of Public Health; and at Belfast in 1937 he was president of the Section of Hygiene and Public Health. He was also president of the Ulster Medical Society in 1934–5, and from 1942 to 1945 he represented Queen's University on the General Medical Council. He was appointed a member of the University Senate, and for over 20 years was a governor of his old school, being elected chairman of the board in 1942. When the Northern Ireland Tuberculosis Act was passed in 1946 he became a member of the Tuberculosis Authority.

As the years passed, "W. J.," as he was familiarly known, became more and more a character identifying in himself the Faculty. Though a quiet man, he could be roused to battle on behalf of his medical flock and through sheer persistency accomplished much for all. By his personality, hard work, and unity of purpose he has left his name deeply engraved on the annals of the University and on the medical life of Northern Ireland. He leaves a widow, a daughter, and three sons, who are members of the medical profession.

The death of Dr. DOUGLAS J. NICOL on May 8 at the age of 59, after a long period of ill-health, has deprived Birmingham of a much-loved general practitioner and the St. John Ambulance Brigade of one of its most distinguished surgeons. Douglas John Nicol was born in Glasgow. The first world war interrupted his medical studies at Glasgow University and he served as a captain in the Highland Light Infantry from 1914 to 1917, being awarded the Military Cross. He then returned to Glasgow University, where he graduated M.B., Ch.B. in 1919. After holding the appointments of house-physician and house-surgeon at the Royal Southern Hospital, Liverpool, he settled in practice in Birmingham, where he spent the rest of his life. His war-time experiences having shown him the great importance of skilled first aid to the wounded, he joined the St. John Ambulance Brigade as a divisional surgeon in 1923, being promoted corps surgeon in 1938 and county surgeon three years later. He did outstanding work as an instructor in first aid to the police and fire brigade, and later he advised the British Electricity Authority and other nationalized industries on first-aid training. It was indeed as a teacher of first aid that Nicol made his greatest contribution. He was one of the pioneers of the new spirit of realism in first-aid competitions in which "patients" were not only made up to represent the actual injuries from which they were supposed to be suffering, but were also trained by him to behave as though they really were injured. The effect on first-aid teams was unmistakable, and the value of the experience gained was shown in their greatly improved approach when actually called upon to deal with an accident. This encouraged

Nicol to extend the realism to the basic first-aid training in the "black book." He devised a series of what he termed "little cases," and these, carefully prepared and admirably demonstrated, served to teach the essential do's and don'ts of first-aid. Candidates were often nervous of meeting him, but they realized that to be examined and passed by Nicol was to be indeed an efficient first-aid. He demonstrated his methods to many hundreds of St. John surgeons and lay members all over the country. As a visiting industrial medical officer Nicol realized the great importance of the provision of efficient first-aid training to the responsible persons in charge of first-aid boxes in the thousands of small factories in Birmingham, and during his years as chairman of the St. John Ambulance Association in that city he had the joy of seeing hundreds of men and women so trained and to receive the valuable support of the public health department, the Birmingham Accident Hospital, the Factory Department, and many industrialists. For these services he was promoted Commander of the Order of St. John, an honour rarely given to anyone below the rank of county commissioner. A somewhat shy and dour manner hid a kind and understanding heart, for one had only to hear his patients praise him to realize what a tower of strength he was to them in their times of serious illness and anxiety. He had a very high professional standard and never allowed his outside activities to encroach upon his practice. Dr. Nicol leaves a widow, who is the St. John County (Nursing) Superintendent for Birmingham and who ably assisted him in all his work, a daughter, and two sons, one of whom is following his father's profession.—J. G. B.

Medical Notes in Parliament

HOSPITAL JUNIOR MEDICAL STAFF

Dr. A. D. D. BROUGHTON (Batley and Morley, Lab.) discussed the shortage of resident medical staff in hospitals in the House of Commons on May 28. He asked what were the reasons for the shortage of junior medical staff in the smaller hospitals. The main factor, he thought, was that those seeking hospital appointments preferred the larger hospitals because there they gained a wider clinical experience; another factor was that in the larger hospitals they worked as members of a team. The second choice of applicants was for the most pleasant parts of the country, such as seaside resorts. Applicants went either for rich experience or a good holiday. Who could blame them, since the salary was the same in all hospitals? The salary itself was an important factor, for junior appointments in hospitals were less profitable than national service in the R.A.M.C. and in strong contrast with assistantship in general practice.

Dr. Broughton also suggested that the recent substantial increase in the number of actions for negligence brought against junior house staff was having an effect in deterring recently qualified men and women from undertaking duties which exposed them to the danger of such charges. Would the Minister consider allowing beds to be used for patients under the care of the general practitioners?

Miss PAT HORNSBY-SMITH, the Parliamentary Secretary, replied that various methods had been tried during the past two years, and some progress had been made, but the causes were very deep, and were not capable of immediate solution. The two main features were supply and demand on the one hand and fair distribution of the available staff on the other. The supply of junior hospital staff fell short of the maximum establishment by something under 10%. The check on establishment had meant that, while the teaching and large hospitals had no difficulty in getting staff, there was a trickle to the more needy and in some ways less attractive hospitals. The priority needs of the small hospitals, it was felt, should come first, and this policy had already brought results.

The most difficult problem was in distribution, and it was particularly felt at the peripheral hospitals, especially those

dealing with a narrow range of work. The cause was not any decrease in supply, but a substantial increase in demand, often due to the upgrading of the smaller local hospitals with additional specialties. From the record of claims in the Ministry they had no evidence that claims for damages arose more particularly in respect of the peripheral hospital than elsewhere.

It was not practicable to increase the number of qualified doctors. There were about 2,000 a year. The number of probable vacancies in "career" posts appeared to be fairly well balanced in relation to intake, which a little while ago was a source of great concern. They could not reduce the number of doctors called up; apart from the undesirability of treating doctors exceptionally, the Services could not do without them. The most hopeful lines were to encourage general practitioners to work in hospitals, and to encourage men returning from national service to enter the hospitals for a period rather than go straight into general practice. The additional payment of £50 a year for house officer posts that were difficult to fill had not been found an efficacious method—it tended to "blacklist" a hospital; and the Ministry looked with considerable reserve on the idea of incentive pay for what should be a comparable job, and also on any suggestion that posts should be graded above their true worth.

Hospital Resident Officers

Dr. A. D. D. BROUGHTON (Batley and Morley, Lab.) asked the Minister of Health what was the total number of resident medical officers in hospitals in England and Wales, and how far this was below the establishment figure. Mr. IAIN MACLEOD, replying on May 26, said the information was not available in that form, but at the end of 1953 there were in the hospitals the whole-time equivalent of 7,815 medical officers other than specialists and senior registrars, compared with an establishment in December, 1952, of 8,499.

Dr. BROUGHTON also asked what means were available to regional hospital boards and hospital management committees for filling vacancies in the resident medical staffs of hospitals. Mr. MACLEOD said that the usual method was advertisement in the medical press, supplemented as necessary by direct contact with medical schools and other appropriate bodies and persons.

Pay in the R.A.M.C.

Dr. A. D. D. BROUGHTON (Batley and Morley, Lab.) asked the Secretary of State for War on May 25 what was the rank and the pay of a registered medical practitioner on joining the Royal Army Medical Corps for the period of national service, and after one year's service; and how far it was possible for a medical officer to hold higher, acting rank, with pay, during the period of national service. Mr. A. HEAD stated that a doctor was commissioned in the rank of lieutenant and got basic pay of £401 a year. After one year he was promoted captain and got £511 a year, and after a further six months £593 a year. He might get temporary promotion to the rank of major, and there were 20 National Service officers holding this rank: the basic pay was £785 a year in the first 18 months' service and £912 a year in the last six months. In addition to basic pay, marriage allowance of £117 a year for an officer under 25 and £228 a year if he was older, and specialist pay of £73 a year, were paid where appropriate.

Dr. BROUGHTON also asked what was the annual cost to the War Office of advertising to invite applicants for commissions in the R.A.M.C. Mr. HEAD said that up to last year advertising was mainly for specialists and the yearly cost was under £300. Last year just under £1,000 was spent on special publicity for the new terms of service of officers of this corps.

Cost of Training Students

Dr. A. D. D. BROUGHTON (Batley and Morley, Lab.) asked the Minister of Education on May 24 what was the annual

cost to her department for the education and training of medical students in the medical schools of England and Wales. Miss FLORENCE HORSBROUGH stated that the number of students taking medical courses in the current academic year with grants from the department was 1,948, of whom 1,121 held State scholarships and 827 held awards under the Further Education and Training Scheme. She estimated the cost in fees and maintenance for the year at approximately £574,000. In addition, the department admitted for grant the expenditure of local education authorities on making awards to students taking medical courses; but the returns of the authorities did not enable her to isolate this expenditure from their other expenditure on awards.

Tracing Trichinosis

Mrs. ELIZABETH BRADDOCK (Liverpool, Exchange, Lab.) asked the Minister of Food if he was aware that, in the outbreak of trichinosis in Liverpool recently, it was found to be impossible to trace the infected pig beyond the abattoir; and, in view of the serious infection which could be caused, what steps he was taking to have complete records of the movement of pigs available to medical officers of health responsible for tracing infections. Dr. CHARLES HILL, the Parliamentary Secretary, replied on May 26 that the movement of pigs was subject to the provisions of the Movement of Animals (Records) Order, 1925, which required records of movements to be kept in a prescribed form; this order was enforced by the local authorities responsible under the Diseases of Animals Act, 1950, and the records should be available to medical officers and others when tracing infections. He also said that he shared the concern about the Liverpool outbreak. In only two of the 89 cases was the infection traced to pork, and in those cases difficulty was experienced in tracing the infected pig back to the piggery. He was looking into those cases. In the remaining cases the infection came from sausages, and it was extremely difficult in a large sausage-factory to trace a carcass.

Television Advertising

In the resumed debate in committee on the Television Bill on May 31 Dr. EDITH SUMMERSKILL (Fulham, West, Lab.) moved an amendment to prohibit the advertisement of articles recommended as medicines. She said the purpose was to protect a small section of the community against the glib patter of the salesmen who represented the drug firms. An unscrupulous advertiser might play upon their fears with some worthless preparation.

Dr. BARNET STROSS (Stoke-on-Trent, Central, Lab.) said that the societies and associations in the medical profession would soon be creating an unholy row if doctors found their time was being wasted in having to explain to patients that these preparations were not as good as they were said to be, or that doctors could not prescribe them.

Mr. L. D. GAMMANS (Assistant Postmaster-General) said that all would agree with the spirit behind the amendment, but the authority already had sufficient powers. The standards laid down by the advertising bodies were very rigorous, and the advertising interests had volunteered to set up an advisory committee. The B.M.A. had volunteered to nominate representatives to sit on the committee. This method would provide a most effective safeguard against abuse.

The amendment was withdrawn.

Medico-Legal

ACTION AGAINST GENERAL PRACTITIONER FAILS

[FROM OUR MEDICO-LEGAL CORRESPONDENT]

On May 14, 1954, Mr. Justice Cassels gave judgment for the defendant, Dr. R. K. R. Henry, in an action brought against him by Mr. F. Sadler alleging that the death of his daughter, Kathleen Sadler, was due to Dr. Henry's negligence. Kathleen Sadler, a single woman aged 26, had died on April 27, 1952, from acute meningitis due to suppurative

otitis media, and the plaintiff's case was that Dr. Henry had been negligent in failing to diagnose otitis media or treat her for it; to recognize the symptoms of meningitis; to pay attention to a swelling behind the right ear; to examine the retinae; to consider or advise operative treatment or the administration of penicillin; or to send her to hospital until too late to save her life.

On Thursday, April 24, at about 10.45 p.m. Miss Sadler, who a day or two before had had a cut in her arm sutured at Barnet Hospital but was otherwise in good health, complained to her fiancé of pain in her right ear. In December, 1950, she had had wax syringed from her ears but otherwise had no previous history of ear trouble. Next day she complained to her fiancé of pain and told him she had been up all night. Between 9 and 10 a.m. she went to see Dr. Henry at his surgery, gave a history of having had a cold earlier, and complained of earache. Dr. Henry examined her ear with an auriscope, took her temperature, which was 99° F. (37.2° C.), looked and felt behind her ear, and saw partial inflammation of the right eardrum. He saw no discharge or sign of perforation, diagnosed "catarrhal drum," and prescribed drops to relieve the pain and a sedative. He told her to see him again after the weekend but if the condition did not resolve within 24 hours to call and tell him.

That evening she was restless and in pain from her ear, which discharged blood and pus, and she vomited during the night. On Saturday morning Dr. Henry was called, and saw her at about 11 a.m. He removed the stitches from her arm. He was told she had had a headache and some vomiting, and that she had "rushing noises like the sea" in her head. He again examined her ear through the auriscope and thought it slightly improved. He saw no discharge nor bulge at the drum nor perforation, and was not told that there had been a discharge. She seemed worried about her arm and he ascribed the vomiting to her nervous condition. He saw no indication of suppurative otitis, nor anything such as neck rigidity to indicate meningitis. Her temperature was still 99° F. and she talked rationally. He ordered glucose and codeine tablets.

On Sunday morning she vomited back a cup of tea, and there was discharge from her ear and some nose bleeding, but she said she felt better. At 12.15 p.m. she asked for the curtains to be drawn because she did not like the light. At 2 p.m. she vomited again and complained of her head. At 3 p.m. she complained of loss of use of her legs, and that her fingers felt funny. At 6.30 p.m. Dr. Henry called and made a thorough examination. He found her ear clean and that she could move her legs, and he could find nothing clinically wrong. Her temperature was again 99° F. and she was worried and emotional. He saw no signs of irrationality, no discharge from the ear, no perforation of the drum, no swelling, and no rigidity of the neck. He thought she had acute hysteria, and recommended her family not to fuss her.

At 8.45 she became irrational and Dr. Henry, communicated with by telephone, arranged for her admission to hospital. At 11.50 p.m. she died, almost immediately after admission.

At necropsy the mastoid cells were found to be full of pus. The eardrum had a small perforation at the back of a diameter of 1/32 in. (0.8 mm.), and the tegmen tympani had become eroded and was perforated by a hole 1/16 in. (1.6 mm.) in diameter resulting in fulminating meningitis, giving rise in turn to uncus herniation, which was the immediate cause of death.

The principal complaint against Dr. Henry put forward by the expert witness, Mr. T. E. A. Stowell, called for the plaintiff, was that on the Saturday he ought to have used an ophthalmoscope, and would then have seen early changes of optic neuritis, indicating meningitis; and that while neck rigidity may not have been present on Saturday morning it must have been by the afternoon. He conceded that on Saturday morning the usual symptoms of otitis media and meningitis were probably masked.

The expert witnesses called for the defence were Mr. Terence Cawthorne, Dr. Denis Williams, Dr. A. H. Douthwaite, and Dr. J. C. Gregory, a general practitioner. The defence's evidence was that the condition found at necropsy was consistent with no neck rigidity whatsoever

before death, and that there were no signs or symptoms present early enough to enable a reasonably careful doctor to take action to prevent death. Fatal brain infections could occur with no warning signs or symptoms at all.

Mr. Justice Cassels found that there were no signs or symptoms which could reasonably have led Dr. Henry to suspect localized meningitis. His diagnosis of hysteria was as it turned out a mistake, but one which others might well have made in the circumstances. He therefore gave judgment for the defendant, saying that Dr. Henry impressed him as a careful general practitioner who had failed in the difficult circumstances of the case to diagnose the real condition, which the necropsy disclosed. That did not prove him negligent, and he was entitled to return to his practice with a clear conscience.

The Medical Defence Union instructed Messrs. Hempsons to act for Dr. Henry. The defendant's costs of the action, which lasted 13 days, were about £3,500, but the M.D.U. was unable to recover them because the plaintiff was without means and had brought the case under the free legal aid scheme.

Vital Statistics

Week Ending May 22

The notifications of infectious diseases during the week included pneumonia 520, scarlet fever 832, whooping-cough 2,419, diphtheria 22, measles 1,940, dysentery 1,104, acute poliomyelitis 25, paratyphoid fever 4, and typhoid fever 3.

Infectious Diseases

In England and Wales during the week ending May 15 the largest variations in the number of notifications were increases of 279 for whooping-cough, from 2,381 to 2,660, 179 for scarlet fever, from 719 to 898, and 83 for dysentery, from 948 to 1,031.

The largest rises in the trends of whooping-cough were 59 in Lancashire, from 219 to 278, 47 in Warwickshire, from 122 to 169, and 45 in Yorkshire West Riding, from 156 to 201. A small rise in the incidence of scarlet fever occurred throughout the country; the largest was 39 in Lancashire, from 91 to 130. 1,706 cases of measles, 28 fewer than in the preceding week, were notified. The only variations of any size in the local trends of measles were a fall of 57 in Staffordshire, from 195 to 138, and a rise of 56 in Lancashire, from 355 to 411. 9 cases of diphtheria were notified, being the same as the record low level of the preceding week. 3 cases were notified in Lancashire and 3 in Warwickshire, Birmingham C.B. 4 of the 7 cases of paratyphoid fever were notified in Staffordshire, Burton-on-Trent C.B.

19 cases of acute poliomyelitis were notified. These were 1 fewer for paralytic and 3 fewer for non-paralytic cases than in the preceding week. 4 cases occurred in Essex and 2 cases in Gloucestershire, Staffordshire, Lancashire, and Yorkshire West Riding.

The largest rises in the number of notifications of dysentery were 59 in Yorkshire West Riding and 46 in London. The largest returns were Lancashire 272 (Stretford M.B. 54, Irlam U.D. 37, Rawtenstall M.B. 24, Bolton C.B. 21, Liverpool C.B. 20, Salford C.B. 18, Swinton and Pendlebury M.B. 16, Eccles M.B. 14, Manchester C.B. 13, Denton U.D. 12), Yorkshire West Riding 177 (Dewsbury C.B. 59, Sheffield C.B. 45, Baildon U.D. 10), London 153 (Islington 38, Lewisham 23, Deptford 10), Leicestershire 49 (Leicester C.B. 45), Sussex 38 (Uckfield R.D. 19, Brighton C.B. 16), Middlesex 33, Cheshire 33 (Ellesmere Port U.D. 21), Warwickshire 29 (Birmingham C.B. 14), Nottinghamshire 28 (Beeston and Stapleford U.D. 15), Staffordshire 26, and Gloucestershire 22 (Bristol C.B. 21).

In Scotland the notifications of dysentery rose from 311 to 335. The largest returns were Glasgow 226, Lanark county 20, Dundee 19, and Edinburgh 17.

Graphs of Infectious Diseases

The graphs below show the uncorrected numbers of cases of certain diseases notified weekly in England and Wales. Highest and lowest figures reported in each week during the nine years 1945-53 are shown thus -----, the figures for 1954 thus -----. Except for the curves showing notifications in 1954, the graphs were prepared at the Department of Medical Statistics and Epidemiology, London School of Hygiene and Tropical Medicine.

INFECTIOUS DISEASES AND VITAL STATISTICS

Summary for British Isles for week ending May 15 (No. 19) and corresponding week 1953.

Figures of cases are for the countries shown and London administrative county. Figures of deaths and births are for the 160 great towns in England and Wales (London included), London administrative county, the 17 principal towns in Scotland, the 10 principal towns in Northern Ireland, and the 14 principal towns in Eire.

A blank space denotes disease not notifiable or no return available. The table is based on information supplied by the Registrars-General of England and Wales, Scotland, N. Ireland, and Eire, the Ministry of Health and Local Government of N. Ireland, and the Department of Health of Eire.

Medical News

Opening of New Institute of Urology.—The new building of the Institute of Urology in Henrietta Street, Covent Garden, just opposite St. Peter's Hospital, was opened by Viscount WAVERLEY on June 1. The Institute is an adapted house dating back to Caroline days. It now contains a museum and lecture room, laboratories, library and reading-room, a photographic studio, and a records department. Viscount Waverley said that the inauguration of these premises was an important step towards realizing the conditions which must be fulfilled if the Institute were to remain a recognized unit of the Postgraduate Medical Federation. The ideal arrangement would be proximity to a large teaching hospital, but that was unattainable at present. St. Peter's, which had engaged in postgraduate training of urological surgeons as long ago as 1860, and St. Paul's which had taken a share in this work since 1928, were fairly close together, and the Ministry had also given ward accommodation at St. Philip's. The Institute now had available 138 beds in three separate buildings within easy reach. This should make possible the fundamental researches on which the Institute must rely to attract young workers interested in the academic aspects of urology.

New Chairman of W.H.O. Executive Board.—Dr. HENRY VAN ZILE HYDE, chief of the Division of International Health of the United States Public Health Service, has been elected chairman of the World Health Organization executive board for the coming year. He succeeds Dr. Melville Mackenzie. Dr. Hyde was born in Syracuse, New York, in 1906, and studied medicine at Yale and Johns Hopkins. Before turning to public health he was for several years in private practice. During the last world war he served in the Middle East, and subsequently was in charge of six U.N.R.R.A. refugee camps in that region. In 1945 he was appointed assistant chief of the Health Branch of the U.S. Department of State, and since then has been engaged in various capacities in international health affairs.

Westminster Hospital.—The old students dinner of the Westminster Hospital and Medical School was held at Grosvenor House on May 28 with Mr. A. GOODWIN, F.R.C.S., in the chair. In proposing the health of the hospital and the medical school Mr. Goodwin referred to the great loss sustained by the hospital in the untimely death of Dr. J. L. Lovibond. In giving the toast "The Guests," Dr. G. GARMAN, in a refreshingly witty speech, illustrated how a psychiatrist should tackle this familiar theme. Sir JOHN CHARLES responded. Mr. A. C. H. BELL, F.R.C.S., proposing the health of the chairman, said that he would always be remembered with deep affection by his colleagues; Mr. Goodwin was a great teacher and a first-class surgeon, and they all regretted his approaching retirement from the hospital staff. In his reply Mr. GOODWIN entertained the company with his reminiscences as a big-game hunter.

Clinical Research Unit at Glasgow.—The Secretary of State for Scotland, Mr. JAMES STUART, opened a new building at the Western Infirmary, Glasgow, for the Medical Research Council's clinical chemotherapeutic research unit. He described the building, which cost £50,000 and was paid for by the Western Regional Hospital Board for Scotland, as the first specially designed research unit to be built in Scotland since the war. The clinical chemotherapeutic research unit was established in 1946, under its present director, Dr. James Reid, and has been concerned mainly with the development and investigation of drugs for the treatment of rheumatic disorders. Until recently the unit was housed at the Gairdner Institute of Medicine. Other speakers at the opening ceremony included Sir HAROLD HIMSWORTH, secretary of the Medical Research Council, Sir HECTOR HETHERINGTON, principal of Glasgow University, Sir ALEXANDER MACGREGOR, chairman of the Western Regional Hospital Board, and Dr. REID.

Scottish Research Committee.—The following new appointments have been made by the Secretary of State for Scotland to his Advisory Committee on Medical Research: Professor R. W. B. ELLIS, Department of Child Life and Health, University of Edinburgh; Professor R. J. KELLAR, Department of Obstetrics and Gynaecology, University of Edinburgh; Professor R. B. HUNTER, Department of Materia Medica, University of St. Andrews; Professor W. M. MILLAR, Department of Mental Health, Aberdeen University; Professor C. M. YONGE, F.R.S., Department of Zoology, University of Glasgow. The chairman of the committee is Sir EDWARD APPLETON, F.R.S. They advise the Secretary of State on the initiation, direction, co-ordination, and conduct of medical research.

District Nursing in London.—Sir ZACHARY COPE was elected chairman of the Central Council for District Nursing in London at the annual meeting at County Hall on May 27. There had been great changes, he said, in the nurse's position during the last 50 years—changes in training, accommodation, remuneration (5s. to 10s. a week was the salary in 1905), and status. The changes were still continuing. Possibly the work of the district nurse had changed less than that of other branches of the profession, because, while the hospital nurse was to a certain extent tending to become more administrative, the district nurse was still primarily engaged in the actual nursing of the sick. She was closer to the patient than any other class of nurse, and often had to be the adviser, confidante, and friend as well. She was the "general practitioner of the nursing world." It was very necessary, continued Sir Zachary, that there should be more integration of the nursing services of the country, so that patients leaving hospital could receive proper care and attention, while the use of hospital beds for some patients who could quite well be nursed at home would be saved. Too often after patients left hospital their condition deteriorated owing to lack of aftercare.

Conference of Prison Medical Officers.—The annual conference of prison medical officers and psychologists was held at the Home Office on May 28. Dr. H. K. SNELL, Director of Medical Services, Prison Commission, was in the chair. Dr. D. S. MACPHAIL and Dr. R. C. SIMPSON, visiting psychotherapists at Wormwood Scrubs Prison, spoke on "Psychotherapy in Prison and Advances made in Group Treatment." In the afternoon Dr. A. A. S. McDONALD, Medical Officer, H.M. Prison Parkhurst, and Dr. M. R. P. WILLIAMS, Medical Officer, H.M. Prisons Bristol and Leyhill, read papers on "Some Medical Aspects of Long-term Imprisonment." The papers were followed by discussions. On May 29 the psychologists held a separate session.

Treponematoses Award.—An international award to honour outstanding workers in the field of venereal diseases and non-venereal treponematoses is planned. It will be administered by the W.H.O. and will consist of a bronze medal and a scroll. Individuals and organizations are invited to contribute. Cheques should be made payable to "The International Treponematoses Award Fund," and sent to Dr. R. R. WILLCOX, St. Mary's Hospital, London, W.2.

Colyer Medal.—Last year the Faculty of Dental Surgery of the Royal College of Surgeons instituted a medal for outstanding work in dentistry, in honour of Sir FRANK COLYER. The first award of the medal will be made to Sir WILLIAM KELSEY FRY at the annual meeting of the Faculty on July 16, for his work on maxillo-facial surgery.

Naval Awards.—Surgeon Commander D. D. STEELE-PERKINS, R.N., has been appointed C.V.O. and Surgeon Lieutenant-Commander A. P. M. NICOL, R.N., has been appointed M.V.O. (5th Class). These medical officers held appointments in the *Briannia* and the *Gothic* during the recent royal tour.

Medical Golfing Society.—At the summer meeting on May 27 Dr. A. J. MAY won the Lancet Cup with a score of 73. Dr. LESLIE HARTLEY was the winner of the Henry Morris Cup, 4 up.

Professor L. J. Witts, of Oxford University, has been elected an honorary member of the Danish Society of Internal Medicine and of the Association of American Physicians.

Dr. J. Greenwood Wilson, medical officer of health of Cardiff, has been appointed chairman of the Royal Sanitary Institute's standing committee on the hygiene of food.

Dr. J. L. A. Groat, honorary lecturer in radiology at Sheffield University, is to receive the honorary degree of M.D. from the University on July 3.

COMING EVENTS

Commonwealth Tuberculosis Problems.—The N.A.P.T. will hold an open meeting on June 11 at 6.30 p.m. in the Old Library, B.M.A. House, London, when the following speakers will describe tuberculosis work in their countries: Dr. A. R. SOUTHWOOD, Director General of Public Health, South Australia; Mrs. A. SONI, medico-social worker, India; Dr. S. C. HAWES, of New Zealand. Details from N.A.P.T., Tavistock House North, Tavistock Square, London, W.C.1.

Stewart Lecture.—Professor G. R. CAMERON, F.R.S., will deliver the first Matthew Stewart Lecture at Leeds on June 17. His subject will be "The Exploration of the Cell." The lecture will take place in the Littlewood Hall of the General Infirmary at 4 p.m.

Bakerian Lecture.—Professor A. R. TODD, F.R.S., will deliver the Bakerian Lecture to the Royal Society on June 17 at 4.30 p.m. His subject is "Chemistry of the Nucleotides."

Cambridge Graduates Medical Club.—The annual general meeting of this club will be held at Emmanuel College on Friday, June 25, at 7 p.m., followed by a dinner at 7.30 p.m. at an inclusive price of 32s. Those intending to be present should send their names and the names of their guests, with a cheque, to Dr. T. B. ANDERSON, 1, Huntingdon Road, Cambridge, not later than June 10.

NEW ISSUES

Abstracts of World Medicine.—The June issue (Vol. 15, No. 4), which is now available, contains abstracts of important papers drawn from medical and other scientific journals published in some 20 different countries and in all five continents. The subjects covered range over the whole field of clinical medicine and therapy; there are also sections dealing with medical genetics, public health, industrial medicine, anaesthetics, radiology, and history of medicine. Issued monthly; annual subscription £4 4s., single copy 8s. 6d.; a specimen will be sent free on request.

SOCIETIES AND LECTURES

A fee is charged or a ticket is required for attending lectures marked ●. Application should be made first to the institution concerned.

Monday, June 7

EDINBURGH UNIVERSITY.—At Physiology Class Room, University New Buildings, 5 p.m., Dr. D. J. Guthrie: The School of Salerno: Systematic Teaching.

Tuesday, June 8

INSTITUTE OF DERMATOLOGY.—5.30 p.m., Dr. B. F. Russell: Pyococcal Infections.

● INSTITUTE OF NEUROLOGY.—5.30 p.m., Dr. Macdonald Critchley: Migraine and the Vascular Neurologies.

● INSTITUTE OF OBSTETRICS AND GYNAECOLOGY.—At Chelsea Hospital for Women, 3 p.m., Professor J. Louw (Capetown): Vesico-Vaginal Fistulae.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m., Ophthalmology Lecture by Professor A. Sorsby: Nature of Refractive Errors.

WRIGHT-FLEMING INSTITUTE OF MICROBIOLOGY.—5 p.m., Altmouth Wright: Lecture by Sir Edward Mellanby, F.R.S.: Some Actions of Vitamin A as a Controller of Structure and Function of Tissues.

Wednesday, June 9

INSTITUTE OF DERMATOLOGY.—5.30 p.m., Dr. Barbara M. Partridge: Infections due to Yeast-like Organisms.

● INSTITUTE OF OBSTETRICS AND GYNAECOLOGY.—At Hammersmith Hospital, 3 p.m., Professor J. Louw (Capetown): Indications for Caesarean Section.

OXFORD UNIVERSITY.—At Radcliffe Infirmary, 5 p.m., Litchfield Lecture by Professor A. D. Gardner: Bacteriological Episodes.

ST. MARY'S HOSPITAL MEDICAL SCHOOL.—At Wright-Fleming Theatre, 5 p.m., Dr. D. F. O'Neill: Lecture-demonstration in psychiatry.

UNIVERSITY COLLEGE, LONDON: DEPARTMENT OF PHARMACOLOGY.—At Physiology Theatre, Gower Street, 5 p.m., public lecture by Professor J. R.appenheimer (Harvard): A Theory for Renal Haemodynamics.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Vascular Effects of Pneumonectomy

Q.—Please may I be informed of the effects of pneumonectomy on the vascular tree of the remaining lung in a young person, say aged 20 years? What type of occupation should such a person follow in the future, and is a cardiovascular cause of death a likely possibility?

A.—This is a very pertinent question. No immediate ill effects of pneumonectomy are discernible on the vascular tree of the remaining lung of a young person, provided the lung is healthy. It has, for instance, been shown that the pulmonary artery pressure is unaltered; immediate compensation occurs.

Not enough time has yet elapsed for the very late results to be observed; the first successful pneumonectomies were done only 20 years ago. It is possible that no adverse changes occur if the remaining lung is not overdistended; if the mediastinum remains in the midline. Disability would be more likely to accompany progressive emphysema if this followed overdistension; this emphysema could be accompanied by secondary vascular degenerative changes leading to pulmonary hypertension and possibly secondary heart failure. This would be more likely if the remaining lung was not, initially, entirely healthy; if it had been damaged by non-tuberculous or tuberculous infection. The only direct evidence the writer has seen of the possibility of a late cardiovascular death was in the case of a man of 60 who was dying from right-sided heart failure and who had a lung agenesis. This was in some ways the equivalent of a pneumonectomy in infancy. The single lung was grossly overdistended and filling both sides of the chest.

A young adult, after pneumonectomy, should definitely avoid a strenuous occupation. Really hard physical work could be carried out for many years without obvious disability, but it would surely result in earlier onset of disability. The only wise thing is to select a sedentary occupation or one that does not involve regular physical work; in this way a long life free from disability is much more likely to be attained.

Masturbation in a Married Woman

Q.—A happily married woman of 24, mother of two children, has recently been greatly distressed by an uncontrollable desire to masturbate. The habit began in early childhood and has recently returned, and a deeply satisfying orgasm always results, though this never follows normal coitus. I should be most grateful for your assistance in helping this patient.

A.—This patient's condition is by no means ideal; but, in fact, it is not a very uncommon one, and, provided she understands the nature of her difficulty and conducts her marital life wisely, she need not fear any grave consequences. Most young children masturbate and many psychiatrists believe the activity to be part of normal development. Like this patient, many adult people fail, for varied and abstruse reasons, to reach a fully normal sexual development. When, therefore, orgasm cannot be attained in marital intercourse, it is not surprising that earlier outlets are sought. These situations are probably commoner in men than in women; they bring some difficulties in marital adjustment, just as do all other sexual inhibitions. Usually, perhaps, it is wisest not to tell the other partner, for the difficulty is not of his or her making. Since this woman is unable to get orgasm with her husband it is more normal for her to relieve the

Thursday, June 10

ALFRED ADLER MEDICAL SOCIETY.—At 11, Chandos Street, W., 8 p.m., Professor A. P. Cawadias: Psychological Factors in Graves's Disease. EDINBURGH UNIVERSITY.—At Physiology Class Room, University New Buildings, 5 p.m., Dr. D. J. Guthrie: William Harvey: The New Outlook.

INSTITUTE OF CHILD HEALTH.—5 p.m., Dr. Lawson Wilkins (Baltimore, U.S.A.): Endocrine and Non-endocrine Causes of Stunted Growth. INSTITUTE OF DERMATOLOGY.—5.30 p.m., Dr. J. O. Oliver: Pyogenic Cocci in Skin Disease.

● INSTITUTE OF NEUROLOGY.—5.30 p.m., Mr. Harvey Jackson: Traumatic Intracranial Haemorrhage.

● INSTITUTE OF OBSTETRICS AND GYNAECOLOGY.—At Queen Charlotte's Hospital, 12 noon, Professor J. Louw (Capetown): Surgical Emergencies in Pregnancy.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m., Hunterian Lecture by Professor H. S. Morton: Potentialities of the Electrogastrograph.

ST. ANDREWS UNIVERSITY.—At Physiology Department, Dundee, 5 p.m., Lord Boyd-Orr, F.R.S.: Widening Field of Medicine.

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL.—5 p.m., neurology demonstration by Dr. J. H. Paterson.

Friday, June 11

● INSTITUTE OF DERMATOLOGY.—5.30 p.m., clinical demonstration by Dr. A. D. Porter: Pyococcal Infections.

POSTGRADUATE MEDICAL SCHOOL OF LONDON.—2 p.m., Mr. J. K. Monro: Some Observations on Urinary Stone. 4 p.m., Professor A. Bradford Hill, F.R.S.: The Clinical Trial.

ROYAL SANITARY INSTITUTE.—At Pump Room, Bath, 10.15 a.m., Dr. B. A. Astley-Weston: Personal Standards of Hygiene; Mr. A. Tyler: Chemical Agents and Poisonous Metals in Food.

ST. MARY'S HOSPITAL MEDICAL SCHOOL.—At Wright-Fleming Theatre, 5 p.m., Professor W. C. W. Nixon: Inertia in Labour.

Saturday, June 12

INSTITUTE OF ORTHOPAEDICS.—At Brockley Hill, Stanmore, 10 a.m., Dr. F. H. Stevenson: Teaching ward round.

NORTH-EAST METROPOLITAN REGIONAL TUBERCULOSIS SOCIETY.—At North Middlesex Hospital, Edmonton, N., 10.30 a.m., Mr. M. Bates: Thoracic Actinomycosis; Dr. J. V. Davies: Incidence of Tuberculosis in School-children and Their Contacts. 2 p.m., demonstration of clinical cases. 3 p.m., business meeting.

APPOINTMENTS

CHARING CROSS HOSPITAL.—Josephine Barnes, D.M., F.R.C.S., F.R.C.O.G., M.R.C.P., Consultant Part-time Assistant Obstetrician and Gynaecologist. P. B. S. Fowler, D.M., M.R.C.P., Consultant Part-time Assistant Physician.

EDGAR, WILLIAM, M.B., Ch.B., D.P.H., D.C.H., Deputy Medical Officer of Health and Deputy School Medical Officer, Borough of Luton.

HOSPITAL FOR SICK CHILDREN, Great Ormond Street, London, W.C.—Rosemary W. Lawrence, M.B., Ch.B., House-surgeon to Orthopaedic and Plastic Departments; Lillian F. Jones, M.B., Ch.B., M.R.C.P., House-physician; F. J. Hedden, M.B., B.Ch., F.R.C.S.Ed., Part-time Senior Registrar to Orthopaedic Department.

MCARTHUR, CATHERINE B., M.B., B.S., D.P.H., Medical Officer of Health, Oswestry Borough and Rural District Councils, and Assistant County Medical Officer, Salop County Council.

MACARTHUR, PATRICK, M.D., F.R.F.P.S., D.C.H., Consultant Paediatrician, Northern Regional Hospital Board (Scotland), Raigmore Hospital, Inverness.

NABARRO, J. D. N., M.D., M.R.C.P., Assistant General Physician, Middlesex Hospital, London, W.

SEAL, ROGER MARTIN EWART, M.B., B.Ch., M.R.C.P., Consultant Pathologist to Cardiff Hospital Management Committee (Sully Hospital).

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Heller.—On May 18, 1954, at Robroyston Hospital, Glasgow, to Betty, wife of Lieutenant M. D. A. Heller, R.A.M.C., a son.

Martin.—On May 27, 1954, at Sedan House, Stanley Place, Chester, to Dr. Rosemary (formerly Bolam), wife of Dr. Geoffrey Martin, a son.

DEATHS

Dewar.—On May 1, 1954, at Saxilby, Lincs, Thomas Dewar, M.B., C.M., aged 82.

Dudding.—On April 25, 1954, Thomas Scarbrough Dudding, O.B.E., M.R.C.S., L.R.C.P., D.P.H., Colonel, late R.A.M.C., retired, of Greystone Holme, Lincoln, aged 75.

Elliott.—On April 28, 1954, at Oakburn, Toward Point, Dunoon, Argyll, William Marley Elliott, M.B., Ch.B., D.P.H., late of Glasgow.

Hendry.—On April 20, 1954, at Aberdeen Royal Infirmary, James Leith Hendry, M.C., L.R.C.P.S.Ed., aged 66.

Lister.—On April 18, 1954, at his home, Seaford, Sussex, Septimus Rayner Lister, M.D., late of Terrington St. Clement, Norfolk.

Logg.—On April 20, 1954, at St. John's Hospital, Lewisham, London, S.E., Matthew H. Logg, M.D.

Lowe.—On April 28, 1954, Frederick Boulton Lowe, M.R.C.S., L.R.C.P., M.R.C.V.S., of 23 Pearl Court, Eastbourne, Sussex.

McCart.—On April 19, 1954, at 2, Leigh Road, Havant, Hants, Frederick Buick McCart, M.C., M.B., F.R.C.S.

McEwen.—On April 20, 1954, at the Oval, Doncaster, John Dugald McEwen, M.B., F.R.C.S.Ed.

MacLachlan.—On April 16, 1954, at Tigh-na-Coille, Hunter's Quay, Argyll, Julia Crawford MacLachlan, M.B., Ch.B.

O'Donnell.—On April 27, 1954, at "Rostrevor," King's Avenue, Carshalton, Surrey, John David O'Donnell, M.B.E., F.R.C.S.Ed., late of Mysore Province, South India, aged 89.

Richmond.—On March 25, 1954, at his home, 5, Ruskin Terrace, Glasgow, Arthur Stanley Richmond, M.B., Ch.B., D.T.M.

Sturrock.—On April 27, 1954, at "Turlundie," Hillside Road, Radcliffe-on-Trent, Notts, George Sturrock, M.B., C.M., late of Woodborough Road, Nottingham, aged 87.

Thomas.—On April 24, 1954, Ellis Rae Thomas, M.D., of Kyrton House, Gillingham, Kent.

sexual tension herself than to live in continual frustration. It is important, however, for the medical attendant to make sure that a common source of confusion is not being overlooked—that is, that the woman is not just suffering from vaginal anaesthesia and would be able to get clitoral orgasm by digital stimulation, were this not, for some reason, being withheld. If such should be the case, her husband must be instructed how to provide this so that she can achieve orgasm either before coitus or after, whichever suits the couple best.

Sterility of Mucous Membranes at Birth

Q.—Are the mucous membranes of the nose and throat of a newborn baby sterile? If organisms are present, how did they establish themselves in a sterile amniotic cavity?

A.—The nasopharyngeal mucous membrane of the newborn baby is sterile if delivery occurs soon after the membranes are ruptured—that is to say, before the liquor has had time to become infected. If, on the other hand, delivery is delayed a considerable time and the liquor does become infected, then inevitably the mucous membranes of the nose and throat of the baby are contaminated with the organisms infecting the liquor.

These organisms are a mixed flora and vary considerably. The commonest to be recovered from the baby's throat are coliforms (including *Proteus*), diphtheroids, staphylococci, and streptococci (both anaerobic and aerobic).

Scarring from Boils

Q.—What can be done to improve the appearance of the back of a neck badly disfigured by pitting and scarring due to chronic furunculosis? The condition is now inactive, although the patient received a single course of superficial x rays for it about six months ago.

A.—This is one of the most difficult conditions to treat. In the chronic stage, when it is often due to acne as well as to hair follicle infection—and as a rule evidence of infected hair follicles can be seen throughout the scarred surface—epilation by tweezer is a satisfactory method of keeping the infection down and allowing healing to become complete. Only after healing is complete should any surgical means be adopted, and even then it is only too often true that in many cases the scarring must be accepted. In particularly bad cases excision of the entire area and free grafting is the only alternative, but it should be a last resort, for the graft is certain to make a prominent white patch on the back of the neck.

Treatment of Leukoplakia of the Tongue

Q.—I have a case of leukoplakia of the tongue which has been present for the past nine months. It started as quite a small area and is now almost the size of a halfpenny. It is quite superficial, and the Wassermann reaction and Kahn test are negative. I have given the patient large doses of vitamin A, and bland mouth-washes. In my student days the recommended treatment was excision. Will you please tell me the latest views on this condition and its treatment?

A.—There has not been much change in our views on the treatment of leukoplakia of the tongue. Some surgeons have always been inclined to more radical measures than others. It is certain, however, that many cases of leukoplakia persist for years without showing any tendency to malignant change. In the present case, with a negative Wassermann reaction, the correct attitude is probably an expectant one.

All sources of irritation, such as irritant foods, dental sepsis, smoking, etc., should be eliminated, and a regular and careful watch kept for the appearance of papilliferous overgrowth, fissuring, or ulceration. At the first recognition of any of these a local excision should be done, preferably by diathermic cutting. It is best not to use any local application—for example, chromic or silver salts—but the normal mild antiseptic hygiene of the mouth and teeth should be continued. The presence of dissimilar metals

in dentures and fillings which might set up an electrolytic couple should be looked for and corrected if necessary. Incidentally, lichen planus of the tongue, although rare, may closely resemble leukoplakia and must be excluded. It is usually of a lavender hue and there may be similar lesions on the skin.

Drowsiness in an Old Man

Q.—What is the likely cause of drowsiness amounting to narcolepsy in an old man, with some prostate obstruction (but no elevation of the blood urea), auricular fibrillation, and early evidence of heart failure? He can fall asleep while eating a meal or standing up. There is no sugar or albumin in the urine. Can any treatment be recommended? Methylamphetamine hydrochloride and amphetamine have had little influence.

A.—The presence of a normal blood urea and the absence of albumin in the urine do not, of course, exclude the possibility of renal failure being the cause of the drowsiness. However, the type of drowsiness is unlike that of renal failure in that it occurs when the patient is standing or eating a meal, as well as, presumably, at other times. This, as the questioner points out, is like true narcolepsy. It seems most likely that the drowsiness is due to a combination of cerebral arteriopathy and probably heart failure leading to a local ischaemia in the hypothalamic region, and thus to the symptoms of narcolepsy. In such a case methylamphetamine hydrochloride and amphetamine are unlikely to have much influence unless given in large doses, and treatment of the co-existing cardiac failure and anaemia, if any exists, is probably the most important factor in producing relief of the drowsiness. However, no great benefit from treatment can be expected in this case.

Plasma Potassium Estimation

Q.—What is the simplest reliable method of estimating the plasma potassium?

A.—Flame photometry is the simplest and most reliable method of estimating the plasma potassium, given a flame photometer and an experienced operator. In the absence of such facilities, the best method is cobaltinitrite precipitation, which is described in detail by King (*Micro-analysis in Medical Biochemistry*, Churchill, 1946). Samples of blood must be unhaemolysed, as the cells contain twenty times as much potassium as the plasma and contamination by cell content would lead to gross error; for the same reason, separation of plasma and cells should be done as soon as possible after withdrawing blood. It is also important to remember that the plasma potassium level may be misleading as an index of the state of potassium balance—for example, in diabetic coma the plasma potassium level may be high or normal until dehydration is corrected, although there is potassium depletion.

Correction.—In Table II in the paper on "Arsenamide Treatment of Filariasis due to *W. bancrofti* and *A. perstans*" by Drs. J. A. McFadzean and F. Hawking (April 24, p. 956) the weights of patients 19 and 23 ought to have been 51 kg. and not 31 kg. as printed.

ENGINEERING AND INDUSTRIAL HYGIENE*

BY

PHILIP DRINKER, Sc.D., LL.D.

Professor of Industrial Hygiene, Harvard School of Public Health; Senior Fulbright Fellow, Queen's University, Belfast

Industrial Disabilities and Compensation Insurance

Of the disabilities falling within the jurisdiction of our various State Compensation Boards in the United States roughly 97% are accidents; about 3% are chronic diseases like benzol poisoning or silicosis. Of these 3% about two-thirds are dermatoses. In cost of time lost and of medical care the occupational diseases rank high, and actually may assume the spotlight of attention.

Our compensation awards are covered by insurance placed by the employers through insurance companies or through State insurance. In Ohio, for example, compensation insurance is a State monopoly, while in New York an employer can insure either with a private company or with the State. If the employer posts a bond for an amount approved by the State he can be self-insured. The premiums paid are revised periodically according to the experience or record. When the experience is very bad the premium charges may be so high that the employing company cannot afford to insure, or the insurance company can simply refuse to accept the risk. In such an event the Insurance Commissioner of the State can pro-rate the policy among companies doing business in the State, and the companies then become the reluctant recipients of the business.

The result of this method of compensation insurance is that the companies writing the policies have developed first-class inspection schemes, with excellent staffs of industrially minded physicians, engineers, industrial hygienists, and chemists, and it is to the interest of insured and insurer to cut lost time to the minimum. In the policies freedom of entry and inspection is given to the insurance companies. Their men visit the insured companies and give them valuable consulting service.

The insurance companies' inspection scheme reminds one very much of your British Government inspectorate. Yours is more than a century old while ours is very young. But your Governmental inspectors, operating from your Ministry of Labour in London and distributed all over industrial Britain, have no opposite number in our Federal Government set-up. The industrial hygiene laboratories of the Public Health Service are available to industry for consultation and research. Their surveys of various industries have often set the

health standards under which the industry operates. The laboratories of the Bureau of Mines and the Bureau of Standards likewise function for the service of industry (employer and employee alike). None of these three Federal Bureaus is in any sense administrative, and they have not the right of entry or inspection. That last function is vested legally in the States, every one of which zealously guards its "States' rights" as granted under our constitution.

Your statistics of industrial illness are consistently better than ours. In fact, they are so much better that I use them as a guide in estimating our American industrial illnesses—a somewhat humbling admission. But our accident figures I think are as good as or perhaps better than yours.

Development of Industrial Hygiene in U.S.A.

In 1906 New York State provided for the appointment of a physician to be known as a medical inspector of factories. The staff was gradually increased, and in 1913 included a mechanical engineer and a chemist in addition to the physician. In 1924 the Division of Industrial Hygiene of New York was made an independent body as the "Bureau of Industrial Hygiene," and started publishing its *Industrial Hygiene Bulletin*. In 1936 Leonard Greenburg, a physician who started out as a sanitary engineer, became executive director of the Division. The various bulletins, codes, and rules formulated by New York have set the pattern for such things throughout all the States of the Union.

One of our oldest governmental departments is the Public Health Service. In 1914, within its Division of Scientific Research, there was created an office of Industrial Hygiene and Sanitation Investigations. This same year A. J. Lanza and others from the Bureau of Mines and the Public Health Service began their study of the silicosis problem in our tri-state district (Oklahoma, Kansas, and Missouri). From 1920 to 1930 the Office of Industrial Hygiene was under the direction of L. R. Thompson, a physician of great experience in the general field of public health. He initiated the Service's series of surveys of the dusty trades, which were continued and expanded by his successors. In 1937 the organization became the Division of Industrial Hygiene under the very able leadership of R. R. Sayers, who had been for some years surgeon for the Bureau of Mines. Sayers had taught electro-chemistry and physical chemistry at Buffalo, where he took his medical degree in 1914.

The Bureau of Mines was established in 1910 within the Department of the Interior. About 1917 during the first world war the Experiment Station at Pittsburgh was under the charge of a chemist, A. C. Fieldner. One of the

*Taken from papers presented at the London School of Hygiene and Tropical Medicine on April 20, 1953, and at the Annual Provincial Meeting of the Association of Industrial Medical Officers, Newcastle-upon-Tyne, on July 4, 1953.

Bureau's duties was the supervision of safety in mines, so it was natural that these should include the testing of safety equipment and the appraisal of masks for protection against gases. Its special knowledge was used by the Chemical Warfare Service, and after the first world war the Bureau began issuing its specifications for protective equipment of all kinds. Industry accepted these specifications with alacrity, and industrial hygiene benefited.

The *Journal of Industrial Hygiene* appeared in 1919. The chief editors were physicians—David L. Edsall for the United States, and Thomas M. Legge (later Sir Thomas) for Britain. My brother, Cecil K. Drinker, a physician and physiologist, and his wife, Dr. Katherine R. Drinker, carried the real responsibility, and the prompt success of this journal was due to them on our side of the ocean, and to Professor Edgar L. Collis in England. Early contributors included a few men in general public health, like Professor C. E. A. Winslow, and, occasionally, chemists like Fieldner, Katz, and Yant, of the Bureau of Mines, but the general tone of the papers was medical. Dr. Alice Hamilton and Dr. C. K. Drinker, of Harvard School of Public Health, suggested that the journal's field should be expanded to include some engineering. I became managing editor, and we asked Yant to join the journal's editorial staff. From then on we took papers directed more towards industrial hygiene and industrial medicine and less towards industrial surgery.

In 1935 a group of industrialists, physicians, and industrial hygienists, with the Mellon Institute for Industrial Research, formed the Air Hygiene Foundation, later changed to the Industrial Hygiene Foundation as its scope and interests expanded. In 1938 the American Conference of Governmental Industrial Hygienists (A.C.G.I.H.), with J. J. Bloomfield, of the U.S. Public Health Service, as co-ordinating figure, formed a group which included all those in Federal and State industrial hygiene bureaus. In 1939 the American Industrial Hygiene Association was formed. From then on these last two societies have met annually with the much larger and older society, the Industrial Physicians and Surgeons. The combined programmes run over a period of about eight days and are usually held around mid-April. For a time the American Public Health Association had an active section devoted to industrial hygiene, but interest lapsed. Now it is again becoming an active unit. It meets in the autumn, as does the Industrial Hygiene Foundation.

The National Safety Council, with headquarters in Chicago, is supported by industry and concerns itself with accidents of all kinds, but especially with those of industry. Traffic accidents are a major problem in the United States. Many of our industrial physicians, our engineers, and our industrial hygienists are active in the field of accident prevention.

Establishing Standards of Industrial Hygiene

The word "hygiene" implies control of one's well-being, while "health" defines one's status at the moment. We are in good or bad health. The Surgeon General reports upon the health of the nation. The medical director of an industry reports upon the health of workers (and he may even include their families). These reports are based upon the results of medical practice.

Industrial hygiene is concerned primarily with prevention. It is the duty of the industrial hygienist to determine the causes of, and to prevent, industrial illnesses, not to diagnose and treat them. He reports upon the extent of the hazard, if any exists, and its control. The industrial hygienist may be able to define the aetiology of industrial illnesses better than the medical practitioner. If this state of affairs results in a little duplication, or confusion even, it does no harm. Clearly, the person held responsible for prevention must ferret out the cause if he is to see his preventive measures put into force.

The industrial hygienist's most convenient criterion of working conditions is the nearness with which the worker's environment approaches the ideal. We measure the quality

of the environment by our arbitrary specifications. In the United States these specifications are set up by different committees chosen from the qualified personnel of the nation.

About 1940 the American Standards Association, at the instigation of the late Steven R. Whiting, of Liberty Mutual Insurance Company, formed a committee to formulate "allowable concentrations" of such impurities as carbon monoxide, lead dust, and various solvent vapours. The series of approved reports began to appear in 1941. A few years later the governmental industrial hygienists started their less formal but more realistic series, "threshold limit values," which now are revised and published annually. As a practical guide to control of conditions they are most valuable, and are used all over the world. For some years the American Society of Mechanical Engineers has had specifications covering permissible stack emissions from power plants. The City of Los Angeles, troubled by a vexing smog problem, passed legislation covering emissions from chimneys: a reasonable minimum degree of cleanliness is required of all, while large plants are rated in terms both of the quantity of material charged into the process and of that emitted. In London, the large power plants like that at Battersea are required to control the emission of smoke and to scrub out sulphur dioxide gas from the stack gases, so that less than 35 p.p.m. escapes a specification many times more severe than ours.

To-day we have specifications governing the purity of water, milk, food, and various drugs. These have the force of law behind them. Why should we not have the same degree of hygienic protection from air-borne contaminants and from unfavourable working conditions? One often meets with a timid reluctance on the part of some of our colleagues to set limits for pollution. I have no sympathy with such timidity. If you are practising industrial hygiene and refuse to state what conditions should be attained, you are simply evading your issues. If you ask your doctor what régime you should follow and he won't tell you, the chances are that you'll get another doctor. I am fully aware of our great lack of data in establishing, and of the many practical difficulties in attaining, satisfactory standards of air cleanliness, but I insist that standards must be sought if we are to make intelligent progress in this field.

Our opinions vary on the precise figures or limits we use, but most of us now adopt these limits in our routine work. Yet we recognize the limitations of these quantitative figures. I think we should supplement our appraisal of working conditions by personal observation and by every illustrative means at our disposal. The concept of dosage—time $\times$ concentration—in all of this work is now generally accepted. In our Atomic Energy Commission plants the environment of the workers, their clothing, and even their persons are inspected and checked thoroughly and carefully, usually one or more times daily. The result has been virtual freedom from the common industrial poisons as well as from the special radiation hazards for which these extra precautions were designed.

In industry the difficult problem is the instilling of a sensible routine to prevent chronic and cumulative occupational disease. Respect for acute poisons like carbon monoxide is much easier to teach and to achieve than respect for repeated—and often not unpleasant—exposure to substances such as benzol vapour. Too often men know of fellow-workers who have seemingly been unaffected by the very conditions we say should be drastically improved. Once management, and then labour, are convinced that something must be done and the new régime instituted, the bad condition can be corrected. But unfortunately an adverse decision in a lawsuit for a compensation case is often the spur to bringing about desired improvements. This is a little like saying that you must be hurt once in an accident in order to avoid future accidents, a concept that is repugnant to the intelligent individual.

It is very rarely necessary to eliminate completely the poison in question, because man's tolerance is such that he

can usually stand a trifling amount of poison, a condition we can generally attain in industry at a reasonable operating cost. If safe conditions cannot be brought about by a change that industry can pay for, then there is usually nothing to be done except to abandon the process entirely.

Some American Standards

We, as engineers, may set up conditions that we deem safe until so proved by the medical records of health in

Threshold Limit Values for 1953. Adopted at the Meeting of the American Conference of Governmental Industrial Hygienists in Los Angeles in April, 1953

Gases and Vapours		Mineral Dusts

the industry in question. The figures from the A.C.G.I.H. Committee (see Table) are the result of the annual canvassing, by the committee, of persons known to be working with these various substances or to have had experience in their use in industry. Many of them are "guesstimates" and are not based upon data scientifically arrived at. They represent what the committee regards as concentrations safe for eight-hour exposures. The persons exposed are presumed to be normal healthy individuals. The limits for gases are given in parts per million by volume, those for toxic dusts are given in milligrams per cubic metre, mineral dusts are measured in millions of particles per cubic foot, and radiations are appraised in the conventional units of roentgens per week. Of these the last are much the newest, and are certain to be revised almost yearly.

These figures should be thought of as the lowest limits in zones and not as precise values. They are no more precise than is the toxicological evaluation of various doses of inhalation, as of quartz dust or benzol vapour or carbon monoxide gas. It probably would be more scientific to give them as definite figures $\pm$ some number, thus showing the unimportance of slight variations.

It has been said to me often by colleagues, especially by Britons, that this idea of toxic limits is needless, and that better results can be had by watching the health of workers, as by blood or urine examinations. Consider for a moment what Sir Thomas Legge, Chief Medical Inspector of Factories, wrote in his memoirs in 1934: "If you can bring an influence to bear external to the workman (that is, one over which he can exercise no control) you will be successful; if you cannot or do not, you never will be wholly successful. Practically all industrial lead poisoning is due to the inhalation of dust and fumes; and if you stop their inhalation you will stop the poisoning."

Dr. Alice Hamilton has always supported this plea for prevention rather than cure. It is easier to prevent or control occupational illness (and even accidents) than it is to define the cause accurately.

Control of Noise

Considerable pressure is being brought on us in the U.S.A. to reduce noise in industry, or at least to isolate noisy jobs so that the number of persons exposed to excessive noise is kept to the minimum. Standards of noise levels concerning both frequency and volume are in the making, and are likely to be included in our standards in the reasonably near future. The trend is towards limits or noise levels which permit ordinary conversation.

This is a fruitful field for some good engineering. It is a nice challenge to ingenuity to devise ways of getting around the noise of a rivet hammer, a drop forge, a rock drill, or a spinning-frame or a loom in a textile mill. We wish we knew more about the expected or usual loss of hearing with advancing years in the life of the average worker. Perhaps physicians will supply the data needed.

Considering the speed with which these movements cross the Atlantic we wonder why you in Britain are not more concerned with the noise problem. A damage suit for

Although long survival in apparent good health is not uncommon in spite of an impaired upper urinary tract, it is incontestable that the development of dilatation and infection and their aggravation when such existed before operation are fundamental factors influencing morbidity and mortality. To what extent, then, is well-being affected by electrolyte changes? The B.A.U.S. survey showed that almost 50% of patients were in electrolyte imbalance at some stage in their post-operative career, and it is now

unquestionable that selective absorption from the bowel can result in hyperchloraemic acidosis and other chemical disturbances.* The capacity to deal with this seems, however, to be closely related to renal function. The analysis of the B.A.U.S. series and of my own revealed that 75% of those whose blood chemistry findings indicated hyperchloraemic acidosis had an elevated blood urea as well as objective evidence of renal impairment on excretion urography. It also showed that only 20% of that number exhibited symptoms of chemical imbalance and that almost without exception chemical imbalance with symptoms was associated with a raised blood urea and dilatation of the upper urinary tract.

I have recounted the mode of death which rapidly ensued after six years of well-being when there was no evidence of hyperchloraemic acidosis or even of acidosis, and for which a sudden overwhelming renal infection seems to have been responsible. Recently another patient died, 11 years and 6 months after transplantation for vesico-vaginal fistula. The Coffey technique had been used and there was no renal or ureteral dilatation at the time of operation. Just over a year before death biochemical examination had shown an elevated plasma chloride with a lowered alkali reserve (Table III). There was then well-marked dilatation in the

TABLE III.—Blood Biochemistry after Transplantation of Ureters in May, 1951

	June, 1951	Nov. 19, 1952	Nov. 26, 1952
Blood urea	28 mg./100 ml.	198 mg./100 ml.	196 mg./100 ml.
CO ₂ combining power	48.1 ml. CO ₂ /100 ml.	35 ml. CO ₂ /100 ml.	21 ml. CO ₂ /100 ml.
Plasma chlorides	109.4 mEq/litre	103 mEq/litre	117 mEq/litre
Plasma sodium	142		
Serum potassium	5.5		3.1

upper urinary tract, but the blood urea was only 28 mg. per 100 ml. She was working as an assistant hotel cook and her only complaint was that she had become very stout. In December, 1952, she was admitted to another hospital in a semicomatose condition, having been unwell for the previous 10 days, suffering from mild rigors and pain in both renal areas. Her blood urea was 198 mg. per 100 ml., but plasma chlorides were actually lower than a year previously. Acidosis was confirmed, the alkali reserve having further fallen. She failed to respond to alkaline therapy and died nine days after admission. Four days before death she exhibited definite hyperchloraemic acidosis though the urine output had risen from 7 to over 70 oz. (200 to over 2,000 ml.) a day. Post-mortem examination showed bilateral renal dilatation, moderate on the right, marked on the left, the kidney on that side having only a strip of functioning tissue, and the left uretero-colic anastomosis stenosed though patent. The histological picture was of advanced pyelonephritis.

The severe electrolyte imbalance which finally developed in the above instance was associated with gross renal damage and uraemia. I can find no evidence of any patient in my series whose death could be attributed solely to chemical imbalance. Indeed, I have had but few incidents in the past three years—during which I have been on a constant lookout for them—of serious disturbances arising from this cause, and such as have been encountered without marked renal damage have been readily corrected by appropriate infusion therapy, alkalis, and an in-dwelling rectal tube. Less severe symptoms, such as anorexia, thirst, salty taste, and polydipsia, are generally improved by regular evacuation of urine, salt limitation, and alkalis. I therefore deprecate transplanting the ureters into a segregated loop of bowel as a precaution against the onset of electrolyte disturbances. This measure will not eliminate the possibility of subsequent renal damage due to faulty union between ureter and bowel, and the wet enterostomy

*The reader is referred to the important contributions on the subject of chemical imbalance after uretero-colic anastomosis, published in the *British Journal of Urology*, 1952, 24, pp. 302, 307, 313, 317.

or colostomy which the procedure necessitates is a negation of one of the main objectives of ureteral transplantation—namely, to restore the patient to a normal-like way of life. It is as well to dispense with the uretero-colic anastomosis and divert the urine by ureterostomy.

Summary and Conclusions

The results of carrying out uretero-colic anastomosis on 162 patients are analysed.

It is evident that, provided the lesion for which urinary diversion is performed is not one which itself predisposes to ill-health and eventual mortality, transplantation of the ureters to the bowel can be followed by well-being and expectation of a long life. This in great measure is influenced by the renal status, which in turn is largely dependent on the success of the actual anastomosis. The union between ureter and bowel must therefore be accomplished with as high a degree of technical perfection as possible.

PSYCHOPATHIC STATES AND ATTEMPTED SUICIDE

BY

I. R. C. BATCHELOR, M.B., F.R.C.P.Ed., D.P.M.
Deputy Physician Superintendent, Royal Edinburgh
Hospital for Mental and Nervous Disorders; Lecturer
in Psychiatry, University of Edinburgh

Suicidal attempts are medical emergencies which the general practitioner and the hospital surgeon and physician alike have to meet, since in many instances it is found necessary to remove the suicidal individual from his home to hospital for resuscitation or repair. When his physical treatment has been completed it often happens that he appears remarkably normal: if, as he may do, he then insists on his discharge from hospital, grounds for detaining him longer may not be found. There is evidently a type of suicidal attempt, dangerous enough to need medical intervention, of which the more obviously morbid mental accompaniments are transient. In some centres these cases are not referred to psychiatrists and pass quickly from observation; this apparently is one of the reasons why a relatively common phenomenon has been so little investigated. Experience over some years in a general hospital where all cases of attempted suicide are examined by a psychiatrist has shown that the large majority of these "birds of passage" are suffering from psychopathic states.

Henderson (1939), focusing attention on the suicidal proclivities of psychopathic individuals, gave a description of the situation which is admirable in its emphasis on the peculiar clinical features and the social implications. His lead has, however, not been followed; and it is thought that a detailed survey of a group of such cases might now promote their more general recognition and stimulate further research, particularly into their aetiology.

There are few papers in the literature which indicate the proportion of cases of attempted suicide which may be attributed to psychopathic states. Dahlgren (1945), in a follow-up study of 237 cases of attempted suicide, gave 12.2% (26 men, 3 women) the diagnosis of psychopathia; but his clinical material was unsatisfactory, being

so heterogeneous as to include morons and apparently also cases possibly based on cerebral trauma or infection. Stengel (1952) reported an incidence of 13.6% (15 men, 6 women) in a series of 138 cases similarly investigated by follow-up, and commented that his group was not representative of the suicidal attempts made in the general population. It is probable that the percentages quoted are too low.

General Characteristics of the Cases

In a series of 200 consecutive cases of attempted suicide admitted to a general hospital in the years 1950-2 and personally observed, 50 (25%) were given initially the diagnosis of psychopathic state. Further investigation has shown that in eight of these cases the diagnosis was perhaps disputable: three were difficult to assess, being foreigners, while in the other five the degree of instability revealed might be held to be insufficient to justify the diagnosis and to merit rather a label of hysterical or schizoid personality. In 42 cases, therefore, the specificity was not in doubt, and these have been investigated in detail.

The sex, age, and marital state of these 42 individuals are detailed in Table I.

TABLE I

Age Group	Male	Female	Total	Marital State	Male	Female	Total
0-19 years	1		1	Single	8	4	12
20-29 "	7	7	14	Married	12	7	19
30-39 "	5	5	10	Widow(er)		2	2
40-49 "	7	4	11	Separated	4	3	7
50 "	5	1	6	Divorced	1	1	2
Total	25	17	42	Total	25	17	42

Family Histories

In 28 (66.7%) of the cases there was a family history of psychiatric abnormalities, which were manifested in 78 of their relatives, 42 of these relatives being alcoholics. Six (14.3%) of the cases gave a family history of suicide, six of their relatives having attempted suicide, two successfully. Two cases had a family history of homicide. In 15 (35.7%) cases a history of mental illness, and in 16 (38.1%) cases a history of alcoholism (in six cases of both) was obtained in first degree relatives. There is apparently a significant relationship between psychopathic states and a family history of alcoholism.

"Broken Homes."—In 31 (73.8%) cases the patients had, in their first 16 years, been deprived of a normal life with their parents. Some of the details are given in Table II.

TABLE II

	Male	Female	Total
Broken home	17	14	31
Illegitimate	2	2	4
Permanent loss of father	6	8	14
" " mother	4	5	9
" " both parents	1	3	4
Alcoholism of father	8	4	12
" " mother	4	4	8
" " both parents	—	4	4

One man and six women had lost their fathers in the first five years of their lives, and one man and two women their mothers. Figures can, of course, indicate only very crudely some items in these childhood situations. They are, however, sufficiently striking: parental alcoholism occurred in 38.1% of the cases, loss of the father in 33.3%, loss of the mother in 21.4%.

The importance of a broken home in the genesis of the suicidal acts of this group seems undoubted, but we have only the roughest clues as yet about how this factor operates. We do not know whether an absence or distortion of parental influences is the more traumatic, nor which parent may be the more essential; nor do we know the ages

at which the greatest harm may be done. The broad implications of these findings have been discussed elsewhere (Batchelor and Napier, 1953a).

Previous Personal Characteristics

This suicidal group was typical of the psychopathic states as a whole. The majority were aggressive, the minority passive and inadequate. Reactions primarily of aggression were usual in the former, reactions primarily of evasion in the latter, but these correspondences were not absolute. All had shown persistent maladjustment, starting in childhood or adolescence, and all were complained of as unpredictable and totally unreliable in word and deed. One-third had previously received psychiatric treatment.

Impulsiveness is highly characteristic of the psychopath who attempts suicide. With equal haste, on the spur of the moment and without heed to the future, he may accept or reject serious social obligations and the most intimate personal ties, leave his home, throw up a profitable job, or act with physical violence. Explosive outbursts of temper, threats, and assault were very commonly reported. Many were described as bullying, vindictive, jealous, cantankerous, trouble-making. Many had been actively cruel to their spouses or to their children.

In this group one often encountered individuals who were egotistical, cold, friendless. Many were morbidly touchy or secretive, with sensitive ideas of reference. Several realized that, unable to tolerate constraint of any kind, they were more content and safer when left alone. A few had had paranoid episodes. Mood swings were common, and some gave a history of neurotic symptoms when under stress.

Exhibitionistic and narcissistic traits were also commonly seen, expressed in endless demands for attention, flamboyant dress or hair styles, fantastic lying, masquerading, tattooing. One woman had burnt on her arm with cigarettes the initials of her lovers. An exaggerated narcissism was in some cases associated with defective personal hygiene.

The majority were maladjusted sexually. Five men and 10 women were heterosexually promiscuous. Eight men and one woman showed homosexual trends, at least one-third of these being practising homosexuals. Five women had had illegitimate children.

Fourteen men and six women gave a history of alcoholism. Five men were drug addicts. Nine men and 10 women had made a total of 29 previous suicidal attempts.

The psychopath is typically a restless Ishmael. Almost half the cases had been truants in earlier years: some individuals still had recurrent overpowering urges to go off alone. Usually there was a history of numerous futile changes of occupation or of long periods of unemployment. In only six cases (one man, five women) was the work record satisfactory.

Religion played very little part in these people's lives. The majority expressed a belief in a personal God, but less than half believed in some sort of immortality or after-life. Three-quarters of the group admitted that they knew attempted suicide was an offence against the law: many had previously been charged on account of suicidal attempts. No evidence was found, however, to show that legal sanctions had acted as a deterrent: the suicidal individual gave no thought to the matter at the time of his act, or did not care, or expected to be dead.

Thirteen men had police records. The commonest offences were theft, housebreaking, assault, and drunkenness with disorderly behaviour; there were also convictions for sexual offences, fraud, begging, truancy, and arson. Two women had police records, convicted of theft and drunkenness. Other individuals were known to the police, or had committed petty thefts which had not been reported. At least five of the men were chronic gamblers.

The social incompetence of the group is further illustrated by their low social status and living conditions, their unemployment, poverty, and isolation, details of which are given below.

Social Data

Table III gives an analysis of the social conditions of the group. Ten individuals suffered from overcrowding, and six others lacked privacy in their living conditions.

Social Circulation and Mobility.—Of the group, 35 were born in Scotland; of these, 17 were born in Edinburgh. Nine were rural bred. A fall in social status had occurred in 19 (45.2%) cases—a circumstance which could easily be correlated with their personality defects. In the past 12 months 14 had changed the localities they lived in (some had made numerous changes); in six cases these moves were local.

Group Membership (including Religious Affiliations).—Among the 42 individuals were 28 Protestants, 10 Roman Catholics, a Salvationist, a Jehovah's Witness, a pantheist, and an atheist. Eight of the Catholics had lapsed. Only three individuals were even irregularly church-going. Four men were loosely affiliated to one of the following organized non-religious groups: Freemasons, Buffaloes, Alcoholics Anonymous, and a camera club. Two women were affiliated to groups, but again only barely so: one was a lapsing member of Alcoholics Anonymous, and another a quarrelsome performer in an amateur theatrical company.

Physical State

The physical state of 17 (68%) of the men was satisfactory. The following were the diagnoses of the eight who were ill: arteriosclerosis (2), osteomyelitis of spine, carcinoma of colon, peptic ulcer, mild bronchitis, disabling inguinal hernia, gonorrhoea. Those complaining of fatigue were physically ill.

The physical state of eight (47.1%) of the women was satisfactory. Three were physically ill, suffering from occupational dermatitis of hands and face, tabes dorsalis, gonorrhoea. Six others were suffering from debility or marked fatigue. In only two cases was the suicidal attempt closely related in time to menstruation.

Setting of the Suicidal Attempts

Nearly one-third of the cases reported no nervous symptoms in the period shortly before their suicidal attempts. The remainder complained of one or more of the following: increased irritability, tension, restlessness, fatigue, anxiety, depression, insomnia; or had somatic symptoms such as headache or head pains, flatulence, and "fibrositis." Some had an access of ideas of reference and believed that everyone and everything were against them. It is rather striking that 15 (60%) of the men and 8 (47.1%) of the women

were not under the care of their own doctors at the time of their suicidal attempts. Only one individual was receiving psychiatric treatment.

In 23 (54.8%) cases the individual gave no warning, either immediate or remote, of his suicidal intentions. Six men and six women had lately made suicidal threats: Four of these and two other men and one other woman had made many suicidal threats in recent years. The husband of one woman said, "She threatens suicide whenever she runs out of cigarettes"; of another it was said, "I couldn't tell you of all the times she has threatened to take her life."

Three men preface their self-injury by assaults on their wives. In two of these cases the assault was accompanied by threats of murder, and in the third case a police charge was brought. A fourth man had recently threatened to murder his wife. Five other men had histories of serious assaultive behaviour at home. One woman attempted to gas the man with whom she was living and then herself. Another woman attempted to strangle her homosexual partner. A third woman assaulted her stepdaughter. These facts make obvious the close relationship of homicidal to suicidal trends in this group.

The Suicidal Attempts

How Long Contemplated?—Table IV shows that 26 (61.9%) of these suicidal attempts were impulsive. The majority of those who had been contemplating the act for

TABLE IV

longer said that their suicidal thoughts had been intermittent. One man claimed that he had been brooding over his act for two years. Nearly identical statements about their attempts were made by many of the group: "I took them on the spur of the moment"; "I didn't think at all." It is interesting that some described their acts in the same phrases as an epileptic might use to recount his fit: "It came on us all of a sudden"; "It just came over me."

Immediate Stimulus.—The specificity of the precipitants in this series is impressive: in 85.7% the immediate stimulus was either a personal quarrel or imminent retribution, the former about twice as commonly as the latter (Table V).

TABLE V

Not known	2	—	2

The quarrel in the cases of four men and two women was over a jilting. In two cases the unexpected loss of a job and in two others the refusal of expected financial assistance contributed materially to a state of irritable discontent.

Drunk or Sober.—Eleven men and one woman were under the influence of alcohol at the time of their suicidal attempts. Enough had been taken to diminish their self-control, but not enough to render them amnesic.

Timing and Situation.—Half of the attempts (male 12, female 9) took place between 7 p.m. and midnight—at a time, that is, when the factors of fatigue and intoxication were most often operative, and the individual was apt to return home quarrelsome to a critical reception. April,

May, and June were the most favoured months. Twenty-seven of the attempts were made in the individual's own bedroom, kitchen, or living-room. Other sites selected were: (a) in own house—lavatory (2), bathroom (1); and (b) elsewhere—in the street (3), police cell (2), acquaintance's house, train, railway station, cinema, public park, hill-top, and house under construction.

Method.—Poisoning, a passive method, was chosen by 38 (90.5%) (Table VI). "Other poisons" employed were methylated spirits, digitalis, bromide and chloral mixture, "izal," potassium cyanide, tincture of opium (the last two combined).

Aspirin	4	1	5
Coal gas	4	1	5
Other	3	2	5
Cutting	3	—	3
Hanging	1	—	1

Reasons for Choice of Method.—In the majority of psychopathic cases availability appears to be the paramount factor determining choice of method. Barbiturates can now be found in a great many homes, coal gas is usually on tap, and aspirins may be bought for the purpose. The subject may report that he used the method nearest to hand: "I saw the box on the sideboard"; "I put my hand in my pocket and felt them there." Another determinant is the expected painlessness of the mode of exit: feelings of guilt do not compel the psychopath to inflict maximum suffering on himself, and he may confess to his hedonism—"I thought I'd sleep away nicely." There is no doubt that in some cases also deeper compulsions operate, and are expressed particularly by those who state, "I couldn't think of any other way." It is likely that the predominance of passive oral methods can in part at least be ascribed to the immaturity of the personalities and the incidence of early deprivations in this group. Direct suggestion seems only occasionally to be a factor.

Loss of Consciousness; Amnesia.—Eighteen men and 14 women lost consciousness as a result of their attempts. It was surprising that none claimed an amnesia for the act itself, since the intense emotional perturbation usually associated with it might have been expected in some cases to cause a clouding of consciousness.

Attitude after the Attempt.—The considerable number who denied their suicidal intentions is noteworthy (Table VII). Some of these admitted to having had feelings of hopelessness. Others stated that they had just wanted to

sleep or to get some release: "It suddenly dawned on me that I could sleep and sleep and forget it all." Eleven individuals were vacillating, evasive, or confused about their acts: "I don't think I wanted to die actually"; "I don't know what I meant"; "Could I do this by mistake?" Attitudes may even be changed during the course of an interview. Remorse is hardly ever expressed.

Estimation of its Seriousness.—It is impossible to give a precise estimate of the seriousness of each of these attempts. One cannot gauge their gravity simply by reference to the means employed, since in many cases the rapidity with which the act was perpetrated marred its efficiency. Also, amongst this group of people one cannot believe all those who claim that they have been in earnest nor all those who

deny it; while others seem to know no more clearly than an observer what they had intended. It is certain, however, that the majority of these people had done things which were highly dangerous to themselves; and that in at least one-third of the cases the act was carried out with great determination. The severest difficulty in assessment arises in those cases in which the individual has felt that he must escape from a situation which has become intolerable to him; the duration of his proposed absence may be problematical. In perhaps a handful of cases in this series the suicidal drive may have been minimal.

Motives

As are probably all suicidal acts, these attempted suicides were complexly determined. Certain psychopathological trends have been isolated, and are discussed below. This atomistic arrangement, while it assists clarity in presentation, does some violence to the intimate interrelationships of the factors concerned and perhaps suggests that these acts are determined at a more conscious level than is in fact the case. The trends discussed here may be compared with the motives discerned in a group of 40 old people who made suicidal attempts (Batchelor and Napier, 1953b).

Hate.—The commonest precipitant of these attempts was a quarrel, mobilizing intense feelings of hatred for a person previously ambivalently loved and hated. In several cases it was quite obvious that the suicidal individual had felt the provocation to murder. In more than one-quarter of the cases motives of spite, pique, and revenge were apparent. The suicidal act may be consciously intended as the most bitter curse. One man's farewell note expressed this succinctly: "Dear Dad, this is Good-bye. You haven't been much of a Dad to me.—Johnny." The aggrieved individual may turn the tables on the hated person by attempting to lay a death at his door and so render him a murderer. For example, a young woman, believing herself jilted, went to her lover's house and gassed herself while lying on his bed. In the case of the morbidly narcissistic individual, a wound to self-esteem which would appear to the average person innocuous may be sufficient to precipitate a suicidal attempt. The culminating incident which provoked a youth to attempt to poison himself with drugs belonging to his mother was her order, which humiliated him before others, to take his cap off in the house.

Evasion.—These individuals often themselves recognized the evasive nature of their reactions. "When I get into a complete jam this sort of thing occurs to me"; "I didn't want to face it." Of alternative modes of escape, alcohol was frequently used. One man, who previously had had a fugue lasting two days immediately after being jilted, made his determined suicidal attempt immediately after he had experienced a similar disappointment. Closely related to fugues, though not associated with amnesia, are the impulsive journeys which psychopathic individuals often embark on. More than one of these people had been planning emigration as a solution of his difficulties; one, when his suicidal attempt had failed, announced his intention of entering a monastery.

Identification with a Dead Person.—Four men had identified themselves with their dead fathers: one of these parents had himself attempted suicide. One of these four men had in addition identified himself with a dead male friend, to whom he had been homosexually attached. Three men and one woman had identified themselves with their dead mothers. The suicidal individual may speak openly of wanting to rejoin the dead person.

Experimentation and the Dramatic Demonstration of Omnipotence.—Defiantly rejecting an unappreciative world, the malcontent may close his account in the most individualistic manner possible to him—by a murder of the self, by the self, for the self. The suicidal attempt in such cases may be deliberately, and romantically, staged. One of this group, after being jilted, climbed the Calton Hill at midnight, placed the girl's Bible beside him, and so slashed his wrist that he nearly died: he was sustained by an

exalted feeling of omnipotence as he looked down on the city of his nurture and the people he despised. Another blasé young man, before poisoning himself, left a long letter in which he took a sophisticated farewell of the world: "Sideral Time marks out the minute fragment of my life against a canopy of stars. I have chosen to shorten it. I am my own executioner. . . . I join Mayakovsky." The suicidal act is in such cases ecstatic. Closely allied to dramatic and erotic motives is the factor of experimentation. The excitement of danger clearly held a vivid appeal for these two men and for some others in this group. Their morbid tensions were geared to it. Feeling different and estranged from their fellow men, one can understand that they were the more ready for a crucial experiment to discover where they belonged. A suicidal attempt may be a form of initiation, a test of manhood.

Manipulation of the Environment.—While efforts to dominate and to punish the environment were clearly evident in the suicidal attempts prompted by frustration, spite, and revenge, efforts deliberately to cajole it were identified in a small minority of the cases. One woman stated later, "I thought it would change my husband"; a man admitted, "I just took the gas simply to frighten my wife; I didn't think it would have gone so far." These two acts may have been bungled gestures, and in any series of attempted suicides there are probably some such cases.

Fears.—Phobias were less common than well-founded apprehensions. In addition to those afraid of social consequences, two men justifiably feared the outcome of their physical illnesses, and one woman an illegitimate pregnancy. Two men and two women feared insanity. Two other individuals had hypochondriacal bodily complaints.

Loneliness.—This factor is more closely related to the suicidal individual's advancing age than to his psychopathic reaction. It strongly influenced an illegitimate girl aged 20, and three individuals past middle age.

Guilt.—In only one case did guilt seem prominently to be a factor. It may have been a factor overlooked in other cases; but one has the strong impression that it is an element of little importance in the genesis of psychopathic suicidal attempts.

Frustration Reactions.—It has been proposed (Batchelor, 1954) that the concept of an acute frustration reaction is applicable to many of these impulsive acts. This concept complements and does not minimize the importance of the psychopathological factors described above.

Disposals

In 35 (83.3%) cases the patients were discharged from the general hospital within two weeks, 22 being detained in the observation ward for a week or less and 13 for one to two weeks; three were detained for two to three weeks, and four for a longer period. Of the 36 (85.7%) discharged home, 16 attended for further out-patient psychiatric investigation and treatment. Three men and three women were transferred to a mental hospital: only one of these was under certificate.

Only one individual has committed suicide in the year following the suicidal attempt.

Discussion

When one compares the suicidal acts of psychopaths with those of individuals suffering from, for example, depressive psychoses, one is impressed with how much in the former is on the surface. Many have obvious environmental precipitants, aggression is more nakedly displayed, frictions in personal relationships are more easily identified, and, while both intrapsychic and external conflicts are undoubtedly operative, the latter are of considerable significance.

Motives of guilt and self-punishment are less potent in psychopathic cases; and for this reason alone these suicidal attempts would tend to be less fatal. Poisoning is more easily treated than many other injuries, and the act—following, for example, a quarrel at home—may be per-

petrated in circumstances which facilitate its detection. The flood-marks of the individual's rage or panic fear may therefore be soon removed, and his quick recovery of poise may belie the intensity of his recent emotional storm. The nearer in time that one stands to these acts the more seriously is one apt to estimate them, while in a retrospect one may be aware less of the act itself and more of its consequences. Impressed in his follow-up study by the modification of the social situation which the individual's suicidal act may effect, Stengel (1952) has drawn particular attention to the social element in suicidal attempts, and, considering these acts as unconsciously directed towards a re-establishment of human relationships as well as towards death, has emphasized their "appeal character."

That nearly half the cases had made previous suicidal attempts might be held to support the hypothesis of their "appeal character." Appeals to others for help might equally be repeated because of their previous failure or because of their learned effectiveness. But we should also link the repetitiveness of these acts with their outstanding quality, which is explosiveness. We are then strongly reminded of the behaviour of the epileptic. There are other correspondences: the psychopath's suicidal attempt, like the epileptic's fit, may come suddenly or be prefaced by a period of increasing tension and irritability; it may be precipitated by emotional frustration, alcoholism, or fatigue; some clouding of consciousness may accompany it (Henderson, 1939); and, while in some cases it may be followed by a period of collapse or of disturbed rather random behaviour, recovery is usually remarkably rapid. The suicidal attempt of the psychopath might often be fairly accurately described as a suicidal fit.

Like the child, the psychopath is self-centred, instinct-driven, and lives in the present; his wishes and his expectations approximate; he is deficient in self-control and natively destructive. His suicidal acts also bear a strong resemblance to those committed by children. Many writers, from Maudsley (1895) to Despert (1952), have drawn attention to the fact that children may embark on self-injury on sudden impulse, in a setting where emotional depression is often not obvious; have instanced motives such as jealousy, revenge, identification with a dead person, and fear of punishment (in the adolescents also disillusion and experimentation); and have emphasized that the precipitants of these acts may appear trivial. Though the evidence is less abundant and established, there is also some suggestion at least of a resemblance between the suicidal acts of psychopaths and those of primitive peoples.

It is likely that even under the most favourable conditions the number of these acts which could be forestalled would be small, since usually the self-injury follows its stimulus so quickly or unexpectedly. Prophylaxis must begin therefore in childhood, when, or before, the first indications of emotional instability or social maladaptation or delinquency become apparent; and it must deal with such severely traumatic factors as parental alcoholism. But here we are gravelled by lack of information: we need to know far more than we do about heredity, for example: about the pathophysiological relationships between psychopathy and epilepsy; about the structure and effects of the "broken home" situation; about the unconscious factors which go to produce criminal behaviour; about impulse and its control.

We are obviously confronted by complex problems. We have to work against a background of social changes outside our effective control, of which the phenomena we are treating are to some extent at least reflections. And we have to deal with a situation which, though it may be more common than formerly, is certainly not new: centuries ago a discontented man was defined as "one that is false out with the world and will be revenged on himself."

Summary

The cases of 25 men and 17 women suffering from psychopathic states, who attempted suicide and were

admitted to a general hospital, have been investigated in detail from psychiatric and social aspects. The sample suggests that at least one-fifth of attempted suicides belong to this group.

A family history of psychiatric abnormality was obtained in 67% and of suicide in 14% of the cases.

Of the group 74% came from "broken homes." Previous suicidal attempts had been made by 45%. The majority of the patients were in the first half of life, and all had shown persistent social maladjustment; most typically they were impulsive, aggressive, restless, egocentric, and affectionless; many gave histories of unemployment, crime, sexual maladjustment, alcoholism, drug addiction. 71% were in the lowest social class.

The physical state was satisfactory in 60%.

Nearly one-third had not been complaining of nervous symptoms, and one-half were not under the care of a doctor at the time of their suicidal attempts. Homicidal trends were in several cases obvious. The majority of the suicidal attempts were impulsive, precipitated by a personal quarrel or the threat of retribution. Alcohol and fatigue were significant factors. Poisoning was chosen by 91%. Many were confused about their real intentions.

The psychopathology of these acts is described and the following motives are considered most significant: hate, evasion, identification with a dead person, fears, experimentation, the demonstration of omnipotence, and manipulation of the environment.

Of the group 86% were discharged home.

The difficulty of judging the seriousness of these attempts is discussed, their resemblances to the episodically disturbed behaviour of the epileptic and to the suicidal attempts of children and primitives are briefly considered, and the need for further research and its possible directions are indicated.

I am grateful to Professor Sir David Henderson for his criticism and advice, and to Dr. J. K. Slater for permission to study these cases in his wards at the Edinburgh Royal Infirmary. I am also much obliged to Miss Margaret B. Napier, senior psychiatric social worker at the Royal Edinburgh Hospital, for her assistance in obtaining data from the families of these patients.

The decision of the Department of Health for Scotland to combine a publicity drive against tuberculosis with mass radiography surveys in selected areas is largely based on experience at Greenock. Here, last autumn, one-fifth of the adult population (13,537) came forward for x-ray examination, and as a result 58 previously unknown active cases of pulmonary tuberculosis were discovered—a yield of 4.3 per 1,000 of those examined. A further 93 patients (6.9 per 1,000) were placed under surveillance. It is pointed out that a far higher proportion of the population would have been x-rayed had not the radiography units been previously committed to routine work such as the examination of National Service men. The Department sums up the Greenock experience in these words: "The case for a change in emphasis in favour of mass x-ray drives is stronger when the incidence of active tuberculosis discovered in Greenock is taken into account."

MECKEL'S DIVERTICULUM AS AN ABDOMINAL EMERGENCY

BY

ERIK CHRISTENSEN, M.B., B.S.

(From Surgical Department A of the Frederiksberg Hospital, Copenhagen)

"Meckel's diverticulum is frequently suspected, often looked for, and seldom found" (Charles Mayo, 1933). This vestigial structure may make its presence known dramatically, and the diagnosis is seldom made pre-operatively. Few surgeons have extensive experience of the condition, and this review is based on a small series of five cases.

Diverticula may be found anywhere in the gastrointestinal tract. Most of them are acquired and have their origin at the point of penetration of the muscle coat by the mesenteric vessels (Edwards, 1939). Among the congenital diverticula are the rare caecal diverticula and Meckel's diverticulum. Meckel's diverticulum is a remnant of the foetal vitello-intestinal duct, which in the foetus forms a channel between the midgut and the yolk sac. As distinct from acquired diverticula it is a true diverticulum, consisting of all the layers of the intestinal wall.

Pathology

Remnants of the vitello-intestinal duct may be encountered in the form of (1) a persistent duct from the ileum to the umbilicus with secretion of mucus, or even faecal matter; (2) a short umbilical sinus or an umbilical polyp; (3) a vitello-intestinal cyst; (4) a fibrous band from the umbilicus to a Meckel's diverticulum; or (5) the band may be attached to intestine, mesentery, or another viscus, commonly in the pelvis; (6) a solitary Meckel's diverticulum is the remnant most often found. An artery may be contained in the above band—namely, the vitelline artery.

The different intestinal diverticula were classified in 1812 by Johann Friedrich Meckel (the younger); he gave a full description of the solitary diverticulum of the ileum which bears his name. It had, however, been described earlier by others. Among the congenital abnormalities of the intestinal canal it has the highest incidence, and in necropsy materials it is found in 1–2% (Treves, 1918). Its average length is 2 in. (5 cm.) (varying from a slight bulge to a 6-in. (15-cm.)-long vermiform process), arising from the anti-mesenteric border of the ileum about 2 ft. (60 cm.) from the ileo-caecal valve, the distance varying from 4 in. to 5 ft. (10 to 150 cm.). It is shaped as a cone or a blunt cylinder protruding at a right angle, or more rarely at an acute angle from the intestine. Ileal mucosa lines its interior, but duodenal or colonic mucosa may also be found, and gastric mucosa is present in 16% of necropsy specimens (Schaetz, 1925). In the clinical material, however, gastric mucosa is encountered in two-thirds of the cases recorded (Schullinger and Stout, 1934; Bussey, 1938; Montant *et al.*, 1950). The French designation "petit estomac" is explained by these facts. Heterotopic pancreatic tissue may also be found.

Infection

Acute inflammation of Meckel's diverticulum, sometimes caused by foreign bodies, gives clinical symptoms and signs quite similar to those of appendicitis.

Case 1

A 5-year-old boy was admitted to Surgical Department A of Frederiksberg Hospital on March 30, 1952, with a diagnosis of appendicitis. He had been treated in the medical department for abdominal pain some months before. There had been short

spells of dizziness, nausea, and abdominal pain four weeks prior to admission. Another attack started the day before with abdominal pain. As the pain grew worse he was sent to hospital. On admission his temperature was 101.8° F. (38.8° C.), pulse 88. Tenderness was found below and medial to McBurney's point, and rebound tenderness and a dubious Rovsing sign were present, but no rigidity. A diagnosis of atypical appendicitis was made, and immediate operation was decided upon. At operation the thickened appendix showing moderate signs of inflammation was removed. As the changes found were not thought sufficient to explain the patient's symptoms, the terminal ileum was inspected. An inflamed Meckel's diverticulum 2.5 cm. long, about 3 ft. (90 cm.) from the ileo-caecal valve, was found and removed. Recovery was uneventful.

Histological Report.—Subacute appendicitis and diverticulitis Meckelii. The pathological changes in the diverticulum were described as more pronounced than those in the appendix.

Perforation

The clinical course is often more stormy than in appendicitis; inflammation may lead to gangrene, early perforation, and peritonitis. Cases of perforation peritonitis caused by foreign bodies, especially fish bones, have been described (see Fig.). Because of the ample and thin intestinal contents

Photograph of removed Meckel's diverticulum with fish-bone perforation, occurring in a 9-year-old girl. (Mr. Wallace Dennison, of the Royal Hospital for Sick Children, Glasgow, has given me permission to use this photograph.)

escaping into the peritoneal cavity and the meagre possibilities of walling off the inflammation at this site, the peritonitis arising is diffuse, and the outlook is more grave than in perforated appendix. Diagnosis is difficult; thus Sibley (1944) reports a case in which delay in operating, because of failure to recognize the inflammatory nature of the intestinal obstruction, led to death from peritonitis and septicaemia. This was partially due to the fact that the patient had been successfully carried through a previous attack with the Miller-Abbott tube and that he seemed to improve under conservative treatment at the beginning of the last attack. The diseased diverticulum may not be looked for at all if an inflamed appendix is found at operation. Discussing this problem, Aalkjær writes (1937): "In several of these cases no discrepancy has been found between the condition of the appendix and the peritonitis, and the surgeon has performed an appendectomy. Some days later necropsy has revealed the perforated Meckel's diverticulum."

Case 2

A 13-year-old boy was admitted to our department on November 10, 1947, with a 36-hours history of abdominal pain about the umbilicus. The pain later moved towards the right iliac fossa; it was moderate and colicky and more pronounced after meals. He complained of nausea, but there was no vomiting. His bowels had been opened several times.

On examination his temperature was 99.8° F. (37.7° C.) and pulse 112. There were no signs of dehydration, and abdominal examination showed definite tenderness at McBurney's point and a positive Rovsing sign. Appendicitis was suspected, and immediate laparotomy was performed through a lower right gridiron incision; the abdominal cavity contained seropurulent fluid. The caecum was fixed and could not be moved out of the wound;

the terminal portion of ileum was found red and inflamed with no distinct line of demarcation. The appendix was difficult to find; it was very long and in the subileal position; it was removed. The changes found were less than those in the ileum, and the surgeon diagnosed ileitis terminalis and closed the abdomen.

The next day, at 3 p.m., the patient had sudden severe pains in his abdomen and a rise of pulse and temperature. Next morning it was evident that a perforation had taken place with subsequent peritonitis, and a further operation was decided upon. At operation on November 12 the abdomen was opened through a lower right pararectal incision. Fibrin-covered intestines were drawn forward, and a ruptured Meckel's diverticulum was found. A simple removal without intestinal resection was possible, and the wound was closed without drainage. Convalescence was uneventful.

Histological Report.—"Meckel's diverticulum with gastric mucosa, severe inflammatory changes and perforation through ileal mucosa. Endoappendicitis levissime gradu."

Intestinal Obstruction

This may be produced by a Meckel's diverticulum. According to Walsh (1949-50) it was the cause in 6% of a large series. A strangulation is the mechanism most frequently met (Lejars, 1921), as the intestine is kinked upon a band extending from the tip of the diverticulum to adjacent mesentery, to the abdominal wall, another coil of bowel, or a pelvic viscus. Sometimes a snare is thereby formed in which an intestinal coil is caught and strangled (Thomsen, 1927). The rarest mechanism is the formation of a real knot in a Meckel's diverticulum around the intestine. This can take place only if the diverticulum is long, mobile, and free, and has an ampullary dilatation of the distal end, designated by French authors as "la clef de l'étranglement."

Among 63 cases of intestinal obstruction caused by Meckel's diverticulum Halstead (1902) found a band in 48, and a band was the cause in 8 out of the 15 cases of Guilleminet *et al.* (1950).

Case 3

A 79-year-old woman was admitted to hospital on July 5, 1947, with a 24-hours history of sudden colicky pains across the abdomen accompanied by nausea and vomiting; no flatus had been passed. There was a slight rise of temperature and she showed signs of dehydration. A straight radiograph of the abdomen revealed dilated coils of small bowel and the erect film many small-bowel fluid levels. Conservative treatment with hot fomentations and fluid diet resulted in an improvement in her condition, and ample flatus and thin stools were passed the next morning. She gradually improved, and some days later another radiograph showed no signs of intestinal obstruction. She returned home on July 23.

On December 23, 1952, she was readmitted as an emergency case. There was a 94-hours history of nausea, faintness, and later constant pains in the upper abdomen. The bowels had not been opened for 36 hours. On examination the patient was moaning and her tongue was dry. The abdomen was a little distended, but followed the respiratory movements. There was generalized tenderness, most pronounced in the epigastric region, but no rigidity. No tumours and no herniae were found. A pelvic examination gave no further information. Intestinal obstruction because of a tumour or constipation was suspected, and a straight radiograph was taken. Several dilated coils of small bowel and fluid levels in the erect position were seen. No gallstones could be detected and there was no air in the bile ducts. Immediate operation was decided upon.

At operation the abdomen was opened through a lower right pararectal incision. The abdominal cavity contained a considerable quantity of serous fluid. Distended coils of small bowel filled with fluid presented in the wound. After some search a fibrous band extending from the great omentum to the tip of an inflamed Meckel's diverticulum, which had strangled an intestinal loop, was found. On section of this band the intestine regained its normal colour, and the obstruction had thus been removed. Excision of the Meckel's diverticulum was then undertaken, followed by closure of the wound. Convalescence was complicated by a slight inflammation of the wound. Histological examination showed a Meckel's diverticulum with no pathological changes.

Volvulus

Volvulus of Meckel's diverticulum, with or without involvement of the coil of ileum bearing it, is well recognized as one of the ways in which the diverticulum may precipitate acute obstruction of the small gut. The obstruction is of the "closed-loop" type, clinically characterized by violent intestinal colic and absence of peristaltic sounds (Smith, 1945). It is a rare lesion; in the 15 cases of Meckelian obstruction of Guilleminet *et al.* mentioned above there was only one case of volvulus. Intestinal resection is often necessary in these cases (Philippe and Chattot, 1950; Tagart, 1953).

Case 4

A 37-year-old mechanic was admitted to hospital with a five-days history of vague and intermittent pains, most pronounced in the epigastrium. For the two days preceding admission he had been confined to bed because of pains and vomiting. On the day of admission his pains had increased in intensity. There had been two loose motions on the day before and a trace of thin faeces and flatus on the day of admission.

On examination he appeared ill, with an anxious expression, lying with his legs drawn up. His tongue was dry; temperature 99.8° F. (37.7° C.), pulse 80. Examination of the abdomen revealed some distension and generalized tenderness, especially around McBurney's point; here rigidity was present. Acute appendicitis with perforation was suspected and immediate operation was decided upon.

At operation the abdomen was opened through a right muscle-splitting incision. As the peritoneum was opened, 0.5 to 0.75 litre of serous fluid gushed out. The appendix was found swollen and red, lying in a subileal position, and was removed in the usual way. On account of the exudate the ileum was inspected after widening the incision, and about 75 cm. from the ileo-caecal valve a torsion of the ileum was found fixed to the root of the mesentery by adhesions around an inflamed Meckel's diverticulum. The gut was distended and bluish-red proximally to this point. After the adhesions had been cut and contracted distally to it. No resection of intestine was necessary as the gut was viable, and after excision of the diverticulum the abdominal wall was closed without drainage.

The patient's condition deteriorated, and he died 24 hours after the intervention, with the clinical picture of intestinal paralysis and hyperthermia. Necropsy gave no further information.

Intussusception

An introversion of a Meckel's diverticulum may take place, causing obstruction of the ileum (Wessel, 1925-6) or an ileo-ileal intussusception. According to Harkins (1933) this variety of intussusception has several distinguishing features: (a) it occurs in older individuals, (b) a history of previous attacks is more frequent, (c) vomiting is more intense, and (d) the course of the disease is more chronic and there is often a mild attack a day or two before the onset of the major illness. A correct diagnosis of this condition is usually made too late, and an intestinal resection is often required (Benson and Sharpe, 1950) because of irreducibility and gangrene. In infants the condition is very rare (Aitken, 1950).

Case 5

A 12-year-old girl was admitted to hospital on December 31, 1952, with a 16-hours history of sudden pains around the umbilicus, gradually subsiding. Fourteen hours before admission a new bout of pains occurred after a meal. She had no appetite, and her mother gave her an aspirin tablet. There had since been pains of constant character localized to the umbilical region and the right iliac fossa, of varying intensity. She had vomited several times and there had been a normal motion just before admission.

On examination her tongue was dry; temperature 99.4° F. (37.4° C.) and pulse 88. The abdomen was slightly distended, with no visible peristalsis and normal intestinal sounds. Direct tenderness and rebound tenderness were elicited about McBurney's point; Rovsing's sign was positive, and a rectal examination revealed tenderness to the right. Immediate operation was decided

upon, with a preliminary diagnosis of acute appendicitis, even if the symptoms were not typical and she appeared more dehydrated than was to be expected with such a temperature.

At operation the abdomen was opened through a gridiron incision; there were large amounts of serous fluid in the peritoneal cavity. The appendix was in a subcaecal position and showed no signs of inflammation, but a small carcinoid was present at its tip. The appendix was removed. Palpation of the uterus and adnexa revealed nothing abnormal. Inspection of the ileum revealed a 25-cm.-long ileo-ileal intussusception located about 30 cm. from the ileo-caecal valve. The intussusception was reduced, and at its apex an inflamed introverted Meckel's diverticulum was found. The diverticulum was excised without intestinal resection. Convalescence was uneventful. Histological examination showed carcinoid of the appendix and a Meckel's diverticulum with severe inflammatory changes.

Similar cases have been described by Vangsted (1918), Langballe (1918), Holst (1928), Pettersen (1928), Taylor (1947), and others.

Associated Conditions

Owing to the aberrant gastric mucosa a peptic ulcer may be formed in Meckel's diverticulum, especially at the junction between the ileal and gastric mucosa at the base of the diverticulum. Complicating the ulcer, perforation or bleeding may take place; numerous cases of this type have been reported—for example, Nielsen (1933-4), Klindt (1933-4), Aalkjær (1937), Manning and McLaughlin (1947), Jay *et al.* (1950), Hancock (1951), Aitken (1953). In melaena with no known cause an ulcer in a Meckel's diverticulum may thus be the origin of the trouble. Dragstedt (1933) has shown that the heterotopic gastric mucosa secretes hydrochloric acid and pepsin. These secretions become irritating to the ileum, producing spasm in the walls of the ileum and the diverticulum (Sibley, 1944). This author defines a condition called "dyspepsia Meckelii," characterized by pain in the lower right quadrant, the epigastrium, or the periumbilical region.

If the communication with the ileum is obliterated the rare retention cysts may arise. Isolated cases of calculi in a Meckel's diverticulum have been described (Allen and Donaldson, 1945; Palmström, 1950). They give symptoms simulating obstructive appendicitis, and the stones consist of faecal material and bile pigment; they are not visible in radiographs.

Solitary cases of carcinoid in Meckel's diverticulum have been reported (Stewart and Taylor, 1926; Hertzog and Carlsen, 1935; Pautler and Scotti, 1951). Even carcinoma of Meckel's diverticulum has been described (Weir, 1937).

A Meckel's diverticulum may be contained in a hernial sac, usually of a femoral hernia, as originally described by Littre (1700). Littre's hernia is a special variety of the so-called Richter's hernia. Inflammation of a Littre's hernia often takes place, and it becomes irreducible. The characteristic complication is incarceration which may go on to abscess and fistula formation (Mair, 1948).

A diagnosis of Meckel's diverticulum is seldom arrived at pre-operatively. Solitary cases of radiographic demonstration of a Meckel's diverticulum have been reported (Aalkjær, 1937; Rousseau and Martin, 1943; Butler *et al.*, 1950), but in the acute cases this method is not to be recommended.

Treatment

In cases of intestinal obstruction, perforation, or diverticulitis the diverticulum should be removed. Opinion on this is unanimous. Removal can often be performed in the same way as an appendectomy. If the base is thick (and the gastric mucosa is often at the base, as mentioned above) a large wedge-shaped excision should be performed, followed by repair. If this is not possible a bowel resection is required, and in our department we prefer a side-to-side anastomosis.

Many authors state that an incidentally found Meckel's diverticulum should be left alone. Sibley (1944), however, recommends the earliest possible removal of any Meckel's diverticulum. Considering the grave abdominal complica-

tions with a high mortality (about 15% according to Wagner *et al.*, 1950) it can provoke, any incidentally found Meckel's diverticulum should be removed if this procedure does not materially increase the operative risk.

Summary

The complications of Meckel's diverticulum which call for emergency surgery are infection, obstruction, intussusception, volvulus, and haemorrhage. The difficulties in diagnosis have been illustrated by five cases.

The incidentally found Meckel's diverticulum should be removed if this procedure does not materially increase the operative risk.

In 1953 the accident section of the London Ambulance Service dealt with 90,896 emergency calls—compared with 87,691 in 1952 and 87,012 in 1951. Thirty-nine ambulances were in commission, operating from the 18 accident ambulance stations; they covered 457,514 miles, an increase of 15,246 over 1952. Fridays and Saturdays are still the busiest days of the week, with averages of 267 and 266 calls, and Sunday remains the quietest day with 188 calls. Unlike 1952, when most calls were received in December, in 1953 the highest average number of calls were received in June—280 calls a day—and May—269 calls a day. These figures reflect the record numbers reached on Coronation Day, when 650 patients were removed by the London Ambulance Service. The general section of the Service, which deals with the non-urgent removal of sick people, carried out 428,946 journeys in 1953, conveying 721,334 patients a distance of 3,625,430 miles. In 1951 550,621 patients were carried, and in 1952 660,206. The majority of these journeys were for the conveyance of out-patient cases to and from hospitals, clinics, etc.

COMPARISON OF SODIUM AND PROCAINE PENICILLIN IN TREATMENT OF EXPERIMENTAL STAPHYLOCOCCAL INFECTION IN MICE

BY

F. R. SELBIE,* M.D., D.Sc.

Professor of Bacteriology, University of London

(From the Bland-Sutton Institute of Pathology, Middlesex Hospital, London, W.1)

It is remarkable that there is still a division of opinion regarding the administration of penicillin in the treatment of infections. It has often been maintained that the therapeutic benefits of penicillin depend on the time during which there is an amount of penicillin in the blood stream sufficient to kill or inhibit the growth of the infecting organism. This possibility was recognized in the early days of penicillin therapy, and the continuous administration of penicillin by intramuscular drip rather than by intermittent intramuscular injection was advocated so that a bacteriostatic level of penicillin in the blood could be maintained throughout treatment. It was, however, pointed out by Hudson *et al.* (1946) that, for the same amount of penicillin over a 24-hour period, the intermittent method of administration gave a much higher average level of penicillin in the blood than the continuous method, and they also contended that intermittent therapy would be more effective in that the high peaks of penicillin obtained in the blood after each injection would enable penetration of penicillin into the foci of infection. The intramuscular drip method was soon abandoned, largely because of technical difficulties in its application, with the result that no clear-cut comparison could be made of its value relative to the more widely used intermittent method.

The question has again been raised with the introduction of depot preparations of penicillin, which have the advantage over sodium penicillin of prolonging the absorption of penicillin from the site of injection, so that effective concentrations are maintained in the blood stream for a much longer time. It is on these grounds that the advocates of the new preparations recommend their use, but it appears that little or no evidence has been adduced to show that they are better than aqueous solutions of sodium penicillin in the treatment of infections. The experiments described here have been designed to provide such evidence so far as it applies to an experimental infection which has been used by Selbie and Simon (1952) in their investigation on the virulence of *Staph. pyogenes* to mice.

Material and Methods

The two strains of *Staph. pyogenes* used for these experiments have been described by Selbie and Simon (1952). Strain No. 221 was used for five experiments, but had to be abandoned because of a fall in virulence. Fourteen experiments were done with Strain No. 144. At the time of the experiments the growth of the strains *in vitro* was inhibited by about 0.04 unit of penicillin per ml.

In each experiment four groups of six mice of about 30 g. body weight were inoculated intramuscularly in the left thigh with 0.2 ml. of an 18-hour culture of *Staph. pyogenes* in tryptic digest broth. The first group was left untreated, and the succeeding groups were treated with an aqueous solution of the sodium salt of penicillin G, a suspension of procaine penicillin G in arachis oil containing 2% aluminium stearate ("avloprocil"), and an aqueous suspension of procaine penicillin G ("distaqueine G"). Each

dose of penicillin preparation contained 30,000 units in 0.1 ml. and was injected subcutaneously in the right axilla so as to be as far away as possible from the site of infection and thus ensure that penicillin would reach the lesion by way of the blood stream rather than by direct diffusion through the tissues.

In two series of experiments treatment with penicillin was started three hours after inoculation, when some swelling of the thigh could already be detected. This was done on the basis of preliminary experiments which showed that earlier treatment rapidly abolished the lesions in most of the mice, whereas when treatment was started at three hours the great majority of the mice showed measurable swellings during the whole of the succeeding week, so that an opportunity could be afforded of measuring differences in response to the various penicillin preparations. In the third series treatment was not started until after 24 hours, when the lesions were first measured. Measurement of the lesions was made at 1, 2, 4, and 7 days after inoculation by determining the diameter of the left thigh by callipers to the nearest millimetre and subtracting the diameter of the normal thigh.

Results

The average effect of six experiments in which only one dose of penicillin had been given three hours after inoculation is shown in Fig. 1. The average effects of two further series of experiments in which four daily doses of penicillin have been given, commencing at 3 hours and 24 hours after inoculation, are shown in Figs. 2 and 3 respectively. The overall mortality rate of 1% has not interfered with the analysis of the results, especially as only one mouse has died in each affected group. Progressive infection, as judged by the increasing average size of the swellings, has been obtained in the untreated mice of all the experiments except for the onset of regression after two days in one experiment, and after four days in three experiments. All three penicillin preparations reduced the size of the lesions as compared with those in the control mice, but there were great differences between experiments in response to the three penicillin preparations.

The results have been submitted to Dr. L. J. Edwards for statistical appraisal. He finds that the most suitable way of dealing with these is to express the sum of the swellings on each day in each experimental group of six mice as a percentage of the sum of the swellings in the

corresponding control group on that day. The means of the percentages for each day in each treatment have been used to construct Figs. 1 to 3. Dr. Edwards has also calculated the variances of the means, and concludes that all three penicillin preparations significantly reduce the size of the swellings on all regimes of dosage and on all days of measurement, but none of them can be said to be demonstrably better than either of the others.

Concentration of Penicillin in Blood of Mice

The concentration of penicillin in the blood serum of mice at intervals after subcutaneous injection of the three penicillin preparations in the dose of 30,000 units used for treatment was estimated by the twofold serial dilution method described by Selbie *et al.* (1945). Each estimation was made on 1 ml. of serum from the pooled blood of three mice which were bled from the heart with a Pasteur pipette immediately after they were killed.

The results are shown in the Table. It will be seen that during the first 10 minutes sodium penicillin gives a concentration in the serum five times greater than the highest level attained at any time by either of the other preparations. It can also be seen that the concentrations given by sodium penicillin are lower than those given by the other two preparations from 30 minutes onwards and are no longer detectable by the method used at 18 hours. The results obtained with the procaine penicillin preparations show a more rapid absorption from the aqueous suspension, which, however, gives detectable levels of penicillin up to at least four days, as against seven days with the oily preparation.

Discussion

The clinical use of procaine penicillin preparations in preference to sodium penicillin is based largely on the contention of Eagle *et al.* (1950) that the curative effect of penicillin depends primarily on the concentration of penicillin in the blood and the total time for which it remains at effective levels. It has, however, been shown here that equivalent doses of sodium penicillin and two preparations of procaine penicillin are equally effective in controlling the lesions of an experimental staphylococcal infection in mice. If the presence of a bacteriostatic level of penicillin in the blood were the principal factor in determining a curative effect, the blood levels shown in the Table would indicate that the dose of sodium penicillin used would become ineffective

Penicillin in Blood Serum of Mice After Subcutaneous Injection of 30,000 Units of Penicillin in 0.1 ml.

Preparation	Units of penicillin per ml. at												
	Minutes			Hours						Days			
	5	10	30	1	3	6	12	18	24	2	4	5	7
Sodium penicillin G	800	800	2.5	1.3	5	1.3	0.64	—	—	2	4	5	7
Oily suspension of procaine penicillin	20	40	160	10	5	2.5	10	N.D.	—	2.5	1.3	N.D.	—
Aqueous suspension of procaine penicillin	40	40	160	160	40	40	20	N.D.	0.64	1.3	0.08	—	0.04

— Less than 0.04 unit per ml. N.D. = Not done.

within 18 hours, whereas the equivalent doses of oily and aqueous procaine penicillin would remain effective for four and seven days respectively.

It is, however, obvious from Fig. 1 that the curative effect following one injection of sodium penicillin continues long after penicillin falls below a detectable level in the blood, and is as good as that obtained after an injection of procaine penicillin. This continuing effect after sodium penicillin treatment is also evident when four daily doses are given, whether the first dose is given at 3 hours or 24 hours after inoculation (Figs. 2 and 3); in both regimes the aggregate time during which effective levels of penicillin would be present in the blood is less than three days with sodium penicillin and seven days with the procaine penicillin preparations.

It would thus appear that the total duration of an effective level of penicillin in the blood is not the only factor that is of importance in determining the curative effect of penicillin in this experimental infection. Two of the factors that have to be considered are the maximum concentration of penicillin attained in the blood and the defence mechanisms of the host. The Table shows that the maximum concentration of penicillin detected in the blood after the injection of sodium penicillin is five times greater than that detected after injection of the procaine penicillin preparations. Sodium penicillin would therefore give a much higher concentration of penicillin in the staphylococcal lesions and so produce a greater therapeutic effect than procaine penicillin. This more intensive effect of sodium penicillin would, however, be maintained over a relatively short period.

The reason why such a short but intensive action of sodium penicillin should be as valuable as the prolonged maintenance of a lower therapeutic level by procaine penicillin may be found by a consideration of the part played by the natural defence mechanisms of the host. These mechanisms are constantly in operation, and are so effective that staphylococcal infections in man and the experimental infection described here are in the end usually overcome even when chemotherapy is withheld. The part played by penicillin may then be regarded as an intervention in this natural process whereby the suppression of the staphylococci by the antibacterial action of penicillin, even if it is only temporary, so tips the scales in the reactions between host and parasite that the defence mechanisms of the host become more effective. The relatively high concentrations attained immediately after an injection of sodium penicillin at an early stage of infection would thus exert a more intensive effect, and the later continuing effect would be entirely due to the operation of the natural defence mechanisms. Procaine penicillin, on the other hand, would have a less intensive initial effect, but the results of the experiments show that it largely overcomes this disadvantage by its much more prolonged intervention at a relatively low intensity.

These conclusions are at variance with the views of Eagle *et al.* (1950). They, however, have based their conclusions on a different type of experimental infection. In one of their recent publications they show that the effect of penicillin in reducing the mortality rate of a streptococcal infection in mice depends primarily on the aggregate time during which penicillin is present in the blood at or above the bactericidal level, irrespective of the dosage regime, pro-

vided that the interval between doses is not too long (Eagle *et al.*, 1953). It must, however, be borne in mind that the streptococcal infection used by Eagle and his co-workers and the staphylococcal infection used here are very different in their behaviour. Mice have little or no immunity to haemolytic streptococci, so that the experimental infection is rapidly fatal. On the other hand, mice are so much more resistant to staphylococcal infection that even the large numbers of staphylococci used for inoculation in the experiments described here produce only a local lesion with a very low mortality rate. The intense exudative response to the staphylococcal infection also appears to make the organisms less accessible to penicillin, as can be judged by the much larger doses required to control the staphylococcal lesions as compared with the streptococcal infection, in which the organisms are more directly in contact with the circulating body fluids. It is therefore not surprising that the two experimental infections should differ in their response to chemotherapy.

The application of these findings to the penicillin treatment of infections in man is difficult because of the highly artificial nature of animal experiments. It can be said that the experimental staphylococcal infection resembles conditions in man more closely than the streptococcal infection of Eagle and his colleagues because most human infections elicit some degree of response on the part of the body defences. If this view is accepted it is then apparent that to give maximum aid to the body defences. The results with sodium penicillin as with procaine penicillin even this view is to be found in the report by Tompsett *et al.* (1949), who have failed to detect any difference in response between 21 cases of pneumococcal pneumonia treated with daily doses of 30,000 units of procaine penicillin in oil, and by daily doses of 300,000 units of sodium penicillin.

Another investigation of this type is that of Griffiths *et al.* (1949), who found no significant difference in response to treatment between a group of 116 patients with acute septic infection, mainly staphylococcal, given a daily injection of 300,000 units of an oily suspension of procaine penicillin and a similar group of 116 patients given twice-daily injections of 300,000 units of sodium penicillin in saline. Both groups of authors suggest that their results warrant the conclusion that a continuous effective level of penicillin is not necessary for the control of the two respective types of infection.

The results recorded here and a search of the literature have been disappointing in that no clear evidence has been found to show whether sodium penicillin or procaine penicillin gives the better results in the treatment of infections. It is probably true that the prolonged blood levels obtained with procaine penicillin are of great value when only one dose of penicillin can be given, as in the mass treatment of syphilis and yaws. On the other hand, even when penicillin can be given only at infrequent intervals, it has yet to be proved in practice whether the prolonged low blood levels provided by procaine penicillin are more efficacious than the short-lasting but high blood levels provided by sodium penicillin in the treatment of the generality of infections amenable to penicillin therapy.

Summary

It has been shown that sodium penicillin is as effective as either oily or aqueous procaine penicillin in the treatment of an experimental staphylococcal infection in mice.

It is concluded that the curative effects of penicillin depend not so much on the aggregate time that an effective level of penicillin is present in the blood as on other factors, of which the most important is the co-operation of the defence mechanisms of the host.

The application of these findings to the treatment of human infections is discussed.

I wish to thank Dr. L. J. Edwards, of the Beecham Research Laboratories, Brockham Park, Surrey, for his help in this investigation.

THE MALE CLIMACTERIC: IS IT AN ENTITY?

BY

A. W. SPENCE, M.D., F.R.C.P.

Physician, St. Bartholomew's Hospital, London

In Dorland's *Medical Dictionary* the climacteric is defined as "a particular epoch of the ordinary term of life at which the body is believed to undergo a radical change," and the male climacteric as "the phenomena attending the normal decrease in sexual function in the male." In an annotation entitled "The Middle-aged Man," in the *British Medical Journal* (1953), the following statements appear: "Claims have been made, and denied, that there is a rare syndrome properly described as the male climacteric. The symptoms of the presumed syndrome, briefly, are depression, irritability, lack of concentration, palpitation, weakness, and sexual impotence. . . . These claims, however, have been refuted by other workers unable to corroborate them. The so-called syndrome, they assert, is a psychiatric illness. . . . No one has described a condition in men with disturbance of hormone secretion as the only symptom of the so-called male climacteric. . . . Until an occult deficiency of testicular androgen—provided this can be estimated—is shown to bear a direct causal relation to the multiplicity of symptoms embraced by the term male climacteric, we have no ground for accepting the concept." These statements were repeated in *Prescribers' Notes* (1953), issued by the Ministry of Health. It is my endeavour in this article to demonstrate that the male climacteric exists as a clinical entity.

Female Climacteric

Before the problem of the male climacteric is discussed it is pertinent to refer to the complexities of the female counterpart, the existence of which, so far as I am aware, has not been denied. Although the climacteric is defined in a modern British medical dictionary as "the menopause," this definition needs correction, for the two terms should not be confused. Menopause simply means "cessation of menstruation" brought about by physiological failure of

ovarian function. All women have a menopause—if they live long enough—but not all women have symptoms of the climacteric; in fact, many women pass through this period of life with few or no disturbances.

As the critics of the existence of the male climacteric have insisted that its alleged symptoms must be shown to be caused by deficiency of testicular androgen, the cause of the symptoms of the female climacteric must be considered. At the time of the menopause the level of oestrogen in the blood falls as a result of the ovarian changes, and at the same time the titre of gonadotrophin (follicle-stimulating hormone, F.S.H.) rises through removal of the inhibiting influence of oestrogen on the anterior lobe of the pituitary gland. Climacteric symptoms may be directly due to oestrogen deficiency, to excessive gonadotrophin, or to some other factor. The improvement which may be effected by the administration of oestrogen is no proof that oestrogen deficiency is the direct cause of the symptoms, for their amelioration may be due to the fall in the level of gonadotrophin which the administered oestrogen produces. On the other hand, there are observations which suggest that neither of these two factors is responsible—namely: (1) many women do not have climacteric symptoms although their oestrogen level is low and their gonadotrophin titre high; (2) climacteric symptoms may appear before menstruation ceases—that is, when the oestrogen level is within normal limits; and (3) they do not occur in oestrogen deficiency due to hypopituitarism or (4) in ovarian infantilism. In fact, on grounds such as these Pratt (1950) concluded that a hormonal basis alone does not explain the symptoms of the female climacteric.

From this very brief and cursory survey it will be seen that the aetiology of the symptoms of the female climacteric is by no means established and that arguments similar to those brought forward against the existence of the male climacteric, such as those mentioned in the first paragraph of this paper, could well be advanced to deny the existence of the female climacteric.

Male Climacteric

Landau (1951), discussing the concept of the male climacteric, has stated that the period of life during which "climacteric" symptoms are presumed to occur is also the time at which the emotional and intellectual adjustment of the shift from maturity to old age must begin to be made, and that some men at that time develop neurotic reactions such as impotence and general subjective disturbances. This statement is undoubtedly true, and in my experience these patients are not improved by the administration of androgens. However, similar emotional and neurotic upsets occur in menopausal women and are not benefited by the administration of oestrogen, but this is not sound evidence that the female climacteric does not exist.

In discussing the problem of the existence of a male climacteric and whether it is due to or associated with testicular deficiency the following observations should be considered.

(1) Comparison of Symptoms of Male Climacteric with Those of Post-pubertal Castration

In post-pubertal castration libido and potency are generally diminished or absent, but this does not happen in all cases. Similarly, potency and libido may or may not be affected in the male climacteric. After castration has been performed in the adult he may experience hot flushes and sweats and suffer from generalized weakness, lack of mental drive and energy, diminished power of concentration, a sense of inferiority, emotional instability, and fits of depression. The same symptoms occur in the male climacteric. The argument, however, has been produced that in the middle-aged man they are primarily of psychological origin and that any improvement that may be obtained by the administration of testosterone is due to suggestion; yet I have had referred to me by psychiatrists castrated and eunuchoid patients with such symptoms which have disappeared or have been greatly improved with

androgen therapy. Should one assume that the improvement in these cases of known testicular deficiency is also the result of suggestion? This is unlikely, although it must be borne in mind that the improvement in these "neurotic" and "psychoneurotic" symptoms may be secondary and due to the attainment of potency (but see (3) below concerning the anabolic action of androgens).

(2) 17-Ketosteroid Excretion

The urinary excretion of 17-ketosteroids is an index of the amount of androgens produced by the Leydig cells of the testicular interstitial tissue and by the adrenal cortex. Because of the production of adrenal androgens it is often impossible by estimation of the urinary 17-ketosteroids alone to distinguish a eunuch from a normal man. Callow *et al.* (1940) found that normal adult men excreted 3.5 to 15 mg. of 17-ketosteroids in 24 hours and that eunuchs excreted 3.1 to 10.9 mg. in 24 hours. By this investigation, therefore, it is difficult to demonstrate androgen deficiency in the male climacteric. However, on the whole in men of middle age the excretion of 17-ketosteroids begins to decline: at the age of 40 the mean is 14 mg. and in old age 3.4 mg. in 24 hours (Dorfman, 1948). Howard *et al.* (1950) observed that in six patients whom they considered to be suffering from the male climacteric the urinary 17-ketosteroids "tended to be low," the values ranging from 3.9 to 10.2 mg. in 24 hours.

(3) Anabolic Action of Androgens

What is often overlooked or not fully appreciated is that in addition to their effect on the sexual organs androgens have a powerful anabolic action. They promote the anabolism of protein and increase muscular bulk and strength: thus are explained the weakness and early fatigue of the eunuch. One does not therefore have to search for a psychological cause to explain these symptoms in the middle-aged man with testicular failure. The effect of androgens on the central nervous system is not yet known. The psychological symptoms which may occur in the eunuch or in the male climacteric may be secondary phenomena resulting from sexual inferiority, or, on the other hand, they may even be primary, arising through deficiency of whatever action testosterone may have on the higher centres. In this connexion it should be noted that the administration of testosterone to women with panhypopituitarism improves their psychological disturbances and gives them a sense of well-being.

(4) Titre of Gonadotrophin

It is well recognized that high levels of F.S.H. of the anterior pituitary gland are present in the urine of men with primary hypogonadism. Heller and Myers (1944) found that in 15 men with psychoneuroses or psychogenic impotence the titre was normal, whereas in 23 men whom they considered to be suffering from the male climacteric the titre was unequivocally higher. Sniffen *et al.* (1951), who have made a careful and extensive study of testicular abnormalities, have stated that it is unusual for elderly men to have raised urinary gonadotrophin, although it is the rule in post-menopausal women, but that some men do suffer from symptoms similar to those experienced by women at the time of the menopause: in these men they found that the urinary gonadotrophin was significantly raised.

McCullagh and Hruby (1949) observed that in cases of severe hypogonadism in the male the titres of urinary F.S.H. were not reduced to normal levels by the administration of testosterone in amounts sufficient to create normal titres of urinary 17-ketosteroids and clinical signs of masculinization. This failure of testosterone to inhibit pituitary activity in doses sufficient to overcome androgen deficiency they cite as evidence in favour of the theory that a second testicular hormone (inhibin) exists normally and that it is this substance which has the power to inhibit the secretion of F.S.H. Howard *et al.* (1950) have also produced evidence in support of the existence of a second

testicular hormone, which they prefer to call "X" hormone: thus, in bilateral mumps orchitis the tubules are destroyed and the titre of F.S.H. is raised, while the appearance of the Leydig cells (which secrete testosterone), virilization, and excretion of 17-ketosteroids are all normal. These authors have brought forward arguments which suggest that the Sertoli cells are the source of X hormone and that F.S.H. stimulates its production. According to this view it is damage not of the Leydig cells but of the Sertoli cells which causes the increase in titre of F.S.H. These observations lead us to a consideration of testicular histology.

(5) Testicular Histology

Heller and Myers (1944) performed testicular biopsy on 8 of their 23 cases of the male climacteric. In five they found reduction in size and in activity of the seminiferous tubules and reduction in size and number of the Leydig cells of the interstitial tissue, and in three hyaline degeneration of the tubules. Nelson (1948), in cases which he classified as the male climacteric, observed essentially normal seminiferous tubules but decreased numbers of Leydig cells with abnormal cytological characteristics. Howard *et al.* (1950) and Sniffen *et al.* (1951), on the other hand, found normal testicular histology in their patients, although the excretion of F.S.H. was raised in all.

Howard and his colleagues divide the climacteric in both sexes into two stages: (a) compensated, and (b) decompensated. They state: "In the compensated stage there is a tendency to decreased production of one of the gonadal hormones (oestrogen in the female and X hormone in the male); this tendency is met by overproduction of F.S.H., so that the gonadal function remains essentially intact. In the decompensated stage this tendency to gonadal hormone production of F.S.H., and gonadal failure becomes clinically demonstrable. In the female the compensated stage lasts a very short time; in the male, on the other hand, one seldom meets the decompensated stage. In the compensated stage in the male, therefore, one would anticipate that the Sertoli cells would be normal microscopically, as indeed they appeared to be."

(6) Effect of Treatment

It has been mentioned above that the improvement obtained in the so-called male climacteric by the administration of testosterone has been imputed to suggestion. Heller and Myers (1944), however, have reported that the injection of an inert oil without the patient's knowledge of any substitution resulted in a relapse.

Conclusion

From these observations and from my own clinical experience I find it difficult to deny the existence of the male climacteric. Heller and Myers (1944) have stated that whereas the climacteric in females is a physiological process, in males it is rare and pathological. Bauer (1944) asserted that on these grounds the syndrome should be termed "testicular insufficiency" rather than male climacteric; he maintained that if the term climacteric is used, as it should be, to designate the cessation of gonadal activity, then there is little justification for using the term male climacteric, for although the functional activity of the testes declines with advancing years there is no definite age at which they stop functioning as do the ovaries. In this respect it would appear that decline of sexual function in the middle-aged and post-middle-aged man is not denied and that the problem is one of terminology. If we adhere to the definition of climacteric as given at the beginning of this paper I do not understand why application of the term to the male should be abandoned merely because cessation of gonadal activity occurs between the ages of 45 and 55 in women whereas in men it occurs between the ages of 50 and 70 or not at all. Further, why should decline in gonadal activity of elderly men be pathological, whereas in elderly women it is physiological? As

Abarbanel (1945) has pointed out, the process of ageing can become manifest in various organs at varying times, and just because the testis may be one of the last to succumb does not mean that it has now become the site of a pathological process while a similar state in the ovary is merely physiological.

Summary

It is considered that the male climacteric is a definite clinical entity, for the following reasons: (1) Similar symptoms occasionally occur in post-pubertal castrates and eunuchs and are improved by androgen therapy. (2) The 17-ketosteroid secretion, while by no means diagnostic of testicular insufficiency, tends to be low. (3) Some of the symptoms can be explained by lack of the anabolic action of testosterone. (4) The urinary excretion of gonadotrophin is raised—indicative of testicular, but not necessarily of androgen, insufficiency. (5) The testicular histology may show structural changes. (6) The symptoms are improved with androgen therapy, but relapse when an inert substance is substituted. (7) Arguments similar to those advanced against the concept of a male climacteric could be raised against the existence of a female climacteric, which, however, has never been questioned.

Can better use of the domiciliary services provided by local authorities help to relieve the pressure on the hospitals? This was one of the questions put by the Minister of Health, Mr. IAIN MACLEOD, when he addressed the annual meeting of the County Councils' Association in London on May 26. Mr. Macleod made a plea not only for closer co-operation between those responsible for the operation of the health and welfare services and the general practitioners, but also for the fullest opportunity to be given for voluntary effort to make this contribution, especially in helping to solve the growing problem of the care of old people. "We know," he said, "that it is possible to relieve the hospitals of some part at least of the burden now falling on them if better and perhaps more intelligent use can be made of the services provided by the local health authorities. It is not only a question of cost. There are many types of patient who, provided always that there is no clinical reason to the contrary, are better cared for in their own homes than in hospital. This applies particularly to many children and old people, and to the majority of maternity cases, and it is even more true that the vast majority of healthy old people and children are far better if they can be enabled to continue living in their own homes and families and to receive there proper care and supervision." The home nursing of sickness, he continued, was entirely dependent on a sufficient number of home nurses and home helps. Local health authorities should carefully watch to make sure that there were enough of them in their areas. He would also like to see local health authorities consulting general practitioners in their areas, through either executive councils or local medical committees, to find out to what extent doctors felt themselves compelled, owing to the shortage of home nurses and home helps, to refer patients to hospital who might otherwise have stayed at home.

ISONIAZID IN TREATMENT OF BONE AND JOINT TUBERCULOSIS

A REVIEW OF 20 CASES

BY

D. LI. GRIFFITHS, F.R.C.S.

Visiting Orthopaedic Surgeon

A. G. QUINLAN, F.R.C.S.

Registrar

AND

H. J. RICHARDS, F.R.C.S.

Senior Registrar

From the Robert Jones and Agnes Hunt
Orthopaedic Hospital, Oswestry

The Medical Research Council's (1952) interim report on the use of isoniazid (isonicotinic acid hydrazide) alone in 173 patients with pulmonary tuberculosis and of streptomycin combined with *p*-aminosalicylic acid (P.A.S.) in 158 others, concluded that, "judging wholly from short-term results," isoniazid is "a very effective drug" in that condition. It therefore seemed necessary to us to make an immediate study of its short-term effects in bone and joint tuberculosis in circumstances in which the drug would be used as the sole chemotherapeutic substance in the patients under consideration. There have already been reports on the use of the drug with and after streptomycin in bone and joint disease, and especially in "advanced" cases with sinuses and other complications, but we are not aware of any reports of its planned use alone in reasonably early uncomplicated cases.

To study such effects means denying our patients the known and very real benefits of streptomycin, and to obtain many suitable cases of bone and joint disease takes a long time. We therefore planned a small short-term study, designed purely as a pilot experiment, to tell us whether or not anything unexpected would occur in the course of the disease under treatment with this drug alone. We decided that six months was as long as we might deny streptomycin to our patients, and, though this is a very short time in the evolution of skeletal disease, we regarded it as probably adequate for a pilot investigation. All we sought was the answer to one simple question, Does anything unusual occur in the early evolution of the disease under the influence of isoniazid?

The Investigation

To give the drug every chance we selected "good" cases, not failures after other measures. Our 20 patients all had short histories of hitherto untreated new tuberculous lesions of bones and joints. We carefully excluded any case which could have been a recrudescence of an old lesion, and any patient who had had previous chemotherapy. The details of the patients are summarized in the Table. All 20 were admitted to the Robert Jones and Agnes Hunt Orthopaedic Hospital. In all save six spinal cases the diagnosis was or had been proved by biopsy or by recovery of the bacillus by aspiration of abscesses and recovery of *M. tuberculosis* therefrom, and in one of these six, all of which were clinically and radiologically typical, we accepted the presence of a proved active tuberculous lesion elsewhere in the body as adequate evidence that the spinal lesion was in fact tuberculous. The patients' ages ranged from 5 to 45 years. Ten were aged 20 or under. There were 13 males and 7 females. The sites of the lesions were: lumbar spine, 6; hip, 5;

Summary of Cases

Case No.	Sex and Age	Site of Lesion	Type of Lesion	Treatment		Iso-niazid (mg./day)	Other Treatment Given	Weight			X-ray Appearances		General Response to Treatment	E.S.R. (mm./hr.)		White-cell Count		Comments
				Began	Ended			Before Treatment	After 3 Months	After 6 Months	Before Treatment	After 6 Months		Before Treatment	After 6 Months	Before Treatment	After 6 Months	
1	F 20	L. knee	Synovial (proved by biopsy)	31/5/52	1/12/52	250	Thomas splint and plaster gutter frame fixation	112 lb. (50.9 kg.)	126 lb. (57.3 kg.)	128 lb. (58 kg.)	Visible synovial thickening. No destruction. Joint space normal	Unchanged	Good	29	12	9,000	8,000	
2	F 37	Lumbo-sacral angle	Bony (not proved)	31/5/52	1/12/52	250	Frame fixation	122 lb. (55.5 kg.)	125 lb. (56.9 kg.)	133 lb. (60.3 kg.)	Uniform destruction of contiguous margins of L3 and S1; loss of disk space. No abscess visible	No further destruction. Some evidence of healing	"	18	18	15,000	8,000	Tuberculous pleural effusion remained unchanged
3	M 18	Dorsal spine (D8-9)	"	31/5/52	1/12/52	200	"	77 lb. (35 kg.)	84 lb. (38.2 kg.)	92 lb. (41.9 kg.)	Narrower disk D8-9. Small area of destruction lower margin D8. Small peri-spinal abscess shadow	No further destruction. Further loss in disk space. Lesion "hardening" a little	"	55	40	9,000	7,000	Psoas abscess present at onset continued to fill, and an abscess developed on the other side after 3 months' treatment
4	M 25	Lumbar spine (L4-5)	Bony (proved by culture of pus from hip)	31/5/52	1/12/52	300	"	124 lb. (56.4 kg.)	138 lb. (62.8 kg.)	144 lb. (65.5 kg.)	Narrower disk space L4-5. Slight collapse of body of L4. Erosion of anterior part of upper margin of body of L5. Diffuse porosis	A little further destruction of body of L5	"	50	48	8,000	5,000	Developed abscess over hip after 3 months' treatment; it continued to fill and pointed through an aspiration. Sinus periauricular. Organism insensitive to isoniazid after 5 months. Originally sensitive. General and local condition immediately improved on streptomycin after 6 months isoniazid
5	M 12	L. hip	Synovial (proved by biopsy of iliac glands)	31/5/52	1/12/52	200	"	88 lb. (40 kg.)	103 lb. (47 kg.)	113 lb. (51.4 kg.)	Narrowing of joint space. Erosion of acetabulum with small sequestrum. Porosis of head	Some loss of joint space and increased destruction of acetabulum. Roof. Sequestration	Moderate	16	4	9,000	5,500	Left gluteal abscess originally present was aspirated once and has not refilled. (Developed abscess, thought not due to isoniazid)
6	M 11	L. hip	Bony (proved by aspiration of knee and culture of pus from hip)	6/6/52	7/12/52	150	"	59 lb. (27 kg.)	70 lb. (32 kg.)	81 lb. (36.8 kg.)	Narrowing of joint space. Erosion of articular surfaces of tibia, femur, and patella	Porosis much less. Appearance of healing. Improved	"	55	27	8,000	5,500	Thick pus was aspirated from the knee-joint before treatment began
7	F 13	R. knee	Synovial (proved by biopsy)	6/6/52	7/12/52	200	Thomas and plaster gutter splints frame fixation	94 lb. (43 kg.)	114 lb. (51.9 kg.)	132 lb. (60 kg.)	Diffuse porosis. No loss of joint space. No soft-tissue thickening on x-ray	Unchanged	Very good	10	3	10,000	5,000	
8	F 23	L. sacro-iliac	Bony (proved by culture of pus from abscess)	13/6/52	14/12/52	250	"	107 lb. (48.6 kg.)	110 lb. (50 kg.)	107 lb. (48.6 kg.)	Widening and porosis of left sacro-iliac joint	Porosis much less. Appearance of healing. Improved	Good	19	4	9,000	5,000	
9	M 20	L. knee	Bony (proved by aspiration of knee and culture)	13/6/52	14/12/52	300	Thomas and plaster gutter splints	138 lb. (62.7 kg.)	150 lb. (68.2 kg.)	182 lb. (82.7 kg.)	Loss of joint space. Erosion of articular surfaces of tibia, femur, and patella	No further destruction. "Hardening" with much clearer definition	Moderate	10	4	7,000	8,000	
10	M 24	Dorsal spine (D9-10 and D11-12)	Bony (not proved)	27/6/52	26/12/52	300	Frame fixation	131 lb. (59.5 kg.)	137 lb. (62.1 kg.)	135 lb. (61.3 kg.)	Loss of disk space D9-10 and D11-12. Collapse of bodies of D9-10-11-12, with erosion of anterior margins. Paravertebral abscess	Slight collapse of D9 body with further destruction on right side	Good	12	4	6,000	9,000	
11	F 14	L. hip	Synovial (proved by iliac gland biopsy)	25/7/52	29/1/53	150	"	70 lb. (31.8 kg.)	81 lb. (36.8 kg.)	87 lb. (39.5 kg.)	Narrowing of joint space. Diffuse porosis	Slightly narrower joint space, but no destruction. Considerable porosis	Good	47	44	6,000	8,000	Abscess developed in thigh during last month of isoniazid therapy
12	M 45	L. hip	Bony (proved by culture of abscess pus)	1/8/52	3/2/53	300	"	131 lb. (59.5 kg.)	115 lb. (52.3 kg.)	146 lb. (66.3 kg.)	Loss of joint space. Erosion of head. Tendency to subluxation. Gross osteoporosis	No further erosion or tendency to subluxation. Erosion of head improved	"

knee, 4; dorsal spine, 3; sacro-iliac joint, 1; sterno-clavicular joint and ankle, 1. One dorsal spine lesion was accompanied by a tuberculous empyema. Three lumbar spinal lesions had produced palpable abscesses, and there was an abscess over the affected sterno-clavicular joint. No other complications were present when treatment was begun.

As soon as treatment was started the patients were immobilized and the affected bones and joints splinted exactly according to the time-honoured practice of the hospital. A full open-air regime was established, but the patients received no other anti-tuberculosis drugs and no operations were performed apart from biopsy and aspirations of abscesses.

Dosage of Isoniazid.—All patients received 5 mg. of isoniazid per kg. of body weight per day, in two divided doses regularly at 12-hour intervals. The various weights of the patients meant that the doses given ranged from 100 to 350 mg. per day. In most of the patients the body weight changed appreciably during treatment, but we did not adapt the dose to this change. The drug used was "tubomet," kindly supplied by Bengers Laboratories, Limited. For the first two months of treatment the concentration of the drug in the serum was checked at weekly intervals in 10 cases, the estimations being made by Messrs. Bengers. As it was found that the dose was constantly giving a level of between 1.15 and 2.3 mg. of isoniazid per ml. of blood plasma, the estimations were stopped after the first two months. This concentration was regarded as adequate. The drug was given continuously for six months in all cases.

Criteria Studied.—The course of the 20 cases was studied with regard to general health and well-being, body weight, local clinical condition, progress of the lesion as revealed by x-ray films, E.S.R., and sensitivity of the organisms in those patients in whom repeated study of this aspect was permissible. The patients were weighed and x-rayed at the beginning of treatment, after three months, and after six months. The E.S.R. (Wintrobe) and full blood counts were estimated at monthly intervals. Regular routine urine analysis and clinical examination completed the study. A careful watch was kept for toxic effects. It was not possible to establish a control series. It takes years to find a group of identical cases of bone and joint tuberculosis, and for the purposes of this purely pilot survey we thought controls unnecessary as well as unobtainable.

Results

Effect on General Health.—It is, of course, manifestly impossible to analyse the results obtained in 20 patients as one would those of a much larger series, but there is no doubt that an immediate and striking improvement

occurred in the general condition of 17. Many of these patients had been pale and miserable on admission. They immediately developed a sense of well-being, with an increase in appetite and a striking improvement in appearance. The three exceptions (Cases 15, 16, and 17) ultimately improved in the same way, though to a lesser degree, but their early response was disappointing. Neither a good response nor a poor one in those respects, however, gave any indication of what was happening to the local tuberculous lesion. In the 17 patients who looked so much better so soon, this improved in nine, remained apparently unchanged in five, and was actually worse in three. In the three patients who made a disappointing general response the local lesion improved in one and was apparently stationary in the other two.

Weight.—Fifteen patients, not all of whom had apparently improved in health, gained weight steadily and at the end of six months were anything from 11 to 46 lb. (5 to 21 kg.) heavier. Two (Cases 16 and 17) lost weight in the first three months and then recovered it, and ultimately exceeded their starting weights. One (Case 8) gained 3 lb. (1.4 kg.) in the first three months and then lost just as much in the second. Another (Case 18) gained 8 lb. (3.6 kg.) and then lost 18 lb. (8.2 kg.). One (Case 10) gained 6 lb. (2.7 kg.) in the first period and lost 2 lb. (0.9 kg.) in the second. Again, however, there was no apparent correlation between the gain in weight and the progress of the lesion itself. Gains of 18 and 21 lb. (8.2 and 9.5 kg.) went with local deterioration, and a net loss of 9 lb. (4 kg.) with improvement.

Abscesses and Sinuses.—Two of the four abscesses which were palpable when treatment started resolved after aspiration during the course of treatment. The third required incision: the wound was sutured after evacuation of the pus; it healed well. The fourth, originally palpable in one flank, increased in size so as to become palpable in both flanks, although the patient (Case 4) gained 20 lb. (9 kg.). One patient (Case 6) developed an abscess, which became a sinus during treatment, despite a gain of 21 lb. (9.5 kg.) in six months and a good general response. Another patient (Case 12) developed an abscess three weeks after the drug was stopped, at which time his disease (a hip lesion) appeared to be much improved clinically and radiographically.

Changes in X-ray Appearances.—It is, of course, well-nigh impossible to judge, except very broadly, the progress of a tuberculous lesion in its early stages, as shown by x-ray films. Allowing, however, for this difficulty, we feel satisfied in saying that the films in 10 cases showed appreciable improvement. In seven there was no demonstrable change, and in three (Cases 4, 6, and 10) bone destruction advanced despite treatment. Case 6 is of sufficient interest to be described in detail (see below).

E.S.R.—This gave no indication of response. In most cases there was a slow fall over the six months, and in only one (Case 15) was the rate higher after that period.

Insensitivity.—Five patients had abscesses. The pus from one was sterile. Two others cleared up too rapidly for pus to be recovered more than once. In the fourth the organism was never grown in culture but produced tuberculosis in the guinea-pig (Case 4); and in the fifth (Case 6) relative insensitivity was demonstrated after five months' treatment. The abscess over the hip of a boy of 11 appeared after three months' treatment. After three and a half months the organism was sensitive to concentrations of 0.2 mg. per ml. after two weeks' incubation at 37° C., but after five months it was insensitive to 1 mg. per ml. and was inhibited only at a strength of 5 mg. per ml.

Toxic Effects.—One patient (Case 14) developed a rash after four months' treatment. Treatment was not stopped, and the rash disappeared in a week. Another's hair fell out (Case 8). We were unable to convince ourselves that these were toxic effects of the drug, and certainly no others were seen. The white-cell count fell in 9 cases, but never below 5,000 per c.mm. In 10 cases it actually rose.

Case Report

The patient was a boy of 11. Pain in the left hip and a limp had been first noticed in March, 1952. The diagnosis of tuberculosis of the hip had been proved by iliac-gland biopsy in another hospital and the patient was transferred to our care in June, 1952.

On admission he was a pale, thin boy, weighing 59½ lb. (27 kg.). His left hip showed a flexion-abduction deformity, with a good deal of soft-tissue thickening around and in front of the trochanter, and marked pain and spasm on attempts at movement. No abscess was palpable. The biopsy scar in the left iliac fossa was well healed.

A radiograph of the hip showed narrowing of the joint space, porosis of the head of the femur, and a little erosion of the roof of the acetabulum. His E.S.R. was 36 mm. in the first hour (Wintrobe).

The child was splinted on a Robert Jones abduction frame, nursed in the open air, and given 150 mg. of isoniazid daily. After three months his general appearance was much improved, he had gained 11 lb. (5 kg.), but a radiograph of the hip showed further destruction of the acetabular roof, with sequestration. Four months after the beginning of treatment an abscess became apparent and 30 ml. of thick pus was aspirated. *M. tuberculosis* was recovered from this pus, the organism being found to be sensitive to isoniazid at a concentration of 0.2 mg. per ml.

The blood concentration of isoniazid during the first two months of treatment had shown that the dose given was producing a concentration of 1.3 mg. per ml. but, despite the fact that a sensitive organism was receiving an apparently adequate dose of the drug, the disease continued.

The abscess was aspirated five times during the next two months and, despite all precautions, a sinus appeared in December, 1952. In November, 1952, the sensitivity of the bacillus had been reduced so that it was now sensitive only to a concentration of 5 mg. per ml. This concentration was not being obtained.

Gain in weight continued; so did destruction of bone, as shown by the radiograph. After six months isoniazid was discontinued and streptomycin with P.A.S. was given. The E.S.R. rapidly fell to 16 mm. in one hour, the next radiograph showed arrest of the bone destruction, and the sinus began to dry up. By June, 1953, the sinus was healed, the hip lesion quiescent, and the patient's general condition very good.

Comment.—This case is quoted in detail particularly because it illustrates our firm impression that isoniazid alone did not appear to make very much difference, at least during the six months in which it was being given. Even in the cases which improved we felt quite convinced that that improvement was no greater than we would have expected in the days when treatment would have consisted of fixation in the open air without chemotherapy. We were never convinced that the improvement was as great as would have occurred had streptomycin been given instead of isoniazid.

General Conclusions

We do not want to attach too much importance to this small experiment, which we regard as nothing more than a guide to future work, but our impression from these 20 patients is that isoniazid alone is no magical cure for early uncomplicated skeletal tuberculosis, and after six months of its use we felt we could no longer withhold the more certain benefits of streptomycin from our patients. Our original question was, Can anything remarkable be expected from this new drug in six months in circumstances as near ideal as possible? The answer in this series of cases was "No."

Summary

Twenty patients with early uncomplicated tuberculous lesions of bone and joint were treated with recumbency, splintage, an open-air regime, and isoniazid, 5 mg. per

kg. per day, for six months. Neither streptomycin nor *p*-aminosalicylic acid, nor any other drug, was used during this period. There was an almost regular improvement in general health, a gain in weight was usual, but the local tuberculous lesions fared no better and no worse than we would have expected had no drug been used.

We wish to record our gratitude to the members of the consultant staff of the Robert Jones and Agnes Hunt Orthopaedic Hospital, Oswestry, who transferred to our care patients whom we thought suitable for this therapeutic trial; and also to Bengers Laboratories Ltd., for supplies of the drug and for the performance of most of the chemical tests and tests of sensitivity.

MASSIVE LEFT ATRIUM AND MITRAL VALVOTOMY

BY

ALBERT VENNER, M.D., M.R.C.P.

Research Fellow, Guy's Hospital

The frequency with which massive (aneurysmal) dilatation of the left atrium in rheumatic mitral valve disease is associated with predominant mitral incompetence (Parsonnet *et al.*, 1946; Daly and Franks, 1949) has been a factor against attempting mitral valvotomy in such cases (Baker *et al.*, 1952). The case reported here is of interest in that the physical signs were purely those of mitral stenosis, which was confirmed at and relieved by a subsequent valvotomy.

Case Report

The patient, a nulliparous housewife aged 33, gave no history of rheumatic fever. Her heart lesion was first discovered at a National Service medical examination at the age of 23. By the age of 26 she had begun to be aware of dyspnoea on exertion and to have recurrent attacks of winter bronchitis. Her effort tolerance steadily decreased; from the age of 30 onwards she rarely left her second-floor flat because of inability to walk upstairs or more than 50 yards on the level. She used extra pillows at night, but had had no nocturnal attacks of dyspnoea. There had been no haemoptyses, nor congestive cardiac failure with oedema. She had atrial fibrillation, which was presumed to have been present for some years, for she had had a cerebral embolism at the age of 28 and had been on digitalis since the age of 25.

On examination she was very thin, with a pronounced mitral facies, and was dyspnoeic talking at rest. The pulse was of moderate volume, and the blood pressure was 125/80. The jugular venous pressure was not raised and showed no abnormal pulsation. The apex was in the fifth space outside the mid-clavicular line and was tapping in character. There was a widespread systolic heave to the left of the sternum. The first heart sound was loud and abrupt; the second sound was increased in the pulmonary area, with first-degree splitting; there was a very loud mitral opening snap, and a long rumbling grade 3 mitral diastolic murmur at the apex. Systolic murmur was not heard. She had impaired resonance to percussion over the right lower chest posteriorly. There was no hepatic enlargement or pulsation.

Radioscopy of the chest showed a large dense heart shadow, mainly due to gross enlargement of the left atrium (see Fig.). No pulsation of the atrium was apparent in either the anterior or the oblique views. The pulmonary arteries were considerably enlarged; the aortic knuckle could not be clearly distinguished; and no calcification of the

valve cusps was detected. The electrocardiogram (multiple unipolar leads) showed atrial fibrillation and considerable right ventricular preponderance.

At cardiac catheterization the following observations were made at rest:—Pressures (in mm. Hg to mid-point of chest): right atrium, mean 4; pulmonary artery, 52/26, mean 34; pulmonary capillary, 23/18, mean 20. Cardiac output,

Radiograph of the chest. Radioscopy showed that the right border of the heart in this view is formed by the left atrium, which owing to its size and density obscured the outline of the right atrium.

2.4 litres a minute. Cardiac index, 1.7 litres/sq.m./min. Blood oxygen saturation: pulmonary artery, 59%; brachial artery, 96%. Blood oxygen combining power, 17.7 ml./100 ml. Calculated pulmonary arteriolar resistance, 560 dynes/sec./cm.²

As her disability was considerable and her physical signs were those of mitral stenosis, mitral valvotomy was carried out by Mr. R. C. Brock on January 21, 1954. The pressure in the pulmonary artery was 48/27, mean 34 mm. Hg; and in the left atrium was 25/19, mean 21 mm. Hg. The enormous size of the atrium was confirmed. A large amount of old and recent thrombus was encountered in the appendage and in the body of the atrium, much of which was washed out by permitting free bleeding. It was regarded as impracticable to attempt to remove all clot from the atrium. Embolism of the carotid vessels was guarded against by occluding them by tapes while the valve and deeper parts of the atrium were explored. To the examining finger the valve orifice appeared to be about 4 mm. in diameter; the edges were fibrous, but no calcium was felt in the cusps; no regurgitation could be detected. Complete separation at both commissures was effected by means of a valvotome. The chordae tendineae were fibrous and fused, but the cusps opened completely at the medial commissure and partly at the lateral commissure. The resulting valve orifice was large and there was a little regurgitation.

Three weeks after the operation she was able to walk up three flights of stairs; at the time of writing her exercise tolerance was still improving.

Comment

The case of massive left atrium reported by Parsonnet *et al.* (1946) showed gross rheumatic mitral incompetence at necropsy. A review of the reported rheumatic cases suggested that this association was invariable, and they concluded that mitral incompetence was a causal factor in the production of massive left atrium, and that mitral stenosis was not. Similarly, Daly and Franks (1949) found clinical evidence of mitral incompetence in all their 15 cases of massive left atrium.

It is generally agreed that the severe fibrosis and loss of muscle fibres seen in the atrial wall in this condition are evidence of particularly severe local damage from the original rheumatic process, and that this is the prime causal factor of the extreme dilatation. Observation that the pressures in the left atrium are as high in mitral stenosis as in mitral incompetence (Venner and Holling, 1953) suggested that mitral incompetence need not be a concomitant factor, and it was of particular interest to observe this patient, in whom the physical signs were clearly those of mitral stenosis and in whom the left atrial pressure (at operation) was only moderately increased.

The diagnosis of mitral incompetence is difficult, and many of the accepted physical signs are unreliable, especially when there is also stenosis—although it seems to be general experience that where the physical signs are purely those of mitral stenosis alone (tapping apex beat, slapping first heart sound, mitral opening snap, rumbling apical mid-diastolic murmur), incompetence of an important degree is not found at operation. The case reported here offers a further illustration of this point and also shows that massive dilatation of the left atrium is not unequivocal evidence of mitral incompetence. In rheumatic heart disease both massive left atrium and gross mitral incompetence appear to result from a particularly severe rheumatic injury and their observed association probably depends on this fact alone.

I wish to thank Dr. C. G. Baker and Mr. R. C. Brock for encouragement to prepare this report.

INTRA-ARTERIAL THERAPY IN OCCLUSIVE VASCULAR DISEASE

BY

J. WOODROW BETTS, M.B., F.R.C.S.

Surgical First Assistant, Royal Infirmary, Sheffield
(From the Peripheral Vascular Clinic, Royal Infirmary, Sheffield)

Degenerative arterial disease of the lower limbs produces intermittent claudication, ischaemic necrosis, or both. At the present time it is not possible to reverse this degenerative process. Consequently, treatment aims at the opening up of a collateral circulation and the abolition of sympathetic tone. Since occlusive vascular disease affects all the vessels in some degree, the best that can be hoped for is the maximal dilatation of all the arteries in the limb. In order to obtain the greatest local effect without a general vasodilatation, injection of drugs direct into the femoral artery has been advocated. Trying a series of drugs, Edwards *et al.* (1952) found papaverine and tolazoline (benzyl-imidazoline, or "prisco") to be most effective in their action, and reported some success in the treatment of these cases.

Selection and Technique

The present investigation was deliberately kept on an entirely clinical basis, as the object was to assess the value of these two drugs as a routine method of treatment in a busy peripheral vascular clinic. No attempt was made to measure the effects instrumentally by temperature change, oscillometer, or claudicometer. It was thought that if such therapy was to be of practical value it must produce symptomatic improvement. With this in mind the following procedure was adopted. Any patient arriving at the peripheral

vascular clinic suffering from intermittent claudication or ischaemic necrosis due to occlusive vascular disease was, without selection, started on a course of injections. The first 20 were given papaverine and the next 20 tolazoline. Both legs were treated when both were the subject of complaint. The course consisted of one injection a week into each artery for six consecutive weeks. The amounts used were papaverine 40 mg. in 20 ml. of saline and tolazoline 100 mg. in 20 ml. A 20-ml. syringe fitted with a No. 17 B.W.G. needle which had been ground down to a short bevel was used and the injections were made into the femoral artery immediately below Poupert's ligament. After a little practice no difficulty was experienced in the introduction, the injection being made against the flow of the blood. No local analgesic was used, and the patients were allowed to travel home shortly after the treatment. No untoward happenings occurred.

The sex and age groups of patients in the series are shown in Table I.

TABLE I.—Sex and Age Groups of Patients

Drug	Male	Female	Age Range			
			40-49	50-59	60-69	70+
Papaverine	18	2	2	8	7	3
Tolazoline	16	4	2	9	8	1

Results

Immediate Effect.—On making the injection most patients showed a rapid response with a local flush. This was most pronounced in the thigh, and almost always demonstrated the territory of the superficial external pudendal artery by a flush over the pubes. However, the extent down the limb varied, as did the patient's impression of warmth. In some it went as far as the knee; in others it included the whole limb. With tolazoline a general vasodilatation rapidly followed, and often shivering. The local flush was quite transient, lasting between 10 and 30 minutes. After this the patient felt quite normal. These injections were made by four different workers.

Assessment of the result was made by seeing the patient two weeks after finishing the course and again a month later. In the case of intermittent claudication he was asked how far he could now walk, and he was allowed to compare this with some definite distance he had to walk during the day. His own estimate had already been recorded before starting treatment. Usually it was possible to find how far he walked without pain first thing in the morning—for example, on going to work. In assessing these results alleged improvements or deteriorations of a few yards were

TABLE II.—Response in Intermittent Claudication

Drug	No. of Cases	Immediate Flush to Toes	Final Improvement

Total	28	16	2

TABLE III.—Response in Ischaemic Necrosis

Drug	No. of Cases	Immediate Flush to Toes	Final Improvement
Papaverine	5	5	5
Tolazoline	7	5	4
Total	12	10	9

neglected—bearing in mind the stated object of the inquiry. Again four persons were engaged in the assessing. In ischaemic necrosis the healing was taken as the criterion, local treatment being confined to a dry dressing and crêpe bandage.

Tables II and III summarize the results in intermittent claudication and ischaemic necrosis respectively.

Discussion

Although this series was kept small because of the possible consequences of repeated arterial puncture, I feel that the results are significant. It seems that in intermittent claudication the benefits do not warrant this treatment. In ischaemic necrosis it would appear to be a worth-while procedure, especially as it can be performed in an out-patient clinic. Moreover, it seems to be a good alternative to lumbar sympathectomy, and can, of course, be applied to patients unfit on general grounds for a major operation. However, the results seem to suggest that the mechanism is just like that of sympathectomy in that the skin receives more benefit than the muscles; and this observation agrees with the findings of Lynn (1950), although he quotes Dr. H. T. C. Swan as having found increased blood flow in the sympathetomized hand after intra-arterial injection. Perhaps, too, the explanation lies partly in the transience of the response, the healing of an ulcer being helped even by a short-lived increase in blood supply. Indeed, Wilson and Quash (1951), studying the effects of tolazoline, also came to the conclusion that it was valuable in the treatment of refractory leg ulcers. It is worthy of note that Douthwaite and Finnegan (1950) were impressed by the results of oral tolazoline in patients with intermittent claudication.

It would be interesting to compare the results of intra-arterial injection with those of lumbar sympathetic block with phenol in the cases of ischaemic necrosis. Such a series is at present being investigated, but, of course, takes a longer time to complete, as ischaemic cases are less frequent than those with intermittent claudication.

Summary

A series of cases is described in which obliterative arterial disease of the lower limb has been treated by intra-arterial injections. Broadly, two groups of cases arise, one complaining principally of intermittent claudication and the other of ischaemic necrosis. The drugs used were papaverine and tolazoline. The results are assessed on a clinical basis with a view to finding a practical line of therapy.

The opinion is expressed that in intermittent claudication the method is not warrantable, whilst in ischaemic necrosis it may be a valuable adjunct to local treatment.

I wish to thank Mr. Clifford Jones, in whose peripheral vascular clinic this work was carried out, for his help and encouragement; and Mr. H. Ellis, Dr. F. Lothe, and Dr. H. W. Chambers for practical assistance.

The Minister of Health, Mr. IAIN MACLEOD, speaking at the annual luncheon of the Hotel and Catering Institute in London, said that he was looking to hospital authorities to give a lead in standards of cooking and kitchen hygiene. He was pleased to say that the national scheme for training apprentice cooks in hospitals was getting off to a good start. Although the hospital authorities were only given details of the scheme in March, preliminary inquiries had already been received from over 80. Some idea of the extent of catering in hospitals could be gained from the budget for food in hospitals in England and Wales, he continued. In the year 1952-3 the cost was over £30m., or about one-eighth of the total expenditure of the hospital authorities. In addition, the wages of catering officers, dietitians, and other senior catering staff amounted to nearly £7m.

Medical Memoranda

Ulcerative Stomatitis Associated with Symptoms of Peptic Ulcer

The following case is of interest from both a diagnostic and a therapeutic point of view, and is one which I have had the opportunity of observing over a long period.

CASE REPORT

A woman aged 56 had had intermittent indigestion for many years. Her pain was epigastric, occurred half to one hour after food, was increased by meat, soups, and any form of alcohol, and was relieved by alkalis. There were periods of freedom, and the picture appeared to be typical of peptic ulceration. The blood count was normal. This diagnosis was reinforced by the family history. Her father had had a gastro-enterostomy for duodenal ulcer, a paternal uncle had died of a perforated duodenal ulcer, and two paternal cousins had had duodenal ulcers, in one of whom the ulcer had perforated. On the other hand, a paternal grandfather had died of pernicious anaemia.

Eighteen months previously the patient had developed ulcers of the mouth and tongue. At first they were intermittent, but later the exacerbations became so frequent that she was never entirely free. She could not eat with comfort, and spiced foods, vinegar, and alcohol produced considerable distress. During this period the indigestion also became worse, and invariably followed a heavy meal. Six months later she had agreed to have a barium meal and a gastric analysis. The x-ray film showed no abnormality and the gastric analysis a complete achlorhydria. Hydrochloric acid was given, but was soon abandoned as it increased the dyspepsia, which indeed continued to be relieved by alkali. The ulceration of the mouth got worse and nothing gave any relief, although the pain subsided temporarily with an alkaline mouth wash.

Two months ago I decided to try vitamin B₁₂, which was given in the form of "cytamen." At first she had an injection of 50 µg. (1 ml.) twice weekly; this was reduced to 1 ml. a week and eventually to 1 ml. a fortnight. Within a few days the ulcers had improved and in a week they had disappeared and have never returned. The indigestion also improved and she was able to take a normal diet and an occasional glass of sherry without any discomfort. She felt better than she had been for many years.

COMMENT

In this case all the symptoms suggested peptic ulcer, but the x-ray examination was negative and achlorhydria was present. There was an ulceration of the mouth and tongue, which was intermittent as in peptic ulceration. The family history of duodenal ulcer suggested that hyperchlorhydria was present in many members. On the other hand, the history of a grandparent who suffered from pernicious anaemia is evidence of another hereditary factor which produces an achlorhydria.

The theory I would put forward is that in my patient the two factors were present, but the tendency to ulceration was kept in check by the absence of acid, which prevented any gross and demonstrable ulceration from occurring. The administration of acid undoubtedly increased the indigestion, and it is probable that it would have led to frank ulceration if it had been persisted in. The simultaneous appearance of ulceration in the mouth and the increase in the indigestion, together with the immediate relief of both by vitamin B₁₂, suggests that the superficial ulceration of the mouth was associated with a similar condition in the stomach, and that the cause of both was the absence of some constitutional factor which was replaced by the injection.

The temporary relief from the indigestion brought about by alkali cannot be explained by neutralization, but was due to some other cause, and its action was similar to that

experienced in the relief of pain from ulcers in the mouth. I would suggest that a trial of vitamin B₁₂ might be helpful in the early stages of peptic ulceration.

T. H. OLIVER, M.D., F.R.C.P.

Bronchial Adenoma

Adenoma of the bronchus, a relatively rare condition occurring in approximately 6% of all bronchial tumours (Kramer and Som, 1935), is often not diagnosed for a considerable time after the onset of symptoms. The following case occurring in general practice is reported as a reminder of the disease and to record its unusual features.

CASE REPORT

A housewife aged 67 was in good health until April, 1952, when she developed a mild respiratory tract infection with an irritant cough, producing a symptom described by the patient as "like a bell ringing" in her chest. The illness resolved in 14 days with only symptomatic treatment. She became well and symptom-free, apart from slight loss of weight. Four months later (August) she developed a similar though more severe illness, with continued fever (maximum temperature 103° F.—39.4° C.), irritant cough, and a little sputum. Physical signs of right lower zone bronchopneumonia developed. Her condition was not improved after a course of "sulphatriad," and her fever and physical signs resolved slowly during the next two weeks, after six daily injections of procaine penicillin, 300,000 units.

Chest x-ray examination as soon as she was ambulant, 18 days after the onset of symptoms, showed a rounded shadow adjacent to the right hilum, with no apparent peripheral collapse. There was no relevant past history or family history; she was an occasional smoker (one or two cigarettes a day).

On September 17 she was seen by Mr. O. S. Tubbs, who found no abnormal physical signs. Two weeks later, while awaiting admission for investigation, she suddenly collapsed in her home with acute pain in her right lower chest. On examination shortly afterwards she was found to be collapsed and dyspnoeic, her pulse was 90, temperature 98° F. (36.7° C.), respirations 26. The trachea was displaced to the left, and physical signs of a right pleural effusion were present. Chest x-ray examination confirmed the findings of collapse of the right middle and lower lobes, with an effusion.

She was admitted urgently to the Thoracic Unit, St. Bartholomew's Hospital, where diagnostic aspiration of the effusion in three places produced blood only. The sputum showed no tubercle bacilli, and grew only a scanty growth of *Neisseria catarrhalis*.

Bronchoscopy (Mr. O. S. Tubbs) showed: "Protruding out of the right middle lobe bronchus was a small pale-pink cherry-like tumour. The bronchoscope could be passed beyond this into the lower lobe, which appeared normal. Biopsy specimen taken; rather profuse bleeding." The histological report on this specimen is of a "poorly differentiated adenocarcinoma."

At thoracotomy five days later a massive—2–3 pints (1–1.5 litres)—heavily blood-stained effusion was found, thought probably to be due to pleural carcinomatosis in view of the biopsy report and clinical picture presented. Accordingly, a right pleuropneumectomy was performed.

The patient made an uninterrupted recovery, and was discharged from hospital 15 days later. She has remained well since.

It was subsequently evident from examination of the specimen that haemorrhage had occurred into the middle lobe behind the tumour, and that the middle lobe itself had ruptured, causing considerable haemorrhage into the pleural cavity. This undoubtedly occurred two weeks before her operation, and had caused her collapse in her home and her subsequent sudden deterioration at that time.

Pathology.—The tumour measured 7 by 6 by 5 cm. The only remaining lung tissue of the right middle lobe was a

portion of the medial segment and a thin peripheral zone stretched over the tumour mass. Anteriorly there was a rupture of the middle lobe and visceral pleura, with haemorrhage into the adjacent rim of lung tissue and into the pleural cavity. Histologically, the tumour was found to be projecting into the lumen of the bronchus, to have an adenomatous appearance, and to show no infiltration of deeper structures. The specimen was examined at the Institute of Diseases of the Chest, Brompton, London, and five different opinions were given: (1) Columnar-celled carcinoma of the bronchus; (2) bronchial adenoma of low-grade malignancy, or possibly secondary malignant change in pulmonary adenomatosis; (3) benign adenoma; (4) malignant adenoma; and (5) adenoma.

COMMENT

Adenoma of the bronchus is slightly commoner (62%) in females (Foster-Carter, 1941). Symptoms may occur at any age, the average age of onset being 28. Diagnosis is most commonly made during the fourth decade, an average of five years after the onset of symptoms (Foster-Carter, 1941). Cough, haemoptysis, and symptoms due to bronchial obstruction and its sequelae are predominant.

Radiological evidence of bronchial obstruction and/or the presence of an opaque tumour point to the diagnosis, which must then be confirmed by a bronchoscopic biopsy. The tumours are more commonly in the main bronchi, and therefore relatively accessible to the bronchoscope. Histologically the precise nature of the tumour is often difficult to assess, and differences of opinion are common. The cells are usually uniform in shape and size; the cytoplasm is clear, and forms a fringe round the large deeply staining nucleus.

The tumours should be regarded as borderline between innocence and malignancy (Jackson and Norris, 1951). They may be locally invasive, and, very rarely, metastases have occurred through lymphatics (Adams *et al.*, 1942). Malignant adenocarcinoma developing in an adenoma has been demonstrated histologically (Umiker and Storey, 1952).

Treatment of this potentially malignant condition varies from pneumonectomy, lobectomy, resection of the bronchus with end-to-end anastomosis (D'Abreu and MacHale, 1952) to piecemeal bronchoscopic resection, varying with each individual case. Opinion is now more in favour of exploratory thoracotomy and lobectomy as the operation of choice (Delarue, 1951). Radiotherapy is not of proved value in treatment (Jackson and Norris, 1951).

I wish to thank Mr. O. S. Tubbs for permission to publish his case notes, and for his help and encouragement; Dr. G. J. Cunningham, senior lecturer in morbid anatomy, St. Bartholomew's Hospital; and the Department of Pathology, St. Bartholomew's Hospital, for the preparation of slides.

The United States Armed Forces Institute of Pathology is to collaborate with a group of Japanese pathologists headed by Dr. TORU MIYAJI, professor of pathology at the Osaka University Medical School, in preparing a Japanese textbook on histopathology. The Institute will contribute about 300 standard photomicrographs to illustrate typical pathological conditions. The textbook is for use by Japanese medical students. Co-operation from the United States was requested for illustrations because of the difficulty of obtaining such material in the Far East. The project is expected to be completed within six months.

Reviews

THE VIRUS FRONT

Advances in Virus Research. Volume I. Edited by Kenneth M. Smith and Max A. Lauffer. (Pp. 362; illustrated. \$8.) New York: Academic Press Inc. 1953.

The problem of keeping abreast of the literature of any subject these days is one with which everyone engaged in medical research is only too familiar, but it is probably true to say that virus workers face this problem in its most acute form. Viruses are the cause of disease in animals and plants as well as in man; they are susceptible of investigation by a variety of scientific disciplines and their literature is widely scattered through a large number of journals. It is difficult, therefore, for the virus worker to keep himself widely informed of what is happening in all fields of virology, and it is with a view to remedying this that *Advances in Virus Research* is being produced. It is planned to publish in successive volumes authoritative review articles on all important aspects of virus research, and it can safely be predicted that if the standard set by Volume I is maintained in the rest of the series the editors will have amply achieved their object.

This volume begins with an article on the properties of the bacteriophage by H. T. Epstein which is especially valuable, since these viruses and their bacterial hosts have been used extensively for the study of problems concerned with host-virus relationship and in particular the nature of virus multiplication; in fact our views on this latter question have been largely coloured by the findings obtained with the bacteriophage. The interaction between viruses and virus strains, which include the interference phenomenon, is considered by C. W. Bennett; there is much of interest here, even though the illustrative examples are drawn almost exclusively from plant pathology. Another section by a transplant pathologist is on the role of leaf hoppers in the transmission of plant viruses by L. M. Black, and, following this, mission of plant viruses by G. H. Bergold provides a most instructive and beautifully illustrated account of insect viruses. This is of particular value, since there is probably no aspect of virology of which those who work with animal viruses are more ignorant. It is interesting to note how these viruses resemble the influenza viruses in the possession of both spherical and rod forms; it is also of interest that the author seems in no doubt as to the nature of these insect viruses—for him they are micro-organisms.

Of the viruses peculiar to man those of influenza and poliomyelitis find a place in this volume. Henle writes of the multiplication of influenza virus, and a first-class article it is. It is, of course, well known that a great deal of the work on this subject has been done by Henle and his colleagues, so the excellence of this particular section is not surprising. What is particularly attractive about it is the detached and unbiased way in which the author examines the evidence and draws his conclusions, which is by no means invariably the case in writings on this highly controversial subject. A most valuable article on poliomyelitis comes from J. L. Melnick, who has been in the forefront of research on this disease and its causal viruses during the last ten years or so. The volume is completed by a section on the purification and properties of animal viruses contributed by Dr. Gordon Sharp, and a short but most interesting account of virus nucleic acids by Roy Markham.

S. P. BEDSON.

INTERPRETATION OF AGGRESSION

Aggression and Its Interpretation. By Lydia Jackson, D.Phil., B.Sc.(Oxon.). Foreword by Felix Brown, D.M., M.R.C.P. (Pp. 237. 21s.) London: Methuen and Co. Ltd. 1954.

Miss Jackson has built up a considerable body of experience of child therapy which fully justifies her in writing a book. Moreover, she has added to her clinical statement a compara-

tive study of three groups of children based on her particular form of projection test.

While the reviewer can recommend this book for reading and for study, there is a peculiar difficulty arising out of the fact that Miss Jackson, while choosing to write on the subject of aggression, has "scotomized" the pioneer work which has enabled psycho-analysis and psychotherapy in general to take aggression into account. It is well known that it is through the work of Melanie Klein, dating from about 1923, that the theory underlying our work has come to include destructiveness and aggressiveness and the complex relationship of these to the erotic instinctual life. There is a complex theoretical construction here which covers the origin of guilt feelings and the important relationship of restitution tendencies to aggressive ideas, to which the author refers. It is certainly not necessary for Miss Jackson to agree with the Klein development of psycho-analytic theory, but it is not possible, in writing a book on aggression, simply to ignore this work and to give 38 references without mention of Mrs. Klein.

An intuitive flash of the author quite possibly goes very deep: "the primary, powerful innate urge to self realization as the basis of aggression."

As the author is apparently unaware of the theory of the very complex early development of the child, she is thrown back on the idea of the transformation of the child's destructiveness and hostility into constructive and friendly co-operation as something that results from the friendliness and tolerance provided by the therapist. One thoroughly believes in her results, which in some cases have been good, but Miss Jackson's theory as stated in this book appears to the reviewer to be deficient. One consequence of the naïveté of her theory as it is stated is that the author seems to leave out the important subject of aggressiveness related to paranoid organizations.

INTRODUCTION TO TROPICAL PATHOLOGY

An Introduction to Pathology and Bacteriology for Medical Students in the Tropics. By the late E. C. Smith, B.A., M.D., D.P.H., Sc.D.(Dubl.), M.R.C.P.Lond., M.R.C.P.I., D.T.M.&H.Eng. Second edition. Revised by R. Kirk, O.B.E., B.Sc., M.D., D.P.H., F.R.F.P.S.Glas., M.R.C.P. Lond., F.R.S.Ed. (Pp. 390; 78 figures and 18 coloured plates. 50s.) London: Staples Press Ltd. 1953.

The harassed student is often at a loss to know just how much he is expected to learn for his examinations. Lecture notes are apt to be sketchy and disjointed, while the standard textbook is too elaborate and detailed to be easily mastered. Kirk's revision of Smith's *Introduction to Pathology and Bacteriology* can justly claim to fill the gap, being practical rather than academic, and neither too long nor too short. It is eminently readable and lucid, and is sufficiently detailed to provide the student with a sound background which will enable him, when the time comes, to make intelligent use of more advanced textbooks. The illustrations are numerous and clear, and the arrangement of the chapters logical. The first four deal with pathological processes and tumours; the next fourteen, with the pathology of diseases caused by infective agents of all kinds, which is of course the predominant type of illness in the Tropics. The last four chapters are devoted to the special pathology of certain organs and systems. Although the descriptions of the different conditions are necessarily brief, it is obvious that they have been written by someone with a wide practical knowledge of the subject. All the more important details are emphasized, and little that is of practical importance is omitted. The chapters on fungal, protozoal, and helminthic diseases deserve special mention, and within the space available give a well-balanced account of the pathological changes in and the diagnosis of these infections. An appendix in which the various causes of lymphadenopathy are tabulated will be of much practical use, and another on post-mortem technique should go a long way to improving the standard of necropsies when these have been carried out by someone with little previous experience.

This book can be strongly recommended not only to medical students in the Tropics, for whom it is written, but to anyone who may need a succinct and reliable account of the pathology of tropical diseases.

J. S. K. BOYD.

NEUROANATOMY

Human Neuroanatomy. Third edition, revised. By Oliver S. Strong and Adolph Elwyn. (Pp. 481; 357 illustrations. 57s. 6d.) London: Baillière, Tindall and Cox. 1953.

A book is obviously meeting with a demand when it reaches its third edition and has had no fewer than four reprints of its earlier editions. The present volume has undergone much judicious revision, for which, presumably, Dr. Elwyn was responsible, as his name alone is attached to the preface. There has been much re-writing and some expansion, including the introduction of a number of new and useful figures. The advances in neuroanatomy and neurophysiology made during the past ten years have been handled with discretion, and are woven rather than intercalated into the text. Consequently the staccato effect, so obvious and so irritating in many revisions, is pleasantly absent. A sense of proportion, too, is shown in the manner in which the more recent contributions have been handled, and the bibliography, though extensive, is judiciously selected. Some parts of the text, however, notably that on the olfactory system, would benefit from even more revision.

A good feature of this text is the attempt to link up the central nervous anatomy with the arrangements in the periphery. That this attempt is not always satisfactory is in the nature of things not surprising, and some attention to the figures, which are not always lucid or well considered, meant to demonstrate the integration of centre and periphery would make the book more useful. For example, Figs. 141 and 142 both show the brachial plexuses, but they show absences of correspondence that are bound to be confusing to the student; indeed, Fig. 142 contains the error of deriving the thoracodorsal and long thoracic nerves from the medial cutaneous nerve of the arm.

But it would be churlish to end this brief review with a critical note. The volume under consideration is one example of the contemporary attempt to bridge the gap between our knowledge of the structure of the nervous system and established facts and suspicions about its function. That such attempts should at this stage of the integrative process be, in some degree and in certain directions, faltering is not surprising. The important thing is that the integration is made, and in due course the details will doubtless sort themselves out. Certainly no student will be at a disadvantage for having read this new edition of Strong and Elwyn, and some teachers might even find it advantageous.

J. D. BOYD.

NEUROLOGY AND PSYCHIATRY

Physiological Foundations of Neurology and Psychiatry. By Professor Ernst Gellhorn, M.D., Ph.D. (Pp. 556. \$8.50 or 68s.) Minnesota: University Press. London: Geoffrey Cumberlege. 1953.

The subject-matter of this volume is intentionally far more restricted than is indicated by its title and depends on the interests of the author, who states in his preface: "By no means all, but only some, physiological foundations of neuropsychiatry are treated, those with which the writer is familiar through his own experimental work." Thus certain subjects are considered at greater length than their importance in clinical neurology and psychiatry would warrant—for instance, the autonomic nervous system and the physiological foundation of carbon dioxide therapy. On the other hand, there is no mention of some problems which are often encountered in practice and which in addition have a well-understood physiological basis: in this category migraine and the premenstrual tension state come to mind.

This intentional restriction of choice of subject-matter, however, is of less importance than the limitations of

approach due to the disproportionate consideration of the results of animal experiment. These limitations are of particular importance in this field of inquiry, since few neurological and probably no psychiatric disorders can be adequately reproduced in animals. Thus, to take the instance of E.C.T., it is doubtful what relevance the physiological response of a normal animal may have to the psychological response of a patient suffering from an endogenous depression. The author has failed to take advantage of one way of overcoming these limitations—namely, by drawing upon clinical neurology, whether for illustration, as for instance of the state of stupor, or for the enlightenment that animal experiments cannot give, as is the case with the problems of phantom limb and of anosognosia.

Within these limitations this book gives a competent and readable account of various selected aspects of the physiology of neurology and psychiatry. The neurologist has been well served of late with monographs and published symposia on various aspects of neurophysiology, and will be well advised to refer to these rather than to the corresponding sections of this book, with the exception of the chapters on the physiology of the motor cortex, which are excellent. On the other hand, the psychiatrist will find much information not well summarized elsewhere, in particular in the sections on physiological changes in emotion, on modifications in conditioned reflexes and autonomic reactions by shock treatments, and on the prognostic value with respect to response to E.C.T. of the blood-pressure changes after the injection of mecholyl. These sections give rise to hope of further advances in the understanding of the mechanisms involved in the physical treatments in psychiatry.

R. T. C. PRATT.

THERAPEUTIC ACCIDENTS

Maladies Medicamenteuses d'Ordre Therapeutique et Accidental. By Claude Albahary. Preface de A. Tzanck. Avec le concours de D. Christol, B. Damoiseau, N. Pardon, R. Umdenstock, J. Vacher. (Pp. 752; 55 illustrations. Paper bound 4,400 fr. Leather bound 5,500 fr.) Paris: Masson et Cie. 1953.

Fortunately for the reviewer, Dr. Albahary says in the introduction to his book that he does not expect that anyone will read it through from cover to cover; it is meant rather for someone looking up information about a case or about a treatment with which he is not familiar. Professor Tzanck in his preface makes clear the distinction between intoxication and intolerance. Intoxication is the result of an overdose of a drug, actual or relative; it can be reproduced in animals and the symptoms are specific for the drug. Intolerance, which is much more common in practice, occurs with a normal or even with a very small dosage. It is the result of individual predisposition, the symptoms cannot be reproduced in animals, and they are not specific for the particular drug. The therapeutic revolution of the last half-century has been associated with the introduction of large numbers of drugs from which people develop symptoms of the second type. We are by now familiar with the fact that the symptoms and frequency of intolerance cannot be predicted from experiments in animals and often require a decade of clinical trials for their assessment. The book is arranged under the headings of mineral compounds, synthetic compounds, antibiotics, drugs from plants, hormones, and glandular substances, vitamins, haematinics, transfusions, sera, vaccines, inoculations, and shock-therapy. There is a good table of contents and a reasonable index, and it is easy to find one's way about the book. References are perhaps not so copious or conveniently arranged as in comparable American and English books. There are just over 50 diagrams and illustrations in black-and-white. The text is extremely up-to-date and has stood up well to sampling. For the moment, at any rate, the book appears to be unique in the range and depth of the information it provides on the accidents of therapeutics.

L. J. WITTS.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY JUNE 12 1954

RADIOACTIVE IODINE IN THE TREATMENT OF ANGINA

In a recent review of the treatment of angina pectoris Dr. Paul White referred to the use of radio-iodine in this condition.¹ Several years ago Lev and Hamburger² pointed out that thyrotoxic patients may suffer from angina, which usually disappears after thyroidectomy. This observation led Blumgart and his colleagues^{3,4} to propose thyroidectomy as a possible method of treatment for angina and congestive cardiac failure in patients with normally functioning thyroids. They argued that when the basal metabolic rate was retarded the demands on the heart might be correspondingly reduced. Several series of patients were treated in this way, and in at least half the cases improvement is said to have occurred. The selection of patients was such as to make it most unlikely that the successes were due to spontaneous recovery. In a few cases the results were quite spectacular, some patients who had been bedridden for years with attacks of angina at rest being able to go back to a full day's work after the treatment.

Owing to the dangers of surgery in patients with advanced cardiac disease thyroidectomy could not be extended to all those for whom it might otherwise have been suitable.⁵ But when thiourea and other antithyroid agents became available there were grounds for hoping that the same results could be achieved without the risks of an operation. Good results were soon reported by several groups of workers.⁶⁻¹² There are, however, certain rather serious drawbacks to this type of "medical thyroidectomy" by substances acting by inhibition of the synthesis of thyroid hormone.¹³ The normal thyroid contains a large store of hormone and only a very

small part of this store is secreted each day; consequently the B.M.R. does not fall until the antithyroid drug has been given continuously for several months. Moreover, the treatment must usually be continued for the remainder of the patient's life and entails the constant danger of drug sensitivity or damage to the blood-forming organs.

Radioactive iodine has been shown by Blumgart and his co-workers to be a more satisfactory method of inducing hypothyroidism.^{14,15} The thyroid accumulates radio-iodine to a much greater extent than any other tissue, so that it can be completely destroyed by a dose of I¹³¹ which is without harmful radiation effects on the rest of the body. For example, a normal person's thyroid can be destroyed by a dose of I¹³¹ which will give to the blood a radiation dosage less than twice that to the abdomen during a diagnostic x-ray examination of the gastro-intestinal tract. This method of treatment has now been used extensively for several years.¹⁶ The patients who respond most favourably are those with angina due to coronary atheroma, but some cases of congestive cardiac failure from other causes may also benefit. The clinical response occurs more rapidly than is the case with antithyroid drugs, and the side-effects are generally trivial and short-lasting. In a few patients given the largest doses there may be a temporary exacerbation of symptoms owing to the rapid liberation of thyroid hormone into the blood stream, but this can probably be avoided by giving the radio-iodine in divided doses. In Blumgart's series of cases the best results were obtained by total destruction of the thyroid, followed by a daily dose of thyroid hormone sufficient to keep the B.M.R. at about 20% below the normal level. Patients treated in this way are said to have obtained great relief from their symptoms without suffering from the discomforts of myxoedema. But other workers have found it more difficult to strike this balance.

The mechanism by which thyroidectomy relieves some patients of angina is not altogether clear. It has been shown that the resting cardiac output is reduced in myxoedema¹⁷; this seems to be due not only to the diminished oxygen requirement of the tissues at rest, but also to more efficient utilization of oxygen,¹⁸ so that for a given oxygen demand by the body a smaller blood flow is required in the hypothyroid state. However, these factors can hardly explain the greatly increased exercise tolerance observed in some of Blumgart's patients, because during muscular work the basal oxygen consumption is only a small proportion of the total. It is difficult to see why a man who gets attacks of angina at rest when using 300 c.c. of oxygen per

minute, and is free from attacks at rest after his B.M.R. has been reduced by thyroidectomy, should not get his pain again when he increases his oxygen consumption to, say, 600 c.c. per minute by walking along the flat. Evidently the relation between thyroid function and anginal pain is far from being the simple one originally postulated by Blumgart. Emotional stimuli are known to precipitate attacks of angina at rest and may also increase the ease with which angina is brought on by muscular effort. The increased emotional stability which usually follows thyroidectomy might be expected to reduce the number and severity of attacks at rest or during exercise.¹⁵ It has also been claimed that thyroidectomy lessens the sensitivity of the cardiovascular system to adrenergic stimuli,⁶ but the evidence for this is not conclusive in humans. A further possibility is that the heart uses its oxygen supply more efficiently and so is able to do more work without becoming anoxic. Evidence on this point could be obtained with the methods now available for the direct study of cardiac metabolism by catheterizing the coronary sinus.¹⁹

There is now little doubt that "radio-iodine thyroidectomy," because of its permanence, simplicity, certainty, and freedom from serious side-effects, is the best available method for reducing the activity of the thyroid in patients with intractable cardiac disease. But more experience is needed before it can be said whether the induction of a state bordering on myxoedema should be more widely extended or should be reserved for a few patients who fail to respond to all other forms of treatment. Carefully controlled studies are needed to show whether thyroidectomy prolongs the comfortable life of these patients or whether it tends to shorten life by accelerating the development of coronary atheroma.

QUESTIONNAIRES IN CLINICAL TRIALS

Some clinical trials have been carried out in such a way that, in spite of the difficulties of measuring clinical responses, they can stand as models of scientific procedure. One example is the investigation by the Medical Research Council¹ into the use of streptomycin in pulmonary tuberculosis, though not all successful trials are on such a large scale, and not all are recent. The help which a study of these reports can give may perhaps be supplemented by considering separately some of the errors and difficulties that may arise in clinical trials, especially those in which the assessment of symptoms rather than of signs is an important feature.

Glaser and Whittow² have just reported the results of an interesting study carried out mainly on two

groups of students at Singapore. On eleven occasions at the end of a lecture period the students filled in a brief questionnaire in which they gave information about the presence of eight symptoms commonly found after taking hyoscine hydrobromide, and about two symptoms, hunger and backache, commonly found on routine inquiry. This simple procedure, carried out for the first three lectures, led to the surprising result that the frequency of the three major symptoms, sleepiness, dryness of the mouth, and headache, was initially very high but declined during the period of observation. The interpretation of the authors was that the symptoms were suggested by the questionnaires, so that the first response was unduly high, but subsequently habituation to the questionnaires took place and in consequence the frequency of symptoms showed a significant decline. It seems reasonable to suppose that the need for a subject to observe his own reactions should make him notice, or imagine, symptoms of which he would otherwise be unaware. This point is of interest because it is becoming increasingly popular in the U.S.A. for a patient to provide his medical history by filling in a questionnaire such as the Cornell Medical Index. It has been claimed by the authors who introduced this technique that they were able to detect a patient's need for general medical care much better than a physician who took the usual oral history.³ Glaser and Whittow, in the light of their findings, issue the warning that the questionnaires themselves may produce symptoms. Even so, this claim might well be as true of a patient's oral replies to questions as it is of his written replies to a questionnaire. At any rate the experiences of Cochrane, Chapman, and Oldham⁴ show clearly enough that different doctors attempting to elicit the same piece of information may vary greatly in their estimate of whether a symptom is present or not. These doctors were questioning miners, who had been allotted to them in such a way that there was no reason to suspect anything other than random variation in the frequency with which various symptoms would be found. An attempt was made to conduct similar types of interviews. Nevertheless, one physician found, for example, a history of cough in 40% of 300 subjects and another in as few as 23% of 261 subjects. The one encouraging feature of this investigation was that there were apparently some questions such as, "Have you ever had pleurisy?" which were so unambiguous that the various observers obtained substantially the same answer.

¹ *British Medical Journal*, 1948, 2, 769.

² *Clin. Sci.*, 1954, 13, 199.

³ *See British Medical Journal*, 1952, 2, 1246.

⁴ *Lancet*, 1951, 1, 1007.

⁵ *Biometrics Bulletin*, 1946, 2, 87.

⁶ *Brit. J. prev. soc. Med.*, 1953, 7, 163.

⁷ *British Medical Journal*, 1953, 2, 1284.

Glaser and Whittow were unable to detect any further significant variation in the level of symptoms after the third test, except on occasions when certain special factors were introduced. Thus, on the fourth and fifth day, the questionnaires were filled in both before and after the lecture, and fewer symptoms were recorded before the lecture than after. Most readers will not be surprised at this result, but it does serve to emphasize the variability of the subjects under different conditions. Throughout the study there were consistent differences between the frequency of symptoms in the two groups of students, group A showing more symptoms than B. However, group B was questioned at 9 a.m. and group A either at 11 a.m. or at noon. In the absence of a cross-over type of experimental design we are left to assume that these differences in the two classes were due to the different times at which the students reported their findings, and there is some confirmatory evidence for this.

In the main tests at Singapore a tablet containing 1 mg. of hyoscine hydrobromide was given before the ninth lecture, and produced characteristic symptoms in most of the students. Dummy tablets given before the sixth, seventh, eighth, tenth, and eleventh lectures produced no significant changes in the frequency of symptoms. In assessing the effect of placebos the reader must keep in mind the fact that the subjects were healthy, and the investigators were therefore concerned with the production, not the relief, of symptoms. The important part that a placebo may play in experiments of the latter type has been demonstrated by the careful work of Jellinek.⁵ He wished to find out whether the omission of certain ingredients from an analgesic tablet affected the ability of the tablet to relieve headache. Drug A contained all the usual ingredients; drug B had been deprived of ingredient b and drug C of ingredient c, and drug D was the placebo. The subjects were 200 patients who suffered from repeated headaches. They were divided into four groups; the members of each group used each type of drug for a period of two weeks, but the groups differed in the order in which they tried the various drugs. Thus one group received the placebo for the first two weeks, one for the second, and so on; and this admirable design separated the effects of the drugs from the effects of the order of administration. A first analysis of the results showed that the placebo was successful in 52% of cases, drug A in 84%, B in 80%, and C in 80%. From a less carefully designed experiment it might have been concluded that the effects of A, B, and C were not different, though each was superior to the placebo. However, in this case it was possible to compare A,

B, and C separately on those patients who responded to the placebo and on those who did not. The latter were clearly the better discriminators of analgesic effects, and in the results obtained from them it was found that there were clear differences, the order of efficiency being: A, 88% success; B, 77% success; and C, 67% success.

In contrast to this use of modern statistical methods is a paper by Hogben and Sim⁶ in which such methods are deliberately avoided. They described a technique for conducting a complete clinical trial on a single individual, in this way exploring those differences between individuals which are especially important to the clinician. The main feature of the method is to master the problem so thoroughly that the investigator can invariably obtain, in any individual, a particular response from a particular treatment. The anti-statistical approach here advocated is all the more effective because of the authors' great knowledge of conventional statistical methods. The difficulty is that the solution proposed would work best when least needed—that is, when knowledge is fairly complete. It would offer little guidance to an investigator struggling, as most investigators are, with interesting but obstinately variable phenomena. An essential requirement in these cases is that the methods of sampling used should be as sensitive and as representative as possible. In a recent paper White⁷ has outlined some of the methods of achieving this and some of the common causes of failure.

PYRIDOXINE DEFICIENCY AND CONVULSIONS

Epileptiform convulsions in infants, occurring sporadically in all parts of the U.S.A. during 1951–3, have been reported.^{1,2} There were no distinctive clinical or laboratory signs of organic disease of the central nervous system, and the only factor common to all cases was that the babies had been fed since birth on an artificial fluid milk mixture which had been sterilized in the process of manufacture by "rigorous autoclaving"; this had reduced its pyridoxine (vitamin B₆) content to less than 60 µg. per litre. In all cases the convulsions were cured at once by treatment with pyridoxine or by changing the milk mixture. More recently another case has been reported³ in a newborn infant of a woman who, during her pregnancy, had had hyperemesis treated with three to four intramuscular injections weekly of 50 mg. pyridoxine hydrochloride. After a prolonged and stormy clinical course in which many convulsions occurred while the responsible factor was being sought, the child was eventually maintained free of convulsions on 2 mg. pyridoxine hydrochloride daily by mouth. In spite of this, at 20 months of age she was mentally retarded. This case falls into a somewhat different category from the others, since the child has been kept

free of convulsions only by giving supplements of pyridoxine in addition to the normal diet, whereas the others have been controlled by the pyridoxine present in milk mixtures which were not reinforced with the vitamin.

Vitamin B₆ was first recognized as a separate entity in 1934⁴ and identified with the Factor Y which Chick and Copping described in 1930.⁵ Its indispensability in the nutrition of lower animals was established in the years that followed,⁶ but it was not until 1950 that unequivocal evidence was reported of the effects of its deficiency in human adults⁷ and infants.⁸ Snyderman *et al.*⁹ treated two mentally defective infants aged 2 and 8 months with a diet deficient in pyridoxine for 76 and 130 days respectively. Both children failed to gain weight, but apart from this the syndrome which resulted was different, the younger infant developing convulsions on the seventy-sixth day, the older a severe hypochromic microcytic anaemia which was refractory to treatment with iron. Both quickly responded to treatment with pyridoxine. It seems that the age at which deficiency is established has some bearing on whether the clinical picture should be a neurological one or not, since the age group affected by the artificial milk mixture^{1,2} was 5 weeks to 4 months, with a mean of 2½ months. It is during this period that myelination of many of the association tracts of the fore- and mid-brain is being completed, and it may be significant that degenerative changes take place in the myelin sheaths of peripheral nerves and the spinal cord of pyridoxine-deficient dogs,⁹ and epileptiform convulsions occur in pyridoxine-deficient rats.¹⁰ Pyridoxine is involved in fat and protein metabolism, and in its absence tryptophan is not converted to nicotinic acid. Snyderman *et al.*¹¹ noted inability to excrete N'-methyl nicotinamide in the urine after a dose of tryptophan as early as the twentieth day of the deficiency period in their two cases, and they suggested that this might form the basis of a clinical laboratory test for pyridoxine deficiency. However, Hunt *et al.*³ did not find an abnormal response to tryptophan loading in their patient or in her mother.

Pyridoxine is heat-stable but vulnerable to ultra-violet light,⁶ and presumably to autoclaving. In America whole human milk contains 11 µg., and cow's milk 48 µg., per 100 ml.¹² No British figures are available. The minimum requirement of pyridoxine in infancy has not been determined, but Snyderman *et al.*¹¹ maintained their cases on 0.67 mg. of pyridoxine daily before starting the experimental deficiency period. On this intake both infants were able to metabolize tryptophan normally, though unable to do so when the intake was cut to 0.15 mg. daily. No cases similar to the American ones have yet been reported in Britain. There is no doubt, however, that deficiency of pyridoxine in

the diet, and even inability to use pyridoxine in the amounts supplied in a normal diet, can cause convulsions in infancy.

NURSING-HOMES

Figures given in the annual reports of the county medical officer for London show that the second world war and the National Health Service Act caused great changes among the nursing-homes of London. At the end of 1937 170 nursing-homes were registered in the L.C.C. areas. Evacuation, damage by enemy action, shortage of staff, and other difficulties reduced the number of active homes to 108 in 1945, and the homes which survived the war had great difficulty in maintaining their standards. The replacement of equipment (particularly linen), rationing, and the shortage of skilled staff had to be surmounted during the difficult war years, and most nursing-homes were then faced with heavy expenditure on repairs and redecoration in the immediate post-war years. This alone was often enough to discourage the owners of the smaller type of home from continuing. In addition the pre-war nurse's salary of £60 to £90 a year, all found, had by 1953 become £350 plus a living-out allowance. It was not surprising, therefore, that between 1947 and 1953 there was a further drop in the number of nursing-homes from 63 to 48. This drop of 24% in the number of homes in London since the National Health Service began, when measured in number of beds available, shows a decrease of 9.4%. During this same period 19 new homes were registered, but 34 were closed.

Rising costs have alarmed the users as well as the owners of nursing-homes. Accommodation which before the war cost 5 to 8 guineas a week, with a maximum of about 12 guineas, to-day costs from 11 to 25 guineas a week—not a disproportionate increase when compared with rises in costs. Fees of this magnitude which may be borne for a short period by the acutely ill are an impossible burden on patients of advanced age with small fixed incomes: in many cases the expense is met for a time out of capital or by relatives or friends. This is one of the main reasons why the number of empty beds has increased in nursing-homes. There are still some small homes with from 6 to 10 beds charging about 6 guineas upwards, but at such a figure and with present-day prices no more than the bare minimum of nursing staff can be provided, and the food could hardly be expected to be of the highest quality. Homes of this type appear to be on the border of solvency, and it may well be that few can survive. On the other side of the picture are a few homes charging fees as high as 30 to 35 guineas a week. These homes are in constant use by physicians and surgeons of high standing, and the professional skill and care are matched by a service similar to that of a luxury hotel.

The introduction of the National Health Service came at a time when the falling birth rate was reducing the admissions to maternity beds in nursing-homes, and coincided with a period when maternity wards were being expanded in the hospitals. The number of confinements taking place in nursing-homes in London was 3,167 in 1947: in 1952 this had fallen to 1,091. This large drop

cannot be wholly accounted for by the fall in the birth rate from the exceptionally high figure of 20.9 per 1,000 of the population in 1947 to 15.3 in 1952. Recent annual reports of the medical officers of health of other large cities show the same trend. Most homes found that in the post-war years less use was being made of their operating theatres and more beds were being used for medical cases, particularly for the treatment of the chronic sick or senile patients: in 1948 30% of the beds in nursing-homes were occupied by patients in those two categories. By 1953 this figure had risen to 44%, and in the same period the proportion of beds occupied by maternity cases fell from 10% to 5%, and of all beds occupied from 75% to 71%.

State-registered nurses are not as a rule keen to work in private nursing-homes, and the comparatively uneventful nursing of the chronic sick does not greatly attract them. It is the State-enrolled assistant nurses, or the older women, trained but without State registration, who nurse such cases. The organization of comprehensive home-nursing and home-help services under the local health authority, and the establishment of old people's homes under welfare provisions, while in no sense a replacement of the private nursing-home, have added to the facilities available and undoubtedly had some effect in reducing the numbers of those who might have gone into a private home. The borderline between what constitutes nursing of the sick and caring for the old and enfeebled is very ill-defined. Establishments which provide care for the aged by ordinary unskilled staff fill a real need, and there are good reasons why some of the smaller nursing-homes should turn their attention to this type of elderly person who so often fails to find the accommodation for which he or she is seeking.

EPHEDRINE AND URINE FLOW

Recently letters to the *Journal* have referred to difficulty in micturition caused in elderly male patients who are sufferers from asthma, when using ephedrine. It is true that little attention has been given to this troublesome effect of ephedrine, but it is known and described. The earliest discussion seems to be that of Balyeat and Rinkel,¹ who observed that ephedrine caused urinary retention in asthmatics in 1925, those complaining being women as well as men. In men over 60 they noted a lack of desire to pass urine. They found no satisfactory explanation. They stated in their article that according to Pottenger² and to Kuntz³ the parasympathetic supply stimulates, while the sympathetic supply relaxes, the bladder, but that the reverse is true of the sphincter, which is therefore contracted by ephedrine since it potentiates sympathetic effects. Goodman and Gilman⁴ also stated that under the influence of ephedrine the tone of the trigone and of the sphincter is increased as it is by the trigone and of the sphincter is increased as it is by drugs like morphine. They pointed out that urinary discomfort is prone to occur in those approaching the age of prostatic hypertrophy. Dr. Hugh Cartwright⁵ referred in his letter to similar symptoms following the use of amphetamine and related substances. This is to

be expected, since their action in the body is similar to that of ephedrine, though usually they are given for different reasons. The fact that the spasm of the sphincter ceases on withdrawal of the drug indicates that there is no question of obstruction, and emphasizes that there is an important element of transient spasm as distinct from permanent obstruction in the difficulties of micturition met in advancing years. Some have observed that a slight amount of physical exertion relaxes the spasm. There is need for research in this field.

SERVICE IN THE COLONIES

Health in the Colonies continued to improve in 1953, and the year was a more fortunate one than usual in that no epidemics of communicable disease appeared.¹ In most respects the Colonial Office can report favourably on the health of the very diverse peoples under the care of its medical officers. But for these "there is still an urgent need for recruitment in the United Kingdom." The main difficulty is to attract candidates for Nigeria and the Gold Coast; demands in other parts of the world have been met fairly well, even other parts of Africa. Uncertainty about future prospects in West Africa is a deterrent, though, as Mr. Ian Fraser reported² in this *Journal* last year, the need for British doctors is great, particularly for specialists. The B.M.A. has had consultations with the Colonial Office on this problem, and meanwhile a reassuring statement of intentions has come from Nigeria. Leaders of Nigerian Delegations assembled at Lagos for the Constitutional Conference have affirmed that "the interests of overseas officers who continue in the future to serve in the public services of Nigeria shall be fully safeguarded." Pensions liabilities will be honoured, and appointments are to be kept free of political control. The whole statement should be obtained from the Colonial Office and studied by candidates who are considering applying for the Nigerian posts advertised in the *Journal* this week at advertisement page 45.

The remarkable variety of practice awaiting those medical officers who venture abroad is evident from the Colonial Office's report. While the year was, epidemiologically, a quiet one, it yet brought such tremendous challenges to medical relief as a tidal wave in Fiji, an earthquake in Cyprus, a disastrous fire in Hong Kong, and the worst drought for twenty years in the island of Antigua. Nor are fire and flood the only rivals to the tropical diseases as a cause of misery in hot climates, for some of the diseases characteristic of temperate climates are scourges there also. Outstanding among these is tuberculosis, while pneumonia, despite widespread use of antibiotics, "is still a killing disease." Some of the puzzles posed during the year included an unexpected epidemic of kala azar in Kenya, rabies caused by infected bats in British Guiana, and sixteen cases of undulant fever in Gibraltar, traced to imported goats' milk. But, in spite of environmental difficulties and staff shortage, the Colonial medical services' record of work in the year is one of which they may well feel proud.

CLINICAL PATHOLOGY IN GENERAL PRACTICE

LABORATORY INVESTIGATION IN THE HYPERCHROMIC ANAEMIAS

BY

JOHN F. WILKINSON, M.D., M.Sc., Ph.D., F.R.C.P., F.R.I.C.
Physician and Director, Department of Haematology, Royal Infirmary, Manchester;
Reader in Haematology and Lecturer in Medicine, University of Manchester

It cannot be stressed often enough that an anaemic patient should be investigated at least by a blood count and a bone-marrow biopsy before anti-anaemic treatment is started. Unfortunately this is often not done. As a result, the physician is faced later with the almost insuperable problem of trying to decide, for example, whether a patient has or has had pernicious anaemia, when he has already been given active treatment with liver, folic acid, or vitamin B₁₂ without a proper laboratory diagnosis having been made. Since the patient with pernicious anaemia must continue treatment for life, it is of vital importance to be certain of the correct diagnosis in the beginning.

Varieties of Macrocytic Anaemia

Now hyperchromic macrocytic anaemia, although most often seen as pernicious anaemia, may occur in a number of other less common conditions not necessarily related aetiologically to pernicious anaemia. These conditions sometimes cause difficulty in diagnosis, but it is important to make a correct diagnosis, as they often require different types of treatment. Thus, the achylic, or "agastric," macrocytic group comprises primarily the classical pernicious anaemia, but also an identical but much rarer hyperchromic macrocytic anaemia which sometimes follows the removal of the gastric secreting cells by total gastrectomy or the destruction (as by corrosive poisons) of the haemopoietin- and acid-secreting cells of the stomach. If untreated, this anaemia is fatal.

The non-Addisonian group of hyperchromic macrocytic anaemias includes a number of conditions of varying aetiology and treatment. These anaemias are not necessarily progressive and fatal, nor are they usually associated with atrophy of the gastric mucosa or with achylia. They are seen in tropical sprue, idiopathic steatorrhoea (non-tropical sprue), and occasionally in coeliac disease in children; pregnancy; malnutrition; certain diseases of the liver or endocrine disorders; certain neoplastic changes affecting the bone marrow (myelosclerosis); and very occasionally in childhood. There is also a group of idiopathic refractory megaloblastic anaemias.

Patients with a macrocytic anaemia show a variable degree of anaemia, and, according to its severity, there may be a brownish, but more usually a light or pale (lemon) yellowish, colour of the skin and mucous membranes. Those with an achylic anaemia—for example, pernicious anaemia—will frequently have a sore smooth tongue with an atrophic mucous membrane, flatulent dyspepsia, often recurrent mucous diarrhoea, some tingling and numbness in the fingers and toes, and histamine-resistant achylia gastrica. These symptoms are usually quite mild and may be intermittent in the early stages but become persistent and much more severe as the anaemia becomes worse. On the other hand, those with one of the non-Addisonian macrocytic anaemias may show slightly different and often quite diagnostic features. Thus in the anaemias secondary to disturbances of the bowel we find, for example in tropical sprue, that there may be severe malnutrition, loss of weight, glossitis, and typical light-coloured, frequent fatty stools, with changes in fat balance, which may be relieved wholly or in part on return to temperate climates and after a reduced fat intake; usually the gastric secretion

contains both haemopoietin and a more or less normal amount of hydrochloric acid, although sometimes there is achlorhydria gastrica, but it is not necessarily histamine-resistant. In the non-tropical type of sprue, or idiopathic steatorrhoea, similar features are seen usually in adults in temperate climates, but the fatty diarrhoea may be quite mild and vary very much with the dietary fat intake, and it may be necessary to make a fat-balance test to detect this abnormality; the gastric acidity is usually normal, but there may be some decalcification of bones. Coeliac disease, the counterpart of idiopathic steatorrhoea in children, is much more rarely associated with a hyperchromic anaemia; usually there is a hypochromic microcytic or normocytic type of anaemia.

All these sprue-like conditions if associated with a macrocytic anaemia respond to folic acid but not to vitamin B₁₂.

The tropical hyperchromic macrocytic anaemias represent a heterogeneous group probably having several aetiological factors, according to the geographical situation, but in general they are nutritional anaemias probably caused by severe nutritional deficiencies of extrinsic factor and other vitamins and food factors. They often occur in young pregnant women with normal gastric acidity and a normal fat balance, and only rarely are they associated with glossitis and gastro-intestinal symptoms.

There is a definite but relatively uncommon macrocytic or megaloblastic anaemia of pregnancy in which the symptoms and the blood and bone-marrow pictures resemble very closely pernicious anaemia, but the gastric secretion is normal and a therapeutic test shows a rapid remission with folic acid but not following vitamin B₁₂. The patient remains cured and does not require treatment subsequently.

A very uncommon macrocytic (often megaloblastic) anaemia is encountered in children, and has been described as being pernicious anaemia, but it is not a genuine Addison's anaemia; achylia is not necessarily found and the anaemia appears to respond only to folic acid and, poorly, to vitamin B₁₂. Hyperchromic macrocytic anaemia with a megaloblastic marrow and usually normal gastric secretion may be seen in cirrhosis of the liver, and occasionally in diseases of the pituitary and thyroid (hyperthyroidism) glands, severe malnutrition, and neoplastic conditions mainly affecting the marrow as in myelosclerosis.

A typical hyperchromic megaloblastic anaemia without achylia or the Addisonian symptoms of glossitis, flatulent dyspepsia, diarrhoea, paraesthesiae, or neurological symptoms is seen in achrestic anaemia. This is due apparently to inability on the part of the liver to release its anti-pernicious-anaemia "liver principle" when required in the bone marrow.

Occasionally cases of idiopathic refractory megaloblastic anaemia are seen that do not respond properly to any treatment and whose aetiology is unknown. They may have normal or diminished gastric secretion, and often nutritional factors are involved.

Blood Examination

A full examination of the blood will show the following features in pernicious anaemia: a macrocytic hyperchromic anaemia, usually with a much greater reduction in the red-cell count than in the haemoglobin value so that the colour index (although a very inaccurate measure) may be very high (1.3 to 1.6). These changes are paralleled by an

increase in the mean cell volume (M.C.V.) to 95–160 μ^3 (normal 82–95 μ^3), and mean corpuscular haemoglobin (M.C.H.) 33–56 $\gamma\gamma$ (normal 27–31 $\gamma\gamma$); the mean corpuscular haemoglobin concentration (M.C.H.C.) is 32–36% (in iron-deficiency hypochromic anaemia this value is often considerably less than 30%). In the stained blood smear the red cells show marked variety in size (anisocytosis) and bizarre, oval, and pear shapes (poikilocytosis). The cells seem well filled with haemoglobin (mainly owing to their being bigger and thicker in strong contrast with the thin, pale, ring-like cells of hypochromic microcytic anaemia).

In a severe anaemia there will be polychromatophilia, basophilia with fine or coarse basophil stippling, and often some nucleated red cells (normoblasts) may be seen; the last are often noted in haemolytic anaemia. The presence of megaloblasts in the peripheral blood is not common, but is thought to be confirmatory evidence of pernicious anaemia. Sometimes unusual cells such as Howell-Jolly bodies may be seen, but they are not of any diagnostic significance in pernicious anaemia.

The platelets may be diminished in numbers, especially when there is severe anaemia, and may be lower than 50,000 per c.mm.; they increase rapidly with anti-pernicious-anaemia treatment. Clinically, purpuric manifestations, bleeding from the gums, epistaxis, and retinal haemorrhages occur only when severe anaemia is associated with a platelet reduction below about 40,000 per c.mm.

The reticulocytes are usually less than 2% except under two conditions, namely: (a) during spontaneous remissions which are accompanied by a reticulocytosis, and (b) during the first 14 days after adequate anti-anaemic treatment, when a peak of 15–60% occurs at about the sixth to the tenth day, the level being inversely proportional to the initial red-cell count. A persisting irregular reticulocyte count of 5–30% or more suggests a haemolytic anaemia.

Most of the secondary group of macrocytic anaemias described above (sprue, steatorrhoea, pregnancy, etc.) show an almost identical blood picture to that of pernicious anaemia, but, while there are no characteristic differences, tests of the gastric secretions and a therapeutic test allow further differentiation.

Generally the leucocyte count is somewhat reduced (3,000 to 5,000 per c.mm.). Usually there is a relative but sometimes an absolute lymphocytosis (1,000 to 4,000 per c.mm.) due mainly to a reduction of the granular cells. Quite often some large multiseptated (6–10 lobes) polymorphonuclear neutrophilic leucocytes (macropolycytes) are found in the blood smear, and these may appear even before there are gross changes in the red cells; much less frequently a few immature cells, usually myelocytes or metamyelocytes, may be seen.

In passing, it should be mentioned that it used to be common to see a temporary eosinophilia after treatment with liver or liver extracts, but this is a less frequent observation with modern forms of therapy.

Occasionally a patient with a hyperchromic macrocytic anaemia may be found to have a leucocytosis of, say, 10,000–14,000 per c.mm., with 8,000–12,000 being polymorphonuclear leucocytes. This should always suggest either a complicating infection or some other lesion such as a neoplasm of the stomach or lungs for which careful search must be made.

Marrow Biopsy

This has now become an essential procedure in the investigation of any disease of the blood, particularly in early and difficult cases. By its use some of the anaemias previously thought to be refractory have been elucidated and in other blood diseases diagnosis has been established with certainty and at earlier stages.

The technique for obtaining suitable material is simple. The best site in adults is generally the centre of the manubrium sterni, but in children an iliac crest or sometimes a vertebral spine may be easier. The skin is cleaned and infiltrated with a local analgesic, down to and including the periosteum. The sample is obtained with a Salath needle,

gentle suction being applied with a dry 1-ml. "tuberculin" syringe. In children the procedure is much simplified by the use of light anaesthesia, such as with ethyl chloride for two or three minutes, while the iliac crest is punctured at right angles to and just below the upper surface.

Failure to obtain a sample of marrow because of thickened hard bones, or absence of or failure to find a marrow cavity, suggests myelosclerosis.

The specimen obtained, which consists of marrow fragments in a variable amount of blood, is examined after making smears. Some prefer to examine the small fragments of marrow on a slide after they have first been expressed from the syringe on to a watch-glass.

The slide is stained by the Jenner-Giemsa or a similar technique, and examined under the 1/12 oil-immersion lens. An estimate is made of the degree of cellularity, the different types and relative numbers of erythroblasts, granulocytes, lymphocytes, plasma and reticulum cells, and megakaryocytes are ascertained, and any predominating type is noted. In pernicious anaemia and the other hyperchromic (macrocytic) megaloblastic anaemias the marrow picture will be absolutely characteristic. The marrow will be very active (hyperplastic) and contain a high proportion of megaloblasts of all types, sometimes proerythroblasts, often showing various nuclear patterns and active mitosis, but relatively few normoblasts; in milder cases there may be only a few megaloblasts.

In sprue, steatorrhoea, and the tropical macrocytic anaemias quite a number of normoblasts are commonly found, with a transitional rather than a fully megaloblastic type of myelogram; this may be even more marked in coeliac disease in children, who usually show a fully normoblastic marrow.

There is quite often evidence of an unusual and increased leucopoiesis, mainly demonstrated by an increase in the numbers of granular leucocytes and large metamyelocytes; giant hypersegmented polymorphonuclear cells may be noted and probably give rise to the macropolycytes seen in the blood film. On the other hand, there may be a definite reduction in the number of megakaryocytes which parallels the thrombocytopenia in the peripheral blood.

Since this whole marrow picture is typical and pathognomonic for pernicious anaemia and megaloblastic hyperchromic anaemia, it will be realized how important it is to make this examination before giving any treatment. The characteristic picture is completely converted to a normoblastic hyperplasia, with disappearance of the megaloblasts, within a few days of giving liver extract, vitamin B₁₂, or folic acid; it thus becomes impossible to make a correct diagnosis afterwards.

In the haemolytic anaemias the marrow shows a very active picture, with plenty of normoblasts of all types (which may be prematurely haemoglobinized), proerythroblasts, and sometimes haemocytoblasts; there are no megaloblasts. Owing to the intense erythroblastic reaction, which may occupy 75% of the cell space, there may be some reduction in megakaryocytes and early granular leucocytes.

Gastric Secretion

Some of the most striking symptoms in the hyperchromic anaemias are referable to the gastro-intestinal tract. Thus the glossitis, flatulent dyspepsia, gastritis, and recurrent mucous diarrhoea are all associated with atrophy of the gastric secretory glands. Every patient with pernicious anaemia (as well as with subacute combined degeneration of the cord) has a complete and irreversible histamine refractory achylia gastrica (commonly a familial hereditary feature), and normal gastric secretory function is never regained, even after treatment and relief of the gastro-intestinal symptoms.

Whatever may be the other pathological and haematological findings, if free hydrochloric acid is found in the stomach secretion, then the diagnosis cannot be one of pernicious anaemia. On the other hand, the secondary non-Addisonian types of hyperchromic macrocytic anaemias

usually have a normal or slightly reduced gastric acidity, although in patients with tropical sprue, and occasionally in non-tropical steatorrhoea, achlorhydria (not always histamine-refractory) may be noted quite often.

Fat Absorption

While in patients with tropical sprue the typical bulky fatty stools are obvious, it may only be necessary to determine the fat distribution in a simple sample to confirm the gross failure of absorption. In mild cases of sprue and in most cases of non-tropical steatorrhoea and coeliac disease, a single fat analysis may be inconclusive. It is then necessary to carry out a fat-balance test in which the patient is given a fixed diet containing 70 g. of fat, and the fat or fatty acid contents of the faeces are determined daily over a twelve-day test period. The first three daily totals of faeces are bulked together, and the average figure determined for fatty acids. If there is 95% absorption there is no abnormality of fat-splitting and absorption, but less than 70% indicates definite abnormality. If the fatty-acid determination indicates 80-93% fat absorption, further daily estimations must be made until the daily output of fatty acids or fats remains constant. If the value for fatty acids in the daily output is equivalent to less than 90% of the total daily fat intake, the steatorrhoea is confirmed.

Therapeutic Test

When all the preliminary and confirmatory examinations have been made the final test is the therapeutic one.

In pernicious anaemia and the agastric anaemias requiring or expected to respond to hog's stomach, liver extracts, or vitamin B₁₂ (cyanocobalamin), the appropriate dose is given, 1 to 2 ml. of liver extract intramuscularly daily for three days or 100 µg. vitamin B₁₂ subcutaneously daily for two to three days. A reticulocyte count is made daily and determinations of the haemoglobin and the red blood cell count twice weekly. No other treatment should be given during this test. If the diagnosis and treatment are correct then the reticulocyte count will rise rapidly in the course of the following four to eight days to a maximum peak of 15 to 60%, depending on the dosage and potency of the specific treatment and the initial depression of the red-cell count. At an initial level of 1,000,000 red cells per c.mm. a peak of 30 to 40% reticulocytes would be expected, while at 2,000,000 per c.mm. a peak of only 15 to 25% reticulocytes would appear. At the same time the number of red blood cells and the haemoglobin value would rise steadily and progressively to normal levels with further treatment. These results would thus confirm the diagnosis of a macrocytic hyperchromic anaemia due to the expected deficiency.

The non-Addisonian macrocytic hyperchromic anaemias do not respond to liver extracts and vitamin B₁₂. But, after a negative response in the above test, the administration of folic acid, 50 to 100 mg. parenterally for two or three doses, or of 10 to 20 mg. orally daily, will produce a similar haematological response. Failure to respond suggests an error in diagnosis, inadequate or inactive treatment, or some other complicating and concomitant disease or factor.

Conclusion

As a rule the differential diagnosis of these hyperchromic megaloblastic anaemias can be made quite readily by a full blood count, marrow biopsy, and an evaluation of the gastric secretory function.

A diagnosis of pernicious anaemia is certain if there is a macrocytic hyperchromic anaemia, with an active (hyperplastic) megaloblastic bone marrow, and an achylia gastrica, and there is a full haematological and clinical remission after adequate treatment with an active liver extract, vitamin B₁₂ parenterally, or hog's stomach orally. (Note: Folic acid must not be given to patients with pernicious anaemia or subacute combined degeneration of the spinal cord, as it causes the onset or worsening of the cord symptoms.) If there is additionally a history of total gastrectomy or

destruction of the gastric mucous membrane, then the pernicious anaemia is secondary to such gastric secretory deficiency.

A hyperchromic macrocytic anaemia with a megaloblastic marrow, but with a normal or reduced gastric acidity, may be seen in sprue, idiopathic steatorrhoea (non-tropical sprue), or coeliac disease. Clinically there may be a history of large bulky frequent pale stools with a variable degree of disturbance of fat absorption as shown by the fat-balance test. This type of anaemia fails to respond to vitamin B₁₂, but improves with folic acid or the less purified types of liver extract. The non-tropical sprue-like conditions may also be associated with a normoblastic marrow, in which case they will not respond to folic acid but will require iron.

A similar hyperchromic anaemia, with megaloblastic marrow, but without achylia gastrica, in a pregnant woman indicates macrocytic or megaloblastic anaemia of pregnancy. This again will respond to folic acid, but not to vitamin B₁₂. It does not require continued treatment.

RESETTLING MENTAL DEFECTIVES PSYCHOLOGICAL AND SOCIAL ASPECTS*

BY

L. T. HILLIARD, M.B., D.P.M.

Physician-Superintendent, Fountain Hospital, London

The type of adult female defective here discussed is determined primarily by administrative considerations. The ordinary mental deficiency colony caters for all types of defectives and can occupy a considerable proportion of the higher grades in work useful to the institution. A children's hospital such as the Fountain Hospital, which caters for 700 mentally defective children, has no such labour available, as any child who is at all trainable is in the hospital school and occupation centre. For many years, therefore, it was the custom to transfer adult "working" patients from other institutions to the Fountain Hospital to work in the wards and laundry. About 80 such patients were accommodated in the hospital itself, but in 1950 they were transferred to the newly opened annexe, South Side Home, at Streatham.

These patients came from other mental deficiency institutions. It must be stressed that they were classified as unsuitable for licence to a job in the community but possibly suitable for occupation as so-called "workers" in the Fountain Hospital, for which they would receive a small amount of pocket money—formerly sixpence a week but now a few shillings.

Material under Review

Transfers.—From 1918 to the time of writing 327 such adult patients were transferred to the Fountain Hospital. As institutions tend to keep their best workers, those sent to other hospitals are seldom of

*Paper read to the Section of Psychiatry of the Royal Society of Medicine on December 9, 1952.

a high standard. Consequently a large proportion of those transferred were incompetent or emotionally disturbed defectives. As a result nearly half of these patients were in due course returned to their original or some other institution. The remaining 166, plus nine patients who came as children and remained as adult workers, form the group of 175 adult females which is discussed. During the last 10 years an experiment has been conducted to see how these patients would fare in the community. As they had not been sent out on licence by their previous hospital, the presumption had been that they were regarded as unsuitable for supervised life in the community. It seemed, therefore, rather a forlorn hope to work on this group of failures specially selected by others for their unsuitability for licence. Nevertheless the experiment was made.

Discharge Rate.—So far 140 out of the 175 have been found employment in the community, and 101 of these have already been discharged under the Mental Deficiency Acts. Of 100 consecutive patients placed on licence 73 were discharged. Even with carefully selected licence cases a discharge rate of 73% would be a high one, but, as has been pointed out, these patients were regarded as unsuitable for licence, hence their transfer to the Fountain Hospital.

What do we know about the patients in this group? The outstanding feature is that they are a very mixed sample with a wide range of attributes. Their ages range from 16 to 66; their ages at certification as defectives ranged from 3 to 39. The dates of first certification extend from 1909 to 1950. Their ages when first licensed from the Fountain Hospital varied from 17 to 59. In view of this very wide scatter there is no particular type of patient that can be regarded as characteristic of his group, but on an average patients were 20 years old when certified and were placed on licence after an average of 20 years in institutions. It is remarkable that after so long an absence from the world they have been able to survive when suddenly returned to it.

Social Factors

Of the 100 consecutive patients put on licence, of whom 73 have been discharged, 17 (17%) were illegitimate. Children born to unmarried mothers have no normal home life, and illegitimacy nearly always means separation from the mother and institutional upbringing from a very early age. Emotional and apparent mental retardation is common in such children, and one may wonder whether they would all have been certified as mental defectives if they had had a more stimulating and secure childhood. Of the 72 legitimate patients whose sibship is known the average number of siblings is seven. In this relatively small group six patients were one of 11 siblings, and there were families of 12, 13, 14, 15, 16, 17, and 18 children. In the days before family allowances such large families must have implied poverty and overcrowding. The resulting lack of supervision and early training may well have been a factor in the mental immaturity and intellectual subnormality of these patients.

Standard of Education.—Some patients had been to elementary schools but had made poor progress. The majority had gone to special schools, but others had had very little schooling at all because of truancy, bad homes, or too early certification as defectives. A large proportion were therefore almost illiterate. Some later learnt to read and write on their own; others attend L.C.C. evening classes at the South Side Home for reading and writing. It is difficult to assess the level of intelligence of these patients because several factors obscure the true picture. Inadequate opportunities for special education, the stultifying effect of many years in an institution, and the unsuitability of the Binet type of test for these patients make the usual I.Q. figure meaningless.

Intelligence.—In the 100 consecutive licence cases the Binet I.Q. prior to licence ranged from 34 to 73, but experience of the world enabled most of these patients to

improve their score on this test. There was usually a gross discrepancy between the Binet and the Wechsler-Bellevue I.Q. Many patients score 20 points more on the latter test, which is a much better measure of their capacity, and some show differences of as much as 35 points. Some of our recent admissions have had I.Q.s of 100, which raises the vexed question of the relationship between intelligence and mental defect. Whatever the I.Q., these patients need experience of the normal world if they are to survive in it. In an institution they are cut off from many aspects of normal life, with a resulting atrophy of cognitive and affective functions. The first step to the rehabilitation of these defectives is to give them possessions and a locker to keep them in, clothes of their own and money to buy them with, stimulating work with adequate rewards for working, and a day off each week when they can go out on their own and exercise their initiative and broaden their experience on buses, in shops, and in cinemas.

Freedom.—For several years those patients at the South Side Home not on licence have been allowed one free day every week, when they go out, usually with another patient, but without any nurse or escort. Armed only with a card giving the hospital address and telephone number, they learn the ropes from each other and from their own experience. Some go to Brighton for the day, and, what is more, come back. It is this opportunity of freedom and experience which is the basis for successful licensing and ultimate discharge. In some institutions patients remain on licence for many years, with the constant threat of recall, and lose all hope of freedom. I believe that in general these patients appreciate their discharge and will not risk recertification. If a female is going to get herself into trouble she will do it while on licence or even in the hospital. Her opportunities are no greater if she is discharged.

Pregnancy

When dealing with female defectives the biggest single problem is the risk of pregnancy. Of the 100 consecutive patients on licence, only one, the hundredth, became pregnant while on licence. Lest it be thought that this group was singularly infertile, I should explain that before their transfer to the Fountain Hospital, and usually prior to certification, 31 of these 100 women had between them had 52 children. Many people believe that almost all of the offspring of defectives are themselves defective. It is encouraging to find that many of these children are normal, and that some, having grown up, have had their mothers discharged to their care.

It will be realized that, whatever the reason given at the time for certification of these patients, illegitimate pregnancy was the precipitating factor in a considerable proportion of the cases. Better facilities for the unmarried mother will reduce the need for certification under the Mental Deficiency Acts. Illegitimate pregnancy is not in itself a sign of mental defect. In view of the high percentage of first pregnancies conceived outside matrimony in the population as a whole, proper evidence of mental defect should be furnished when a slightly subnormal woman is in trouble.

When the large sibships of some of these patients (16, 17, 17, and 18) are remembered, it may be that their fall from grace was precipitated by an inherent fertility while other equally poorly endowed citizens avoided certification by not producing a baby.

Employment; Marriage

These defectives have learnt to do laundry work and various jobs in a gas-mantle factory, but most have obtained domestic jobs in private houses or hospitals. Hospital jobs are the more popular, as the girls are used to institution life and get more company and better pay. As resident hospital domestics they get the full scale of £4 18s. 6d. a week, less tax, insurance, and superannuation, and a charge of 33s. for board and lodging. Some are improvident and spend their money, others have several hundred pounds in

their Post Office accounts. One girl who became a senior maid in a hospital flew to Dublin for her holiday.

The regulations state that the patient while on licence must not form attachments to members of the opposite sex. Usually such behaviour results in the recall of the patient to the institution. This is one of the most difficult problems for the superintendent who wants to give his patients a fair chance in the world but must keep at least one eye on his reputation with the authorities.

It is natural for girls working with normal domestics and earning their living on the same terms in hospitals to behave in the same way as their colleagues. They will go out together and visit dance halls, etc., and meet boys. It is very difficult for a licensed patient to announce that she is a certified mental defective and is not allowed to meet boys.

My attitude has been that if such conduct is forbidden it is usually driven underground and becomes more dangerous in its results. I have encouraged the girls to feel that we should prefer to know if they have men friends and will not automatically ban them. As a result several men have come for a talk. Sometimes the undesirable type out to take advantage of the defective girl is warned of the legal situation with regard to intercourse with a known mental defective. If the friendship seems to be a genuine one the defective's discharge is recommended so that she is free to make normal emotional attachments, and, what is more, is free to get married. If the defective is forbidden to marry she can hardly be blamed if she eventually produces an illegitimate child. Several of my patients who were discharged in good time have since married and settled down satisfactorily in their own homes. Some have produced normal, healthy children; one is proud of her twins.

If ultimate success on licence is to be achieved those responsible for the welfare of this type of patient must be willing to risk several apparent failures with each case. One must persevere in finding alternative jobs until the patient has learnt to adjust herself to outside employment. If failure in the first job on licence is followed by recall and a further period in the institution, the patient has to re-adjust herself to a different mode of life, and will later be no better able to cope with the world after an interval away from it.

Learning comes by experience, and the maturation which is so evidently delayed in many of these patients will not occur simply with the passage of time spent in an institution. To develop towards normality the individual must experience and be able to respond to the formative stimuli of the ordinary world. Living is itself a conditioned response.

Certification

A scrutiny of the medical certificates which originally formed the basis for the detention of these patients makes one wonder if enough care was given in some cases to the evidence on which the diagnosis of mental defect was based. A practical difficulty in the borderline cases is that there are still so few alternatives to detention in a mental deficiency institution once a social problem case has come to the notice of the authorities. There is as yet no method of providing training and supervision on a voluntary basis comparable to the voluntary status under the Mental Treatment Act or the even freer access to neurosis centres.

Hostels

A considerable proportion of the patients in this experiment welcomed help and guidance if it was offered freely, but rebelled against coercion. This is shown by the behaviour of those who would run away from South Side Home while under a detention order, but who wanted to come back and live there temporarily if they were out of a job after their discharge. There is a need for a special hostel to help patients who have been discharged. If such hostels could be developed they would be available also for those who need help on a voluntary basis if they are to avoid certification.

Such hostels would work in close co-operation with, but distinct from, the mental deficiency institution and share the same team of social worker, psychologist, and psychiatrist to ensure continuity of supervision and follow-up. They could deal with the psychological and social aspects of the resettling of defectives more effectively than can the large institution designed for custodial care.

Conclusions

Mental deficiency practice has consolidated within the framework and experience of an Act designed 40 years ago in very different social circumstances. This has resulted in a wastage of human capabilities which I believe can, in more favourable circumstances, be developed and utilized to better advantage both to the individual and to the community. Mental deficiency of the so-called feeble-minded category is in many cases not a clear-cut clinical entity of an irreversible nature. Too often, as I have tried to show, it is the diagnosis which has created the disease.

THE CONCEPT OF RACE

A conference on "The Concept of Race" was held in London on May 15 under the auspices of the Medical Association for the Prevention of War. The discussion was opened by Professor L. S. PENROSE, F.R.S., who spoke of the mental and psychological characteristics of populations. He deprecated the way in which conclusions in this field were still so often based on impressions, as, for example, that the Chinese were "cunning and impassive," the Irish "bellicose," and the Germans "sentimental and ruthless." These traditional characterizations were not supported by scientific evidence.

So far as the evidence of psychiatry went, the types of mental disorders prevalent in different parts of the world were the same. According to a U.S. Army survey, levels of intelligence were highest in men of West European and Japanese origin, lower in people of Eastern European origin, and lowest in Negroes. In fact, there was great variation between the residents of different States, and the Negroes of New York and Pennsylvania ranked higher than Whites from Mississippi, Kentucky, and Alabama. Where differences were found, they might be either hereditary or environmental in origin; they did not necessarily imply that one group was inferior to another.

Dr. N. A. BARNICOT said that individual variation within groups was usually greater than the differences between groups. It was impossible to group individuals biologically according to geography, nationality, or religion. For example, judged by skin colour the African and Australian natives were similar and were distinguished from the European; judged by MN blood groups the European and African were similar and were distinguished from the Australian; judged by the sickle-cell trait the European and Australian were similar and were distinguished from the African.

There was evidence that characteristics which had been thought to be fixed could be altered by the environment—for example, the basal metabolic rate of Eskimos—and what was at one time regarded as a genetic weakness might have had a real adaptive value. The inheritance of one factor for the sickle-cell trait had been shown to give protection against malignant malaria.

Mr. S. SACHS discussed the social differences between races, and Dr. D. G. LEYS examined the question of whether there was any scientific justification for the separation of society into strata. Doctors, he said, had an opportunity to counter the tendency towards racial embitterment by helping to ascertain and spread knowledge about the biological truths behind the concept of race.

Reports of Societies

SURGERY OF THE ADRENAL CORTEX

At a meeting of the Section of Urology of the Royal Society of Medicine on May 27 the subject of adrenalectomy was discussed. Dr. A. C. CROOKE (endocrinologist, Birmingham United Hospitals) opened, and in reviewing Cushing's syndrome said that subtotal adrenalectomy was the elective operation. It aimed at reducing the level of circulating corticoids from pathologically high to normal levels and might be compared to subtotal thyroidectomy in hyperthyroidism; it could give equally good results.

In the treatment of hypertension adrenalectomy appeared to be of great value in carefully selected cases of rapidly progressive disease, provided arteriosclerosis was not gross. It might act by reducing the level of circulating corticoids from normal to lower levels, by preventing the normal rise in response to stress, or by removing noxious types of corticoids, which were replaced by less noxious cortisone.

In cancer, the object of adrenalectomy was to remove the sex-steroid element of adrenocortical secretion, but this could be achieved as effectively by giving cortisone in a dosage of about 50 mg. daily by mouth. This would cause atrophy of the adrenal cortex and suppression of its secretion. He questioned whether adrenalectomy for cancer could be regarded as an ethical procedure until it had been shown beyond question that a couple of pills of cortisone a day by mouth would not achieve the same result—pills which the patient would have to take anyhow.

Adrenogenital Syndrome

Mr. D. INNES WILLIAMS (genito-urinary surgeon, Great Ormond Street Hospital, London) confined his remarks to the adrenogenital syndrome, and confessed that he could add little to Dr. Lawson Wilkins's masterly review of the subject before the Endocrinological Section on the previous evening. Children with adrenal cortical hyperplasia presented with sex changes (virilism or pseudohermaphroditism in girls, and iso-sexual precocity in boys); an acceleration of somatic growth, followed by premature fusion of the epiphyses; and, during the infant years, a biochemical disturbance resembling in some respects Addison's disease. 17-ketosteroid excretion was raised even from the time of birth. Cortisone, in comparatively small doses, had a remarkable effect; it halted or reversed the virilizing trend, and caused an immediate fall in 17-ketosteroid output, and enabled the electrolyte balance to be rapidly restored. Cortisone treatment had to be continuous, and appeared to be replacement therapy.

It had been postulated that in these adrenal glands the precursors of the gluco-corticosteroids could not be synthesized into hydrocortisone but formed pregnanetriol, a substance found in great excess in adrenal tissue taken from one case in the series investigated. The lack of circulating one case in the series investigated. The lack of circulating hydrocortisone led to over-production of A.C.T.H., and so to stimulation of the adrenal cortex and excessive output of androgen.

Mr. Williams reported 12 cases (11 female, 1 male), seen in consultation with various medical colleagues. Seven of the females were treated with cortisone, and there had been two deaths from sudden biochemical storms. Two female pseudohermaphrodites had been brought up as boys, and it was thought unjustifiable for psychological reasons to try to reverse the accepted sex, so that cortisone was withheld.

Where the adrenogenital syndrome was produced by tumour as opposed to cortical hyperplasia, the administration of cortisone formed a useful diagnostic test, since in the tumour cases the 17-ketosteroid excretion could not by this means be brought down to the normal level.

Adrenalectomy for Cancer

Mr. L. N. PYRAH (director of surgical research, Leeds University) reported a series consisting of 25 cases of carcinoma of the breast and 3 of carcinoma of the prostate, all having metastases, which had been submitted to bilateral adrenalectomy and gonadectomy. Of the breast cases, 9 had had a major remission; 4 of these were still alive, 5 had later relapsed and died; one case had shown moderate improvement; of the cases showing no improvement, 5 were still alive and 8 had died of cancer. With regard to the prostate cases, 2 had had clinical improvement followed by relapse and death, and one had died of cancer without clinical improvement.

There had been 2 post-operative deaths. The majority of patients stood the operation well. In cases in which there was a major regression the patient experienced a sense of well-being very soon after operation and pain disappeared within 48 hours. Even when there was not much regression of growth, pain was very greatly relieved. The post-operative hormone therapy was that recommended by Huggins, and no difficulty had been found in regard to electrolyte control. The patients who had a remission (which was shown clinically, radiographically, and histologically) sometimes improved in a dramatic fashion.

Mr. J. D. FERGUSON (surgeon, Central Middlesex Hospital) reported similar experiences in 32 cases of total adrenalectomy for advanced malignant disease (17 prostatic cases and 15 breast cases). Before embarking on this form of treatment he liked to have evidence that the tumour had previously been hormone-dependent. A remission of symptoms was obtained in about three-quarters of the cases together with evidence of growth regression in many instances. Most of the prostatic cases lost their pain, and marked benefit was experienced in breast cases with pulmonary metastases. Patients previously bedridden had returned to normal activity.

Total Adrenalectomy in Hypertension

The case for total adrenalectomy in the treatment of progressive hypertension was presented by Mr. HOWARD G. HANLEY (surgeon, St. Peter's and St. Paul's Hospitals, London). The rationale of the therapy was to remove the source of salt-retaining steroids. He first reviewed the results of past workers who had employed a subtotal resection. He had operated on five patients with hopeless malignant hypertension. The results had been surprisingly good even when the blood pressure had not fallen appreciably, as in the two cases with advanced arteriosclerosis. All, however, had shown marked improvement in the eye changes, while signs of cardiac failure had disappeared. He quoted the case of a woman of 46 with pyelonephritis whose urea clearance had risen from 45% of normal to 85%. Renal failure was the main contraindication to this form of therapy. It might be justifiable in the future, he said, to perform adrenalectomy at an earlier stage of the disease, before the onset of arteriosclerosis, and the long-term follow-up of these cases would be invaluable in determining this point.

LOCAL MEDICAL SOCIETIES

Manchester Medical Society

Woman, unlike the cow, declared Dr. F. Charlotte Naish, speaking to the Section of General Practice on March 22, had not been bred for her good milking powers; on the contrary, we had kept alive the children of the poor milkers by wet-nursing and later by clean and careful artificial feeding. Possibly there were 15% of very poor milkers, 25% of moderately good milkers, and 65% of fully adequate milkers. What should we do with the 25% of moderately good milkers? They should be taught complementary feeding, she said. It had been stated that complementary feeding took too much time, but it was just a matter of suitable techniques. There was no need to do test-weighing if the baby was fed to its appetite.

Correspondence

Cortisone and Aspirin in Rheumatoid Arthritis

SIR.—The interesting and important M.R.C. report on the relative values of cortisone and aspirin in rheumatoid arthritis, published in the *Journal* of May 29 (p. 1223), has already received glaring publicity in the lay press, and will undoubtedly have considerable medical and political repercussions. Like all statistically controlled trials, it will be surrounded by an aura of sanctity, and will provide an unchallengeable "gospel" for years to come. Those who read it superficially will merely conclude that aspirin is as effective as, and a far safer treatment for rheumatoid arthritis than, cortisone. They will naturally relegate the latter to the rubbish heap of extinct remedies. Those who read it carefully—especially if they have had experience of the drug—will accept the conclusions that cortisone given in this particular way, to this particular group of patients, and judged by these particular criteria, is not a justifiable form of therapy. But they will still await statistical guidance on the wider and far more fundamental issues about the indications for cortisone therapy.

As Professor Hill has stated,¹ there are an infinite number of questions we might ask about any new regime, but the statisticians prefer to answer a single question at a time—that is, "If to a defined type of patient Y gr. of drug X are given daily by one particular route in so many divided doses, what happens?" Without wishing to appear facetious, I can tell him what happens: the correspondence columns of the medical press are filled for weeks to come by letters which, being paraphrased, read, "Ah, yes, but if you use another group of patients and give the drug in different dosage, and by a different route, you will get startlingly different results." And so the controversy continues.

My comments on this trial are largely a text on which to hang a plea to the statisticians to modify their rigid approach to clinical trials. Perfect statistical techniques are not possible when dealing with biological material, nor is it possible at the early stage at which the Medical Research Council generally formulate their trials for them to lay down the optimum regimes which are not liable to subsequent criticism. I would suggest that a more useful, if less perfect, protocol on which to base a clinical trial is: "Does drug X, given under optimum conditions (as judged by experienced, reliable, and unbiased clinicians), give better results than drug Y?"—leaving the clinicians to select both the patients and to adjust the dosage schedules to individual requirements. Possibly the "cross-over" technique mentioned in your leading article (p. 1249)—in which the patient becomes his own control—is the best compromise. A trial based on this essential degree of flexibility would give a far more useful and a broader picture of the problem, and at the same time would lack some of the specious sanctity which now arises from the statisticians choosing certain highly inaccurate assessments (such as joint tenderness and range of movement) as a means of overall assessment, whilst ignoring entirely such imponderable but important clinical features as the degree of stiffness and the patient's sense of well-being. As a *reductio ad absurdum*, unless we insist on some degree of clinical discrimination, we will soon be handing over these trials to technical assistants who will make a set of measurements without even asking the patient how he feels. We would do far better to learn to evaluate subjective factors in our patients than to ignore them.

To return to the cortisone-aspirin trial: *Selection of patients*.—The protocol laid down that the patients must have had the disease for not less than three months and not more than nine months. They should be suitable for either cortisone or aspirin therapy. Patients fulfilling even the first part of this criteria were exceptionally hard to find in two large clinics, drawing patients from all over England.

When such a patient did materialize, he was usually unsuitable for both types of therapy, either because the disease was too mild or because (as is so characteristic of this early stage of the disease) it was so unstable that it was almost impossible to evaluate any therapeutic results. No responsible clinician would give cortisone at this stage. None the less, they were included in the trial in most cases because more suitable material, fulfilling the criteria, was not forthcoming. This is probably the reason why the functional capacity assessments were identical in each group at the end of the year. It is of some interest that the one case (case 1 on p. 1225), whose disease was rapidly progressive, "drew" aspirin, and after six months he refused to continue in view of his deterioration. He was withdrawn from the trial, and was subsequently treated independently with cortisone. He is now back on full employment as a gold blocker; his disease is still very active, but well controlled. Thus he provides an excellent example of the "cross-over" technique. I am quite confident that no other type of drug would have controlled this man's disease. I am not convinced that in a small sample (such as the present one of thirty pairs) such anomalies are automatically ironed out by "pairing" on the basis of age and sex alone. It is of greater importance that one should aim to pair, if possible, similar clinical types.

Dosage.—Hench *et al.*² have laid down that it is of extreme importance to "individualize" the dose in cortisone therapy, and to give the minimum necessary to control most of the symptoms. The Medical Research Council trial required an initial dosage of 300 mg./200 mg./100 mg. followed by a sudden drop to 50 mg. in the second week, culminating in a period of abstinence on the thirteenth week, twenty-sixth, and twenty-ninth weeks, etc. It is difficult to imagine a regime so calculated to insult the psyche and the adrenals of the rheumatoid patient, and there is even some evidence (Lansbury, personal communication) that to allow the patient to get out of control in this way is very liable to spread the rheumatoid process. Certainly my own personal experience suggests that whenever a patient's disease breaks through the cortisone suppression, as a result of dose reduction, it may need considerably higher dosage to get him under control again. There are many other minor points of assessment on which one might comment in this trial, but they are of insignificant importance compared to those already mentioned.

To summarize: This trial has been expensive and laborious; it answers fairly conclusively, in spite of its technical imperfections, a problem with which few clinicians would disagree—namely, that there are very few cases of early rheumatoid arthritis for which cortisone is indicated. It completely fails to shed any light on the main problems of cortisone therapy. A plea is made that statistical rigidity in the planning of clinical trials should be modified so as to take some account of the clinician's discretion. In other words, the pendulum away from therapeutic empiricism has swung too far.—I am, etc.,

London, E.1.

SIR.—In the admirable report (*Journal*, May 29, p. 1223) by the M.R.C. and Nuffield Foundation Joint Committee it is said that cortisone or aspirin was given "together with any other basic treatment that might be required (splints, physiotherapy, etc.)." One wonders what are the criteria which determine that physiotherapy is "required," and what particular variety of physiotherapy is in mind. This method of treatment embraces massage of various kinds, remedial exercises of infinitely variable scope, radiant heat, cold, diathermy, wax baths, hydrotherapy, and several types of electrotherapy. Is there any evidence that any of these remedies, with the possible exception of remedial exercises, gives any benefit beyond, in some cases, symptomatic relief? And is this symptomatic relief as great as that derived from regular aspirin, which is so much cheaper

and which can be had so easily, without dislocating the patient's life? May I suggest that the M.R.C., whose committees have done such useful work in obtaining evidence as to the value of drugs, gives its attention to examining the claims made for physiotherapy in treating rheumatoid arthritis?

May I also suggest that the M.R.C. inquires into the value of rest for this disease? It is categorically stated in the latest medical articles that rest is "essential," though the authors maintain an attitude of judicious reserve in the matter of the duration and degree of this rest in various circumstances. In *Medical Treatment*,¹ for example, it is said: "First, rest, mental and physical, general and local, is of paramount importance. In all cases, this rest is as essential as it is in pulmonary tuberculosis, and it is especially indicated when shock, worry, and fatigue have been the major factors in causing the onset of the disease. An initial period of rest in bed away from worry, which in a particular case means away from home, is most necessary." It may be conceded that when the joints of the feet or legs are badly affected, or when the patient has marked constitutional symptoms, a period in bed is indicated. Even that greatly abused word "essential" may be cated. But is there any evidence that rest of a degree greater than that dictated by the symptoms has any effect on the course of the disease? How grateful we should be to the M.R.C. if it provided such evidence and we were no longer dependent on the *ex cathedra* pronouncements of the textbooks.—I am, etc.,

Farnham, Surrey.

J. W. TODD.

Women in Medicine

SIR.—The pre-registration year of internship mentioned by Mrs. Ruth D'Arcy Hart in her letter (*Journal*, May 29, p. 1266) is a statutory requirement prescribed by the Medical Act, 1950, and the Medical Act, 1950 (Period of Employment as House Officers), Regulations, 1951, made thereunder by the General Medical Council. Section 2(1) of the Act requires "employment in a resident medical capacity in one or more approved hospitals or approved institutions..." but Section 2(5) states that "reference to employment in a resident medical capacity shall be construed as reference to employment in the practice of medicine, surgery or midwifery, where the person in question is resident in the hospital or institution where he is employed or conveniently near thereto, and is by the terms of his employment required to be so resident" (my italics). Thus employment required to be so resident is not a statutory requirement, and it is to be hoped that hospital authorities will not overlook this fact when considering an application to live out from a married woman house officer with family responsibilities in a "pre-registration post." It is, of course, the general practice to require all house officers to be resident owing to the nature of the duties involved and the difficulty in finding living-out accommodation conveniently near to the hospital. It would be a pity, however, if, in areas where suitable arrangements can be made, hospital authorities fail to realize that Parliament itself has recognized that "employment in a resident medical capacity" does not necessarily mean compulsory living-in during the pre-registration year.—I am, etc.,

London, W.C.2.

ALISTAIR FRENCH.

SIR.—Non-resident "residents" can be very useful to hospitals, but only on condition that they pull their weight. This means that they must live near enough to the hospital, be on the telephone, and if necessary possess means of transport, so that they can do their proper share of night work. Nor, however much we may pity her dilemma, may a woman opt out of this duty because, for instance, the baby has whooping-cough. In any hospital post the patients' needs must be paramount.—I am, etc.,

Hove.

C. M. OTTLEY.

Tuberculin Testing

SIR.—I would like to add my experiences in tuberculin testing to the recent correspondence. This winter I have jelly-tested approximately 250 children, using the "flour-paper" technique and checking these results with a Mantoux test. While I have had many positive jelly tests and a negative Mantoux, I have never had a negative jelly test and a positive Mantoux. The jelly tests were only read as positive when there was vesiculation and erythema on the old tuberculin side of the intra-scapular area. The point I cannot understand is that these false jelly tests should give a reaction on the old tuberculin side and no reaction on the control side. I find no association between upper respiratory catarrh and false positive jelly tests.

While there is no doubt that the Mantoux test is the more accurate, it would seem that the jelly test using the "flourpaper" technique is of value when negative.—I am, etc.,

Surbiton, Surrey.

T. J. C. WARRINER.

Pleural Effusion in Young People

SIR.—A fundamental principle in the management of tuberculosis is involved in the plea for "proper assessment and treatment of cases of pleural effusion in young people" and the advocacy of "treatment in special units" (presumably residential) with educational facilities, made by Drs. F. J. Bentley and S. Grzybowski (*Journal*, May 29, p. 1263). They suggest that "antibiotic therapy in selected cases, together with an adequate period of graduated rest and subsequent rehabilitation, will prevent the development of serious tuberculous trouble in many instances later in life." They are really pleading that children should be separated from their parents and incarcerated in an institution for long periods, since in their recently published book¹ they state that the average period of bed rest in High Wood Hospital was 17.8 weeks and the average stay in the sanatorium 8.5 months for children with benign primary tuberculosis complicated by pleural effusion. Is this undesirable separation from parents, and this most expensive form of treatment, really necessary? It can be justified, perhaps, as a short-term measure for children deprived of parental care and adequate nutrition and housing, provided that the main efforts of the State are directed towards improvements in these conditions, for these are the real foundation of the total individual resistance that must be maintained after proper management of the acute stage, if serious secondary disease is to be prevented. In the case of children with good homes, sanatorium treatment of pleural effusion is of course quite unnecessary. Their assessment by general practitioners and the chest clinics is done well at present, and the rest treatment, which is all that is necessary, is best given in their own homes where the normal parental relationship can be maintained and strengthened, and perhaps the seeds of juvenile delinquency prevented from germinating. Even antibiotic therapy can be given at home if this is proved to be worth while; but, in 19 out of 167 chest clinic cases of benign primary disease complicated with pleural effusion which I observed under treatment with antibiotics the results were in no way different from 148 cases being treated by rest alone during the same period.

Treatment of pleural effusion complicating the benign primary complex by rest for a few months is certainly to be strongly advocated, but its only effect is to hasten quiescence of the primary complex and the concomitant building up of acquired resistance. Once this has been achieved, even in untreated cases, the treatment given during the active stage of the primary disease has no influence on the subsequent development of secondary tuberculous disease. That depends wholly on the maintenance of acquired resistance during the subsequent period of quiescence, and especially in the first three years of it. In a series of 184 active primary cases which I have observed to quiescence, or which were diagnosed quiescent at first

examination, and all of which subsequently developed secondary pulmonary tuberculosis, the observed interval between quiescent primary and active secondary disease was three years or less in 67%. Accordingly it is the maintenance of a high level of resistance during the first few years of quiescent primary disease that is the most important factor in the prevention of secondary pulmonary tuberculosis. This means that the accidental and physiological factors in resistance—namely, standard of living, good working conditions, housing and nutrition, and special care in relation to age and sex—are more important in this respect than management of primary disease in institutions. The efficiency of management of the primary disease merely determines the duration of its activity, while efficiency in maintaining resistance determines the duration of the period of quiescence.—I am, etc.,

New Apparatus for Insufflation Test

SIR,—The importance of Rubin's CO₂ insufflation test from a therapeutic and diagnostic point of view is to-day universally acclaimed. That being so, it is essential that the requisite apparatus should be in every gynaecological operating theatre, out-patient department, and consulting-room. But such an instrument must be strong, simple and not fragile, transportable, and independent of varying types of electricity, for there are still a great many places throughout the Commonwealth and Colonies where such an instrument is required but electricity does not exist.

For these reasons, with the help of Messrs. Down Bros. and Mayer and Phelps, Ltd., I have devised a simple, sturdy, foolproof, and readily portable apparatus which is worked by clockwork as was the original Rubin instrument. The picture shows the machine. The kymograph is on a horizontal disk and the pen with its perspex container is activated by a CO₂ cylinder fitted with a reducing valve. This cylinder is of standard 1 lb. (0.45 kg.) size enabling more than 200 patients to be dealt with. It will also permit continuous insufflation of not less than 30 cases during any operation such as salpingostomy or salpingolysis. The whole unit is housed in a leather-covered case with a detachable lid allowing free access to all the controls. It is fitted with the correct cannula and rubber connexion tubing for immediate use.—I am, etc.,

London, W.1.

V. B. GREEN-ARMYTAGE.

Varicocele and Male Subfertility

SIR,—I was most interested to read Dr. J. K. Russell's article (*Journal*, May 29, p. 1231) pointing out the high incidence of varicoceles in subfertile males. Having to deal with about 2,000 subfertile men every year, I can confirm his findings and would say that the incidence is probably even higher than his figures suggest. Since I have been collecting data on this problem from a different point of view—namely, that of therapeutic possibilities—I felt that the following observations might be of interest to your readers.

In my opinion, the effect of varicoceles on the semen picture represents only one aspect of a larger group—that is, that of disturbances of testicular temperature regulation. This group should include hydroceles, incomplete descent of the testes, and the wearing of scrotal supports. For normal spermatogenesis testicular temperature has to be kept about 2° C. below that of the body. A varicocele acts as a radiator at blood heat which follows testicular movements and thus counteracts the local thermoregulatory mechanism. This would explain the fact that a unilateral varicocele may depress spermatogenesis in both testes, as Dr. Russell points out. The semen picture in many cases falling within this group is characteristic, showing increased volume, oligozoospermia, poor morphology, and desquamated precursors of spermatozoa. If both the surgeon and the patient understand the underlying principle so that as much as possible of the varicocele is excised, and no scrotal support worn longer than necessary, the results of treatment are surprisingly good. Of a series of subfertile men treated by varicocele excision (mostly unilateral) twelve of the first fourteen completed cases showed unmistakable improvement, with seven pregnancies within six months of operation. Details of this series which was begun in 1950 are ready for publication, but may be reserved until the proposed series of fifty is completed later this year.

As to the risks of surgical treatment, provided it is in highly skilled hands my experience does not confirm this. Of the more than forty cases operated on by Mr. H. G. Hanley we have not seen a single case of infection, epididymitis, or testicular atrophy. Regarding the latter, we must remember that the testis on the affected side is often small and soft to begin with, and this may be mistaken for post-operative atrophy afterwards. On the other hand, both Mr. Hanley and myself, and sometimes the patients, have noticed that the testis increased in size after operation, as one would expect with increased spermatogenesis. In concluding, I would express my conviction that if we paid more attention to the problems of faulty testicular temperature regulation we should have far fewer cases of "intractable oligozoospermia" and might begin to emerge from the therapeutic pessimism so widespread in this field.—I am, etc.,

London, W.1.

H. A. DAVIDSON.

SIR,—Dr. J. K. Russell's excellent paper (*Journal*, May 29, p. 1231), which demonstrates the higher incidence of varicoceles in subfertile than in fertile men, lends further support to Dr. H. A. Davidson's,¹ which shows that a failure of the scrotal temperature-regulating mechanism can depress normal spermatogenesis, and that a common cause of such a failure is the presence of a varicocele. Having operated upon over 50 varicoceles for this condition, I am quite convinced of the therapeutic value of removing such a scrotal radiator, which, even if unilateral, can obviously influence both testes.

Any surgical procedure can be dangerous and should only be performed for very good reasons, but it is perhaps unfortunate that a surgeon of Professor Charles Wells's eminence, as quoted by Dr. Russell, should overstate the dangers of this particular operation. If the varicocele is grouped with the piles and varicose veins at the end of the list, to be done by the house-surgeon, I would agree with Professor Wells, but would add that all three operations are equally potentially dangerous. However, while humbly realizing

that—but for the grace of God—there go I, we have not seen any serious complications following the excision of a varicocele so far. I have used a scrotal incision as advocated by Sir Heneage Ogilvie (*Journal*, April 17, p. 934) ever since it was taught to me in 1935 by the late Mr. F. McG. Loughnane at all Saints' Hospital, and I have not encountered any of the serious complications hinted at by Mr. C. J. Cellan-Jones in his letter to your *Journal* (May 1, p. 1039).

The very high incidence of male subfertility is not generally appreciated, and Dr. Russell's paper, quite apart from its academic value, has done a service in drawing attention to this fact.—I am, etc.,

London, W.1.

Sex Diagnosis of Blood

SIR,—For some time we have been considering the possibility of sex differences in the human blood and have been particularly interested in the nuclear morphology of the polymorphonuclear neutrophil leucocytes. We have found a structural difference between the nuclei of the neutrophils in the two sexes. In the female there are typical drum-stick appendages which cannot be found in the male. In over 50 films studied of blood from over 25 males and 25 females the examiner diagnosed the sex accurately on this basis without previous knowledge of the origin of the blood. A paper giving a detailed description of the morphological differences has been submitted for publication and will appear shortly in this *Journal*.—We are, etc.,

London, S.E.5.

WILLIAM M. DAVIDSON.
D. ROBERTSON SMITH.

A New Oral Diuretic

SIR,—A potent oral diuretic is now available. "Mercloran" ("neohydrin," "chlormerodin"), however, was reported in your annotation (*Journal*, January 16, p. 144) to cause serious gastro-intestinal symptoms in a large proportion of patients, so that it had to be withdrawn in about two-thirds. I was interested to read that Dr. William A. Leff (*Journal*, May 8, p. 1093), using therapeutically effective doses, found the incidence of toxic symptoms to be only 10%. My own experience has been similar, and in the hope that this valuable drug will not be withheld because of reputed toxicity, I venture to record the results of a small clinical trial.

The subjects, 28 men and 4 women, were patients in a hospital for the elderly chronic sick, their ages ranging from 60 to 90. Thirty-one were suffering from chronic congestive heart failure, one from hepatic cirrhosis with recurrent ascites and oedema. Degenerative heart disease was the cause of failure in 22, hypertension in 6, and cor pulmonale in 3. Most of them had been receiving mersalyl regularly once or twice weekly, in addition to digitalis, but salt had not been restricted; fifteen were in frank congestive heart failure. Mercloran was given in a single dose each morning for six days per week. The initial dose in each case was 3 tablets (each containing 18.3 mg. of mercloran, equivalent to 10 mg. of mercury). This dose was gradually adjusted to the minimum which controlled oedema and orthopnoea. The daily maintenance dose was 2 tablets in 7 patients, 3 tablets in 5, 4 in 10, and 5 or 6 in the remaining 10 patients. Toxic effects were encountered in 8 of the 32 patients (nausea and vomiting in 4, diarrhoea in 4), and in each case the symptoms appeared within the first four weeks. In 6 cases the drug had to be withdrawn, usually because of vomiting, but further experience leads me to believe that a smaller initial dose enables more patients to develop tolerance. The remaining 26 patients have received the drug for 8 to 12 weeks. Most patients have felt better, and their oedema has either disappeared or been substantially reduced. The responses have in my opinion been superior to those given by parenteral

mersalyl. Outside hospital, long-term dietary salt restriction is unsuccessful, and frequent parenteral therapy may be irksome. Mercloran is therefore suitable for wider trial in chronic heart failure.—I am, etc.,

Sheffield.

F. J. FLINT.

Skin Responses in Asthma

SIR,—In view of the recent correspondence in your columns, our recently concluded investigations of skin responses in bronchial asthma¹ may be of interest to your readers. We have used the prick test in order to test the skin responses of 300 patients with respiratory allergy and of 100 normal subjects, and have found their outcome in the same subject most variable. Only in 3 out of 21 patients could we reproduce exactly the same result on two different occasions. The correlation between the positive skin reactions and history and clinical manifestations was poor. Although in many cases of clinical allergic disease the offending allergen gave a positive skin reaction, many other allergens produced positive reactions whose causative agency was improbable or could be excluded. This was not surprising: about 50% of our normal subjects had also one or more positive skin reactions, as other observers have noted. We have concluded that in respiratory allergy tests of the skin, as of any shock organ other than the respiratory passages, are of very limited value. They may be used as a guide in those cases in which the history gives no clue to the offending allergen, but without environmental or bronchial tests they cannot be regarded as conclusive evidence.—We are, etc.,

A Question of Seniority

SIR,—With reference to Dr. M. W. Littlewood's letter (*Journal*, May 22, p. 1210), the Hospital of St. Bartholomew was founded in 1123 by Rahere, the court minstrel of Henry I. It was established as a public hospital with an organization distinct from that of the Priory of St. Bartholomew. The date of foundation of these two institutions is known from the *Liber Fundacionis Ecclesie Sancti Bartholomei* written by a canon of the priory 29 years after the death of Rahere.¹ The first royal charter to the hospital was given by Henry I in 1133, and copies of this document exist in the hospital and in the Public Record Office. The hospital archives contain a deed of Rahere himself dated 1137 and many other documents of the twelfth century.

The Priory of St. Mary Overy in Southwark is known to have been in existence between 1120 and 1125, and may or may not have been founded as early as 1106. No documentary evidence proving the existence within this priory of a public hospital has yet come to light. The earliest reference to a hospital in connexion with it occurs in 1212, when, consequent upon the fire in Southwark which destroyed most of that suburb and all the priory except the refectory, the canons of St. Mary founded a "hospital" on their own lands near the priory, in which they celebrated divine service until the priory was rebuilt. The reference occurs in the *Annals of Bermondsey Abbey*. In 1213, in the Cartulary of St. Thomas's Hospital (now in the British Museum) and in the Curia Regis Rolls, mention is made of Amyas, Archdeacon of Surrey, who is called the Master of the New Hospital of St. Thomas. After that date references to this hospital abound. The claim of St. Bartholomew's Hospital to date from the twelfth century is founded on documentary evidence, that of St. Thomas's appears to rest so far on conjecture alone.—I am, etc.,

GWENETH WHITTERIDGE,
Archivist to St. Bartholomew's Hospital.

Acute Post-operative Laryngeal Obstruction

SIR.—Since the breathing end of the patient is very much the otolaryngologist's affair, it may be permissible for one to enter the forum of the anaesthetist, the more so if he can go back to the days when he passed many of the endotracheal tubes himself. Some of the newer recruits to anaesthesia seem to resent any guidance about children and tend to dismiss the advice of a middle-aged laryngologist as so much out-of-date fuss. Nevertheless, some things are worth repeating.

The narrowest diameter in the child is not at the glottis; it is below the glottis, and here the lining membrane is so sensitive that it may become oedematous with no more than a bad cold. Its reaction is such that modest pressure will produce oedema, and the longer the pressure the greater the oedema. A tube which is passed easily may not be withdrawn quite so easily, unless the operation has been short. A little oedema in the subglottic space of the small child, let us say a millimetre or two all round the circumference, is enough to cause a croupy cough and sometimes distress; slightly more may cause severe obstruction. It is to be noted that the same absolute quantity of oedema in the larger lumen of the adult may not even be an inconvenience. I speak as one who has carried out the tracheotomies or sat by the bedside wondering whether to act or not.

I fear that there is a growing tendency to use tubes which are far too big for small children, and this without any reference to the chance of injury in the passing; and I would say that far too little attention is given to the probable duration of operation in the child who is about to be intubated. It is quite salutary to observe children who have been intubated, to ask them to cough, to listen to the noise, and to meditate thereon. And sometimes the cough may have something to do with the cuff.—I am, etc.,

Newcastle-upon-Tyne, 2.

F. MCGUCKIN.

Motor-cyclists' Protective Hats

SIR.—Some prominence was recently given in sections of the lay press to a fatal accident in which the motor-cyclist victim was wearing a protective hat made to the requirements of British Standard 2001. A member of the medical profession who gave evidence at the inquest was reported as saying that the helmet was "too flimsy," and the jury in the case expressed the opinion that the "safety standards of certain makes of motor-cyclists' crash helmets should be investigated."

It would, we think, be of some value to the profession at large if the relevant facts on this matter were recalled. The British Standard for protective hats for motor-cyclists was based on all the information at the time of its publication—including the extensive researches of the Radcliffe Infirmary. The late Professor Sir Hugh Cairns represented the B.M.A. on the Technical Committee of the British Standards Institution which prepared the standard, and the Association's present representative on that Committee is Mr. D. W. C. Northfield, of the London Hospital. The Committee also included representatives of the Road Research Laboratory, the Royal Society for the Prevention of Accidents, the Ministry of Transport, and other Government departments, as well as the Auto-cycle Union and industrial groups concerned both with materials used in protective hats and with their manufacture. Before publication all these bodies and groups received copies of the draft standard for approval.

The salient features of the standard are: that the outer shell shall be durable, smooth, and free from projections; it shall be attached to an inner harness with space between the harness and the outer shell; it must withstand an impact test, pressure tests both fore and aft and sideways, a test for strength of harness, and a substantial weight test on the chin strap to ensure that the helmet is not likely to come off in an accident. The standard also stipulates that if a peak is fitted this must be pliable, so that it cannot possibly operate as a fulcrum, and, if in fact it should receive a

frontal blow, would bend and give added protection to the face and particularly to the eyes.

The Safety Division of the Road Research Laboratory has for some time been carrying out investigations on protective hats, and all the results tend to endorse the provisions of the present British Standard. The only new feature to improve the standard which is at present being considered is the possibility of incorporating additional padding between the harness and the shell. An adequate safety hat for the ordinary motor-cyclist must obviously be a compromise between what is economically possible for him to purchase, attractive enough for him (or her) to wear, and, while giving the maximum possible protection to the skull, not so resistant that it might transmit the shock to other equally vulnerable parts of the body. The standard as published represented the most carefully considered compromise between these factors which the available scientific and technical knowledge could provide.

A final point which should be recorded is that practically all the responsible makers of motor-cyclists' hats are now licensed to use the British Standards mark as an independent assurance of conformity with the requirements of B.S. 2001. The B.S.I. employs inspectors who regularly visit makers' factories and check both their production methods and their test procedures. Failure to maintain the standard would result in the manufacturer losing his licence to use the British Standards mark.

It is unfortunate that, although there are numerous known cases of very severe accidents at high speeds where certain death would have resulted if the rider had not been wearing a protective hat made in accordance with the British Standard, these incidents never achieve the publicity given to the much rarer cases in which a motor-cyclist wearing a protective hat suffers serious injury or death.—I am, etc.,

London, W.1.

E. WOODBRIDGE,
Assistant Technical Director,
British Standards Institution.**Standard of Anaesthetics in Britain**

SIR.—I would like, through you, to thank Dr. Geoffrey Organe (*Journal*, May 29, p. 1267) for his reproof, so urbane, even at times paternal, arousing in me all the emotion of George Washington as he stood beside his misdeed in the garden. Yet his letter misses the main point—namely, that never again should his innovation of admission of press reporters to surgical meetings be repeated. None of the speakers were warned, and I am still thanking God that I stopped where I did, because if I had gone on to some poignant case records it would have been terrible. Lay press reporters mean well, but cannot separate wheat from chaff: contrast your absolutely accurate six-worded report—"Mr. Dickson Wright discussed cardiac arrest," all wheat, no chaff—with that of the three columns of the *Daily Express*, all chaff and no wheat.

If I might make my point again, as it is rather hard to gather it from either account: Heart stoppage is easily overcome and does no harm, provided the preoccupied surgeon is told immediately. Modern anaesthetic machines give a semblance of life after it has departed and the finger, if it happens to be on the temporal or radial pulse, does not seem good enough. For the present, the price of safety must be perpetual vigilance, until some certain machine arrives to tell us (a) when the heart is wavering and (b) the moment it stops.—I am, etc.,

London, W.1.

A. DICKSON WRIGHT.

SIR.—Dr. Geoffrey Organe, as president of the Association of Anaesthetists of Great Britain and Ireland (*Journal*, May 29, p. 1267), is to be congratulated for taking Mr. Dickson Wright to task for certain remarks he made about British anaesthetists before an assembly of American surgeons on May 18 at the Royal College of Surgeons of England. Admittedly the situation was intensified by the fact that these remarks were made the basis of a rather sensational article in the *Daily Express* the following day; this could not have happened, however, unless these disparagements

had been made in the first place. Had they been meant seriously the Council of the Association of Anaesthetists might well have been advised to report the matter to the ethical committee of the General Medical Council. Assuming, however, that Mr. Wright was merely indulging in his peculiar "form of jocularity" he appears to have fallen into the trap against which all teachers of elocution warn those who endeavour to enliven their discourses with humour.

Even the most elementary manuals on the art of public speaking emphasize that there are three distinct factors involved in delivering a speech: "The audience, the speech, and the speaker. In other words, the occasion, the oration, and the orator; or to whom you speak, what, and how." It is noteworthy that all these manuals impress upon readers that the audience is the most important element in the understanding of any speech. Mr. Wright delivered his talk before an assembly of American surgeons whose sense of humour differs from our own and who are less familiar than we with the technique of introducing humour to lighten an otherwise stodgy scientific discussion. It is not unlikely, therefore, that, in common with the reporter from the *Daily Express*, many of them took these remarks at face value. This is unfortunate, for I am sure that anaesthetists in Great Britain are no less conscientious than those in the U.S.A. or other countries. Unlike surgeons, they spend all their working hours in the enervating atmospheres of operating theatres; and, owing to the shortage of junior staff, those of them who work in peripheral areas do more emergency work than their surgical colleagues, and are usually hard put to it to find a locum tenens to enable them to take even part of their statutory holidays.

Reverting to Mr. Wright's exaggerations, the lessons to be learnt are to curb the impulse to be amusing at the expense of the reputations of other colleagues, and to modulate the mode of delivery of all speeches to suit the particular audience concerned. Beau Brummell witticisms which may go down big among private friends, and the histrionic hyperbole which animates an after-dinner speech, have only a limited place during an international scientific congress, and then only when the entire audience is familiar with or conditioned to the sense of humour of the speaker concerned.—I am, etc.,

London, S.E.5.

A. H. GALLEY.

REFERENCE

- ¹ Pelsma, R. J. (1924). *Essentials of Speech*, part II, chapter 2, p. 179. Sir Isaac Pitman & Son Ltd., London.

SIR.—Addressing a surgical section meeting of the American College of Surgeons held recently at our own Royal College of Surgeons, Mr. Dickson Wright, of St. Mary's Hospital, London, is quoted in a national daily newspaper as saying, "The lives of hospital patients undergoing operation are being endangered because anaesthetists are relying too much on their machines instead of watching the patient's condition. . . . It will not surprise me to find that the latest anaesthetic machines are fitted with an ash-tray and a stand for holding a newspaper." The report continues that Mr. Dickson Wright revealed that several times during operations anaesthetists have told him that the patient had a good pulse when, in fact, the heart had stopped beating, and the quotation continues: "By the time the anaesthetist tells the surgeon that a patient's heart has stopped, it is sometimes too late to do much about it."

Mr. Wright has chosen this particular opportunity when speaking to a great audience to deliver an accusation of gross carelessness and slackness against anaesthetists all over the world. For years there has been continuous work undertaken by anaesthetists and manufacturers towards making anaesthetic machines safer. British manufacturers, Government departments interested, and individual anaesthetists are giving considerable time and thought to the design of anaesthetic machines.

Anaesthetists are junior members of the surgical team, but they have a contribution to make to that team and in doing so the surgeon often welcomes them as colleagues.

In this way surgical successes and advancement of knowledge may sometimes result. What Mr. Dickson Wright has said might appear to destroy this widely held belief in the value of the surgical team, but let him have no fear, he will not do this: modern surgery of all types has thrived on the experiences of surgical teams fashioned in the second world war. These teams continue under different titles in friendship and solid work throughout the large medical centres of this country. But what harm is caused to the patients unfortunate enough to have read the report in the newspaper quoted above? Here is something far more serious, and I ask Mr. Dickson Wright to reflect upon what a patient must have felt awaiting major surgery in the afternoon who happened to have read that newspaper in the morning. Also, what must that patient's relatives have thought as well? It is clear from his attitude that Mr. Dickson Wright had not considered in any way this effect of his address, and it would be a most generous action on his part if now he could see his way to withdraw the whole of his opinion about anaesthetists.—I am, etc.,

London, W.C.1.

R. W. COPE.

Complaints about Catgut

SIR.—During the last ten years or so my advice as a surgeon has from time to time been requested by a firm of manufacturers with regard to complaints from hospital surgeons concerning the alleged unduly easy breakage of their catgut in use during surgical operations. On these occasions the remainder of the accused batches of catgut have been returned to the makers and tested by them—the tensile strength of this catgut has invariably been found to be considerably in excess of B.P. requirements, and I have been able to confirm this high tensile strength; it has been impossible to cause breakages except by ill-usage.

It is perhaps not always realized how easy it is to treat catgut unfairly in the operating theatre. It may be weakened by immersion in watery solutions before use by the surgeon. Faulty tying of knots tends to cause fraying at any acutely kinked point with consequent increased risk of breakage. A most important factor would appear to be the ease with which, unwittingly, a pull is exerted on catgut many times in excess of the pull to which the gut is tested to fulfil minimum B.P. requirements, and, of course, equally many times in excess of the minimum pull needed to occlude a bleeding vessel or to tie a secure knot.

Complaints of faulty material, with their associated implications, can be very distressing to the manufacturers, whose catgut is subjected to rigid tests at all stages of its manufacture. It is unfortunate that such complaints appear in so many cases to be insufficiently well founded, particularly as the manufacturers are precluded by their position from adequate defence in reply.—I am, etc.,

Birmingham, 30.

H. G. V. MENCE.

Herpes Zoster and Chicken-pox

SIR.—I was interested to read the letter of Dr. C. Spencer Whitehouse (*Journal*, May 8, p. 1097). When I was a student in the out-patient clinic of Dr. John Franklin at the Westminster Hospital I was fortunate to see a similar case of the simultaneous eruption of herpes zoster and chicken-pox. The patient was a man who had had girdle pains originating in the lumbar region, followed by a widespread vesicular eruption on face, limbs, and trunk. In the left loin the vesicles were almost confluent and were arranged in a broad stripe extending round on to the anterior abdominal wall. Elsewhere the lesions were identical with the rash of chicken-pox.

This patient was also suffering from monocytic leukaemia, for which he was attending another department of the hospital. I remember the observation being made at the time that an association has been described between leukaemia and this uncommon manifestation of herpes zoster.—I am, etc.,

London, E.8.

JOAN M. CURTIS.

Obituary

F. L. HOPWOOD, D.Sc.

Dr. N. S. FINZI writes: While endorsing every word that Professor A. Wormall has said about Frank Hopwood (*Journal*, May 15, p. 1157) it might not come amiss to add a few personal reminiscences of my dear friend. Soon after the beginning of the first world war he joined us in the x-ray department at Bart's as a clinical assistant, probably the first who was neither a medical student nor a medical man. In this way he acquired a practical knowledge of the difficulties of a radiologist that enabled him to realize our problems more than any other physicist of the time. The early workers in x rays had to pick up their knowledge of radiological physics mainly from books, and it was extraordinarily helpful to myself to have his lucid explanations of difficult problems. After that war he helped me much, on my taking charge of the x-ray department, in designing a considerable extension of it and subsequently as it grew and grew. Very soon after I was appointed in charge of the x-ray department I got the medical council of Bart's to appoint him physicist to the x-ray department, probably the first appointment of this nature in Great Britain. In 1921 and on several later occasions groups of us visited various different clinics abroad, always, I think, with Hopwood accompanying us, and some of these visits had a considerable influence on our work. On one of them we were joined by Stanford Cade, and it had decisive influence on his subsequent work with radium.

Hopwood's help in starting high-voltage x-ray work culminated first of all in our million-volt machine, and now in the linear accelerator of 15 million volts, the construction of which is nearing completion. He was a member of the British delegation at several of the international radiological congresses. One small bit of research work miscarried, although it was the method subsequently used. A jewel merchant was worried about detecting cultured from natural pearls, and Hopwood could have obtained money for the x-ray department if he could have discovered the method. He tried various things but relied most on x-ray diffraction. However, there was no difference in the two pearls supplied, and yet this was the method subsequently used. I have always thought that there was a mistake in the pearls.

In all our long friendship I have never known him in a temper or ever speak a cross word. I valued his friendship more than I can tell.

Dr. T. D. LLEWELLYN, for many years medical officer of health for the borough of Port Talbot, died suddenly on March 29 at Bridgend, where he had been living in retirement. He was 66 years of age. Tudor David Llewellyn was born at Ogmore Vale, Glamorganshire, on May 5, 1887, the son of a chemist, and from Christ College, Brecon, he entered the Cardiff medical school, completing his training at St. Thomas's Hospital, London, and qualifying M.R.C.S., L.R.C.P. in 1918. Three years later he took the D.P.H. of the University of Wales. After qualification he was assistant to Dr. A. W. Anderson at Ogmore Vale for a short time until, in 1919, he was appointed an assistant school medical officer under the Glamorgan County Council. Later, he was medical officer of health for Pontardawe until 1927, when he took up a similar appointment at Port Talbot. He retired in 1945 on account of ill-health. In addition to the duties of his public health appointments, Dr. Llewellyn took an active interest in the work of the Order of St. John of Jerusalem as a lecturer and as an examiner for twenty-five years. He was exceedingly conscientious in all he did and never spared himself, and his death has brought great grief to his colleagues and to a host of friends. For recreation, he enjoyed a round

of golf, and he had the national love of music. He was a member of the Honourable Society of Cymmrodorion and of the Cambrian Archaeological Society, membership of the latter indicating another of his outside interests. He leaves a widow and one daughter.

The sudden death on May 14 of Dr. A. M. D'COTTA at the age of 50 came as a great shock to all his friends and colleagues in Singapore. Adrian Milnes D'Cotta, who was born at Singapore on August 17, 1903, had a brilliant career at the King Edward VII College of Medicine in that city. After qualifying in 1926 he held the appointment of house-surgeon at the College until 1928, when he came to Britain for postgraduate study, taking the Scottish triple qualification in that year and the conjoint diplomas of the English Royal Colleges in the following year. He returned to Singapore in 1930 and became first assistant in the obstetrics and gynaecology department of the King Edward VII College of Medicine, holding a resident post at the Kangand Kerbau maternity hospital, where he rendered good service. He gave up the appointment in 1935 to enter general practice and consequently was one of the first general practitioners in Singapore to possess a sound knowledge of the principles and practice of obstetrics. In 1946 he obtained the D.C.H. of the English Royal Colleges. B.H.S. writes: Few men have ever held the position of high esteem which was Dr. A. M. D'Cotta's these many years, and all of us felt towards "Mills," as he was generally known among his close colleagues and friends, the same respect and admiration in which he was held throughout the medical profession. It was my privilege to know "Mills" through the years from his student days in 1923. He combined with his personal charm and unlimited energy the highest standards of professional ethics. His genial personality, generous instincts, and keen clinical acumen will be missed not only by his colleagues in the profession but by the whole staff of the Catholic Medical Guild, of which he was president at the time of his death. We find a measure of consolation in the fact that he lived a fine, full life, a life enriched by the knowledge that he had the friendship and respect of all who knew him.

The sudden death on May 24 at the early age of 39 of Dr. H. JEFFERSON, consultant anaesthetist to the Belfast City Hospital, came as a profound shock to his many friends. Harold Jefferson was born in 1914 and was educated at Belfast Royal Academy and at Queen's University, Belfast, where he graduated M.B., B.Ch. in 1940. After graduation he held the post of resident medical officer at the Royal Victoria Hospital, Belfast, and then was commissioned in the R.A.F.V.R. early in 1941. Soon afterwards he went overseas, with the rank of flight lieutenant, but already ill-health had begun to dog his footsteps, and in April, 1945, he was flown back from India. J.F.B. writes: When "Jeff," as he was affectionately known, came back to this country he was invalided out of the R.A.F. and underwent a very serious operation. This did not daunt his natural enthusiasm, however, and very soon he was back at work. He began to specialize in anaesthetics, taking the D.A. of the English Royal Colleges in 1947. Early in the following year he was appointed visiting anaesthetist to the Belfast City Hospital and quickly established himself as one of the leading young specialists in the province. His popularity with his colleagues was a just tribute to the excellence of his work. His never-failing good humour and genial manner were well known in many Belfast hospitals, while his tact and courtesy, especially with the junior staff, will long be remembered. In May last year he suffered another serious reverse in health and was off work for some three months. He came back to practise with all his usual verve and energy. Perhaps better than anyone he realized how serious his illness had been; to those of us meeting him frequently in the past nine months it was at times difficult to appreciate how precarious his health was. As recently as January this year he was awarded the Fellowship of the Faculty of Anaesthetists. He was at work on May 23 but collapsed later that day and died the following

morning. His passing is a tragic loss to the profession in Belfast, and he is mourned by all his colleagues, but more particularly by those of us who were privileged to know him as a friend. R. G. V. writes: While convalescent after a severe illness, which developed when stationed in India during the war, Dr. Jefferson took up the study and practice of anaesthetics and quickly became a skilful practitioner in this specialty and was a much-loved figure in the hospital world in Belfast. "Jeff" was possessed of an inimitable sense of humour and comradeship, and many an operating session or surgical emergency ran the smoother for his mere presence in the theatre, to say nothing of his completely unruffled calmness and sure technique. A host of friends in all walks of life delighted in his charm and wit and marvelled at his surpassing courage in the face of serious illness. At the time of his death he was consultant anaesthetist to the Belfast City Hospital, where his gallant and debonair figure will ever be sadly missed by all his colleagues and associates. Deep sympathy will be felt for his widow and three children in their great and untimely loss.

Dr. HENRY ADAMS, who died on May 26 at his home at Bournemouth, where he had been living in retirement, was formerly in practice for many years at North Shields, where he was held in high esteem by all his colleagues. He was 80 years of age. Born on December 3, 1873, Henry Adams was educated at Gordon's College, Aberdeen, and at Aberdeen University, where he took a degree in arts in 1894, graduating in medicine four years later. He then held the appointment of house-surgeon at Aberdeen Royal Infirmary. In 1901 he settled in practice at North Shields, where he remained until 1943, except during the first world war. He then served as a captain in the R.A.M.C. from 1915 to 1918, first in the Mediterranean theatre of war and later in France, where he was a surgical specialist with a casualty clearing station attached to the 59th Division. After demobilization he returned to North Shields, and from 1918 to 1928 was a member of the honorary surgical staff of the Tynemouth Jubilee Infirmary. On his retirement he was elected a life governor of the Infirmary. During the last war, in addition to conducting a busy general practice, he served on medical boards and as medical officer at a first-aid post at Preston Hospital, North Shields, during the air raids. These additional duties, however, served to undermine his strength, with the result that in 1943, at the age of 69, he was forced to retire from practice. Five years later he moved to Bournemouth, but never really recovered his normal health. A member of the British Medical Association for fifty-five years, Dr. Adams was chairman of the Tyneside Division from 1927 to 1936. For many years he was also chairman of the Tynemouth local medical committee and vice-chairman of the Tynemouth local insurance committee. He was a past president of the Newcastle-upon-Tyne and Northern Counties Medical Society. Throughout the forty-two years he worked on Tyneside Dr. Adams gave of his best to his patients. His attention to their needs, provided as it was conscientiously and without stint, earned him their high regard and trust. His colleagues in the medical profession, too, had complete faith in his integrity, a faith they clearly demonstrated by repeatedly re-electing him to the chairs of the local Division and medical committee.

Lieutenant-Colonel H. G. ALEXANDER, I.M.S. (ret.), writes: As late medical superintendent of Mount Vernon Hospital, Northwood, might I be permitted to pay my tribute of great admiration and affection to the memory of one of the most courageous and gallant gentlemen that I have been privileged to know, my friend the late Mr. W. E. SPRINGFORD, whose obituary was printed in the *Journal* of May 29 (p. 1270)? In the face of two of the greatest disabilities to which humans are subjected this gallant gentleman met life and his great responsibilities as a surgeon with the utmost fortitude and resolution. He was a brilliant surgeon who in his short life lived up to the highest traditions of British surgery, and his high ideals remain an inspiration to all of

us who knew, loved, and respected him. He was full of human kindness, humour, and great courage, and his memory will ever remain dear to all of us at Mount Vernon. We extend our deepest sympathy to his widow.

Medico-Legal

THIOUREA ON ORANGES

Six Spanish oranges bought during April at a shop in Nottinghamshire and found to contain thiourea as a preservative were the subject of a hearing at Newark County Magistrates Court on June 2. A firm of wholesale fruit importers were charged under the Food and Drugs Act. They pleaded not guilty. It was the second case of its kind, the first, in Derbyshire, having been dismissed.

The prosecution explained that the only preservative allowed in oranges was sulphur dioxide. Thiourea was a toxic substance used by the medical profession for the treatment of abnormality of the thyroid gland. It was first used as a preservative in America in 1946, but experiments showed that in small concentration the substance was lethal to small animals such as rats, and the public health authorities in America prohibited its use. Thiourea was a poison, but it was because of its use as a preservative that this case was brought.

Mr. Hugh Childs, a public analyst, said that although thiourea had dangerous properties he did not think the amount used for preserving oranges would have any effect on normal human beings.

The manager and secretary of the defendant firm claimed that they had acted as brokers for a Spanish firm. They had no reason to suspect that the oranges contained the preservative. There was no danger of a repetition of this offence, because the Spanish Government had now prohibited the use of thiourea.

The magistrate found the case proved. A fine of £5 was imposed and defendants were ordered to pay £10 towards costs.

Universities and Colleges

UNIVERSITY OF OXFORD

On April 29 the degree of B.M. was conferred on D. R. Wright, M. P. Wright, and E. S. N. Hazel.

The Board of the Faculty of Medicine has re-coopted Dr. A. H. T. Robb-Smith for the statutory period of two years from the first day of Trinity Term, 1954.

Dr. Janet M. Vaughan, Principal of Somerville College, has been reappointed as a delegate of the University Museum for three years from the first day of Michaelmas Term, 1954.

UNIVERSITY OF CAMBRIDGE

On May 1 Professor H. R. Dean, Master of Trinity Hall, was appointed a manager of the Benn W. Levy Fund until December 31, 1957.

The following medical degrees were conferred on May 1:

M.D.—E. K. Westlake.
M.B., B.Chir.—P. O. Jones.
M.B.—J. C. Newell Price, R. J. Blow, J. P. Dickson, Betty Holt, Evelyn J. Mitchell.

The following degrees were conferred on May 15:

M.D.—P. A. Emerson, D. V. Bates, R. J. R. Cureton, A. P. Waterson.
M.Chir.—J. S. W. Whitehead.
M.B.—D. G. Dingle.

*By proxy.

UNIVERSITY OF LONDON

On March 24 the degree of M.D. (Internal) was awarded by the Senate to B. W. Lacey.

The following candidates at the London School of Hygiene and Tropical Medicine have been approved at the examination indicated:

ACADEMIC POSTGRADUATE CERTIFICATE IN PUBLIC HEALTH.—N. J. Al-Chokhachi, M. A. Hamdi, G. H. K. Niazi, A. M. Nur, I. Suliman, Gladys M. Vanniasingham.

The following scholarships at the Royal Free Hospital School of Medicine have been awarded for 1954-5: A. M. Bird Entrance Scholarship, Miss M. Wharf (Chesterfield St. Helena School), Sir Owen Roberts Memorial Scholarship for Women, Miss S. M. V. Jeffery (Royal Free Hospital School of Medicine), Elizabeth Garrett Anderson Scholarship for Women, Miss V. J. Everett (Royal Free Hospital School of Medicine), Elizabeth Bolton Scholarship, Miss M. R. Chaplin (Royal Free Hospital School of Medicine), Florence Hughes Scholarship for Women, Miss N. Bogdan (Royal Free Hospital School of Medicine).

The degree of M.D. was awarded to S. G. Browne and E. C. Turton on April 6.

The following candidates at the Institute of Psychiatry have been approved at the examinations indicated:

ACADEMIC POSTGRADUATE DIPLOMA IN PSYCHOLOGICAL MEDICINE.—J. E. A. Bartlett, J. L. J. Lumey, Mary M. McQuade, M. J. Rosenthal, Part I: R. W. A. C. Barton, P. H. Connell, P. S. Cook, R. de Alarcon, R. Emery, P. Haden, S. N. R. Pestonjee, B. A. Samarawera, T. A. C. Sirkwardena, A. Sittampalam, A. C. R. Skinner, Nancy I. Swift, J. D. Waldman, J. S. Whiteley, J. K. Wing.

UNIVERSITY OF BIRMINGHAM

At the annual meeting of the Court of Governors of the University held on February 18, the title of emeritus professor was conferred on Humphrey F. Humphreys, Vice-Chancellor of the University in 1952-3, and Professor of Dental Surgery from 1935 to 1952. At a reception in his honour on February 8, Professor Humphreys was presented with a portrait of himself, painted by Waldron Wells.

The title of honorary part-time lecturer in the Department of Experimental Pathology has been given to Dr. W. Weiner, director of the Regional Blood Transfusion Service, and that of University Research Fellow to Dr. Sylvia M. Saddington during the tenure of her present post in the same department.

The following appointments are announced: Dr. F. P. Lisowski, Lecturer in Anatomy; Dr. H. E. Robson, Lecturer in Anatomy; and Mr. A. Gourevitch, Clinical Lecturer in Surgery, as part-time Lecturer in Surgery, in place of Mr. Fauset Welsh, who has resigned.

Professor S. Zuckerman, F.R.S., and Professor T. McKeown will represent the University at the World Population Conference to be held in Rome in September, 1954.

Representatives of the University have been appointed as follows: Professor McKeown on the United Kingdom Committee for World Health Organization of the United Nations; Professor C. F. V. Smout on the Birmingham Regional Medical Recruitment Committee; Professor W. Melville Arnott, Professor E. Brodie C. Hughes, and Emeritus Professor W. H. Wynn on the Standing Joint Committee of the University, the United Birmingham Hospitals, and the Birmingham Regional Hospital Board; Dr. C. G. Parsons on the Regional Advisory Committee on Infectious Diseases; Professor J. W. Orr and Professor J. R. Squire on the Regional Advisory Committee on Pathological Services. Dr. J. W. T. Patterson has been reappointed representative of the University on the governing body of Queen Elizabeth's Grammar School, Hartsbury.

Dr. Margaret Jefferson resigns her appointment as part-time Lecturer in Medical Statistics on July 31, 1954.

UNIVERSITY OF SHEFFIELD

Dr. Joseph Magri has been appointed full-time demonstrator in anatomy.

The following resignations are announced: Dr. R. Wheeler Haines, senior lecturer in anatomy, on his appointment to the Chair of Anatomy in the Royal College of Medicine, Bagdad; and Dr. J. L. A. Grout, honorary lecturer in radiology.

ROYAL COLLEGE OF PHYSICIANS OF LONDON

At a quarterly comitia of the College held on April 29, with the President, Sir Russell Brain, in the chair, Dr. E. R. Boland, Dr. T. C. Hunt, and Dr. J. B. Harman were re-appointed representatives of the College on the Central Medical Recruitment Committee, and Sir Alun Rowlands on the Central Council for District Nursing. Sir Charles Dodds was appointed the College representative on the National Committee on Cancer.

The following, having satisfied the Censor's Board, were elected Members of the College:

K. D. Bagshawe, M.B., Katharine M. Baker, M.B., F. H. Burns, M.B., S. I. Cohen, M.D., J. Colvin, M.B., P. B. Cook, M.B., J. J. Daly, M.B., Lieutenant R.A.M.C., J. R. Edsall, M.B., I. E. Evans, M.B., Yvette A. P. Franklin, M.B., R. G. Gibbs, M.B., A. J. Goble, M.D., J. D. S. Hammond, M.B., P. J. D. Heaf, M.D., Cherry D. Heath, M.D., J. B. Hickie, M.B., Alison Hunter, M.B., J. D. Hunter, M.B., J. Knox, M.B., P. J. Lawther, M.B., D. G. Le Roux, M.B., D. V. Mackenzie, M.D., J. McE. Neilson, M.B., Patience Proby, B.M., A. J. Proust, M.B., P. M. Rooze, L.R.C.P., J. F. Southill, M.B., M. D. Turner, M.B., H. E. Webb, B.M., E. Wilkes, M.B., M. M. Zion, M.B.

Licences to practise were conferred upon 129 candidates (including 36 women) who have passed the final examination in medicine, surgery, and midwifery of the Conjoint Board, and who have complied with the by-laws of the College, as follows:

S. L. Adesuyi, L. N. Allen, T. D. Annear, Diana Austin, Jacqueline E. Banbury, L. Barsey, D. G. Bennett, A. Berry, H. R. Bisson, D. A. S. Blake, Gwyneth, J. D. Botherway, Angela I. Brooks, Jean Brown, D. C. L'E. Burges, Patricia Burne, P. M. C. Camm, Jean Carberry, June M. Cheetham, Brenda A. P. Clark, R. M. Clark, D. Constad, I. J. Cope, I. C. Cree, M. R. Crompton, R. N. Davis, B. Dawson, Jean E. Drake, P. Dromgoole, D. P. Duffield, Lise L. Einerl, R. A. Ellis, P. A. S. Evans, C. D. Farrier, A. S. E. Fowle, J. K. Frost, P. Garmon-Jones, Grace M. Gee, Mary H. Godwin, P. Gortval, R. A. Grande, Brenda Grant, W. B. Hanley, L. Harbin, L. M. Hart, D. Hide, G. M. R. Holliday, P. E. Hoogewerf, A. B. Hugo, L. H. Hurrell, W. M. Huse, I. Ingley, Barbara M. Isles, D. C. Jackson, P. D. C. Jarman, P. Jenkins, A. R. Jones, Erica J. Jones, F. W. Jones, H. D. Jones, J. A. Kay, P. Kellett, C. E. Langham, Diana E. Lathbury, N. A. G. Leadbeater, J. E. Leaney, J. J. Lewis, D. C. Linahan, Patricia J. Lindop, B. A. Lowe, C. Lowson, J. A. McMillan, W. M. Mee, Margaret S. Meyer, H. N. Middleton, K. F. Mole, A. A. D. Moore, Janet E. Morgan, O. Morton, Patricia E. Moul, Sheila M. Mullally, D. D. Munro, T. W. Nicholson, Wendy E. Noble, Patricia Painter, M. S. K. Palmer, A. Pearce, K. I. Pearce, Valerie J. Perkins, J. M. Phillips, C. W. Pook, D. Pownall, J. A. Purcell, J. R. Rawstron, Dorothy S. Read, Kathleen M. Reid, J. E. S. Relton, Corinne J. Richardson, D. F. Rideout, G. D. Ripley, D. Roberts, Margaret Russell, J. G. Sanderson, Count Andrew C. Skarbek, J. C. Smith, R. W. Smith, D. L. Smithson, B. K. Sood, G. P. C. Starck, L. Stimmler, Jane Sweatman, Eileen N. Thomson, T. M. Tibbets, W. R. Tidy, E. E. D. Tomlin, Annie M. N. Tustin, Heather F. A. Vickery, D. Vuckovic, J. G. Wall, D. R. Whitehouse, D. H. Williams, H. R. Willinga, J. H. P. Willis, A. J. Winterston, Joan M. Woodley, Celia B. M. Wooley, Enid M. Wozencroft, R. T. Yip-Choy, C. F. A. Younger, A. Youatt.

Diplomas were conferred, jointly with the Royal College of Surgeons of England, as follows:

DIPLOMA IN ANAESTHETICS.—A. J. Sims.
DIPLOMA IN CHILD HEALTH.—Susanne M. Salvisberg, and to the other successful candidates whose names are printed in the report of the meeting of the Royal College of Surgeons of England on April 8 (see below).
DIPLOMA IN TROPICAL MEDICINE AND HYGIENE.—R. M. Ajina, Evelyn C. Cummings, J. S. Dodge, N. D. Gosavi, A. E. Gunders, V. K. Nivarkar, Hla Kyaw Pe, C. E. P. Samarasinghe, S. Sen Gupta, T. K. Sweeney, S. A. Talib, and to the other successful candidates whose names are printed in the report of the meeting of the Royal College of Surgeons of England on April 8 (see below).
Diplomas in Physical Medicine and in Ophthalmology were also conferred, jointly with the Royal College of Surgeons of England, on the successful candidates whose names are printed in the report of the meeting of the Royal College of Surgeons of England on April 8 (see below).

ROYAL COLLEGE OF SURGEONS OF ENGLAND

At a meeting of the Council of the College, held on March 11, with Sir Cecil Wakeley, President, in the chair, it was reported that Mr. J. Johnson Abraham had been elected a Hunterian Trustee. A Hunterian Lectureship was awarded to Dr. Howard C. Naffziger (San Francisco).

Mr. R. R. Simpson (Hull) was elected to the Fellowship *ad eundem*.

J. E. Gardiner, Ph.D. (Leeds), was appointed Junior Lecturer in the Department of Pharmacology.

Dr. I. K. R. McMillan (St. Thomas's) was reappointed Mackenzie Mackinnon Research Fellow for the year ending June 30, 1955. The Hallett Prize was presented to A. Mitra (Calcutta). The Hancock Prize was presented to Sheila C. Hay (Sheffield) and Margaret S. Meyer (Royal Free).

The Council of the College met on April 8 for the last time in the old council room of the College, in which for over a hundred years their predecessors had held their meetings. The next meeting will be held in the new room in the rebuilt College.

The death of Sir Frank Colyer (Honorary Curator of the Odontological Collection and Hunterian Trustee) was reported and the Council unanimously adopted a resolution of condolence.

The Honorary Fellowship of the College was conferred on Dr. G. Gavin Miller, of Montreal.

The following were elected Fellows of the College without examination as being medical practitioners of at least 20 years' standing: Mr. J. W. H. Grice (Tunbridge Wells), Mr. D. M. E. Thomas (Sully, Glam), Professor G. Hadfield (London), Mr. J. Trueta (Oxford), Mrs. Dorothy R. Campbell (Coventry).

Mr. W. A. Jackman (Bristol) was elected to the Fellowship *ad eundem*, and Mr. R. R. Simpson (Hull) was admitted to the Fellowship.

Dr. W. D. M. Paton (University College Hospital Medical School) was admitted as the first Professor of Pharmacology at the College.

The Jacksonian Prize for 1953 was awarded to Mr. J. H. Peacock (Bristol) for his essay on the pathology and surgery of peripheral vascular occlusion.

The first Mitchiner Medal was awarded to Brevet Colonel H. D. Chalke, and the first Lady Cade Medal to Squadron Leader R. R. L. Pryer. Professor Martin A. Rushton (Guy's) was awarded the John Tomes Prize.

A Hunterian Lectureship was awarded to Professor Milroy A. Paul (Ceylon).

The Council selected diaphragmatic hernia as the subject for the Jacksonian Prize for 1955.

It was decided to institute a badge of office to be affixed to the Fellow's gown to distinguish the Members of Council.

Diplomas in Child Health, in Physical Medicine, in Ophthalmology, and in Tropical Medicine and Hygiene were granted, jointly with the Royal College of Physicians of London, as follows:

DIPLOMA IN CHILD HEALTH.—Dierdre Airey, Enid Atkins, H. Aufrichtig, Doris M. Beaton, Elaine M. Belton, Elizabeth F. Bennett, J. R. Bhatia, Flora M. Bisset-Smith, Audrey M. Bolton, E. M. Broadfoot, J. A. Browne, D. W. Bull, June M. Burger, A. P. Camilleri, Kai Hang Chau, J. A. Cheese, Omara A. Cherlyan, E. Chigier, J. H. Clyde, G. J. Cousins, Mary Crawford, Joan M. St. V. Dawkins, S. R. Deenadayala, J. M. Doyle, Catherine M. Durkin, J. G. Edgar, C. P. E. Elliott-Binns, J. M. Fisk, D. M. Fraser, S. P. Ghosal, Sheila M. Gough, Margaret L. Gladstone, Isobel H. Grant, S. T. Gunewardene, Anne M. Haines, Margaret E. Hall, Mary Hollowell, M. J. T. Hewetson, Sai Kong Ho, Kathleen A. Hockey, K. S. Holt, Megan D. M. Johnson, Jocelyn Johnston, P. Kapur, M. Pathmarani Kathiravelu, R. E. Kotler, Sylvia Lath, J. B. Lewis, M. Lewis, Siew Whye Loh, G. C. Love, Margaret Luig, M. F. McDowall, T. McKendrick, Sheila L. McKinlay, S. S. Manchanda, Cicely J. Millbank, R. A. Morgan, Marion E. Morris, Marion B. Morton, Chitra Rhona E. Morgan, K. A. Muller, N. V. O'Donoghue, R. M. Oliver, Ida S. Mukherjee, B. K. A. Muller, N. V. O'Donoghue, R. M. Oliver, Ida S. Paranjoti, Hawa Patel, G. N. St. J. Penney, Jean Poole, Frances E. Powell, Edith I. Proctor, S. D. Roche, Sonia Rollin, Carol J. Rubidge, H. H. Shawdon, Isabel G. Smith, M. H. Southall, Joyce K. Starkie, Joan V. Staver, K. Stewart, Mary Suggden, Majuree Sundaravell, C. G. W. Sykes, I. G. Thomson, J. N. Urc, D. Vardy, Claudine M. R. Vesey, I. S. Wallman, Ruth M. Walters, M. A. Warley, S. M. Don, G. R. Willegunarte, P. S. W. Wilkins.

DIPLOMA IN PHYSICAL MEDICINE.—D. J. E. Cheshire, P. R. Travers.

DIPLOMA IN OPHTHALMOLOGY.—J. A. Akingbehin, M. R. Ashbridge, M. H. Ashroff, D. J. Bowerman, G. Davidson, M. S. Faridi, K. C. Garg, M. H. Hardy, B. A. E. Harley, S. U. Joshi, A. bin A. Kadir, R. C. K. Loh, Marguerite C. Macdonald, Laurel J. Macintosh, M. H. Malik, D. L. E. Paine, R. A. Quesada-Guardia, J. N. Rohatgi, S. Roy, G. S. Sandhu, G. Singh, K. S. Subramaniam, A. A. Tye, J. H. W. Wessels.
DIPLOMA IN TROPICAL MEDICINE AND HYGIENE.—J. C. Aickin, F. L. Ashworth, A. S. Beare, C. Bhambarsuta, N. K. Bharucha, Z. M. A. Cader, A. T. Cook, T. M. Desai, J. K. Gajjar, G. H. K. Gentle, J. E. J. Hurman, L. S. Jainandana, A. C. Kail, A. M. Khatib, Y. J. Kiladlian, A. G. S. Jainandana, W. S. Millar, H. R. Miller, K. P. Milne, A. Muir, I. G. Murray, Leishman, W. S. Millar, H. R. Miller, K. P. Milne, A. Muir, I. G. Murray, L. Noronha, Magdelen K. E. Oberhoffer, M. K. Panikkar, K. H. Patel, H. N. Ray, W. Rollingshoff, P. D. Scheffel, E. K. Tagboto, P. Yates, P. Yoganathan.

ROYAL COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS

At a meeting of the Council of the College held on March 27, with the President, Mr. Arthur A. Gemmell, in the chair, Edward Solomons was admitted to the Fellowship.

At a meeting of the Council of the College held on May 22, with the President, Mr. Arthur A. Gemmell, in the chair, the following were admitted to the Fellowship:

H. Agar, A. F. Anderson, A. J. S. L. Boyd, J. C. McC. Browne, J. A. Chalmers, Mary P. John, W. Kearney, O. Lloyd, D. J. Malan, Patricia J. H. Massey, G. P. Milne, R. B. K. Rickford, C. S. Russell, J. M. Scott, Ruby G. Sharp, A. M. Sutherland.

The following were admitted to the Membership:

G. T. D. Barr, E. R. Broadberry, Vivienne A. Croxford, H. F. Daghastany, P. J. Dwyer, A. L. T. Easton, J. R. Elliott, G. A. Humphreys, T. P. Grant, J. Greenwell, K. Greig, R. W. Hughes, G. A. Humphreys, F. D. C. Jackson, K. B. Layton, C. V. Love, A. C. McInnis, P. Manolis, M. Mukerji, F. A. Murray, R. F. O'Donoghue, G. D. Pinker, D. E. M. Savage, S. G. Singh, H. J. Tighe, J. R. D. Tomlinson, A. C. Turnbull, R. Vaish, P. S. Watson, V. T. White.

The Council received a further grant of £3,000 from the Leverhulme Trust Fund for research purposes.

CONJOINT BOARD OF IRELAND

The following candidates were duly admitted Licentiates in Medicine and Midwifery on April 2, having passed the final examination in medicine, surgery, and midwifery of the Conjoint Board of Ireland: Una E. Batt, A. I. Booth, S. A. A. Carson, D. R. Chinoy, Margaret T. Coyle, Laura Cullen, Veronica O. Egbuna, Bridget Finnegan, Patricia J. Finnegan, P. D. N. MacAllister, Grainne McCarthy, P. J. Ward.

The Services

Major-General J. M. Macfie, C.B., C.B.E., M.C., late R.A.M.C., has been appointed Honorary Colonel of a Territorial Army unit.

Captain A. M. Ferrie, R.A.M.C., has been mentioned in dispatches in recognition of gallant and distinguished services whilst a prisoner of war in Korea.

Flight Lieutenant R. R. Macdonald, R.A.F., has been mentioned in dispatches in recognition of gallant and distinguished service in Malaya.

INFECTIOUS DISEASES AND VITAL STATISTICS

Summary for British Isles for week ending May 22 (No. 20) and corresponding week 1953.

Figures of cases are for the countries shown and London administrative county. Figures of deaths and births are for the 160 great towns in England and Wales (London included), London administrative county, the 17 principal towns in Scotland, the 10 principal towns in Northern Ireland, and the 14 principal towns in Eire.

A blank space denotes disease not notifiable or no return available. The table is based on information supplied by the Registrars-General of England and Wales, Scotland, N. Ireland, and Eire, the Ministry of Health and Local Government of N. Ireland, and the Department of Health of Eire.

CASES In Countries and London	1954					1953

* Measles not notifiable in Scotland, whence returns are approximate.
† Includes primary and influenzal pneumonia.
‡ Includes puerperal pyrexia.

nine years 1945-53 are shown thus -----, the figures for 1954 thus _____. Except for the curves showing notifications in 1954, the graphs were prepared at the Department of Medical Statistics and Epidemiology, London School of Hygiene and Tropical Medicine.

The number of workpeople (other than seamen) in the United Kingdom whose deaths from accidents in the course of their employment were reported in April, 1954, was 112, compared with 118 in March and 121 (revised figure) in April, 1953.

The number of cases of industrial diseases in the United Kingdom reported during April was as follows : Lead poisoning 6, other poisoning 0, anthrax 3, epitheliomatous ulceration 7, and chrome ulceration 11; total 27. There were no deaths.—*Ministry of Labour Gazette*, May, 1954.

The notifications of infectious diseases during the week included pneumonia 428, scarlet fever 911, whooping-cough 2,207, diphtheria 13, measles 2,046, dysentery 1,136, acute poliomyelitis 16, paratyphoid fever 2, and typhoid fever 1.

The largest variations in the trends of infectious diseases in England and Wales during the week ending May 22 were increases in the number of notifications of 234 for measles, from 1,706 to 1,940, and 73 for dysentery, from 1,031 to 1,104, and decreases of 241 for whooping-cough, from 2,660 to 2,419, and 66 for scarlet fever, from 898 to 832.

The largest rises in the incidence of measles were 88 in Yorkshire West Riding, from 59 to 147, 48 in Surrey, from 16 to 64, and 41 in Cheshire, from 75 to 116. The largest fluctuation in the trends of whooping-cough was a fall of 51 in Kent, from 188 to 137. Only small variations were reported in the local returns of scarlet fever. 22 cases of diphtheria were notified, being 13 more than in the preceding week. The chief features of the returns of diphtheria were rises from 0 to 4 in Devonshire, 3 to 7 in Lancashire, and 0 to 3 in Glamorganshire. The largest centres of diphtheria were Liverpool C.B. 5 and Plymouth C.B. 4.

26 cases of acute poliomyelitis were notified. These were 3 more for paralytic and 4 more for non-paralytic cases than in the preceding week. Three cases were notified in the counties of Warwickshire (Birmingham C.B. 3), Lancashire, Yorkshire West Riding, and Durham (Sunderland C.B. 2).

The incidence of dysentery this year has been very high, and the number of notifications has risen for the last four weeks. Notifications rose steadily from 322 in the first week of the year to 1,642 in the thirteenth week, then fell to 711 in the sixteenth week, and have risen steadily since. During the first 20 weeks 17,834 cases of dysentery have been notified. The largest centres of infection during the week reviewed were Lancashire 239 (Irlam U.D. 58, Bolton C.B. 20, St. Helens C.B. 17, Manchester C.B. 15, Stretford M.B. 14, Rawtenstall M.B. 14, Liverpool C.B. 12, Salford C.B. 10, Eccles M.B. 10, Farnworth M.B. 10), Yorkshire West Riding 152 (Dewsbury C.B. 69, Sheffield C.B. 24), London 144 (Islington 49, Lewisham 14), Leicestershire 81 (Leicester C.B. 69), Staffordshire 67 (Newcastle-under-Lyme M.B. 31, Cannock U.D. 22), Middlesex 54 (Tottenham M.B. 18, Willesden M.B. 11), Sussex 43 (Brighton C.B. 29), Cheshire 39 (Dukenfield M.B. 21), Surrey 31 (Croydon C.B. 21), Northumberland 27 (Castle Ward R.D. 14), Warwickshire 27 (Birmingham C.B. 16), Kent 22 (Chatham M.B. 10), Nottinghamshire 22, and Essex 21.

The largest returns of dysentery in Scotland were 205 in Glasgow, 44 in Edinburgh, and 15 in Lanark county.

The graphs below show the uncorrected numbers of cases of certain diseases notified weekly in England and Wales. Highest and lowest figures reported in each week during the

Smoke Abatement.—The National Smoke Abatement Society has published, as a printed booklet, a memorandum of proposals for action that it has submitted to the Government committee on air pollution (the Beaver Committee). The Society considers present legislation on the subject outdated, and calls for a new Act. Provisions that the Society would like to see in the new Act include: more stringent control methods for checking the emission of smoke; prior approval of all new fuel-burning installations (except domestic, for which only approved appliances should be sold); power for local authorities to set up smokeless zones without having to promote private Bills; and, to ensure that the law is respected, the employment of qualified smoke inspectors. The memorandum also makes a number of proposals for immediate action. The memorandum is obtainable for 1s. from the Society, at 30, Grosvenor Place, London, S.W.1.

New Mental Deficiency Hospital.—The picture on this page shows the Minister of Health, Mr. IAIN MACLEOD, laying the foundation stone of Greaves Hall, near Southport, last month. Greaves Hall is the first major hospital

to be started in England and Wales since before the war, and it will be used for mental defectives. Its estimated cost is about £3m., and it will provide beds for over 1,000 patients. The new hospital will be in the area of the Liverpool Regional Hospital Board. Speaking at the foundation ceremony, Mr. Macleod said that more than 2,500 new mental-deficiency hospital beds were expected to be built from centrally financed schemes in the next two years in addition to the schemes in the hospital boards' normal programmes. But new building was not the only way in which it was hoped to improve the mental health services. The services provided by local health authorities for mental defectives living at home were of great importance and had increased considerably in the last few years. But, although in recent years nursing recruitment had made great strides, the mental hospitals had lagged behind the general advance and were still very short of nursing staff. It was not yet sufficiently well known that the whole atmosphere of the mental and mental deficiency hospitals had been revolutionized by modern methods of care and treatment and that these branches of the nursing profession now offered a career with interesting work and excellent prospects. Other speakers at the ceremony included Mr. T. KEELING, chairman of the Liverpool Regional Hospital Board, the BISHOP OF LIVERPOOL, Sir HENRY COHEN, and Mr. C. AVELING, chairman of the Southport and District Hospital Management Committee.

Diabetic Association.—Founded in 1934, the Diabetic Association, which is primarily an association of laymen, has contributed greatly to the welfare of the whole diabetic community. Membership is now about 18,000. Among the association's activities are the financing of research from a fund set up about seven years ago, the organizing of summer holiday camps for children, and the giving of detailed advice to diabetics. Great Britain was the first country to form a diabetic association, and its example has now been followed in nearly all other countries. The association asks medical practitioners to call the attention of their diabetic patients to its aims and achievements, full particulars of which may be obtained from the secretary-general at 152, Harley Street, London, W.1.

Florence Nightingale Centenary Concert.—The United Hospitals Festival Choir presented a concert at the Royal Albert Hall on June 3 to commemorate the 100th anniversary of Florence Nightingale's mission to the Crimea. H.R.H. the PRINCESS ROYAL was present to hear Mendelssohn's Symphony and Hymn of Praise pleasingly interpreted by the London Symphony Orchestra (conductor COLIN RATCLIFFE) and the United Hospitals Festival Choir, with soloists ENA MITCHELL, PAULINE BROCKLESS, and ALEXANDER YOUNG. Earlier Dame MYRA HESS and the orchestra had given a performance of Schumann's Piano Concerto in A Minor. The Choir, of about 300 voices, was formed in 1951 by Colin Ratcliffe, and is drawn from the medical, nursing, administrative, and technical staff, and students of over 50 hospitals in and around London, under the Presidency of Lord Horder. Its purpose is to enable hospital staff to help medical and allied causes while contributing to the field of music. The concert at the Albert Hall was in aid of the National Florence Nightingale Memorial Fund. The Fund was launched with the joint objects of maintaining Florence Nightingale House as a residential home for nurses attending postgraduate courses in London, and of promoting nursing education by the award of scholarships.

Travelling Medical Bookshop.—Hospitals far from teaching centres and well-stocked bookshops are now being visited by a travelling medical book service organized by John Wright and Sons Ltd., of Bristol. A large motor vehicle has been adapted to carry and display a comprehensive range of books, about 1,000 in number, on medical, dental, nursing, and allied subjects. The vehicle will follow an itinerary covering the south-west, South Wales, and the west Midlands, stopping at hospitals for an hour or two so that the staff can have an opportunity to see the latest medical publications.

European Office of W.H.O.—The Executive Board of the World Health Organization has endorsed the choice of Copenhagen as the permanent site for the Regional Office for Europe. Other cities considered were Nice, Frankfurt, The Hague, Vienna, Florence, and three in Switzerland. In the final ballot there were 11 votes in favour of Copenhagen and 10 in favour of Nice.

Study Tours in Europe.—The German Educational Travel Association has arranged four study tours for doctors in connexion with congresses on (1) gynaecology, at Geneva; (2) poliomyelitis, at Rome; (3) orthopaedic surgery, at Berne; (4) tuberculosis, at Madrid. This travel association is a non-profit-making organization. Details from Deutsche Studienreisen-Gesellschaft, Nürnberg, Veilloderstrasse 1.

Consulting Surgeon to the Army.—Sir ARTHUR E. PORRITT has been appointed honorary consulting surgeon to the Army at home in succession to Sir HENEAGE OGILVIE.

Royal Dental Hospital.—Lord WEBB-JOHNSON has been appointed consulting surgeon to the Royal Dental Hospital of London and School of Dental Surgery.

Faculty of Anaesthetists.—Dr. BERNARD JOHNSON has been re-elected dean of the Faculty of Anaesthetists of the Royal College of Surgeons for the ensuing year, and Dr. R. F. WOOLMER has been elected vice-dean.

R.M.B.F.—The annual general meeting of the Royal Medical Benevolent Fund was held on June 4. A report will be given in our next issue.

Queen Charlotte's and Chelsea Hospitals' Research Prizes.—The prizes for 1953 have been awarded to Dr. J. H. GIBSON (£200) for a paper on pyrexia in the puerperium written in conjunction with Dr. R. M. CALMAN, and to Dr. W. E. HUNT (£50) for one on acute oesophagitis in the newborn.

Sheffield Old Students.—The recently formed Sheffield Medical School Old Students Association will hold its inauguration dinner at Sheffield on October 2. Details of this, and of membership, from the secretary of the Pathology Department, The University, Sheffield, 10.

COMING EVENTS

Mackenzie Industrial Health Lecture.—This lecture will take place on July 13, not July 19 as stated in our issue of May 29 (p. 1276). The lecture has been arranged by the B.M.A. in conjunction with the Association of Industrial Medical Officers and will be delivered during the latter's annual provincial meeting in Manchester.

Medical Research Society Lecture for 1954.—This lecture will be delivered by Dr. G. W. THORN, of Harvard, at 5.30 p.m. on June 18 at the London School of Hygiene and Tropical Medicine. His subject is "Adrenal Cortical Response to Stress in Man."

Faculty of Radiologists.—The annual meeting will be held in Dublin on June 18 and 19. Further details from the secretary, 45, Lincoln's Inn Fields, London, W.C.2.

British Association of Urological Surgeons.—The annual meeting will be held in Dublin from June 24 to 26. The main discussion will be on "Irradiation Therapy in Urology," and there will also be short papers. Further information may be obtained from the secretary of the association, 45, Lincoln's Inn Fields, London, W.C.2.

International Congress for Individual Psychology.—The congress will be held in Zurich from July 26-29. Further information from Frau Dr. E. Schmid, 14, Krönleinstrasse, Zurich, Switzerland.

International Congress on Thrombosis and Embolism.—A conference will be held at Basle, Switzerland, from July 20 to 24. Further information may be obtained from the general secretary, Gynaecological Clinic of Basle University, Switzerland.

NEW ISSUES

British Journal of Ophthalmology.—The new issue (Vol. 38, No. 6) is now available. The contents include:

FOVEAL VISION IN AMBLYOPIA. Mary Pugh.
VALUE OF ABNORMAL RETINAL CORRESPONDENCE IN BINOCULAR VISION. M. Levine.

CATARACT SUTURES. W. L. Hughes.
ACRYLIC GONIO-SUBCONJUNCTIVAL PLATES IN GLAUCOMA SURGERY. S. A. Gadeer.

FREE AMINO ACIDS IN THE HUMAN AQUEOUS HUMOUR. C. Wunderly and B. Caglianini.

ACUTE HYPOTONIA. Valdemar Hertz.
INTRA-OCULAR FOREIGN BODIES: REPORT OF 102 CASES. Kazimierz Rubenstein.

EXTRA-CONJUNCTIVAL IMPLANT. M. L. Nairac.

ADENOMA OF THE CONJUNCTIVA. A. J. Borse.
CONGENITAL MEMBRANOUS CATARACT, DENTIGEROUS CYST, AND MULTIPLE FIBROPLASIA. L. P. Agarwal and I. N. Raizada.

Issued monthly; annual subscription £4 4s.; single copy 8s. 6d.; obtainable from the Publishing Manager, B.M.A. House, Tavistock Square, London, W.C.1.

Annals of the Rheumatic Diseases.—The new issue (Vol. 13, No. 3) will be available in a week's time. The contents include:

ON THE MECHANISM THROUGH WHICH OBSTRUCTIVE JAUNDICE INFLUENCES INFLAMMATORY PROCESSES. Hans Selye.
ANKYLOSING SPONDYLITIS AND PROLONGED A.C.T.H. THERAPY. H. F. West and G. R. News.

STUDIES ON THE EFFECT OF PROBENECID ("BENEMID") IN GOUT. R. M. Mason.

EFFECT OF POST-PARTUM PLASMA IN RHEUMATOID ARTHRITIS. David H. Neustadt, Jacob Geiser, and Otto Steinbrocker.

THE ARTHRITIS OF RHEUMATOID ARTHRITIS. Bruce Cruickshank.
OSTEITIS CONDENSANS ILII AND ITS DIFFERENTIATION FROM ANKYLOSING SPONDYLITIS. Malcolm Thompson.

SHOULDER AFFECTIONS IN RHEUMATOID ARTHRITIS. Veikko A. I. Laine.
Kauko I. Valio, and Kalle Pekkanmäki.
REITER'S SYNDROME AND CORTISONE. H. A. Reid.

Issued quarterly; annual subscription £2 2s.; single copy 12s. 6d.; obtainable from the Publishing Manager, B.M.A. House, Tavistock Square, London, W.C.1.

SOCIETIES AND LECTURES

A fee is charged or a ticket is required for attending lectures marked *. Application should be made first to the institution concerned.

Monday, June 14

EDINBURGH UNIVERSITY.—At Physiology Class Room, University New Buildings, 5 p.m., Dr. D. J. Guthrie: The Monros and the Edinburgh Medical School.

INSTITUTE OF NEUROLOGY.—5 p.m., Guest Lecture by Dr. E. H. Butterell (Toronto): Management of Spinal Cord Injuries and Studies on Spinal Man.

INSTITUTE OF OBSTETRICS AND GYNAECOLOGY.—At Chelsea Hospital for Women, (1) 3 p.m., Professor J. Louw (Capetown): Abortions. (2) 4.30 p.m., Professor Bruce Mayes (Sydney): Infertility.

POSTGRADUATE MEDICAL SCHOOL OF LONDON.—4 p.m., Dr. H. E. Holting: Ballisto-cardiography.

Tuesday, June 15

INSTITUTE OF DERMATOLOGY.—5.30 p.m., Dr. W. N. Goldsmith: Tuberculosis.

INSTITUTE OF NEUROLOGY.—5.30 p.m., Dr. Helen E. Dimsdale: Intracranial Vascular Anomalies other than Aneurysms.
POSTGRADUATE MEDICAL SCHOOL OF LONDON.—4 p.m., Dr. A. M. Cooke: On Writing for a Medical Journal.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—5 p.m., Mitchell Lecture by Dr. J. L. Livingstone: Observations on the Treatment of Pulmonary Tuberculosis at the Present Time.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—3.45 p.m., Arnold Demonstration by Professor M. F. Lucas Keene: Embryological Background of Some Common Abnormalities.

Wednesday, June 16

INSTITUTE OF DERMATOLOGY.—5.30 p.m., Dr. C. D. Culnan: Ringworm Infections and Their Treatment.

INSTITUTE OF OBSTETRICS AND GYNAECOLOGY.—At Queen Charlotte's Hospital, 12 noon, Professor Bruce Mayes (Sydney): Could the Chapter on Eclampsia Disappear? (The Present-day Management of Toxaemia in Sydney.)

LIVERPOOL MEDICAL INSTITUTION.—At Warrington General Hospital, clinical demonstration arranged with Warrington Division, B.M.A.

MIDDLESEX COUNTY MEDICAL SOCIETY.—At Shenley Hospital, 3 p.m., Film: A Two-year-old Goes to Hospital. To be introduced by Dr. C. H. A. Wedeles, followed by a discussion.

ROYAL EYE HOSPITAL.—5.30 p.m., Mr. G. C. Pritchard: Visual Fields (2).

Thursday, June 17

EDINBURGH UNIVERSITY.—At Physiology Class Room, University New Buildings, 5 p.m., Dr. D. J. Guthrie: Modern Medical Education in Historical Perspective.

INSTITUTE OF DERMATOLOGY.—5.30 p.m., Dr. H. Haber: Specific Granulomas.

INSTITUTE OF NEUROLOGY.—5.30 p.m., Dr. W. W. Gooddy: Birth Injuries.

INSTITUTE OF OBSTETRICS AND GYNAECOLOGY.—At Hammersmith Hospital, 3 p.m., Professor Bruce Mayes (Sydney): The Pregnant Diabetic.

LEEDS UNIVERSITY.—At Littlewood Hall, Instructional Block, General Infirmary at Leeds, 4 p.m., First Matthew Stewart Lecture by Professor G. R. Cameron, F.R.S.: The Exploration of the Cell.

LONDON JEWISH HOSPITAL MEDICAL SOCIETY.—At Medical Society of London, 8.30 p.m., annual general meeting. Short papers by general practitioners.

NORTH-WESTERN TUBERCULOSIS SOCIETY.—At Baguley Hospital, Wythenshawe, Manchester, 3 p.m., summer meeting.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m., Hunterian Lecture by Sir Stanford Cade: Adrenalectomy.

ROYAL EYE HOSPITAL.—5.30 p.m., Miss I. Kane: Retrolental Fibroplasia.

ROYAL SOCIETY.—4.30 p.m., Bakerian Lecture by Professor A. R. Todd, F.R.S.: Chemistry of the Nucleotides.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE.—7.30 p.m., annual general meeting. Dr. C. C. Chesterman: The Training and Employment of African Auxiliary Medical Personnel.

Friday, June 18

INSTITUTE OF DERMATOLOGY.—5.30 p.m., clinical demonstration by Dr. R. M. B. Mackenna: Tuberculosis and Sarcoid.

INSTITUTE OF OBSTETRICS AND GYNAECOLOGY.—At Queen Charlotte's Hospital, 2 p.m., Professor J. Louw (Capetown): Rupture of the Uterus.

KENT AND CANTERBURY HOSPITAL.—8 p.m., clinical meeting.

LONDON ASSOCIATION OF THE MEDICAL WOMEN'S FEDERATION.—At Royal Free Hospital School of Medicine, 8.30 p.m., social meeting with music.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.—5.30 p.m., Medical Research Society Lecture by Dr. G. W. Thorn (Harvard): Adrenal Cortical Response to Stress in Man.

POSTGRADUATE MEDICAL SCHOOL OF LONDON.—2 p.m., Mr. J. E. Laing: General Principles of Plastic Repair. 4 p.m., Dr. D. V. Hubble: Investigation of Endocrine Syndromes.

Saturday, June 19

BIOCHEMICAL SOCIETY.—At Department of Biochemistry, Cambridge University, 11 a.m., 330th meeting. Scientific papers will be read.

INSTITUTE OF OBSTETRICS AND GYNAECOLOGY.—At Chelsea Hospital for Women, 11 a.m., Mr. C. W. A. Kimbell: Subtotal, Total, and Vaginal Hysterectomy.

APPOINTMENTS

BRITISH TRANSPORT COMMISSION (BRITISH RAILWAYS): LONDON MIDLAND REGION.—C. R. May, L.M.S.S.A., and H. H. Whincup, M.B., Ch.B., Assistant Medical Officers.

EAST ANGLIAN REGIONAL HOSPITAL BOARD.—J. B. Lyon, M.B., B.Chir., M.R.C.P., Consultant Dermatologist, with charge of Venereal Disease Clinics in Ipswich Hospitals Area; W. J. Crawford, M.B., B.Ch., Anaesthetic Registrar, East Suffolk and Ipswich Hospital; Kathleen M.

McNamara, L.R.C.P.&S.I., Anaesthetic Registrar, Newmarket General Hospital; Lucy T. Lee, M.B., B.Ch., Anaesthetic Registrar, United Norwich Hospitals; Marion B. Morton, M.B., B.S., D.C.H., Paediatric Registrar in Peterborough Area.

HARDING, H. E., F.R.C.S., Orthopaedic Surgeon, Hospital of St. John and St. Elizabeth, London, N.W.

KNAPMAN, W. B., M.R.C.S., L.R.C.P., Assistant Psychiatrist, Bowden House, Harrow-on-the-Hill.

JAMIESON, JOHN G., B.M., B.Ch., D.C.H., Senior School Medical Officer, Leeds.

MACTAGGART, DOUGLAS K., M.B., Ch.B., D.P.H., Assistant County Medical Officer, Devon County Council, and Medical Officer of Health to the Borough of Dartmouth, the Urban Districts of Brixham and Paignton, and Brixham Port Health Authority.

MANCHESTER REGIONAL HOSPITAL BOARD.—A. Glass, M.B., Ch.B., F.R.C.S., Consultant Orthopaedic and Accident Surgeon to North Manchester Hospital Centre and Booth Hall Children's Hospital. J. D. Heppleston, M.B., Ch.B., D.C.P., Consultant Group Pathologist to South Cheshire Hospitals.

MENZIES, ALEXANDER, M.B., Ch.B., D.P.H., Medical Superintendent, Inverness Group of Hospitals.

MILLIGAN, H. C., M.B., Ch.B., D.P.H., Deputy Medical Officer of Health, Walsall County Borough.

NEWMAN, NOEL, M.B., B.Ch., D.P.H., Deputy Medical Officer of Health and Deputy Principal School Medical Officer, City of Bath.

NORTH-EAST METROPOLITAN REGIONAL HOSPITAL BOARD.—J. B. Enticknap, M.D., D.C.P., Full-time Consultant Pathologist, East Ham Memorial Hospital. H. W. Balme, M.D., M.R.C.P., full or maximum Part-time Consultant Physician, Whipps Cross Hospital. A. Russell, M.D., M.R.C.P.

D.P.H., D.C.H., Part-time Consultant Paediatrician, Harold Wood Hospital. Iford Maternity Hospital, Iford, F.F.A.R.C.S., Part-time Consultant Anaesthetist, King George Hospital, Iford, Iford Isolation Hospital.

G. C. Thick, M.B., B.S., D.A., F.F.A.R.C.S., Part-time Consultant Anaesthetist, Hertford Group of Hospitals.

PRESTON, FRANK S., M.B., Ch.B., D.A., Regional Medical Officer (Eastern), British European Airways.

REYNOLDS, G. MORTON, M.B., B.Ch., D.P.H., Deputy Medical Officer of Health, School Medical Officer, and Deputy Port Medical Officer, County Borough of Great Yarmouth.

WILSON, JOHN GREENWOOD, M.D., F.R.C.P., D.P.H., Medical Officer of Health, Port of London (the appointment will subsequently be amalgamated with that of the City of London).

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Harris.—On May 15, 1954, to Juliette, wife of L. H. Harris, M.B., B.S., of 2, Durrice House, Lyndale, London, N.W., a sister for Adrian and Darrell—Yulanie Cherie.

Henry.—On May 19, 1954, at British Military Hospital, Klagenfurt, Austria, to Hilda (formerly Loble), wife of Captain E. R. Henry, R.A.M.C., a daughter—Alicia Claire.

DEATHS

Aldridge.—On May 15, 1954, Arthur William Aldridge, M.B., B.S., of Basford Avenue Road, Great Malvern, Worcs, late of Thickthorn, Northfield, Worcs, aged 79.

Beesly.—On May 9, 1954, at his home, Newbury, Berks, Lewis Beesly, F.R.C.S.Ed.

Blake.—On May 15, 1954, at Orchard Cottage, Nailsworth, Glos, Anthony Fewster Blake, M.R.C.S., L.R.C.P., formerly of Grays, Essex, aged 84.

Brown.—On May 9, 1954, at Ardeer House, Shankhouse, Cramlington, Northumberland, William Brown, M.B., Ch.B., aged 53.

Butler.—On May 17, 1954, at 53, Charlotte Street, Leith, Edinburgh, James Butler, M.B., C.M.

Chambers.—On May 13, 1954, at 51, Bushey Hall Road, Bushey, Herts, Elsie Blair Chambers, M.B., Ch.B.

Corbett.—On May 19, 1954, at Fairwinds, Kingswear, South Devon, George Holmes Uvedale Corbett, M.B., B.C., aged 75.

Ellis.—On May 5, 1954, John Stanley Ellis, M.R.C.S., L.R.C.P., of 32, Combe Park, Bath.

Fraser.—On May 7, 1954, at Swansea General Hospital, George John Fraser, M.B., Ch.B., of Brynheulog, Mayals, Swansea, late of Glen Urquhart, Inverness-shire.

Garson.—On May 15, 1954, John Ross Garson, M.B., B.S., of 3, Daleham Avenue, Egham, Surrey.

Hardcastle.—On May 17, 1954, in hospital, Douglas Noel Hardcastle, M.R.C.S., L.R.C.P., D.P.M., F.B.Pa.S., of 48, Warwick Road, Bishop's Stortford, Herts, aged 62.

Higgins.—On May 11, 1954, at the Royal Infirmary, Lancaster, James Basil Higgins, M.B., Ch.B., D.M.R.E., aged 62.

Hirson.—On May 18, 1954, Bernard Hirson, L.R.C.P.&S.I. & L.M., of 409, Cheetham Hill Road, Manchester.

MacQuistan.—On April 15, 1954, John Archibald MacQuistan, M.B., Ch.B., of Upper Oldfield Park, Bath, Somerset, formerly of Glasgow.

Plicher.—On May 4, 1954, at Cleveland, Ohio, U.S.A., J. Douglas Plicher, M.D., husband of Jean Lorrain Plicher (formerly Smith), M.B., Ch.B.

Sheddy.—On May 4, 1954, at Yelverton, Devon, Thomas Sheddy, O.B.E., L.R.C.P.&S.I. & L.M.

Slidebotham.—On May 11, 1954, at St. Thomas's Hospital, London, S.E., Francis Nasmyth Slidebotham, M.D., of Bendarroch, Ottery St. Mary, Devon.

Smith.—On May 11, 1954, at Stroud, Glos, Charles Charnock Smith, M.R.C.S., L.R.C.P., J.P., late of Woburn, Beds, and Hastings, Sussex, aged 82.

Wilshire.—On May 16, 1954, at University College Hospital, London, W.C., Basil Hamilton Wilshire, M.R.C.S., L.R.C.P., D.A., L.D.S.R.C.S., of Purley, Surrey.

Yarrow.—On May 14, 1954, at Stamford Hill, London, N., Philip Yarrow, M.R.C.S., L.R.C.P.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Decompression of the Bladder

Q.—What are the rules about decompressing bladders? Chronic retention should be decompressed slowly—how slowly, and what is a fool-proof method? Acute retention can be decompressed rapidly—but what actually constitutes a safe definition of acute retention?

A.—The safest clinical distinction between acute and chronic retention is that the former is painful, the latter relatively or absolutely painless. The pain of acute retention may be relieved by catheterization while arrangements are made for the patient to be admitted to hospital. In chronic retention there is no pain to relieve, and it is wrong to empty the bladder either quickly or slowly until the patient is in hospital, where the obstruction can be removed or drainage continued until the operation is considered safe. In advanced cases of chronic retention where preliminary drainage is thought to be necessary the safest method is the small suprapubic catheter; the initial decompression should take 12 hours.

An Epileptic Relative and Marriage

Q.—What advice should be given to a young couple who want to marry, but there is a history of epilepsy in a near relative on one side (in this instance a brother)? Will an electroencephalographic examination of both partners definitely exclude increased risk of epileptic children if the tracings are normal in both? What should be said if one or both of the tracings are abnormal?

A.—It is assumed that the only history of epilepsy in the family of either partner is the case of the brother mentioned in the question and that neither partner has had any fits. In these circumstances the likelihood of children of the marriage developing idiopathic epilepsy is very small, and this would be strengthened if both partners have normal E.E.G. records. If both partners should have typical epileptic records it is probable that the chance of a child developing epilepsy is considerably increased. Complete dogmatism in answering this question is impossible, as there are still considerable gaps in our knowledge about the inheritance of epilepsy. An important contribution to the subject was published by W. G. Lennox.¹

Dangers of Liquor Arsenicalis

Q.—Is there any evidence that very small doses of arsenic, such as a minim (0.6 ml.) of liquor arsenicalis daily, taken over long periods give rise to cirrhosis of the liver? Doses of this order are sometimes included in sedative mixtures.

A.—There are numerous reports of hepatic damage occurring during prolonged administration of liquor arsenicalis in therapeutic amounts in the treatment of leukaemia, etc.¹ However, there is little information in the literature about the maximum daily dose of inorganic arsenic which may be given without causing toxic effects. I know of no positive evidence that the daily taking of 1 minim of liquor arsenicalis over long periods has given rise to cirrhosis of the liver. Gowers is quoted by Stockman² as saying that the smallest amount of arsenic which he had ever known to give rise to pronounced arsenical pigmentation was equivalent to about 11,000 minims (7.3 g. of arsenic) of liquor arsenicalis during two years. This implies an average daily

intake of some 15 minims, and it is usually believed that in chronic arsenical poisoning skin manifestations precede toxic effects on the liver. After animal experiments prompted by the Manchester "epidemic" of arsenical poisoning in beer drinkers, Delépine³ concluded that a dose of 1/150 to 1/25 gr. (0.4 to 2.6 mg.) daily was capable of producing injurious effects in the ill-fed or weak individual. The 1 minim dose of liquor arsenicalis contains about 0.6 mg. or 1/100 gr. of arsenic trioxide. The development of chronic arsenical poisoning depends on the dose, the form in which the arsenic is taken, the duration of exposure to risk, and any special susceptibility. It may be expected that the effects of alcohol, arsenic, infection, etc., may well be synergistic and lead to changes in the liver which might not occur with one agent alone.

It is difficult to justify the inclusion of liquor arsenicalis in sedative mixtures, and in view of what has been said above it would be wiser not to prescribe for repeated use mixtures containing even such small quantities of a potentially dangerous cumulative poison.

Sudden Loss of Hair

Q.—A healthy man of 42 lost every hair on his body more or less overnight over five years ago, and there was no sign of any regrowth until recently following an emergency gastrectomy for severe haematemesis with transfusion of four pints of blood. What could be the cause of such a sudden loss of hair in the absence of any illness or emotional upset? Is the recent regrowth connected with either the shock following haemorrhage and operation or the blood transfusion?

A.—It seems almost certain that this is a case of alopecia totalis, usually regarded as a severe form of alopecia areata. The cause of this disorder is quite unknown, though if there has been an antecedent illness, stress, or shock it is tempting to attribute the baldness to this. Recovery from alopecia totalis is sometimes complete, but when it has already existed for some years the chances of much hair regrowing recede.

It is less often that regrowth of hair can be attributed to shock or other disturbances. However, Dillaha and Rothman¹ have reported recovery as a result of cortisone treatment, and presumably the recovery in the case mentioned may be related to this mechanism. In Dillaha and Rothman's cases the hair fell out again when cortisone was stopped.

Where to Sit for Television Viewing

Q.—Is there any ratio between the size of the television screen and the distance between that screen and the eye for obtaining the optimum clarity of image, yet at the same time freedom from visual discomfort?

A.—Since the number of lines in the structure of television images is fixed, there is a ratio between the size of the screen and the viewing distance at which the lines will be indistinguishable. The value of this ratio will depend on the visual acuity of the viewer. The number of lines in the B.B.C. transmissions is such that persons whose vision is not better than 6/6 will not distinguish the line structure of the picture on a 12-inch (30 cm.) diameter television tube at a viewing distance greater than about 6 feet (1.8 metres). The vision of many people is, however, 6/4.5 or better, and the lines on such a screen will be visible, though not unpleasantly conspicuous, at a viewing distance of 8 feet (2.4 metres) or more. If a receiver having a larger screen is used, it follows that the viewing distance must be proportionately increased if it is desired not to see the lines. However, freedom from visual discomfort when viewing television depends chiefly on other factors than line visibility. It is important to have the viewing room moderately illuminated, though in such a way that viewers

cannot see the light sources directly nor see images of them mirrored by the screen they are watching. If this is done the screen should not prove glaring, nor will the brightness contrasts of which the picture is composed be spoiled. It is also important that the angle subtended by the screen at the viewer's eyes (the angular size of the field of attention) should not be too small, since unwonted restriction of eye movements is a potent cause of feelings of strain and ocular fatigue. For this reason it is better to have a relatively high ratio of screen size to viewing-distance, and accept the consequent visibility of the lines, than to insist on a ratio which is low enough to prevent detection of the lines.

Uric Acid Gravel

Q.—I have a patient, a robust man of 35, who has repeated attacks of renal colic, not confined to one side. He then passes several small calculi about the size of a large pin's head. Analysis of the calculi show them to consist of uric acid and urates. Two complete urological investigations reveal no abnormality; there is apparently no mechanical defect, and his kidney function is excellent. Are there any measures, dietary or therapeutic, which would prevent the formation of these small calculi?

A.—Uric acid gravel can to some extent be prevented by maintaining an alkaline urine and avoiding food rich in purines. The patient should avoid strong tea and black coffee, and the rich protein foods associated in idea with a Lord Mayor's banquet. Liver, kidneys, sweetbreads, and offal in general should be forbidden. The diet should contain an abundance of fruit and vegetables, and a fluid intake of about 5 pints (3 litres) a day should be the aim.

Cloudy Urine after Acetic Acid

Q.—Are all phosphates in a cloudy urine dissolved by dilute acetic acid, or are some not soluble, or is the residual cloudiness due to something else?

A.—All phosphates in a urine are dissolved on the addition of acetic acid. Any residual cloudiness might be due to oxalates or bacteria. If the cloud is due to oxalate it will become soluble on the addition of a little hydrochloric acid.

NOTES AND COMMENTS

Corrections.—In Table II in the medical memorandum on "Extreme Sensitivity to Insulin," by Dr. A. I. Roith (June 5, p. 1306), the amount of insulin given should have been 0.03 unit per kg. body weight, not 0.3 unit.

In the report of Mr. Ivor Lewis's contribution to the luncheon discussion on massive gastro-intestinal haemorrhage, at the recent sectional meeting of the American College of Surgeons in London (May 29, p. 1258), the number of cases on which he had operated personally should have read 96, not 196.

In the report by the Joint Committee of the Medical Research Council and Nuffield Foundation on "A Comparison of Cortisone and Aspirin in the Treatment of Early Cases of Rheumatoid Arthritis" (*Journal*, May 29, p. 1223), under the heading "Allocation to Treatment," "(c) . . . seven to nine months" should have read " . . . six to nine months." Similarly in Table I "Duration of symptoms" should be 6-9 months and not 7-9 months. In Table V under "Week 8 to 1 Year" +0.8 should have been -0.8.

LONDON SATURDAY JUNE 19 1954

GENERAL PRACTICE IN AMERICA AND GREAT BRITAIN
SOME OBSERVATIONS AND COMPARISONS

BY

CHARLES M. FLEMING, M.A., M.D., F.R.C.P.Ed.

Principal Medical Officer, Department of Health for Scotland

In the spring of 1952, through the generosity of the Rockefeller Foundation, I was enabled to make a three-months visit to the United States, the main object of which was to study conditions in general medical practice. The time seemed most opportune to see what range of work was actually undertaken there by the general practitioner, and to find out how the patient fared—the ultimate test—under the conditions of American practice. It was no part of my purpose to try to assess the general standard of American practice. Not only would that have been impossible of achievement in the time, but it was unnecessary. My object was simply to see what opportunities are available to the American doctor and how they are actually utilized.

First-hand knowledge of what happens to the American patient when he consults his doctor seemed to me essential. I had expected difficulty in at least some practices in being present during actual consultations. In the event, my fears were groundless; no doctor or patient showed even hesitancy about my presence, and I was made most welcome. A second requirement was to see what advantages accrued to patients of group practices and other medical-care schemes. From my point of view, only the scope and quality of medical care in these schemes was of special interest, since in Britain we are no longer concerned with questions of contributions, entitlement to medical care, and the many organizational aspects of such schemes. I confined my attention, therefore, mainly to what happened to the patient when he presented himself for treatment. Finally, I was anxious to visit medical schools and other bodies interested in medical education in order to learn about undergraduate and postgraduate training for general practitioners.

The task was a formidable one, and I cannot pretend to have done much more than make a rapid and limited survey. I should like to say at once that I do not claim an exhaustive or a meticulously accurate knowledge either of medical education or of practice conditions in the United States. I am satisfied about the value of what I saw and heard for the purpose I had in view, and of its correctness in principle if not in detail; but I appreciate that there must be many features of practice in the United States about which I am still ignorant. Nothing spectacular or dramatic was expected or discovered. I was able to cover only a very small part of that vast country—though my journey took me long distances by our standards—but I saw both urban and rural practice under widely varying conditions.

At all stages of my tour I was given the greatest possible help, and was enabled to see and hear far more in the time available than I should have thought possible. The simplicity and efficiency of the arrangements made for me by the Rockefeller Foundation contributed very largely to this result. Wherever I went appointments were made in advance with key people in my particular sphere of interest. But ample time was left free for other meetings and visits suggested in the course of discussions. In this way I was able to study, as my journey progressed, what I felt was likely to be of greatest value to me. The broad plan was sketched for me, but I was left completely free to fill in the details.

Places Visited

My tour began in New York, and I returned there at the end. The Health Insurance Plan of Greater New York, a very large and highly organized system of group practice, took up a good deal of my time there and proved of great interest as regards both its headquarters organization and its various group centres. I also saw the work of individual general practitioners. The three medical schools I visited—Columbia, Cornell, and New York Universities—provided a wide range of information of the greatest value, and helped me to get a working knowledge of the general set-up of American health services. During my last days in New York discussions with officials of the American Public Health Association, the Commonwealth Fund, and other bodies enabled me to put into perspective many things I had learned in the course of my visit.

Baltimore, my next stopping-place, afforded a great wealth of experience. The Johns Hopkins School of Hygiene was my temporary spiritual home, and I cannot put too high a value on the privilege of the casual daily contacts there, quite apart from attendance at more formal interviews, seminars, etc. I was able also to see something of the Johns Hopkins University Medical School, the famous Johns Hopkins Hospital, and its diagnostic clinic. In particular, I spent a considerable time studying the work of the Baltimore Medical Care Scheme clinics at Johns Hopkins Hospital, the University of Maryland Hospital, and the Sinai Hospital. This gave me a very close insight into one form of group practice and enabled me to see many general practitioners actually at work. I also attended office consultations and did house calls with private practitioners both in Baltimore and in several rural areas of Maryland. I had numerous discussions with officials of the City Health Department, and also of the State Health Department, including county health officers.

I paid a short but very profitable visit to Washington, where most of my time was spent with officials of the U.S. Public Health Service. From them I received a great deal of background information which was invaluable in assessing much of what I saw and heard during my whole visit. I also saw something there of group practice, and learned from an authoritative source about the work of the American Academy of General Practice.

The next stage of my journey took me to Cleveland, Ohio, where I was privileged to attend the annual meeting of the American College of Physicians. In itself this was a fascinating and instructive experience, but it also proved an enormous saving of time by enabling me to meet teachers from several widely separated American medical schools.

From Cleveland I went to the South, where I spent a week in New Orleans and a week in Jackson, Mississippi, and paid a flying visit to Chattanooga, Tennessee. The officials of the two medical schools whom I met in New Orleans took the greatest pains to help me in every possible way, and my visit there was one of the most useful of the whole tour. I was able to see general practitioners at work in urban and suburban practices. Jackson proved a valuable base for visits to rural doctors, and the State Health Department took endless trouble to provide information and assistance.

Returning to New York, I made short visits to Toronto and Boston. On my way to Canada I saw a very interesting development in group practice, at the Rip Van Winkle Clinic and Foundation in Hudson, N.Y. My stay at Toronto was a brief but intensive introduction to Canadian medicine, made with the help of officials of the School of Public Health, the Medical School, and the Canadian Medical Association. Here also I was able to see general practice at close quarters.

Boston was well up to expectation and I had a short concentrated visit which included the Harvard Medical School and School of Public Health, Boston University, and the New England Medical Center.

In this report I have not attempted to record my experiences in detail. That was done in diary form each day during my trip. While I have found my diary a most valuable personal *aide-memoire*, it is by no means a complete account of all the many interviews and discussions in which I took part. In common with all visitors to the United States, I experienced boundless hospitality, and on these social and semi-social occasions I obtained a great deal of information of high professional interest and value. Indeed, I am tempted to believe that many of the most useful lessons of all were learned in this way. Impressions of American medical practice acquired by either of these methods are insensibly and inevitably modified by all the other experiences packed into such crowded days. What I have written here is based on my experience as a medical officer concerned in the administration of general practice in the National Health Service, modified by my experiences in the United States. I have tried to describe briefly the training and working conditions of the American general practitioner and to make some comparisons with what obtains in Britain. I have then attempted to define the scope of general practice. Finally, I have put forward some suggestions on what might be done for the future development of general practice in Great Britain.

I. THE AMERICAN GENERAL PRACTITIONER

School, College, and Undergraduate Medical Training
In the United States most children go to school at the age of 6, and they are in the primary school for approximately eight years. They then proceed to their secondary education at a high school for about four years.

A prospective medical student, on leaving school, usually takes an arts or science course at college. At least three years, and often four, are spent in this way, and most students graduate with an A.B. or B.S. degree. Certain subjects, such as physics, chemistry, botany, and zoology, are obligatory. English and mathematics are usually taken, and many schools also require a foreign language. Not more than the minimum is required in science, and stress is placed on sociology and philosophy. The intention clearly is to encourage the student in every way to get a good general education.

Undergraduate education at a medical school lasts four years and leads to the M.D. degree. Speaking broadly, the course consists of the subjects which in this country follow the first M.B. examination.

In the United States, as here, it is being appreciated in many quarters that the student who sees only people in hospital beds or who attends out-patient departments is missing a most important section of illness in the community. Moreover, two present-day trends—the smaller number of house visits made by American doctors, with the consequent tendency for the patient to become the sole judge of when he should see his doctor, and the shortened average stay in hospital—result in the medical student seeing even less than formerly of the beginnings and consequences of illness. Some medical schools have therefore made provision for students to gain experience in domiciliary medical practice. Patients are assigned to students, who look after them both in hospital and at home. Guidance is given by a senior, every care being taken to avoid interfering with the rapport established between the student and the patient. The student stands in something of the relationship to the senior that the general practitioner does to the consultant. The value of team-work is emphasized by showing the use that can be made of social workers, health visitors, and the full range of community resources. The importance of such teaching in clinical and social medicine is obvious. The student is given an early opportunity of appreciating the practical value of the concepts of preventive medicine as applied to the individual patient and his family.

The Internship

The next stage consists of one year's training as an intern (H.P. or H.S.). According to Pullen (1952a) about half the States require a doctor to have served an internship before they will grant him a licence to practise. The licensing examinations are, incidentally, quite separate from the degree examinations. An American Medical Association report states that for over 20 years practically every graduate of an American medical school had voluntarily acquired a year of hospital experience and that by the mid-thirties more than 75% were completing two years and more of hospital training before entering on the practice of their profession (Diehl *et al.*, 1950a). The rotating internship, consisting of three months each of internal medicine, surgery, paediatrics, and obstetrics and gynaecology, is the most common type. Great importance is attached to this form of training, and it is an absolute prerequisite to many later appointments and advancement. There are also "straight" internships in these subjects. In a straight internship in surgery, eight months would be spent at general surgery and the remaining four months at surgical specialties. Similarly, the last four months of an internship in internal medicine would be spent in paediatrics, psychiatry, neurology, etc. The American Medical Association controls this training, in so far as it certifies hospitals at which credit may be given for an internship. At present there are many more internships than young graduates of American medical schools. In 1951 there were only 6,135 medical graduates to fill 10,044 internships (Pullen, 1952b). This leads to competition, with the result that some hospitals pay much more attractive salaries than others. It is said that some of these hospitals do not make any great effort to teach.

Graduate Training

Graduate or residency training is intended for the trainee specialist, and may be said to correspond to the period of a registrarship in Britain. It may last from two to five years, according to the specialty. There are over 20 specialty boards in the United States; each lays down what the training for its own specialty should comprise and conducts the examinations. The American Medical Association has begun to certify hospitals which should be approved for specialty training. As with approved internships, there are more residency vacancies than there are trainees, and this has again given rise to unfortunate results. The percentage of failures at the examinations of the specialty boards is considered by many to be unduly high. Actually, it is probably not very different from what obtains in this country in the higher examinations in medicine and surgery. Darley (1952a) put the proportion of failures in 1949 at an even third. In his presidential address to the American College of Physicians in 1952, Pincoffs (1952) attributed the high percentage of failures partly to the inadequate training given by some hospitals.

Some American schools have in recent years provided, in addition to the year of internship, a three-years general practice residency—consisting of one year of internal medicine, one year of surgery, and one year of obstetrics and gynaecology. This is a particularly interesting development in that it places general practice on the same level with regard to length of training as most of the major specialties. Unfortunately, and for various reasons, according to some of those intimately concerned in the promotion of these residencies, they have not been an unqualified success. It is suggested, for example, that the general-practitioner resident takes second place in training to the specialist resident. An alternative—attractive in more than one way—has been put forward whereby, after a period as an ordinary resident, the trainee general practitioner would go to a special hospital where the staff would not be members of a university faculty or medical school, but would, of course, be thoroughly imbued with the spirit of teaching.

Postgraduate Training

At least two agencies in the United States are actively engaged in stimulating postgraduate education with an enthusiasm and energy not equalled in this country. The American Academy of General Practice requires of its members certain minimum amounts of formal and informal instruction, and its local branches arrange to have the necessary courses and other forms of instruction made available. A number of medical schools are concentrating on providing general-practitioner postgraduate training, even to the comparative neglect of specialist training. There are, of course, variations in the courses provided at different medical schools, but the following are the main types:

(1) Short intensive courses of from one to three days are held perhaps every two to four weeks. Lectures, clinical pathological conferences (C.P.C.s), and panel discussions are given. The short length of some of these courses makes it easier for the general practitioner to attend without leaving his practice, a point of great importance in the United States. This type of instruction is very popular and the demand is steadily increasing. One medical school had 1,000 registrations in one year—a most impressive achievement, as the total number of general practitioners in the State is 1,600. The greatest care is taken to appeal to the general practitioners by framing the courses to meet their calculated needs and by employing a number of carefully designed methods of holding their interest.

(2) Through the generosity of the Kellogg Foundation, about 20 medical schools are now providing a most attractive scheme of postgraduate instruction. The essence of it is to bring the doctor to the doctor in his practice. A teaching team of instruction to the doctor in his practice. A morning ward peripheral hospital of perhaps 50 to 80 beds. A morning ward round is made and the doctors see their own patients examined and demonstrated. In the afternoon more of the doctors' patients are seen as out-patients. The evening may be employed for a lecture or talk. Variations of this programme are, of course, used by different teaching schools.

(3) Evening courses once a week for 12 weeks are held by some schools. Each week a different team, usually of two, attends. Patients may or may not be used. These courses are normally built around the local medical society.

Perhaps the most striking feature to the British visitor of all these courses is the care devoted to making them attractive and useful to the general practitioner.

General Practice

Entry into Practice.—The American general practitioner enters practice as a rule straight from an internship and learns his new job by experience. Some doctors, before beginning practice on their own, serve a period as an assistant to an experienced practitioner, though this arrangement seems to be less common than in Britain. Naturally, a certain number of entrants to general practice have had residency training for varying periods. Some of the latter aim at becoming specialists in, for example, internal medicine. To do so, they may seek the Certificate of the Board of Internal Medicine or of one of the other specialty boards; but such doctors can acquire consulting practices solely by gaining the confidence of their fellows.

The "Family Specialist."—It is necessary to consider in relation to American general practice a type of practitioner unknown in Britain—the "family specialist," he might be called. These doctors may be orthodox specialists with the certificate of the appropriate board, or they may merely have taken a long period of hospital training. They do, however, limit their practice to their specialty, which is usually internal medicine or paediatrics; but they are prepared to accept patients direct in the same way as a general practitioner. In addition they may do some consultant work. Such practitioners are still relatively uncommon; but the total number of doctors specializing in internal medicine is growing rapidly in America. The President of the American College of Physicians stated that in 1940 there were roughly 6,400 and in 1950 about 11,600. He predicted that the number would have risen by 1960 to 20,000 or 25,000, and that there would be a growing demand by the public adequate to absorb at least all those who engaged in this form of family practice (Pincoffs, 1952).

Types of Practice.—In urban areas, individual practice is still the usual form seen; but group practice is now quite common and is widely accepted. The object of such groups is to provide practically complete medical care on a prepayment basis, and the staffs comprise both general practitioners and specialists. Individual practices in these areas may be run by general practitioners or by the family type of specialist. In semi-urban areas one or more doctors may endeavour to limit their practice to internal medicine and may combine such a family practice with a limited amount of consulting work. No doubt examples of group practice in these areas are also to be found, though I did not encounter them. I did see, however, in a rural area, an interesting example of group practice, though as a rule in such places the individual general practitioner still reigns supreme. Indeed, the rural practitioner in America commonly goes beyond the usual scope of general practice as we know it; he may do a considerable amount of specialist work—in particular, major surgery.

Accommodation, Equipment, and Staffing

The American practitioner often has professional accommodation and equipment on a scale seldom seen in this country. It is perhaps dangerous to generalize on the basis of such a limited number of doctors' offices as I had the opportunity of seeing, but I can say that I never met any doctor who had less than three rooms and whose equipment was not well above the British average. The three-roomed suite—waiting-room, consulting-room, and examination or treatment room—is gradually appearing here, and is advocated in all reports and articles on health centres or group practice. In the United States it was, in my experience, the basic minimum. More elaborate accommodation, often in *ad hoc* buildings, was quite common. Developments of this

sort were by no means limited to urban areas, and indeed perhaps two of the best *ad hoc* buildings I saw were in small rural practices in Mississippi. While I did see examples in country practices of old-fashioned waiting- and consulting-rooms with well-worn furnishings—to me, not at all unpleasant features—these were uncommon. Even so, they differed from many similar premises in Britain in that they contained all the essential modern diagnostic equipment of general practice.

Equipment was usually elaborate by our standards. Examination couches were of particularly good quality and design and, more important, were not merely for ornamental purposes. It was quite common to find a short-wave diathermy machine, ultra-violet ray lamp, electrocardiograph, and a well-equipped x-ray and dark room. B.M.R. apparatus, surprising to the British visitor, was by no means a rare piece of equipment to encounter. Oxygen and anaesthetic apparatus were sometimes in evidence. Refrigerators for the storage of biologicals, dressings trolleys, and weighing machines with height measures might be said to be standard equipment in most doctors' offices.

Domestic staffing was in keeping with the amount of accommodation. Practitioners made great use of ancillary staff, such as nurses, technicians, and secretaries. I saw only two doctors who did not have a nurse (not necessarily fully trained) to assist them; the wife of one of them, however, did a certain amount of less skilled nursing work. Commonly, the nurse undertook simple laboratory tests and secretarial work, but a separate secretary-receptionist was often employed, and sometimes also a technician. In group practices, furnishing and equipment are on at least as good a scale as in the best type of individual practice. Sometimes a standard is reached which has to be seen to be believed by the visitor from this country. The first experience I had of a waiting-room belonging to a New York group made me feel I was in the lounge of a luxury hotel. Laboratory work in such group practices is sometimes quite complete, and no work has to be sent elsewhere.

Laboratory Facilities

Clearly, many American practitioners are equipped to carry out a considerable number of diagnostic investigations in their own premises. In addition, they seem to have no difficulty in getting more elaborate work done at hospital laboratories or at other laboratories run on a purely commercial basis. Indeed, some city doctors rely almost completely on commercial laboratory investigation, rather than employ a technician or do their own laboratory work. It is a common criticism of American medicine—heard more often, I should say, in America than in Britain—that too many laboratory tests are performed. Hawkins (1952), describing his impressions of postgraduate education in America, remarks that “in Britain the clinical approach and good bedside teaching are characteristic, whereas in America the laboratory aspect is highly developed.” He at once adds that such a generalization does “an injustice to the many outstanding medical men of the U.S.A. whose clinical acumen is beyond reproach.” Arnott (1952) was greatly impressed in America by the emphasis placed on the simple clinical methods of history-taking and physical examination, and saw no tendency whatsoever to rely on esoteric laboratory tests. These British writers refer to hospital practice.

The opposite view, this time in relation to practice outside hospitals, is expressed by McCombs (1950), of Boston, who speaks of certain doctors employing as a means of profit diagnostic tests that they are not qualified to use. My own experience was that the good general practitioners, like the hospital clinicians quoted above, did not abuse laboratory tests. It is a foolish attitude, that is sometimes assumed by critics of American practice, that few of the laboratory tests used are really required. General practitioners in Britain would do well to avail themselves of all useful corroborative diagnostic evidence according to the best standards of modern hospital practice.

Hospital Appointments for General Practitioners

Attitude to the Problem

A large proportion of American general practitioners have some form of hospital appointment. This seems to apply in both town and country practice; almost every doctor whom I met had some form of association with a hospital. A statistical investigation made in Baltimore in the early 'forties showed, I was informed, that approximately 45% of practitioners had really satisfactory attachments to hospitals, that 35% had no attachment, and that the rest had rather slender attachments. A statement that in one large city only 56% of the general practitioners had a recognized hospital affiliation appears in the recent Report by the President's Commission on the Health Needs of the Nation (1952a). The figures for these two cities are quoted as disappointingly low from the American point of view. In Britain such proportions of general practitioners with hospital attachments would be regarded as startlingly high. I am unable to say accurately to what extent hospital appointments for practitioners are available throughout the whole country; but there is ample evidence to show how vastly different is the American attitude to our own in this important question.

For example, the Report of the Hospital Survey for New York (1937), after stressing that the public must be concerned with the relationship of the hospital and the practitioner, goes on to state: “To keep up with the ever-changing methods of diagnosis and treatment, the medical practitioner needs the stimulus provided by association with the organized medical staff of a well-equipped modern hospital.” Similarly, the Hospital Council of Greater New York (1951a) states that not only should a practitioner have the privilege of caring for his own private patients in hospital, but that he must have the opportunity to work under supervision in the wards and out-patient department and to participate in the teaching and training of medical students, members of the house staff, and other physicians. The Subcommittee on Medical Care of the American Public Health Association (1949a) reported: “General elevation of medical standards requires the closest possible contact of all practitioners in the community with the hospital facilities that are available. Good care is impossible to provide in isolation from the consultants, laboratories, equipment, and other facilities of the modern hospital.”

Types of Appointment

In the United States a regular staff appointment gives the opportunity of looking after patients in the wards and out-patient department. The holder is given specific duties and responsibilities towards public patients, and he takes part in all the educational activities of the hospital. Where a practitioner merely has the right to attend his private patients in hospital he is said to have private-patient privileges. Private patients and semi-private patients may be in single rooms or occasionally private wards. In general, patients in wards are those who cannot pay for private care, and they are looked after without charge by a doctor on the staff. The doctor with only “privileges” may, in a well-organized hospital, be subject to certain limitations in the procedures he may carry out; his work is to some extent supervised. But he has no responsibilities in the wards or out-patient department, and he is not required to attend staff conferences or participate either as a learner or teacher in the educational side of the work of the hospital. Where a doctor has both a regular appointment and private-patient privileges he is said to have a combined appointment.

New York City Appointments

In New York City on January 1, 1948, there were 17,703 licensed medical practitioners, of whom 14,850 were doctors in active practice. Doctors in related fields (administration, public health, research, teaching, etc.) and doctors in training (residents, interns, etc.) were excluded in calculating the number in active practice. Over 80% of these doctors,

including specialists and general practitioners, had hospital appointments, as the following figures show:

No. of doctors with hospital appointments:			
Combined or regular appointments	10,602	71%	
Private-patient privileges only	1,770	12%	
	12,372	83%	
No. of doctors with no hospital appointment	2,478	17%	
Total No. of doctors in active practice	14,850	100%	

As there are estimated to be 7,000 specialists in the city, most of whom have hospital appointments, then more than 5,000 general practitioners must have hospital appointments. It is also estimated that most of those 2,478 doctors with no hospital appointments are general practitioners. In other words, two-thirds of the general practitioners have hospital appointments (Hospital Council of Greater New York, 1951b).

A Comparison with Scotland

The Hospital Council makes the claim, which at first sight is quite astonishing to the British reader, that to provide combined appointments for all doctors in active practice in New York City would require no appreciable increase in the existing 32,652 general-care hospital beds. (This number of beds is little short of the 33,600 recommended for 1950 by the Master Plan for Hospitals and Related Facilities. It is said, however, that a redistribution is required in view of the relative shortage of semi-private facilities: there were 12,724 private and semi-private beds.) (Hospital Council of Greater New York, 1951c.)

In Scotland in 1952 there were 2,400 principals and 306 assistants in general practice under the National Health Service, making a total of 2,706; and specialists numbered 826, including those working both part-time and whole-time (registrars, interns, and specialists not engaged in general care excluded). The number of general practitioners not working under the National Health Service is probably less than 50, so that the total number of doctors in active practice seems to be about 3,500. General-care beds are about 27,583 for a population of 5,000,000 (Report of Department of Health for Scotland, 1952).

In New York City there are then, in proportion to the population of 7,888,000, more than two and a half times as many doctors (general practitioners and specialists) in active practice and more than five times as many specialists as in Scotland. Relatively, general practitioners are almost twice as numerous in New York. On the other hand, Scotland has proportionately about four beds for every three in New York. The highly urbanized needs of New York cannot truly be compared with the needs in Scotland either of doctors or of hospital beds, but the ratios are so different that they may well not be completely accounted for by differences in the type of population. Indeed, it could be argued that any difference in needs would serve only to accentuate the differences in the ratios shown above.

At least two points stand out. First, it would be simple, if our Scottish hospitals were run on the American principle, to find hospital appointments for all doctors in practice. Such a revolutionary change, even if desirable, could clearly not quickly be effected. But, at the very least, it is reasonable to argue that no vast modification is required to find useful employment in hospital for a considerable number of general practitioners. Secondly, the question at once poses itself: does the American method of practice not seem to be much more economical in the use of hospital beds?

Conditions for American General Practitioners in Hospitals

Among the recommendations of the Hospital Council of Greater New York (1951d) it is urged: (1) that all hospitals appoint general practitioners to their staffs and, under the jurisdiction of the chiefs of the various services, give them the opportunity of working in different departments; and the educational advantages afforded by the institution; and (2) that general hospitals establish appropriate professional units to guide the activities of general practitioners on their staffs, and work out a programme for each individual practitioner with the various clinical departments. It is under-

stood that the extent of hospital privileges given to a doctor should depend on his training, experience, and competence, and that his work should be supervised.

Departments of General Practice in Hospitals

The American Academy of General Practice has prepared “A Manual on the Establishment and Operation of a Department of General Practice in Hospitals.” In the preparation of the Manual the Academy obtained advice from the American Medical Association, the American College of Surgeons, and the American Hospital Association (Editorial, 1950).

The Manual advocates that the general practitioner as well as the specialist should be able to use the modern hospital to the degree that his training and experience warrant. It is recommended that the medical staff should be organized into at least three departments, consisting of medicine, surgery, and general practice, and that within the last-mentioned section the general practitioner should be given hospital privileges in the practice of internal medicine, paediatrics, obstetrics, and surgery as determined for each applicant by the credentials committee of the staff. It is laid down how the evaluation should be made of the qualifications and ability of those members of the general practice staff who feel that they have had the necessary training and experience to engage in more advanced work within a specialty field.

Scope of General Practice in America

The scope of the general practitioner's work in America is a good deal wider than here. This, at least in part, explains his more elaborate diagnostic and therapeutic equipment, much of which he must find really necessary for his work. It is not entirely a matter of his own choice that he practises a wider range of medical work; his patients expect it of him. This may explain the occasional major surgery by general practitioners which is still done in places like New York and Baltimore, where expert surgical skill abounds. This situation has both its good and its bad features. There is great interest and stimulation for the general practitioner to investigate and treat his patients with a full range of diagnostic and therapeutic facilities, such as is available here only to the hospital specialist. This seems to be accepted practice, for the Subcommittee on Medical Care of the American Public Health Association (1949b) stated: “With the receipt of complete consultation reports, the general practitioner can usually continue with the management of all but the most specialized therapeutic procedures.” Moreover, American general practitioners seem to have a familiarity with the appropriate methods for such work almost unknown among their British colleagues. It is idle to discuss, on my slender experience of American practice, whether the work done is on the whole more efficient than in British practice. What I endeavoured to learn was what the general practitioner could do, given the necessary facilities. I am satisfied that he can and does do a better job in many, but not all, ways than is done by the general practitioner here.

Group Practice in America

Definition of Group Practice.—The term “group practice” has a different meaning in the United States from what is usually implied when it is used in this country. The Medical Group Practice Council (1946a) has laid it down that “in order to be considered a medical group practice unit, an association of physicians of different skills, using medical equipment and nursing, technical, and administrative personnel in common, must have a formal pattern of professional collaboration, a definite relationship as a group with a hospital or hospitals in the community, and a unified administrative and financial organization.” A formal pattern of professional collaboration means that the consultation and co-operation between the different types of doctors in the group are definitely planned so that they are

readily available for the patient's benefit. A unified administrative and financial organization requires the pooling of incomes and that financial relations with patients are handled in the name of the group. It is accepted that three or four doctors sharing accommodation and auxiliary personnel are not engaged in group practice, although they may enjoy some of its advantages.

Types of Group Practice.—This form of organization is, of course, merely an extension to outside practice of what has long obtained in teaching hospitals. As Clark and Clark (1941) put it: "Having been trained in the group method, the medical graduate of to-day is well-fitted to continue his career as a member of a professional group where he can practise the type of medicine he has been taught. It is often difficult, on the other hand, for him to adjust himself to the professional and financial limitations of individual practice." We are not concerned here with reference groups such as the Mayo Clinic, or diagnostic groups like those at Johns Hopkins Hospital and elsewhere. The principal other type is that which provides general family care and specialist services.

Advantages of Group Practice

The doctor is able to do his best work, having readily to hand access to the necessary specialist advice and diagnostic and therapeutic facilities. At the same time economy is effected through sharing of accommodation, equipment, and ancillary personnel. The saving has been estimated at from 15 to 30% (Medical Group Practice Council, 1946b). There is also an economical use of medical manpower in that the young doctor is at once fully employed and has no long period of waiting for patients in a newly established practice. Indeed, the view has been advanced that the United States "cannot afford the wastage entailed in the partial idleness of the solo practitioner while he is building up a practice" (Report by the President's Commission on the Health Needs of the Nation, 1952b). Moreover, the doctor has opportunities for private study and attendance at postgraduate courses, and is enabled more easily to work at any specialty in which he may wish to develop his knowledge. All doctors in group practice have, of course, the benefits of sharing night duty, emergency calls, and so on.

For the patient the advantages are not limited to having the advice of the appropriate specialist: that could be obtained under almost any form of practice. The fundamental justification for group practice is the opportunity it offers for greater efficiency in the key member of the team—the family doctor. He is enabled to continue the best features of his training period throughout his professional life—"the stimulation to keep up with medical progress through constant appraisal by informed colleagues and ready access to consultations and technical assistance" (Report by the President's Commission on the Health Needs of the Nation, 1952c).

Examples of Group Practice

The Health Insurance Plan of Greater New York (HIP) has as its aim to provide comprehensive medical care—preventive, early diagnostic, and curative. The entire cost is covered by combined HIP and some form of hospital insurance such as Blue Cross. It began in March, 1947, and was responsible for the care of almost 400,000 persons by 1953. Medical services are available in the homes of patients, in doctors' offices, in medical group centres, and in hospitals. There are 30 medical groups scattered throughout the city. Each group has a sufficient number of family physicians for its size, the appropriate number of specialists representing the 12 basic specialties, and it has the requisite laboratory, x-ray, and other diagnostic and therapeutic services. Almost a half of the 950 doctors employed in the scheme are diplomates of the American specialty boards.

The medical groups are autonomous and each is a professional partnership. They are required to meet definite professional standards and to provide specified facilities.

The scheme is, of course, a prepayment one, and subscribers may choose any medical group and any one family physician. After deduction of administrative expenses the income is distributed to the groups on a capitation basis.

The family physicians see most of their patients at their own private offices, which are usually nearer the patients' homes; but generally they also have certain office hours at the group centre. The specialists see most of their patients at the centre.

The medical director claims that the maximum amount of diagnostic and therapeutic procedures is carried out on an ambulatory basis and that in consequence many hospital beds are saved. He also claims that in hospitals where members of the staff practise group medicine the family physicians in the scheme become essential members of the hospital group and enjoy all the educational advantages of an intimate hospital relationship. Moreover, the hospital has the advantage of being more intimately related to the medical and socio-medical problems of the community (Baehr, 1953).

Many other schemes in the United States provide in one way or another useful and continuing postgraduate associations with medicine as practised in hospitals. In addition to HIP, I have referred above to the medical care scheme in Baltimore. I was also able to see the Bingham Associates Plan in Boston. It is impossible here to give a detailed description of these schemes. Many of their features are, of course, concerned with means of providing medical care, but they afforded me excellent opportunities of studying certain aspects of general practice in the United States, and particularly the association of the family doctor with the hospital and teaching centre.

Is the Pattern of American General Practice Wholly Satisfactory?

I certainly saw much in the United States that showed me how our own standards could be improved. I realize there may be, as I have been told, general practitioners of poor standard. But I was concerned only with the achievements possible under American conditions, the potentialities of that type of practice. Obviously the American doctor has more time to see his patient: he requires it to practise his wider range of skills. Again, he must give a patient who is paying a high fee a consultation of some length. These things are in his favour and, apart from cost, in favour of the patient. But sufficient time for every patient will probably long remain, even in America, a counsel of perfection. There will always be a need to do what must be done and to leave at least some of the other less necessary things undone. The art of practice—and it is still an art despite modern scientific resources—will consist then in doing for each patient what he or she most requires.

I should hesitate to criticize American general practice on the basis of the small sample of it I saw. It did seem to me, however, that more time might sometimes have been given to consideration of the patient as a person. It may be this is due in some measure to preoccupation with instrumental investigation, laboratory tests, x-ray examinations, etc.—and time, as always, is the enemy. At any rate, the "history" sometimes seemed rather a stereotyped interrogation. It is but fair to say that one of the doctors who best appreciated the importance of establishing rapport with his patient, of considering emotional factors, and of viewing the patient as a person, was the possessor of quite the most elaborate accommodation and equipment I saw anywhere.

It is also difficult on my limited experience properly to assess the value of the American family internist. For some Americans, possibly an increasing number, he takes the place of the general practitioner, within the limits of his restricted form of practice. Possessed of over-average experience in internal medicine, he may surpass the general practitioner in the technicalities of medicine. If the general practitioner neglects what he is best qualified to do—act as

family guide, philosopher, and friend—and enters into competition in another's chosen field, he is destined to defeat. However able the family internist may be, he is bound to be at a disadvantage in the role of family doctor as compared with the general practitioner adequately grounded in internal medicine, who is present when the children are born, who advises the mother about the bringing up of her family, and who is the first to be called in time of illness. The family internist is not, of course, a specialist in the ordinary sense. He seems usually to do at least some very minor surgery, dermatology, eye work, etc. Clearly, it must be well-nigh impossible for him to limit himself rigidly to his specialty, though he will certainly not engage in obstetrics or paediatrics.

The family paediatrician also has no British equivalent. Much of his work is child welfare; and in that he probably has more experience than the paediatric specialist in Britain, who is mainly concerned in the care of sick children. I have discussed the question of the family paediatrician with doctors in that form of practice and with paediatric teachers in medical schools. They agree that a general practitioner who is adequately trained in internal medicine and has a reasonable knowledge of other branches of his work, including paediatrics, can give entirely adequate care to children, well or ill, provided he has access to specialist help when necessary.

If, then, these family specialists have a technical lead in their own sphere over the good general practitioner, it must be reduced by a relative lack of the real basis of general practice—knowledge of the patient, his family, his work, and his background. There are undoubtedly some who consider that the internist is the one who should be concerned chiefly with the very personal type of care which most people require, that he should take over such duties from the general practitioner. Darley's (1949) wise answer is: "If this is to be so, the training of the internist will have to be much different from what it is to-day."

At the beginning of my visit a knowledgeable adviser told me that someone of considerable standing in the profession had recently said to him that the general practitioner in America was a disappearing entity. He added that he did not himself believe the statement but would be interested to hear what conclusions I came to after my survey of general practice. I can answer emphatically that I saw no reason to fear for the future of general practice in America.

Darley (1952b) states that between 1938 and 1949 there was a 19% increase in the total number of doctors, and that specialists increased 98%. Pullen (1951), after quoting the similar figures, says "the pendulum is swinging and the general practitioner is coming into his own." He quotes student polls by the Council on Medical Education and Hospitals of the American Medical Association which indicate that the percentage of students planning to enter practice has increased from 36 to 47%, and that the number planning to specialize has decreased from 36 to 31%. What may be said of these figures, general practitioners still constitute 47.5% of doctors registered in the United States, while specialists form only 27.3%; the remaining 25.2% are interns, residents, Government servants, etc.

I was most impressed, not by figures, but by the standard of work I saw done by certain general practitioners, the reactions of patients, and the refreshing confidence of all in the future of general practice. This confidence was undoubtedly contributed to by the success of the American Academy of General Practice. With its membership of 17,000 it has already done a great deal to enhance the status of the general practitioner.

II. THE BRITISH GENERAL PRACTITIONER School and Undergraduate Medical Education

In Britain, school education begins and ends, generally speaking, at the same ages as in the United States. I have no information on the relative standards of attain-

ment; but, presumably, any balance in favour of one or other country must be a small one. The American medical student has then a rather longer preparation for the study of medical subjects, while his British counterpart devotes a little more time to the medical course proper. Everyone who has written about the place of general cultural studies in the training of doctors agrees about their importance. If the preliminary cultural requirements in the United States are greater than here, we must acknowledge their value and criticize, if at all, only on the grounds of cost and practicability. Whether as much ground is covered in their shorter medical course I cannot say, but most people who have intimate knowledge of American medical schools speak of the great industry of the students. No doubt there will be difference of emphasis in the teaching as between the two countries, but it is enough here to say that in Britain and America the medical student receives a very high standard of training.

As in the United States, some medical schools in this country have made provision for introducing the student to the problems of general practice. Similar developments in association with health centre practice are now being introduced.

Graduate Training and Entry to Practice

In Britain to-day there is so much competition for practice vacancies that the doctor without adequate postgraduate experience in hospital and as an assistant has little chance of becoming a principal. Most informed people agree that entry into practice is at present too difficult, and a good deal of harm has resulted from this state of affairs. On the other hand, one beneficial consequence is that adequate preliminary training is now practically ensured. Other developments are leading in the same direction. From January 1, 1953, a doctor must serve a year as an intern before registration.

A committee under the chairmanship of Sir Henry Cohen produced a report on "General Practice and the Training of the General Practitioner" (British Medical Association, 1950a). The report recommends for general practitioners a three-year period of training after registration—that is, four years after graduation. The first of these three years will be spent under the supervision of a general practitioner, the second year in specially designed hospital appointments, the third year will include a choice of opportunities in hospitals and as an assistant or locum in general practice. The Report of the Working Party on the Distribution of Remuneration among General Practitioners (1952) laid down as a qualification for an Initial Practice Allowance (a grant to assist doctors to set up in practice) that the applicant must have been in general practice for not less than two years or have been registered as a medical practitioner for not less than four years. The trainee assistant scheme under the National Health Service has enabled many specially suitable doctors, not otherwise available as trainers, to have assistants; it has thus provided young doctors with an opportunity of an assistantship under favourable conditions for real instruction in the problems of general practice.

The Registrar Problem

A somewhat special situation, presumably temporary, has arisen as a result of more registrars (trainee specialists) being employed in the hospital service than seem likely to be absorbed by promotion to the rank of full specialist. Some of these doctors have decided to give up their attempt to become specialists and have tried to enter general practice. It is natural that, having been qualified for perhaps three and often more years, they should attempt to obtain a practice without a period of assistantship, but such attempts have not as a rule been successful. These doctors should eventually prove to be valuable recruits to general practice if they have the requisite qualities of personality. Even where their postgraduate training has been of a very special nature it should be by no means wasted. The

In a discussion on "The Future of Public Health" at the Johns Hopkins School of Hygiene, which I was privileged to attend, one of the principal speakers asserted that the future of public health lay in the development of medical care schemes which would ensure for the patients the services of a really good physician who was alive to the preventive aspects of medicine and who would strive hard to educate his patients in health matters. The control of communicable diseases, sewerage problems, and water supplies were all very necessary in their day and were still of paramount importance in certain more backward

of work, and the interest general practice provides to the right kind of doctor. Requisite standards of equipment, accommodation, and staffing should be taught to students by someone of undoubted authority in the field of general practice. If exact information on these topics were known to all young doctors the standard would rise as they entered practice and influenced their seniors.

Health Centres

Experimental health centres such as are now ready and those about to be constructed may well provide useful indications for future policy. It might be worth while at least to experiment with centres designed with the aim of providing practitioners not only with full diagnostic and therapeutic facilities but also with intimate association with specialist work. The diagnostic and therapeutic facilities at present available in health centres are generally speaking of the simplest type. Such a new type of centre might go further towards meeting the needs of the present-day practitioner. Moreover, buildings of the same size as those presently contemplated could serve a much larger number of doctors and thus be more economical. It would seem possible also in this way to bring the benefits of group practice to many rural areas, except where distances are very great. At the Rip Van Winkle Clinic at Hudson, N.Y., for example, two practices, 5 and 10 miles respectively from the centre, form an integral part of the group.

Centres of the type described could be planned somewhat on the lines of the medical group centres of the Health Insurance Plan of Greater New York. Doctors could continue to practise from their existing accommodation and be associated with their group centre. It is unlikely that any financial association between the doctors would at first be possible, but that should not be an insuperable difficulty. Diagnostic and therapeutic facilities would either be available at the centre itself or, where appropriate, they would be readily obtainable through an associated centre or elsewhere. The appropriate staff of specialists would work in the centre on a part-time basis; at least some of the remainder of their time would have to be devoted to hospital ward work. It might be possible to link a number of subsidiary centres of an even less expensive type with a major centre. In some cases major centres could well be established at existing out-patient departments of hospitals; in any case, a link with hospital would be necessary, directly or indirectly, for each centre or group of centres.

This may seem merely to be a plan for building out-patient departments, sometimes in physical isolation from the hospitals themselves. So far as buildings are concerned that is probably true. But the essence of the scheme has yet to be added: it is the presence at these centres of the family doctor. Not only would the family doctor have direct use of diagnostic and therapeutic facilities and specialist advice on request, but he would himself be a member of the staff. He might consult at the centre at certain times, but he would also have a much more intimate relationship with his specialist colleagues than he has at present with out-patient department staff. The specialists would be seeing patients for family doctors in a group—a relatively limited number, since certain specialists would be allocated to each group. Like the family doctors, the specialists would come, as members of a group, to know their patients as persons and to appreciate them against their home background, and would be enabled to take their share of preventive and social medical responsibilities. Such a scheme at least not only holds out promise of providing the family doctor with the opportunity of practising preventive medicine better than he can do at present and of employing to the full for the benefit of his patients the clinical skills he has acquired and could develop, but it would enable the specialist to limit his work to cases of real difficulty and at the same time to see important aspects of medicine not now open to him.

There can be little doubt that in groups of this type the family doctor could deal on an ambulatory basis with many patients who at present are admitted to hospital. And

a further number could be treated in their own homes by the family doctor, backed by specialist facilities and advice. Under present conditions both specialist and family doctor naturally expect the patient to be taken over by the hospital and specialist service if any diagnostic and therapeutic measures of the type now available only in hospital are required. Under the scheme suggested it would be incumbent on both specialist and doctor to use their group resources to the full before seeking to have the patient admitted to hospital. And the family doctor would himself be accustomed to and capable of carrying out a far wider range of work; so that he could do more on his own, apart from what further efforts he could make under specialist direction.

Not only would this method of group practice lessen hospital costs, but it might help to solve the medical manpower difficulties of hospital and family practice. There are to-day too many registrars in hospitals: they do not wish to leave hospital work, and, in any case, cannot easily enter general practice. Some of these doctors might be employed as specialists in such a scheme, while others might be attracted to general practice under group conditions. Lastly, they could have a part in both camps and practise a specialty and general practice. On the family doctor side there would be scope to develop skill in a specialty and eventually, if desired, to practise it partly or exclusively. It is not merely desirable, but essential, if the level of family doctor practice is to be raised, to secure hospital experience for the general practitioner. It will be difficult to achieve and may never be possible for all, but group practice offers a solution that could be a means of providing on a very large scale an association with the methods and practice of specialism outside the actual hospitals.

I wish to express my thanks to the Rockefeller Foundation for making possible the experience on which this report is based: and to the Department of Health for Scotland for granting me the necessary leave of absence.

ULCERATIVE COLITIS WITH REPORT OF A CASE

BY

FRED FRANKEL, M.B., B.Ch., D.P.M.

Johannesburg, South Africa

It is the purpose of this paper to review some of the literature on ulcerative colitis, and to present the case report of a patient with this disease in whom a successful outcome was obtained by psychotherapeutic means.

Review of Literature

Murray (1930a) investigated the life histories and mental attitudes of 12 patients suffering from ulcerative colitis, and found a close association in time between the emergence of a difficult emotional situation and the onset of symptoms. Mental conflicts concerned with marriage were more common than other types of situations which might evoke anxiety. Murray felt that the outstanding trait in ulcerative colitis patients, besides fearfulness, was their emotional immaturity, and stressed the childish elements in the make-up of his patients. In his seven male patients the onset of the symptoms was associated with the conflict between the mother attachment and the desire for marriage. Of the five female patients in his series, three were involved in marriages of a significant nature, the husbands being obvious father-substitutes, one was engaged but could not marry on account of her colitis, and the fifth was unapproachable on the subject of marriage. In a later publication Murray (1930b) dealt with the analysis of a patient with ulcerative colitis and pointed to the fact that the character and sexuality of his patient corresponded quite closely to the so-called anal level described by Freud, and the masochistic and sadistic components which are so generally associated with anal temperament were very conspicuous in this patient.

In 1936 Sullivan drew attention to the long-recognized association of emotion and diarrhoea, and pointed out that psychotherapy had been astonishingly successful in the treatment of ulcerative colitis. Bagen et al. (1939) discussed pregnancy associated with ulcerative colitis in a series of 17 women sufferers with colitis who had 18 deliveries and 4 miscarriages among them. They concluded that the effect of pregnancy on ulcerative colitis was variable. In 1942 of Daniels, in a review of 14 cases of ulcerative colitis, was of the opinion that these patients were apt to be too dependent on some member of the family, usually the mother, and conflict developed in situations threatening this dependence, especially engagement and marriage. The emotional conflict in these patients was held responsible for the appearance of colitis symptoms. He found childbirth another frequent precipitating factor.

Lindemann (1945), in a review of 45 patients with ulcerative colitis, maintained that various forms of bereavement were the most important precipitating factors in the illness, and for 26 of the 45 patients a close time relationship existed between the loss of an important person and the onset of the illness. He felt that rewarding patterns of social interaction seemed not to be indigenous to these patients, and that this state of affairs became conspicuous only when a key person on whom the patient was dependent and from whom he had borrowed patterns of interaction was removed from the "social field." He warned against deep exploration in the psychiatric handling of these cases, and recommended a superficial supportive therapy, during which the patient could identify with the therapist, and in fact imitate him in order to achieve new patterns of conduct.

In 1946 West reported three cases of ulcerative colitis in which the symptoms greatly improved after superficial psychotherapy. One of the patients subsequently passed into a psychotic state. Crohn (1947) pointed to the strong

association between the stress of marriage, pregnancy, parturition, and the onset or relapse of ulcerative colitis, and indicated the onerous responsibility borne by the physician whose advice is sought regarding marriage and maternity for those of his patients suffering from ulcerative colitis.

In 1948 Daniels attempted to show how ulcerative colitis fitted into the present concept of psychosomatic disease, and pointed out that it had proved to be amenable to psychotherapy when other treatments had failed to bring results. He maintained that somewhat over 75% of sufferers had emotional conflict as a primary causative factor, but he was of the opinion that the emotional factors did not represent the "whole reason" for the condition. Kirsner et al. (1948) reviewed the clinical course of 100 patients suffering from chronic non-specific ulcerative colitis. They found that emotional stress, infections of the upper respiratory tract, and physical fatigue, in that order, were most often associated with the recurrences of symptoms.

Meyer et al. (1948) presented evidence which could possibly elucidate the psychosomatic link in ulcerative colitis in terms more definite than merely a dysfunction of the sympathetic and parasympathetic systems. In their study of the stools of patients with ulcerative colitis they demonstrated that the enzyme lysozyme was present in a higher concentration than in the stools of normal individuals. They found, too, that concomitant with clinical improvement the lysozyme titre in the stools fell. These facts and the experimental production of ulcerations in the small and large intestines of the dog by oral lysozyme administration suggested to them that lysozyme may be the chemical agent initiating the local lesions of ulcerative colitis. They assumed two stages in the pathogenesis of the disease: (1) removal of the surface mucus with dissolution of the mucous cells, and (2) necrosis of the denuded tissue by proteolytic enzymes presumably furnished by micro-organisms. They felt that the reason for localized overproduction of the enzyme by the mucosal cells, in the disease, was obscure.

In 1949 Lindemann drew attention to the fact that in some patients the disappearance of colitis symptoms is associated with the appearance of a psychotic illness, and that when the psychosis passes the colitis symptoms reappear. Mahoney et al. (1949), in a study of 20 patients with ulcerative colitis, found numerous neurotic traits in their subjects, and indicated that most of these traits existed long before the development of the evidence of ulcerative colitis, and that therefore these individuals were either overtly or potentially neurotic prior to the development of the bowel symptoms. Their study indicated, further, that there was a major abnormal parent-child relationship in the early lives of patients suffering from ulcerative colitis. They maintained that none of the personality traits found in colitis patients, when taken alone, were specific for the disease.

In April, 1949, Stewart also drew attention to the fairly typical history of emotional problems which seem to play a part in the pathogenesis of the disease. He pointed out that in the case histories and psychiatric investigations of patients with ulcerative colitis the precipitating factors and the basic personalities were often found to be similar, and he confirmed the fact that these patients give evidence of the presence of neurotic disturbances before the onset of their somatic illness. In the basic personality pattern he stressed their extreme dependence, emotional immaturity, subservient yet subversive attitude to domination, their overt passivity, and their high intelligence. He advocated a reassuring form of psychotherapy, in which dependence on the therapist is fostered, to be replaced by the gradual development of independence.

Maine and O'Neill (1949) presented the case report of a young girl with ulcerative colitis to show how psychological rehabilitation had been followed by disappearance of symptoms and maintenance of good health. They pointed out that the mother's personality made it inevitable that any aggressive feeling or activity on the part of the patient

would be met not only with maternal suppression but with a strong emotional response from the mother, leading to feelings of guilt in the daughter. Further, they indicated that the mother's possessive attitude fostered the patient's dependence upon her and discouraged any attempt at the establishment of an independent life.

In 1950 Glass, Pugh, Grace, and Wolf published the result of further work on lysozyme, which Meyer *et al.* (1948) had previously felt might be the factor initiating the local lesions of ulcerative colitis. They treated human gastric and colonic mucus with lysozyme, and concluded that lysozyme did not exert a lytic action on human gastric and colonic mucus *in vitro*. They admitted, however, that their experiments did not preclude the fact that lysozyme in physiological concentration may actually be capable of destroying or initiating destruction of mucosal cells.

Later in 1950 Grace, Wolf, and Wolff, from their observations of the large bowel in four fistulous subjects, showed that feeling states characterized by anger and resentment were associated with hyperfunction of the colon. This hyperfunction was manifested by hyperaemia, engorgement, hypermotility, and hypersecretion of mucus and of the enzyme lysozyme. They observed that hyperfunction of the colon resulted in increased fragility of the colonic mucosa, and that sustained feelings of anger and resentment associated with sustained hyperfunction of the colon resulted in submucosal bleeding and ulceration.

Lindemann (1950), in the presentation of a case of ulcerative colitis in a man aged 27, drew attention to the morbid relationship which had developed between the patient and his mother. He felt that in this patient, as in some others having abnormal bowel movements, the transition from an impulse to its execution was blocked, and that the man had a marked poverty of expression.

In September, 1950, Tumen and Cohn reported their experience with six patients regarding the influence of pregnancy on the development and the course of ulcerative colitis. In three patients the disease began during or towards the end of pregnancy, and in each of the other three pregnancy occurred during a remission, but failed to bring about reactivation of colitis. They point out that all had had poor relations with their parents, notably their mothers.

In November, 1950, in a report on 173 cases of ulcerative colitis, Pauley was impressed by a similarity in the case history and personality of many of his patients. He found them to be excessively dependent and parent-controlled, usually in respect of the mother. He found that the precipitating factors in the onset of the disease and in the relapses were almost always to be found in the emotional field and in interpersonal relations inside the family.

In December, 1950, Gray *et al.*, in their studies of lysozyme in the stools of patients with ulcerative colitis, failed to observe clinical improvement following prolonged inhibition of faecal lysozyme by the oral administration of a detergent ("aerosol OT"). These authors believed that this raised some doubt concerning the significance of lysozyme in the pathogenesis of the disease, but they emphasized, however, that the inhibition of lysozyme in the faeces by detergents does not necessarily reflect inactivation of the enzyme within the mucosal cells of the colon.

In January, 1951, Almy, in a report of experimental studies on the irritable colon, demonstrated that when both healthy persons and patients with irritable colon are under stress induced by experimental stimuli the sigmoid colon may show engorgement and disturbances in motility coincident with periods of emotional tension. He concluded that in most instances irritable colon was a bodily change accompanying emotional conflict in response to environmental stress.

In March, 1951, Groen and Bastiaans reported on 29 cases of ulcerative colitis observed during the period from 1939 to 1949 and treated by psychotherapeutic measures alone. They stressed the efficiency of superficial supportive psychotherapy.

In May, 1951, a committee on psychosomatic relationships in gastro-enterology under the chairmanship of Dr. Stewart Wolf (1951) reported that, as in the case of most bodily organs and organ systems, the gastro-intestinal tract showed significant changes in form and function in association with life situations which the individual consciously or unconsciously interpreted as threatening. The committee considered the relevance of these changes to the occurrence of structural disease of the viscera to be still incomplete, but maintained that a gathering body of data indicated that the changes may be of first-grade importance in the pathogenesis of such disorders as peptic ulcer and ulcerative colitis. Although at first altogether functional and transitory, the changes may, when unduly sustained, lead to structural damage and disease.

Grace, Wolf, and Wolff (1951) published a study of direct observations made on exposed segments of colon of four fistulous human subjects, and included indirect measurements made on a variety of intact healthy subjects, on subjects with diarrhoea and constipation, and also on 19 subjects with ulcerative colitis. They concluded that life situations provocative of abject fear and dejection were associated with hypofunction of most of the large intestine, and that life situations provocative of conflict, with feelings of anger, resentment, and hostility, or of anxiety and apprehension, were found to be associated with hyperfunction of the colon. They viewed ulcerative colitis as a stress disorder, and were of the opinion that a constructive physician-patient relationship was of the greatest benefit to the patient receiving treatment, and that favourable results in treatment were not obtained without such a relationship. They found the patient with ulcerative colitis to be characteristically an outwardly calm, superficially peaceful individual of more than usual dependence. On probing beneath this calm exterior it became apparent that this outwardly placid person was "sitting on a powder keg" of intense hostility, resentment, and guilt.

Psychogenetic Features

As can be seen from the above review of some of the recently published work, a distinct personality type in sufferers from ulcerative colitis has not been uncovered, but a few personality facets common to almost all patients with colitis have been revealed. Arising out of their observations, most writers have stressed the following characteristic features in their patients: (1) their immaturity and childishness; (2) their extreme dependence and passiveness; (3) the strong parent- (or substitute-) patient relationship, with its suppressed resentment and guilt; (4) their poverty of expression; and (5) their above-average intelligence.

Likewise in dealing with the precipitating environmental factors there is not unanimity, but workers have emphasized the importance of: (1) the marriage situation, with its demand for maturity and independence from parents, and with its responsibilities; (2) pregnancy and parturition, with their attendant stress; and (3) the loss of security, especially that pertaining to the loss of another person of emotional significance.

Case Report

In this report the psychiatric aspect of a case of ulcerative colitis is presented. The interplay of the major personality features and precipitating environmental factors outlined above are illustrated. The patient responded well to psychotherapy, remained symptom-free for two years despite many stressful situations, and then relapsed to a considerable degree in the wake of a minor incident. After five weeks of psychotherapy her symptoms again disappeared, and at the time of preparation of this report she had been well for 16 months.

A housewife aged 35 was admitted to the medical wards of the Johannesburg General Hospital on November 3, 1949, under the care of Dr. M. M. Suzman, with the complaint of recurrent attacks of diarrhoea with blood and mucus in the stools, of 11 years' duration.

The first attack, which lasted a few weeks, took place in August, 1938. The symptoms reappeared in January, 1939, and lasted for 12 months. During this period she passed between 25 and 30 stools on some days, and at one stage weighed only 65 lb. (29.5 kg.). In 1942 mild symptoms of colitis reappeared, but they lasted only a few weeks. In December, 1947, the symptoms again appeared, and, apart from a few remissions lasting some months, the colitis progressed until the time of admission. At that stage stools were frequent, up to 10 daily, and contained blood and mucus. There were fever, the temperature reaching 101.6° F. (38.7° C.) on occasions, colicky abdominal pains, fatigue, and debility, and a fall in weight from 136 to 105 lb. (61.7 to 47.6 kg.) over a period of three months.

Physical examination was essentially negative, apart from the state of undernutrition and generalized abdominal tenderness. Sigmoidoscopy revealed the presence of two bleeding ulcers in the lower colon. The appearance was consistent with a diagnosis of ulcerative colitis. Repeated stool examinations failed to reveal parasites or pathogenic or aberrant bacteria. A blood count showed: haemoglobin, 12 g.%; erythrocytes, 4,300,000; leucocytes, 8,400 per c.mm. The sedimentation rate was 31 mm. in one hour (Wintrobe). Gastric analysis revealed a low acid curve.

There was no record of the medication given in the months before admission to hospital, but according to the patient it had been extensive. In the hospital, medication consisted of the administration of 15 g. of aureomycin over a period of 10 days, a bismuth mixture, compound vitamin-B tablets, and phenobarbitone, $\frac{1}{2}$ gr. (32 mg.) thrice daily during the same period. As no improvement followed, psychiatric investigation was started.

Psychiatric Investigation

Interviews of an hour each, two or three times a week, began on November 14 and continued for 10 weeks. The patient was born in New Zealand. Her mother was a Jewess, and her father a Gentile. He had been injured during the 1914-18 war, was a nervous and ineffectual person, and died in his early forties when the patient was 11 years old. Her mother, aged 68, was alive and well, and had always been a capable and domineering person, being the main financial support of the family during the patient's childhood; she was a school-teacher by profession. The patient had one sister, seven years her senior, who was a school-teacher in New Zealand.

The patient completed her secondary schooling and became a sales lady. At the age of 21 she migrated to South Africa with her mother, but her sister did not accompany them. Both the patient and her mother obtained employment in the same firm, and both had held senior positions for some years. Until the time of her marriage at the age of 33 she and her mother shared an apartment. Her past medical history was not remarkable.

Stress and Symptoms

Her symptoms of ulcerative colitis first appeared at the age of 24, following a proposal of marriage which she refused, ostensibly on the grounds of religious differences. She now feels that she refused the proposal because she was anxious about leaving her mother. The symptoms lasted about 12 months.

Four years later the symptoms returned. This episode began a few days after the arrival in South Africa of her sister, who came to pay her mother a visit. Within a few days of her sister's departure for New Zealand the symptoms subsided.

Five years later, at the age of 33, the symptoms recurred. This coincided with her husband's proposal of marriage. Many months elapsed before she finally married him, during which time the symptoms were severe. There was a remission during the weeks prior to the marriage, but on the second day of the honeymoon the colitis reappeared.

and necessitated an early return to Johannesburg and her mother. During the next two years, until the time of her admission to hospital in November, 1949, the symptoms of ulcerative colitis had continued, with only short remissions.

She described her marriage as a happy one, and this was confirmed by her husband, who was of the same age and who appeared to be understanding, pleasant, and co-operative. They both claimed that the sexual aspect of the marriage was satisfactory. They devoted a great amount of time to the patient's mother and to the husband's parents, spending each day of the week with either one or the other. The relations between the husband and his mother-in-law were very strained, and he strongly resented her domination of, and interference in, his wife's affairs, but seldom spoke about it for fear of upsetting the patient.

Psychotherapy and Progress

The whole psychotherapeutic approach was one of sympathetic understanding and support. The concepts of psychogenesis and psychosomatic disease were explained to her, and efforts were made to establish a sound rapport and to correlate the onset of symptoms chronologically with stress situations. The aim was to foster emotional dependence upon the therapy situation initially, and then to wean her of that gradually. The central theme of most of the interviews was her hostile-dependent relationship with her mother, and she eventually expressed resentment freely. After about four weeks her symptoms subsided, and there were only minor relapses during the next six weeks, at which time she would herself try to correlate the symptoms with emotional stress.

She was discharged from hospital in January, 1950, 10 weeks after the beginning of the psychiatric investigation. She was then passing one well-formed stool a day, without blood or mucus.

Progress after Discharge

Within the first few weeks after going home the symptoms threatened to return on a few occasions. This was shown by a softer consistency and an increased number of stools. She immediately communicated with me, sometimes by telephone, and after a short discussion of the immediately preceding significant social events the stools returned to normal. These events were wholly concerned with her mother.

From April 7, 1950, until June 13, 1952, she remained completely free of symptoms. During this time she had given birth to her first child, her mother had died of a coronary thrombosis, her father-in-law had died, and her mother-in-law had come to live with her; and in December, 1951, she became pregnant for the second time.

She had seen me at three-monthly intervals at my request, apart from two interviews which she asked for at the time of her mother's death.

The Relapse

On June 13, 1952, when her symptoms had been absent for over two years, and when she was in the last trimester of her second pregnancy, there was a relapse. Initially mild, within two weeks she was having 10 stools a day, accompanied by blood and mucus. Out-patient interviews were resumed for six weeks. By the fifth week of therapy she was again symptom-free, and has remained so for 16 months. Her second child is 15 months old.

During the week prior to the beginning of the symptoms in June, 1952, I had asked the patient to meet another woman suffering from ulcerative colitis, in an attempt to show her that psychotherapy had a place in the treatment of her condition. My patient became too interested and involved in the solving of the other person's difficulties, and, unknown to me, saw her twice more during the same week. The day after the third meeting she received a letter from her sister in New Zealand discussing the proposed wording of the plaque to be erected to the memory

of their mother. The wording suggested was "To live in the hearts of those we love is not to die." This had tremendous emotional significance for the patient, whose feelings of guilt became overwhelming. Next day the symptoms began.

Psychosomatic Assessment

The major personality features in cases of ulcerative colitis described by other authors are easily recognizable in this patient. She was emotionally immature, particularly in her relationship with a dominant and possessive mother, and the keynote of that relationship was the hostile-dependence which evoked a considerable degree of guilt. Her intelligence was well above average.

Environmental stress situations immediately preceded the onset of symptoms on each occasion. The situations were associated with marriage, proposed marriage, or with a threat to the security of her emotional dependence on her mother, such as the visit of her sister in 1942. It was felt that her desire for marriage and emancipation from her mother's domination was in conflict with her basic personality pattern.

The resentment, and emotional tension resulting from her conflict, apparently manifested in disturbances in the function and ultimately the structure of the lower bowel, as has been described by other authors.

This case report seems to strengthen the plea for psychiatric investigation in patients with ulcerative colitis.

Summary

The literature on the psychosomatic aspects of ulcerative colitis has been reviewed.

The report of a case of ulcerative colitis is presented in which the patient displayed disturbances in interpersonal relationships, characterized by emotional immaturity, guilt, dependence, and resentment towards a dominating mother. The stressful situations evoking the disturbances were associated with marriage, proposed marriage, and situations threatening the security of the patient's dependence.

The major personality features and the precipitating environmental factors in the report conform to those stressed by other authors.

It is felt that this case report strengthens the plea for psychiatric investigation in patients with ulcerative colitis.

I wish to record my thanks to Dr. M. M. Suzman, specialist physician on the staff of the Johannesburg General Hospital, for his constant encouragement and guidance, both in the handling of this case and in the preparation of this article, and to Dr. Stanley Cobb, psychiatrist-in-chief, Massachusetts General Hospital, for his most helpful suggestions regarding the review of the literature.

(Late Tutor in Child Health)(From the Department of Child Health,
University of Sheffield)

Mestrezat (1912) first focused attention on the diagnostic value of the chloride content of the cerebrospinal fluid (C.S.F.) in tuberculous meningitis, and he and other workers (Mestrezat, 1924; Greenfield and Carmichael, 1925; Foord and Forsyth, 1933) have all laid great stress on the value of a low C.S.F. chloride in the diagnosis of this disease. Merritt and Fremont-Smith (1937) observed a correlation between the chloride contents of the C.S.F. and plasma, and found a lowered concentration of chloride in the C.S.F. in any condition in which the plasma chloride concentration was low. As a low C.S.F. chloride associated with a low plasma chloride is often found in purulent meningitis, in intracranial disease, and in any condition causing vomiting, the occurrence of a low C.S.F. chloride in tuberculous meningitis cannot be regarded as being specific.

The use of streptomycin in the treatment of tuberculous meningitis has made possible the long-term study of the hypochloreaemia and other electrolyte disturbances, of which a lowered C.S.F. chloride concentration is a manifestation. Rapoport *et al.* (1951) studied three children aged between 2 and 3 years by load-clearance techniques one week, two weeks, and three months respectively before death, when the patients whose food intake was poor were more or less comatose and having mild convulsions, but were not vomiting. The effects of loads of hypertonic saline, ammonium chloride, potassium chloride, and sodium thiosulphate were studied in these three children and one control. These workers concluded that, because the concentration of sodium and chloride in the urine did not fall to minimal amounts when the levels in the plasma were low, there was some "disturbance in renal electrolyte control," probably located in the proximal tubule of the kidney. At post-mortem examination the kidneys of these children were normal macroscopically and microscopically.

Further studies on the electrolyte disturbance in tuberculous meningitis were made by Harrison, Finberg, and Fleishman (1952). They investigated 16 children, finding that plasma concentrations of sodium and chloride were reduced, but that no consistent change in the potassium occurred. They found the sodium concentration in red blood cells and skeletal muscle to be increased, and the potassium to be normal in the former and reduced in the latter. Although they concluded that a disturbance governing ion equilibrium existed in these cases, no definite hypotheses on the causation were advanced.

It is conceivable that successful therapy against these electrolyte disturbances may complement specific therapy in tuberculous meningitis and assist recovery.

In the present investigation the electrolyte patterns of children with tuberculous meningitis have been related to their clinical conditions. Cases showing abnormal patterns have been followed for long periods, and the effects of intravenous injections of hypertonic saline and potassium salts orally have been studied.

Material

Nineteen patients with tuberculous meningitis and two with miliary tuberculosis only have been studied in this investigation. Their ages ranged from 1 to 13 years. Thirteen of these were receiving streptomycin by intrathecal and intramuscular routes, and one of these, who had gross internal hydrocephalus, was also receiving "purified protein derivative" (P.P.D.) intrathecally. Five patients who were improving had finished their course of intrathecal treatment but were still receiving streptomycin intramuscularly, and the two with miliary tuberculosis only were receiving the same. One patient was on the point of discharge and was receiving no treatment. Four, all in a poor general condition with an electrolyte disturbance, were given loading doses of saline intravenously. They were all vomiting at the time and were receiving streptomycin intramuscularly and intrathecally. Two of these who were still in the same condition were given potassium salts orally. All these patients were under treatment in the Streptomycin Unit of this department. Hypertonic saline was given to two cases in the general wards as controls for the saline-loading investigations.

Procedure

Blood was collected from the 21 patients at various stages of the disease, and the plasma CO₂ content, plasma or serum chloride, and serum sodium concentrations were determined. Urine was collected at the same time and the urine chloride content estimated. The estimations of various electrolytes in plasma or serum were repeated in seven children with hypochloreaemia at intervals varying from 6 to 164 days after the initial investigations.

Infusions of hypertonic saline were given to four patients with hypochloreaemia who were in the active stages of the disease. The loading dose of saline was given intravenously as a 15% (w/v) solution in amounts calculated to bring the plasma chloride back within the normal range, assuming that the Cl ion is mainly extracellular and that the extracellular compartment is approximately 25% of the body weight. Two controls received an arbitrary dose of sodium

chloride. Three of the patients and the two controls were given 30-40 ml. of water every half-hour for three to four hours before the load and one and a half to two hours after it. One patient was given N/5 saline by mouth in doses of 30 ml. every half-hour for four and a half hours before the load and for one and a half hours afterwards. Urine was collected for a period before the hypertonic saline injection and for one and a half to two hours afterwards: the volume was noted and the sodium and chloride concentrations were estimated. Samples of blood for estimations were collected before the hypertonic saline injection and at intervals afterwards.

To test the hypothesis that these children might be suffering from a potassium deficiency two children were given potassium orally in amounts equal to an arbitrarily chosen deficit of one-quarter of their total body potassium. The potassium was given in divided doses over a period of five and four days respectively as a mixture of the citrate and chloride in a ratio similar to the ratio of bicarbonate to chloride in the extracellular fluid. This was done to avoid, so far as possible, any secondary effects on the acid-base state. In both these cases the diet was checked so that potassium intake did not suffer large fluctuations. Urine was collected during the four days before administration, during the time potassium was given, and for a period of four days afterwards.

All cases in this study were receiving *para*-aminosalicylic acid in the form of the sodium salt. The dosage was always approximately 0.5 g./kg., and it has been calculated that each case received around 60 mg./kg./day of sodium in this way.

Analytical Methods

Chloride was estimated on 0.2 ml. of plasma by Sendroy's (1937) method. Plasma CO₂ content was estimated on plasma which had been collected and centrifuged under liquid paraffin in either the volumetric or manometric apparatus of Van Slyke (Van Slyke, 1917; Van Slyke and Neill, 1924). Sodium was precipitated from a serum filtrate as sodium zinc uranyl acetate according to the modification of Butterworth (1951). The method of Jacobs and Hoffman (1931) was used for the determination of serum potassium. All the urine potassium determinations and many of the sodium estimations were made on an E.E.L. flame photometer.

Results

1. Electrolyte Patterns in Blood and Urine

Details of 21 cases are given in Table I. The cerebral condition was assessed in most cases by the presence or absence of papilloedema. Although many cases had air

+ = Occasional vomiting. ++ = Vomiting once or twice a day. +++ = Vomiting more than twice a day.

studies, only one showed definite hydrocephalus, most of the patients with papilloedema being too ill for air studies to be done.

Ten patients (Cases 1-10) had a plasma chloride concentration of 92 mEq/l. or less, whereas nine patients with tuberculous meningitis (Cases 11-19) and two with miliary tuberculosis (Cases 20 and 21) had plasma chloride values within the normal range (95-106 mEq/l.). The serum sodium concentrations also showed a definite difference, although this was not so marked as in the case of the chloride values. Although only one child in the group with hypochloraemia had a serum sodium as high as 140 mEq/l., all but one of the other group had values above this figure. In nine of the children with hypochloraemia the chloride content of one specimen of urine (collected at the same time as the blood) was estimated. In all of them there were more than minimal amounts of chloride (18 mEq/l. or more) in the urine, in the presence of low concentrations of chloride in the plasma. The occurrence of serious vomiting in the fortnight preceding these investigations is confined to the group with an abnormal electrolyte pattern, as is abnormality in the cerebral condition (Cases 1-10). On the other hand, all 11 children with a normal electrolyte pattern had a normal cerebral condition (Cases 11-21). Nine of them had been treated for periods of three months or longer and had no recent vomiting. The remaining two children in this group had been ill for a shorter time. They were vomiting occasionally but had miliary tuberculosis only and no meningitis (Cases 20 and 21).

2. Changes in the Electrolyte Pattern with Changes in Clinical Condition

Table II gives the results of determinations of electrolytes in serum or plasma, together with any changes in cerebral condition and vomiting, in seven cases of hypochloraemia,

TABLE II.—Follow-up Blood Electrolytes in Seven Cases

Case No.	Plasma Cl (mEq/l.)	Plasma CO ₂ Content (mEq/l.)	Serum Na (mEq/l.)	Urine Cl (mEq/l.)	Cerebral Condition	Vomiting in Preceding 2 Weeks	Days between Investigations

In none of which had there been any persistent attempt to adjust the electrolyte disturbances. The second set of determinations (in Cases 3, 4, and 6) were just prior to the load of hypertonic saline, but this load is unlikely to have affected the subsequent determinations, which were done after intervals of at least 64 days. Similarly, it is unlikely that the third set of determinations (in Case 9) were affected by potassium therapy, which finished 50 days before.

A progressive improvement in the electrolyte values is seen in all children except Case 8. The increase in the concentration of chloride and sodium in the serum or plasma coincided with improvement both in the general condition and in the state of the meningitis, and simul-

taneously there was a diminution in vomiting. Case 3 was developing hydrocephalus during the investigations, but the meningitis healed and his general condition improved and vomiting ceased. Similarly, in Case 4 there was an improvement in the electrolyte pattern at the third estimation, when vomiting had ceased, but hydrocephalus was still present. One patient (Case 8) was extremely ill. She did not respond to treatment, deteriorated rapidly, and died three days after the second set of determinations recorded in Table II.

3. Load of Hypertonic Saline

The injection of hypertonic saline produced a rise in the concentration of plasma chloride and serum sodium in all cases at the second estimation, which was made within one hour of the injection. A third estimation 27-30 hours later was made in two cases of tuberculous meningitis (Cases 6 and 8) and one control. Case 8 was very ill and died a few days later. Homeostasis must have been seriously disturbed, as very little urine was passed through the indwelling catheter for 174 minutes after the injection. In the other two (Cases 6 and Control 2) the serum chemistry returned to the pre-injection levels within 30 hours. Case 6 had a normal serum sodium, but a low plasma chloride, which after a transient rise returned to a low value, indicating an inability to maintain the plasma chloride at a level approaching normal (Table III).

TABLE III.—Results of Sodium Chloride Loads (Electrolyte Levels)

Case No.	Pre-injection Levels (mEq/l.)			Post-injection Levels (mEq/l.)								
	Na	Cl	CO ₂	Time	Na	Cl	CO ₂	Time	Na	Cl	CO ₂	
3	134	93	25	1.0	136	102	23	—	—	—	—	—
4	137	89	31	0.5	143	101	27	—	—	—	—	—
6	143	89	33	0.75	147	96.5	30	30	143	92	31	—
Control 1	137	88	34.5	0.75	139	94	23	—	—	—	—	—
Control 2	149	96	26	0.5	150	105	34	27	139	96	37	—
Control 2	142	99.5	28.5	0.5	144	109	27	29	144	100	29	—

The basic excretion of chloride in mEq/min. during the pre-injection period was assumed to be the same throughout the whole study, and this amount was subtracted from the total excretion in any period. Table IV shows the

TABLE IV.—Results of Sodium Chloride Loads (Excretion)

Case No.	Hydration Prior to Injection	Weight in Kg.	Dose of 15% NaCl in ml.	Time of Study after Injection in Minutes	% Excreted in Period of Study	
					Na	Cl
3	N/5 saline	8.2	17	122	27	4.5
4	Water	15.0	35	162	17	18
6	"	27.7	50	129	17	9
8	"	18.6	30	174	0	0
Control 1	"	24.1	40	228	21	11
" 2	"	22.7	35	177	64	47

percentage of the dose of sodium and chloride that was excreted in the four cases and two controls. The excretion of sodium and chloride during the pre-injection period in Case 3—hydrated with N/5 saline—was much higher than in any other cases, and there was little increase in the excretion of chloride after the hypertonic saline injection. Control 1 showed a response indistinguishable from that of Cases 4 and 6, whereas Control 2 excreted a much greater percentage of the injected dose in 177 minutes. In Case 8 the child was extremely ill and unconscious, and excreted none of the injected dose within 174 minutes. A few days later she became grossly oedematous and died.

4. Administration of Potassium

The effect of potassium administration on the plasma pattern and on the excretion of potassium in the urine of two children with tuberculous meningitis and hypochloraemia is shown in Figs. 1 (Case 6) and 2 (Case 9). Case 6 was given 143 mEq of potassium a day, and

excreted 74% of the ingested potassium during the five days of administration and the subsequent four days. About 26% of the dose was therefore retained, unless it was lost by vomiting.

Fig. 1.—Case 6. Effect of potassium administration on the plasma pattern and the excretion of potassium.

Fig. 2.—Effect of potassium administration in Case 9.

two cases of hypochloraemia resulted in retention of potassium and an improvement in the electrolyte pattern in the case with a normal serum sodium level, while it caused an insignificant retention of potassium and no change in the plasma pattern in the case with a low serum sodium level.

Discussion

This investigation shows, as was to be expected, that the occurrence of an abnormal electrolyte pattern in a group of children suffering from tuberculous meningitis was confined to those in whom the illness was of recent origin or in whom the cerebral condition was abnormal. On the other hand, children who had been under treatment for longer periods or who had miliary tuberculosis only did not show any abnormality in the electrolyte composition of the plasma. The clinical feature, however, which distinguished the two groups in the period preceding the collection of the blood was the food intake and the vomiting. The children with tuberculous meningitis and an abnormal electrolyte pattern had a low food intake and had been vomiting for two or more weeks before the initial estimation of the electrolyte content of the plasma. The importance of vomiting as the immediate cause of the electrolyte disturbance is further demonstrated by the fact that the most marked and most consistent of the changes was the hypochloraemia.

A direct effect of an abnormal cerebral condition on the causation of hyponatraemia and hypochloraemia becomes unlikely in view of the progress of Cases 3 and 4. In both these cases vomiting had ceased, but hydrocephalus was still present at the time that the electrolyte pattern had returned to normal.

In view of the suggestion by Rapoport *et al.* (1951) that defective kidney function accounts for the electrolyte disturbance in tuberculous meningitis, an attempt was made in the present investigation to assess the role of the kidneys. The experiments with the load of hypertonic saline were unfortunately inconclusive because of the different response of the two control cases, one of whom showed no difference from the response of the children with tuberculous meningitis.

Although it is realized that the estimation of the chloride content of one isolated specimen of urine may not give a true picture of the chloride excretion over 24 hours, it is thought that the presence of more than minimal amounts of chloride in the urine on more than one occasion in all the children with hypochloraemia is of significance. Such an occurrence might be due to a hypofunction of the electrolyte-regulating hormones of the adrenal cortex—that is, an Addisonian syndrome. A similar disturbance, however, is observed in potassium-deficient patients, and an experiment with potassium loads orally was planned to test this hypothesis. The retention of 81% of the potassium by a child with hypochloraemia and with a normal serum sodium resulting in a normal electrolyte pattern, and the retention of only 26% of the administered potassium by a child with a low serum sodium, suggests that in some cases at least there is a deficit of potassium and also that large doses of potassium cannot be retained in the presence of a sodium deficit and therefore cannot correct the electrolyte disturbance. It seems that the position is analogous to that in which, in the presence of a deficit of potassium, large amounts of saline do not restore the plasma pattern to normal until potassium is given as well.

Our present study suggests that vomiting and reduced food intake leading to a deficit of the main electrolyte ions Cl, Na, and K can explain the electrolyte disturbance in children with tuberculous meningitis. This study has not excluded the presence of a "disturbance in renal electrolyte control" (Rapoport *et al.*, 1951), neither has it excluded "a disturbance of the mechanisms governing ionic equilibrium between cells and extracellular fluid" (Harrison *et al.*, 1952). We think, however, that it is unnecessary to postulate that such disturbances exist, unless it can be proved that the observed abnormalities in electrolyte metabolism cannot be accounted for by the more simple phenomena of vomiting and reduced food intake.

Although this work is inconclusive, it seems to us that the maintenance of adequate electrolyte intake in the early stages of tuberculous meningitis may be an important factor in assisting these children to recovery.

Summary

The electrolyte disturbance in tuberculous meningitis has been studied. In a group of 19 children with tuberculous meningitis and 2 with miliary tuberculosis only, 10 were found to have an abnormal electrolyte pattern.

A correlation was found between the abnormal electrolyte pattern (hypochloraemia, hyponatraemia, and an increased CO₂-combining power) and the occurrence of serious vomiting.

The abnormal electrolyte pattern was not seen in children who had been treated for long periods, and it disappeared after cessation of vomiting, on improvement in the cerebral condition, and on increase of the oral intake to within normal limits.

Injections of hypertonic saline in four cases did not increase the plasma chloride permanently. Transient rises were noted.

Potassium as a mixture of chloride and citrate was administered to two children by mouth and balance studies were made. In one child with a normal serum sodium 81% of the potassium given was retained. In another child, who had a low serum sodium, only 26% was retained.

It is suggested that the electrolyte disturbances in tuberculous meningitis can be explained by the serious vomiting and prolonged low food intake in the early stages of the disease. The abnormality is not due to a deficiency of any one electrolyte, but is probably due to a combined deficit of sodium, chloride, and potassium. Ensurance of an adequate electrolyte intake may be an important contributory factor to the recovery of patients with tuberculous meningitis.

Thanks are due to Professor R. S. Illingworth for permission to study cases under his care, and to him and Professor H. A. Krebs, F.R.S., for helpful criticism in the preparation of this paper. We are indebted to the staff of the Biochemistry Laboratory, Royal Infirmary, Sheffield, for making many of the urine electrolyte investigations.

CLINICAL AND CHEMICAL STUDIES IN HUMAN LACTATION

VII. THE EFFECT OF DIFFERENCES IN YIELD AND COMPOSITION OF MILK ON THE INFANT'S WEIGHT GAIN AND THE DURATION OF BREAST-FEEDING

BY

F. E. HYTEN, M.B., B.S.

Midwifery Department, University of Aberdeen

Although it is recognized that there are individual differences in the yield and composition of milk, the practical effect of these differences in terms of successful breast-feeding has received almost no attention. In Sweden, Sydow (1952) investigated the relationship between the milk yield on the sixth post-partum day and the duration of breast-feeding, and found that if the sixth-day yield was under 300 ml. there was a considerably diminished chance of breast-feeding. This was an insensitive index, however, since only 25% of cases were in this low-yield group. Moreover, under "breast-feeding" were included those who were only partly breast-feeding, so that the overall figure of over 90% still breast-feeding at the end of two months, which is well in excess of any reported in this country, is difficult to interpret.

In an earlier study, Sydow (1944-5) gave an indirect indication of the effect of differences in fat content on the weight gain of the infant. Infants whose mothers donated to a milk bank milk which was stripped from the breast after feeding and therefore contained a high proportion of the fat gained less weight than those

whose mothers gave milk which was removed before the feed and contained relatively little fat. The average weight gains were 765 ± 62 g. and 866 ± 42 g. a month respectively. Sydow states that the material was unsuitable for comparison, since the birth weights and ages of the infants were not taken into account, and claims no significance for the results.

Kon and Mawson (1950) found no relationship between the weight gain of the infant after the eighth week and the fat content of the milk; but the milk yield was not known and, moreover, their technique of manually expressing a single morning sample gives no accurate indication of the daily fat output, and no conclusions can be drawn from it.

Gunther and Stanier (1951) found a significant relationship between the amount by which the baby was below its birth weight on the eighth day, and the eighth-day milk volume, but none with the fat content of the milk. The interpretation of this finding is not simple, since the initial weight loss varies very widely and is not related to food intake.

The terms "lactation" and "breast-feeding" must be differentiated. Lactation is a largely automatic physiological function showing wide individual variation. Successful breast-feeding is obviously dependent in the first instance on adequate lactation, but the efficiency with which this basic capacity is exploited depends on such factors as a desire to breast-feed, social custom, intelligence, and general living conditions. It is, in many ways, a test of the capability and character of the mother.

The various circumstances which determine the difference between the number of women having successful lactation and the number who breast-feed successfully will be discussed in subsequent papers, but, in order that the significance of the figures presented here can be appreciated in their proper context, the "official" attitude towards breast-feeding in this community must be described, since the proportion of women breast-feeding can to some extent be influenced by pressure of opinion from doctors and health visitors.

In Aberdeen, preparation of the breast as recommended by Waller (1946) is not practised, although Waller's shields are sometimes used for the treatment of inverted nipples. In hospital, unless there are definite medical contraindications, or unless a woman has firmly stated her intention to bottle-feed, it is tacitly assumed that all women will breast-feed, and much care is taken and time spent encouraging the mother in the lying-in wards. Excess milk is manually expressed after feeds as a routine during the first four or five days. Engorgement of the breast is treated along orthodox lines, which include the use of oestrogens. If the puerperium is uncomplicated the mother remains in hospital for eight to ten days.

If breast-feeding is not fully established in hospital, and if the woman is anxious to persevere, she may be sent home partly bottle-feeding, but there is an increasing tendency, if lactation is obviously poor, to begin artificial feeding in hospital so that efficiency in this technique can be acquired in the security of the hospital rather than in the general turmoil of failing lactation at home. Complementary feeds are given to breast-fed infants in hospital at the ward sister's discretion. There are no rigid rules governing their use, but they are generally given after the third day if the baby is still losing weight or when, after feeding, it still appears

hungry and test weighing reveals that the intake of milk has been inadequate.

The mother is visited within 24 hours of leaving hospital by a health visitor of the maternity and child welfare service. Further visits are made, at least weekly, for the first four weeks, and less frequently thereafter, although they are made more often when necessary. Breast-feeding is encouraged, but when lactation is clearly inadequate full artificial feeding is usually agreed to be a more practical alternative than prolonged complementary feeding.

It is the general experience that the majority of women who make the change to bottle-feeding do so without consulting a health visitor. The Aberdeen general practitioner is frequently consulted, but is less enthusiastic than the health visitor about breast-feeding.

Method

All the women in this investigation were confined in the Aberdeen Maternity Hospital, and details of the progress of lactation and of the infant were recorded during the lying-in period. They included the birth weight and subsequent daily weights until discharge, and records of any complementary feeds. The weight gain in hospital was taken as the gain from the third to the seventh day, since the weight changes during the first three days are almost wholly unrelated to food intake. Information about subsequent progress until the end of the thirteenth week was obtained from the records kept by health visitors of the Maternity and Child Welfare Department. The follow-up was limited to the first three months, because mixed feeding is often introduced during the course of the fourth month, and the contribution of breast milk to the baby's total food intake is then unknown.

The duration of breast-feeding was taken to be the time, up to a maximum of 13 weeks, during which full breast-feeding was carried on. The addition of any complementary or supplementary feeding was taken to mark the end of breast-feeding.

The reason for the cessation of breast-feeding was obtained from the health visitor concerned. In many cases this rested on the mother's own story, which usually took the form of "the baby cried all night" or "he didn't seem satisfied," and all such instances, together with those where there was definite evidence of inadequate nutrition, such as falling weight, were classified together as "failure of lactation."

Of the 167 women whose milk was sampled on the seventh day of lactation 148 were followed up for 13 weeks, and in all of these information was available about the time full breast-feeding stopped and the reason (or presumed reason) for stopping. For the remaining 19, 16 of whom left Aberdeen, data were available for periods of less than 13 weeks.

Beyond the first month of life accurate weights of infants were available for only 83 who had attended child welfare clinics, and these weighings were often at irregular intervals. In order that weights at fixed intervals could be used for statistical analysis, weight curves were constructed for each infant, and the presumed weights at four weeks, eight weeks, and twelve weeks were read from the curve. Weights were recorded only while full breast-feeding was in progress, so that if, for example, breast-feeding had ceased at six weeks, only the weight at four weeks would be available from the curve. Extrapolation beyond the last recorded weight was not attempted.

The method of collection of the milk samples, and the chemical analyses, have been described in previous papers (Hyttén, 1954a, I, II, III).

Results

In testing the relationship between seventh-day milk and the clinical data on breast-feeding and infant weight gain,

the milk yield and the several constituents were each tested separately. Only the yield and the fat content were related to the clinical findings, and, since these are not related to each other, it seemed logical that a stronger relationship could be found by multiplying them to give the total fat output for 24 hours. In practical terms, a milk with a poor fat content might be clinically satisfactory if it were associated with a high yield, and, conversely, a high fat content might compensate for a low yield. This proved to be so, and total fat output has been used for most of the following results.

Weight Gain of the Infant in Hospital

In assessing the infant's progress in hospital, 10 cases were excluded—five because the weight was not recorded on the third day, and five because artificial feeding was used during the first week, when breast-feeding had been temporarily suspended because of sore or cracked nipples.

Fig. 1 shows, in the remaining 157 infants, the relationship between the seventh-day milk fat output and the weight gain of the infant from the third to the seventh day.

FIG. 1.—The relationship of the fat output in the seventh-day milk to the weight gain of the infant and the need for complementary feeding from the third to the seventh day.

In the group where the fat output was less than 5 g., 40% of the infants either lost weight or required complementary feeding, and only 20% gained more than 4 oz. (113 g.). With higher fat outputs the weight gains were correspondingly better, and in that group in which the fat output was 20 g. or more 58% of the infants gained more than 4 oz. and only 7.5% lost weight or required complementary feeding. There was a statistically significant difference between the amounts of fat in the milk of those infants requiring complementary feeds compared with the rest ($P < 0.01$), but in the infants not having complementary feeds there was no significant correlation between the fat output and the infant's weight gain. This was partly due to the wide range of values for both weight gain and fat output and to the relatively small numbers, but there is also a contributory factor, which is best illustrated by the four cases in which the fat output was over 35 g. In this group one infant lost 2 oz. (57 g.); the other three gained only 1½, 2½, and 4 oz. (43, 71, and 113 g.), for the reason that where there was a gross excess of milk the infant had a full feed well before the breast was empty, and the remaining milk, which contained much of the fat, was expressed for the milk bank.

Weight Gain During the First Three Months

The seventh-day fat output was related to the weight gain of the infant during the first four weeks ($P < 0.01$), but not at later stages.* It must be pointed out, however, that the weight gain at eight and twelve weeks refers only to

*The regression equations were:

Ounces weight gain (3rd day-4 weeks)	$= 25.2 \pm 0.50$ (Fat output ± 0.18 in grammes)	-0.05 (3rd day ± 0.08 weight in oz.)
Ounces weight gain (3rd day-8 weeks)	$= 98.2 \pm 0.14$ " ± 0.34 "	-0.35 " ± 0.16 "
Ounces weight gain (3rd day-12 weeks)	$= 121.4 \pm 0.24$ " ± 0.61 "	-0.22 " ± 0.29 "

those infants who were still breast-feeding at these stages, and by the eighth week the majority of infants whose mothers had a low fat output had ceased breast-feeding.

Duration of Breast-feeding

Of the 148 mothers for whom data are available up to the thirteenth week, 23 were excluded from this part of the study because breast-feeding had been discontinued for reasons clearly unrelated to the adequacy of lactation. Of these 23, 11 had cracked nipples or mastitis, 8 stopped because of vague ill-health, 2 refused to continue breast-feeding after leaving hospital, one wished to return to work, and in one case feeding was abandoned because of an acute illness of the baby.

Of the remaining 125, 64 (51.2%) stopped breast-feeding before the thirteenth week because of "failure of lactation." Fig. 2 shows the percentage of infants still being breast-fed at stages up to 13 weeks, in the five fat-output

FIG. 2.—The relationship of the fat output in the seventh-day milk to the duration of breast-feeding.

groups. In the group having the highest fat output (20 g. or more), 89% breast-fed for thirteen weeks. With lower fat outputs, correspondingly fewer women succeed in breast-feeding, and in those with the poorest fat output (less than 5 g.) only 18% breast-fed for thirteen weeks. The relationship between fat output and the duration of breast-feeding is statistically significant ($P < 0.01$).

It has been shown in a previous paper that yield and fat content on the seventh day are not related to each other (Hyttén, 1954b, V), and Tables I and II demonstrate that both yield and fat content are associated separately with the duration of breast-feeding.

TABLE I.—Relationship of 7th-Day Milk Yield to Duration of Breast-feeding

No. of cases Proportion breast-feeding at 13 weeks	7th-day Milk Yield (ml.)			
	<300	300-449	450-599	600+
	35 26%	41 46%	31 58%	18 78%

TABLE II.—Relationship of Fat Content of 7th-Day Milk to Duration of Breast-feeding

No. of cases Proportion breast-feeding at 13 weeks	7th-day Milk Fat Content (g./100 ml.)			
	<2.51	2.51-3.25	3.26-4.00	4.01+
	28 36%	50 40%	32 62%	15 80%

Discussion

It has been suggested on somewhat slender evidence that breast-fed infants may suffer from deficiencies of certain amino-acids (Clements, 1949; Albanese, 1951); or of some

vitamins (Jeans and Marriott, 1947; Naish 1948); but in everyday practice the adequacy of milk as an infant food is judged in terms of its calorie content. The baby who cries or who fails to gain weight because of hunger is the practical problem and the subject of this study.

It is held by some enthusiastic advocates of breast-feeding that almost all women can breast-feed if they want to, with the implication that failure is due to an unwillingness of the mother to make the effort. Jeans and Marriott (1947) make the categorical statement that breast-feeding "is possible at least for the first few months in over 85% of cases," and Illingworth (1953) states: "Another diagnosis which is commonly made by doctor, nurse, or mother—particularly the latter—is that the breast milk is too watery. For practical purposes this diagnosis is always wrong. At least, I have not yet seen such a case" (author's italics). In confirmation of this claim, Illingworth quotes the following authors who have published figures showing a very high incidence of breast-feeding. Yung-en Kao (1948) described an incidence of 95% at six months in a series of hospital out-patients at Mukden, and Richardson (1925) an incidence of 92.1% at one month in a district of New York. In neither instance is there any reason to believe that breast milk was necessarily the sole source of nourishment for the child. Read (1949) published a series of 480 women, of whom 98% were discharged from hospital breast-feeding on the twelfth day, but 15% were classified as "breast-feeding—poor," 26% as "breast-feeding—fair," and 46% of the babies had not regained their birth weight. There is no record of the breast-feeding performance after leaving hospital.

A belief in the universal ability to breast-feed is difficult to reconcile with the evidence of deficient lactation presented in this paper. It might be argued that the milk yield can readily be reduced by such emotions as antagonism to, or lack of enthusiasm for, breast-feeding, and to some extent this may be true. However, it has been previously shown (Hyttén, 1954c) that the major source of variation in milk yield is in the gross differences which occur in the development of the breasts during pregnancy, and it is unlikely that such well-marked physical changes in the breast are due to emotional factors. Again, the fat content of the milk is closely associated with breast-feeding success, and there is no evidence that the percentage of fat can be altered at will. In fact, the level of fat content has been previously shown (Hyttén, 1954b) to be remarkably stable after the first week of lactation.

The evidence strongly suggests, then, that "failure of lactation" is a real phenomenon, and that those women who produce less than 10 g. of fat on the seventh day are very unlikely to be able to breast-feed successfully. This group constitutes one-third of the cases in this series.

Although it is necessary to know the fat content of the milk in order to judge fully the adequacy of lactation, it is clear from Table I that yield alone is of considerable prognostic value. The seventh-day yield, calculated from test weighing the baby and measuring strippings from the breast, is a relatively simple clinical test, and of those women in this series who produced a pint (570 ml.) of milk or more on the seventh day 81% breast-fed for three months at least.

However, although the level of lactation is a major underlying influence in the success of breast-feeding, there are clearly other factors involved. For example, all women secreting more than 15 g. of fat on the seventh day probably had an adequate lactation, and yet 26% of them failed to continue breast-feeding for three months. These factors will be discussed in a future publication.

It has been shown previously (Hyttén, 1954b) that such differences as occur in the lactose and protein contents of

the seventh-day milk are due to differences in the speed of maturation, and that in more mature milk the variation in these constituents has practically disappeared. In this study there were no differences in the success of lactation which were associated with the protein content of the seventh-day milk, so that the speed of maturation is apparently of no particular importance in this connexion. That is, milk which is slow to "come in" does not necessarily portend unsuccessful breast-feeding.

The rapidity with which women with poor lactation stop breast-feeding emphasizes the importance of studying human milk composition as early as possible in lactation, if the full range of variation is to be appreciated. Any investigation of human milk secreted after the second or third month of lactation would be carried out on a highly selected population. Those women with poor lactation would, of necessity, have abandoned breast-feeding, and although a considerable variation in milk composition may remain among the rest there will be little or no really poor milk discovered. This may, in part, be the basis for the widely held belief that variations in milk composition are unimportant.

Summary

The success of lactation, judged by the duration of breast-feeding and the weight gain of the baby, is shown for 167 subjects whose milk was analysed on the seventh post-partum day. Both milk yield and fat content were related to the clinical data. The total fat output had a stronger relationship than either.

There was a marked relationship between the seventh-day fat output and the baby's weight gain in hospital.

The breast-feeding history of 148 of these subjects was known until the 13th week. In 23, breast-feeding was terminated for reasons unconnected with the adequacy of lactation. In the remaining 125 there was a marked relationship between fat output on the seventh day and the duration of breast-feeding.

Accurate weights during the first three months of life were known for 83 of the infants, and, although there was a strong relationship between fat output and weight gain during the first month, there was none after this time. This effect is presumably due to the elimination of those infants initially fed on milk of low nutritive value, leaving at the breast only those for whom the milk was at least adequate.

I am grateful to Professor Dugald Baird and the staffs of the Midwifery Department and the Aberdeen Maternity Hospital and to the health visitors of the Maternity and Child Welfare Department for invaluable help; to Professor John Craig, of the Department of Child Health, and Dr. I. Leitch, of the Commonwealth Bureau of Animal Nutrition, Bucksburn, for criticism and advice; and to Mr. J. F. Scott for statistical assistance.

CARCINOMA OF THE MIDDLE EAR

BY

MAXWELL ELLIS, M.D., M.S., F.R.C.S.

Surgeon, Royal National Throat, Nose and Ear Hospital, London; E.N.T. Surgeon, Central Middlesex Hospital

AND

ROBERT PRACY, M.B., B.S., F.R.C.S.

Senior E.N.T. Registrar, South Manchester Group of Hospitals; Late Registrar, Royal National Throat, Nose and Ear Hospital, London

This report is concerned with carcinoma arising primarily in the epithelium of the middle-ear cavity or mastoid air cells. The disease is rare. We have been able to find only 120 cases in the literature, and even this figure is only approximate, as the accounts often include cases of growth arising in the external meatus. Risch and Lisa (1938) gave a full account of many previous case reports and a comprehensive bibliography. It is usually impossible to decide clinically whether one is dealing with a carcinoma of the tympanum or of the external meatus, but the former has some distinct features, illustrated by the following six cases.

Case 1

A married woman aged 62 was first seen in July, 1947, complaining of having had right-sided otorrhoea for five months and pain in the right side of the lower jaw for three months. She was found to have an incomplete right facial paralysis of the lower motor neurone type, induration in the inferior portion of the right parotid gland, granulation tissue deep in the meatus, and a blood-stained discharge. Malignant disease was suspected, and was confirmed by biopsy of the aural granulation tissue, which revealed "a well-differentiated squamous-cell carcinoma, almost completely keratinized." It was decided that irradiation should be the first means of treatment, and 8,200 r was given from August 18 to October 9 by tele-radium (5-g. unit) and deep x rays.

On December 19 the temporal bone was explored through a post-aural incision. As the mastoid process and the middle ear were found to be largely replaced by tumour an extensive excision was performed. The facial nerve, although not identified, was removed with the tumour tissue, as the facial paralysis was later found to be complete. The dura and the temporo-mandibular joint were not involved. The pain disappeared after the operation, and the disabilities resulting from the facial paralysis became the patient's chief concern and were to some extent rectified by a right tarsorrhaphy and a fascial sling. There has been no evidence of recurrence.

Case 2

A man aged 44 was seen for the first time in November, 1951. He had suffered from bilateral otorrhoea for twenty years, but came for advice because of increasing deafness. Both middle ears were extensively damaged, but both were dry. A hearing-aid was prescribed. One month later he developed a right facial paralysis. Examination then showed granulations protruding through a large postero-superior perforation in the right drum. He complained of severe pain in the ear, but there was no mastoid tenderness. A right radical mastoidectomy was performed (post-aural approach) in the belief that this was a case of chronic infection with an acute exacerbation. A good deal of granulation tissue was found in the mastoid process and tympanum, together with much erosion and destruction of bone. The horizontal portion of the facial nerve was exposed. The wound was packed with bipp ribbon gauze

and left open, and a fortnight later, as the cavity appeared clean and was covered with healthy granulations, a skin graft was applied and the posterior incision closed.

Shortly after this operation the patient complained of increasingly severe pain in the ear. The cavity was dressed after a week, when much of the graft was found lying free in the cavity, and granulations covered the facial ridge. It was then felt by one of us (R. P.) that the abnormal course of the case was suggestive of a growth, and biopsy confirmed this suspicion, revealing "active squamous-cell carcinoma." The cavity was explored again and all diseased bone and muscle was excised, leaving the sigmoid sinus, jugular bulb, and parts of the membranous labyrinth exposed. The temporo-mandibular joint was opened, as the growth had invaded it and had also spread to the dura overlying the tegmen tympani. Permission to remove the pinna had not been obtained, and it was removed a week later. The material excised at this operation showed "a fairly well differentiated squamous-cell carcinoma with invasion of the temporal muscle, the facial nerve, and the temporal squame." A course of irradiation was given to the open wound, 5,455 r by deep x rays and teleradium (10-g. unit) over 55 days. The cavity appeared to heal well from the bottom, but the pain persisted. By July, 1952, he began to suffer from fits, and he died of an intracranial extension in September, 1952.

Case 3

A man aged 75 was first seen in February, 1952, having had severe left-sided earache and otorrhoea for four months. Both the pain and the discharge, which was blood-stained, had increased steadily and were associated with a recent increase in deafness. The pinna was displaced downwards and outwards by a brawny oedema over the mastoid process, and in the external meatus there was a bloody and foul-smelling discharge, whilst bare bone was palpable in the floor of the canal. A diagnosis of carcinoma of the tympanum was made on clinical grounds, and on March 17 the left mastoid was explored through a post-aural incision. The whole of the temporal bone lateral to the labyrinth capsule had been replaced by a growth, which was also invading the temporo-mandibular joint. A wide excision was performed. The operation was followed by a partial left facial paralysis of the lower motor neurone type. Material removed at operation was sent for microscopical examination and showed, "extensive invasion by squamous-cell carcinoma of the pinna, the parotid gland, and the mastoid process." He was then treated by a combination of deep x rays and teleradium (10-g. unit), and a total dose of 3,855 r over 36 days was given. The pain was unrelieved, although, as in Case 2, the operation cavity was left wide open. He died of coronary occlusion in June, 1952. Post-mortem examination revealed residual carcinoma in the petrous apex.

Case 4

A spinster aged 52 was referred by her doctor with a diagnosis of carcinoma of the right ear, for which a limited local excision had been performed nine months previously. She complained of severe and constant earache, and there had been three recent attacks of bleeding from the ear. The right external auditory canal was very stenosed and contained a thin and foul-smelling blood-stained discharge. There was a complete conductive deafness. In a smear of material taken blindly from the depths of the stenosed meatus carcinoma cells were found.

Accordingly, on February 11, 1952, the right temporal bone was explored through a post-aural incision. The epitympanic space and the posterior meatal wall were replaced by a growth, which was also spreading forwards into and above the temporo-mandibular joint, as well as deeply and anteriorly into the dura of the middle fossa. As much as could be reached of this growth was excised, and the anterior and superior walls of the cavity were coagulated by diathermy. The posterior bony wall of the cavity was

covered with a Thiersch graft, a large meatal opening was fashioned after Ballance's method, and the wound was closed. The material obtained at operation was examined and showed "(1) no neoplastic change in the meatal skin. (2) invasion of the medial end of the meatal skin tube, and (3) active islands of squamous-cell carcinoma in the tegmen tympani." The patient was then treated by irradiation, receiving a total dose of 5,900 r in 69 days by a combination of teleradium (10-g. unit) and deep x rays. She died on November 11, 1952, from intracranial spread of the original lesion. The local pain was unrelieved by treatment.

Case 5

A married woman aged 68 was first seen in February, 1953, with a history of discharge from the left ear for many years. For the past year she had had pain in the left side of the face and head, and the discharge had become blood-stained. Examination showed signs of previous suppuration in the right ear. On the left side there was a partial facial paralysis, and granulations were growing out of the middle ear into the meatus. Because of the history and the clinical findings, some of this granulation tissue was removed for biopsy, and a squamous-cell carcinoma was revealed.

On March 10 the left temporal bone was explored through a post-aural incision. The mastoid portion of the bone and the whole tympanum had been replaced by tumour tissue, which did not, however, appear to have penetrated the dura. So far as possible, the growth was removed, and examination of the material obtained at operation showed: "(1) In one area there is evidence of chronic inflammation with lymphocytes and foam cells. There is an area of hyperplastic squamous epithelium loosely attached to this tissue. (2) Squamous-cell carcinoma with cornification. There are areas of fairly deep infiltration." After operation the patient was treated by a combination of teleradium (10-g. unit) and deep x rays, receiving a total dose of 5,560 r in 39 days. Pain was not a pre-operative feature of importance, and disappeared after treatment. There is still no evidence of recurrence, and the radical cavity is soundly epithelized. A slight facial palsy persists.

Case 6

A married woman aged 55 was first seen on January 12, 1954. She had suffered from left otorrhoea since childhood and from lumps below and anterior to the ear for six months. A fleshy polypus occupied the meatus, and there was a hard nodule the size of a pea in the pre-auricular region and a much larger mass in the subdigastric area. Biopsy of the polypus revealed an early squamous-cell carcinoma developing in granulation tissue. The patient was referred to the Radiotherapeutic Research Unit of the Hammersmith Hospital, and the ear was treated on the 8-million-volt linear accelerator. From February 1 to March 15 a dose of 5,820 r was given. The middle ear became dry and fibrotic in appearance and the pre-auricular gland disappeared. A very extensive block dissection of the left side of the neck was carried out on April 24. Nodes in the subdigastric area and others from behind the mastoid attachment of the sternomastoid muscle contained squamous-cell carcinoma. The patient left hospital on May 7.

Discussion

Clinical Features

Previous writers have emphasized certain points which are to be found in these cases.

1. *Pain*.—This was a feature in all of our cases, and in three of them was unrelieved by treatment. Furstenberg (1924) and Bowman (1940) believed that the pain was due to the pressure of the expanding tumour within a rigid bony framework. However, an expanding lesion like a cholesteatoma does not cause pain by its presence, although pain may occur when an acute infection supervenes. The

pre-operative pain in these cases may well be due to secondary infection, but the persisting post-operative pain, occurring even in a widely laid open cavity, is inexplicable. It cannot be due to direct involvement of the dura, as the dura over the temporal bone is not a site from which painful stimuli can be elicited (Wolff, 1948). Nevertheless, in Cases 2, 3, and 4, in which pain was a dominant symptom, the dura was invaded by the growth, whereas the pain disappeared after operation in Cases 1 and 5, in which there was no dural involvement. We are not prepared to offer any explanation of these observations. Pain is a common symptom in cancer, and its cause is often obscure.

2. *Chronic Suppuration*.—A history of genuine chronic suppuration was obtained in only two of our six cases. In the other cases the otorrhoea could be attributed to the presence of tumour rather than to pre-existing suppuration.

3. *Facial Paralysis*.—This was a presenting symptom in two cases, and was present but unnoticed by the patient in one case.

4. *A Blood-stained Aural Discharge*.—This was present in four out of the five cases.

5. *Sequestration of Bone*.—This was present in one case.

6. *Post-aural Swelling*.—This was present in one case.

7. *Metastasis*.—Neighbouring or distant metastasis has rarely been reported in the literature, but it occurred in Case 6. Whether the method of treatment adopted was the correct one remains to be seen, but the result so far has been satisfactory.

From our experience it seems that pain and the presence of a blood-stained discharge, particularly if there is also a facial palsy, are the most reliable indications of malignant disease in the middle ear. The diagnosis must be clinched by biopsy.

Cause of Death

The cause of death is usually given as malignant cachexia. In some cases invasion of the meninges leads to fatal intracranial complications. In others a fatal haemorrhage occurs from erosion of the jugular bulb or the carotid artery. Death from a distant metastasis has not been recorded.

In our series, one patient died from coronary occlusion and two from direct intracranial spread of the disease.

Treatment

In so far as so rare a disease can be said to have any settled mode of treatment, it would be a combination of surgery and radiotherapy. One of our cases received radiotherapy before surgery, whilst the others were treated by post-operative irradiation (at the Royal Cancer Hospital, London, under the direction of Dr. M. Lederman). The extent of the operation varied with the extent of the disease. As in all cancer surgery, no anatomical boundaries were respected, and no attempt was made to preserve any involved structure which could be excised.

For instance, in most cases the inner ear was removed in whole or in part; in two cases considerable portions of the capsule of the temporo-mandibular joint were excised; the capsule of the temporo-mandibular joint was sacrificed. When the region and in one case the pinna was involved in growth no attempt to preserve the nerve was made at the expense of a skimped excision.

However, in Cases 2, 3, and 4, pursuing the disease anteriorly would have meant excision of the temporo-mandibular joint and the adjacent part of the base of the skull, with no certainty, even then, of reaching the limits of the growth. In the light of subsequent events, this is probably the course which should have been followed to give the patient the best possible chance, as it seems clear that radiotherapy is unavailing in growth so deeply buried in bone. In Case 3 the whole bony meatus and the parotid gland should perhaps also have been excised in order to comply with the essential requirements of tumour surgery. These are speculative suggestions, offered after reflecting

on the clinical course of these few cases, and applying general surgical opinions which are commonly accepted. The tumours are not highly malignant, and distant metastasis is almost unknown. The problem, then, is entirely one of adequate local removal, and this seemingly applies particularly to the bone, as irradiation appears to be effective in controlling the soft-tissue invasion. Before embarking on any case a clear idea must be entertained of the possible directions of spread in the bone and a feasible means of excising these areas. Such excisions are not insurmountable technical problems, provided they are not presented suddenly in the course of an operation conceived in lesser terms.

Prognosis

The prognosis of middle-ear carcinoma is very poor indeed. Only one case is to be found in the literature in which the patient has survived for more than five years. In this series six cases are reported; one patient is alive and well six and a half years after coming under observation, and one other, treated a year ago, was also alive and without any evidence of recurrence at the time of writing. In both these cases the disease did not involve the dura, which is the factor enormously worsening the outlook.

Summary

Six cases of carcinoma of the middle ear are described. Suggestions for more radical surgical excision are offered.

ANGULAR STOMATITIS AND ITS ASSOCIATION WITH ARTIFICIAL DENTURES

BY

J. G. HARKNESS, M.B., Ch.B.

Registrar in the Department of Dermatology, the General Infirmary at Leeds

Angular stomatitis is seen by the general physician as evidence of nutritional (especially vitamin B) deficiency or of anaemia; but such patients rarely visit the dermatologist. Nevertheless, many patients suffering from angular stomatitis are seen in dermatological and dental departments, and few of them are found to be suffering from general nutritional disease. Most of these patients show a local infective cause for the condition or have some dental fault or both.

The series of patients reviewed in this paper were drawn from the dermatology department of the General Infirmary at Leeds, and the work was done in conjunction with the staff of the dental school.

The literature on the subject is vague; but Vickers (1949) made an important contribution, and his approach has been followed.

There appears to be little doubt that there are several aetiological factors, and in some cases more than one of these may be contributory, so that careful consideration of each particular patient is necessary if treatment is to be successful. Generally accepted aetiological factors include: (1) infection; (2) ariboflavinosis; (3) generalized seborrhoeic or flexural eczema; (4) sensitization to dental materials; and (5) malocclusion.

Infection

Angular stomatitis may occur as a manifestation of lues in the secondary or tertiary stages. Other infections, especially of the respiratory or gastro-intestinal tract, may also cause the condition, including moniliasis. In Case 14 attacks of angular stomatitis were coincidental with recurrent tonsillitis, and in Case 16 relapses always followed a common cold.

Ariboflavinosis

Although in this series ariboflavinosis does not seem to be important, this may be explained by the direction of such cases to general medical rather than dermatological clinics. Blood vitamin levels were not undertaken as a routine; but all patients were questioned closely with a view to establishing possible dietetic deficiency or finding evidence of a malabsorptive syndrome: Case 23 proved interesting in this respect. This patient suffered from Crohn's disease for many years, and her stomatitis cleared soon after operation for this condition and has not recurred. Her case was also interesting in that there appeared to be a familial tendency to angular stomatitis, as both her brother and her sister (Case 12) suffered from the condition, though neither gave any similar history suggestive of malabsorption.

Generalized Seborrhoeic or Flexural Eczema

Angular stomatitis often occurs as part of a generalized seborrhoeic or flexural eczema and clears or relapses with the general condition; but it may occur as the sole manifestation.

This condition involves more of the skin adjacent to the angles of the mouth than usual and proves very resistant to treatment and liable to relapse readily. An example of this type is Case 17, which proved extremely resistant to various local measures, including antibiotics, dental treatment, and to x-ray therapy, but cleared on the administration of ung. steroxin and had not relapsed six months later.

Sensitization to Denture Materials

Some patients become sensitized to the material of their dentures, and in such cases the condition usually clears with the substitution of a different denture material. In most instances of sensitivity to denture material an area of hyperaemia, and in some cases actual oedema of the underlying mucous membrane, is present; but in three patients (Cases 1, 6, and 11) there were no mucosal changes, although patch tests to denture material were positive. Further, 12 patients (Cases 4, 8, 12, 18, 21, 26, 28, 32, 36, 41, 43, and 45) with mucosal changes were negative to patch tests. It is noteworthy that acrylic dentures were concerned in all these cases except one. As a control, colleagues at the dental school examined 100 random cases in the prosthetics department, and in only one of these was there any definite mucosal lesion without accompanying angular stomatitis or complaint of soreness of the gums. These people had been wearing dentures for from one year to forty years.

Patch Testing

This means of investigation of the presence of sensitivity was used, the method followed being that of Vickers—namely, the application of scrapings from the patients' own dentures to the skin, held in place by adhesive plaster. In several instances positive patch-test reactions were delayed, and it would seem advisable to retain the material in position for at least 96 hours, with a preliminary reading at 48 hours. Cases 1, 2, 3, 24, 33, and 44 demonstrate this delayed reaction.

It might well be argued that these delayed positive reactions could be due to mechanical friction or chemical

action; but a control series of 20 medical students failed to produce any such mechanical positive reaction even after a week.

Further, all cases were tested at the same time against clear acrylic and other denture materials, and all positive results were very definite, no possible mechanical positive reactions being obtained with the other materials.

There were, as is usual in most series of patch tests, some anomalous results, and one in particular (Case 7) proved interesting. This patient gave a positive patch reaction to vulcanite dentures in January, 1952, at 48 hours. There appears to be little doubt about this, as he was demonstrated to a class of medical students at the time as a good example of a positive reaction. New dentures were made for him in acrylic, and his angular stomatitis cleared rapidly. He happened to have retained his old dentures, and in March, 1953, the patch test was repeated and proved to be negative at 96 hours.

Another patient (Case 3), who gave a delayed positive patch reaction to acrylic scrapings from his own dentures, failed to reproduce this when tested against acrylic applied direct to the skin. (These pieces were specially made and processed for two, four, six, and eight hours respectively.)

Although the evidence here is slender it is possible that some physical or electrochemical factor is concerned with these reactions and that the presence of saliva may in some way be bound up with this.

Nature of the Sensitizing Material

Lain (1932) states that the substance probably responsible for the sensitivity in vulcanite is vermilion, but as this material is rapidly becoming obsolete it was decided to investigate only the newer and more fashionable acrylic materials. Naturally, it was decided first to investigate the colouring material; but the makers were unwilling to disclose its nature or to supply any for patch testing.

All patients were therefore patch-tested against coloured scrapings from their own dentures and clear acrylic scrapings. In only two cases (Nos. 6 and 46) was a positive result obtained to the coloured and a negative to the clear.

It was then decided to investigate a theory that sensitization is due to incomplete polymerization of monomer during the actual process of making the dental plates. This process consists in mixing liquid monomer and polymer powder into a dough, which is then heated in a mould, during which process the monomer polymerizes and the finished article results. This process probably depends on the presence of an organic peroxide or some such substance in the powder which acts as a source of free radicals which can initiate the polymerization of the added monomer. This reaction is slow at room temperature, but is nevertheless appreciable, since the mixture will set into a fairly hard material in a few days.

On heating, polymerization occurs more rapidly, the normal plate being processed at 100° C. for about six hours.

Since polymerization takes place slowly at room temperature it seems unlikely that any monomer would be present, at least on the surface, even in an under-processed plate, after it had been made for a few weeks. However, it is possible that monomer could be trapped in the rigid polymer material in positions remote from initiator molecules, and it might thus be unchanged.

It seemed that the theory might be tenable if the monomer was a primary irritant or sensitizer, or if appreciable differences could be demonstrated in the amount of monomer present in acrylic material processed in different ways.

To test the first point all patients were patch-tested as a routine with monomer when being tested against denture materials, and in addition a control series of students and nursing staff were also tested. In no case did a patch test to monomer give a positive result even after 96 hours. It would therefore seem that liquid monomer is neither a primary irritant nor a potent sensitizer.

TABLE I.—Summary of Results

Case No.	Age (Years)	Duration of Condition (Years)	Past Medical History	Worn at Night	Material of Dentures	Duration of Wearing (Years)	Mucosal Lesions	Patch Test Results	Ultimate Diagnosis	Treatment	Result

A.—Acrylic. B.—Bakelite. V.—Vulcanite. N.B.—Normal bite. O.B.—Opened bite.

Secondly, investigation of the presence of monomer in denture material was carried out by submitting to a vacuum for several hours finely shaved particles of material made under varying conditions. Any loss of weight was taken to indicate loss of free monomer in the material.

Investigation of Denture Material

Sample I: Material processed at 100° C. for two hours, and brought to 100° C. slowly; age, several days. Sample II: Material brought to 100° C. slowly and chilled suddenly without processing. Sample III: Material processed at 100° C. for four hours; age, two days. Sample IV: As for Sample III, but aged five days.

TABLE II.—Results

	Sample I	Sample II	Sample III	Sample IV
Initial weight of sample (g.)	0.0862	0.4277	0.2375	0.2592
Loss of weight (g.)	0.0000	0.0200	0.0021	0.0016
Percentage loss	0	5	0.9	0.6

The conclusions drawn from these results after allowance had been made for experimental error and other factors which might influence them were that, while it seems likely that some monomer is present in extreme cases of under-processed material, it is impossible to say whether there is any in normally processed and aged material; but if any is present at all it is probably only a fraction of 1%.

Malocclusion

Apparently, because it prevents discomfort when dentures are fitted, it is standard dental practice to close a patient's normal bite. This causes sagging of the mouth with accentuation of the angular creases. These tend to retain saliva and form an excellent nidus for organisms, increasing the likelihood of angular stomatitis. There is no doubt that this is a contributory factor in some cases; but many edentulous people never develop the condition.

In these series, results of opening the bite to remove the mechanical sagging proved rather conflicting. Some cases rapidly cleared completely, others cleared temporarily and relapsed, and one (Case 35) showed no improvement whatever.

The standard procedure here was to open the bite 3/16 in. (4.8 mm.), but in many instances this proved impracticable, mainly because of resultant discomfort in the nature of temporo-mandibular joint arthritis. To obviate this, it was decided to open the bite gradually 1/16 in. (1.6 mm.) at a time every few months; but as yet there has not been time to assess the value of this technique.

It is to be noted that only one patient in this series (Case 29) did not wear dentures, and in this instance there was some malocclusion and apparently no other contributory cause, although the patient admitted to having had

the habit of licking his lips in childhood. There was usually a quick response to any mild antiseptic applied locally, so that there was probably an infective cause.

Results

Table I gives the relevant findings in 46 cases. The nature of the study did not lend itself well to statistical analysis, and it was not thought profitable to pursue this line of investigation.

Of the 46 cases treated, 22 cleared completely, 9 cleared but relapsed, 10 improved, and in 5 there was no change. Of those that were cleared, 18 had new dentures and 4 were given only local treatment.

Summary and Conclusions

A series of 46 cases of angular stomatitis associated with artificial dentures have been investigated.

There are several aetiological factors concerned in the production of angular stomatitis, and a full investigation of each case is necessary.

Patch tests to denture materials may be delayed, and patches should be left *in situ* for at least 96 hours.

The nature of the sensitizing material remains obscure, but may be connected with the colouring material.

Opening of the dental bite will result in the cure of some cases, but cannot be guaranteed to be permanent.

My thanks are due especially to Dr. J. T. Ingram for his helpful criticism and permission to use his cases in this investigation; to Drs. F. F. Helier and S. T. Anning, who also permitted me to use their cases; and to the staff of the dental school, without whose co-operation the practical work could not possibly have been carried out. Mr. McNaughton, of the chemistry department of the University of Leeds, also helped considerably in connexion with the investigation of incomplete polymerization of dental plates.

According to a report in the *Manchester Guardian*, it was made known at the Annual Conference of the National Institute of Houseworkers on May 18 that the Institute is now operating a programme for training hospital domestic workers. This scheme is being carried out in conjunction with the Leeds General Infirmary and the London Hospital. Domestic workers already employed in the hospital will receive a short part-time training, while a longer period of training is available for new employees between the ages of 15 and 18. A diploma will be awarded. The programme of training is being financed by grants from the Nuffield Provincial Hospitals Trust and the London Hospital free endowment funds.

KATAYAMA DISEASE, EARLY TOXAEMIC STAGE OF BILHARZIASIS

WITH A REPORT ON A CASE SHOWING PULMONARY INFILTRATION

BY

J. RITCHKEN, M.D.

AND

MICHAEL GELFAND, M.D., F.R.C.P.

Salisbury, Southern Rhodesia

It may be many months after the bilharzial parasite has entered the body that the disease becomes recognized. However, in a small number of cases symptoms and signs develop after the first month, and these manifestations are referred to as the Katayama syndrome or the early stage of toxæmia. Though reported as occurring more commonly in patients infested with *Schistosoma japonicum*, this syndrome is seen in *S. mansoni* but only occasionally in *S. haematobium* infection.

We have had occasion to treat a child soon after initial exposure to bilharzial infestation. He displayed the classical signs of the Katayama syndrome. We record this case as the literature on the subject is extremely sparse, particularly concerning the pulmonary changes. The pathogenesis and clinical features of this interesting condition are also reviewed.

Case Report

A boy aged 7½ years paddled on a single occasion (December 8, 1952) in a river known to be infested with bilharzial snails. He could not recall any itching of the skin at that time and remained in good health until January 3, 1953. On that day he felt tired and had no appetite; his temperature was 100° F. (37.8° C.). During the following five days his temperature ranged from 100 to 104° F. (37.8 to 40° C.), but, apart from recurrent vomiting attacks, he did not complain of any specific symptoms.

Physical examination was entirely negative. A blood slide showed no malaria parasites, but revealed a marked increase of eosinophils. He was thereupon admitted to hospital for further investigation. Soon after admission he developed a persistent dry cough and became slightly cyanosed and breathless. Examination showed coarse rales scattered over both lungs, but no other physical signs. Without any specific treatment his temperature fell by lysis to normal ten days after the onset of illness. The cough and vomiting rapidly improved, and apart from loss of weight and a pallid complexion he appeared perfectly normal.

Laboratory Investigations.—On January 9 the white blood cells numbered 36,100 (neutrophils 42%, lymphocytes 11%, monocytes 3%, eosinophils 44%), and on January 12 27,400 (neutrophils 42%, lymphocytes 8%, monocytes 1%, eosinophils 49%). Repeated urine tests revealed no abnormalities. No pathogenic cysts, ova, or parasites were seen in numerous tests of the faeces. X-ray examination of the chest on January 10 showed a diffuse miliary type of lesion confined mainly to the middle and lower zones of both lungs, especially the left, where the lesions appeared to be almost confluent. A cercarial skin test was negative.

A diagnosis of probable Katayama disease was made and the patient was discharged and kept under observation.

He was examined again on February 8. He complained of feeling tired, his appetite was poor, and his mother expressed concern at his listlessness and pallor. His cough had disappeared. A further chest x-ray film showed complete clearing of the focal pulmonary consolidation. On

February 10 the white blood cells numbered 16,900 (neutrophils 38%, lymphocytes 23%, monocytes 2%, eosinophils 37%). Examination of the urine and faeces was again negative.

On February 24 he again became pyrexial and complained of severe abdominal pain and diarrhoea. The spleen was now palpable and he was very tender over the liver area. On the following day diarrhoea persisted and the lateral spined ova of *S. mansoni* were found in the faeces. Treatment with "anthiomaline" was started, and within two weeks he showed a marked improvement. A follow-up examination four months later showed complete restoration of health.

Discussion

The clinical picture of the toxæmic stage in Southern Rhodesia is very variable. It may be mild or severe (Gelfand, 1942; Gelfand and Osburn, 1943). In many it may simply be labelled "urticaria due to food allergy"; in others the picture may cause undue alarm and the diagnosis of acute miliary tuberculosis may even be considered. The essential features comprising this syndrome are:

Age.—In our experience the toxæmic stage is seen in the child and not in the adult, and only a small proportion of infected children are so affected.

Pyrexia.—This may be prolonged over many days, but more often is characterized by periodic rises with long afebrile intervals. In most cases, despite a high temperature, the child does not seem to be seriously disturbed.

Symptomatology.—General malaise, loss of appetite, and frequent vomiting are usually the only symptoms. With lung involvement a cough is characteristic, and in the later stages tenderness over the liver area is a frequent finding.

Loss of Weight.—This is often a noticeable feature, and appears to be mainly related to the frequent vomiting and poor appetite.

Urticarial Eruptions.—These often appear in crops and at times assume the features of angioneurotic oedema affecting the orbits, face, penis, and scrotum.

Splenomegaly.—Splenic enlargement is usually noted towards the end of the toxæmic stage, and subsides even though no antibilharzial treatment is given.

A High Blood Eosinophilia.—This is constantly present in all cases, and is the one feature which is maintained throughout the course of the disease. The actual count is usually between 20 and 60%. It is probable that the eosinophil count remains elevated until active treatment is started.

Lung Involvement with Radiological Changes.—It is probable, because of failure to examine the lungs radiologically and owing to the transitory nature of the radiological features, that these are rarely demonstrated. In the above case extensive miliary changes were shown, and it is probable that these reveal the severest degree of pulmonary involvement.

Pathogenesis

In view of the non-fatal nature of the early toxæmic stage of bilharziasis, there are no pathological data available. However, the general symptomatology and major signs such as urticaria, eosinophilia, and transient pulmonary infiltration suggest an allergic reaction to the developing schistosome.

In the case reported the toxæmic stage appeared 35 days after exposure. It is known that mature female schistosomes with fully developed ova in their uterine canals are found in the portal vein four to six weeks after the cercariae have pierced the skin or mucous membrane. It is therefore probable that 35 days after exposure the fully matured female has found her way via the mesenteric vessels to the small venules of the large intestine, and that ova deposition has begun. It is therefore suggested that the early bilharzial toxæmia is an intense allergic reaction towards this stage of the life cycle of the schistosome. This reaction occurs usually in children, and often, as in the present case, in a child known to suffer from other allergic conditions.

This concept of the nature of Katayama disease has received much confirmation in recent years by work done on closely

related subjects. Crofton *et al.* (1952) reviewed the entire subject of pulmonary eosinophilia. The latter they define as a condition in which pulmonary infiltration on the radiograph is accompanied by blood eosinophilia, but in which any of four conditions (the resolving stage of pneumonia, hydatid disease of the lung, Hodgkin's disease, and sarcoidosis) can be excluded. According to their classification of pulmonary eosinophilia, the Katayama syndrome would be grouped under that of simple pulmonary eosinophilia (Loeffler's syndrome).

The pathology in simple pulmonary eosinophilia has not been studied, as the condition is not fatal. However, Von Meyenburg (quoted by Crofton *et al.*) described changes which he considered to be those of Loeffler's syndrome in three soldiers who died from trauma. Irregular bronchopneumonic foci were noted which were seen microscopically to consist of small areas of alveolar exudate with many eosinophils. In one there was an eosinophilic infiltration of the interstitial tissue. In two cases ascarides were found in the intestine. Crofton *et al.* conclude that the entire group of pulmonary eosinophilias represent a hypersensitivity reaction of the body to various stimuli. When the hypersensitive reaction is brief and involves only the alveoli the manifestation is a simple pulmonary eosinophilia.

The breakdown of normal, abnormal, or foreign protein in the body tissues results in the release of histamine. Vaughn (1953), by injecting extracts of ascaris and of histamine into guinea-pigs, was able to demonstrate a great concentration of eosinophils in the pulmonary tissue. Twelve hours after the injection widespread thickened areas with a patchy consolidation were a common finding, and microscopical study showed a gross eosinophilic infiltration of the perivascular and peribronchial connective tissue. The changes, though similar, were more extensive after ascaris extract than after histamine injection. In Vaughn's opinion the biological purpose of this eosinophilic infiltration lies in the fact that the eosinophil, being in effect a carrier of histamine, is performing its function in delivering a substance to the lung, where it is inactivated by histaminase or another related enzyme.

In 1949 Sprent (quoted by Crofton *et al.*, 1952) sensitized mice to various ascaris extracts by parental injection and also produced striking pulmonary changes, including an eosinophilic infiltration. In a case of ascariasis it is known that the life cycle includes a stage of pulmonary migration, but as the result of Sprent's and Vaughn's experiments it is probable that the transitory pulmonary shadows seen in that condition are also better explained as an allergic phenomenon than as a reaction to the migrating larvae.

Further evidence of the allergic nature of this group of diseases is recorded by Wright and Gold (1945), who describe nine cases of pulmonary eosinophilia associated with creeping eruption, a local condition of the skin caused by the filariform larvae of *Ancylostoma braziliense*. Furthermore, in view of the similarity of the lung changes associated with eosinophilia which occurs in other parasitic diseases such as ascariasis, trichiniasis, cutaneous helminthiasis, amoebiasis, and liver-fluke infestation, the pulmonary changes seen in Katayama disease can best be accounted for on an allergic basis.

At this stage attention should be brought to the recent interest shown in the eosinophilia hepatomegaly syndrome of young infants and children caused by infestation with the larvae of *Taxocara canis*, a dog roundworm.

Beaver *et al.* (1952) and Milburn and Ernst (1953) have demonstrated the larvae in the liver of affected patients. The latter authors suggest that other diseases, such as Loeffler's syndrome and tropical eosinophilia, may also be due to visceral nematode larvae migrations. In this connexion Muhleisen (1953) demonstrated filariform hookworm larvae in a patient who developed asthmatic symptoms one week after the onset of creeping eruption. Such symptoms had previously been regarded as being of allergic origin.

To our knowledge, no sputum studies have been done on patients in the toxæmic stage of bilharziasis, but it is

thought most unlikely that the transient pulmonary infiltrations and other symptoms of the Katayama syndrome could be accounted for by cercariae trapped in the capillary bed of the lung or by migrating schistosomes. There is no evidence that the mature schistosome migrates anywhere but to the vesical and intestinal venous plexuses. All extra-urinary and intestinal forms of bilharziasis are due to embolization of ova from the above sources.

If the syndrome was due to cercariae trapped in the lung capillaries, symptoms would be expected soon after infestation, and would not appear three to four weeks later.

Summary

A case of Katayama disease caused by *Schistosoma mansoni* is reported. Symptoms developed 26 days after a single exposure to infected water.

In addition to the well-known symptoms and signs of this condition, a marked transient pulmonary infiltration is demonstrated.

The pathogenesis of pulmonary eosinophilia in schistosomiasis is briefly discussed, and it is thought that the symptoms are best explained on an allergic basis.

Medical Memoranda

Use of the Hodge Pessary in the Sling Operation

The use of a Hodge pessary in assisting diagnosis and as a test of the desirability, or otherwise, of carrying out a sling operation in cases of retroversion with symptoms is too well known to warrant further consideration here.

Its employment, however, as an instrument in the technique of the Baldy-Webster sling operation has never come to my notice, and I have not been able to find any such reference in the literature, nor have the many colleagues whom I have questioned. During the past 18 months I have used the pessary in 12 cases in which the Baldy-Webster sling operation has been carried out.

On the evening before operation the vagina is cleansed in the usual way and a Hodge pessary of suitable size inserted, or insertion may be left until the following day, when, with the patient anaesthetized and ready for operation, the pessary is introduced with adequate antiseptic precautions. At operation it is found that the uterus is maintained in good position, and the actual sling procedure is facilitated and simplified. In some of the cases the pessary has been removed 24 hours post-operatively, whilst in others it has been kept *in situ* for five days. In no instance has there been any indication of infection or other untoward effects, and the immediate results have been excellent. So far as can be judged at present by follow-up examination at the gynaecology post-operative clinic, the relatively long-term results leave nothing to be desired.

COMMENT

The use of a vulsellum forceps or a catgut traction suture in the fundus of the uterus to hold this organ forward in a reasonable position whilst operating is largely condemned, as damage may be done to the myometrium, and the punctures and knots may form points to which adhesions may attach, with possible unhappy results, especially for a woman of child-bearing age. An assistant's hand may support the uterus, but frequently this is found to be a doubtful

benefit, as it is often cumbersome, it obscures the field of operation, and it interferes with manipulation. With the use of a Hodge pessary to support the uterus in a normal position from below, through the vagina, damage is not done to the uterine fundus, the field of operation is left clear, and an assistant is hardly necessary.

Further, if a pessary of correct size has been used for diagnostic purposes and has relieved the symptoms, it is reasonable to assume that it has maintained the uterus in the optimum position, and that a similar pessary should be in position during the operation. Without its use the uterus may be supported too loosely, in which case the operation may fail in its purpose, or the uterus may be supported too tightly, with the possible substitution of symptoms such as dragging or pain in the iliac fossae and groins. Either of these contingencies is not unknown. Viewed in this light, the Hodge pessary should serve a useful purpose in other operations for correction of retroversion, such as the Gilliam procedure.

I thank Dr. Hugh Stirling, obstetrician and gynaecologist, Eastern District Hospital, Glasgow, for his interest and for permission to publish.

Assistant Obstetrician,
Eastern District Hospital, Glasgow.

Treatment of Actinomycosis with Aureomycin

Reported cases of actinomycosis treated with aureomycin are few. As clinical trial is the only effective guide to dosage with this therapy a case is reported and the literature is reviewed.

CASE REPORT

A farmer aged 31 was admitted to hospital complaining of a lump in the neck which had been present five weeks.

Cases of Actinomycosis treated with Aureomycin

Authority	Site	Length of History	Period of Treatment in Days	Total Dose in G. *
Glahn (1952)	Cervico-facial	(?) 6 months	21	42
Grant (1951)	"	3 months	26	52
			(21 days' interval)	
			40	Not stated
Kelly (1951)	Intestinal	14 "	107	116.5
	Cervico-facial	5 "	28	99 + local irrigation
	"	6 "	28	66 + local irrigation
	"	3 "	28	66
McVay <i>et al.</i> (1950, 1951)	"	2 years	58	21 intravenously; 158 by mouth; + local irrigation
	Hepatic	22 months	Not stated	Not stated
Ten Berg (1950)	Ileo-caecal	3 "	29	42
Thompson and Wax (1950)	Tibia	3 "	Not stated	Not stated
Wright and Lowen (1950)	Cervico-facial	22 years	Not stated	Not stated
Zoeckler (1951)	Chest wall	3 months	13	26

* Administered by mouth unless otherwise stated.

Examination disclosed a lump 2.5 cm. in diameter in the skin of the right side of the neck. It was spherical, smooth, ill-defined, firm, and fluctuant. The skin over it was indurated and reddened but not warm, and no sinuses were present. There were no other abnormal physical signs. Blood counts and x-ray films of the jaw, spine, and chest were all normal. The Wassermann reaction was negative. Aspiration of the lump produced pus which showed *Actinomyces israeli* on anaerobic culture.

Aureomycin was given: 3 g. daily for two days, 2 g. daily for eight days, and 1 g. daily for 23 days. It was administered six-hourly, to a total of 45 g., together with vitamin-B complex. The lump subsided rapidly and was no longer visible within one week of the beginning of treatment, although on palpation the skin was fibrosed, and this persisted.

Within a month of cessation of treatment, however, the lump had recurred and the presence of *A. israeli* was again confirmed bacteriologically. Aureomycin was recommenced, 3 g. daily being given for 28 days, in divided doses, together with vitamin-B complex. Once again there was the same rapid subsidence of signs, only a nodule of fibrous tissue

remaining. Four months later there had been no recurrence. The only toxic reaction noted throughout both courses was occasional vomiting.

DISCUSSION

In vitro tests of sensitivity of actinomycetes to aureomycin have been carried out by Hager *et al.* (1949), Strauss *et al.* (1951), and Garrod (1952), but conditions necessary for the growth of actinomycetes are highly unfavourable to the action of aureomycin.

Cases of actinomycosis treated with aureomycin are reviewed in the accompanying Table, but two need further comment. The case treated by Grant (1951) was associated with a fractured mandible. Treatment was interrupted by the patient taking his own discharge and the condition recurred, but was cured by a second course of aureomycin. A case of actinomycosis of the chest wall with clinical pericarditis was reported by Zoeckler (1951). Only 26 g. of aureomycin was given over the course of 13 days, but there was no recurrence three months later.

In all the cases reported *A. israeli* was isolated by culture. All were regarded as cured, and in most cases other methods of treatment had already been tried without notable success. Rapid improvement followed administration of aureomycin in all cases, and indurated tissues with draining sinuses healed, leaving only minimal scarring. Surgical drainage was thought to be unnecessary in all cases except one of a hepatic actinomycotic lesion. Comparable results have not been reported with any other form of therapy.

Although Zoeckler's case was cured with only 26 g. of aureomycin, the table shows that a course of aureomycin 3 g. daily for ten days, followed by 2 g. daily for a further 18 days in divided doses, as used by McVay *et al.* (1950,

1951), to be indicated for most cases, although some—for example, abdominal actinomycosis—will need a heavier dose.

Aureomycin must be regarded as the treatment of choice in actinomycosis, but adequate treatment is necessary if relapse is to be avoided.

I should like to thank Mr. C. J. Cellan Jones, under whose care this patient was admitted, for permission to publish this case.

Reviews

A COMPLETE GUIDE TO INFLUENZA

Influenza and Other Virus Infections of the Respiratory Tract. By C. H. Stuart-Harris, M.D., F.R.C.P. Foreword by C. H. Andrewes, M.D., F.R.C.P., F.R.S. (Pp. 235; 98 figures. 30s.) London: Edward Arnold, 1953.

Although the virus of influenza was discovered only 21 years ago, it has now been more extensively studied than any other. It has been adapted to ferrets, mice, and to growth in eggs, classified into several varieties, purified, analysed, "re-combined," and made into several kinds of vaccine; and the phenomenon of erythrocyte agglutination by it has been examined from every conceivable point of view. One practical result of this study has been to make it possible to diagnose an attack of influenza by any of several different laboratory methods: this in its turn has been the basis of a world-wide survey of epidemiology, the headquarters of which are in this country. Very little information about all this work has yet found its way into textbooks, but after the appearance of this monograph their authors will have no further excuse for dealing with the subject inadequately. The latter part includes chapters on psittacosis, primary atypical pneumonia, Q fever, the common cold, and "febrile catarrh" and pharyngitis of unknown aetiology; concluding chapters discuss prevention by hygienic measures and immunization, and treatment—whether by chemotherapy or mere rest in bed, a steam kettle, and some aspirin and codeine.

The author is that unusual combination in this country—though a more familiar figure in the U.S.A.—the clinician-cum-laboratory worker. He can describe not only the pathology of these diseases and the laboratory methods used in connexion with them but their clinical features, of which indeed he has made a special study throughout a career largely devoted to this subject. He therefore writes with unusual authority, and another book dealing in this way on the one hand with aetiology, laboratory diagnosis, and epidemiology, and on the other with symptomatology, clinical diagnosis, and treatment, would be hard to find. The analyses of symptoms and signs in different varieties of acute respiratory disease and the well-illustrated discussions of radiological diagnosis are a valuable feature. There are also many well-produced illustrations of the histology of influenza lesions in the ferret and man: the latter show the consequences of secondary staphylococcal infection, and the implication in the text that a pure influenza virus infection is non-destructive of the mucosa and indeed is not known to produce any characteristic lesion may occasion some surprise. The distinction drawn between terramycin and aureomycin as anti-staphylococcal drugs is contrary to the general experience that cross-resistance between them is almost invariable.

Different parts of this work will appeal to a variety of readers. To the investigator it performs a valuable service in throwing into relief two apparently distinct and fairly well characterized diseases of which the causes are still unknown. Of these the acute angina which is not streptococcal seems particularly to deserve rescue from its comparative neglect.

L. P. GARROD.

CLINICAL SURGERY

Progress in Clinical Surgery. By various authors. Edited by Rodney Smith, M.S., F.R.C.S. (Pp. 414; 112 illustrations. 36s.) London: J. and A. Churchill, 1954.

The science and art of surgery continue to advance, and no one nowadays will be rash enough to say that the end of achievement is in sight. It is impossible for textbooks to keep quite up to date, and there is need for such a book as this which is "intended to supplement, and not to re-

place, the standard surgical textbooks." The volume is designed to give help "particularly to the postgraduate student working for his final F.R.C.S. examination and the younger surgeon with a recent hospital appointment." We have no doubt that it will adequately fulfil those functions, though in some chapters the young surgeon might look for greater detail in technique. The various sections are written by experts of acknowledged authority, and throughout the book the editor has maintained unity and balance.

The volume opens with a startling sentence: "It is possible that nearly as many patients are killed by fluid replacement as are cured by it." Can it be so? As one looks back one remembers patients who did not improve as they should have done by fluid replacement, and it may have been due to the fact that the past generation did not know so much about electrolytes and the equivalents of sodium and potassium. Anyway, the young surgeon now has the opportunity to learn all about them.

Throughout the volume the recent advances in surgery are well set forth and a judicious clinical attitude maintained. During the past five years the most spectacular advances have been in the surgery of the heart and great blood vessels, and there are excellent chapters summarizing the new work. Yet even while this book must have been in preparation further remarkable advances took place, for it is within the past two years that large aneurysms involving the descending aorta or its main branches have been extirpated and the excised length of aorta replaced by a graft.

One of the most valuable chapters, and the best illustrated, is that dealing with the injured hand. Let the young surgeon learn and apply the principles laid down in this chapter and the earning capacity of thousands of injured workmen will in future be greatly increased. A useful book.

ZACHARY COPE.

NUTRITION IN INDIA

Nutrition in India. By Dr. V. N. Patwardhan. (Overseas Ed. Pp. vi and 345; 27 illustrations. Rupees 15.8.) Bombay: The Indian Journal of Medical Sciences, 1953.

Dr. Patwardhan, who is director of the well-known Nutrition Research Laboratories at Coonoor, appears to have had two reasons for writing this interesting book. Doubtless his first concern was to draw further attention to the defective diets on which many Indians have to subsist, and to describe the forms of ill-health caused by this malnutrition. His second desire has been to review the research on nutrition that has taken place in India during the last forty years, both on points of local interest and on more fundamental problems. He observes that research workers in other countries must often have difficulty in obtaining access to Indian publications on nutrition. The present volume will help to make good this deficiency.

The topics covered include Indian foodstuffs, rice, wheat, and other cereals, pulses and legumes, milk and milk products, proteins, fats, minerals, vitamins, basal metabolism, nutrition surveys, deficiency diseases, and nutrition in relation to public health. British readers will perhaps be most interested, however, by accounts of the widespread poisoning which can be caused by certain common Indian foods. Thus when poverty necessitates the consumption of certain easily grown pulses the condition known as lathyrism often develops and leaves the victim permanently crippled by paralysis of the legs. Another form of poisoning, epidemic dropsy, is caused by the contamination of mustard seeds by the weed *Argemone mexicana*. The author acknowledges the debt of India to McCarrison for the initiation of nutritional research early in the present century. For its literary clarity and for the excellent arrangement of its subject matter this book may be warmly recommended to all who are interested either in nutrition or in India.

T. MOORE.

MEDICAL ELECTRONICS

Medical Electronics. By G. E. Donovan, M.D., M.Sc., D.P.H. (Pp. 215; 36 figures. 30s.) London: Butterworth and Co., 1953.

In his preface the author says that the literature on the applications of electronics in medicine is no longer a stream but a river in full flood. It is a river in which one feels that most doctors would be likely to drown. The reviewer is a radiotherapist and therefore probably has a more ready acquaintance with the subject matter of the book than most doctors, and yet, after reading it, his first symptoms were those of mental congestion.

The technique of electronics and the technicalities are all so new that only a nodding acquaintance with the numerous applications of the subject resulted from reading about it in this book. The difficulty is in the vastness of the subject, and lack of insight of the reader into the procedures used, and the fact that the language is different from what one usually reads. For instance, few doctors, of whom the reviewer is not one, could understand the following: "The apparatus uses a scanning technique known as the intercept length method and consists essentially of a Muirhead facsimile transmitter and a pulse width analyser counter circuit incorporating dekatron scaling tubes." Such statements abound.

There is no doubt that the author is a master of his subject, and there is equally no doubt that the subject offers to the medical profession new methods of investigation and recording of the very existence of which most of us are ignorant. If he is writing for a medical public the author should leave out most of the technicalities, simple and essential as they might be to him, and concentrate on a few more examples showing the value of the methods in medicine. If the technicalities are to stay they should be explained and defined better—for instance, by an early simple chapter on the physics of the subject associated with a glossary of terms to be used. As an indication of the wonderful possibilities open to us in accurate quantitative work carried out with minimal trouble to the doctor the book should be read by all medical students and by all those working in hospitals. The obvious way to make use of the facilities offered seems to be to appoint each hospital someone like the author in a place easily accessible to all members of the staff so that each may ask the electronics expert to produce the particular apparatus he is interested in.

FRANK ELLIS.

ADMINISTRATIVE MEDICINE

Administrative Medicine: Transactions of the First Conference March 9, 10 and 11, 1953. New York. Edited by George S. Stevenson, M.D. Foreword by Willard C. Rappleye, President, Josiah Macy Jr. Foundation. (Pp. 176. 53s.) New York: Josiah Macy Jr. Foundation, 1953.

This is a verbatim report of an interesting discussion by some 20 experts representative of every aspect of medicine and sociology of how best to integrate all concerned in an ideal system of medical care. No resolutions were submitted, discussion was quite free, and many differences of opinion emerged; but team-work was declared to be essential in any system aiming to be complete. The team must include not only the obvious medical elements but representatives of every branch of social service, with those of labour. The question of a State medical service was carefully avoided, but strong support was given to the numerous voluntary medical aid schemes now in operation, though all were deemed incomplete. The medical curriculum came in for severe criticism as ignoring the social sciences and as a consequence turning out doctors ignorant of these vital elements in civilization, and, therefore, essential to any form of medical practice. Such emphasis was laid on this criticism that one participant in the conference asked if it was intended that the social as well as the natural sciences should be a prerequisite to the study of medicine. He was not alone in thinking that if this was the case the future doctor might be a more learned man but possibly a less useful one to the average patient.

The book left on me certain definite impressions. (1) Of the great difficulty of establishing a national medical service in a country constituted as is the U.S.A.; (2) of the obvious sincerity of the conference in advocating group practice; (3) of the risk, if the idealists had their way, of the medical profession being organized to death; and (4) that no conference of this kind is complete without the presence of some ordinary potential patients who might be able to keep the feet of the idealists on the ground.

ALFRED COX.

PHYSICAL MEDICINE AND REHABILITATION

Physical Medicine and Rehabilitation. Edited by Basil Kiernander, M.B., B.S., M.R.C.P., D.M.R.E., D.Phys.Med. Introduction by the Rt. Hon. Lord Horder, G.C.V.O., M.D., F.R.C.P. (Pp. 610+xiv; illustrated. 63s.) Oxford: Blackwell Scientific Publications, 1953.

There have been many developments both in physical medicine and in rehabilitation in the past decade. Good textbooks are badly needed, but few are available and none are entirely satisfactory. The main reason for the shortage is that both subjects, to a greater or less extent, find their application in all branches of clinical practice, and few authors are willing to tackle such a wide field. Dr. Kiernander has tried to produce a combined textbook with the help of 25 contributors on both sides of the Atlantic, and credit must go to him for attempting a difficult task which so many have shunned. As Lord Horder points out in the introduction, the justification for combining the two subjects in a single book is that so much of physical medicine deals with the restoration of function after illness, while rehabilitation, of concern to all branches of medicine and surgery, depends, perhaps above all else, upon efficient physical medicine.

There is much to commend in this book. Many excellent chapters are contributed by leading experts and should be studied by everyone interested in the theme. But some chapters are so indifferent that they spoil the rest of the volume and should be omitted from future editions or given to authors better fitted for these tasks. Some authors, who have previously written books on their subjects, have tried to compress so much into a single chapter that they have sacrificed important detail in an attempt to be comprehensive. Others have included, apparently as padding, unnecessary details of treatment programmes in use in their hospitals. There are too many spelling and printing errors in the text and the indexing is quite inadequate; but, in spite of the many criticisms that can be made, this book has achieved much of its objective. As it stands it can be recommended for the excellent material it contains, much of which is not readily available elsewhere; but substantial re-writing and a great deal of editing must be undertaken before a second edition appears.

F. S. COOKSEY.
D. A. BREWERTON.

STEREOSCOPIC RADIOSCOPY

Die Objektive Stereoskopie an Röntgenbildern: Eine Diagnostische Methode. By Professor Dr. A. Hasselwander. (Pp. 187; 125 illustrations. D.M.27.) Stuttgart: Georg Thieme (Verlag), 1954.

This is a monograph on stereoscopic radiology in which the advantages, uses, and difficulties of the method are very fully discussed. New apparatus invented by the author is described by means of which exact measurements may be taken in the third dimension, and even solid models produced from a study of stereoscopic radiographs. The author has devoted his life to the study of three-dimensional anatomy, especially from the point of view of the radiologist, who may find many ideas of use in this special field. Of great practical value to every anatomist is a series of drawings on a reduced scale of the famous coloured lithographs by Wilhelm Braune of frozen sections of the human body. The originals are not always accessible, and these perfect reproductions should be very welcome.

DRUG TREATMENT OF HYPERTENSION

The bewildering number of drugs which are said to lower blood pressure has not only made the selection of the best form of medical treatment for hypertension a matter of some difficulty but has underlined the necessity for a knowledge of the natural history of the disease and of its clinical types. Women appear to tolerate high levels of blood pressure better than men, except when hypertension is in the malignant phase¹; and in elderly persons surprisingly high pressures are often compatible with good health for many years.² This is specially noticeable when the blood pressure has risen slowly over many years. By contrast, a rapid increase in blood pressure in young persons is a grave sign and often associated with arteriolar necrosis, which ushers in malignant hypertension. The diastolic blood pressure is a far more important guide to severity than the systolic.

For purposes of treatment patients with essential hypertension—a term used to describe high blood pressure not attributable to any other disease—may be considered in three groups based on McMichael's³ classification of the condition: first, those with labile hypertension whose diastolic pressure is below 120 mm. Hg and who show no signs of complications; secondly, those with sustained hypertension, with a diastolic pressure around or over 120 mm. and with developing or established complications (encephalopathic attacks, cardiac enlargement, and retinitis) but normal renal function; and, thirdly, patients with hypertension in the pre-malignant or malignant phases, with diastolic pressure rising to 130 mm. Hg or even higher. In the first group the prognosis is good, and the only treatment needed is reassurance and mild sedation. These patients are often obese, and they should be encouraged to lose weight: they often complain of headaches, which are more likely to be due to anxiety—sometimes caused by an injudicious remark about high blood pressure in the consulting-room⁴—than to hypertension.⁴ The patient rather than his blood pressure should be treated, and there is no place for powerful hypotensive drugs, which themselves carry a risk.

Treatment of patients in the second group is a different matter, for they may suffer from vascular damage and other hypertensive complications, and effective reduction of blood pressure is obviously desirable; while in the third group control of hypertension is a matter of vital importance and great urgency.

For patients in the pre-malignant or malignant stages of the disease the methonium drugs offer the best prospect of relief: they cause vasodilatation and hypotension by blocking transmission of nerve impulses in autonomic ganglia, and several recent reports have shown that they are a useful addition to therapy.⁵⁻⁷ A single subcutaneous injection of an adequate dose will reduce the blood pressure towards normal for two to three hours—an effect which the upright position helps to increase. It is possible to obtain a longer action by using a similar compound (M & B 2050 A or "ansolysen") dissolved in 25% polyvinyl pyrrolidone to which 0.1% ephedrine has been added.⁸ In a recent issue of this *Journal* Professor F. H. Smirk⁹ has described his results in a series of 250 cases treated with methonium compounds for periods up to 3½ years. In his experience this form of treatment has improved the prognosis in severe hypertension, and this is borne out by the fact that, out of 28 of his patients with malignant hypertension, 21 are still living—an average survival time of 22.8 months. Professor Smirk has also noted that an attack of hypertensive left ventricular failure can be terminated by fractional intravenous injection of hexamethonium. Among the notable results of reduction in blood pressure are the disappearance of papilloedema—a finding also noted by Morrison⁷—a decrease in the size of the heart, improvement in the electrocardiogram, and an easing of headaches.

Treatment with the methonium compounds is far from easy: oral administration is unsatisfactory, and may be dangerous, since absorption is irregular and control difficult.¹⁻¹⁰ The drug has to be given by subcutaneous injection two or three times daily, and

careful observation is essential in the first weeks of treatment, since tolerance quickly develops.⁷⁻⁹ Side effects—such as giddiness and faintness on standing due to postural hypotension, dry mouth, difficulty of micturition, constipation, and visual disturbances caused by vagal inhibition—are unfortunately common, although they can be mitigated by careful control of the dosage and by lying down for half an hour after the injection. Patients should always be admitted to hospital for initial treatment with hexamethonium bromide, and they have to be watched carefully after discharge, although they can, like diabetics, be taught to give their own injections. When renal function is impaired the excretion of hexamethonium bromide is retarded, and therefore injections are required less often. McMichael¹ has noted no tendency for moderately increased blood urea to rise during therapy. Dyspnoea, associated with organized fibrinous pulmonary oedema, has been observed in three patients with severe hypertension who were having hexamethonium therapy.¹¹ This lung change was attributed to some modified sequel of left ventricular failure and to prolongation of survival by treatment: it is not a contraindication to continued therapy.

In spite of the encouraging results achieved with methonium compounds there is clearly a need for a safer hypotensive drug which is easier to use and can be given by mouth. Thiocyanates have largely been abandoned owing to their inefficient hypotensive action, the need for controlling the concentration of drug in the blood, and their unpleasant side effects. The alkaloids of *veratrum viride*, which cause a reflex vasodilatation, have been reported on recently by Kauntze and Trounce,¹² who obtained good results in only 20% of their cases. The frequent occurrence of vomiting, sweating, and other side effects greatly limits the usefulness of these drugs. The dihydrogenated alkaloids of ergot, which have a sympatholytic action, have a slight hypotensive effect, and a mixture of three such alkaloids ("hydergine") can be given by mouth, although the results are not striking.¹³ Hydralazine hydrochloride (1-hydrazino-phthalazine) lowers blood pressure by a central action and by inhibiting the action of histaminase, and is widely used in the U.S.A.¹⁴⁻¹⁶ According to Schroeder¹⁷ it has a synergistic action with methonium, and the use of the two drugs together has been advocated. Unfortunately, hydralazine causes severe headache, tachycardia, and an increase in cardiac output; moreover, a syndrome resembling disseminated lupus erythematosus has been observed in patients taking the drug.¹⁸ Many clinicians believe that these complications make hydralazine an undesirable drug for the purpose of reducing blood pressure.

Alkaloids extracted from *Rauwolfia serpentina* ("rauwiloid," "serpasil") have mild hypotensive and sedative properties and reduce the pulse rate.¹⁹⁻²⁰ They can be given by mouth for long periods and apparently have no serious toxic action. Their effectiveness still remains to be assessed, but they may prove useful in the treatment of anxious patients with tachycardia,²¹ or of patients with uncomplicated sustained hypertension whose diastolic blood pressure is below 120 mm. Hg. The practice of using two or even three different hypotensive agents together has some vogue, but is generally undesirable, since assessment of the hypotensive, or toxic, effects of one of the drugs becomes difficult, and the patient is likely to be bewildered by the variety of tablets he is receiving. Finally, the use of a low sodium diet, although not strictly a drug treatment, is worth considering in the treatment of hypertension.²² Restriction of sodium is the basis of the rice diet introduced by Kempner,²³ but to be effective the daily intake of sodium must not exceed 0.5 g. (or 1 g. NaCl). This makes food very unpalatable, and the diet can be strictly maintained only in hospital, although the use of ion exchange resins may permit the patient to take meals with a higher salt content. Too rigid salt restriction, however, may precipitate uraemia in patients with impaired renal function, so that a low salt diet, like most other forms of therapy for hypertension, also has its limitations.

THE AGED SICK AND INFIRM

The care of old people, and the problems which it raises, command an ever-increasing share of public attention. This is not entirely due to the fact that there are more old people in the community nowadays. It is partly the result of the altered social circumstances in which we live, with fewer children able and willing to look after their aged relatives; partly of medical advance, especially antibiotic therapy, which is reducing deaths among the elderly from pneumonia—in other days a quickly fatal disease (this has increased the number of potential victims to cardiovascular degenerations or malignancy, both of which are apt to cause prolonged illnesses necessitating nursing care); and partly of the difficulty of securing admission to hospital for those old men and women who require it, and particularly for those suffering from chronic disease. While it has become increasingly important to make hospital accommodation available for those old people for whom there is no alternative, at the same time it is essential to do everything possible to assist those who are able, with help, to continue to live in their own

homes. As things are, there are many old people, gravely ill, living at home under conditions almost unbelievably bad. Many of them have no hope of full restoration to health, for one of the important lessons emphasized again in a book by Professor T. Ferguson and Dr. A. N. MacPhail,¹ published last month, is that the patient's health may owe far more to his home conditions than to the disease he suffers from or the treatment he receives for it. The plight of these seriously disabled and elderly people, many of them lying in dreary squalor, is the most compelling of all the problems of old age. Recent articles in the lay press have drawn attention to the urgency of their need, a need painfully well known to medical men and often described in this *Journal*. Six years ago, just before the National Health Service came into operation, Ferguson² described the condition of 300 old persons, 62 men and 238 women, who were being treated in their own homes in Glasgow by district nurses, often under shockingly bad conditions. The large majority had been ill for more than six months. Of the 300 patients, 27 suffered from heart disease, 40 from cerebral haemorrhage and hemiplegia, 52 from diabetes, 21 from rheumatism, 17 from cancer; and 52 were described as cases of "senility." Fifty-two were incontinent, and 107 were wholly bed-ridden. Apart from the ministrations of the district nurse, 78 of the 300 old people looked after themselves without any other assistance, though by no means all of this group could care for themselves in any satisfactory way.

Many old people suffering from chronic sickness of this kind can be treated satisfactorily only in hospital, but there is often great difficulty and long delay in securing their admission to hospital, a difficulty which existed even before the new order of 1948 and not likely to be adequately met by the restoration of relieving-officer powers. The report³ of the British Medical Association's Committee on the Care and Treatment of the Elderly and Infirm directed particular attention to patients not able to fend for themselves. There is need not only for additional beds for these cases and for their sorting and energetic treatment, but for the development of accommodation of the "half-way" type, since lack of home care on discharge from hospital is a common cause of early breakdown, calling for readmission to hospital. The concept of the "day hospital" is being developed at Oxford,⁴ and the results of the experiment there will be watched with interest all over the

country. During the past five years the National Corporation for the Care of Old People has had encouraging results from a scheme which enables old people who have been patients in certain hospitals to go away to convalescent homes for periods up to eight weeks. Payment is made by the regional hospital boards.

In these days any kind of institutional care is relatively expensive; and sometimes old people are unwilling to go to hospital, however great their need, fearing that to do so will entail the irretrievable disruption of what home is left to them. Sheldon⁵ found that the great majority of the old people whom he studied in Wolverhampton were able to lead independent lives, though some of them required a measure of help which they could not always reasonably obtain from members of their own family. Many efforts have been directed to making life easier for old people, the provision of "meals on wheels," laundry services, and chiropody among them. But, apart from medical and nursing care, what most old people who live in their own homes want is help that will enable them to carry through the ordinary routine of independent living. Sometimes this help can be provided by members of the family circle; sometimes the elderly are dependent for it on the good offices of neighbours. For others a home-help service is essential; many aged invalids at present dependent on neighbourly help place on their neighbours a load which it is unreasonable to expect them to bear. That is not to say that there is not a great place for voluntary effort and voluntary service, but the care of an elderly patient should not be allowed to develop into an intolerable burden. The nursing of these old people by district nurses affords a notable example of what can be achieved under unpromising conditions, given an organization—such as the Queen's Institute—imbued with the spirit of service. The amount of call on home-help services will obviously depend on individual circumstances; for some patients help with the weekly washing may suffice, for others help on two or three days a week, or for an hour or two daily. Obviously no home-help scheme can provide a 24-hour service; but old people who require such a service should not be left in their own homes. The clubs for old people which are being so widely developed might be encouraged to function not merely as centres in which old people could gather for social intercourse and recreation, but as centres from which a voluntary service might radiate to the homes of those who are unable to visit the club premises.

As a long-term policy, the approach to the welfare of old people must be along much more positive lines,

directed to the promotion of healthy living, the conservation of active interest, and the prevention of invalidism. But in the meantime the wretchedness of many decrepit old men and women is unworthy of a civilized society. When the matter was raised in the House of Commons recently the Minister of Health⁶ referred to this as perhaps the most baffling problem in the whole of the National Health Service. He thought the solution lay rather in the home than in the hospital. "Let us by all means ask if the State has failed," he said, "but let us also ask if the family and the neighbours are doing all they can . . . the local authorities, the voluntary bodies, and the Church." Although it is certainly true that few facets of the social service offer greater scope for voluntary effort than the care of old people, it is equally true that there has not always been that clear lead from official sources so essential to overcoming a problem of such magnitude.

ANAESTHESIA FOR CHILDREN

Clinical medicine demands a clear memory, the ability to correlate disjointed stories, and sound judgment. Surgery demands, in addition, good eyesight and manual dexterity. Joining all these qualities should be one on which greater stress should be laid—namely, kindness. Lacking it, no boy or girl should start a medical career with any intention of practising clinical medicine. Without kindness and gentleness the exercise of the highest technical skill will bring little reward either to the doctor or to his patients. The need for these humane qualities is most clearly seen in the preparation of children for surgery and the management of their anaesthesia. Attention has been directed to these aspects of the surgery of childhood in recent years. Eckenhoff reports an investigation into the effect of premedication or its absence on the post-operative mental state of young patients.¹ Over a period of eighteen months questionnaires were sent to the parents of all children admitted to the Hospital of the University of Pennsylvania for an otolaryngological operation. Eckenhoff found that 17% of the replies indicated a personality alteration which might be traced to anaesthesia or to the hospital experience. The changes reported were night terrors, temper tantrums, fear phenomena, and bed-wetting. The incidence of personality change was highest in the youngest children—that is, aged 2 or 3 years—but study of children in all age groups showed that if there was crying and struggling during induction then one of these personality changes was more likely to occur. In this series premedication consisted of pentobarbitone and scopolamine and usually morphine in a dosage recommended

by Leigh and Belton.² Anaesthesia was administered by resident or staff anaesthetists, or medical students or interns under supervision. It should be noted here that the dosage of oral pentobarbitone recommended by Leigh and Belton and other American workers is far lighter than that normally used by British anaesthetists, who find that 0.6 gr. per stone (6 mg. per kg.) is satisfactory.

Commenting on his report Eckenhoff writes: "A previous report has demonstrated a clear-cut relationship between the type of pre-anaesthetic medication and the incidence of crying prior to induction of anaesthesia. It was shown that 35 to 40% of children 5 years of age or less who received only atropine or scopolamine cried. It was further shown that the use of a barbiturate with the belladonna drug, plus careful attention to the time of administration of the drugs, significantly reduced the incidence of crying. In this respect it was reasoned that the crying child might be the one in whom personality changes were most likely to develop. Obviously, skill of administration of anaesthetics remains of prime importance." In a survey of the subject of children in hospital Mac Keith³ does not describe any personal follow-up of surgical cases from his own department but states that a "considerable number, chiefly among those under 5, show changes in behaviour for a shorter or longer period after [hospital admission]." He believes that "the three main anxieties which centre round an admission to hospital are the separation from home, the anaesthesia, and the operation," and he gives the sound advice that, "when a child does not have a pre-operative sedative, he should be carried to the anaesthetic room by a familiar nurse, or accompanied by a nurse if a porter carries him, and that this nurse should stay with him until he is unconscious. Certainly being trundled in a trolley lying flat, so that one cannot see where one is going, is alarming."

Children are characteristically highly responsive to the power of suggestion, and by its kindly application anaesthetists are constantly rewarded with a peaceful phase of induction of anaesthesia. This approach to a child patient combined with a careful intravenous induction with thiopentone after adequate sedation with morphine and scopolamine must guard the child's mind from any harmful fears, either real or imaginary. Sheila Anderson⁴ has described the details of this method of premedication in detail. More recently H. E. Pooler, of Chesterfield Royal Hospital, has made a short colour film which beautifully shows the value of care and consideration by nurses, orderlies, and anaesthetists towards children undergoing tonsillectomy. There are others who consider their child patients are better protected by the use of narcotics given to the child in its own bed. These drugs usually consist of rectal thiopentone or of one of the oral barbiturates. All have their advocates, and it is impossible to dogmatize on the most successful procedure. The details of the actions of these and other powerful drugs are important to understand, but, having learnt them, let the anaesthetist mingle kindness with his pharmacology. Then no more may be heard of personality changes after operation.

FRACTURES COMPLICATING E.C.T.

Violent involuntary muscular contractions are apt to cause fractures and dislocations, and such injuries have been encountered in particular in cases of tetanus and idiopathic epilepsy. When convulsions are induced in psychiatric treatment the incidence of these complications is high. The most frequent of such injuries complicating convulsive therapy is compression fracture of one or more vertebrae, though humeral fracture and dislocation of the shoulder and temporomandibular joints have been reported also.

When convulsions are induced with metrazol the recorded incidence of vertebral fracture has varied from less than 1% to 47%. In a careful investigation of 800 patients in whom convulsions were thus induced, and in whom radiographs of the spine were taken before and after treatment, Easton and Sommers¹ record an incidence of fracture of 26.1%—the figure being 37.2% for men and 16.8% for women. In the presence of osteoporosis the incidence of fracture was doubled, and it was found that the 4th, 5th, and 6th thoracic vertebrae were those commonly injured. With electrically induced convulsions Lingley and Robbins² report a fracture incidence of 23% in 230 patients. In this series fractures occurred almost three times more frequently in men than in women, and the incidence was doubled in the group of patients showing osteoporosis. Meschan and others³ report on the incidence of fractures in a group of 212 male patients, in whom a careful radiological examination was made before and during the course of electroconvulsive therapy. The incidence was 35.4%—the 3rd, 4th, and 5th thoracic vertebrae being most commonly affected; 80% of these fractures occurred during the first five treatments. They state that the fracture is often symptomless and that when back pain does occur after therapy fracture is likely to be the cause. These authors also found that the incidence of vertebral fracture was reduced to 19.5% when curare was administered. Dewald and others⁴ investigated this complication in a group of 263 cases. When treatment was carried out with the muscle-relaxant drugs the incidence of fracture was 20.8%, 42% in the male and 14% in the female; when decamethonium bromide was used the fracture incidence fell to 1.9%. They find that the fracture incidence with the direct and Glissando techniques is the same and confirm the greatly increased risk of fracture in the presence of osteoporosis. Fracture usually occurred during the first three treatments, and the 4th, 5th, and 6th thoracic vertebrae were those commonly affected; all the fractures were in the dorsal region, their number in individual cases varying from 1 to 6, with an average of 2.2. Usually the fracture was a minimal compression, and in only two of 49 cases with fracture did the degree of compression exceed one-third of the original height of the vertebral body. Fracture caused no symptoms in 30.6% of the cases, and of the patients complaining of back pain after treatment 75.6% had fractures.

¹ *J. nerv. ment. Dis.*, 1944, 99, 256.

² *Radiology*, 1947, 48, 124.

³ *Ibid.*, 1950, 54, 180.

⁴ *J. Amer. med. Ass.*, 1954, 154, 981.

The high incidence of vertebral fracture as a complication of convulsive therapy is clear from these studies. While the skeletal injury is usually slight and frequently not productive of symptoms, its prevention is desirable, and the use of muscle relaxants is of proved value here. Since fracture usually occurs early in treatment and the injury may become more severe with subsequent treatment, the value of prophylaxis by means of relaxants from the beginning of therapy is obvious. The greater incidence of fractures in the male would appear to be due to his more powerful muscles. It is also of interest that the vertebrae commonly injured are the 4th, 5th, and 6th dorsal. The position of these vertebrae at the height of the dorsal kyphosis, the normal slight anterior wedging of thoracic vertebral bodies, and the relatively small degree of movement normally occurring here perhaps account for the site of these fractures.

NEUROLOGICAL COMPLICATIONS OF INOCULATION

That neurological complications occasionally follow a prophylactic inoculation has been recognized for many years, and some of the more dramatic, such as post-vaccinal encephalitis, are well known. Miller and Stanton¹ have recently provided an excellent review of this subject and contribute some further detailed examples of their own. As they point out, these cases "lie in a neglected borderland between the fields of neurology, preventive medicine and paediatrics and have been the subject of many isolated case reports but of little systematic study." Their paper confirms the impression that, although uncommon, such cases are not very rare. When neurological complications do ensue, a variety of reactions can occur to any one type of inoculation, although there is a tendency for one clinical picture to be commoner than others. Thus, after serum injections such as A.T.S. a brachial radiculitis is the common pattern, while after T.A.B. it is cerebral involvement, and with pertussis inoculation convulsions are the usual type of neurological complication.

Interest in this subject has been more widespread of late because of the observation that poliomyelitis may apparently be evoked by pertussis and diphtheria inoculations. This association is specifically excluded from Miller and Stanton's review. However, the possibility that an allergic reaction may upset a symptomless symbiosis between a host-cell and an already indwelling virus will occur to many. The authors dismiss this as highly improbable, though the occurrence of differences in the clinical picture between one type of inoculation and another could as well argue for as against such a view. In deciding the point it would be helpful to know more than we do at present of the intracellular changes associated with "immunity." In general, the authors incline to the opinion that all the manifestations discussed are examples of hypersensitivity, and they marshal the evidence for this well. It may be, however, that the various neurological syndromes which occur

¹ *Quart. J. Med.*, 1954, 23, 1.

are produced in different ways, even though allergy in the broadest sense is a common link. The wider suggestion that certain "spontaneous" neurological diseases may be similarly conditioned is certainly an interesting speculation. From the practical point of view the implications of these views for treatment are clear. The antihistamines and cortisone and A.C.T.H. should evidently be given a trial. They may serve both as treatment and as a test of the hypothesis. Here the beneficial results of cortisone in post-exanthematous encephalitis are relevant and encouraging.

This review of a somewhat neglected subject has a twofold merit. The authors bring together compendiously much scattered clinical observation, and, in interpreting it, put forward a hypothesis in a form which already suggests ways of clinical and even experimental confirmation. This is a methodological advantage often overlooked in reporting clinical observations.

FAT EMBOLISM

Fat embolism is one of the most serious complications of fractures, and also, occasionally, of operative procedures on bones. It is probably more common than is generally realized, and the less severe cases must often escape recognition. It occurs most commonly in young adults after fractures of the tibia and femur. The first symptoms, which usually present 36–48 hours after the fracture, are heralded by a sudden change in the patient's general condition. Cyanosis, dyspnoea, and pain in the chest are common, and the patient rapidly becomes restless, drowsy, or irrational, or he may pass into a deep coma. This last symptom indicates massive involvement of the cerebrum, and implies a bad prognosis. These early symptoms are usually accompanied by an equally rapid rise in temperature, pulse rate, and respiration. The sudden development of incontinence of urine was reported by Alldred¹ in six patients of a series of nine studied by him. Of the physical signs the most striking is the petechial rash which may develop over the upper chest, neck, and shoulders, sometimes spreading to the arms and lower part of the trunk. It fades quickly, but is usually present for several days. In the chest the signs are those of acute pulmonary oedema: there will be moist sounds and scattered areas of consolidation. In some cases the symptoms and physical signs are confined to the chest, and the correct diagnosis may be overlooked. Alldred reported spasticity of the limbs in one patient and hemiplegia in another, evidence that the central nervous system was affected. The diagnosis may be confirmed by the presence of fat in the sputum and urine and by radiological examination of the chest.

The treatment of fat embolism is entirely symptomatic, there being no specific measures available. Cyanosed patients should be given oxygen, which may be life-saving. It can be administered by nasal catheter, B.L.B. mask, or by placing the patient in an oxygen tent. Pulmonary infection should be controlled by antibiotics. Fluids should be administered, either by mouth or intra-

¹ *Brit. J. Surg.*, 1953, 41, 82.

venously, and the restless patient will require sedation. Newman has suggested tying the profunda femoris vein, but it is doubtful if this procedure is of any value once embolism has occurred.

BIRTHDAY HONOURS

The conferment of a baronetcy on Sir Russell Brain, who was knighted in 1952, is a further recognition of his great services to medicine and of the importance of his high office as President of the Royal College of Physicians of London. It is an honour which will be warmly welcomed by his friends and colleagues as a tribute to a man of many gifts and attainments who in achievement and personality upholds the traditions of the great profession he serves so unstintingly in so many ways. Mr. R. C. Brock, who is made Knight Bachelor, is known throughout the world for his remarkable contributions to the surgery of the heart and so to the relief of cardiac cripples. The report on his first six successful cases of valvulotomy, for mitral stenosis was published in the *British Medical Journal* four years ago, written in a style that was a delight to read. Mr. Brock has brought renown to British surgery. As editor of the *Guy's Hospital Reports* and author of *The Life and Work of Astley Cooper*, he has taken his place in a distinguished line of scholar-surgeons. The profession in this country will acclaim the honour done to their Australian colleagues by the conferment of a knighthood on Dr. A. P. Murphy, President of the Royal Australasian College of Physicians, and on Mr. H. H. Schlink, who is consulting gynaecological surgeon to the Royal Prince Alfred Hospital, Sydney. Australia has also been honoured in the awards of C.B.E. to Dr. A. J. Metcalfe, director-general of health and director of quarantine, Canberra, and to Dr. C. J. M. Walker, member of the Medical Board and of the Board of Health, New South Wales. Dr. P. P. Lynch, a member of the Dental Council and of the Medical Research Council of New Zealand, has been appointed C.B.E. Dr. R. S. F. Hennessey, Director of Medical Services in Uganda, and Dr. Andrew Topping, Dean of the London School of Hygiene and Tropical Medicine, both receive the C.M.G. Among other medical men honoured his old colleagues will note with interest the award of the O.B.E. to Dr. E. A. Cockayne "for services to entomology," and recall his classical contribution to medical genetics: *Inherited Abnormalities of the Skin and Its Appendages*, published in 1933.

Medicine has a special affection for her "stickit" doctors, among whom Mr. Somerset Maugham, now admitted as a Companion of Honour, is *facile princeps*. Mr. Maugham entered St. Thomas's in 1892 and qualified M.R.C.S., L.R.C.P. The medical profession will wish, too, to congratulate Mr. Alfred Chester Beatty upon his knighthood. An American who became a naturalized Briton, Mr. Beatty has been a great benefactor to medicine. In 1937 he bought the old Freemasons' Hospital in Fulham and presented it to the Royal Cancer Hospital to house the well-known Chester Beatty Research Institute.

CLINICAL PATHOLOGY IN GENERAL PRACTICE

INVESTIGATION OF HAEMOLYTIC ANAEMIA

BY

JOHN F. WILKINSON, M.D., M.Sc., Ph.D., F.R.C.P., F.R.I.C.

Physician and Director, Department of Haematology, Manchester Royal Infirmary; Reader in Haematology and Lecturer in Medicine, University of Manchester

Red cells are normally removed from the circulation within 120 days, a process which involves the daily destruction of some 2.7×10^{11} erythrocytes in a man with a blood volume of 5 litres. An equivalent number of newly formed cells are provided by the bone marrow, which is able within certain limits to increase its rate of red-cell production as required. Thus, the marrow can cope with sudden extra demands caused by abnormal red-cell destruction or loss, and the presence of a mild haemolysis may be obscured; when red-cell destruction becomes too great for full replacement to be achieved by marrow hyperplasia, then a haemolytic anaemia becomes manifest.

Clinical Types

Haemolytic anaemias form a group of blood diseases, not easy to classify, caused by a variety of intrinsic and extrinsic factors producing excessive red-cell destruction. In general, the acute or subacute haemolytic anaemias are due primarily to extrinsic factors, while most of the chronic types have familial or hereditary features and the red cells themselves may be abnormal; in the latter group we find, among others, acholuric jaundice and familial haemolytic spherocytic anaemia (with spherocytes), sickle-cell anaemia (with sickle cells), thalassaemia or Cooley's anaemia (with leptocytes or target cells).

The acute haemolytic anaemias may be caused by the toxic or haemolytic effects on the normal red cells of severe bacterial or protozoal infections—for example, septicaemia, malaria—many chemical poisons such as compounds of arsenic, lead, bismuth, silver, and phosphorus; chlorates and methyl chloride; derivatives of benzene and toluene (aniline, phenylhydrazine, acetanilide, sulphonamides); haemolytic agents such as saponin, lysolecithin, snake venom, and *Vicia fava*, the broad bean. Severe acute haemolytic anaemias also arise following incompatible blood transfusions (α and β agglutinins), the production of anti-Rh agglutinins causing, for example, erythroblastosis foetalis, and in the presence of cold iso-haemolysins. Acute or subacute haemolytic anaemia may also be a secondary feature to other conditions such as Hodgkin's disease, carcinomatosis, hypersplenism, and leukaemias among others.

While the severity of the haemolytic process may modify the symptoms, in general all these haemolytic anaemias clinically show a varying degree of jaundice and evidence of excessive red-cell destruction; there will be the usual general symptoms associated with, and proportionate to the degree of, anaemia; haemorrhagic or haemolytic manifestations may occur, and pigment gall-stones are common. Pyrexia, malaise, headaches, and haemoglobinuria may be noted; the spleen is often enlarged, the liver less often, and occasionally also the lymph nodes. Glossitis, neurological symptoms and signs, and flatulent dyspepsia are not seen, in contrast to their occurrence in pernicious anaemia, although sometimes there are other gastro-intestinal disturbances. In mild cases, on superficial clinical examination, the patient may appear to be suffering from pernicious anaemia or cholecystitis until blood and other examinations have disclosed the true condition.

The essential laboratory investigations in a case of haemolytic anaemia include a full blood count with estimation of daily reticulocytes, estimation of the osmotic fragility of the red cells, bone-marrow biopsy, examination of the gastric juice, and a search for abnormal agglutinins in the blood. Subsidiary tests may include estimations of faecal and urinary urobilinogen, and special tests for specific agglutinins or other haemolytic factors.

Blood Count and Osmotic Fragility

It is important to make a full blood examination, including reticulocyte and differential white-cell counts and an estimation of the osmotic fragility of the red cells. The anaemia, which is usually macrocytic but may be normocytic or less commonly microcytic, may be severe (R.B.C. 1,000,000 to 2,000,000, and Hb 2.3 to 5.9 g. per 100 ml.). The severity varies with intermittent remissions and frequent crises. One of the most striking and diagnostic features is the notable reticulocytosis (10 to 80%) that may persist with varying severity for many months or years. Reticulocytosis with anaemia, in the absence of haemorrhage or treatment with liver, iron, etc., and persisting for weeks or months despite treatment, is almost pathognomonic of a haemolytic anaemia. It is common to find normoblasts, but rarely megaloblasts, in the peripheral blood. Many of the red cells have a bluish tinge (polychromasia) reflecting their immaturity. Small darkly staining red cells (microspherocytes) are often seen in acholuric jaundice.

The osmotic fragility of the red cells varies in different patients, and the sizes and shapes of the cells depend on the particular type of anaemia. An accurate quantitative fragility test is necessary to detect the mild forms of chronic haemolytic anaemia (acholuric jaundice). The old method of reading the haemolysis visually is inaccurate and has been replaced by the quantitative method of estimating the liberated haemoglobin in the various hypotonic solutions by means of a photoelectric colorimeter. While a significant increase in the red-cell osmotic fragility is pathognomonic of a haemolytic anaemia it does not indicate the particular type other than a spherocytic haemolytic anaemia; a variable increase is found in many but not in all haemolytic anaemias of acquired type, as well as in the classical familial chronic type.

A slight leucocytosis or occasionally a leucopenia with a few immature white cells (myelocytes and myeloblasts) may be seen, perhaps occasioning some difficulty in differentiating the condition from acute leukaemia. The marrow picture in these cases is of great value, for the absence of a significant number of "blast" or "stem" cells excludes an acute leukaemia. The platelets are usually normal in number but may be decreased in patients in whom haemorrhages are occurring.

To demonstrate sickle cells it is necessary to reduce the oxygen tension of the blood by sealing a drop under a cover-slip; sickle-cell haemoglobin becomes crystalline with deoxygenation, loses water during the process of crystallization, and so changes its shape and becomes sickle-shaped. A person in whose blood sickle cells can be demonstrated, but who shows no obvious signs of haemolysis, is said to have the sickle-cell trait. In thalassaemia (Cooley's anaemia) many of the red cells have a "target appearance" (target

cells); adults usually exhibit mild or symptomless forms known as thalassaemia minor; the complete major disease is usually fatal in childhood.

Bone-marrow Biopsy

Examination of the marrow is a necessary step in the diagnosis of many of the haemolytic anaemias, for it helps to exclude leukaemia, pernicious anaemia, and other conditions having similar clinical and blood findings. In haemolytic anaemia there is a marked hyperplastic marrow reaction with large numbers of early basophilic, intermediate, and late normoblasts. Proerythroblasts may also be increased in number. In the long-standing haemolytic anaemias the normoblasts may show changes in nucleus and cytoplasmic details that differ somewhat from those seen in other macrocytic anaemias, for there may be many mitoses present in the prematurely haemoglobinized cells. The myeloid-erythroid ratio is often less than unity, the total nucleated red cells constituting 60 to 80% of the total nucleated count. Megaloblasts are rarely found. Activity in the ated count. Granulocytic and megakaryocytic series may be observed, although there may be a total reduction in their number.

Blood Pigments

A normal serum does not give a direct van den Bergh reaction and contains not more than 1 mg. of bilirubin per 100 ml. In haemolytic diseases, jaundice is due to the liver cells being unable to excrete fast enough the increased bilirubin formed from the excessive breakdown of haemoglobin. The van den Bergh reaction is based on the hypothesis that bilirubin reacts differently with the diazo-reagent according to whether or not it has been excreted by the liver cells. Bilirubin formed from haemoglobin has been termed *indirect* bilirubin, since it does not give an immediate direct reaction. Bilirubin which has been excreted by the liver cells (as is found in the blood in obstructive jaundice) gives an immediate direct reaction and has been termed *direct* bilirubin. In haemolytic jaundice there is an increase in *indirect* bilirubin so that indirect reactions or direct delayed reactions are obtained. In some forms of haemolytic disease the agent acting on the red cells may also have a toxic action on the liver cells, in which case a biphasic reaction may be reported.

In acholuric jaundice the serum bilirubin may rise as high as 16 mg. per 100 ml., and in some forms of acute haemolytic anaemia similar or higher values may be obtained. The quantitative estimation of serum bilirubin is useful in subclinical jaundice, the demonstration of small increases in serum bilirubin to between 1 and 2 mg. per 100 ml. is usually of diagnostic value. When intravascular haemolysis is rapid, haemoglobin and methaemalbumin are found in the peripheral blood. This occurs in some severe haemolytic anaemias (blackwater fever, septicaemia, incompatible transfusion) and in the paroxysmal haemoglobinurias.

Haemoglobin appears in the urine when the plasma level is over about 130 mg. per 100 ml. Haemoglobin liberated in the plasma is partly excreted as haemoglobin in the urine, and some is converted into methaemalbumin. The presence of methaemalbumin in the serum shows that intravascular haemolysis has occurred. Methaemalbumin does not appear to be formed when there is increased breakdown of haemoglobin in the reticulo-endothelial system. It is found in the plasma in malaria, and in many of the acute haemolytic anaemias in which the haemolysis is intravascular, but not in acholuric jaundice and such conditions in which the haemolysis is non-vascular. Methaemalbumin has a large molecule and is excreted by the liver as coproporphyrin III.

Urinary and Faecal Urobilinogen

Urobilinogen is formed in the intestines by the reduction of bilirubin, and thus the amount of faecal urobilinogen depends on the amount of bilirubin entering the intestines.

Faecal urobilinogen (normal 40–280 mg. a day) is increased in haemolytic anaemias in which there is

increased breakdown of haemoglobin to bilirubin. In acholuric jaundice and chronic haemolytic anaemias values of 500 to 1,500 mg. may be obtained. The dark colour of the faeces in these conditions is due to the large amount of pigment present.

Urinary urobilinogen (normal 0.5–2 mg. a day) is derived from the urobilinogen absorbed from the intestines and not excreted by the liver. The amount depends both on the quantity of bilirubin entering the intestines and on the capacity of the liver to excrete the urobilinogen coming to it from the intestines. In haemolytic diseases the urinary urobilinogen tends to be a little raised, since the liver is unable completely to excrete the increased amounts of urobilinogen absorbed from the intestines. Values up to 10 mg. a day are usually found.

Whenever there is active blood regeneration in the haemolytic anaemias coproporphyrin I appears in the faeces. In compensated haemolytic disease in which there is no appreciable anaemia an increased excretion of faecal urobilinogen may be the only confirmatory evidence of a haemolytic process.

The *haemolytic index* (normal 11–20) is sometimes determined in children, in whom the total circulating haemoglobin is less than in adults. The index is found from the following equation:

$$\frac{\text{Average daily output of faecal urobilinogen} \times 100}{\text{Total Hb (g. per 100 ml.)} \times \frac{\text{Total blood volume}}{100}}$$

It is a time-consuming investigation and is seldom used for routine clinical work.

Auto-immunization

The cause of the haemolytic state in a variety of diseases is the production of antibodies against the patient's own red cells (auto-antibodies). In many of these cases no reason for this can be demonstrated, but in others an associated disease is found and in these the condition is symptomatic. Many of the reticuloses, chronic lymphatic leukaemia, Hodgkin's disease, periarteritis nodosa, and disseminated lupus erythematosus are primary causes of auto-immune haemolytic disease.

The way in which antibodies bring about haemolysis is not certain. In some cases haemolysins appear which produce haemolysis in the presence of complement. In others, with a high concentration of cold haemagglutinins, haemolysis occurs after cooling. The abnormal antibody in most cases of acquired haemolytic disease is a haemagglutinin which can be demonstrated by the Coombs test or by suspending the sensitized cells in a protein medium (bovine albumin). The nature of these antibodies is such that agglutination will not take place if saline is used as the medium for suspending the red cells.

The Coombs test is used to detect the presence of incomplete antibodies* in the serum and to help in the diagnosis of haemolytic disease of the newborn by demonstrating that the infant's corpuscles have absorbed the antibody. To identify such antibodies Coombs prepared an anti-human globulin serum by injecting human globulin into rabbits. When red cells sensitized by a non-agglutinating antibody are washed in saline and then suspended in the antiglobulin serum they become agglutinated.

In most cases of idiopathic acquired haemolytic anaemia the Coombs test is positive, indicating the presence of globulin antibodies adsorbed to the surface of the red cells, and in these cases no agglutination occurs in saline-serum suspensions. Agglutination may also be demonstrated by suspending the cells in a colloid such as bovine albumin, but the Coombs test is thought to be more sensitive and is more commonly employed.

Trypsinized red cells were found to be good indicators of incomplete antibodies, and do not require a protein medium

*An antibody that agglutinates red cells only in the presence of albumin or plasma and in the absence of sodium chloride.

for suspending the cells. Many of the abnormal incomplete agglutinins are haemolytic when incubated with complement against trypanized red cells.

Haemoglobinuria

Patients with haemoglobinuria have a haemolytic disease and present many of the features associated with the haemolytic syndrome. Several varieties of paroxysmal cold haemoglobinuria are recognized.

With a Cold Auto-haemolysis.—This type occurs most frequently as a complication of syphilis, either congenital or acquired. It is characterized by haemoglobinuria following exposure to cold. The Donath-Landsteiner test is diagnostic of cold haemoglobinuria. In this test, red cells suspended in the patient's serum are exposed to a low temperature so that the cold haemolysin may be absorbed, and then to a higher temperature so that haemolysis may be completed by the action of the serum complement. Normal red cells can be used in this test. In life the haemolysin becomes fixed to the red-cell surface during exposure to low temperatures, and when the blood circulates and becomes warmer haemolysis occurs.

With Cold Agglutinins.—Raynaud's syndrome, with acrocyanosis and pain in the extremities, may occur in paroxysmal cold haemoglobinuria associated with cold agglutinins. When titrated, the cold haemagglutinin may exceed 1/1,000 and rarely be demonstrated at up to 1/100,000. Cold haemagglutinins have been found in a number of conditions not necessarily associated with demonstrable haemolytic disease. In atypical pneumonia, for instance, they are often reported to be present.

Paroxysmal Nocturnal Haemoglobinuria

In this chronic haemolytic disease, haemolysis becomes intensified during sleep and nocturnal haemoglobinuria occurs. The patient's corpuscles are sensitive to thermolabile components of normal serum, but acidification is necessary to bring the pH of the cell-serum suspension to about pH 6.8 before the serum factors will act. This is the principle of the Ham test which is employed to diagnose this condition. Acidification is necessary because defibrinated blood becomes slightly alkaline owing to loss of carbon dioxide. Clinically, patients with nocturnal haemoglobinuria show an abnormal sensitivity to minor changes in blood pH. This may also be a factor in other haemolytic mechanisms.

Next Article on Clinical Pathology.—"Polycythaemia, Leukaemia, and Cytopenia," by Dr. Ronald Bodley Scott.

Refresher Course Book.—The first collection of articles in the Refresher Course for General Practitioners (fully revised) are available as a book containing 55 chapters, price 25s. Copies can be obtained either direct from the Publishing Manager, B.M.A. House, Tavistock Square, London, W.C.1, or from booksellers.

According to the Eighth Annual Report of the Institute of Child Health, the number of full-time students in 1953 was just under one hundred and there were also 40 part-time students. While most of the students attending were from the Commonwealth, it is interesting to note that 14 full-time students were from countries outside the British Empire. This perhaps signifies the growing importance of London as a postgraduate centre. More emphasis was laid in 1953 on clinical instruction. The number of lectures was reduced and opportunities were provided for increased ward teaching. Arrangements were made for small groups of two or three students to "sit in" with registrars during the out-patient sessions.

BEDSIDE MANNERS

BY

ERIC D. WITTKOWER, M.D.

Associate Professor of Psychiatry, Allan Memorial Institute of Psychiatry, McGill University, Montreal, Canada

AND

KERR L. WHITE, M.D.

Assistant Professor of Medicine and Psychiatry, University of North Carolina School of Medicine, Chapel Hill, N.C.

A dermatologist told the following story. A patient came to him with eczema in one axilla. A previous doctor had told the patient that the eczema was due to sweating. "I sweat here and I sweat there," the patient argued, pointing to his two axillae; "how can the eczema be due to sweating?" "What do you think it is due to?" the dermatologist asked. "I believe," the patient said, "that it is due to sugar diabetes." "You would have sugar diabetes here and there," the doctor said, pointing to the patient's two axillae, hence you can't have sugar diabetes." Subsequently the patient felt greatly relieved, and incidentally the eczema disappeared. The patient was extremely grateful.

This story serves to introduce the subject of this paper—"bedside manners" and psychotherapy. Bedside manners may be defined as an unsystematized understanding of a patient's emotional needs, whereas psychotherapy is their conscious systematized counterpart.

Systematic psychotherapy is predominantly the domain of the psychiatrist; bedside manners is a term applied to the intuitive approach used by general practitioners and specialists not specifically trained in psychiatry. Both bedside manners and psychotherapy are based on interaction between patient and doctor. It is proposed to discuss some of the more common psychological problems of patients and doctors, and some principles governing reciprocal physician-patient relationships.

The Patient

A patient is a person who seeks the help of a physician because he deviates in mental or physical health from the norm. He is not necessarily a sufferer as the word patient connotes. In view of his sickness a patient has to assume a role which imposes on him in many cases the necessity of forgoing his usual activities, of retiring to bed, and of accepting another person's help to restore him to his previous state of health. If he is very sick he may have to abandon his functional status of an adult and perhaps be attended to in a baby-like fashion.

Research in psychosomatic medicine has shown that emotional factors often play an important part in the aetiology of so-called "organic" diseases. Be this as it may, in any given patient illness as such, and the change in mode of living which it comprises, leads to a backward movement towards earlier stages of emotional development and behaviour. This state of regression, as it is called, manifested by changed attitude and feelings, is particularly significant in chronic illness. It may have the following interrelated effects: (1) patients may become childish in their behaviour; (2) they may, and usually do, become selfish; (3) they may invest the interest which they withdraw from the external world on the affected part of the body and consequently develop superadded hysterical or hypochondriacal formations; (4) they may distort reality

in other ways—for example, by wishful self-deception about their own unmistakable condition; and (5) they may manifest towards the physician positive or negative feelings of great intensity patterned after those experienced towards their parents, particularly their fathers. This mechanism is often operative in patients who show apparently irrational awe, subservience, hostility, panic, anxiety, dependence, or affection towards their physicians. If the unconscious sources of these reactions are not recognized the physician may respond inappropriately and trammel up rather than facilitate the physician-patient relationship.

Illness of necessity affects a person's mood. Dependent on the nature, site, and severity of the illness, on his previous personality and past experience, feelings of depression and of anxiety are commonly experienced. These emotions may be appropriate responses; or they may be inappropriate or at least disproportionate to the actual condition. In the latter case, feelings of badness and of unworthiness which previously existed may be subjectively experienced by the presence and "badness" of the illness; or fear of punishment for previous misdemeanour may disproportionately intensify justifiable fear regarding the outcome of the illness. Psychological defences against feelings of depression and of anxiety are denial and projection. Denial may take the form of unreasonable—and often foolhardy—denial of obvious handicaps, or it may find expression in false optimism or jocularly, so commonly encountered in incurable illness or in the terminal stages of illness. Patients may project resentment at their own condition or their environment, or they may fasten their internal anxieties on some external event such as an impending operation. The word "complaint," not only in its colloquial but also in its medical usage, signifies dissatisfaction. Consciously or unconsciously, patients may complain about their suffering, their pain, their fate, or about the lack of attention or affection which they sorely need.

Illness mobilizes aggressiveness, which may be due to inability to accept dependency or any imposed restrictions or frustrations. No longer is the patient able to discharge his duties, to earn his wages, or to enjoy sports and other pleasures. He may be restricted in body movement or debarred from items of food which he previously relished. No wonder that many a patient becomes irritable and irritable. Whether or not he freely expresses or checks aggressiveness engendered in this way depends on patterns of behaviour established in the past and proved to be useful. The patient who pathetically appeals to us for sympathy may achieve his ends just as successfully as the old arthritic lady who angrily thumps a stick on the floor if her wishes are not immediately fulfilled.

The patient's environment responds to his moods, anxieties, needs, demands, and reactive aggressiveness, and as these responses are fed back to the patient a vicious circle may well be established. Usually people feel sorry for a person afflicted by illness; after all, it could happen to them, and should it happen to them they would like to be cared for tenderly. But as the illness drags on, and the demands of the patient continue, and the economic strain makes itself felt, the patient feels a burden and is felt as such by others. Members of his family and good friends may still cover up their resentment and hostility by lavish gifts and apparent over-kindness, but, especially if previous bonds had not been close, the veneer may wear thin and crack. Unfortunate are the marriages which have been broken up by the serious prolonged illness of husband or wife.

The Physician

Are doctors always fully aware of their patients' needs and anxieties and of the many problems and conflictual situations which exist in their patients' families and may be produced or developed by their illness?

Let us look for a moment at the doctor's problems and "dilemma." There are many reasons why a person becomes a doctor—for example, a doctor is highly respected in the community, and, provided that he is competent, he earns a

reasonable income. Hidden behind conscious altruistic wishes to serve his fellow men, four psychological factors seem to play a part in the choice of the medical profession: (1) identification, (2) sublimated infantile curiosity, (3) sublimated and/or overcompensated aggression, and (4) persistence of infantile omnipotence fantasies.

Identification may be positive or negative. A person may become a doctor because he wants to emulate his father, who is a doctor, or because he wants to rise in the social scale above his father, who is a tradesman or owns a small business. We all played the doctor's game as children. Instinctual trends operative then may have been carried over into adult life and canalized into professional interests. Sadistic trends dating back to childhood may find sublimated expression in surgical skill or may be warded off and overcompensated by concentration and devotion to healing.

Most doctors derive much satisfaction from helping suffering humanity, but little do many doctors realize that beyond reasonable ambitiousness their wish to score success, especially where others have failed, is based on a perpetuation of infantile omnipotence fantasies.

Each of the factors mentioned may give rise to difficulties. For instance, we all know doctors whose attempts to identify with a successful father or older brother have miscarried or who could not allow themselves to outstrip their father's modest achievements or live up to their mother's over-ambitious expectations. There are doctors who had to give up surgical interests or even a promising career as a surgeon because of their inability to inflict pain or to be held responsible for the death of some of their patients. How commonly are doctors afraid of giving bad news to their patients when telling the truth and nothing but the truth would obviously be right? Why do we sometimes act in this manner? We act in this manner because cultural pressures do not allow us to tolerate free display of emotion in ourselves and in others, because we tend to identify ourselves with our incurable patients, because we are averse to inflicting pain, and because our vanity makes it difficult to admit failure. Let us admit—at least to ourselves—our limitations instead of reaching out for and taking on tasks beyond our capacities, and instead of basking in the glory of our therapeutic successes.

Some Problems

There are other problems which beset the medical practitioner.

(1) The doctor, analogous to the patient's closest kin and friends, is a person who can be trusted with the most private and intimate affairs and feelings of the patient. But at the same time the doctor does not admit his patients to intimacies with himself, does not "reveal" himself to the patient, physically or mentally. If he happens to be a personal friend of the patient he will be well advised to segregate the two roles.

(2) The doctor's "trustworthiness" and authority are based on his assumed technical competence. This technical competence, in accordance with the patient's wish to be cured and in keeping with his regressive state, is exaggerated out of proportion. Any situation or occasion which shatters the patient's primitive belief in the doctor's magic powers accentuates previously hidden negative feelings and doubts and may lead to change of doctor in the partly rational and partly irrational hope of finding someone who can repair what perhaps cannot be repaired.

(3) The doctor is an authority and wields authority as a technical expert. He can give "orders" but is in no position to enforce them or to penalize a patient for not carrying them out. His authority is strictly segmental in nature: it is confined exclusively to matters concerning the patient's health. He can impose restrictions in diet and on physical activities. He can sometimes justifiably counsel a change in occupation, but he trespasses on his legitimate rights and does more harm than good by telling a patient that all she needs is a husband, a child, or sexual intercourse.

(4) A doctor should treat his patients equally, regardless of colour, creed, nationality, social and economic status, or other distinctive features. But who of us has not been influenced at one time or another by the appearance and manners of his patients, or by their social status in the community? And who of us has not been guilty at times of giving more careful attention to a wealthy patient than to an indigent one?

(5) A doctor is supposed to assist the needy irrespective of monetary gains; but we also have to live and support our families. Moreover, living as we do in an acquisitive society with keen and often unscrupulous competitiveness, monetary gain is frequently regarded as a sign of success and as a means of much-needed recognition. Consequently the temptation is often great to place self-interest before the interest of the patients, to promise "miracle cures" against better knowledge, to prescribe injections which are not needed, or to play up to the patient's requests for gadgets which may not be required. Perhaps there is more than a grain of truth in the charge that the Hippocratic oath is in danger of being replaced by salesmanship based on the "get-rich-quick" principle.

(6) The doctor, like his patients, has unconscious conflicts which may interfere with his capacity to understand and treat his patients. For example, doctors unable to recognize their own shortcomings may be unable to tolerate similar inadequacies in their patients. Detached, aloof physicians may be threatened by patients' attempts to form close, dependent relationships with them. Other physicians may become unduly attached to or over-identified with patients whose problems are similar to their own, or whose personalities resemble those of relatives with whom they have intense relationships.

Physician-Patient Relationships

From this background discussion of patients and physicians we may return now to the principal topic—bedside manners. The points which we have been trying to make are: (a) that the practice of medicine not only consists in the application of biological knowledge but also demands considerable degrees of social and psychological understanding, described as bedside manners and psychotherapy; (b) that certain definable principles can be identified and are operative in bedside manners; and (c) that, analogous to systematic psychotherapy, bedside manners require an intimate knowledge and understanding of the emotional, social, and economic problems of the patients and their families as well as those of the doctors themselves. The classic dictum "know thyself" is an essential prerequisite for the knowing of others. From time immemorial good doctors have always paid attention to the emotional aspects and the environmental stresses of their patients. To do so, general practitioners are in a better position than consultants, who, in view of their special functions, do not see their patients over prolonged periods in their home environments. Few doctors would fail to listen to a patient's chest in a case of prolonged coughing, but many doctors fail to listen to their patients' words, which may reveal more than auscultation ever can.

Rather than speak to their clergymen, in whose presence they may feel embarrassed, patients often take their troubles and worries to the general practitioner, who is well advised to listen patiently and benevolently without taking sides, showing disapproval, or giving advice. The very fact that the patient can "get it off his chest" relieves feelings of tension and anxiety.

Psychological examination and assessment require skill and time. Yet the time factor is often overrated. Just as the beginner spends more time on a physical examination than an experienced physician, psychiatric appraisal takes less time as experience grows. One may listen for hours to a person who speaks Chinese, but would not understand a word unless one had learned the language. Symptoms are the language of disease, and behaviour is even more specifically the language of psychological disorder. Physicians can familiarize themselves with the varying ways in which patients communicate their emotional discomfort and indicate their need for help. Not infrequently the presenting complaint is only a plausible excuse couched in the language of somatic symptoms, to indicate the patient's general distress. The source of this distress—that is, its emotional and conflictual origin—may be confused readily with its somatic localization.

Time, money, and effort could be saved if patients suffering from psychosomatic and psychoneurotic illness would not again and again be submitted to elaborate laboratory examinations. Overemphasis on minor organic lesions fosters

iatrogenic illness and may by-pass the real cause of the patient's suffering. The presence of emotional conflicts whose aetiological relevance to the illness may be all-important can be revealed only by direct examination. Familiarity with the basic principles of psychopathology is essential if one wants to understand one's patients' needs, anxieties, misconceptions, faulty attitudes, and psychological defences. A patient's heroic or stoic attitude towards his illness may be most impressive but may conceal a great deal of anxiety.

In keeping with their regressive states and wishes for recovery, patients suffering from prolonged and serious illnesses are apt to elevate their doctor to the position of a god. Doctors are well advised not to be taken in by the flattery and to behave as such. Doctors should realize their limitations but need not admit them to their patients. A pose of omnipotence and omniscience, if recognized as such, may be appropriate in the case of emotionally immature, anxious, or severely regressed patients, but would obviously be out of place with mature individuals who like to know where they stand.

Methods of approach naturally have to vary from patient to patient. By and large, it is true that the "don't worry," "take-it-easy," "pull-yourself-together," or "cheer-up-old-man" approaches are ineffectual. Patients may have plenty to worry about, and if they could pull themselves together they certainly would. Equally, the general practitioner may defeat his objectives by telling psychoneurotic patients that there is "nothing the matter," or that "it is all imagination." If there were "nothing the matter" the patient would hardly consult him. Nor can much benefit be expected from vacations, sedatives, or placebos, which obviously do not solve the patient's conflicts.

Constructive help can be offered by an understanding of the family situation. As has been stated before, the patient's illness affects his family, and their conscious and unconscious responses reverberate in the patient's physical and mental condition. In this respect, a thorough knowledge of community resources through which changes may be effected is obviously essential.

Conclusion

Another story may give added emphasis to the principal points of this paper. Some time ago the charming young wife of a doctor sought help for severe and intractable vomiting. Her case had puzzled many doctors. She had been submitted to elaborate examinations of her stomach, of her gall-bladder, and of her pancreas; chronic pancreatitis had been suspected. She had spent many months in bed and had been placed on a very rigid diet, all without benefit.

Had one of her physicians spent 10 minutes talking to the patient he would have found out that this young woman felt neglected by her husband. She entered marriage knowing full well that much of her husband's time would be taken up by his flourishing practice. But she had failed to realize that he would devote himself, almost to the exclusion of everything else, to his patients. She was frankly jealous of his patients. If she wanted to attract his interest and attention there was nothing left but to be a patient herself, and an interesting patient at that. When this unconscious mechanism was made conscious to her she recovered rapidly. Needless to say, when her husband recognized her motivation his attitude towards her changed.

The annual competition of the Manchester and District Medical Golfers' Association was held on the course at Wilmslow on May 19. There were 57 competitors. The challenge cup was won by Dr. J. J. MANNING (Warrington) with a net score of 70. The Walter gold medal was awarded to Dr. R. W. FAIRBROTHER (Wilmslow) with the best gross score of 77, and Dr. D. C. ATTWOOD (Bolton) secured the Captain's prize for the second best net score of 73.

MEDICAL BIRTHDAY HONOURS

The names of the following members of the medical profession were included in a Birthday Honours List published in *Supplements to the London Gazette* on June 10:

Baronetcy

Sir WALTER RUSSELL BRAIN, D.M. President of the Royal College of Physicians of London. Physician to the London Hospital and the Maida Vale Hospital for Nervous Diseases.

Companion of Honour

WILLIAM SOMERSET MAUGHAM, Hon.D.Litt., M.R.C.S., L.R.C.P. Author and dramatist.

Knighthood

RUSSELL CLAUDE BROCK, M.S., F.R.C.S. Surgeon, Guy's Hospital and Brompton Hospital.

ALEXANDER PATERSON MURPHY, M.C., M.D. President of the Royal Australasian College of Physicians.
HERBERT HENRY SCHLINK, M.B., Ch.M., F.R.A.C.S., F.R.C.O.G. Consulting Gynaecological Surgeon, Royal Prince Alfred Hospital, Sydney, New South Wales.

C.B. (Military Division)

WILLIAM ALEXANDER DUNCAN DRUMMOND, C.B.E., F.R.C.S., D.L.O. Major-General (temporary), late R.A.M.C.
RICHARD MURPHY, C.B.E., M.B., B.Ch. Major-General, late R.A.M.C. Honorary Surgeon to the Queen.

C.M.G.

ROBERT SAMUEL FLEMING HENNESSEY, M.D., F.R.C.P.I., D.T.M.&H., Dip. Bact. Director of Medical Services, Uganda, Colonial Medical Service.
ANDREW TOPPING, M.D., F.R.C.P., D.P.H. Dean of the London School of Hygiene and Tropical Medicine.

C.B.E. (Civil Division)

CHEWYND JOHN PERSHALL GROSVENOR, M.B., B.Chir. Principal Medical Officer, Ministry of Pensions and National Insurance.
JOHN LEWIS ANDERTON GROUT, M.C., F.R.C.S.Ed., F.F.R., D.M.R.E. Senior Consultant Radiologist to the Sheffield United Hospitals.
MAXWELL SHAW JONES, M.D., M.R.C.P.Ed., D.P.M. Director, Social Rehabilitation Unit, Belmont Hospital, Sutton, Surrey.
NEVILLE LANGDON LLOYD, M.B., B.S., M.R.C.P. Chief Medical Officer, Ministry of Supply.
PHILIP PATRICK LYNCH, M.D., F.R.A.C.P. A member of the Dental Council and of the Medical Research Council of New Zealand.
ARTHUR JOHN METCALFE, M.B., Ch.M. Director-General of Health and Director of Quarantine, Canberra, Australia.
CECIL JULIAN MANNING WALTERS, M.B., Ch.M., F.R.A.C.S. Member of the Medical Board and of the Board of Health, State of New South Wales.

O.B.E. (Military Division)

GEORGE LUSH FOSS, V.R.D., M.D. Surgeon Commander, R.N.V.R.
MARK JOHN LINDSEY, M.C., T.D., M.B., B.S. Brevet Colonel, R.A.M.C., T.A. (now T.A.R.O.)
HERBERT CLIFFORD SERASINGHE, E.D., L.M.S. Lieutenant-Colonel, Ceylon Army Medical Corps.
ROBERT ALEXANDER STEPHEN, M.D., F.R.C.S. Lieutenant-Colonel, R.A.M.C.

O.B.E. (Civil Division)

RICHARD FRANK BOLT, M.R.C.S., L.R.C.P. Chairman, Willesden (No. 4) Medical Recruiting Board.
NOEL HAWLEY MICHAEL BURKE, M.R.C.S., L.R.C.P., D.P.M., D.M.R.E. Lately Medical Superintendent, Cell Barnes Hospital, St. Albans.
EDWARD ALFRED COCKAYNE, D.M., F.R.C.P. For services to entomology.
JOHN EDGAR DAVIES, M.C., M.R.C.S., L.R.C.P., L.D.S.R.C.S. Senior Medical Officer (Wales), Ministry of Pensions and National Insurance.
MICHAEL GELFAND, M.D., F.R.C.P., D.P.H., D.M.R. For services to medicine in Southern Rhodesia.
DESMOND GEORGE McCULLY, M.B., B.Ch. Lieutenant-Colonel, I.M.S. (ret.). Medical Officer for the Trucial Coast, Persian Gulf.

IAN GREGOR MACGREGOR, M.B., Ch.B., F.R.C.S.Ed., D.T.M.&H. Senior Specialist, Nigeria, Colonial Medical Service.
EUGENE PIERRE LARNACH MASSON, M.B., Ch.B., D.P.M. Superintending Medical Officer (Specialist), St. Ann's Memorial Hospital, Port of Spain, Trinidad.

EVERARD ARNOLD MILLS, M.B., Ch.B. Professor of Bacteriology in the Royal College of Medicine, Bagdad.

DOUGLAS WILLIAM LEIGH PARKER, M.Ch.Orth., F.R.C.S.Ed., F.R.A.C.S. Director of Orthopaedic Services, State of Tasmania.
BERNARD THOMAS SQUIRES, D.M. Medical Officer, Bechuanaland Protectorate.

ROBERT STANLEY STEEL, M.B., Ch.M., F.R.A.C.P., M.R.C.P. Commissioner of the St. John Ambulance Brigade, State of New South Wales.

JAMES TAYLOR, M.B., Ch.B., D.P.H., D.T.M.&H. Director of Medical Services, Seychelles, Colonial Medical Service.

ARTHUR WAI-TAK WOO, M.B., B.S., F.R.C.S. For public services in Hong Kong.

M.B.E. (Military Division)

STANLEY GEOFFREY FOX LINTON, M.R.C.S., L.R.C.P. Surgeon Lieutenant-Commander, R.N.

JOHN FOSTER FENTON ROONEY, M.B., B.Chir. Major (temporary), R.A.M.C. In recognition of services in Korea during the period July 28, 1953, to January 31, 1954.

M.B.E. (Civil Division)

GERALD HENRY COORAY, M.D., D.T.M.&H. Professor of Pathology in the University of Ceylon.

ISABEL MARY AGNES DOBO, M.B., Ch.B. Lady Medical Officer, Bahrain Government.

GOPAL KONDOPANT JOSHI, L.C.P.S. Senior Sub-assistant Surgeon, Medical Department, Nyasaland.

ROYAL MEDICAL BENEVOLENT FUND

The annual general meeting of the Royal Medical Benevolent Fund was held on June 4, with Lord WEBB-JOHNSON in the chair. Dr. R. COVE-SMITH, the honorary secretary, said that during 1953 the total charitable distribution of the Fund amounted to £46,897. No appeal for money was made to the general public. The income of the Fund was derived entirely from the medical profession itself by way of subscriptions, covenant deeds, donations, and legacies, and from interest on the capital which the Fund had succeeded over the years in building up. The overhead or administrative expenses were down to 6%, which excellent result was due to the efficiency of the staff.

On the proposition of Sir ZACHARY COPE the officers nominated by the committee of management were elected—namely, Lord Webb-Johnson as President, Mr. F. A. Juler as Honorary Treasurer, and Dr. R. Cove-Smith as Honorary Secretary. The retiring members of the committee of management were also re-elected.

A Subscribers' List

Lord WEBB-JOHNSON made certain suggestions for the study of the management committee. One was that, if possible and not too expensive, a list of subscribers should be published, partly with the object of going after those whose names were not on the list. Members of hospital staffs—especially teaching hospitals—should be written to, if they were not already subscribers, suggesting that they should become such. He had himself done this to some extent, with very good results, including three covenants from new people in one medical school only.

A vote of thanks was accorded to Mrs. Rayner, who is retiring from work at Westmoreland Lodge, Wimbledon Common—a home for doctors' widows or daughters who were not infirm, which was established in 1946 by the generosity of the late Dr. Arthur Holdsworth, the first benefactor. Mrs. Rayner, said Lord Webb-Johnson, had done wonderful work and would be greatly missed.

Other recipients of votes of thanks were the B.M.A. Charities Committee, the honorary auditors and solicitors, and the Ladies' Guild. The Guild, said Lord Webb-Johnson, did personal work that could not be done by letter and made the Benevolent Fund a live body. Bene-

ficiaries felt that there was a personal link between them and the ladies who had helped them so much.

The brief proceedings concluded with a vote of thanks to Lord Webb-Johnson for his great services as president.

MEDICAL SERVICE ON WINGS

THE AUSTRALIAN "FLYING DOCTOR"

[FROM OUR OWN REPORTER]

Dr. Allan Vickers, senior medical officer of the Australian Flying Doctor Service, is on an extended visit to this country, undertaking postgraduate study with the aid of a Nuffield Foundation grant, and also seeking to make known the facts of the Flying Doctor organization for the benefit of other parts of the British Commonwealth where a similar medical service might usefully be provided. He sees no reason why there should not be autonomous services on the Australian pattern, with co-ordinating headquarters in London, for territories where stretches of continent or intervening seas make it difficult to bring prompt medical aid. Dr. Vickers, who has been on the service for 24 years, during the last 10 of which he has operated from Charleville in south-central Queensland, says that for some time past inquiries have been reaching Australia from other countries.

Australia, with its immense territories sparsely populated, is the pioneer in this field. Its experience goes back for a quarter of a century, and it is still virtually the only country to have a service where the doctor systematically goes out by plane to see patients.

The progenitor of the service was a Presbyterian minister, John Flynn, who died three years ago. He had no more than a layman's knowledge of medicine, aviation, or radio—the tripod on which the service rests—but he had a knack of choosing doctors and engineers who translated his vision into reality. Only after the first world war did aeroplanes of a suitable type, containing a cabin in which a patient on a stretcher could be carried, become available, and even then there remained the problem of communication of messages. The telephone was not the answer; it would have been hopelessly expensive and subject to accident. A radio engineer, A. H. Traeger, of Adelaide, developed a portable transmitting-receiving set, the power being supplied by a treadle dynamo, simple enough for people in the bush to operate, and sturdy enough to stand up to its job. The man or woman at the outpost has only to use the pedal set to have a two-way talk with the doctor at the base station hundreds of miles away.

Medical advice is now given on the radio on more than 5,000 occasions in a year. The first actual flight was made from Cloncurry, Queensland, in 1928. In that year 50 flights were made, each averaging 400 miles, 255 patients were seen, and the first radio "mother" station was established, the first link in an aerial service which now covers two-thirds of the continent. The number of Flying Doctor bases is now 9, and with them are connected many hundreds of outposts (926 is the latest figure).

Control and Cost of the Service

The service was at first under the control of the Australian Inland Mission of the Presbyterian Church, but as it developed the Mission relinquished its control (though not its interest), and in 1933 in the capital of each State there was set up an executive council, consisting of persons in public and commercial life who serve in an honorary capacity. The co-operation of many bodies, such as chambers of commerce and women's institutes, and including the Federal Council of the British Medical Association in Australia, has been warmly forthcoming. Each section has been formed into a non-profit-making company, with articles of association, identical in every State, the first

of which recites the objective "to foster, develop, and safeguard the health of residents in the sparsely populated areas of the Commonwealth of Australia, its dependencies and mandated territories, by ensuring readily available medical and nursing facilities. . . ." In Western Australia, in addition to the section based on Perth, there is another, serving the eastern goldfields, based on Kalgoorlie. The smallest State, Victoria, which is no more than the size of Great Britain, is too closely settled to need this type of medical aid, and it takes under its wing, literally, the service of the Kimberley area, Western Australia, 1,800 miles from Melbourne. A federal meeting of representatives of the State councils is held once a year.

The annual expenditure on the service is about £130,000, of which £75,000 is contributed by the people for whom the service is rendered. No charge is made, but they give according to their means. They are people of all income levels, but, of course, the operating costs are heavy—a single flight may cost £80—so that a patient's contribution can often be only a token payment. A Government subsidy (which in no way implies Government control) varies from State to State, but totals about £30,000, and the remainder is raised by voluntary contributions and bequests.

Remote Diagnosis

A series of small communal hospitals or nursing-homes have been established and are visited by the flying doctors on routine inspection once a month. Every effort is made to carry out preventive treatment. Immunization of children against diphtheria, whooping-cough, and other infections is instituted. Antenatal clinics are set up. The doctor on his flight may on occasion be accompanied by an ophthalmic or other specialist or by a nursing sister. But this complex radio network is not used merely for summoning the doctor in emergency. The doctor at the base is called up constantly to make remote diagnosis and give advice and treatment over the radio. Here is a mother, 200 miles from hospital and perhaps 50 from her nearest woman neighbour, anxious about her baby. One can imagine the reassurance given by the doctor's voice on her radio set. A standard medicine chest is made available at every outpost. It contains the more usual medicines, palliatives, appliances, and accessories, all of them not only named but numbered. Patients or their relatives are encouraged to describe symptoms and appearances over the radio. They are given time to tell the story in their own words. Many of these outback settlers are well-educated people; and, even if not, they are more than usually intelligent, as one would expect, and accustomed to make keen observation. Dr. Vickers strongly insists that this is not a makeshift. The people know, too, that, if necessary, no matter how far away they may be, the doctor will visit them after an interval scarcely longer than an urban practitioner takes to answer a call from another part of the town in a busy practice, and that, again if necessary, they will have air ambulance transport and hospital care. The flying doctors themselves are highly trained men, often with special qualifications in addition to a thorough experience of general practice, and specialists in the cities are also available if need be.

It is computed that in the Flying Doctor service last year over 300,000 miles were flown, the individual flights numbering 1,100. Ten thousand patients were seen, of whom about 400 were transferred to hospital, and in addition 6,000 patients were given medical advice by wireless. Until last October there had not been a fatal accident, and there has never been an accident involving a patient. The educational possibilities of the radio system are also opening up, and it may expand in the direction of other communal amenities. But its first object is to cast, as it has done, a mantle of safety over these vast spaces, to break the dreadful silence for the lonely peoples, to bridge the gulf of geographical isolation, to make medical succour a matter of minutes or hours whereas it formerly meant days or weeks. But this is to be "glamorous," and that is what Dr. Vickers dislikes.

Correspondence

Cortisone and Aspirin in Rheumatoid Arthritis

SIR,—Dr. J. H. Glyn writes (*Journal*, June 12, p. 1376) that statisticians prefer to answer a single question at a time—that is, "If to a defined type of patient Y gr. of drug X are given daily by one particular route in so many divided doses, what happens?" He appeals to them to modify this "rigid approach" and to make the question asked of a trial read: "Does drug X, given under optimum conditions (as judged by experienced, reliable, and unbiased clinicians), give better results than drug Y?"—leaving the clinicians to select both the patients and to adjust the dosage schedules to individual requirements. Dr. Glyn quotes from a paper I published in 1952, and yet he seems to have ignored the fact that I fully answered his appeal in that paper of two years ago. This is what I wrote:

"In testing a new form of treatment knowledge at first is necessarily scanty, being usually based upon laboratory work and a few scattered clinical observations. In Medical Research Council trials we have thought it proper, therefore, to choose such a regimen as promised to reveal the potentialities (and often the dangers) of the drug (or whatever may be concerned). Thus we have a tidy question—for example, if to a defined type of patient 2 gr. of drug X are given daily in four divided doses by intramuscular injection and for three months, what happens?"

"But perhaps the question is too tidy. We can, of course, extend it after its answer has been reached by experimenting with variations upon the original theme. It may, however, be argued, and sometimes, I think, legitimately, that allowance should have been made during the basic trial for individual idiosyncrasies, that the clinician should have been free to vary the dosage according to his own judgment of the patient's needs as shown by the latter's responses. Statistically, I see no reason why that should not be done. . . . The question asked of the trial . . . now runs 'if competent clinicians in charge of defined types of patients use drug X in such varying amounts and for such varying durations of time, and so forth, as they think advisable for each patient, what happens?' The moot point is which question, in given circumstances, is the better one to ask."

Dr. Glyn also accuses statisticians of "choosing certain highly inaccurate assessments (such as joint tenderness and whilst range of movement) as a means of overall assessment, whilst ignoring entirely such imponderable but important clinical features as the degree of stiffness and the patient's sense of well-being." Personally, I have repeatedly said and written how important it is to bring the "imponderable" features into clinical trials, particularly when that can be achieved in such a way that bias in the observer (or patient) can be discounted. There is nothing new in that idea. Where Dr. Glyn goes particularly astray, in my view, is in his odd ideas of the part statisticians play in these trials. He seems to regard them as dictators and the "experienced, reliable, and unbiased clinicians" as their puppets. That, fortunately, has not been my experience. I have spent many hours, as a co-worker in a trial, listening to clinicians framing the questions, deciding on the dosages, determining diagnostic criteria and arguing about means of measuring the results. It is clearly their job to do so and mine to collaborate in determining the appropriate "experiment" that flows from their desires and views. It is entirely collaborative work. If "highly inaccurate assessments" are introduced at that time, then the clinicians must take the major part of the blame—after all, it is their field of knowledge. If during the trial clinicians admit wholly unsuitable patients to it—that is, they ignore the rules they themselves framed—then they are wholly to blame. But in working with clinicians I have always found them more than anxious to abide by their own rules.

I am not here concerned with the particular trial which has moved Dr. Glyn to these criticisms but with the general issues that he has raised. In brief, the statistical rigidity against which he tilts is far less than he imagines and the

statistical dictatorship is a myth. If it should ever cease to be a myth I would be happy to enlist under his flag and to join in the attack.—I am, etc.,

London. W.C.1.

A. BRADFORD HILL.

Fitness, Fertility, and Blood Group

SIR,—Your annotation under this heading (*Journal*, May 22, p. 1197) ends by referring to the need for studies of blood group distribution in (amongst other populations) children of different ages and sexes. It has recently come to my notice that the material for one such study is available from data obtained by Vuori¹ in an effort to find a relation between the ABO groups and the weight, height, and intelligence of healthy Finnish State and high school children. Having found that samples of group B individuals give consistently different results from samples of A and O individuals in investigations relating to viability and fertility—a fact which might be thought to lend some support to established phylogenetic belief—I have found it useful, on occasion, to consider A and O as a single group. When this is done with Vuori's data (table I) it is seen

TABLE I.—Distribution of ABO Blood Groups in Finnish Children and Adolescents

Total No. of Children	Ratio of B to A + O Children		Age of Children	Age of Adolescents	Ratio of B to A + O Adolescents		Total No. of Adolescents
	Male	Female			Male	Female	
178	0.27	0.18	8, 9	13	0.24	0.21	825
447	0.24	0.24	10	14	0.23	0.22	646
705	0.21	0.22	11	15	0.25	0.23	418
841	0.21	0.26	12	16	0.23	0.27	341
				17	0.31	0.28	246
				18	0.18	0.35	142

that, in later childhood and again in adolescence, the incidence of B in this sample, relative to that of A plus O, shows, for the most part, a fall in males and a rise in females as age increases.

The only other relevant data known to me is that provided by ten of the twelve samples making up Waterhouse and Hogben's² series of 1,239 families with 4,139 children of unstated age but stated birth-rank. Here, omitting the families with twins or only one child, the ratio of male to female children is 1.24 (63:51) for the B youngest children and 1.08 (57:53) for the B oldest children, whilst it is 0.97 both for the A and O youngest children together (365:377) and for the A and O oldest children together (370:381); and there are slightly fewer B's and slightly more A's and O's in the oldest than in the youngest children. It may be recalled that in Sanghvi's³ sample of newborn infants of unstated birth-rank, the ratio of males to females is 1.33 (281:212) for B and 1.12 (827:739) for A and O together. Certain findings on the sex-ratio of well and ill adults—that is, British blood donors and Finnish hospital patients—will appear elsewhere.

Your annotation also refers to my analysis of the Waterhouse-Hogben series from the standpoint of fertility, but this analysis can be taken a further step in view of the circumstance that the Waterhouse-Hogben series is made up of six samples with an average of 2.69 children per family and six with an average of 4.16 per family. The possible importance of this variation in family size is seen from the fact that while in the smaller-family samples as a whole the descending order of fertility of fathers is B-O-A, in the larger-family samples as a whole it is O-A-B, whether the father's group is the same as, or different from, the mother's (table II). Should such differences prove to be real, one of their possible explanations, or part explanations, would be that fertility in B males may decline with age more quickly, from a higher level, than fertility in A or O males (see Hirsfeld's⁴ heterogeneous series of 7,700 families with only 2.13 children per family, and also the work of Kirk, Kirk, and Stenhouse⁵ on fertility in mothers).

TABLE II.—Comparative Fertility of Fathers (White)

Samples with an Average of 2.69 Children per Family			Samples with an Average of 4.16 Children per Family		
Father's Group, and Average Family Size, when Mother's Group the Same	Father's Group, and Average Family Size, when Father's Group Different from Mother's	Father's Group, and Average Family Size, when Mother's Group the Same	Father's Group, and Average Family Size, when Father's Group Different from Mother's	Father's Group, and Average Family Size, when Mother's Group the Same	Father's Group, and Average Family Size, when Father's Group Different from Mother's
B 3.20 O 2.82 A 2.62	B 2.94 O 2.65 A 2.58	4.23 4.21 4.16	O 4.27 A 3.87 B 3.83	O 4.27 A 3.87 B 3.83	O 4.27 A 3.87 B 3.83

In the Waterhouse-Hogben series the descending order of fertility of mothers of a different group from their husband is A-O-B in both the smaller-family and larger-family samples as a whole—a fact which gives interest to Vuori's small-scale material on abortion. In Vuori's series of 348 matings the incidence of abortion was nearly twice as high in the B mothers as in the A or O mothers—this finding has lately been repeated both by Sjöstedt, Grubb, and Linell¹ and by Allan²—and when one omits the matings where husband and wife have the same group, the incidence of abortion in the remaining B mothers rises to more than twice that of the A and O mothers (table III).

TABLE III.—Incidence of Abortion in Finnish Families with Father and Mother of Different ABO Groups

No. of Families	No. of Abortions	Group of Father	Ratio of Families to Abortions	Group of Mother	No. of Abortions	No. of Families
86	7	A	12.3	A	7	92
84	9	O	9.3	O	7	84
53	7	B	7.6	B	8	45

In addition there are slightly more A mothers than A fathers in Vuori's sample, and considerably fewer B mothers than B fathers. Vuori also ascertained the menarche-age of 244 schoolgirls, and, while the average age at menarche was 14.3 years for both the A and O girls, it was 14.7 years for the B girls.—I am, etc.,

Insulin Resistance

SIR,—The stimulating paper by Dr. J. Beattie (*Journal*, June 5, p. 1287) raises many points of interest, but I would like to be allowed to criticize his interpretation of the results. The author's view that insulin resistance in adrenal-medullectomized animals with hypothalamic lesions is due to increased amounts of growth hormone and adrenal cortical steroids appears to be untenable. The most striking findings in these animals are the hypoglycaemia and the low glycogen content of liver and muscles. Both growth hormone and adrenal corticoids have been shown to increase blood sugar and glycogen stores. Moreover, the author has already shown that the hypothalamic lesions probably do not interfere with pituitary function,¹ and it seems strange that a procedure designed to disturb autonomic control should result in such profound changes in hormonal balance.

It has long been suspected that the autonomic pathways are concerned in the emergency response of the organism to hyperglycaemia and excess insulin. In the present experiments, interruption of the hypothalamic-adrenal system resulted in a complete unresponsiveness to glucose and insulin. This is certainly what one would expect in the case of glucose, though it is difficult to explain why these animals were not more, instead of less, sensitive to insulin. Is it possible that the adrenal response to insulin is not due to

hypoglycaemia, but occurs earlier as a direct effect of insulin on the autonomic nervous system? This is, of course, highly speculative, but it seems that some alternative explanation for the present findings must be sought, since there is little evidence of true insulin resistance.—I am, etc.,

Undergraduate Education

SIR,—In reference to Mr. Aleck Bourne's letter (*Journal*, June 5, p. 1321) on undergraduate education, I feel that "what have been the opinions of many of us for years" need re-emphasis, and now more so than ever, since we seem in medicine to be entering a period when the call on the laboratory, the ancillary aids, and the physicist is growing.

I will not agree that it is wrong for students to be told what can be done in rare, major, or obscure cases, but I feel that the primary function of teaching in medicine is to turn out general practitioners who can use their tongues to ask the patient questions, their ears to hear their replies, and their fingers to feel the lesion. This, I am sure, is not forgotten, but, as one who is not connected with a teaching school and who frequently has a new product to deal with, one undoubtedly gets the impression that the present-day student is taught more about the various forms of gastrectomy, pneumonectomy, and cardiovascular surgery, and laboratory diagnosis than was the case in the past and that this, unfortunately, seems to mean a sacrifice in the type of knowledge which is needed in practice—for example, the diagnosis of strangulated hernia, the reduction of dislocated shoulder, the treatment of varicose ulcer, and the recognition of the acute abdomen and the knowledge of when a patient is ill. I am quite sure that many of the very best general practitioners know little or nothing of the techniques of major surgical or laboratory procedures and would be wasting their time to learn, and that emphasis should be on the common things in practice, and attaining enough knowledge to deal with them or refer their difficulties to the correct place if necessary. I cannot help feeling that giving the student sound and definite teaching on what to do with the type of cases he is likely to meet would result in the young practitioner having greater confidence and make the hospital out-patient department less necessary to him. Less of the academic and more of the realities of medicine must be kept before the student, and for this reason there is much to be said for him doing a period of work with a general practitioner.

I feel sure that the good student of to-day is as good as in the past, and the worst no worse, but that the emphasis on what is important is tending to be misplaced. Could it be that now in the teaching schools the house-surgeon has less responsibility than in the past, since registrars and others have increased in number and the duties of house-surgeons now were largely the duties of students in the past, and the student of to-day does little of a practical nature in the ward as part of the team?

With regard to the teaching of psychology, I have no suggestions to offer. The *sine qua non* of this subject I feel is that the doctor must not "lose the common touch." For a doctor to regard his case as a "chest," a "heart," a "gastric," or anything else, and to carry out treatment, however correct, without reference to the patient's thoughts, feelings, or fears, stamps that doctor as one on whom no amount of teaching of psychology will have any effect. The rest of us have, perhaps, learnt a little psychology through force of circumstance. The height of my own knowledge of mental disease was that I once thought that I knew when a patient was mad, though not perhaps the medical term to put on his particular madness. Now, I am not so sure that I even know madness when I meet it.—I am, etc.,

Ballymena, Eire.

W. S. HANNA.

Blood Groups and Gynaecological Cancer

SIR,—The data on blood groups of patients with gynaecological cancer given in the article by Drs. Erik Krokfors and Olavi Kinnunen (*Journal*, June 5, p. 1305) do not bear the interpretation which the authors place on them. Deviations from expectation equal to or greater than those reported would be expected in 15% of similar series even were there no difference between the groups.

Group	A Control	B Total Cancer Patients	C Cancer Patients Under 45 years
O	98	113	42
A	139	110	33
B	48	57	17
AB	25	20	8
Total	310	300	100

The analysis of two 2×4 tables gives values of χ^2 (for 3 degrees of freedom) of 5.609 for the comparison of A with B, and 5.025 for the comparison of A with C; both values correspond to a probability of about 0.15.—I am, etc.,

London, N.W.10.

GEORGE DISCOMBE.

Syme's Amputation

SIR,—In your brief report of Mr. J. H. Shelswell's remarks on Syme's amputation at the annual meeting of the British Orthopaedic Association (*Journal*, May 29, p. 1258) the point is made that the necessary prosthesis is bulky, and therefore this amputation "was seldom indicated in women." Yet there is an important consideration in favour of this level of amputation from a long-term "cosmetic" point of view.

Unfortunately, the very young sometimes suffer grave foot injuries from run-over accidents. When foot amputation in these young people is necessary, a Syme's amputation allows constant weight-bearing and an early fitting prosthesis that has not to be changed at frequent intervals as growth proceeds. With such constant weight-bearing the lower limb grows to its normal length. When growth is ended the choice of a higher level of amputation can be made by the lady herself. Yet I have a patient who in her first decade of life had a Syme's amputation and now, 65 years later, she has a leg equal in length and, with its prosthesis, apparently equal in function to its normal fellow. I doubt if she would at any stage have appreciated the attention of a "cosmetician."—I am, etc.,

Birmingham, 15.

WILLIAM GISSANE.

Restriction on Aureomycin

SIR,—I was astonished to see on sale to the public a veterinary preparation containing 3.6 g. of aureomycin. Surely it is time that the ludicrous situation in regard to this valuable drug was ended. Aureomycin has been extensively used in this country for six years. Its attributes and limitations are widely known. Judging from reports in medical journals, it is lavishly used in hospitals, perhaps too lavishly. A general practitioner, however, can only obtain it on application to a recognized centre, for the treatment of a few uncommon diseases.

Aureomycin has been manufactured in this country for at least four years. It is available in a poultry food. Why is it being withheld for general practice? Erythromycin, a drug with fewer applications, is freely available. The discovery that aureomycin and terramycin are practically identical makes the ruling even more difficult to understand. Aureomycin is a well-established drug, and it seems absurd that its use should still be monopolized by hospitals. It is hoped that the practice of withholding drugs from general practitioners will end with the early release of aureomycin.—I am, etc.,

Wells.

J. PINCHING.

Geriatric Nursing Annexes

SIR,—It is clear from the survey of the geriatric unit in St. Alfege's Hospital for 1952 by Dr. A. J. Mester (*Journal*, June 5, p. 1317) that this unit is doing most valuable work, but I do not think that his advocacy of "nursing annexes" should pass unchallenged. Such annexes when established would soon become veritable homes of the unwanted dying and perpetuate the depressing hopelessness of such institutions. Admission to them would be worse than a death sentence and would have a most unhappy reaction on patient and relatives alike. It is possible that the very dread of them might stir up some to undertake the care of their aged relations, but there are other more humane ways of teaching the duty to provide for parents in their old age. Let us rather mix the cases for whom treatment may be of avail to relieve if not to cure with the less hopeful who need only nursing, so that by their improvement or recovery hope may pervade and stimulate the minds of the sick and their kin, and the work of the attendants on them, whether professional or lay.—I am, etc.,

London, E.C.1.

C. O. S. BLYTH BROOKE.

Chloramphenicol for Athlete's Foot

SIR,—May I ask Dr. Francis J. Evans (*Journal*, May 29, p. 1267) if he had an opportunity of confirming the diagnosis and cure of his cases of epidermophytosis by direct or cultural investigation? Also, what type of fungi were found to be present?—I am, etc.,

Leicester.

JAMES OVERTON.

An Unusual Case of Acute Retention in Women

SIR,—Recently a lady of 67 years of age was admitted to hospital complaining of lower abdominal pain of 12 hours' duration and the inability to pass urine for 24 hours. On examination the bladder was found to be almost as high as the umbilicus. The vagina showed signs of a senile vaginitis, and its upper part had been obliterated, presumably by these changes. Examination per rectum revealed a large, tense, uniform swelling anterior to the rectum. A tentative diagnosis of impaction of a fibroid was made and laparotomy was decided upon. At operation the uterus was exposed through a lower midline incision. The swelling was seen deep down on the posterior aspect of the uterus. Hysterectomy was considered the treatment of choice. During the freeing of the "fibroid" it burst, releasing a large quantity of dark viscid blood. On examination the "fibroid" was revealed as a large haematocolpos. The uterus was removed and a drain was made to pass through the obliterated vagina.

Later it was found that she had been treated for a stenosing senile vaginitis with tab. stilboestrol, 1 mg. every day, some two months before (menopause occurred at 47 years of age). Apparently uterine bleeding had occurred into the upper portion of the obliterated vagina to produce this haematocolpos which led to acute retention.—I am, etc.,

London, N.18.

EDWARD T. R. HOLT.

Alcohol

SIR,—I often think that the attitude of our profession to the use of alcohol might be more clearly defined. G. K. Chesterton in his book *Heretics* says: "There is only one legitimate use of alcohol and that is to get drunk on it." I believe this to be a perfectly true statement. By getting drunk he means that its use is to make a man merry and of a glad countenance when he is in cheery company. Few will deny that a dinner or a dance goes with more swing and fun when champagne goes round. This is probably due to the fact that it lessens one's powers of self-criticism and makes one have a better opinion of oneself. I do not deny the scientific fact that alcohol is ultimately a depressant and that it lengthens one's time of reaction to stimuli. But, and it is a very big but, there are many who do not use alcohol for its legitimate purpose. They use it to fulfil a

physical or mental need either to relieve a pain or because they are tired, or because they have a job in front of them which will tax all their energies and they hardly feel up to it, or because they are afraid. Worst, and most unsocial, of these is the man who has a long cold drive in front of him and takes "one for the road." These people are walking on the edge of a precipice. In my young and unregenerate days I have to confess that I often drank more than was good for me, but it was always in good cheery company, and I was never a bit the worse except for an occasional "head" and a rise in my mess bill. I am now well into my 85th year and can put in a 10-hour day's work seven days a week.

When I was in India and had a very large and hard practice in a somewhat trying climate, often when I paid one of my visits at the end of the day someone would say: "Oh, you are looking tired. Have a whisky and soda." I always answered: "Yes, I am tired and that is why I won't have a whisky; a cup of coffee if you have it. When I have had a bath and a change and get to the club and meet a few cheery friends I will have a drink, perhaps even two." When I commanded a hospital in Mesopotamia I used always to say to my youngsters: "The Old Man shuts his eyes on a guest night, but if I see you taking short drinks through the day to help you get through your work—well, I don't like it and I shan't like you," and their response was excellent. We should preach this doctrine far and wide: "Never, never take alcohol to fulfil a physical need."—I am, etc.,

Taymilt, Argyll.

P. F. CHAPMAN.

Sickle-cell Anaemia in Uganda

SIR.—It is time to correct the impression, several times referred to in your columns, that sickle-cell anaemia is rare in Uganda; rare, that is, in comparison with its expected frequency on the supposition that it is the expression of the homozygous state for the sickling gene in children. Since one of us was partly responsible for this impression as regards Africa as a whole, it is appropriate that we should record our denial of it as far as Uganda is concerned. The original statement was made after a comparison of the published reports up to 1949, from America and Africa respectively. At that time the information about African children in this respect was meagre in the extreme, and the idea of the homozygous basis of the anaemia was only being formulated. Having noted a difference in the reports of the incidence of anaemia in sickling persons from the two continents, Raper¹ concluded: "Any deductions drawn from this difference must of course be treated as subject to revision if more accurate information should be obtained." No conclusions were drawn as to the frequency of the anaemia in Uganda.

In subsequent years more accurate information rapidly accumulated, notably in the excellent study by J. and C. Lambotte-Légrand² from the Belgian Congo, which showed the anaemia to be as frequent as expected around Leopoldville. These authors insisted that one should look for the anaemia amongst very young children, a notion that did not appear even by implication in the American literature before the days of the homozygous theory. Foy and others³ reached similar conclusions in Kenya. In Uganda, Hutton⁴ has analysed the admissions to the children's ward of Mulago Hospital, Kampala, and concluded that the anaemia occurred with about the expected frequency. We have examined haematologically a series of children under 10 years of age, attending (for whatever cause) the out-patient clinic at the same hospital. Amongst 350 children, 4 definite cases of sickle-cell anaemia were detected, and 2 others were recorded in whom this was the probable diagnosis, though not yet confirmed. The expected frequency is in the region of 1% of all children born.

The above figures refer to children selected by their attendance at hospital. However, for some years we have been making clinical and pathological observations on children under 5 years of age attending child welfare clinics

around Kampala. In the last two years, 422 new entrants to the clinics were Baganda, and 237 were Nilotics. In the former the gross sickling rate was 18.5%, and in the latter 20%. Amongst these 659 children there should have been (if the parents exhibited a similar sickling rate) about 7 homozygous for the sickling gene. In fact we observed 12 unrelated cases of sickle-cell anaemia amongst them. Though less selected than hospital cases, children attending the clinics would present a somewhat higher proportion of the sick than exists in the general population. We therefore consider that sickle-cell anaemia is at least as common in this part of Africa as would be expected on genetic grounds.—We are, etc.,

Kampala, Uganda.

Diagnostic Difficulties in Conservative Treatment of Perforated Ulcers

SIR.—In his article (*Journal*, February 13, p. 374) Mr. T. G. Crombie is right to suppose that conservative treatment will stand or fall by the number of errors of diagnosis and their results. It is a pity, however, that his criticism is based, not on practical experience, but on the theoretical results of what he imagines would have happened if his own patients, treated by operation, were treated by the alternative method; and it is a pity also that he deliberately refrains from considering the results of mistakes of the operation policy—that is, operating on wrongly diagnosed coronary thrombosis for example. Finally, he is mistaken in supposing that the surgeon, having decided on treatment by aspiration, is bound to follow the method according to rigid rules instead of altering his treatment according to the progress of the case.

It is possible to illustrate these points by taking the last two years at this hospital. There have been 64 actual perforations and many more cases of "widespread peritoneal irritation" due to other causes. Four of the latter were erroneously considered to be perforated ulcers and were treated initially by aspiration. In fact two cases were appendicitis and two were internal strangulations. The error in each case soon became apparent by the clinical progress; operation was undertaken and all four cases made a satisfactory recovery. Of the 64 actual perforations, the diagnosis was uncertain in five; laparotomy was performed and the ulcer was sutured. In another five cases conservative treatment was not satisfactory and operation was performed. All these ten patients recovered. The remainder were treated without operation. Four patients were moribund on admission and died. They were not at any time suitable for operation. There were no deaths in the series other than these. It is difficult to refrain from suggesting that Mr. Crombie should follow John Hunter and "try the experiment," but, if he does, let him please not omit the x-ray. The exact position of the tube and the amount of gas under the diaphragm and in the stomach are crucial points in the management of these cases.—I am, etc.,

Ilford, Essex.

R. P. WARREN.

Infectious Mononucleosis

SIR.—Dr. Peter Wolf's attempt (*Journal*, May 29, p. 1265) to identify infectious mononucleosis with a positive Paul-Bunnell test is deprecated. It is well known, even to haematologists, that a few other conditions may sometimes give rise to a blood-count similar to that found in infectious mononucleosis. It should be emphasized here that one or two odd "glandular fever cells" are not diagnostic and that a repeat blood-count will help in either confirming or excluding the diagnosis. In a case with sufficient clinical (or laboratory) evidence of some other disease, and with a typical blood-count of infectious mononucleosis, I would

not hesitate to declare a mixed infection, even in the absence of a positive Paul-Bunnell test. While it is true that a positive Paul-Bunnell test is probably diagnostic of infectious mononucleosis, it is equally true that a negative test does not exclude this condition, and I feel confident that it is not dishonest to base a diagnosis of infectious mononucleosis either on haematological or on clinical and haematological grounds in spite of a negative Paul-Bunnell test.—I am, etc.,

Sheffield.

S. VARADI.

Dangers of E.C.T. in Cerebral Arteriosclerosis

SIR.—Dr. G. I. Tewfik (*Journal*, April 10, p. 876) refuted the concept of arteriosclerotic dementia in order to replace it by the term "post-apoplectic dementia." There already exists the general term "cerebral arteriosclerosis," which comprises all those cerebrovascular conditions with focal neurological signs which are not associated with dementia. Within this wide group we find a percentage of cases correctly labelled arteriosclerotic dementia, differentiated by psychometric tests¹ which correlate with psychometric findings. Whether the dementia remains static for a number of years between strokes or is progressive is beside the point. To state, as Dr. Tewfik did in his second letter point, that "the dementia, if it occurs, is related to the apoplexy, and not the arterial lesion," is illogical, as both apoplexy and dementia are caused by arterial lesions; it all depends on the site and extent of the lesions and the degree of compensation of remaining healthy brain.

To treat such cases with E.C.T. is risky. The following case illustrates this: Retired bricklayer, aged 66. Complained of breathlessness on exertion, and stiffness in calves on walking 300 yards (0.27 km.), relieved by stopping. Depression one month: believed he had sinned by retiring, that he hadn't a friend in the world, and that the police would arrest him for drawing N.H.I. money without being entitled to it. His memory was markedly impaired, he thought the year was 1935, didn't know his year of birth, and couldn't give the dates of the last war. He knew the correct day and month and knew he was in a hospital. He had partial insight. He was clean and tidy and his behaviour was not very distinguishable from that of a patient in a general hospital. He was orthopaedic and showed marked left heart failure with a blood pressure of 210/115. Blood urea = 37 mg.%. Marked peripheral and retinal arteriosclerosis. Exaggerated deep reflexes, especially left knee jerk. E.C.G. showed left ventricular strain. He had treatment for four weeks with rest, digoxin, and hexamethonium which reduced his blood pressure to 155/85 and lessened his myocardial decompensation. Mentally he became worse, was more depressed and refused food, arguing that he was depriving other patients of what belonged to them. His memory was bad and he admitted it. In view of his refusing food it was decided to give him E.C.T. modified by succinylcholine. He made a satisfactory recovery from the first treatment, but died a few minutes after the second treatment (0.1 g. thiopentone 5% with succinylcholine 0.4 ml., patient weighing 121 lb. (55 kg.)) a week later.

An inquest was held and necropsy carried out. Findings were: Cerebral arteries atheromatous and narrowed, popliteal vessels atheromatous and calcified; left heart much enlarged and myocardium very fatty. Coronaries atheromatous. Mitral and aortic valves and aorta atheromatous. Verdict: "Death by misadventure accelerated by electric convulsion therapy." This case illustrates the risk involved in treating a man with generalized arteriosclerosis and cerebral ischaemia by E.C.T.

Another case illustrates how cerebral ischaemia was produced by E.C.T. and gallamine triethiodide with a resultant permanent hemiplegia. A lady aged 52 was admitted suffering from depression and dizziness. Blood pressure 110/80. History of asthma since childhood. Heart, nothing abnormal discovered. C.N.S., nothing abnormal discovered. W.R. and Kahn negative. X-ray chest normal. X-ray lumbar spine: osteoarthritic changes. Commenced course of E.C.T. with gallamine triethiodide, all went well until the sixth treatment, given exactly one month after the first (0.8 mg. gallamine triethiodide, plus 0.25 g. thiopentone intravenously). There was some coughing after the treatment. Appeared normal till 3 p.m., when vomited greenish material, became cyanosed with rales and rhonchi in left chest. Quite clear mentally till an hour later when vomited again and became semicomatose: colour then good, heart sounds normal. Right face

and leg paralysed next day with right Babinski. Speech affected. Albumin and hyaline casts present in urine. Nine months later she still had little use in her right hand, though her speech was much better. She remained depressed on discharge 11 months after admission.

I feel sure that this patient had had either a cerebral embolism following sudden right heart failure due to chronic asthma, or cerebral thrombosis, in either case resulting from E.C.T. with secondary fall in blood pressure. It follows that in a case of cerebral arteriosclerosis (which may remain latent till a sudden stress arises) one must curb one's natural enthusiasm for E.C.T. till all the pros and cons have been discussed, and the responsibility for any serious consequences shared with another colleague.—I am, etc.,

Wallerby, Yorks.

Chromobacterium Prodigiosum

SIR.—With regard to the rare infectivity of this saprophyte, and to the case reported by Drs. A. J. Hawe and M. H. Hughes (*Journal*, April 24, p. 968), I would like to draw your attention to a case of purulent meningitis, caused by *Chr. prodigiosum*. Papers about its medical and bacteriological aspects were published in *Harefuah*¹ and later abstracted in *Schweizerische Medizinische Wochenschrift*.²

An infant suddenly showed symptoms of nervous irritation. On a slide made of the purulent cerebrospinal fluid were found, between the leucocytes, Gram-negative bacilli, morphologically and biochemically resembling *Serratia marcescens*. This strain proved *in vitro* to be resistant to sulphaguanidine, sulphadiazine, penicillin, and streptomycin, but sensitive to aureomycin and chloramphenicol. It was also pathogenic to mice.—I am, etc.,

Tel Aviv, Israel.

SIR.—Drs. A. J. Hawe and M. H. Hughes (*Journal*, April 24, p. 968) might like this story, which is true. A middle-aged man arrived in my panel surgery about 20 years ago. He was the forty-fifth patient that evening, and I was getting slightly shy. He began with preamble of apology for wasting my time. When it had lasted for five minutes or so, I suggested that he should come to the point. Taking a long breath, he said: "Well, doctor, not to put too fine a point on it, as you might say, I'm sweating blood." So I said, "Oh, God, so am I. Do go away, there's a good fellow. There are still twenty of you outside." So he said, "S'welp me, doctor, it's true," and took off his shirt, and his axillae were all clotted up with what looked like blood clot, only there wasn't any wound. So I cut off his axillary hair and put it in an envelope and took it to that great man Alexander George Gibson, and next day he said (in the language of those days): "It's *Bacillus prodigiosus*. It's what the crooked priests used to use for doing miracles with." Unfortunately, I had given him a mercurial lotion to wash with and it cured him, so I couldn't demonstrate his case to the Section of Ecclesiastical Medicine at the R.S.M.—I am, etc.,

London, W.1.

RAYMOND GREENE.

Weight-lifting

SIR.—Some years before the war, and before qualification, I held a commission in the Royal Corps of Signals. The rigging of airline poles was by means of a hole in the ground sunk with a 14-lb. (6.4-kg.) sledge and a 36-lb. (16.3-kg.) "jumper." The latter is like a vast cold chisel some 2½ in. (6.4 cm.) in diameter, which is driven into the ground for about a foot (30 cm.). It is loosened by a few side blows, and is then pulled out. A regular part of the instruction for pulling it out was that the signalman should straddle the instrument, with his feet together and his knees bent, and then straighten his knees; arms were to be kept

straight all the time, acting merely as linkages. Drs. Cyriax and Herford may be interested to know of this teaching, which was certainly standard twenty years ago.—I am, etc.,

Manchester, 23.

ROBERT OLLERENSHAW.

Apocrine Gland Infection

SIR,—Concerning the annotation on apocrine gland infection (*Journal*, May 22, p. 1198), I saw such a case in 1951, with chronic inflammation of both axillae, much more severe on the left than the right.

At operation on July 3, 1951, the whole of the scarred area of the left axilla was excised and a free graft inserted. The pathological report was as follows: "Chronic purulent inflammation surrounding epidermal inclusions (probably from old scarring) in axilla; dilatation of apocrine sweat glands conspicuous; little inflammation around follicles except in area of epidermal inclusions."

The inflammation of the right axilla was not so severe in degree but later became worse and the patient requested me to operate, which I did on December 8, 1953, again excising the inflamed area and grafting (in both cases a thin razor graft was used). The pathological report on this specimen showed chronic purulent inflammation surrounding partly epithelial-lined cavities.

The stay in hospital on the first occasion was 17 days, and on the second occasion 12 days. This shows the benefit of excision and immediate grafting.—I am, etc.,

London, E.1.

CHARLES L. HEANLEY.

Doctors and Clergy

SIR,—Owing to increasing interest in the relationship of medicine and religion, a meeting has been arranged at Glasgow on July 3 at 8.15 p.m. in the ballroom of the Central Hotel to discuss the subject. The chair will be taken by the Rev. Dr. Nevile Davidson, Minister of Glasgow Cathedral, and the speakers will be Dr. Arthur Pool, previously Medical Superintendent of the Retreat, and the Rev. J. A. C. Murray, Minister of Tolbooth-St. John's Church, Edinburgh. The general title of the discussion will be "The Spiritual Factor in Therapy." All doctors in Glasgow and members of the Association attending the Annual Meeting are invited.

The Churches' Council of Healing, whose President is His Grace the Lord Archbishop of Canterbury, exists to promote co-operation between medicine and the church, and to co-ordinate the various bodies working in the field of the ministry of healing. With the exception of the Roman Catholic Church, practically all Christian denominations are represented; and the British Medical Association

has recently added to its existing representation. The Archbishops of Canterbury and York have recently appointed a Commission to consider "the theological, medical, psychological, and pastoral aspects of 'divine healing,'" and to increase understanding and co-operation between clergy and the medical profession. The British Medical Association is considering evidence which it has been asked to give to the Commission.

We hope that this meeting in Glasgow will stimulate interest in this matter, and direct it along sound and useful lines. Health, in the full sense of the word, is the specific business of both professions or ministries. They have an equal interest in its promotion and an equal responsibility for the tasks which this entails, health of body and soul being one of the ultimate demands of the human spirit. We wish to discuss and study the implications of the matter in loyalty to scientific method, and with minds open to whatever is revealed through men and women inspired by the spirit of truth. In this way, we believe that we can help to make more effective the work of clergy, doctors, and all who realize that health is God's will for us, and that its achievement is something to be claimed and demonstrated.—I am, etc.,

London, W.1.

J. BURNETT RAE,
Chairman, Executive Committee,
Churches' Council of Healing

SIR,—The correspondence initiated by the Rev. Tony Clemens (*Journal*, April 24, p. 983) has shown the interest there is in the profession in the symbiosis between clergy and doctors, but I would go further than Dr. S. F. Gilbert (*Journal*, May 22, p. 1209), who clearly recognizes that spiritual balm is of more value than phenobarbitone. This catharsis he recommends (I use the technical term) is of value, but if the conception behind his use of the word "balm" is that of soothing or finding solace then this is quite inadequate. It is of such an attitude Karl Marx speaks when he refers to religion as the opiate of the masses.

We must as a profession realize that we are merely the attendants at birth, sickness, and death. It is the man of God who can tell us whence we came and whither we are going, and what is the purpose of life, and, though as a profession we are usually sadly guilty of keeping our patients ignorant concerning life and death, we ought to feel that no matter what our personal religion is we should not keep them in ignorance, if they want to know, of the likelihood of their leaving Time for Eternity in the foreseeable future. It is not spiritual balm we mainly need but courage and faith. As Studdert Kennedy so well put it: "We offer too much the comfort of the cushion and not that of the Cross."—I am, etc.,

Southampton.

A. OAKLEY JOHN.

Homosexuality

SIR,—I am sorry that Dr. C. G. Learoyd (*Journal*, June 5, p. 1326) has written such a letter on homosexuality; just as it seemed to me that the article which he recently published in *The Practitioner*¹ was singularly unfortunate. I wonder why he feels competent to write so dogmatically when I can find no record of him having performed any research on this condition. Dr. Learoyd paints a terrible picture of the dreadful results which must follow any alteration of the law. Surely this must be due to ignorance on his part. The Napoleonic Code which has influenced Continental law, and still rules France, makes homosexuality a crime only when committed with a child, a soldier, or in public so as to cause offence. I have not noticed in my visits to France that the French are more homosexual than we are in England—the reverse seems very much the case. One would like to know upon what facts Dr. Learoyd makes his gloomy prophesies.

My own view is that homosexuality is an illness. Naturally the young must be protected from the abnormal, just as the public must be protected from the dangerous schizophrenic. I think that the homosexual who has urges to

interfere with children and youths should be treated, but if he does not respond he should be confined—not necessarily in prison—for the rest of his life where he can do no harm: not given a sentence of a few years and then released more dangerous than he was before. Homosexuality should always be discouraged, since many young men who think that they are abnormal are really only immature. They are balanced on the razor's edge and often can easily be tipped on the right side into normality. However, surely there is a difference between discouragement—possibly by means of a fine and consequent publicity—and sending a man to prison for 15 years because he has indulged in a sexual act with another man with the other man's consent. This is the present state of the law.

The crux of the whole matter is that greater facilities for treatment should be set up, and these would automatically lead to wider research. We shall cure this illness only as we cure other illnesses, by increasing our knowledge and by applying what we have learned—not by bludgeoning the sufferers, no matter how much we disapprove of them.—I am, etc.,

London, W.1.

CLIFFORD ALLEN.

REFERENCE

¹ *Practitioner*, 1954, 172, 355.

SIR,—While we will all honour Dr. C. G. Learoyd's letter on homosexuality (*Journal*, June 5, p. 1326) for its simple honesty of feeling and expression, I suggest that we should refrain from expressing our "confidence that the committee will report" in any particular way. When we make such statements as this it is because we fear that the contrary may be the case, which may reflect on the competence or trustworthiness of the committee and may prejudice their findings. We all, Dr. Learoyd no less than any of us, are in favour of the proposed investigation, as we are only too aware that the present legislation regarding sexual crime is totally inadequate: instead of protecting any victim from assault or illness it invites the potential blackmailer to commit the darkest crimes. As Christians and physicians all our aim and interest is centred in love and healing, neither in condemnation nor punishment.

In my psychiatric practice I have witnessed at first hand the terrible sufferings of the homosexual patient. Analytical psychotherapy has often helped these patients to a considerable degree, and I hope that it will be possible to make such treatment available to all these sufferers. May the committee, under God's guidance, lay the corner stone to a new and more effective attitude towards homosexuality among the people of this nation and their leaders.—I am, etc.,

Edinburgh.

W. P. KRAEMER.

Herpes Zoster and Chicken-pox

SIR,—The letters of Dr. C. Spencer Whitehouse (*Journal*, May 8, p. 1097) and other contributors on herpes zoster and chicken-pox occurring together prompt me to record the following unusual case which might be termed herpes zoster sine herpes with chicken-pox, or chicken-pox producing a focal nerve cell lesion.

A man aged 69 was first seen on March 22, 1954, complaining of three days' continuous pain in the right upper chest and general malaise. The pain had become progressively more severe. On examination the area of pain corresponded roughly with the cutaneous distribution of the first three thoracic nerves on the right. Skin temperature 99° F. (37.2° C.), pulse 80 per min. He had a right Horner's syndrome of which he was unaware, and a few scattered papules and vesicles on the chest, back, and face. No other abnormality of the nervous system was found. Heart and lungs N.A.D. There was no history of contact with either herpes zoster or chicken-pox.

By March 25 there were lesions scattered over the chest, back, and abdomen, with a few on legs, arms, face, and scalp, and a single vesicle on the soft palate. The lesions included macules, papules, vesicles, and pustules, and in character and distribution the rash was indistinguishable from that of chicken-pox. The chest pain, malaise, and Horner's syndrome were I.S.Q. By

March 29 the pustules were all dry and the rest of the rash was aborting; malaise no longer present, chest pain much less severe and Horner's syndrome unaltered. Seen on April 16 he was free from pain and rash and felt well; the Horner's syndrome was still present but less marked. Chest x-ray, differential white cell count, and B.S.R. were all normal. At no time was there any sign of a herpetic eruption in the painful area.

This patient would appear to have had a viraemia producing a rash indistinguishable from that of chicken-pox together with a focal lesion involving posterior-root ganglia and lateral horn cells in the upper thoracic region.—I am, etc.,

Leeds.

G. W. LEWIS.

Relief for Entropion Sufferers

SIR,—Crutch spectacles for both ptosis and entropion have been known to ophthalmologists for more than 50 years,¹ and, although I am unable to supply references, I think it is probable that sight-testing and dispensing opticians have been making them since the introduction of the curl side spectacles. The use of a crutch spectacle in the treatment of entropion has become less popular during the last few decades because the surgical treatment on the whole is simple and effective.

Dr. Cecil W. C. Robinson's letter (*Journal*, May 1, p. 1037) serves to emphasize that the classical "skin and muscle" operation for senile spastic entropion gives little more than 60% success, even in the best hands. Both the term senile spastic entropion and the principle underlying the "skin and muscle" operation are based upon a misconception. The condition is due not to a spasm of the marginal fibres of the orbicularis oculi muscle, as was believed, but to loss of tone and thinning of the part of the orbicularis supporting the lower border of the tarsus of the lower lid. Stretching of the skin and tarsus appear to be contributory factors. The lower lid is kept in snug apposition with the eyeball by a balance in the tone of two groups of fibres of the orbicularis—namely, the fibres along the margin of the lower lid and those in relation to the lower border of the tarsus. If the marginal fibres become lax, the lid margin falls away from the eye and ectropion occurs. If the fibres supporting the lower border of the tarsus are affected, the lower border falls away from the eye and entropion is the result.

The removal of the marginal fibres, as in the skin and muscle operation, may relieve the condition, but operations designed to increase the support to the lower border of the tarsus are more effective. Wheeler² has designed two such operations, and both are simple to perform and most effective. Severer cases of senile entropion or recurrences, in which the lower lid is very lax, are best treated by shortening it as in the Kuhnt-Szymanowski operation for ectropion.³ The principles of treatment are ably discussed in an article by Kirby.⁴—I am, etc.,

Winnipeg, Canada.

POINTS FROM LETTERS

Prostatic Obstruction

Mr. D. M. O'CONNOR (Launceston, Cornwall) writes: Some time before the war I wrote a letter which you published describing a case in which a male patient had complained of retention of urine after taking amphetamine ("benzedrine"), then a relatively new drug (*British Medical Journal*, 1937, 1, 43). Someone more knowledgeable than I am pointed out (*British Medical Journal*, 1937, 1, 93) that this effect was to be expected because of the similarity of its action with that of ephedrine. As the only reference given in your correspondence on May 1 (*Journal*, May 1, p. 1036) is to a book published two years ago (Hale-White, *Materia Medica*, revised by A. H. Douthwaite, 1952, London), others may be as unaware as he that this topic was at least mentioned 15 or 16 years ago.

Obituary

A. O. FERGUSON ROSS, M.D., D.P.H.

The death occurred at Birkenhead on June 3 of Dr. A. O. Fergusson Ross, director of the venereal diseases clinics of the city and port of Liverpool and adviser in venereal diseases to the Liverpool Regional Hospital Board. He was 59 years of age.

Andrew Oliver Fergusson Ross was born at Scone, Perthshire, on January 21, 1895, and was educated at George Watson's College and at Edinburgh University, graduating M.B., Ch.B. in 1917. He proceeded to the M.D. four years later. After graduation he held house appointments at Edinburgh Royal Infirmary, where he was surgeon to the out-patients department, and at Monkwearmouth and Southwick Hospital, Sunderland. He served in the first world war as a surgeon-probationer in the Royal Navy, later becoming a specialist in genito-urinary surgery and venereal diseases at the Royal Naval Hospital, Haslar. After the war he entered a partnership at Manchester, but soon gave up general practice to become a consultant in Glasgow.

Dr. Fergusson Ross was appointed venereal diseases officer for the city and port of Liverpool in 1926, the year in which he took the Liverpool D.P.H. He also became lecturer in specific diseases in the University and consultant to the Royal Liverpool United Hospitals and the Liverpool Seamen's Dispensary. Soon after the inception of the National Health Service he was appointed adviser in venereal diseases for the Liverpool region. He was a member of the British Medical Association's Venereologists Group Committee from 1951 until his death, and when the Association held its Annual Meeting at Southport and Liverpool in 1950 he served as a vice-president of the Section of Dermatology.

R. J. M. writes: The many learned papers Dr. Fergusson Ross has contributed to the literature showed his brilliant brain, his fearless refusal to edit other men's opinions, and his absolute integrity. Though a man of world-wide repute, he always retained the humility of the true student, and in the art and practice of his profession his own financial interests and personal comforts were matters of least moment. Though struggling through the shallows of the mortal illness which finally engulfed him, his stern sense of duty caused him to prepare and deliver six brilliant lectures for the World Health Organization at Rotterdam. Indeed, he never lost the urge to question, to seek, and to verify, so that all his teaching bore these hallmarks. I think it no exaggeration to say that all who met him were impressed by his deep love of humanity, by his unfailing courtesy, and by his forgetfulness of self. No man ever loved the quiet things of life more than he did—his family, his friends, his garden, the way of the countryside, the thrust and parry of good conversation, and the story that was apposite. He was a true Scot, proud of Scottish virtues and achievements, full of pawky humour, jealous for the reputation of his brother Scot; a man of great probity and judgment who found it more blessed to give than to receive. All his life a sincere Christian, he was received into the Catholic church in 1950. Our sympathy goes out to her who knew the secret places of his heart, to his three sons and only daughter, and to all those who are mindful of

"That best portion of a good man's life,
His little, nameless, unremembered acts
Of kindness and of love."

E. E. P. writes: By the death of A. O. F. Ross we have lost not only one of the most distinguished venereologists of the

day but a man possessed of an exceptionally broad background of knowledge. He was keenly interested in the welfare of seafarers, and generations of them have reason to be grateful for his care and attention. Our friendship, begun in 1926, ripened as the years went on, and my association with him, professionally and socially, tended ever to increase my admiration. He was a great doctor and a delightful host. He had unfailing sympathy and understanding and a great sense of humour, the latter making him a most amusing correspondent. His enthusiasm and burning zeal were contagious. He shone as a teacher and never spared himself on behalf of his students, endearing himself to all. Our hearts are heavy at his going.

KATHLEEN L. PRENDERGAST, Ph.D., B.Sc. M.R.C.S.

The death of Major Kathleen L. Prendergast, R.A.M.C., at Glasgow on June 1 has left an empty place, which will be hard to fill, in the small band of medical women who so faithfully serve the Army. Kathleen Laura Prendergast was born in South Australia on November 17, 1910. She graduated B.Sc., with honours in geology, at the University of Western Australia in 1936, taking the Diploma in Education later in the same year. At first she made a special study of palaeontology and had published work on the subject. After a year as palaeontologist to an oil company she continued her work at Newnham College, Cambridge, on a Hackett Research Studentship, and took the Ph.D. in 1939. She then turned to medicine, studied at King's College Hospital, and qualified M.R.C.S., L.R.C.P. in 1944. After holding house appointments at King's and at Horton Hospital, where she was house-surgeon to Sir William Gilliatt, she was commissioned in the R.A.M.C. and went to Germany in 1945. From 1946 to 1951 "Mick" Prendergast, as she was affectionately known, was medical officer to the 1st Battalion the Black Watch, a most unusual appointment for a woman, and one which she filled with great distinction. It was in this position that she was able to give full scope not only to her undoubted talents as a physician but also to her truly remarkable qualities of character and personality. She threw herself heart and soul into the life of the regiment, and was respected and beloved by all ranks and by their families. In the art of medicine she excelled, for her clinical skill and judgment were built on a sure foundation of sound common sense and deep humanity. She was never guilty of treating the disease rather than the patient, and soldiers—not always the most articulate of mortals—would always confide in her. Her greatest attribute was her absolute integrity both of character and of purpose; never did she deviate by one fraction from the line of conduct she believed to be right. In manner she was decisive, outspoken, and often critical, for she demanded of others her own high standards of conduct. She strode through life without fear, and her bravery in her last long illness was in keeping with the rest of her courageous life. Her funeral took place at Glasgow with full military honours. In addition to the traditional pipe-music laments at the graveside, the tune "Australian Ladies" was played as her coffin was borne from the church on the shoulders of the men of the Black Watch—the regiment she served so faithfully and loved so well.—P. C. M.

The Rt. Hon. ARTHUR GREENWOOD, M.P.
Mr. Arthur Greenwood, who died on June 11, was Minister of Health in the short-lived Labour Government of 1929-31. In the earlier Labour Government

of 1924 he had had a brief experience as Parliamentary Secretary to the Ministry. He brought to the task a sound training in economics, in which subject he had been lecturer in the University of Leeds. His tenure of ministerial office was marked chiefly by his zeal for post-war housing, which was then within the scope of his department. At that time the Ministry of Health seemed to be tenanted by flitting figures, and Greenwood himself was the seventh Minister in 10 years. His place in the niche of fame will not be due to anything he did as Minister of Health, but rather to his initiative as one of the progenitors of the Welfare State, for it fell to him as Minister without Portfolio in the Churchill Government during the last war to appoint what is officially known as the Interdepartmental Committee on Social Insurance and Allied Services, which sat in 1941-2. Thus he briefed the then Sir William Beveridge to work out in detail the plan which has had such momentous consequences in the social life of this country. Greenwood, who had been in Parliament with one short interruption since 1922, had a likeable personality. One of his Labour colleagues, the late Harold Laski, writing of him when he was Minister of Health, described him as an idealist but also as a hard-headed Yorkshireman who would be ashamed if any stranger suspected it. He was an excellent chairman of committees, able to reconcile conflicting views, and he secured in an unusual degree the affection of his party and of very many outside it.

Dr. WILLIAM GORDON, a well-known and highly respected general practitioner of Birmingham, died at his home at Moseley on May 19 at the age of 87. William Gordon was born at Banbridge, Co. Down, on March 15, 1867, and was educated at the former Queen's College, Belfast, taking the Scottish triple qualification in 1897. Just before the turn of the century he settled in Birmingham, when he soon built up one of the largest practices in the Sparkhill district. He was most painstaking in his work and never spared himself where the interests of his patients were concerned, many of whom will always be grateful for his kindness and for the fatherly advice which he was ever willing to give when they were in trouble or ill. He was very popular, too, with his colleagues in the medical profession. Dr. Gordon took a keen interest in public affairs. He entered the city council in 1934 and remained on it for 16 years, during which time he served on the public health committee, and he was chairman of the maternity and child welfare committee. He was also a member of the Birmingham Executive Council. A man of perfect integrity, loyal to his many friends, and always co-operative, the sympathy of all who knew him will go out to his widow and his son, Dr. W. L. Gordon.—W. McM.

Dr. C. CHARNOCK SMITH, who was a well-known and highly respected general practitioner at Hastings for a quarter of a century, died at Stroud, Gloucestershire, on May 11, at the age of 82. Charles Charnock Smith was born at Hulcote, Bedfordshire, on November 25, 1871, the sixth son of the Rev. Boteler Charnock Smith—the spelling of the second name was changed later—and was educated at Bedford and at the Middlesex Hospital, where he was captain of the rowing club. After qualifying M.R.C.S., and, later, senior house-surgeon at the County Hospital, York, from 1900 to 1902. A brief period in practice at York followed before he returned to the south of England in 1904, to Steyning, in Sussex. In 1908 he moved to Woburn, Bedfordshire, where he was in practice for the next twelve years. At Woburn, as later at Hastings, he

was held in high esteem, and he was appointed a justice of the peace for Bedfordshire. During the first world war he served as an anaesthetist at the Duchess of Bedford's base hospital. In 1920 Dr. Charnock Smith finally settled in practice at Hastings, where he soon began to take an active interest in the affairs of the British Medical Association. He was honorary secretary of the Hastings Division from 1922 to 1926 and assistant secretary in 1926-7, re-assuming the duties of the honorary secretary during the last war. He was also chairman of the Division in 1927-8, president of the Sussex Branch in 1930-1, and on two occasions he represented his constituency at the Annual Representative Meeting. It was chiefly owing to the energy and enthusiasm that he brought to the work of honorary secretary that the Hastings Division became such an active unit within the Association. A man of fine presence and with the courteous manner of his generation, Dr. Charnock Smith was deservedly popular with his colleagues and patients, both at Woburn and at Hastings. He left Hastings soon after the end of the last war, during which he carried on the practice single-handed while his two partners were on active service, and he went to live in retirement at Stroud. He is survived by his widow, formerly Miss Hermione Pearson.

Medico-Legal

MINISTER'S DECISION FINAL

COURT POWERLESS TO INTERFERE

A case of some importance in a matter of principle was the subject of a considered judgment by Mr. Justice Cassels in the Queen's Bench Division on June 4. Mr. T. J. Healey, a shoemaker, of Bridgend, Glamorgan, employed by the Morgannwg Hospital Management Committee, in an action against the Minister of Health contested the Minister's decision that Mr. Healey was not a mental health officer within the meaning of the National Health Service (Superannuation) Regulations, 1950.

For Mr. Healey it was contended that the Ministry had designated as a mental health officer all who were employed partly or wholly in mental hospitals, and that as Mr. Healey, in his capacity of shoemaker, instructed mental patients in hospital he therefore came within the Ministry's definition. For the Minister it was submitted that under the Regulations and the National Health Service Act, 1946, his decision was final and therefore the court had no jurisdiction to grant the plaintiff any relief.

The Judgment

Mr. Justice Cassels, giving judgment, said that the case raised a question of considerable importance regarding the rights of a citizen to seek redress in the High Court and to contend that a determination of the Minister was wrong, and the powers of the court to review the determination of a Minister made under an Act of Parliament and statutory regulations. The plaintiff by his action was in effect saying that the Minister had determined wrongly, and was appealing notwithstanding that no appeal was provided for in the Act or the Regulations. His lordship said that, in the light of the authorities and the plain words of the regulations, he was precluded from exercising such discretion as he had in favour of Mr. Healey. "I hope," concluded Mr. Justice Cassels, "that Mr. Healey has derived adequate satisfaction in the knowledge that for this departmental decision against him the Minister is answerable to Parliament." There would be judgment for the Ministry of Health on the preliminary issue, with costs.

Leave to appeal was granted.

INFECTIOUS DISEASES AND VITAL STATISTICS

Summary for British Isles for week ending May 29 (No. 21) and corresponding week 1953.

Figures of cases are for the countries shown and London administrative county. Figures of deaths and births are for the 160 great towns in England and Wales (London included), London administrative county, the 17 principal towns in Scotland, the 10 principal towns in Northern Ireland, and the 14 principal towns in Eire.

A blank space denotes disease not notifiable or no return available. The table is based on information supplied by the Registrars-General of England and Wales, Scotland, N. Ireland, and Eire, the Ministry of Health and Local Government of N. Ireland, and the Department of Health of Eire.

† Includes primary and influenza pneumonia.
‡ Includes puerperal pyrexia.

Vital Statistics

Food-poisoning at Brighton

Fifteen of a group of 22 campers spending the Whitsun week-end (June 5-7) at Brighton were taken ill with symptoms of nausea, headache, shivering, drowsiness, photophobia, and in one case delirium. Gastro-intestinal symptoms were not prominent: vague abdominal pain has been common, but diarrhoea occurred in only one case and vomiting was almost absent. The diagnosis appears to be a true poisoning as opposed to acute infection of the gastro-intestinal tract. The differential diagnoses are botulism (or a mild variant of it), an unrecognized bacterial exotoxin, or a chemical poison such as tri-ortho-cresyl-phosphate. The symptoms suggest some form of neurotoxin. The time of onset of symptoms has been variable, and, in view of there being no common latent period or period of incubation, it seems that the same toxic agent has been ingested at varying times rather than that a single common meal has caused the upset. No cases are known to have occurred outside the group of campers, so the implication is that the toxic agent was restricted to the confines of the camp. There was no common food other than tea or coffee, which limits the extent of the investigation. Three girl guides from East Grinstead and one boy scout from Horley who were ill at the same time were not associated with the above episode and were not, in fact, suffering from food-poisoning.

Week Ending June 5

The notifications of infectious diseases during the week included pneumonia 417, scarlet fever 793, whooping-cough 1,989, diphtheria 18, measles 2,834, dysentery 1,017, acute poliomyelitis 34, paratyphoid fever 6, and typhoid fever 3.

Graphs of Infectious Diseases

The graphs below show the uncorrected numbers of cases of certain diseases notified weekly in England and Wales. Highest and lowest figures reported in each week during the nine years 1945-53 are shown thus -----, the figures for 1954 thus -----. Except for the curves showing notifications in 1954, the graphs were prepared at the Department of Medical Statistics and Epidemiology, London School of Hygiene and Tropical Medicine.

Infectious Diseases

The largest variations in the returns for infectious diseases in England and Wales during the week ending May 29 were increases of 106 for measles, from 1,940 to 2,046, 79 for scarlet fever, from 832 to 911, and decreases of 212 for whooping-cough, from 2,419 to 2,207, and 92 for acute pneumonia, from 520 to 428.

The largest increase in the local returns of measles was 118 in Yorkshire West Riding, from 137 to 255; this was due to a rise in Thorne R.D. from 27 to 116. The other large variations in the trends of measles were a decrease of 64 in Yorkshire North Riding, from 147 to 83, and an increase of 67 in Lancashire, from 397 to 464. Only small fluctuations were reported in the local trends of scarlet fever. The chief features of the returns of the preceding week. The chief features of the returns of the preceding week. The chief features of the returns of the preceding week. The only large fluctuation in the trends of the notifications of whooping-cough was a fall of 83 in Lancashire, from 294 to 211.

16 cases of acute poliomyelitis were notified and these were 7 fewer for paralytic and 3 fewer for non-paralytic cases than in the preceding week. The largest returns were Kent 3, London 3 (Westminster 2), Devonshire 2, Lancashire 2.

1,136 cases of dysentery were notified, an increase of 32 on the total of the preceding week. The largest returns were Yorkshire West Riding 193 (Dewsbury C.B. 46, Otley U.D. 33, Sheffield C.B. 28, Leeds C.B. 16), Lancashire 164 (Bolton C.B. 15, Salford C.B. 15, Liverpool C.B. 11, Manchester C.B. 11, St. Helens C.B. 11, Kearsley U.D. 10), London 142 (Islington 58), Staffordshire 104 (Cannock U.D. 35, New-castle-under-Lyme M.B. 37, West Bromwich C.B. 11), Leicestershire 68 (Leicester C.B. 55), Essex 62 (Burnham-on-Crouch U.D. 26, West Ham C.B. 10), Middlesex 46

(Ealing M.B. 11, Tottenham M.B. 10), Cheshire 43 (Dukinfield M.B. 24, Ellesmere Port U.D. 16), Gloucestershire 42 (Sodbury R.D. 33), Sussex 37 (Brighton C.B. 16), Warwickshire 30 (Birmingham C.B. 14, Coventry C.B. 13), Durham 28 (Blaydon U.D. 17), Surrey 28, and Nottinghamshire 24 (Beeston and Stapleford U.D. 11).

In Scotland the largest returns of dysentery were 207 in Glasgow and 37 in Edinburgh.

Medical News

B.M.A. Library.—The Library will be closed and the library service suspended from July 30 to August 16 while redecorating is being done.

British Association of Paediatric Surgeons.—The inaugural meeting of this newly formed association will be held in London from June 30 to July 2 inclusive. The association was founded at the end of last year, when an invitation to join as foundation members was issued to all British surgeons engaged exclusively in the practice of paediatric surgery. In addition, an invitation to join as associate members was given to the members of the Surgical Section of the American Academy of Pediatrics and to 20 other foreign paediatric surgeons. The president is Mr. DENIS BROWNE (London). The inaugural meeting will include lectures and discussions, clinical demonstrations, operating sessions, an exhibition, and films. There will also be a dinner at the Apothecaries Hall. The morning sessions, which are to be held at the Royal College of Surgeons, Lincoln's Inn Fields, will be open to any doctor, without fee or ticket; anyone wishing to attend the afternoon sessions at the Hospital for Sick Children, Great Ormond Street, is asked to write to the secretary, Mr. DAVID WATERSTON, at Great Ormond Street. The programme of the meeting is as follows:

June 30.—Morning: Discussions on "Congenital Malformations of the Rectum and Anus" (opener, Mr. DENIS BROWNE), and "Acute Intussusception in Childhood" (opener, Mr. R. B. ZACHARY). **Afternoon:** Exhibitions of diagrams, photographs, radiographs, and pathological specimens.

July 1.—Morning: Discussion on "Cardio-oesophageal Syndrome in Childhood" (opener, Miss ISABELLA FORSHALL) and "Hiatus Hernia in Childhood" (opener, Mr. DAVID WATERSTON). **Afternoon:** Exhibition and demonstration of operations. Lecture and film, "Surgery of Conjoined Twins" (Professor IAN AIRD).

July 2.—Morning: Discussions on "Intestinal Obstruction in the Neonatal Period" (opener, Mr. H. H. NIXON) and "Peritonitis in the Neonatal Period" (opener, Mr. P. P. RICKHAM). **Afternoon:** Clinical demonstration on the correction of talipes, congenital dislocation of the hip, scoliosis, and torticollis by controlled movement (Mr. DENIS BROWNE).

British Rheumatic Association.—At a luncheon in London on June 10 an appeal was launched by the British Rheumatic Association for the "British Rheumatic Association Fund." It is estimated that rheumatism in one or other of its forms costs the country £250 million a year in production losses, sickness benefits, and medical care, and that three million working weeks a year are lost from the same cause. The object of the fund is to bridge the gap between advances in medical knowledge and the two or three million rheumatic sufferers by promoting services not yet included in official schemes. One of the chief objects is to provide hostels for early diagnosis and treatment and to interest industry in these hostels, and to help rheumatic patients to do useful jobs in home or factory despite their disability. The chairman of the British Rheumatic Association, the Right Hon. TOM WILLIAMS, M.P., presided at the luncheon, and the speakers were Lord HORDER, who emphasized the need to mobilize public opinion, as often it was only public opinion that could open doors; Sir WALTER PUCKEY, a prominent industrialist, who stressed the vital interest of industry in health; and Dr. FRANCIS BACH. The president, Lord NUFFIELD, was unable to be present.

Canadian Medical Association.—Dr. T. CLARENCE ROUTLEY retired on June 15 from the office of general secretary of the Canadian Medical Association, a position he has held for 31 years. He is succeeded by Dr. ARTHUR D. KELLY, formerly deputy secretary.

Dutch Siamese Twins.—On June 12 Dr. H. L. STRAAT, the leader of a team of Dutch surgeons, successfully separated 7-months-old girl Siamese twins at Leeuwarden in Holland. The twins were joined by an abdominal bridge of rather less extent than that connecting the Kano twins (see *Journal*, April 10, p. 831). Before the operation Professor IAN AIRD showed the Dutch surgeons his film of the operation on the Kano twins.

Medical Insurance Agency.—The annual meeting was held at B.M.A. House on June 3, with Dr. JAMES FENTON in the chair. The report presented by the committee of management showed that 1953 had been another year of record progress, in new business, in premiums, and in service to the medical and dental professions in every field of insurance. Correspondingly, the net profit was also greater than ever before: this is distributable solely to the medical and dental charities, which will benefit by £24,550. The total rebates of premiums granted to clients during the year also reached the highest peak hitherto—namely, £18,900. Retiring members of the committee re-elected were Dr. J. A. BROWN, Dr. J. T. INGRAM, Dr. G. ROCHE LYNCH, Sir HENRY SOUTTAR, and Professor R. J. WILLAN. New members elected were Professor ALAN KEKWICK, of the Middlesex Hospital, and Professor G. A. WISHART, of Glasgow. The engagement of additional staff and the leasing of additional premises to cope with the great expansion of business were recommended and adopted. Dr. JAMES FENTON was re-elected to the office of chairman for the ensuing year, and Dr. HENRY ROBINSON was re-elected as honorary secretary. The proceedings terminated with a hearty vote of thanks to the chairman for his services.

Rajkumari Amrit Kaur.—The High Commissioner for India held a reception in London on June 11 in honour of the Minister for Health for India, Rajkumari Amrit Kaur, who is visiting Britain. The reception was attended by British and Indian doctors. The Rajkumari became Minister for Health in the first Dominion Cabinet in 1947, and in 1950 was President of the Third World Health Assembly. She was for 16 years secretary to Mahatma Gandhi.

Royal College of Surgeons.—The medical directors general of the three armed Services attended the meeting of council on June 10 and presented medals for meritorious work in the medical field. Surgeon Commander J. L. S. COULTER, author of *R.N. Medical History of the War*, received the Sir Gilbert Blane Medal, Brevet Colonel H. D. CHALKE the Mitchiner Medal, and Squadron Leader R. R. L. PRYER the Lady Cade Medal (see also *Journal*, May 1, p. 1047). The following were co-opted to the Council for the year 1953-4 as representatives of various branches of medical practice: *General Practice*, Dr. O. C. CARTER; *Gynaecology and Obstetrics*, Professor A. M. CLAYE; *Otolaryngology*, Mr. MYLES L. FORMBY; *Anaesthetics*, Dr. BERNARD JOHNSON; *Ophthalmology*, Mr. A. B. NUTT; and *Radiology*, Dr. E. ROHAN WILLIAMS. Professor F. C. WILKINSON was invited to act as the representative of *Dental Surgery* on the Council.

Royal College of Surgeons in Ireland.—At a meeting of the College on June 7 Mr. IAN FRASER was elected president, and Mr. A. B. CLERY vice-president. Nineteen others were elected to the Council of the College.

Wellcome Research Laboratories.—Colonel H. W. MULLIGAN has been appointed head of the biological division of the Wellcome Research Laboratories, Beckenham, in succession to Dr. J. W. TREVAN, F.R.S. He will

take up his duties there on September 1. Colonel Mulligan was in the Indian Medical Service from 1923 to 1947, for most of the time in the medical research department. During the war he became consultant malarialogist, Persia and Iraq Command. In 1947 he went to West Africa, where he established the West African Institute for Trypanosomiasis Research. During his last three years there Colonel Mulligan was engaged in planning the co-ordination of medical research activities, and his efforts did much to pave the way for the inauguration of the West African Council for Medical Research which was established by Ordinance a few months ago.

Lady Tata Research Awards.—The Trustees of the Lady Tata Memorial Fund announce that, on the recommendation of the (European) Scientific Advisory Committee, they have made the following awards for research on leukaemia and allied diseases in the academic year beginning October 1, 1954:

Grants for research expenses: Dr. Astrid Fagraeus and Dr. Bo Thorell (Sweden), Dr. Jo Nordmann (France), and Dr. Arunachala Sreenivasan (India) (new award). **Senior Research Fellowships:** Dr. Jørgen Kieler (Denmark). **Scholarships (whole-time or part-time):** Dr. Ragna Rask-Nielsen (Denmark), Dr. Roger Robineaux (France), Dr. Flemming Kissmeyer-Nielsen (Denmark), Dr. Niels Aksel Stenderup (Denmark), Dr. Jørgen Ringsted (Denmark) (new award) and Dr. Jørgen Rygaard (Denmark) (new award). **Part-time Scholarship and grant for research expenses:** Dr. Maxime Seligmann (France) (new award). In addition, the period of tenure of a special scholarship awarded earlier this year to Dr. Gavino Negroni (Italy), for work at the Imperial Cancer Research Fund Laboratories, Mill Hill, will continue until April, 1955.

Royal Commission on Mental Illness and Deficiency.—The evidence given by the Ministry of Health and the Board of Control to the Royal Commission on the Law Relating to Mental Illness and Mental Deficiency has now been published as a pamphlet by Her Majesty's Stationery Office, from which it may be obtained, price 3s. net. This evidence was given on the first day of the Commission's hearings, May 4. Other evidence is to follow.

"Family Doctor."—The Trustees of the Medical Society of Victoria, which is amalgamated with the Victorian Branch of the B.M.A., are using part of the money of a bequest for promoting preventive medicine and healthy living to provide *Family Doctor* to 36 public libraries in Victoria.

Mr. Peyton Beale, honorary consulting surgeon to King's College Hospital, will celebrate his 90th birthday on June 20.

Sir Charles Dodds, F.R.S., received the honorary degree of Doctor of Science at the May Week ceremony at Cambridge.

Sir Rudolph Peters, F.R.S., will receive the honorary degree of Doctor of Science at the Foundation Day ceremony at Oxford on November 26.

Professor J. Trueta was invested with the medal of Chevalier of the Legion of Honour by the French Ambassador at a garden party at Oxford on June 9. The award is for his services to France during the war.

Dr. C. B. B. Downman has been appointed to the University readership in physiology tenable at the Royal Free Hospital School of Medicine, London.

Mr. D. J. Tibbs has been appointed to the post of Reader in Surgery tenable in the Newcastle division of Durham University.

Dr. G. Fitzgerald O'Connor has been elected Mayor of Abingdon, Berkshire.

COMING EVENTS

St. Cyres Lecture.—Dr. GRAHAM HAYWARD will deliver the lecture of the Institute of Cardiology in the Barnes Hall of the Royal Society of Medicine, 1, Wimpole Street, London, W.1, on June 25 at 5 p.m. The subject is "Pulmonary Oedema."

Postgraduate Course in Industrial Ophthalmology.—A course will be held at the Birmingham and Midland Eye Hospital from July 19 to 23. Further information may be obtained from the secretary, Department of Research, Birmingham and Midland Eye Hospital, Church Street, Birmingham, 3.

International Association of Gerontology.—The third congress will be held in London from July 19 to 23. Further information may be obtained from the honorary organizing secretary, Mrs. ANNE HUMPAGE, B.M.A. House, Tavistock Square, London, W.C.1.

SOCIETIES AND LECTURES

A fee is charged or a ticket is required for attending lectures marked ●. Application should be made first to the institution concerned.

Monday, June 21

● INSTITUTE OF OBSTETRICS AND GYNAECOLOGY.—At Hammersmith Hospital, 2 p.m., Professor J. Low (Capetown): Pelvic Inflammation. LONDON UNIVERSITY.—At University College Hospital Medical School, 5 p.m., Special University Lecture by Professor B. T. Mayes (University of Sydney): Post-partum Haemorrhage.

Tuesday, June 22

● INSTITUTE OF NEUROLOGY.—5.30 p.m., Dr. S. P. Meadows: Intracranial Aneurysms. ROYAL COLLEGE OF SURGEONS OF ENGLAND.—3.45 p.m., Arnold Demonstration by Professor R. J. East: The Pectoral Girdle.

Wednesday, June 23

BIRMINGHAM MEDICAL INSTITUTE: SECTION OF PSYCHIATRY.—At St. Matthew's Hospital, Burnwood, near Lichfield, 4 p.m., visit, followed by clinical meeting at 5.30 p.m. INSTITUTE OF DERMATOLOGY.—5.30 p.m., Dr. H. Haber: Acantholysis.

Thursday, June 24

HONYMAN GILLESPIE LECTURE.—At University New Buildings, Edinburgh, 5 p.m., Mr. D. L. Savill: Ankylosing Spondylitis. ● INSTITUTE OF NEUROLOGY.—5.30 p.m., Dr. M. J. F. McArdle: Plexus and Peripheral Nerves. OXFORD UNIVERSITY.—At Nuffield Orthopaedic Centre, 8.30 p.m., Professor C. G. Robt: Present Status of Blood Vessel Grafting. ST. BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Henderson.—On June 7, 1954, at York Maternity Hospital, to Joan, wife of Dr. Walter Henderson, of The Cedars, Huntington, York, a daughter. Kennedy.—On June 5, 1954, in Belfast, to Ismene (formerly More), wife of Dr. C. Cotton Kennedy, of Lisnalea, Craigavad, Co. Down, twin sons. Levy.—On June 6, 1954, to Enid (formerly Glynn), wife of Dr. Basil Levy, a son. Moos.—On June 3, 1954, at Hammersmith Hospital, London, W., to Perin (formerly Jungalwalla), M.B., B.S., D.T.M.&H., wife of Jamshed S. Moos, M.D., M.R.C.P., a daughter—Dena.

DEATHS

Ryrd.—On May 23, 1954, at 7, Cecil Avenue, Sale, Cheshire, Elizabeth Caroline Ryrd (formerly Powell), M.B., Ch.B., M.Sc. Forrester.—On May 28, 1954, Mrs. Gertrude Forrester, M.B., B.S., of Polsteads Farm, Bures, Suffolk, late of Enfield, Middlesex. Frost.—On May 26, 1954, at Tenbury, Worcs, George Hewitt Frost, M.B., B.Ch., Lieutenant-Colonel, I.M.S., retired, aged 87. Leslie.—On May 22, 1954, at "Bellevue," Passage West, Co. Cork, Thomas Christie Cyprus Leslie, O.B.E., L.R.C.P.&S.I. & L.M., Colonel, A.M.S., retired. Midgley.—On May 28, 1954, at "Penhurst," Hale, Cheshire, Patrick Haworth Midgley, M.B., Ch.B., aged 64. Ross.—On May 29, 1954, at Brackens, Dormans Park, East Grinstead, Sussex, Thomas Spinks Ross, L.R.C.P.&S.Ed., L.R.F.P.S., D.P.H., Lieutenant-Colonel, I.M.S., retired, aged 81. Silvera.—On May 19, 1954, at Ibadan, Nigeria, Walter D'Aguilar Silvera, M.B., F.R.C.P.E.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Inheritance of Asthma

Q.—A young married couple are anxious to adopt a baby, and have been told that the mother of one child in whom they are interested suffers greatly from asthma. They want to know the chances of the child developing asthma. The mother has three other children, but by a different husband. Unfortunately I have not been given the medical history of the siblings.

A.—There is, of course, a definite risk of the child of an asthmatic mother developing asthma. The most recent work on the subject is by Schwartz,¹ who writes: "Supposing, for instance, that one of the parents has asthma while the other one is healthy, 50% of the children will be carriers of the gene, but only 40% of the latter—that is, about 20% of the children—will acquire manifest disease. Of these 20% about 13% will develop asthma, while the remaining 7% develop vasomotor rhinitis, Besnier's prurigo, or hay fever. If both parents are asthmatics, 75 to 100% of the children will be carriers of the gene, and 30 to 40% will manifest the disease—as asthma in 20 to 25%." (The remaining 10 to 15% would develop vasomotor rhinitis, Besnier's prurigo, or hay fever.)

Bone Development in Treated Cretins

Q.—In cretinism, bone development is often retarded, as indicated by an abnormally low number of epiphyses visible on x-ray examination—for example, of the wrist. How soon after the institution of thyroid treatment may one expect the normal number of epiphyses to be visible on radiography?

A.—Lawson Wilkins¹ studied the development of six cretins who came under observation between the ages of 11 and 28 months. In four cases the bone age was at the newborn level, in one case (aged 24 months) the bone age was that of 3 months, and in another (aged 28 months) 9 months. In 2 to 4 months after treatment with thyroid, 1-3 gr. (65-200 mg.) daily, centres of ossification appeared, and the bone age rose rapidly towards the normal developmental level and sometimes exceeded it.

T.B. in House Dust

Q.—I have heard of several instances of tuberculosis occurring in families occupying houses previously lived in by tuberculous patients. Is the explanation of this that the bacilli persist in the dust and infect the new arrivals? If so, what disinfection should be carried out to make a house safe after a case of open tuberculosis?

A.—Dried tubercle bacilli can survive in the dark up to four or five months, but in unfiltered north room light only for a matter of days.¹ Dust from room surfaces has been said to be an important source of infection,² but Cruickshank³ has been unsuccessful in isolating tubercle bacilli from the dust in two sanatoria and from tuberculosis wards in a general hospital. He estimates that under conditions of desiccation only 1 to 5% of bacilli remain alive after one to three days. It seems improbable that, with ordinary household standards of cleanliness and hygiene, the occupation of a house previously lived in by tuberculosis patients

The real risk of cycling to such a patient is that of injury from the pedals, etc., to the lower parts of the legs, especially the shins. Such injuries might be serious in the presence of a marked degree of skin congestion. For this reason such patients are advised to wear either elastic stockings, crêpe bandages, or even shin guards for cycling.

Q.—*In what order and at what ages do the functions of a baby's eyes develop? Is a premature baby deficient in its powers of vision?*

A.—Babies begin to appreciate a light within a few days of birth, and then a few weeks later they are usually capable of keeping both eyes directed upon moving objects. As the macula has not nearly completed its development by the time of birth it is impossible for babies to discriminate detail until they are a few months old. The higher grades of binocular vision (including stereoscopic vision) take several years to develop. There is wide variation between different subjects. The vision of a premature baby is less acute than that of a full-term baby because the development of a premature baby's macula is behindhand.

Q.—Recent American literature contains several articles upholding the efficacy of oestrogenic injections in the treatment of acne. What are your views on this form of treatment?

A.—The use of ointments containing oestrogens is neither necessary nor desirable in the treatment of acne under ordinary circumstances. It is sometimes employed with advantage in older patients or very resistant cases, but it is an uncertain measure. There is ready absorption of oestrogens through the skin which may have disturbing systemic effects unless care is taken. The normal proprietary ointments contain 2.5% of oestrogen and should be used only for one week in four or upon some such plan.

Rosehip Syrup.—Dr. C. ALLAN BIRCH (Enfield) writes: The method of preparing syrup from rose hips described in "Any Questions?" (May 29, p. 1277) is a rather laborious way of preserving some of their vitamin C. That boiling was detrimental to some virtuous property (vitamin C) in rose hips was evidently known to our forefathers, as shown in an ancient recipe for rosehip conserve which I came across some years ago. It consisted simply in cutting up the hips (minus seeds) and pounding them with an equal weight of sugar or honey. No heat was used. I made some and was interested to find that the vitamin-C content remained the same a year later.

Correction.—Dr. C. L. COPE writes: "In the paper by myself and Dr. J. García-Llaurado which appeared in the *Journal* of June 5 (p. 1290) we wrongly attributed the adrenal cortical extract 'eucortone' to Burroughs Wellcome and Co. Eucortone has, of course, been made by Allen and Hanburys Ltd. for more than twenty years, and we apologize to the firm for any embarrassment we have caused them by this mistake."

Q.—Is it wise for a man of 69 with bad varicose veins to cycle in moderation? Does not exercise without putting weight on to the limb help to strengthen the muscles and improve the circulation?

A.—In the absence of any other contraindication there would appear to be no objection to a man of 69 with bad varicose veins cycling in moderation. Any form of rhythmical activity of the lower limbs, such as walking, dancing, cycling, etc., tends to diminish the venous congestion caused by varicose veins. For these reasons patients are often much more comfortable when performing these rhythmical activities than when standing, sitting, or walking slowly and un rhythmically. In this way cycling in moderation could be described as "improving the circulation." In addition the improvement in muscle tone would probably increase the subjective comfort of the limbs.

LONDON SATURDAY JUNE 26 1954

A PRELIMINARY REPORT

BY

RICHARD DOLL, M.D., M.R.C.P.

Member of the Statistical Research Unit of the Medical Research Council

AND

A. BRADFORD HILL, C.B.E., F.R.S.

Professor of Medical Statistics, London School of Hygiene and Tropical Medicine; Honorary Director of the Statistical Research Unit of the Medical Research Council

In the last five years a number of studies have been made of the smoking habits of patients with and without lung cancer (Doll and Hill, 1950, 1952; Levin, Goldstein, and Gerhardt, 1950; Mills and Porter, 1950; Schrek, Baker, Ballard, and Dolgoff, 1950; Wynder and Graham, 1950; McConnell, Gordon, and Jones, 1952; Koulumies, 1953; Sadowsky, Gilliam, and Cornfield, 1953; Wynder and Cornfield, 1953; Breslow, Hoaglin, Rasmussen, and Abrams, 1954; Watson and Conte, 1954). All these studies agree in showing that there are more heavy smokers and fewer non-smokers among patients with lung cancer than among patients with other diseases. With one exception (the difference between the proportions of non-smokers found by McConnell, Gordon, and Jones) these differences are large enough to be important. While, therefore, the various authors have all shown that there is an "association" between lung cancer and the amount of tobacco smoked, they have differed in their interpretation. Some have considered that the only reasonable explanation is that smoking is a factor in the production of the disease; others have not been prepared to deduce causation and have left the association unexplained.

Further retrospective studies of that same kind would seem to us unlikely to advance our knowledge materially or to throw any new light upon the nature of the association. If, too, there were any undetected flaw in the evidence that such studies have produced, it would be exposed only by some entirely new approach. That approach we considered should be "prospective."^{*} It should determine the frequency with which the disease appeared, in the future, among groups of persons whose smoking habits were already known.

To derive such groups of persons with different smoking habits we wrote in October, 1951, to the members of the medical profession in the United Kingdom and asked them to fill in a simple ques-

*O.E.D. Characterized by looking forward into the future.
(Leigh Hunt: "He was a retrospective rather than a prospective man")

tionary. In addition to giving their name, address, and age, the doctors were asked to classify themselves into one of three groups—namely, (a) whether they were, at that time, smoking; (b) whether they had smoked but had given up; or (c) whether they had never smoked regularly (that is, had never smoked as much as one cigarette a day, or its equivalent in pipe tobacco, for as long as one year). All present smokers and ex-smokers were asked additional questions. The former were asked the ages at which they had started smoking and the amount of tobacco that they were smoking, and the method by which it was consumed, at the time of replying to the questionnaire. The ex-smokers were asked similar questions but relating to the time at which they had last given up smoking.

The questionnaire was intentionally kept short and simple in the hope of encouraging a high proportion of replies, without which the inquiry must have failed. In a covering letter the doctors were invited to give any information on their smoking habits or history which might be of interest, but, apart from that, no information was asked for about previous changes in habit (other than the amount smoked prior to last giving up, if smoking had been abandoned). It was, of course, realized that the habits of early adult life might well be more relevant to the development of a disease with a long induction period than the most recent habits. On the other hand, we regarded the procedure adopted as justified, not only because of the extreme difficulty of obtaining sufficiently accurate records of past smoking habits, but also because of the experience of our previous retrospective investigation (Doll and Hill, 1952). This investigation, in which nearly 5,000 patients were interviewed, had shown that the classification of smokers according to the amount that they had most recently smoked gave almost as sharp a differentiation between the groups of patients with and without lung cancer as the use of smoking histories over many years—theoretically more relevant statistics, but clearly based on less accurate data.

From their replies to the questionnaire the doctors were classified into broad groups according to age, the amount

of tobacco smoked, the method of smoking, and whether smoking had been continued or abandoned. These groups, based upon smoking habits at the end of 1951, form the "exposed to risk."

To complete the investigation it was necessary to obtain information about the causes of death of all those doctors who had replied to the questionnaire and who subsequently died. Through the courtesy of the Registrars-General in the United Kingdom a form showing particulars of the cause of death has been provided for every death of a doctor registered since the questionnaire was sent out. Each form relating to a doctor who had completed the questionnaire has been extracted and allocated to the smoking group in which that doctor had previously been placed. Hence it has been possible to calculate the death rates from different causes within each of the main smoking categories.

The Exposed to Risk

The questionnaire was sent out on October 31, 1951, to 59,600 men and women on the *Medical Register*. Of the 41,024 replies received, 40,564 were sufficiently complete to be utilized. Of this total, however, 10,017 related to men under the age of 35 and 6,158 to women of all ages. Since lung cancer is relatively uncommon in women and rare in men under 35, useful figures are unlikely to be obtained in these groups for some years to come. In this preliminary report we have therefore confined our attention to men aged 35 and above. The numbers of them who had (a) never smoked regularly, (b) smoked greater or less amounts of tobacco, or (c) smoked cigarettes or pipes or both cigarettes and pipes are shown in Tables I and II. It will be seen that in this population the distribution of

TABLE I.—Amount of Tobacco Smoked. Male Doctors Aged 35 Years and Above

Age in Years	No. of Non-smokers	No. of Men Smoking† a Daily Average of:			Total No. of Men
		1 g.—	15 g.—	25 g.—	
35-44	1,457	2,864	2,888	1,716	8,925

All ages (Crude %)	3,558 (16.7%)	4,504 (21.2%)	13,234 (62.1%)	21,296 (100.0%)

‡ The few men who smoked cigars have been classed as mixed pipe and cigarette smokers.

*The Registrars-General of England and Wales, Scotland, Northern Ireland, the Isle of Man, Jersey, and Guernsey.

smoking habits varies considerably with age. Since cancer incidence also varies greatly with age it will be necessary to use death rates at specific ages, or a rate standardized for age, when comparing the mortality among the men in the different smoking categories.

It may well be that the smoking habits of the 40,564 doctors who replied to us are not representative of the smoking habits of all doctors. One category may have tended to reply more readily than another. We shall not, however, need to use the replies in total but always separately within the four smoking divisions. All that we require are sufficient numbers within each of those divisions.

The Deaths

In the 29 months that have elapsed since the questionnaires were sent out (November, 1951, to March, 1954, inclusive), 789 deaths have been reported among the male doctors who were aged 35 years and above at the time that they completed the questionnaire. Of these deaths, 35 were certified as due to lung cancer; in one further case lung cancer was reported as contributing to death without being the direct cause. We wrote to the doctor certifying the cause of death in each of these 36 cases and asked him to tell us the nature of the evidence upon which his diagnosis was based. The information received is analysed in Table III. There were firm grounds for the diagnosis in at least 33 of the cases, and in only three was the evidence limited to clinical examination.

TABLE III.—Criteria on Which Diagnosis of Primary Lung Cancer was Established

Diagnostic Criteria	No. of Cases	% of Total
I. Histological evidence of carcinoma, plus evidence of the site of the primary tumour from necropsy, operation, bronchoscopy, or radiological examination	21*	58
II. Evidence of the site of the primary tumour from operation (2), bronchoscopy (3), or radiological examination (7), without histological evidence	12	33
III. Evidence from clinical examination only	3	9
All cases	36	100

* 7 squamous-cell carcinoma, 9 oat-cell and anaplastic carcinoma, 3 adenocarcinoma, and 2 cell type undetermined.

Preliminary Results

Amount of Smoking

Death rates from six groups of diseases have been calculated for each of the categories of men classified as non-smokers or as having smoked greater or smaller amounts of tobacco. The rates have been standardized for age (by the direct method), using the total male population of the United Kingdom on December 31, 1951, as the standard population.† The resulting annual rates for each smoking category from all causes of death and from six causes separately are shown in Table IV. It will be seen that the death rate from lung cancer increased steadily from 0.00 per 1,000 in non-smokers to 1.14 per 1,000 among the men daily. A similar but less steep rise is also seen in the death rate from coronary thrombosis (from 3.89 per 1,000 in non-smokers to 5.15 in the heaviest smokers). In the other disease groups the changes in mortality are irregular and, for the most part, small.

The statistical significance of these differences in the death rates can be more easily assessed from the actual numbers of deaths recorded; that is, by comparing them with the numbers which would have been expected to occur in each smoking category if smoking were quite unrelated to the chance of dying of lung cancer. For example, 13 men aged

† Thus for each of the four smoking categories in Table I death rates were separately calculated, for each age group. These age rates were then applied to the corresponding U.K. population in 1951 to reach the death rate at all ages that would have prevailed in the U.K. population if it had experienced the various rates at ages of a particular smoking group.

TABLE IV.—Standardized Death Rate Per Annum Per 1,000 Men Aged 35 Years and Above in Relation to the Most Recent Amount of Tobacco Smoked

Cause of Death	No. of Deaths Recorded	Death Rates of Non-smokers	Death Rates of Men Smoking a Daily Average of			Death Rate of All Men
			1 g.—	15 g.—	25 g.—	
Lung cancer	36*	0.00	0.48	0.67	1.14	0.66
Other cancers	92	2.32	1.41	1.50	1.91	1.65
Respiratory disease (other than cancer)	54	0.86	0.88	1.01	0.77	0.94
Coronary thrombosis	235	3.89	3.91	4.71	5.15	4.27
Other cardiovascular diseases	126*	2.23	2.07	1.58	2.78	2.14
Other diseases	247	4.27	4.67	3.91	4.52	4.36
All causes	789	13.61	13.42	13.38	16.30	14.00

* 1 case in which lung cancer was recorded as a contributory but not a direct cause of death has been entered in both groups.

55-64 when the questionnaire was completed subsequently died of lung cancer. The proportions of all the men in this age group who were non-smokers, smoked 1-14 g. a day, 15-24 g. a day, or 25 or more g. a day were 9.3%, 33.9%, 31.6%, and 25.3%. If the mortality from lung cancer is unrelated to smoking, then the 13 deaths should be distributed to the smoking groups in these ratios. Similar calculations have been made for the numbers of men dying of lung cancer in the other age groups—namely, 1 at ages 35-44, 8 at ages 45-54, 6 at ages 65-74, and 8 at ages 75-84. The total numbers of deaths expected in each smoking category were then obtained by adding the numbers for the separate age groups. The results were as follows:

	Non-smokers	Smokers of a daily average of			Total
		1 g.—	15 g.—	25 g.—	
Observed deaths	0	12	11	13	36
Expected deaths	3.77	14.20	10.73	7.33	36.03

These differences between the observed and expected deaths are statistically significant ($\chi^2 = 8.5$, $n = 3$, $P = 0.04$). We may note, too, that the ordinary χ^2 test of significance fails to take into account the biologically important finding that there is a continuous increase in the proportion of observed to expected deaths as the amount of tobacco smoked increases—a finding which makes it possible to attach a simple interpretation to the results.†

In none of the other disease groups are the differences between the observed and expected number of deaths found to be significant. The continuous change in the ratio between the observed and expected deaths from coronary thrombosis is, however, suggestive.‡ For all causes of death taken together, there is an excess mortality among smokers of 25 or more g. a day and a corresponding deficiency of deaths, almost equally divided, among the non-smokers and the men in the less heavy smoking categories. The differences are statistically significant ($\chi^2 = 8.8$, $n = 3$, $P = 0.03$). When, however, the lung cancer deaths are omitted, the differences are no longer significant ($\chi^2 = 6.5$, $n = 3$, $P = 0.09$).

The distinction between the systematic variation in the mortality from lung cancer with the amount smoked and the irregular (or small) variation observed in the other disease groups studied is perhaps shown more clearly in the Chart.

Method of Smoking

With the very simple form of questionnaire that we deliberately employed we can distinguish the different types of smokers only according to whether they were smokers of a cigarettes, of pipes, or of both cigarettes and pipes, at a given point of time—that is, for smokers at the time they

† The present data provide a special case of the general problem of assessing the significance of a trend, considered by Yates (1948). By his method we obtain $\chi^2 = 7.7$, $n = 1$, $P < 0.01$.

‡ By Yates's method it is statistically significant. $\chi^2 = 4.6$, $n = 1$, $P = 0.03$.

Chart showing variation in mortality with amount smoked. The ordinate shows the ratio between the number of deaths observed and the number expected (as entered in each column).

filled in the questionnaire and for ex-smokers at the time that they had previously given up smoking. It is clear, therefore, that the real numbers of "pure" cigarette smokers and of "pure" pipe smokers must be less, and, almost certainly, appreciably less, than those we have allocated to those groups. Evidence of this was, in fact, provided by some doctors who volunteered additional information that they had in previous years smoked their tobacco by different methods and in different amounts. Any real difference between the risks associated with cigarette and with pipe smoking must therefore be blurred in our figures, since each group will contain men who have also been exposed, in part, to whatever risks may be associated with the other type of smoking.

With that very material proviso in mind, we note that, of the 36 men with lung cancer, 25 had reported themselves as cigarette smokers, 4 as pipe smokers, and 7 as smokers of both cigarettes and pipes. If the method of smoking were entirely unassociated with the risks of lung cancer we would have expected (by the method of calculation described above) these 36 cases to be subdivided in the following proportions: 19.6 cigarette smokers, 7.6 pipe smokers, 8.8 cigarette and pipe smokers. While there is an observed excess of cigarette smokers and a deficit of pipe smokers amongst the deaths, the differences are not statistically significant ($\chi^2 = 3.5$, $n = 2$, $P > 0.10$), and with the present number of deaths it has not been possible to allow adequately for differences in the amount smoked.

In none of the other five disease groups studied was there a significant difference between the observed and expected deaths for the different types of smokers, and the actual differences were, in fact, smaller than those we have reported above for the deaths from lung cancer.

Comparison Between the Results of the Retrospective and Prospective Inquiries

The relative excess of cigarette smokers and the corresponding deficit of pipe smokers in the 36 cancer of the lung deaths amongst the doctors, though not formally significant, at least does not run counter to the tentative conclusion of a lower risk to pipe smokers that we drew from the data obtained from hospital patients. More striking, however, is the similarity we find in the two inquiries in the upward trend of the death rate from cancer of the lung that accompanies increased amount of smoking. In our previous "backward" inquiry we made estimates of the death rates among residents in Greater London in 1950 who had smoked different quantities of tobacco. These estimates we have now recalculated to bring them into line with the slightly different methodology of our present analysis—that is, we have limited the rates to ages 45–74, we have standardized them on the total male population of the U.K. at December 31, 1951, and we have based them upon the most recent smoking history of the patient instead of upon a longer-term history. The results, together with the corresponding figures for doctors, are set out in Table V.

TABLE V.—Standardized Death Rates from Cancer of the Lung Per 1,000 Men Aged 45–74 Years in Relation to the Most Recent Amount of Tobacco Smoked, Estimated from (a) the "Backward" Inquiry into the Histories of Patients with Cancer of the Lung and Other Diseases in London (1952), and (b) from the Present "Forward" Inquiry into the Mortality of Doctors (1954)

	Non-smokers	Smokers of:			All Groups*
		1–14 g./day	15–24 g./day	25 g. +/day	
Standardized rates					
"Backward" study of patients' histories	0.11	1.56	2.20	4.00	1.97
"Forward" study of mortality of doctors	0.00	0.50	0.97	1.45	0.73
Each rate as % of the rate for all groups					
"Backward" study of patients' histories	6%	79%	112%	203%	100%
"Forward" study of mortality of doctors	0%	68%	133%	199%	100%

* The unweighted average of the four rates.

The actual rates for the doctors are, it will be seen, very materially less than those we have estimated for the males of Greater London. On the other hand, there is a remarkable similarity in the increases in mortality from non-smokers to "light" smokers, from "light" smokers to "medium" smokers, and, finally, from "medium" smokers to "heavy" smokers. In the "backward" group the percentages of the average rate are 6, 79, 112, and 203; in the "forward" group they are 0, 68, 133, and 199. Remembering that at these ages we have only 27 deaths of doctors to analyse, the similarity is perhaps too good to be true; it may well be due partly to chance. We would, however, suggest that it is at least reasonable to conclude that there is no incompatibility between the results of the two inquiries in their measurements of the increase of mortality from lung cancer in relation to the increases in smoking.

The incompatibility lies, as observed above, in the actual level of the rates in the two inquiries. Why should the rates for the doctors be so much lower? One important reason—and one which applies to all causes of death and not only to lung cancer—is, we believe, that doctors who were already ill of a disease likely to prove fatal within a short space of time would have been disinclined, or indeed unable, to answer our inquiries. In other words, we should learn of their deaths, but we would have no corresponding completed questionnaire on our files. That this may well be true is shown (a) by the relatively low death rate from all causes that we have recorded—namely, 14.0 per 1,000 per annum, against 24.6 per 1,000 for men of all social classes in the same age group in the U.K. in 1951, and (b) by the

fact that over the 29 months of the investigation there has been a rise in the proportion of the deaths sent to us by the Registrars-General for which we have been able to find a completed questionnaire. If persons sick of a fatal illness were unwilling to reply, or, indeed, never saw our communication, that bias would tend to wear off with the passage of time—as it shows signs of doing.

The question is whether such a bias would differentially affect the mortality of the smoking group. Could it artificially produce the gradient that we have observed with cancer of the lung, and probably with coronary thrombosis, whilst not producing any gradient with other causes of death? For such an effect we should have to suppose that the heavier smokers who already knew that they had cancer of the lung tended to reply more often than non-smokers, or lighter smokers, in a similar situation. That would not seem probable to us. As evidence to the contrary we would also add (a) that, although the numbers of deaths are admittedly very small, we have not seen any obvious change in the lung cancer gradient over the 29 months of the inquiry, and (b) that it would be surprising if a gradient produced in this way so closely resembled the gradient we obtained in our retrospective inquiry.

Other factors than this may have contributed to the lower death rates from cancer of the lung recorded for the doctors. There may well be differences between them and our male London patients in methods of smoking (use of pipes as against cigarettes), and there may be differences in the age of starting to smoke. The London rates are, too, we know, higher than the rates for the country as a whole, and it was from the latter that the doctors were drawn.

The Diagnoses

It might perhaps be argued that physicians in reaching a diagnosis of cancer of the lung have been biased by the patient's smoking history. We have, however, already shown in Table III that there was little doubt of the diagnosis in the great majority of the deaths. That would not, of course, meet the point that the physician might take more active steps to make a diagnosis in a heavy smoker than in a light or non-smoker, but, if that were the case, deaths from other causes would have to be proportionately less in the groups of heavier smokers. There is certainly no sign of that in our present figures, and the steadiness of the upward gradient among smokers would seem to make such a bias very unlikely.

Conclusion

If, as we think, the association between smoking and the disease is real and not due to some such bias as we have discussed, it is likely that the increase in mortality with the amount smoked is, in fact, greater than that indicated by our present figures. The rates we give were calculated from the limited data obtained in reply to a simple questionnaire, and related (apart from non-smokers) to smoking habits at a single point of time. No attention was paid to the changes in smoking history that many men experience—even when we had evidence of such changes. Consequently the group of doctors classified by us as light smokers (smokers of 1–14 g. a day) may well contain an appreciable proportion of persons who have for many years—and possibly for the more relevant years—smoked larger amounts of tobacco; and (perhaps to a less extent) the group of heavy smokers (smokers of 25 or more g. a day) may contain men who for the most part of their lives have smoked much less.

Evidence of these changes was provided, as pointed out previously in relation to the relative risks of cigarette and pipe smoking, by some doctors who volunteered statements on their forms that they had previously smoked different amounts of tobacco. We know, for instance, that among those who subsequently developed lung cancer one had been smoking 25 cigarettes a day and 1 oz. of pipe tobacco a week until he cut down to 12 cigarettes a day on his retirement in 1945. Another had changed from 25 to 30 cigarettes a day to 5 oz. of pipe tobacco a week (equivalent

ORAL CORTISONE THERAPY IN PERIARTHRITIS OF THE SHOULDER

A CONTROLLED TRIAL*

BY

N. J. BLOCKEY, F.R.C.S.

J. K. WRIGHT, F.R.C.S.

AND

J. H. KELLGREN, F.R.C.P., F.R.C.S.

(From the University Departments of Orthopaedic Surgery and Rheumatism Research, Manchester Royal Infirmary)

Periarthritis or capsulitis of the shoulder is a fairly well defined clinical entity characterized by pain in the shoulder region, often extending down the arm, with limitation of all movements at the shoulder-joint, producing in severe cases the "frozen shoulder." One or both shoulders may be affected. There are neither clinical nor radiological signs of arthritis and there is no constitutional disturbance.

The onset of the shoulder lesion is usually spontaneous, but it may sometimes follow trivial trauma, coronary thrombosis, or cerebral vascular lesions. The condition tends to be self-limiting, recovery taking place in six months to three years, but during this period pain may be severe and disability considerable.

Simmonds (1949) found minimal inflammatory changes in the fibrous capsule of the shoulder-joint in cases of this type, and Coventry (1953) believes that the syndrome results from the interaction of pain, disuse, and what he calls the periarthritic personality, but little is really known about the pathogenesis of this condition. It is, however, generally agreed that active movement of the stiff shoulder may expedite recovery, but that it is difficult to persuade the patient to exercise the shoulder adequately, so that adjuvants such as various forms of physiotherapy or x-ray therapy are widely employed. If the shoulder movements are not rapidly regained the stiff shoulder is often manipulated under general anaesthesia.

Sigler and Ensign (1951) and Solomon *et al.* (1951) claimed that short courses of cortisone or A.C.T.H. expedited recovery and reduced the need for manipulation in cases of periarthritis of the shoulder. More recently, Coventry (1953) claimed that a few weeks' treatment with oral cortisone gave most satisfactory

*Based upon a report to the Medical Research Council and Nuffield Foundation Joint Committee on Clinical Trials of Cortisone, A.C.T.H., and Other Therapeutic Measures in Chronic Rheumatic Diseases.

to 20 cigarettes a day) in September, 1951. In another instance, the doctor had described himself as smoking 3½ oz. of pipe tobacco a week, but a friend, who signed the death certificate and had known him for 25 years, stated he had previously been one of the heaviest smokers of both cigarettes and pipe he had ever known. Such factors not only could not produce an exaggeration of the true relationship but must lead to an understatement of it by inflating the mortality among light smokers and reducing the mortality among heavy smokers.

The investigation has not, as yet, continued long enough to show whether there is a relationship between smoking and the mortality from any other disease, but from the preliminary figures it would seem unlikely that there is any as close as that observed with lung cancer. The numbers of deaths, however, from some potentially interesting diseases are as yet small (for example, from cancer of the buccal cavity and larynx and from duodenal ulcer). There have, on the other hand, been a large number of deaths attributable to coronary thrombosis. It seems clear that smoking cannot be a major factor in their production, but the steady increase in mortality with the amount of tobacco smoked recorded suggests that there is a subgroup of these cases in which tobacco has a significant adjuvant effect.

Summary

At the end of 1951 some 40,000 men and women on the British Medical Register replied to a simple questionnaire relating to their smoking habits. On that basis they were divided into non-smokers and three groups of smokers (including ex-smokers) according to the amount they smoked at that time (or when they gave up).

The certified causes of death of those men and women who have since died have been supplied by the Registrars-General of the U.K. over the ensuing 29 months. This preliminary report is confined to the deaths among the 24,389 men over the age of 35.

Though the numbers of deaths at present available are small the resulting rates reveal a significant and steadily rising mortality from deaths due to cancer of the lung as the amount of tobacco smoked increases. There is also a rise in the mortality from deaths attributed to coronary thrombosis as the amount smoked increases, but the gradient is much less steep than that revealed by cancer of the lung. The other groups of deaths so far analysed reveal no gradient (other forms of cancer, other forms of cardiovascular disease, respiratory diseases, all other causes).

The figures for cancer of the lung are in conformity with those found previously in an extensive inquiry into the smoking histories of patients with cancer of the lung and with other diseases.

The death rates of doctors here reported are, almost certainly, artificially low. There is evidence that this is due to a reluctance, or inability, of persons suffering from a fatal illness to reply to the questionnaire. In spite of this defect and the present small numbers of deaths, we thought it necessary, in view of the nature of the results, to lay these preliminary observations before the survivors of the 40,000 men and women who made them possible.

We are most grateful to the British Medical Association for having dispatched the questionnaires and letters to the doctors on our behalf; to the individual doctors for having completed the questionnaires; and to those practitioners and consultants to whom we wrote for details of the evidence on which the diagnosis of lung cancer was made. We are deeply indebted to the Registrars-General of the United Kingdom for information about the deaths of doctors. We also offer our thanks to Dr. P. Armitage, who suggested the use of Yates's method of assessing the significance of a trend, and to Mrs. Joan Bodington, Miss Muriel Greening, and Miss Keena Jones for the onerous work of filing, coding, and enumerating the questionnaires.

results and reduced the frequency of manipulation under anaesthesia. In view of these claims it seems desirable to report the results of a blind trial in which cortisone was compared with an inert substance in a series of 32 cases.

Selection of Patients

For inclusion in the trial a patient had to have periarthritis of one or both shoulders, be over 20 and under 70 years of age, and have no symptoms or signs of disease in other joints. Radiographs of the shoulder had to show no evidence of arthritis or bone disease, the blood sedimentation rate (Wintrobe) had to be under 20 mm. in the first hour, and the chest radiograph had to be within normal limits. Any patient with a history suggesting coronary disease was excluded.

The patients were allocated to two treatment groups, A or B, on a prearranged random order devised separately for those with symptoms of over and under six months' duration, to ensure that cases of short duration would be evenly distributed between the two groups. The treatment register was held by the hospital pharmacist, and the two surgeons admitting patients to the trial and assessing their progress did not know which patients were receiving cortisone until after the whole trial had been completed.

Method of Treatment

Patients allocated to Group B received cortisone acetate suspension made up in syrup to a concentration of 12.5 mg. per ml. The drug was taken orally in four divided doses during the day, and the daily dose was 200 mg. for the first three days, and 100 mg. thereafter until the fourteenth day. The daily dose was then tailed off in decrements of 12.5 mg. every two days, the complete dosage for one four-weeks course being 2.5 g.

Patients allocated to Group A received an inert suspension in similar dosage. This was made from magnesium hydroxide, syrup, and concentrated infusion of quassia. In both appearance and taste it was indistinguishable from the cortisone suspension.

All patients were observed for one week, during which the preliminary investigations were completed; they were then started on the treatment and instructed to exercise their shoulders vigorously, but they were not referred to the department of physiotherapy. At the end of four weeks the patients who had not progressed satisfactorily had their shoulders manipulated under general anaesthesia, the object of the manipulation being to obtain a full range of motion. This manipulation was followed by a second four-weeks course of cortisone or inert suspension, and all cases were followed, where possible, for 18 weeks.

Assessment

The assessment of progress was exclusively clinical and was concerned with pain, range of shoulder movement, and employment status. Both spontaneous pain and pain on movement were recorded in four grades: none (0), slight (1), moderate (2), and severe (3). Range of motion was recorded separately for total abduction, scapulo-humeral abduction, and rotation at the shoulder-joint.

The first assessment was made when the patient was first seen, the second immediately before treatment was started (week 0), and subsequently at the end of the first and fourth weeks of treatment and at the end of the fifth and eighth weeks, and finally at 18 weeks.

Comparability of Treatment Groups

The treatment and control groups were reasonably similar on entry into the trial; thus the 16 patients in the control group comprised 11 males and 5 females whose ages ranged from 45 to 60, with a mean of 52 years; whereas the 16 patients in the cortisone group comprised 7 males and 9 females whose ages ranged from 45 to 70, with a mean of 58 years. The disease duration was not very different.

Thus 15 patients in both groups had a duration of symptoms of one year or less, the mean duration in these 15 patients being 5.1 months in the cortisone group and 6.1 months in the control group. One patient in the cortisone group with a disease duration of nine years made a good recovery, and one patient in the control group with a disease duration of two years made a partial recovery. The mean ratings for pain in the two groups and the mean ranges of shoulder movement both before treatment and on subsequent assessment are shown in Tables I and II, and it will be seen that before treatment the two groups were very similar.

TABLE I.—Mean Grading for Pain

" " rotation	54	+17	+19	+28

lar with regard to pain, but that the cortisone group had by chance a slightly greater range of shoulder movement. Only two patients were completely unable to follow their normal occupation, so that employment status had to be abandoned as a method of assessing progress.

Two patients, both in the cortisone group, were lost to the trial. The first was a man of 69 years with a two and a half months' history of periarthritis who died suddenly from coronary occlusion during the third week of treatment. The second was a woman of 53 years who developed follicular dermatitis during the fourth week of treatment and became a defaulter. As a result of these losses the figures for the cortisone group are based on only 15 cases at the end of the fourth week and 14 cases at the eighteenth week.

Results

At the end of the fourth week 11 of the 16 patients in the control group were not progressing satisfactorily and therefore their shoulders were manipulated. Only 6 out of 15 patients in the cortisone group were thought to require manipulation. In one of these patients manipulation was not carried out as she was found to have mitral stenosis. Thus the total number of patients who had their shoulders manipulated and were given a second course of treatment was 16, of which 11 were from the control group.

The behaviour of the two treatment groups in respect of pain was somewhat different. Both started with an identical rating of 1.4, and both ended with a similar rating at eighteen weeks—0.5 as against 0.6. At week 1, the control group showed little change, the reduction in pain being spread throughout the whole period of observation, while in the cortisone group the main reduction in pain occurred between week 0 and week 1, and although there was a further improvement between week 1 and week 4, there was actually a slight deterioration between week 4 and week 18—that is, after treatment had been stopped. Thus, cortisone appears to produce a reduction of pain during the first week of treatment.

In considering the changes in the range of shoulder movement it must be remembered that the cortisone group started with some advantage. Again the end-result at 18 weeks is extraordinarily similar in the control and cortisone groups, but, as with pain, the two groups behave differently during the earlier periods of observation. Thus, in the cortisone group the ranges of movement showed a greater

increase during the first four weeks than between the 4th and 18th weeks, while in the control group the main increase of range occurred during the later weeks.

Thus, a four-weeks course of oral cortisone would seem to have expedited the relief of pain and the recovery of mobility in the shoulder and decreased the number of patients requiring manipulation.

The behaviour of individual patients differed greatly. Although several patients in the cortisone group appeared to improve remarkably during the first week of treatment, at least one patient was completely unrelieved by cortisone; and in the control group at least one patient improved remarkably, although there were several others who remained unrelieved. Because of this great individual variability none of the separate differences between the cortisone and the control groups reach conventional levels of statistical significance. The apparent differences between the two treatment groups might have been related to their differing sex composition, but it has never been suggested that periarthritis behaves differently in the two sexes, and an analysis of the male and female patients separately showed that their shoulders behaved in a like manner.

Tables III and IV show the effect of manipulation and subsequent re-treatment with cortisone and control suspensions. The control group of 11 patients showed a

TABLE III.—Mean Grading for Pain Following Manipulation

Cortisone group (5 cases)	0.9	1.1	0.7

TABLE IV.—Mean Range of Motion in Degrees Following Manipulation

Relation to Manipulation:	Before	After	
		1 Week	4 Weeks
Control group (11 cases):			
Total abduction	95	+5	+23
Shoulder-joint abduction	36	+14	+2
" " rotation	38	+7	+16
Cortisone group (5 cases):			
Total abduction	92	+9	+13
Shoulder-joint abduction	53	+5	+13
" " rotation	78	+2	+28

marked increase of pain in the first week after manipulation, which in many cases had not subsided completely by the fourth week following manipulation; whereas the cortisone group of five patients showed only slight or negligible increase of pain in the first week after manipulation. In spite of these marked differences in pain, the range of movement following manipulation continued to increase slowly and equally in both groups.

Discussion

The findings of this trial would seem to confirm previous clinical impressions that a four-weeks course of cortisone may expedite the relief of pain and the recovery of shoulder-joint mobility in cases of periarthritis of the shoulder, and that its use may reduce the number of patients subsequently requiring manipulation under anaesthesia. Furthermore, in patients who have their shoulders manipulated, cortisone therapy appears to reduce the amount of pain experienced during the first few weeks after manipulation. However, some patients appeared to derive no benefit from cortisone therapy in the dosage used in this trial, and, since none of the separate differences between the control and cortisone groups reached conventional levels of statistical significance, the value of cortisone therapy in periarthritis of the shoulder still remains to be proved. In considering the possible advantages of cortisone therapy in this condition it must be remembered that in the present trial cortisone was compared with an inert medicine, whereas in other recent trials (Medical Research Council

and Nuffield Foundation, 1954) cortisone has been compared with simple analgesics such as aspirin or tab. codein. co.

The one death from coronary occlusion is probably not attributable to cortisone therapy, since there is a known association between periarthritis of the shoulder and coronary disease; and in a recent three-year study of 78 patients with periarthritis of the shoulder who did not receive cortisone, Meulengracht and Schwartz (1952) report seven deaths, though not all of these were due to coronary disease.

Summary

In a series of 32 cases of periarthritis of the shoulder the effects of a four-weeks course of oral cortisone have been compared with those of an inert control medicine.

Cortisone therapy appeared to expedite the relief of pain and the recovery of shoulder motion and to reduce the number of patients requiring manipulation, but there was great individual variation in response to treatment, so that none of the differences between the two treatment groups reached conventional levels of statistical significance.

We wish to thank Mr. John Charnley for help in initiating this trial and for referring many of the patients.

CARCINOMA OF THE CARDIA

BY

H. J. ANDERSON, M.B., F.R.C.P.

Physician, and Physician Department of Thoracic Medicine,
St. Thomas's Hospital, London

AND

H. B. KELLY, M.D., M.R.C.P.

Lecturer in Medicine, St. Thomas's Hospital, London

The diagnosis of carcinoma of the cardiac end of the stomach is notoriously difficult in the early stages and, now that surgical resection via a transthoracic approach is a feasible proposition, it is one which it is more than ever important to make. The chief reason for this difficulty is that patients seldom present themselves until they complain of dysphagia, a state of affairs which signifies that there has been involvement of the entry of the oesophagus into the stomach, or that there is spasm of the sphincter secondary to the lesion. True, the lesion may arise at or very near the cardiac orifice and thus cause the patient symptoms at an early stage, but the diagnosis even then can be extremely difficult to establish by such means as oesophagoscopy and barium x-ray films.

Review of the Literature

Most papers concerning carcinoma of the cardia deal with the radiological aspects and the difficulties in arriving at a diagnosis. Garlock (1941) reiterates these and stresses the frequency of dysphagia, often painful, as the presenting symptom, occurring at whatever stage the cardiac orifice is involved. In addition there may be vague indigestion and loss of weight. He mentions persistent back pain, situated to the left of the spine at about the level of the eleventh or twelfth thoracic vertebra as a late symptom. This was not a feature of the cases in the present series. He presents 15 of his own cases, 13 of which had dysphagia.

Oesophagoscopy definitely established the diagnosis in 14. All 15 cases came to operation, but only five proved to be operable by resection with intrathoracic oesophago-gastrostomy. Two of the five died within a few days of operation, and the other three improved symptomatically but had not been followed up long enough to assess their ultimate outcome.

With regard to the x-ray diagnosis of this condition, Garlock states that in most instances the presence of a tumour will be clearly demonstrated by the usual methods of examination, and that persistence on the part of the radiologist will in most cases demonstrate the growth. This has quite definitely not been our experience, and there is no reason to suppose that the diligence of the radiologists was any less than it should have been.

Numerous other authors discuss the radiological difficulties. They make various points, to be remembered when attempting to detect the presence of a carcinoma at the cardia, but most of them apparent only when the growth has reached a considerable size. These points include, for instance, increase in the distance between the upper pole of the stomach and the diaphragm, a mass visible in the gastric air bubble, dilatation of the lower oesophagus, rigidity of the lesser curvature side of the cardia, etc.

Kinsella (1949) reviewed 10 cases, of which only one had been recognized radiologically. Some of the others had repeated barium meals which were reported as normal. He gives details of his radiological technique and stresses the importance of examination in the supine position, in the anterior, posterior, and lateral planes.

Allison and Borrie (1949) reviewed from the point of view of treatment and prognosis a series of 310 patients with malignant obstruction at the gastro-oesophageal junction who had been treated at Leeds. They condemn gastrostomy and jejunostomy on the ground that they do not relieve the patient's distress, and consider dilatation of the stricture and insertion of a Souttar tube to be much more satisfactory. They suggest that carcinoma of the stomach should be treated by total gastrectomy and block dissection of the lymphatic bed, including the spleen and the tail of the pancreas. Radical removal was practised only after June, 1942, and 108 of their patients had been subjected to an operation since then. Of these only 24 were suitable for radical resection. Seven of them died post-operatively, and a further three from metastases within seven months of operation. The remaining 14, alive at the time the paper was written, had survived for periods varying up to 25 months, but the average was only eight months.

Present Investigation

The course of 26 cases of carcinoma of the cardia at St. Thomas's Hospital during the past few years is reviewed, and the very high incidence of dysphagia as a presenting symptom is noted, in addition to the difficulties involved in establishing the diagnosis at a stage early enough for complete and successful surgical resection. Nearly all the cases were proved histologically to be adenocarcinoma. Cases which proved to be squamous-cell carcinoma have been excluded, as they were thought to be primarily oesophageal.

Age and Sex.—The 26 cases comprise 15 men and 11 women. There was a difference in the average ages for the two groups, that for men being lower than for women—57 against 65. The age spread for men was 40 to 73, and that for women 43 to 73.

Symptoms.—The duration of symptoms before attending hospital was very variable, ranging from seven weeks to one year, but was most often between two and six months. We would stress that a history of many months is by no means uncommon, as in Case 1. The relative frequency of the main symptoms on first attendance was as follows: dysphagia, 24 cases; regurgitation, 21; pain on swallowing, 12; constant pain, 4; loss of weight, 23; frank haemorrhage, 1 (but 2 more later had haematemesis).

Dysphagia (Cases 2 and 3).—Of the 26 patients, 24 complained of food sticking in the lower sternal region; the disability was worse for solids than for liquids. Often pain was felt at the same time, and regurgitation gave immediate relief. In three patients the dysphagia was curious in that it was related to posture; in two of these food stuck more completely in the erect posture or when leaning forwards, whereas it was greatly relieved when they were lying on their backs; and, indeed, one patient (Case 6) had adopted this position for his meals. In the third patient dysphagia was relieved by leaning forwards. In our view postural dysphagia is pathognomonic of a neoplasm of the fundus of the stomach.

Pain.—The commonest type of pain is one which is felt on swallowing in the xiphisternal or retrosternal regions (Case 4), and may radiate to the right or left costal margins, the left breast, or either scapular region. It is not felt apart from swallowing. This pain seems to be identical to the pain so commonly felt by patients with hiatus hernia and free-reflux oesophagitis, and we would ascribe its origin to a similar cause—that is, lower oesophageal inflammation. In some cases an entirely different pain is present, as in Case 5. It is constant and unrelated to meals or swallowing, and may be quite continuous, though in one case it was felt only at night. Its situation is similar to the foregoing pain. In our experience it is very suggestive of a neoplasm involving the lower oesophagus. Three of the four patients who complained of this pain had at operation undoubtedly involvement of the mediastinal structures adjacent to the lower oesophagus. Garlock stated that pain which was felt in the back to the left of the eleventh and twelfth thoracic vertebrae was a not uncommon symptom in his cases, but we have not met it in any of ours.

Indigestion.—Although in a large number of cases the lesion must have been present for many months before involving the cardiac orifice, with consequent dysphagia, it was unusual for there to be any preceding history of indigestion.

Appetite.—Appetite was generally well maintained, and several complained of hunger but were afraid to eat because of painful dysphagia.

Examination.—Findings on clinical examination were generally very few, other than some evidence of loss of weight. A mass was palpable in the epigastrium in only six cases.

Radiology.—Before discussing the radiological diagnosis it would be well to consider certain points. Firstly, the obstruction at the cardia may be complete enough to prevent barium from entering the stomach in sufficient quantity to outline the fundus satisfactorily, and this may be present when the neoplasm is still small, so that, although the fundus is filled, no satisfactory proof of a filling defect is obtained. The obstruction may produce an appearance identical to that seen in primary achalasia (Cases 3 and 6, and Figs. 4 and 5), or even "corkscrew" lower oesophagus—for example, Case 1 and Fig. 2. Thus in the absence of any other demonstrable abnormality the true diagnosis may be missed. Secondly, as there is a partial obstruction at the cardia the "hun-

FIG. 1.—Carcinoma of the cardia, showing narrowed segment eccentrically placed in relation to the oesophagus, with irregularity of the stream of barium beyond.

gry" stomach may pass the barium through the pylorus into the upper intestine so rapidly that a sufficient residue is not obtained to get an adequate outline of the fundus.

If these difficulties are taken into account, the main findings at a barium meal which will suggest the diagnosis of a neoplasm of the fundus involving the cardia are: (1) An irregular filling defect at the oesophago-gastric junction, which may, however, be indistinguishable from a primary lower oesophageal growth. (2) Deformation of the fundus gas shadow by a large neoplasm, but it must be remembered that the outline of this gas shadow is often irregular, especially where the rugal folds are heavy. (3) An irregularity or splitting of the stream of barium as it passes through the cardia, or a narrowed segment at the cardia which may be placed eccentrically in relation to the distended oesophagus (Fig. 1). This may produce the appearance of a "fixed shelf" in this region. (4) "Half shadowing" at the shoulder of the narrowed segment.

Radiological investigation with barium revealed the true cause of the obstruction in 18 patients, in the others (except for one, who was not x-rayed) there was obstruction at the lower end of the oesophagus, but the appearances were reported as those of achalasia of the cardia or just "narrowing" rather than neoplasm.

Oesophagoscopy.—Oesophagoscopy was at times equally misleading or uninformative, as in Case 7. It was performed in only 16 of the cases, and showed a carcinomatous obstruction at the lower end of the oesophagus in 11 of them; in these biopsy confirmed the diagnosis. In one of the other five oesophagoscopy was performed twice with an interval of 11 weeks, and appeared quite normal on each occasion, despite the fact that the patient complained of continued dysphagia. In another the oesophagus and cardia appeared normal, but bougies passed through the cardia were gripped by some obstructing lesion beyond. In three others an obstruction was found at the lower end of the oesophagus, but no definite evidence of carcinoma was seen, and it was thought more likely to be due to achalasia than to a neoplasm. It is interesting to compare these results with those of Garlock's series, in which oesophagoscopy definitely established the diagnosis in 14 out of 15 cases. Estimation of the gastric acidity was attempted in only a few cases, and usually the obstruction made it impossible.

Case 1

An electrical engineer aged 49 attended hospital on July 31, 1950, complaining of increasing difficulty in swallowing for one year. Food seemed to stick in the suprasternal notch. There was no pain and the difficulty was greater for solids than for fluids. He had lost a few pounds in weight, and had recently regurgitated his food. There were no relevant findings on clinical examination.

FIG. 2.—Case 1. "Corkscrew" lower oesophagus with a filling defect in the fundus.

Barium x-ray examination showed obstruction in the lower third of the oesophagus, with dilatation above this level. This part had a "corkscrew" outline, and the appearance of the mucosal folds suggested the presence of

stomach above the diaphragm. In the fundus of the stomach there was an irregular filling defect, the appearances of which suggested a neoplasm (Fig. 2).

He was put on a semi-solid diet and was observed as an out-patient. He improved symptomatically to a great extent, but when seen on December 4 he appeared to be extremely pale and was admitted the same day. He had suffered a head injury at work three weeks previously, following which he had lost three pints (1.7 litres) of blood or more (his estimation) from the scalp laceration. Apart from this he had spat up a mouthful of blood on two occasions a week previously. He denied frank melaena.

His haemoglobin was 20%. No abdominal mass was palpable. Following blood transfusion, oesophagoscopy was carried out. At 35 cm. an ulcerated stricture was seen, the lumen of which was 2 mm. in diameter. On the posterior wall just above the stricture was an area of erosion which bled easily. Gastric contents were seen to regurgitate, and the macroscopic appearances were reported as being those of reflux oesophagitis with stricture formation. Histological examination of the biopsy specimen obtained, however, showed the appearances of a moderately well differentiated adenocarcinoma.

The patient was found to have a histamine-fast achlorhydria. He was advised to continue with his semi-solid diet, and so long as he did so his dysphagia hardly troubled him. Observation was continued on him as an out-patient, but recurrent haematemesis necessitated his admission on two occasions for blood transfusion.

On March 29, 1951, thoracotomy was carried out. He was found to have pleural secondaries from a large growth involving the lower 4 in. (10 cm.) of the oesophagus and the fundus of the stomach. Even a palliative operation was regarded as out of the question.

He recovered fairly well from the operation, and was discharged again. He was finally admitted on June 3, 1951, with complete oesophageal obstruction and a left pleural effusion. He died on June 25.

At post-mortem examination there was a mass of growth filling the upper third of the stomach, spreading up the oesophagus. A mass of secondary growth surrounded the aorta and oesophagus just above the diaphragm. The liver contained numerous metastases, and a mass of growth had infiltrated the wall of the portal vein in the middle of the gastro-hepatic omentum and had extended along its lumen to its bifurcation.

Case 2

A housewife aged 43 was admitted in October, 1950, complaining of epigastric pain for four months which had

gradually become worse. It came on any time, and was unrelated to meals or swallowing. It was aggravated by stooping and relieved by lying down. She also noticed that food, particularly solids, seemed to stick in the xiphisternal region, and she complained of vomiting. She had lost weight.

On examination there was a slight tenderness in the epigastrium, but no mass was palpable. A barium swallow showed some hold-up at the lower end of

FIG. 3.—Case 2. Obvious filling defect at the lower end of the oesophagus and cardia.

the oesophagus, and a filling defect at the cardia was visible (Fig. 3). She was found to have a histamine-fast achlorhydria. No oesophagoscopy was performed.

At thoracotomy the oesophagus appeared normal, but a hard mass was palpable through the diaphragm in the stomach. It occupied the lesser curvature and was fixed posteriorly. The growth was considered irremovable, but the fundus of the stomach was brought up through the diaphragm and anastomosed to the side of the oesophagus. After operation her swallowing was much improved, but her convalescence was interrupted by a recurrent left pneumothorax.

She was discharged four weeks after operation, but was admitted to another hospital following a haematemesis. She was reported to have metastases in the liver. She went steadily downhill and died on April 3, 1951, nine months after the onset of symptoms and five months after operation. No post-mortem examination was made, and thus the histology of the tumour was not determined.

Case 3

A photographic mechanic aged 46 was admitted on October 1, 1951, complaining of having had for ten weeks a burning pain under the lower end of his sternum on swallowing. This became progressively worse, and food seemed to stick in this region. The difficulty was eased slightly by leaning forwards. He did not regurgitate his food, but he would sometimes bring up some watery material after swallowing. He had lost about 14 lb. (6.4 kg.) in weight in three months.

Examination was unrevealing except that some weight loss was apparent. No abdominal mass was palpable and there was no tenderness. A barium swallow, repeated on three occasions, showed only the appearance of achalasia of the cardia, unaffected by octyl nitrite but slightly relaxed by leaning the patient forwards (Fig. 4).

FIG. 4.—Case 3. Obstruction in the lower oesophagus originally reported as showing the appearance of achalasia only.

On operation, oesophago-gastrostomy was performed. A large carcinoma was found to involve the lower part of the oesophagus and aorta, fundus, and posterior wall of the stomach, and was too extensive for removal. No biopsy was taken as it was thought that this would lead to haemorrhage or spread to the pleural cavity.

The immediate post-operative period was satisfactory, but he died at home on January 9, 1952. Necropsy was not performed.

Case 4

A police constable aged 40 was admitted to another hospital on August 25, 1952. He had for about three years been troubled with indigestion, which had consisted mainly of belching, but three months before admission he began to notice a high retrosternal pain on swallowing which would be immediately relieved by vomiting all the food he had just eaten.

A barium swallow showed dilatation of the lower third of the oesophagus, with a large irregular filling defect at

its lower end. The appearances were those of a carcinoma which appeared to be involving the fundus as well.

Oesophagoscopy showed a bleeding ulcer at the level of the diaphragm. Biopsy proved this to be an adenocarcinoma of the stomach. He was transferred to St. Thomas's Hospital on September 12 for radical resection of the growth. This was performed on September 22, and almost the entire stomach from just proximal to the pylorus and the lower part of the oesophagus to a point well above the growth, including the adjacent diaphragm, spleen, and tail of the pancreas were removed. The gut was reconstituted with an end-to-side oesophago-jejunostomy.

The growth arose from the fundus of the stomach and ulcerated out the posterior wall of the lower part of the oesophagus. On microscopy it was seen to be a well-differentiated tubular columnar-cell carcinoma. No carcinoma was seen in any of the lymph nodes removed.

He made an uneventful recovery from the operation and was discharged in good general condition on October 24, and he was still alive at the time of writing, one year later.

Case 5

A labourer aged 60 was admitted on June 10, 1949, having for two months vomited immediately after eating. He noticed difficulty with swallowing and complained of an aching lower sternal pain, which occurred any time and was not related to food. It radiated to the interscapular region. He could manage fluids better than solids. He had lost about 28 lb. (12.7 kg.) in weight.

Apart from his thinness, there were no abnormal physical signs and no mass was palpable in his abdomen. A barium swallow showed no hold-up in the oesophagus, but the cardia did not look normal, and the radiologist was suspicious of the presence of a carcinoma.

At oesophagoscopy a friable growth was seen at 40 cm. A bougie was passed without difficulty. No biopsy was taken.

Operation was then performed. Through a thoraco-abdominal approach the growth, about the size of a tangerine, was identified in the fundus of the stomach near the cardia. The oesophagus up to 2 in. (5 cm.) above the growth, the entire stomach, and the spleen were removed and oesophago-jejunostomy was performed. On opening the stomach a thick ulcer 4.5 cm. in diameter was found at the cardia and spreading up in the lumen of the oesophagus. On section it proved to be a well-differentiated cuboidal and columnar-cell carcinoma.

The patient recovered uneventfully from the operation and was discharged from hospital three weeks later. His swallowing was normal, and he was symptom-free except that he had to eat small meals. A barium swallow showed a satisfactory anastomosis.

He remained well for a further three months, when he began to get various pains, mostly in relation to the lower part of his spine. He continued to swallow well. X-ray examination of his spine showed no bony abnormality, but he was given a course of radiotherapy to the sacral region. He was only slightly improved as a result of this, and went steadily downhill. His swallowing was unsatisfactory, and a barium swallow showed no evidence of local recurrence. He died at home on February 9, 1950. Necropsy was not performed.

Case 6

A butcher aged 56 was admitted on July 21, 1952. He complained that for ten weeks he had noticed food sticking in the xiphisternal region. The dysphagia had increased and at the time of admission the obstruction was almost complete. The difficulty was lessened if he lay on his back, so that he had adopted this position for his meals; it was much worse if he leaned forwards. He had been regurgitating most of his food, and had lost about 42 to 56 lb. (19 to 25.4 kg.) in weight.

He was slightly tender in the epigastrium, but no mass was palpable. A barium swallow showed what appeared

JUNE 26, 1954

to be a spasm at the lower end of the oesophagus. It was not possible to examine the stomach, as not enough barium entered it (Fig. 5).

Oesophagoscopy showed an obstruction at 40 cm. which had the appearances of achalasia, though the possibility of carcinoma of the

FIG. 5.—Case 6. Carcinoma of cardia. X-ray appearances reported as being those of spasm.

the operation it seemed that the anastomosis was leaking. His condition deteriorated, and he died on August 6.

A post-mortem examination was not carried out, but the microscopic appearances of the tumour removed at operation were those of a well-differentiated adenocarcinoma.

Case 7

A man of 62 was admitted on September 3, 1951. He complained of dysphagia for 10 weeks and of the loss of 28 lb. (12.7 kg.) in weight.

No abnormality was found on clinical examination and oesophagoscopy on September 5 was normal to 40 cm. A barium swallow showed a hold-up at the cardia, the appearances of which were those of spasm rather than new growth.

He was discharged, but was readmitted for further oesophagoscopy on November 23. Again the oesophagus appeared normal, though possibly slightly dilated. The oesophagoscope passed into the stomach without hindrance, and no lesion was seen in the first 1½ in. (3.8 cm.) of stomach. A further barium swallow again showed obstruction at the cardia, and it was thought that the appearances were those of a neoplasm of the fundus involving the cardiac orifice. A histamine test showed complete gastric achlorhydria.

On December 12 a laparotomy was carried out. A large neoplasm of the cardiac end of the stomach, which was invading the diaphragm, was found. It was not considered operable, and a gastrostomy was performed.

He was discharged from hospital on January 10, 1952, and was seen as an out-patient two weeks later. Though asked to return after a month he did not do so.

Discussion

It is not part of our intention to discuss treatment or prognosis, as these are fully dealt with in other reviews, but we concur with the uniformly depressing picture these present. However, we wish, by considering the clinical and radiological aspects of the disease, to stress important diagnostic features, close attention to which will suggest the diagnosis earlier in the course of the illness. Unfortunately, the growth is usually completely silent until dys-

phagia occurs and indicates that the gastro-oesophageal junction has been involved. Even then it is quite a step from this presenting symptom to ultimate diagnosis and one with many pitfalls, as both radiology and oesophagoscopy can be misleading.

It is essential not to attach too much weight to a negative x-ray report, as even with the utmost perseverance the radiologist may be unable to demonstrate the growth. There is, unfortunately, no secret of success. The physician must from the history suspect the diagnosis and inform the radiologist of his suspicions, and the radiologist must always bear in mind the possibility when investigating any case of dysphagia resulting from an obstruction at the lower end of the oesophagus, where there is no apparent cause for it. "Achalasia" in anyone past middle life must be especially suspect. The smaller the lesion the harder it will be to diagnose.

Summary

A series of 26 cases of carcinoma of the cardiac end of the stomach is presented. Symptoms, radiology, and results of oesophagoscopy are discussed.

The prominence of dysphagia as the presenting symptom is due to the fact that the growth is usually silent until the gastro-oesophageal junction is involved.

Even the most careful radiology may fail to reveal the stomach carcinoma as the cause of the obstruction at the lower end of the oesophagus, and oesophagoscopy may at times be misleading.

Largely as a result of this tardiness of the lesion to declare itself, and partly because the significance of the symptoms in middle-aged patients is still not clearly recognized, the results of surgical treatment are extremely bad.

We are indebted to the members of the staff of St. Thomas's Hospital for allowing us to include their cases in this series; to Dr. J. W. Pierce for advice about radiology; and to Mr. K. G. Moreman for the x-ray photographs.

As part of its policy of studying the needs of old people, the Nuffield Foundation has asked Mr. F. LE GROS CLARK to make studies of the factors affecting continued employment of elderly workers. By permission of the London County Council, the first study was carried out in the maintenance depots of its Housing and Valuation Department, and a report has been published on the findings in 320 of the department's ageing maintenance workers. It is hoped to follow this with a series of inquiries in other industries. The purpose is to find out, if possible, what actually happens to men as they age under various industrial conditions—in building, transport, mines, etc. In the study now reported the conditions were very favourable for the retention of elderly craftsmen and labourers, because in the immediate post-war years many of the local authorities had some difficulty in securing young labour for their building staffs. Most of the 320 men studied were traced from the age of 60 down to the end of their working lives as building employees, though some of them may possibly have found further employment. They were all on maintenance and repair work; and this is usually to the advantage of an elderly man. They were all apparently quite fit for the job as they approached their sixties. But of every hundred men who were fit at 60, not many more than seventy were still fit as building workers by 66 years. After that the decline in numbers through age or ill-health was steady and continuous, so that at 70 years only about thirty of the original hundred men were still in the labour force. Most of the men who remained after their mid-sixties could probably not have stood the pace of work in modern housing construction.

CARCINOMA OF THE OESOPHAGUS

A REVIEW OF FIFTY CASES

BY

M. MEREDITH BROWN, F.R.C.S.

Formerly Chief Assistant (Thoracic) to Surgical Unit,
St. Thomas's Hospital

Fifty patients with malignant disease of the oesophagus were referred to the Thoracic Surgical Unit of St. Thomas's Hospital during 1951 and 1952. All the patients referred are included in this analysis, so it is an unselected series, except for the fact that they were sent to a surgeon. In one-third of the cases the involvement of the oesophagus was secondary. These are included because from the point of view of symptoms, treatment, and all clinical aspects the lesion was essentially oesophageal.

The lethal nature of this disease and its normally rapid progress are indicated by the fact that at the time of writing (January, 1954) only six of these patients are alive. It is some consolation that five of these have been treated by radical surgery and the sixth by radiotherapy. The various palliative treatments attempted were often successful in relieving the most distressing symptom, inability to swallow, and probably in prolonging life by a few months. They were, however, accompanied by a very high mortality, justified only by the imminence of death from starvation, cachexia, or secondary bronchopneumonia.

There were 29 men and 21 women affected. Over half of them were over 60 years of age; three were under 40. The youngest patient was 37 when her first symptoms appeared. This series shows the same high incidence in old age as does the longer one reported by Raven (1948), but not such a preponderance of males as his did. No patient gave a family history of oesophageal cancer or a past history suggesting oesophageal trauma.

Symptoms

The commonest symptom of oesophageal cancer is difficulty in swallowing, which nearly all patients eventually develop. Forty-four of these patients complained of dysphagia when they were first seen, and this was usually the symptom which had led them to seek advice. The dysphagia is persistent and progressive but may fluctuate, though remissions are short-lived, and seldom complete. Typically, difficulty is first noticed with a poorly masticated piece of meat or a dry biscuit. Dysphagia gradually advances until only thin fluids can be swallowed; finally it becomes complete and even saliva must be regurgitated. The patient may locate the level of the obstruction accurately, but this cannot be relied on, as he will often point to a spot higher than his lesion, probably because distension of the oesophagus occurs here. In no case did the patient point to a lower level. Dysphagia is usually due to narrowing of the lumen of the oesophagus by the growth, which most commonly results from scirrhous infiltration of the wall, but sometimes from internal obstruction by a proliferative lesion or occasionally from external pressure. Dysphagia may also occur before there is appreciable narrowing, when it is due to interference with the normal muscular action.

Almost as common a symptom as dysphagia is loss of weight, of which 42 patients complained when first seen. It is primarily due to malnutrition; although four patients who had lost weight did not complain of dysphagia, they were all found on investigation to have oesophageal obstruction.

Thirty-five patients complained of regurgitation of food or of vomiting. Although patients might say they vomited, careful questioning usually confirmed that they were in fact regurgitating undigested food from the oesophagus above the obstruction. The regurgitation often caused coughing. Mild or occasional cough on swallowing is due to overflow of saliva or food particles into the trachea. Severe and persistent cough on swallowing usually indicates a fistula between oesophagus and trachea or bronchus, but it may also be due to incompetence of the glottis from paralysis of one or even both vocal cords caused by invasion of the recurrent laryngeal nerves by the growth, or to invasion of the larynx itself. Either complication indicates that radical operation is impossible.

Twenty-five patients complained of pain, usually felt only on or after swallowing, but sometimes as a dull ache in the back and beneath the sternum. The site of pain was an accurate indication of the level of the lesion. In no case was pain severe when the patient was first seen. Although segmental pain indicating involvement of spinal nerve roots and invasion of the vertebral column may occur in oesophageal cancer, it was not met with in this series. Oesophageal pain carried no such sinister import; six of the seven patients in whom radical resection was possible complained of pain, and in none of these was there involvement of the parietes by the growth nor was there visible peri-oesophagitis at operation.

The history was short in nearly all these patients. From onset of symptoms until attendance at hospital it was three months or less in 26, four to six months in 17, seven to twelve months in 4, and over twelve months in 3. Many patients were wasted and anaemic and some were obviously dehydrated. Only the upper oesophagus is accessible to palpation, so that local physical signs are unusual. In none of these cases did physical examination reveal any abnormality of the gullet. Only one patient showed any clinical evidence of metastases—a stony gland above the right clavicle.

Several patients when first seen had clinical or radiological evidence of pulmonary lesions: bronchopneumonia, 5; emphysema, 4; atelectasis, 3; broncho-oesophageal fistula, 1; pulmonary tuberculosis, 1; fibrosis after radiotherapy, 1. Most of the cases of bronchopneumonia and of atelectasis were probably due to bronchial aspiration of particles of food or stagnant saliva with secondary infection. Usually, in cases of malignant oesophageal obstruction there is not time for the development of the destructive and suppurative changes in the lungs sometimes seen complicating achalasia (Belcher, 1949).

Barium Swallow and Oesophagoscopy

Two special investigations are all-important in diagnosis—barium swallow and oesophagoscopy. If necessary, both can be conducted on out-patients. No special preparation is needed for the barium swallow. If a plain chest radiograph has not already been taken this should be done. The barium investigation should include films as well as fluoroscopy. Firm reliance should seldom be placed on this investigation alone, but it usually gives an accurate indication of the level of the lesion, and, if the typical appearances of an unchanging and irregular filling defect are seen, carcinoma can be confidently diagnosed. In the present cases the report of the radiologist was never dogmatic, and in only four was a suggested diagnosis subsequently proved incorrect.

Results of Barium Swallow.—The following were the diagnoses made in the 50 cases: suggestive of carcinoma, 36; stricture or obstruction, without indicating nature, 5; suggestive of extrinsic mass, 4; suggestive of achalasia, 3; suggestive of oesophagitis, 1; investigation not done (patient too ill), 1.

The results were most accurate in middle-third growths. Upper-third lesions, especially post-cricoid cancer, are difficult to visualize unless large, as the barium passes so

quickly. A plain lateral soft-tissue film may sometimes show a suggestive forward displacement of the larynx or trachea. A small growth at the cardia may give exactly the same appearances as achalasia because it also results in spasm of the muscle of the cardia; the malignant infiltration may be too limited to detect or may be mainly in the fundus of the stomach, which is difficult to outline. Marked dilatation of the oesophagus is unusual.

Oesophagoscopy confirms the level of the lesion. If a growth is seen the upward extent of mucosal involvement can be estimated, but microscopic invasion may be higher, as emphasized by Churchill and Sweet (1942). The nature of the lesion can be surmised by observation, and more valuably determined by biopsy. There were no complications following diagnostic oesophagoscopy in these cases.

Findings at Oesophagoscopy.—These were: appearances suggesting carcinoma, 39; benign lesion suggested, 2*; no abnormality detected, 2; appearances of extrinsic glandular mass, 1. Oesophagoscopy not done, 6.

Of the 44 cases in which oesophagoscopy was carried out the biopsy was positive in 39 and negative in 4; in one case a biopsy specimen was not taken. As well as a method of investigation, the same oesophagoscopy in many cases provided a means of treatment by dilatation or intubation.

If the growth lies in the upper or middle third, oesophagoscopy should be followed by bronchoscopy to examine the posterior wall of the trachea and left main bronchus. In one case ulceration of the trachea was seen; another had a deformity, contraindicating operation.

Pathology

The growth occurred in the upper third in 4 cases, in the middle third in 24, and in the lower third in 22. Thirty-two growths arose primarily in the oesophagus. In 17 it was involved secondarily in direct extension of a neoplasm arising in an adjacent viscus—the bronchus in one case and the stomach in the others. In the fiftieth case the oesophageal lesion was a metastasis from a carcinoma of the rectum.

The primary lesions all showed the histological picture of a squamous-celled carcinoma. With growths at the lower end of the oesophagus, a biopsy report of a squamous-celled carcinoma always implied that the neoplasm originated in the mucosa of the oesophagus itself (five cases). A report of a carcinoma of a different cellular pattern, such as adenocarcinoma, polygonal-celled carcinoma, or mucoid carcinoma, indicated a neoplasm originating in the gastric mucosa (17 cases). The difference is probably not of great practical importance, as in either case spread to lymph nodes and to other tissues can occur both upwards to pleura and mediastinum, and downwards to coeliac glands and peritoneum (Allison and Borrie, 1949). One patient had a sarcoma of the stomach.

The spread of the primary oesophageal growths was first by direct invasion of adjacent structures, particularly trachea or bronchus, pleura, and pericardium, and by the lymphatics to the peri-oesophageal glands in the mediastinum. Subsequent glandular spread occurred both upwards and downwards, so that abdominal glands near the diaphragmatic hiatus, in the small omentum, and around the coeliac axis might become involved. Finally, spread to other organs occurred by the blood stream and sometimes by transpleural and transperitoneal migration. Post-mortem examinations were carried out on nine patients with primary oesophageal carcinoma who died of their disease or its effects; in only three were distant metastases found—in one case in the heart and ribs, in another in the stomach, and in a third in many organs, including bones. Widespread dissemination is unusual, because the patient usually dies of starvation or of bronchopneumonia before it takes place. Raven (1948) found no metastases in nearly half the necropsies done in his series.

*In one of these biopsy was positive.

Treatment

The policy adopted in the treatment of these patients was that a radical operation should be done when possible, and that when it was not possible an attempt should be made to relieve the patient's dysphagia. When the diagnosis had been established, and no evidence of spread beyond surgical limits found, an exploratory operation was advised if the patient's general condition permitted this major undertaking. If radical resection was found to be impossible, a palliative resection or an anastomosis without resection was done if feasible. Table I shows the treatments carried out.

When major surgery was contraindicated two methods of palliative treatment were considered—oesophagoscopic dilatation and intubation, and radiotherapy. Gastrostomy was not usually advised, as it was felt that it prolonged the patient's life in misery without relieving his main symptom of dysphagia; when obstruction becomes complete even saliva must be regurgitated, and tube feeds give little satisfaction.

In two patients in whom repeated intubation had been unsuccessful and who were about to die, an experimental operation was carried out, resecting the major part of the growth and bridging the gap in the oesophagus with a plastic tube—a method which has proved successful in healthy dogs (Berman, 1952). These operations failed, both patients dying from leakage.

TABLE I.—Treatment Carried Out

		Deaths in Hospital
Major operation	26	8
Radical resection	7	2
Palliative resection	6	2
Palliative anastomosis	5	1
Exploration only	6	1
Reconstruction with tube	2	2
Minor operation	12	3
Intubation by oesophagoscopy*	21	3
Gastrostomy	1	0
Jejunostomy	1	0
Radiotherapy	8	0
No treatment given	4	3

*Some of these were also treated by other methods.

After preparation, as described by Franklin (1952), an exploratory operation was done on 24 patients. In only seven was radical resection possible. In one the growth involved the cervical oesophagus; it was possible to bring the mobilized stomach up into the neck and perform a satisfactory anastomosis above the clavicles as described by Nissen (1949) but the patient, doing well, died suddenly from a pulmonary embolus. Another patient, with a middle-third growth, treated by right thoracotomy and anastomosis to the stomach (Lewis, 1946), is well. In five patients the lesion lay in the lower third. In three it originated in gastric mucosa. In these patients a total gastrectomy was done by a thoraco-abdominal approach, removing the spleen and lymphatic fields with the stomach, and restoring alimentary continuity by anastomosing oesophagus to a Roux-en-Y loop of jejunum within the thorax (Yudin, 1944). One of these patients died from pericardial haemorrhage following anticoagulant therapy; the others are alive and well. In the other two patients the carcinoma originated in the oesophagus. One was treated similarly, and remains well; the other, also well, by oesophago-gastrostomy (Sweet, 1947).

At the exploratory operation, if a radical resection was impossible, an attempt was usually made to by-pass the obstruction. The simplest and safest way used was to bring a pouch of stomach through the diaphragm and anastomose it to the oesophagus above the growth. This was not possible, however, when the stomach was extensively involved or when the growth lay in the middle third. In these cases a palliative resection was done, with anastomosis to the gastric stump, or else an oesophago-jejunostomy (Allison, 1946). In six cases even such procedures were considered unwise, as the growth appeared too advanced or the patient's condition too poor.

into another as growth proceeds. The classification which we have adopted and the percentage incidence are as follows: (1) ulcerative, 69.2%; (2) papular, 7.7%; (3) cystic, 5.3%; (4) plaque, 10.5%; (5) superficial, 5.3%; (6) pigmented, 1.4%. There was no significant sex difference in the type incidence.

Size of Lesions at Beginning of Treatment.—These are shown in Table V. Some rodent ulcers penetrated fairly deeply, but none had apparently invaded cartilage or bone; those that did, being unsuitable for radiotherapy, were treated surgically. An attempt was made to correlate the extent of the lesions with their duration. No direct relationship, however, could be found, and in fact many of the patients with the smallest lesions gave the longest histories. Contrary to what one might expect, women did not seem to seek treatment earlier than men.

TABLE V.—Size of Lesions at Beginning of Treatment

Size of Lesions in cm. ²	<1	1-	2-	3-	4-	5-	10-20	>20	
No.	364	185	43	41	24	39	10	5	711
%	51.1	26.0	6.0	5.8	3.4	5.5	1.4	0.7	99.9

Biopsies.—Clinical diagnosis of rodent ulcers is usually accurate in radiotherapeutic centres where large numbers of skin cancers are seen. A biopsy was therefore thought to be unnecessary in all cases. In this series 228 lesions (32%) were confirmed by biopsies, including a few cases in which the clinical diagnosis was in doubt.

Methods of Treatment

X-ray therapy was used in 703 (98.9%) lesions. The type of apparatus used—that is, low-, medium-, or high-voltage units with the range of 45–220 kV—varied with the estimated penetration of the lesion. The majority (595 lesions) were treated with a 60-kV unit. Radium or radon in the form of an applicator or implant was used in only 8 cases, which were technically difficult to treat with x rays.

All X-ray treatments were classified into the following three groups:

(I) **Single Dose.**—This method was used only in small and very superficial lesions, the prescribed dose being given in a single application; 171 lesions were so treated, 159 at doses between 2,000 and 3,000 r.

(II) **Fractionated into one or two treatments a week** over a period of one to three weeks. The lesions included in this group were all superficial and small to medium in size; the total number treated was 150, of which the majority received a total dose of between 3,500 and 5,000 r.

(III) **Fractionated into three to five treatments a week** over a period of one to three weeks. Most of the earlier cases in the series were treated by this method irrespective of their size or penetration; but since 1948 it has been our policy to reduce the number of treatments so as to minimize the inconvenience to the patient. This form of treatment has therefore been reserved for the larger and/or more penetrating lesions. In the vast majority the treatment was given over two weeks, and the total dose varied between 4,500 and 6,500 r.

The dosage and fractionation used from 1948 onwards are summarized in Table VI.

TABLE VI.—Dosage and Fractionation in Use Since 1948

Diameter of Treatment Area	Degree of Penetration of Lesion		
	Superficial	Moderate	Deep
	Low-voltage Therapy	Medium-voltage Therapy	High-voltage Therapy
<2.5 cm.	3,600 r, 3T, 14D or 2,300–2,500 r, single dose	3,300 r, 3T, 14D	4,000 r, 15T, 21D
2.5–5 cm.	3,600 r, 3T, 14D	4,000 r, 10T, 14D	4,000 r, 15T, 21D
5–10 cm.			4,000 r, 20T, 28D
>10 cm.			

T=Treatments. D=Overall time in days.

Results of Treatment

In expressing these results it was decided to use a net cure percentage (as being the most accurate method in this disease, in which there is such a high rate of cure). This is usually estimated by subtracting those who have died and disappeared free of cancer symptoms from the total number of lesions treated, and calculating the symptom-free rate from the remainder. Table VII shows, however, that we have also deducted from the total 14 cases (3 in women, 11 in men) which underwent little or no regression following maximum dosage. We are aware that these cases would be classified as recurrences in some centres; but, since we define recurrence as the reappearance of evidence of disease after a period of complete apparent tumour regression, in our opinion they should be classified separately as primary radiation failures in that they are for all practical purposes completely resistant to radiation. In this series they formed 1.9% of the total number of lesions.

TABLE VII.—Results of Radiotherapy in 711 New Basal-cell Carcinomata in Both Sexes, 1939–50

No. of Years Since Treatment	No. of Lesions Treated	Cases of No Regression	Died of Inter-current Disease Cancer-free	Un-traced	Recurrences	Symptom free	
						No.	%
2½–3	95	2	9	5	5	74	93.6
>3	616	12	62	51	21	470	95.7
>5	309	9	38	31	17	214	92.6

Table VII shows the results of radiotherapy in 711 previously untreated basal-cell carcinomata—366 in men and 345 in women. There was little difference in the symptom-free rate in men and women treated more than three and five years ago. The combined three-year symptom-free rate is 95.7% and that for five years is 92.6%. The symptom-free cases include seven of incomplete regression which required a second course of treatment before healing occurred.

Recurrences

Out of the total of 711 rodent ulcers there were 26 known recurrences, of which 8 were cured with further radiotherapy—4 of them for periods of over five years—and all 8 were symptom-free when last seen. Recurrence of basal-cell carcinoma following radiotherapy therefore does not always indicate incurability by radiotherapy, and second courses of treatment may cure; but it must be emphasized that this is possible only in recurrences which are small, and provided that the original dose was moderate and marked skin changes have not resulted, otherwise there is a serious risk of producing radionecrosis. The aim in radical irradiation, however, is and has been for many years to cure with one course of treatment and one only.

In an attempt to discover if recurrences had a predilection for any site, their distribution was compared with that of the primary lesions. The actual figures of recurrences at the various sites, however, were too small to be of any statistical significance.

Time of Appearance of Recurrences.—Most analyses show that the majority of recurrences appear within the first five years after irradiation and in diminishing numbers from the first to the fifth years. In those cases treated more than five years ago 17 recurrences were discovered, and, of these, 6 were found in the first year after treatment, 2 in the second year, 5 in the third, 1 in the fourth and the fifth years, and 2 in the sixth. Thus 76.4% of these recurrences were in the first three years and 88% in the first five years.

Recurrences Related to Size of Lesions.—Since difficulty is often experienced in assessing the depth of medium-sized lesions, it was decided not to attempt to make a division into superficial and infiltrating groups, but to show only

TABLE VIII.—Results Related to Sizes of Lesions

Size of Lesion in cm. ²	No. Treated	No. response	Died of Inter-current Disease Cancer-free	Un-traced	Recurrences	Symptom-free	
						No.	%
<1	364	2	30	26	14	292	95.4
1–	185	3	9	13	5	155	96.8
2–	43	5	7	6	1	24	96.0
3–	41	0	9	2	1	29	96.6
4–	24	1	4	4	1	14	93.3
5–	39	3	5	3	1	26	92.8
10–20	10	0	4	2	1	3	75.0
>20	5	0	3	0	1	1	50.0

the relationship between the number of recurrences and the surface extent of the primary lesions. Table VIII shows the results. It is interesting to note that 14 (53.8%) of the recurrences occurred in the first and the smallest group, indicating clearly that smallness of size is not the sole criterion of success in treatment. The recurrence-free rate is highest (96.8%) in the second group (1–2 cm.²), thereafter remains remarkably uniform until over 10 cm.², when it drops; but the figures for the last two groups are too small for comparison.

Causes of Recurrence.—We have analysed the treatment details of all the lesions which have recurred to see whether any technical reason for the failure could be found. Nine cases were without doubt due to failure to irradiate a wide enough margin of apparently healthy tissue round the lesion, and one case was due to inadequate dosage. For the remaining 16 recurrences there was no obvious technical reason, but included among them were two advanced lesions.

Radionecrosis

There were seven cases of radionecrosis—one acute and six late. The acute case followed a moderate dose to a scalp lesion, and can only be ascribed to idiosyncrasy to radiation. It was successfully excised. The six late cases appeared five months to three and a half years after treatment. Four followed minimal trauma to the irradiated area, one followed sunburn, and one followed infection of the adjacent eye. In only two of the cases could the dose given be regarded as slightly excessive. No case had followed the retreatment of a recurrence. Three cases had to be excised; the other three, however, amounted only to slight but persistent scabbing, and expectant treatment was adopted with success.

Cosmetic Results

The results obtained in 664 lesions treated by all methods are listed in Table IX. Cases of recurrence, necrosis, or no response are excluded. They may present a rather too optimistic picture, as there is a tendency for the cosmetic result to worsen slightly as time goes by. There was no evidence that the quality of radiation, dose (provided it is within the therapeutic range and not excessive), fractionation, or type of lesion has any direct relation to the cosmetic result which may be expected. Factors, however, which did appear to influence it were: (a) the penetration of the lesion—a deeply penetrating lesion never gave better than a fair cosmetic result; and (b) size of lesion—no excellent cosmetic results were obtained in lesions over 5 cm.² in area.

TABLE IX.—Cosmetic Results

Result	Both Sexes	
	No.	%
Excellent (no scar visible with normal inspection)	105	15.8
Good (pale scar with no pitting, pigmentation, telangiectasia, or contraction deformity)	508	76.5
Fair (slight pitting, pigmentation, telangiectasia, or contraction deformity)	39	5.8
Poor (marked changes as above)	12	1.8
Total	664	99.9

Comparison of Different Methods of Treatment

Any comparison of different treatment methods must take into account the extent of the tumours, and is thereby made the more difficult.

TABLE X.—Comparison of Results of Different Methods of Treatment

Method of Treatment	No. treated	No. re-sponse	Died of Inter-current Disease Cancer-free	Un-traced	Recurrences	Symptom free	
						No.	%
X rays:							
Group I, single dose	171	3	16	10	5	137	96.4
Group II, 1–2 doses a week	150	1	15	9	2	123	98.4
Group III, 3–5 doses a week	382	10	38	37	18	279	93.9
Radium	8	0	2	0	1	5	83.3

It will be seen in Table X that the lowest x-ray results (93.9%) are in Group III, as one would expect, since it contains all the more advanced lesions. The highest x-ray results (98.4%) are in Group II, these being 2% better than those in Group I. The difference of 2% is statistically not significant, but the advantage of the Group II method is possibly more apparent when one considers that in many cases it was used for larger tumours than Group I. Nevertheless, it will be seen that the single-dose technique has proved a very satisfactory method for treating early lesions, thus confirming the results of Mallender (1950). It will also be seen that to date there has been no deterioration of results due to our policy of reducing the fractionation of the treatments in all but the large and/or penetrating lesions.

Finally, the results of the eight lesions treated by radium are shown, but it must be emphasized that the number is too small for fair comparison.

Summary

An analysis is made of 711 lesions treated by radiotherapy during the years 1939–50 inclusive. The sex, age, and site incidence are discussed and the sizes of tumours at the beginning of treatment are given.

Of the lesions 98.9% were treated by three x-ray techniques, the remaining eight by radium. Our policy in reducing the number of treatments over which the x-ray dosage is given, and the effect of this as regards both cure and cosmetic results, are discussed.

The cure rate for all lesions treated over three years ago is 95.7% and for all those treated over five years ago 92.6%. The results have been related both to sizes of tumours and to different treatment techniques. The cosmetic results obtained are given.

The incidence, cause, treatment, etc., of recurrence and radionecrosis are given and discussed.

We express our gratitude to Dr. J. A. C. Fleming for permission to publish this paper and for his helpful advice and encouragement. We also acknowledge our indebtedness to Mrs. N. Kaye for the tremendous amount of work she has done in writing for follow-up reports on patients who could not attend hospital; and to Mr. W. A. Langmead for his advice on statistical significance.

INTRAVENOUS ACETYLCHOLINE IN TREATMENT OF THE NEUROSES

BY

R. M. PHILLIPS, M.B., B.S., D.P.M.

AND

J. T. HUTCHINSON, M.D., D.P.M.

(From the Department of Psychological Medicine, St. Thomas's Hospital)

A great deal is known about the actions of acetylcholine, but little has been written about its value as a therapeutic agent. It is known that cholinesterase rapidly destroys acetylcholine *in vivo*. Hence in using the drug intravenously the chief difficulty lay in choosing the optimum dose which would avoid the lesser danger of too rapid destruction and the greater danger of arresting the heart's action (Carmichael and Fraser, 1933). In spite of the handicaps a number of uses have been found for the drug, given as an intravenous injection. It has been considered an effective method of treating paroxysmal tachycardia (Martindale, 1952), and Williams (1941) found it helpful in the diagnosis of epilepsy, since it could provoke epileptic discharges in the E.E.G. records of certain epileptic patients. It was used first in the treatment of psychiatric patients by Fiamberti (1940, 1950), who gave intravenous doses of 600 mg., by which he produced syncope, unconsciousness, and often a convulsion. This approach was considered to be of value in treating the early stages of schizophrenia, and a recovery rate of 80% was reported. The basis for this form of treatment was the apparent similarity to the convulsive shock produced by leptazol or E.C.T. Poort and Stigaard (1944) found that doses of up to 1,000 mg. could be injected safely. However, it did not gain wide repute, and unsatisfactory results were obtained by several workers, notably Harris and Pacella (1943).

A more modified form of treatment, using an intravenous dose of up to 200 mg. of acetylcholine chloride, was introduced in Spain by Lopez Ibor (1950, 1952), who found this approach useful in the treatment of certain neuroses and particularly of patients suffering from recurrent attacks of tension. Following a visit to Spain, Sargent (1952) introduced the treatment at St. Thomas's Hospital and reported on the initial findings.

The present paper describes a series of 211 patients who have been treated over a period of two and a half years at the same hospital.

Method

The Roche preparation of crystalline acetylcholine chloride was found to be the most reliable form of the drug. It was freshly prepared as a 10% solution in dis-

tilled water, usually as 200 mg. in 2 ml. The patients were given the injection intravenously, at least one hour after a meal, and initially a dose of 50 mg. was injected very slowly to test the sensitivity of the patient. This initial dose was then generally increased during subsequent treatments by 50 mg. to the total amount of 200 mg. A reaction usually occurred after the rapid injection of 50 mg. of acetylcholine chloride, but the remainder of the 200 mg. could then be given more slowly to prolong the reaction. Extra care has to be taken in those very sensitive to doses as small as 25 mg. The response took two forms: one showed coughing, flushing, salivation, lacrimation, sweating, etc., and was accompanied by momentary slowing of the heart; the other was primarily syncopal in form and was associated with prolonged cardiac arrest, unconsciousness, and convulsive movements. Physiological observations on these effects, including a description of a syncopal attack of 28 seconds, have been reported elsewhere (Phillips *et al.*, 1952). Barlow and Howarth (1953) have shown that the second, more severe reaction is similar to a Stokes-Adams attack. However, the aim of the treatment was to produce the first, milder reaction, and this could be achieved by gauging the rate of injection to suit the individual patient. There was little in the way of after-effects, and most patients were able to leave hospital five minutes after the injection, although the more elderly benefited from resting for 20 to 30 minutes afterwards.

Before a course of injections was begun the cardiovascular system was examined particularly, and in middle-aged patients a routine E.C.G. was done. It was also found possible to control attacks of spontaneous auricular fibrillation, which occurred in four patients, by giving a prophylactic dose of quinidine sulphate, 5 gr. (0.32 g.), half an hour before injections, and treatment could be continued. No fatalities occurred in over 6,000 injections when care was taken to gauge the dose correctly by gradually increasing speed and amount, especially in the sensitive patient.

The usual course of treatment consisted of 30 injections given over a period of six to ten weeks, depending on how often the patient was able to attend for treatment. Daily clinics have been held at St. Thomas's, and most patients found it possible to continue at work at the same time.

Results

The 211 patients consisted of 125 men and 86 women. The majority of patients who had this treatment, and incidentally the group which was helped most, suffered from symptoms which we have chosen to call "obsessive" (Sargent, 1952) or obsessional. These may result from exposure to stress, either psychological or physical, such as an acute debilitating illness, may start abruptly, and can often become self-perpetuating. The obsessional aspect of the condition commonly takes the form of a recurrent thought of an unpleasant nature or a particular phobia which is associated with a great deal of tension. This tension is experienced inwardly, and there is little or no overt evidence of its existence except the complaints of the patient. The reason why care has been taken to define this condition is because the drug proved to be of little value in the treatment of the classical obsessional neurosis, often dating from early childhood or accompanied by compulsive ritualistic behaviour.

Until it became clear that this particular obsessional group reacted best to this treatment, a wide selection of patients with anxiety symptoms were treated, including some in all of the following diagnostic categories: obsessional states as defined above, conversion hysteria, varied types of depression, schizophrenia, anxiety hysteria, classical obsessional neuroses, psychopathy, and chronic eczema.

Obsessional or Obsessive Tension States.—This category comprised 104 patients (Table I), of whom the surprisingly large number of 73 (70.2%) were improved by the treatment (Table II). Many were people who experienced the inner sense of tension already described, and they often

TABLE I

		O.S.	A.H.(M.)	A.H.(Po)	S.	O.N.	P.
Male	No. of patients	71	19	16	6	2	8
	Average No. of injections	34.8	25.9	8.25	20	30.5	20
Female	No. of patients	33	15	30	2	3	2
	Average No. of injections	28	29.6	6.16	88	71	23

O.S. = Obsessional state. A.H.(M.) = Conversion hysteria (monosymptomatic). S. = Schizophrenia. A.H.(Po) = Anxiety hysteria (polysymptomatic). O.N. = Obsessional neurosis. P. = Psychopathy.

Note:—Four skin cases are not included in Tables I and II: none derived any benefit from acetylcholine injections.

TABLE II

had fears of insanity or of dying. One such patient, who had fought through the Burma campaign without significant upset, was debilitated by dysentery, helminthic infection, and orchitis complicating mumps. He suddenly developed an irrational fear of insanity, became tense and anxious about travelling, and had had panic attacks of fluctuating intensity over a subsequent period of six years. However, he carried on with his work so far as was possible. These patients often gave a history of previous attacks or a periodic course in which attacks might partially lift, and then got worse again. Others showed phobic states which were monosymptomatic in nature—for example, a woman with a single obsessive fear of killing her child. The phobia could be replaced by rumination over a single thought—for example, a word such as syphilis. These conditions must be distinguished, however, from those in which, for instance, fear of syphilis might be only part of a chronic generalized anxious and hypochondriacal state.

Anxiety Hysteria.—The classical symptoms of this condition did not respond to the treatment—most patients were made worse. This point is referred to below. Sometimes, however, a conversion symptom presented itself as a single fixed persistent pain, and then some improvement occurred, probably because of an obsessive component to the condition. Of such patients 34 were treated; 14 (41%) were helped, while 5 (15%) complained that they felt worse. An example of this was a patient who developed a pain in his leg after the diagnosis of disseminated sclerosis had been made in his brother, and this symptom had persisted for 15 years. Others helped were a group of patients complaining of bitemporal headache. Gross hysterical states were certainly never helped, although these patients are a group normally improved by treatments with a high degree of suggestive value.

Depressive States.—In general, acetylcholine injections seemed to increase the depth of an endogenous depressive illness. It was a matter of clinical observation that this was an effect it shared with modified insulin therapy. Therefore it was contraindicated in the treatment of depressions showing retardation, etc. However, there was a place for it in the treatment of patients suffering from mixed states of depression and obsessional tension. Such mixed states were generally reactive in nature, but a few depressions were generally reactive in nature, but a few were in the involutional group. These patients usually had one E.C.T. each week, and acetylcholine injections were given throughout the week. This combination of treat-

ments appeared to be efficacious in resolving the illness more rapidly than E.C.T. would have done alone, and can be combined on an out-patient basis. Six patients responded to this combined treatment, and these have been included in the obsessional group described above.

Schizophrenia.—Eight patients were treated, of whom three recovered from their particular attack under treatment. All three were, however, subject to recurrent illnesses of schizophrenic type, and showed obsessive traits in their pre-morbid personalities. They had previously had courses of insulin coma or E.C.T., and two of them had had modified leucotomies. The acetylcholine, however, seemed to help only the tension component to the total picture. These patients had full courses of acetylcholine injections and seemed to derive more benefit from syncopal reactions produced by the rapid injection of 200 mg. intravenously, which were less easily tolerated by the other groups of patients.

Other Conditions.—It will be realized that the term "anxiety state" is not used in this series. The reason is that it became apparent that a distinction had to be made between anxious patients of obsessive personality, who were able to contain their tension, and those with more hysterical trends, who tended to project their anxiety. The former are included in the obsessional group and the latter in the category of anxiety hysteria. Five patients, however, who showed numerous obsessional compulsive phenomena received courses of treatment, and no change for the better occurred. Some cases of psychopathy and eczema were also treated; for, as is usual in all fresh therapeutic ventures, many patients in these difficult categories tend to get referred for treatment. On the whole they were not helped by acetylcholine injections.

Use in In-patients

In addition to the above examples of its use in out-patients, acetylcholine was found to be of value as an adjunct to the standard in-patient treatments. It could be used as a further sedative measure to reinforce the action of modified insulin and, if necessary, could be given twice daily. Its use with E.C.T. was confined to the mixed states of obsessional anxiety and depression, and here its action lay in taking the edge off the tension experienced by such patients after E.C.T. had removed the depressive component. It was of use, too, in clarifying the diagnosis of mixed states of depression and anxiety. Often only a few injections tended to increase depression if this was the most important factor, and E.C.T. could then be substituted. In states of acute tension that can follow abortive treatments in wrongly selected patients, repeated acetylcholine injections were often found better than the barbiturates in damping these down again, because they achieved rapid sedation without producing an added mental confusion. It was also found useful in the follow-up treatment of alcoholics who had had emetine aversion treatment, were now off alcohol, and still had symptoms of residual tension.

Discussion

Early in the investigation some difficulty was experienced in finding the type of patient who might benefit most from the treatment. At first, most of the patients treated were chronic hospital attenders suffering from anxiety hysteria, and the injections served only to increase their fears. At this stage the investigation was nearly given up, but it was continued because of the response of one woman who had been referred for consideration of leucotomy. She was suffering from a monosymptomatic obsession that she might harm her child; this was accompanied by great tension and had lasted for over two years. The (28) injections gradually relieved her symptoms, and the operation of leucotomy was thus avoided; she has remained well for over two years. Another early patient who showed a good response was also noted to be suffering from a recurrent tension state with obsessional features. Then other patients were selected for treatment because mostly

they had single fixed symptoms, the illness showing a fluctuating intensity, and because there was evidence of a good basic personality, as shown by their ability to carry on with their work despite their illness.

With the final analysis of the results it has been possible to distinguish further prognostic criteria. Those helped most were frequently between 30 and 50 years of age. Body-build seemed particularly important. By far the best results were obtained in those of athletic build. These tolerated the treatment well, while the asthenic and the pyknic, especially the young obese patient, were not helped. They proved particularly sensitive to the injections and became easily frightened.

The treatment was certainly contraindicated in patients whose anxiety was overt in nature. Such people complained of palpitations, breathlessness, diarrhoea, vomiting, and frequency of micturition. Many of them showed a marked emotional immaturity, and a tendency to project their symptoms typical of so many of those suffering from anxiety hysteria. Table II shows the poor results obtained in this group.

The chief response noted when treatment was successful was a gradual lessening of tension—the emotional component of the phobia or obsessive thought decreased, and it became less troublesome. Schizoid patients showed an improvement in rapport and sometimes reported an increased clarity of thought.

The benefit alcoholic patients derived from the treatment was in keeping with the fact that they often have an obsessive personality; indeed, their drinking is often of a compulsive nature. They are usually tense individuals experiencing a great deal of subjective anxiety.

It might be argued that the typical patient who has shown a good response to treatment is basically the person of good personality and body build who does well with any form of non-specific therapy. Such patients have good driving personalities; they have mastered various stresses successfully, and they are able to contain their anxiety. But many of them present notoriously difficult problems from the point of view of treatment, and their illnesses may last a long time. It has been our experience that these patients are usually untouched by psychotherapy, E.C.T. makes them worse, and the use of sedatives may result in a build-up to undesirably high and prolonged dosages. A small number of such patients were given injections of normal saline in the same way as other patients were given acetylcholine. No response occurred until acetylcholine was substituted for normal saline. It seemed, in fact, that acetylcholine was often able either to shorten the attack or to produce a more complete remission of symptoms. Our results in this respect were therefore found to confirm those reported by Lopez Ibor (1952).

Summary and Conclusions

An investigation has been described in which intravenous acetylcholine was used in the treatment of varied forms of neurosis. The patients who were helped most fell within a specialized group of obsessive or obsessional tension states, which have been defined. Of 104 patients in this group, 70.2% were improved by the treatment.

It has also been found useful in certain patients as a treatment complementary to E.C.T., modified insulin, and the emetine aversion treatment for alcoholism.

Over 6,000 intravenous injections of acetylcholine have so far been given. The treatment, with the precautions described above, has been found to be a safe one, and is relatively simple to use on an out-patient basis.

Our thanks are due to Dr. William Sargent and many other members of the department who referred patients for treatment and helped us in this investigation. It was initiated by a grant from the endowment funds of St. Thomas's Hospital.

THE PREVENTION OF CONGENITAL SYPHILIS

BY

R. S. MORTON, M.B.E., M.R.C.P.E.D.

Consultant Venereologist, Stockport and East Cheshire

The incidence of early acquired syphilis reached its peak in England and Wales in 1947. This was followed by a rise in the incidence of congenital syphilis in the years 1948 and 1949, since when there has been a fall in the number of reported cases. The Ministry of Health report for 1951 revealed, however, that during that year 1,127 cases of congenital syphilis were seen for the first time at venereal disease clinics in England and Wales. The figure for 1952 was 946. Since congenital syphilis is now regarded as an almost 100% preventable disease (Aron *et al.*, 1947; Cole *et al.*, 1950; MacFarlane, 1950; Marinkovitch, 1951), these figures are alarmingly high. The more especially is this so when they are compared with 699 (1951) and 375 (1952) notifications for diphtheria, a comparably controllable infection.

No data are available to allow an estimate to be made of the number of congenital syphilitics born in the years 1951 and 1952 in whom the disease is as yet undetected, nor are there figures to show the number of abortions and miscarriages in which syphilis played a primary or contributory part.

Early infectious syphilis is now comparatively rare in adults, but many untreated or inadequately treated infections acquired during and after the late war are at present in the latent stage. Many of the females in this category are of child-bearing age, and while their syphilis is not contagious it is transmissible to the foetus. Kampmeier (1946) estimated that, irrespective of the stage of syphilis, 70% of foetuses born of syphilitic mothers are infected. The best hope, therefore, of prevention and ultimate eradication of congenital syphilis depends on detection and treatment of such women during the antenatal period.

Latent syphilitic infections can be adequately diagnosed only by the Wassermann or similar serological test.

MacFarlane found 515 (0.7%) of 71,645 antenatal Wassermann tests to be positive during the years 1944-9. Even with the apparent decline in early syphilis he was still able to detect 45 (0.28%) cases among 15,812 antenatal Wassermann tests made during 1952 (personal communication).

While antenatal Wassermann testing (and, where omitted, post-natal Wassermann testing) has become the established routine in almost every hospital and local authority obstetric practice, the Report of the Venereologists Group of the British Medical Association

(1952), which analyses the figures from 200 venereal diseases clinics in the United Kingdom, shows that routine antenatal Wassermann testing was uncommon in other than organized antenatal services. This fact has been underlined by MacFarlane, who has applied himself to this problem in the Tyneside area. He found that in 1952 (personal communication), when the estimated Tyneside birth rate (including stillbirths) was 31,705, of 15,812 (50%) antenatal Wassermann tests performed only 491 (3%) were made by general practitioners, who according to the local executive councils were remunerated for the care of 15,178 pregnancies.

Conditions in Stockport County Borough

Arrangements have been sought, by the closest possible liaison between all branches of the medical services, to improve the local rate of antenatal Wassermann testing. Such success as can be claimed (see Table I) is largely due to the co-operation between general practitioners and municipal midwives, the midwives with the medical officers staffing the borough antenatal clinics, and these latter in turn with the venereologist at the venereal diseases clinic of the hospital service. Direct liaison exists between the maternity department of the local hospital and the venereal diseases unit.

TABLE I.—Incidence of Serological Tests for Syphilis (S.T.S.) in Stockport County Borough Residents

Year	Birth Rate, including Stillbirths	S.T.S. Performed at Local Authority Clinics	S.T.S. Performed at Hospital Antenatal Clinics	Total S.T.S.	Detected Syphills Cases
1951	2,019	1,102	600 (approx.)	1,702 (85%)	11 (0.54%)
1952	2,101	1,002	700 (approx.)	1,702 (81%)	11 (0.52%)

It has been the practice to make antenatal clinic services available to all practitioners even if only for the purpose of taking a sample of the patient's blood. The busy practitioner, especially during the winter, is relieved of the time-consuming task of preparing for, taking, and dispatching single samples of blood. An increasing number of general practitioners undertaking care of antenatal cases now use this service as a routine—the practitioner himself, or, in most cases now, the midwife "booked" for the confinement, arranging the appointment at the antenatal clinic. This single sample of blood is also available for rhesus determination and estimation of the haemoglobin content.

Cases are usually referred to the venereal diseases clinic as soon as a routine Wassermann or Kahn reaction has been found "positive" or "doubtful." In all cases in which clinical signs are absent it is the practice to confirm the positive result before starting treatment. This precaution eliminates the possibility of clerical error and places the diagnosis beyond reasonable doubt.

During a five-year period covering 1947-52, 42 cases of previously undetected antenatal syphilis were referred. The stage of infection in these cases was: seropositive primary, 4; secondary, 8; latent syphilis, 25; congenital syphilis, 5.

The average age of the women was 25.6 years, with extremes of 17 and 37. The average duration of pregnancy at the time of first attendance at the venereal diseases clinic was 5.14 months, with extremes of 2 and 8½ months.

Management of Antenatal Syphilis

The aim of treatment is not only to protect the foetus but to continue treatment after parturition, with a view to curing the mother. The first problem is the patient's anxiety regarding the diagnosis. The patient has been told the undisputed facts in words best suited to her intelligence and educational standard. It is important that she should fully understand the terms "V.D.," "venereal disease," and

"syphilis," and what they imply. Reassurance is given that if she attends regularly a healthy baby may be expected. The need for the baby to attend later is stressed. The rapport established at these early interviews and examinations is important in securing co-operation in treatment during the months that lie ahead.

The majority of the cases have been treated with penicillin, arsenicals, and bismuth. Penicillin, as the oil-wax preparation and more recently as the procaine salt in suspension, was given in 4 to 6 mega-unit courses spread over eight to ten consecutive days. Two cases developed generalized urticaria and another had weals at the injection site. All three were readily controlled with antihistamine drugs. One patient had a "terror" reaction like that described by Batchelor *et al.* (1951). In spite of this reaction, penicillin was continued and the patient completed the prescribed course uneventfully. The earlier cases were admitted to hospital for daily penicillin therapy, but this is now rarely thought necessary, and no apparent complications have occurred from such practice. No patient attending daily at the venereal diseases clinic defaulted from the prescribed course. If arsenicals were given it was as neoarsphenamine or arsphenamine, 0.45 g. intravenously at weekly intervals. One course consisted of 10 injections. Two cases of neoarsphenamine dermatitis, readily controlled by dimercaprol, were the only complications seen. Bismuth was given as bismuth oxychloride in suspension in 0.2-g. doses deep intramuscularly at weekly intervals, a course consisting of 10 injections.

Of the 42 cases, 29 received penicillin, arsenicals, and bismuth, 15 of them completing one course of each drug or more. Of the 14 who did not complete a full course of each, two developed neoarsphenamine dermatitis, two defaulted, and 10 came to treatment in the last 10 weeks of pregnancy. Of the remaining 13, 2 received arsenicals and bismuth only, and one defaulted before treatment was begun. Seven others, the most recent in the series, received penicillin and bismuth alone.

If the patient was referred early in pregnancy treatment was continued right up to the expected date of confinement. Expectant mothers attended regularly and the opportunity was used to give as much antisyphilitic treatment as time permitted. Earlier experience showed that once the baby arrived domestic problems ensued and these were frequently used as excuses for non-attendance. If the puerperium was spent in hospital it was therefore arranged for the patient to have a further course of penicillin. This meant that the mother need attend the venereal diseases clinic only weekly at the most for the first two to three months after she returned home with the baby.

Twenty patients of the series had 25 subsequent pregnancies. Many of these occurred while the patients were still under treatment. The aim in such cases was to give the mothers at least one course each of penicillin, arsenic, and bismuth, and more recently one course at least of penicillin and bismuth only. If the patient became pregnant after completing adequate treatment for her syphilis, but before she had completed two years' satisfactory surveillance, an "insurance course" of penicillin only was given. Those mothers who had completed treatment and two years' satisfactory surveillance received no further treatment, but were kept under Wassermann review throughout the pregnancy. The babies were examined routinely in all these cases (see below).

When patients defaulted they were persuaded to return to treatment or surveillance by letter, or, if this failed, by visits by the municipal health visitor. Such visits were arranged through the medical officer of health, who has a statutory responsibility for venereal diseases cases much the same as he has for the tuberculous.

Investigation of the Family

The question of following up the patient's family is the task of the venereologist. Stokes *et al.* (1944) estimated that up to 40% of the members of such families may be

found to be infected. The discovery of unsuspected syphilis causes an immediate stir in the family, and as little delay as possible should be allowed before all the other members are examined. Irrespective of the clinical findings, a specimen of blood was taken from each member of the family who attended. It was noted that delay appears to give husbands time to rationalize their position, and when it has been necessary to visit such men they say in effect, "I feel nothing wrong. Therefore there is nothing wrong. Therefore there is no need for a blood test." The position is often rendered more difficult as a wife's diagnosis of syphilis may not be revealed to her husband without her prior consent.

Altogether 27 husbands were examined: there was a history or finding of syphilis in 13, while 14 gave no history and were serologically negative. Of the 15 not examined, five refused to attend, three were separated from their wives and could not be located, while four were consorts of single women and could not be traced. The remaining three were husbands of congenitally syphilitic wives. Once the husband's co-operation was obtained little difficulty stood in the way of examination of children of the marriages concerned (see below).

Outcome of the Pregnancies

Of the 42 pregnancies, 41 ended in live births. There was one miscarriage. Twenty-seven infants were found Wassermann-negative at 3 months of age or older; 12 were not seen at 3 months of age or older, either because the parents refused to bring the children or because the family moved to another locality. Two infants were diagnosed as having congenital syphilis.

The diagnosis of infantile congenital syphilis often seems to present difficulties. It is not generally appreciated that many pregnant women reach confinement with a strongly positive Wassermann reaction in spite of antisyphilitic treatment. In these cases there is often a "carry over" of the mother's reagin into the infant's blood. Thus cord blood or venous blood taken from the infant in the first few weeks of life may well give a positive Wassermann result in spite of the absence of congenital syphilitic infection. The Wassermann titre in such cases usually falls to negativity in four to six weeks. Only when a Wassermann reaction remains strongly positive beyond 12 weeks of age can it be taken as a sure sign of congenital infection. The presence of definite clinical or radiological evidence of congenital syphilis of course makes a diagnosis possible irrespective of the infant's age or the Wassermann titre.

The practice here has been to take a specimen of blood from the babies at 1 month and at 3 months of age. As indicated, the test at 1 month is of little value. It is felt, however, to be important for the mother to bring the child for clinical examination at this age. Experience has shown that if the baby is left until it is 3 months old difficulty may be experienced in persuading the parents of the need to bring along their apparently healthy child.

In regard to the two cases in this series diagnosed as congenital syphilis, one was diagnosed elsewhere on serological evidence only at 6 weeks of age. In the other case the mother completed a 4-mega-unit course of penicillin a few days before her confinement. This baby was first seen at 1 month of age with mucocutaneous syphilis.

Previous and Subsequent Pregnancies

Kampmeier (1946) noted the high morbidity and mortality in untreated syphilitic women. He found 24% of pregnancies ending in miscarriage or stillbirth; 56% of the infants were born with syphilitic infection, and about a quarter of these died within the first month of life.

Wammock *et al.* (1950) pointed out that women treated for syphilis have a better chance in pregnancy than non-syphilitic women. He found an unsatisfactory outcome in 12.4% of 5,596 infants born to non-syphilitic mothers, but in only 3.8% of 271 infants born to 267 treated syphilitic

mothers. It is of some interest, therefore, to compare the outcome of previous and subsequent pregnancies in this series. Eighteen of the women had had 40 previous pregnancies and 20 had 25 subsequent pregnancies (Table II).

TABLE II.—Outcome of Previous and Subsequent Pregnancies

Outcome of Pregnancies	Previous Pregnancies	Subsequent Pregnancies
Miscarriages	4	Nil
Stillbirths	2	Nil
Premature baby (died)	1	Nil
Wassermann-negative at 3 months of age or later	21	21
Not examined	11	3
Diagnosed congenital syphilis	1	1
	40	25

Although the series is small, the high miscarriage and stillbirth rates in the previous as compared with the subsequent pregnancies seem in line with the findings of others. The case of congenital syphilis among the subsequent pregnancies was due to failure, in spite of letters and visits, to persuade the expectant mother to attend for continuation of treatment.

Summary

Although almost 100% preventable, congenital syphilis is still very much with us.

Antenatal Wassermann-testing offers the best hope of early eradication of this infection.

The management of antenatal syphilis is illustrated by a series of 42 cases.

The need is emphasized for close co-operation by all concerned in antenatal care if a high percentage of antenatal Wassermann tests are to be performed.

Thanks are due to the nurses and doctors working in all the branches of medical services in the County Borough of Stockport. Their day-to-day co-operation has made this study possible. I am especially indebted to Dr. Marion W. Davies, assistant medical officer of health, who assisted with the treatment of many of these cases.

The War Office has published a report of the first five years' work of the Army Tumour Registry at the Royal Army Medical College, Millbank. The Registry was established in April, 1948, thanks to the foresight of the late Lieutenant-Colonel J. MANIFOLD, at the pathology department of the College, under Major (now Lieutenant-Colonel) D. W. BELL. For many years this department has been regarded as the Army histological reference laboratory, and it receives specimens from medical officers serving in many parts of the world. The Registry has three primary objects: (1) To ensure accuracy of diagnosis; (2) to assist in the follow-up of cases of malignant disease; and (3) to act as a scientific record of the types of tumour encountered by Army pathologists. A fourth object, which is held out as a hope for the future, is to supply medical officers with sets of representative sections as does the Armed Forces Institute of Pathology in Washington. Unfortunately, incompleteness of registration, lack of detailed information, and small numbers greatly limit the statistical usefulness of the collection.

PILOCARPINE AS AN ANTAGONIST TO THE UNDESIRABLE EFFECTS OF GANGLION-BLOCKING AGENTS IN THE TREATMENT OF HYPERTENSION

BY

J. A. GUNN, D.M., F.R.C.P.

Emeritus Professor of Pharmacology, Oxford

AND

A. M. COOKE, D.M., F.R.C.P.

Physician to the Radcliffe Infirmary, Oxford

A disadvantage in the use of ganglion-blocking agents for the reduction of hypertension is that they block conduction not only through sympathetic but also through parasympathetic ganglia. The desired lowering of blood pressure is due to the action on the former, the undesirable effects mainly to the action on the latter. It would be a clear advantage if the effects on parasympathetic ganglia could be neutralized.

It seemed to us that this ought to be readily done by the use of pilocarpine. This drug acts peripherally on the post-ganglionic terminals, and its action should not be prevented by simultaneous paralysis of the pre-ganglionic fibres to the ganglia. In medicinal doses it has no action on the post-ganglionic sympathetic terminals, so that it should not diminish the hypotensive action for which the ganglion-blocking drug is given. A preliminary trial on a suitable patient has confirmed this anticipation.

Case Report

The patient, a woman aged 45, had been treated since March, 1953, first with hexamethonium bromide intramuscularly, and later, for the past five months, with pentolinium tartrate ("ansolysen") orally. Both treatments gave very satisfactory results in reducing the hypertension and concomitant symptoms, but in doses sufficient to maintain an adequate reduction of blood pressure the side-effects were distressing. These were of the usual type: dryness of the mouth, leading to interference with speaking and swallowing; constipation and loss of appetite; dryness of the eyes and loss of accommodation; and, especially with hexamethonium, difficulty with micturition.

The patient was given orally a tablet containing 1/10 gr. (6.5 mg.) of pilocarpine nitrate. Within half an hour she reported that "instead of my mouth being parched, I can do nothing but spit." As the salivation was unnecessarily copious, half a tablet was next given. This produced slight moistening of the mouth, but not enough. A dose of about 1/13 gr. (5 mg.) (three-quarters of a tablet) has subsequently proved adequate for keeping the mouth in a satisfactory state of moistness. On this dosage the side-effects of pentolinium tartrate have largely disappeared. Certainly the dryness of the mouth and eyes is relieved, and appetite and digestion have improved. This has made a great difference to the patient's sense of well-being, which has been maintained for five weeks on a dose of pilocarpine of 1/10 to 1/13 gr. (6.5 to 5 mg.), during which time she has led a normally active life. The dryness of the mouth, an effect easily appreciated, disappears regularly within half an hour of swallowing the pilocarpine and returns in six to ten hours, depending on the dose. The patient has also remarked, without questioning, that the constipation has been less.

Comment

Pilocarpine, by stimulating all parasympathetic nerve-endings (or by some action equivalent to this), has a wide-

spread action on involuntary muscle and on secreting glands, and is a potential antagonist to all the effects which result from paralysis of parasympathetic ganglia. It would presumably have this effect in the case of any ganglion-blocking agent. In smaller doses it acts more on glands than on muscle, and might therefore be expected to antagonize the effects of ganglion-blocking agents on secretions more readily than those on muscle.

The loss of tone and of contractions of the alimentary tract which often occurs with ganglion-blocking agents is no doubt mainly due to blockage of the motor impulses to the muscle, but the diminution of salivary, gastric, and intestinal secretions can hardly fail to aggravate the constipating effect. Some improvement of this condition may therefore occur even if the dosage of pilocarpine is only high enough to act on secretions. In larger doses it powerfully stimulates intestinal muscle. It has also some action on ganglia, but this could hardly occur with medicinal doses. To what extent it could be safely used to antagonize the various muscular and glandular effects resulting from parasympathetic ganglion-block would require detailed exploration. It would be a question not only of dosage but probably to some extent also of individual variations in quantitative response. Fortunately, medicinal overdosage with pilocarpine can be readily antagonized with atropine should need arise.

We have not encountered in the literature any mention of pilocarpine having been tried for the purpose we have indicated, other than a passing reference by Smirk (1953). Our object in submitting this note is to suggest that it may prove of value for counteracting some at least of the undesirable side-effects which often mar the desired depressor effects of ganglion-blocking agents.

THE ROLE OF SMOKING IN BRONCHITIS

BY

K. N. V. PALMER, M.D., M.R.C.P.

*Senior Lecturer in Medicine, University of Aberdeen;
Assistant Physician, Aberdeen Royal Infirmary*

Many factors which are responsible for the development or aggravation of bronchitis, such as climate, atmospheric impurities, hereditary predisposition (Oswald *et al.*, 1953), and infection (Stuart-Harris *et al.*, 1953), are difficult to control or eradicate. It is important, therefore, to assess the role of factors, such as smoking, which are more easily controlled. This investigation was undertaken to assess the incidence of bronchitis in a group of smokers compared with a similar group of controls who were non-smokers.

The patients studied consisted of a consecutive group of 422 males who were admitted to the Middlesex Hospital during the period from September, 1950, to September, 1952, for elective repair of inguinal hernia or a partial gastrectomy for chronic peptic ulcer. There were 310 smokers and 112 non-smokers.

Method

I examined each patient before the operation, and a postero-anterior radiograph of the chest was taken. The age, the place of residence, and a past history of diseases likely to predispose to the development of bronchitis were noted. Table I shows the distribution of these factors in the groups.

TABLE I.—Comparison of Groups of Smokers and Non-smokers

	No.	Average Age (Years)	Place of Residence			Past History			
			Urban	Sub-urban	Rural	Hay-fever	Asthma	Nasal Catarrh	Pneumonia
Smokers	310	47	152	138	20	12	5	31	33
		S.D. 12	49.0%	44.5%	6.5%	3.9%	1.6%	10.0%	10.6%
Non-smokers	112	48	51	55	6	3	3	10	12
		S.D. 12	45.5%	49.1%	5.4%	2.7%	2.7%	8.9%	10.7%

The patients' smoking habits were classified as follows: heavy, 20 or more cigarettes a day; moderate, 10–19 cigarettes a day; light, fewer than 10 cigarettes a day.

There were fewer than 10 pipe smokers. In these, 1 oz. (28 g.) of tobacco was taken as roughly equivalent to 30 cigarettes.

Patients were classified as non-smokers if they had never smoked, or if they had given up smoking for a year or more before admission. Ten patients had given up smoking more recently, and these were excluded from the series.

Diagnosis of Bronchitis

This was considered under three headings: a history of bronchitis, clinical evidence of bronchitis, and radiological evidence of bronchitis. It is well known that the principal symptom of bronchitis is cough, productive of a variable amount of expectoration. The common history is that the symptoms start in the winter, often following a cold. In succeeding winters the duration of the cough after each attack progressively increases. This phase gradually gives place to a constant cough and expectoration with winter exacerbations (Scadding, 1952). Quite marked winter bronchitis is quiescent in the summer, when some of these cases were interviewed. Thus if the patient admitted to a productive cough which had lasted a fortnight or more during two preceding winters he was deemed to have a positive history of bronchitis. A dry cough, due to pharyngitis, for example, was not considered such a reliable indication of bronchitis, and patients with a dry cough only were not included.

Bronchitis was diagnosed clinically when rhonchi or numerous coarse rales were found on examination of the chest. Minimal fine rales at the lung bases which cleared readily on coughing were not considered to justify a diagnosis of bronchitis, as this is a common finding in patients who are in bed.

The radiological changes of bronchitis are not distinctive. Bronchitic changes were considered to be present radiologically when there was an increase in the density of the bronchovascular markings in the outer two-thirds of the lung fields. These changes were seen only in the more severe cases of bronchitis, and were usually associated with some degree of emphysema. No cases of pulmonary congestion due to heart disease were seen in this series.

Of the 422 patients, 47.4% gave a positive history of bronchitis, 28.4% showed clinical evidence of bronchitis, and radiological changes were present in 14.2%.

Results

In Table II the incidence of bronchitis in the group of smokers is compared with that in the non-smoker group. It can be seen that the incidence was definitely higher in the smokers than in the non-smokers. The incidence

TABLE II.—Incidence of Bronchitis in Smokers and Non-smokers

	No.	History of Bronchitis	Clinical Evidence of Bronchitis	Radiological Evidence of Bronchitis
Smokers	310	166 (53.5%)	100 (32.2%)	53 (17.1%)
Non-smokers	112	34 (30.4%)	20 (17.9%)	7 (6.2%)
Difference		23.1% (S.E. 5.19)	14.3% (S.E. 4.49)	10.9% (S.E. 3.13)

of bronchitis in the groups, moreover, differed by more than twice the standard error, so that these differences are unlikely to have arisen by chance.

The main factors other than smoking which are likely to predispose to a history of bronchitis are satisfactorily distributed between the groups (Table I), so that the higher incidence of bronchitis in the smokers may be reasonably considered to be associated with smoking.

In Table III the incidence of bronchitis is compared with the amount smoked. It is apparent that the incidence of bronchitis increases markedly with increased smoking.

TABLE III.—Incidence of Bronchitis Compared with Amount Smoked

	No.	History of Bronchitis	Clinical Evidence of Bronchitis	Radiological Evidence of Bronchitis
Heavy smokers	42	31 (73.8%)	29 (69.0%)	16 (38.1%)
Moderate "	127	73 (57.5%)	39 (30.7%)	23 (18.1%)
Light "	141	62 (44.0%)	32 (22.7%)	14 (9.9%)
		$\chi^2 = 12.91$ n = 2 P < 0.01	$\chi^2 = 32.05$ n = 2 P < 0.01	$\chi^2 = 18.27$ n = 2 P < 0.01

This trend is very unlikely to have arisen by chance (P < 0.01).

Older people are more likely to have a history of bronchitis than younger ones, but this is unlikely to be the reason for this trend as the average age for the heavy smokers was 45.4 years, for the moderate smokers 48.0 years, and for the light smokers 47.6 years.

Discussion

In this series of adult male patients, bronchitis, based on clinical and radiological findings, was significantly commoner in smokers than in non-smokers. The incidence of bronchitis, moreover, increased significantly with the amount smoked.

Of 1,000 patients with chronic bronchitis studied by Oswald and his colleagues at the Brompton Hospital, only 5% were non-smokers. They also found that there were appreciably fewer non-smokers among 300 patients with bronchitis than among a comparable control group without bronchitis. Moreover, these authors found that half the smokers felt that smoking aggravated their bronchitis, and that a large number had abandoned the habit with benefit.

In a disease with so many aetiological factors as bronchitis, smoking is obviously unlikely to be the only factor concerned. The incidence of a history of bronchitis, for example, was as high as 30% in the non-smoking group in this series, and 26% of the heavy smokers gave no history of bronchitis. Nevertheless, these results suggest that smoking is of considerable importance in the aggravation of bronchitis, and it follows that in the management of these cases, in addition to the usual measures, they should be encouraged to give up smoking.

Summary

In a group of 422 males there were 310 smokers and 112 non-smokers.

The incidence of bronchitis was significantly higher in the smokers than in the non-smokers.

The incidence of bronchitis increased with the amount smoked.

My thanks are due to the Research Grants Committee of the Middlesex Hospital, to the surgeons who allowed me to examine their cases, and to the radiologists who reported on the chest radiographs.

Medical Memoranda

Treatment of Status Asthmaticus with Nitrogen Mustard

Professor C. Jiménez Díaz and his associates (1950, 1951) have reported encouraging results with nitrogen mustard in the treatment of status asthmaticus. The value of cortisone and A.C.T.H. in alleviation, temporarily at least, of severe and exhausting symptoms of the asthmatic state now seems to be definitely established (Bordley *et al.*, 1949; Randolph *et al.*, 1950; Friedlaender and Friedlaender, 1951). A certain relationship seems to exist between these hormones and nitrogen mustard. During the administration of nitrogen mustard there occurs progressive lymphopenia and eosinopenia. The same results can be obtained with A.C.T.H. and cortisone (Dougherty and White, 1943; Thorn *et al.*, 1949). Noting the close relationship that exists between A.C.T.H. and cortisone on the one hand, and nitrogen mustard on the other, Díaz and his associates decided to try nitrogen mustard in asthma. Their extremely encouraging results prompted the use of nitrogen mustard in the following case.

CASE REPORT

A girl aged 13 had been having attacks of bronchial asthma for the past two years. In the beginning these occurred at infrequent intervals and were quickly relieved by the administration of adrenaline. During the second year the frequency and severity of the attacks had gradually increased, but they could still be terminated by adrenaline. On February 1, 1951, the patient had another severe attack. She was given an injection of adrenaline, which brought only slight relief lasting for about one hour. Repeated injections of adrenaline and ephedrine failed to give her any further relief.

On the morning of February 2 she was given an intravenous injection of 0.25 g. of aminophylline. She had prompt relief of her symptoms, which, however, lasted for only about eight hours. In the evening she was given a further 0.25 g. The relief produced this time, however, was not so dramatic and lasted for a shorter time. During the next two days she had repeated injections of adrenaline, next two days she had repeated injections of adrenaline, and khellin with minimal response. Her aminophylline, and khellin with minimal response. Her general condition during the past four days had deteriorated considerably. She was unable to lie down in bed and was completely exhausted. At this stage it was decided to administer nitrogen mustard intravenously. Her white blood cell count at this stage was 10,328 per c.mm. (polymorphs 45%, lymphocytes 39%, eosinophils 14%, monocytes 2%).

Nitrogen mustard, 2.5 mg. dissolved in 2.5 ml. of normal saline, was administered intravenously very slowly. No precautions were taken to prevent the vomiting which usually occurs a few hours after the intravenous administration of the nitrogen mustard, since it was thought that by liquefying the tenacious bronchial secretions the vomiting might further benefit the patient. One hour after the injection the condition of the patient began to improve. Vomiting started two hours after the injection; anything by mouth provoked it. In the next six hours she vomited about 15 to 20 times. As anticipated, the bronchial secretions were to a great extent liquefied, and she was able to expectorate with great ease. Eight hours after the first injection her clinical condition was much improved. There was no more respiratory discomfort, and on examination her chest was much clearer. She was now able to lie down in bed without discomfort. Vomiting, however, was still occurring, and at this stage she was given phenobarbitone, 1½ gr. (0.1 g.), after which the vomiting gradually stopped and she slept an uneventful night. Next morning she had no asthmatic symptoms and no foreign sounds could be heard in the chest. All anti-asthmatic treatment was suspended. Her white blood cell count at this stage was 11,240 per c.mm. (polymorphs 66%, lymphocytes 29%, eosinophils 5%, monocytes 0%).

Further injections of 2.5 mg. of nitrogen mustard were given intravenously on alternate days to a total of four injections. She was given 1½ gr. (0.1 g.) of phenobarbitone immediately after the injections to diminish vomiting, the severity and frequency of which was much diminished by this procedure.

Since her last injection of nitrogen mustard the patient has been seen and examined repeatedly till the time of writing (about three and a half months), and she has remained completely symptom-free.

COMMENT

The management of status asthmaticus often becomes a serious medical problem. It taxes the skill, patience, and experience of all physicians. Rigorous methods of treatment may sometimes be justified in an occasional case. The advent of A.C.T.H. and cortisone in the field of therapeutics is a real advance in the management of severe intractable cases of status asthmaticus; indeed, their use may be a life-saving procedure in certain cases. But the prohibitive cost of these drugs often precludes their use in a really deserving case. Nitrogen mustard, which is a comparatively cheap drug, has given very encouraging results in the hands of Continental workers. The case reported above confirms its versatility. The benefit produced by it parallels the fall in the eosinophil count. But nitrogen mustard is a potentially toxic drug, and it is essential that blood counts be carried out at regular intervals to prevent a serious depression of the bone marrow.

As yet it is too early to draw any conclusions on the therapeutic efficacy of nitrogen mustard in asthma, but the response obtained in the above case and by Continental workers warrants further clinical trials.

ADDENDUM.—Since this case report was written three further cases of chronic bronchial asthma have been treated with nitrogen mustard with encouraging results.

Isolation of Bact. Coli O.26.B.6 from a Child with Recurrent Diarrhoea

Specific serological types of *Bact. coli* are now fairly widely recognized as a factor in the aetiology of infantile gastroenteritis. So far, however, there are few reports of such organisms playing a pathogenic part in the later age groups.

CASE REPORT

In October, 1952, a mother brought her daughter, aged 12, to me suffering from diarrhoea. The girl had been quite well until eight days previously, when her stools became watery and yellow, and she had frequent bouts of abdominal colic. These symptoms lasted two days, and the girl was free from symptoms until the night before seeing me, when again she had abdominal pain followed by diarrhoea.

Asked whether anyone else in the family had had a similar illness, the mother said that her son, aged 1 year, had had stomach trouble for the previous three months. The baby seemed well, but about once a week had had frequent loose stools. She had attributed this to teething.

I requested a pathological examination of the faeces of both these children. A report on the infant stated that *Bact. coli* type O.26.B.6 was present and that no other intestinal pathogens or parasites were found.

I then asked for an examination of the older child's stool, with special reference to the presence of this type

of *Bact. coli*. The organism was found to be present. Both strains were found sensitive to sulphathiazole and chloramphenicol.

Treatment.—While investigations were being made, both patients were treated symptomatically with kaolin. This had no effect, for the condition recurred under my observation—that is, normal bowel action for five days was followed by pain and loose discoloured stools for two days.

I gave a seven-day course of sulphathiazole. During this treatment symptoms were absent, but at the end of treatment the specific strain of *Bact. coli* was still present, and a week later the condition relapsed. Chloramphenicol was then given, diarrhoea ceased at first but returned after five days' treatment (possibly due to the drug). I then instituted a combined course of chloramphenicol and sulphathiazole extending over ten days. Diarrhoea stopped and pains ceased. A week after the end of this treatment, specimens from both children were negative. Further specimens remained negative. After three months both children were well.

COMMENT

Two children, aged 2 years and 1 year respectively, suffered from recurrent diarrhoea and colic. Repeated faeces examinations revealed none of the usual intestinal parasites or pathogens, but a sero-specific strain of *Bact. coli*, Type O.26.B.6, known to be associated with infantile gastro-enteritis, was repeatedly isolated from the faeces of both children, and not until the organism had disappeared from the stools after a course of sulphathiazole and chloramphenicol did clinical recovery take place. Specimens examined from the unaffected members of the household were consistently negative for *Bact. coli* O.26.B.6.

It therefore seems worth while to consider such organisms when investigating cases of diarrhoea even after the age of infancy.

I am grateful to Dr. M. Thomas, of the Public Health Laboratory, Edmonton, for examining the faeces specimens from these cases.

Acute Psychotic Reaction after Inhaling Methylamphetamine

The following case is reported because of its unusual psychiatric interest and also to indicate a possible danger in the indiscriminate use of the amphetamine group of drugs by inhalation of the vapours.

There appear to have been no similar cases reported in the literature or known to the manufacturers of these inhalers. There have, of course, been many cases of addiction and even of psychosis associated with ingestion of amphetamines, and in this connexion inhalers are often used as a ready source of the solid drug.

CASE REPORT

A man aged 41 was admitted on July 8, 1951, to a mental hospital on an urgency order. Physical examination revealed a robust healthy man. He was rather flushed and sweated readily; pulse 100; blood pressure 150/92. There were a few rhonchi in both lung fields. Further investigations showed him to have nasal polypi and chronic maxillary antritis. The urine contained traces of sugar and acetone. The Wassermann reaction and Kahn test were negative. Mentally he was well orientated, but acutely hallucinated both visually and aurally. He was anxious and had severe insomnia. His pockets contained five "methedrine" inhalers, which before use had each contained 250 mg. of methylamphetamine base.

On July 11, after rest and sedation, he was much improved and able to give the following history. He was an Irish unskilled worker who had been separated from

his wife and living alone in this country for many years. He denied alcoholism and any previous mental illness in himself or his relatives. On the evening before admission he had felt unwell and had used his inhalers to relieve his nasal congestion. He often used them three or four times an hour, and thought that on this occasion he may have inhaled as often as every five or ten minutes. He admitted that they gave him a pleasant feeling, described as a "lift" with something sexual about it. After a few hours he had noticed that he "saw" women and animals in the room, although he realized they were unreal.

These hallucinations were in bright colours and were rather diminutive. He also described an illusion in which a coat over a chair "turned into a woman." He had the feeling that these happenings were supernatural, and seeing some shadows at the window of a house opposite he got the idea that he was being hypnotized. He went over the road to investigate and called in the police. It was this that led to his admission to hospital.

By July 15 he had completely remitted, but voluntarily remained in hospital in order that certain tests could be carried out. He appeared intelligent and informative, if not garrulous, but gave the impression of being a rather unreliable witness. His affect was cheerful and congruous, but a little shallow. The hallucinations had gradually disappeared over four to five days.

A Rorschach test was carried out on July 26. With full co-operation the patient could produce only 13 responses. His intelligence was tested on a shortened Wechsler verbal scale; it gave an I.Q. of 120. It seemed likely that his meagre and constricted Rorschach record was due to an "accuracy compulsion" so powerful as to inhibit his ability to make anything of the ink-blots.

On July 27 he was given 30 mg. of methylamphetamine intravenously. He became flushed, his pulse rose to 120, and his blood pressure to 190/120. He expressed a feeling of well-being and a desire to "get up and do things." He stated that marks on the ceiling became more conspicuous and that when he looked up at a certain object he felt as if it looked back at him. Colours appeared to change and he had erotic sensations. He later remarked on the similarity of these feelings to those following methedrine inhalation.

In 30 minutes he appeared to have recovered and was subjected to a second Rorschach test. The number of responses had risen to 47, considerably more than is usual, in spite of the compulsiveness being still very marked. He left hospital the next day, but later claimed that the injection test had produced hallucinations lasting for several days, which he had kept quiet about.

Six weeks later he had a third acute hallucinatory episode following the further use of inhalers. He then underwent an operation for removal of his nasal polypi and has apparently remained well since.

COMMENT

There seems to have been established in this case a causal relationship between methylamphetamine absorbed by inhalation and an acute psychotic reaction. The drug was, of course, used in excess of the recommended dose. Also it appeared that the man's previous personality was such as to predispose to psychotic breakdown and possibly to addiction. The illness was at first thought to be an acute schizophrenic episode, but was subsequently diagnosed as an acute organic confusion, although confusion in the sense of severe disorientation was singularly lacking. However, the overactivity and the paranoid element were fairly typical of previously described amphetamine psychoses. It is thought possible, in view of the time lag of a few hours after injection before the occurrence of definite hallucinations, and their persistence for several days, that the psychotic reaction may not have been directly due to the action of the drug on the higher centres, but to a withdrawal or exhaustion phenomenon.

Reviews

A BOOK FOR GENERAL PRACTITIONERS

Refresher Course for General Practitioners: specially commissioned articles from the British Medical Journal. Second collection: January, 1951, to March, 1952. Fully revised. (Pp. 570; illustrated. £1 5s.) London: B.M.A. 1954.

In these hurrying times when textbooks are out of date before they are printed, it might be thought that a collection of articles from the *British Medical Journal*, first published between January, 1951, and March, 1952, would be stale. That this book seems fresh is no doubt owing to the care with which the editor has chosen his authors. The teaching of the good physician remains true, although he may be a little behind the latest phase or craze of advancing medicine.

With all this variety of refreshment, from which sort of article will the general practitioner derive most benefit? Revision lectures are apt to be dull unless, as in "Malaria" by Sir Gordon Covell, the latest treatments are described, or unless the expert by his very enthusiasm for his specialty provokes controversy, as does Dr. C. J. C. Britton in "Allergy" or Professor Arnold Sorsby in "Infections of the Eye." Many will like the dogmatic approach of Professor R. S. Pilcher, who says in effect that general practitioners should treat common acute infections of the fingers and hand and that this is the way to do it. This at least is a challenge which it is hard to ignore. Others will enjoy the thrilling description of Dr. Desmond Cugran removing the boots from his acute mental case before administering the sedative by injection. Fortunately most general practitioners are conversant with the legal complications of assault. Others, again, will appreciate the balanced argument on the potentialities of "Physical Methods of Treatment in Psychiatry" by Drs. William Sargent and Eliot Slater, and "The Pros and Cons of Immunization" by Professor Robert Cruickshank.

As well as refreshment and provocation and balanced argument there is the sting. How many practitioners examine an eye as Mr. B. W. Rycroft advises? How many think of leukaemia when they see a gingivitis? (Sir Lionel Whitby). Here perhaps is the true worth of this volume. When an author can show that the general practitioner is failing in the very thing that is his specialty, the general health or illness of his patient as opposed to the particular symptom or sign which brings the patient to him, then he gets under the guard of the practitioner's complacency and it hurts. There is no doubt whatever that it does us good to get hurt at times. This book should find a place in every practitioner's library for the good of his soul as well as his mind.

C. W. WALKER.

LEEDS UNIVERSITY

The University of Leeds: The First Half-century. By A. N. Shimmin, C.B.E., M.A. Drawings by Maurice de Sausmarez. (Pp. 229+xv; 28 illustrations. 21s.) Cambridge: University Press for University of Leeds. 1954.

The founding of nine universities or university colleges during the past 50 years is a remarkable achievement in the development of higher education, but perhaps the real interest to educationists and to sociologists is the varied way in which the different localities have each fostered the development of their own "Redbrick" university. The contrasts are particularly striking between the three sister colleges of the old Victoria University—Manchester, Liverpool, and Leeds.

When the Yorkshire College of Science was founded in 1874 the first three chairs were experimental physics and mathematics, geology and mining, and chemistry. It was almost inevitable with a succession of distinguished clinicians such as the Heys, the Teales, McGill, Wheelhouse, Thackrah, and Clifford Allbutt that a strong medical school existed when the College was founded, and that the Royal

Commission of 1894-5 concluded that little work of university standard was being done in the Yorkshire College outside the medical school. Despite the initial limited but essentially practical approach to educational problems, the Yorkshire College attained its charter in 1904, and, with the support of many local worthies, of the Clothworkers Company and of generous benefactors, such as Lord Brotherton and Parkinson, has developed into the flourishing university of to-day. The University has never lost contact with its environment. The technological departments are thus both numerous and strong, but Arts is now the largest faculty, and the establishment of a chair of music, an appointment in fine arts, and the generous bequest of the Gregory Fellowships have more than balanced the developments in engineering, textiles, and metallurgy.

Much of Professor Shimmin's account refers to personalities, both academic and lay, who have played such a prominent part in the development of the University of Leeds, information of great interest to all graduates. Of wider interest are the chapters on "Recurrent Issues," "Student Welfare," and "Town and Gown." The perennial problems of accommodation and of standards, not only for entrance to the University but also for degrees, and the significance of honours, together with the place, if any, of diploma courses, have been, and still are, important issues. The value to the corporate life of the students of being able to organize their own union is emphasized, and has resulted in the encouragement of a wide range of activities—for example, the dramatic societies, which have established a unique tradition within the past 15 years. The study of the development of hostels and the student health service will be of interest to all university teachers and administrators. The relationship of "Town and Gown" has been most happy, and, though the University of Leeds is not merely a civic university, the city is proud of the University and the latter stands high in the esteem of the citizens.

Professor Shimmin has succeeded in capturing for the reader something of the spirit and atmosphere of the University as well as of its struggles and its problems. It is interesting to note that the motto of the University, *Et augebitur scientia*, was the one Evelyn proposed for the Royal Society. The standing of the University of Leeds to-day may be said to justify its motto, and suggests that it may in due course attain the stature of that society which selected for its motto *Nullius in verba* instead of "And knowledge shall increase."

R. E. TUNBRIDGE.

SURGICAL PATHOLOGY

Surgical Pathology. By Lauren V. Ackerman, M.D. (Pp. 836; 913 illustrations. £5 10s.) London: Henry Kimpton. 1953.

This book is "an introduction to the vast field of surgical pathology" and "does not pretend to replace in any way the textbooks of general pathology, its purpose being merely to supplement them, assuming that the reader has a background or access to those texts." The author is professor of surgical pathology of Washington University School of Medicine, and in a clearly written introductory chapter he defines the scope of his subject and the attributes of the perfect surgical pathologist. Antibiotics, modern anaesthesia, biopsies, immediate frozen sections, and exfoliative cytology are responsible for an enormous increase in the volume of diagnostic clinical histology coming to hospital laboratories, and in his introduction Professor Ackerman almost makes a case for regarding a career limited to surgical pathology as being not only satisfying and rewarding to the pathologist but a fully justifiable whole-time activity in the interests of the surgeon and his patient.

Professor Ackerman has written a very sound account of modern surgical pathology, and one of the several merits of his book is that it is based to a large extent on his own experience. Almost all the numerous and remarkably good photomicrographs are from cases he has investigated. He lays considerable emphasis on naked-eye appearances, and with few exceptions deals with common lesions and avoids the rare and curious. Full and clear accounts of the

pathology of diseases of the skin and skeletal tissues will be appreciated by the practising pathologist, and the chapters on the thyroid and male reproductive system are outstanding.

The volume can be recommended to surgeons and radiologists, and will serve as a safe guide to the young pathologist. It is distressing that the high quality of its binding, paper, and illustrations has made the book so costly.

GEOFFREY HADFIELD.

ECZEMATOUS REACTIONS

The Eczemas. A Symposium by Ten Authors. Edited by L. J. A. Loewenthal, M.D., M.R.C.P., D.T.M.&H. (Pp. 267; 77 figures. 35s.) Edinburgh and London: E. and S. Livingstone Ltd.

This is a useful publication to the dermatologist in that it brings together the views of numerous authorities from different parts of the world on various aspects of approach to the complex eczematous reactions.

The main clinical presentations—the contact, allergic, atopic, infective, and seborrhoeic eczematous reactions—are clearly expounded by outstanding teachers of the British, American, and Continental schools. The significance of patch test and of more elaborate investigations, as that of resistance to alkalis, acids, and solvents, is discussed in detail, and a chapter by Haxthausen on theoretical considerations of the allergic mechanism involved is of great interest. Dr. Storck discusses the place of pyogenic organisms in relation to some types of eczema and in the dissemination of eczema by sensitization. There are useful chapters on differential diagnosis and on treatment which will be much appreciated by the practitioner. The illustrations are mostly good and explain much in the text. There are useful lists of appropriate concentrations to be employed for patch-testing and prescriptions for topical application.

It is to be regretted that, with contributions from various centres and climates dealing with patients of different races, including black and white, no more is made of the relative incidence and of the differing characters of eczema in these subjects. It is perhaps not sufficiently stressed that eczema is not a disease entity but a pattern of reaction, and that underlying its protean manifestations there are certain essential and fundamental similarities. However, it is important and valuable to have this body of knowledge on so hotly disputed a subject collected together for reference, and Dr. Loewenthal is to be congratulated upon this service he has done his colleagues.

J. T. INGRAM.

GENERAL VIROLOGY

General Virology. By S. E. Luria. (Pp. 427+xiii; illustrated. 68s.) New York: John Wiley and Sons Inc. London: Chapman and Hall. 1953.

Interest in viruses was first aroused by the recognition of their importance as the causal agents in diseases of animals or plants, and, indeed, many of the books dealing with viruses are concerned with their pathogenic role. The more extensive works are mostly joint efforts by specialists in various aspects of the virus field. This book is the most comprehensive work by a single author that has yet appeared on virology treated as a biological science. In consequence the treatment is more uniform than in larger works with multiple authorship, though the examples chosen from the whole field to illustrate general principles naturally reflect the author's particular interest. In the chapters on virus-host interaction the bacterial viruses are discussed at considerably greater length than are plant and animal viruses. The bacteriophage-bacterium system has yielded more readily to intensive study by biochemists and biologists, and the author's original contributions in the bacteriophage field have been very considerable. Nevertheless, throughout most of the book animal and plant viruses have been considered in parallel with the bacterial viruses, and the uniformity of mechanisms stressed where the data seem to warrant it.

This excellent book is stated to be an outgrowth of a course on viruses for graduate and advanced undergraduate students in biology and biochemistry, but specialists in various fields of virology, including those whose interests are mainly in virus infections of man, will find it stimulating and informative.

A. W. DOWNIE.

CONGENITAL HEART DISEASE

Traité des Cardiopathies Congénitales. Sous la direction de E. Donzelot et F. D'Allaines. Par R. Heim de Balsac, C. Metianu, M. Durand, et C. Dubost. (Pp. 1,118; 1,155 figures. 13,800 fr.) Paris: Masson. 1954.

This treatise on congenital heart disease is based on the work at the Broussais Hospital in Paris over the five years from 1947 to 1952. There the authors have studied some 1,110 patients, of whom about 600 have received surgical treatment. This is a large experience, and rivals in number that of Maude Abbott's Atlas in 1936. But all the cases described here have been investigated by modern methods and by the authors themselves. As a result the documentation is full and exceedingly well set out. The classification adopted is clinical and should be practical. The authors attach great importance to the ether test as an indicator for a veno-arterial shunt, for in these a positive reaction in the superficial vessels of the skin of the face is obtained. The teratology is dealt with shortly; in fact the part on embryology might have been fuller. There is a good chapter on the pathological physiology. The methods of examination include all the modern techniques; the authors indicate well their limits and their advantages, believing that wide experience will show many of the more elaborate to be superfluous. For the most part the skiagrams are good, but some of the angiograms might be better. The cardiograms are clear; it would be easier to follow them if the 12 or 15 (or more) complexes which are usually shown were always arranged in a standard pattern. The diagrams throughout are excellent, and there are many good illustrations of morbid specimens. It is interesting to read that the authors seek to distinguish between the hypertrophy from obstruction and that due to overfilling, and think that the cardiogram may help to show which is present—an idea which goes back to the early days of Corvisart and Bouillaud in their discussion of concentric and eccentric hypertrophy. This is indeed an amazing work, all the personal experience of the authors. There are full lists of references at the end of each chapter. The index is most efficient. This fine work has everything to recommend it, but alas, at what a price!

TERENCE EAST.

POPULAR MEDICAL HISTORY

Bouquet for the Doctor. By Dorothy Fisk. Preface by Sir Alexander Fleming, F.R.S. (Pp. 241+xii; 17 illustrations. 18s.) London, Melbourne, and Toronto: William Heinemann Ltd. 1954.

The publishers of this book well describe it as a "panorama of the progress of medical science—the achievement of a truly international company." It is an attempt to write a popular "History of Medicine," which Sir Alexander Fleming in a preface, with characteristic understatement, calls "a difficult task." I thoroughly enjoyed reading the result. The sketches of the men responsible for marking the epochs described are brilliant, but we are never allowed to forget the labours of the lesser, sometimes unknown, men who made the discoveries possible. The life stories of Harvey, Sydenham, Jenner, Lister, Pasteur, to mention only a few of those commemorated, are told with a sure hand and with an unflinching sense of proportion, as well as with a refreshing sense of humour. One is tempted to quote, but I will limit myself to the author's summary of the amazing career of John of Gaddesden: "His was a well-to-do practice but there is no record that he sent the poor away empty-handed—if they succeeded in approaching him." Though the book is eminently light-hearted there is ample evidence of the trouble taken by the author to get her facts right. The illustrations are excellent and worthy of the text. In short, the book is a credit to all concerned in its production.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY JUNE 26 1954

REHABILITATION

Though rehabilitation is a relatively new term in medicine, those in medical practice have always striven, so far as circumstances allowed, to achieve "the fullest possible restoration to normal life and working efficiency of a person incapacitated by disease or injury."¹ Often, however, especially in the case of severely disabled industrial workers, circumstances were not favourable: medical facilities were sometimes inadequate, means of providing on a large scale such requisites as suitable living accommodation and transport did not exist, and jobs compatible with the patient's disability were unavailable. In times of economic crisis no jobs, either compatible or incompatible with disability, were to be had.

The present differs from the past in two important respects. First, as a result of extensive legislation, including the Disabled Persons (Employment) Act of 1944 and the National Health Service Act of 1946, elaborate machinery now exists for reablement, resettlement, and, if necessary, retraining of the handicapped. Secondly, and of equal importance, there is now almost full employment in this country, so that jobs for the disabled are more readily available. In consequence immense progress has been made during the past ten years in industrial rehabilitation and resettlement. A more recent development is in the field of social resettlement. Under Section 29 of the National Assistance Act of 1948, local authorities can provide for the disabled such facilities as social and occupational centres, hostels, structural adaptations to the home, and transport from home to places of worship and recreation. Social resettlement has a special application in helping the disabled housewife² to lead a more useful and constructive existence; it may also result in freeing for productive work able-bodied men and women previously tied to looking after sick relatives at home. That social resettlement has not developed to the same extent as industrial rehabilitation is partly due to its more recent introduction, but chiefly because local authorities are only now beginning to exercise the powers given to them under the National Assistance Act.

Rehabilitation may be an exceedingly complicated process, its success depending on enlightened team-

work and good administrative integration. The case of a man with loss of function of both lower limbs as a result of anterior poliomyelitis will illustrate what is involved. He lives, perhaps, in an old-fashioned house with steps up to the front door, and it can be assumed that wherever he lives he is some distance from a place of work. His various requirements, together with the bodies charged with providing them, can be listed as follows: (1) a period of reablement in hospital, where he receives physical treatment and occupational therapy, and is provided with callipers and elbow crutches (Ministry of Health through the hospital services); (2) ground-floor living accommodation (local authority); (3) a mechanically propelled tricycle (Ministry of Health); (4) a garage for the tricycle (Ministry of Health); (5) the construction of a special gate and runway between the road and the garage (local authority); and (6) a job suitable for his disability (Ministry of Labour through the disablement resettlement officer). Retraining may be necessary at a Government training centre, possibly after a period of convalescence at an industrial rehabilitation unit (Ministry of Labour). Admittedly the above example is an extreme and fortunately an uncommon one, but in such a case a long period of delay and frustration is inevitable and interdepartmental bickerings likely unless all the officials concerned work closely together. But this is not always so at the present time.

To survey the whole field of rehabilitation an inter-departmental committee was set up over a year ago under the chairmanship of Lord Piercy. Evidence has been given before this committee by many bodies, including the Council of the British Medical Association. The written evidence submitted by the B.M.A. was prepared by a special committee under the chairmanship of Professor R. E. Tunbridge. The committee's report³ is published this week and a short summary appears on page 1490. The report—a most comprehensive document and the fifth on rehabilitation that the Association has produced since 1912—deals with many aspects of the problem, particularly on the industrial side. Much of it is concerned with ways and means of improving administrative integration. One of the most important recommendations is that the duties of each Ministry concerned in rehabilitation should be clarified. At the moment it is often impossible to determine where any of the three Ministries concerned—Health, Labour and National Service, Pensions and National Insurance—

¹ "Report on Rehabilitation," by a Special Committee of the B.M.A., *British Medical Journal Supplement*, 1946, 1, 187.

² See annotation, *British Medical Journal*, 1953, 1, 323.

³ *The Rehabilitation and Resettlement of Disabled Persons*, 1954, British Medical Association, London.

ance—as well as the various local authority committees, should assume full responsibility and where responsibility should be shared. Another important recommendation is that the present series of D.P. (disabled person) forms be replaced by a new, single (and more simple) type. Most of the existing forms are too complex and often impossible to fill up correctly. Moreover, even when completed they serve little useful purpose, since no corresponding data concerning job analysis in industry exist.

The report also recommends that the disablement resettlement officer (D.R.O.) should have more extensive and appropriate training; his office should be a specialized appointment with its own grades, and the practice stopped whereby for the administrative convenience of his Ministry he is transferred from one place to another, often when the work he is doing is most fruitful. It is suggested that far more use should be made of resettlement clinics; these should be an integral part of all major hospitals or groups of hospitals, the clinic being available for general practitioners and D.R.O.s, as well as for the hospital staffs. Finally, the report re-emphasizes that the initial drive as well as the responsibility for the continuation of a rehabilitation service must come from the medical profession.

This leads to a most important question—the place of the doctor in rehabilitation. On this the Council of the Association has definite views:

“Continuous medical supervision of the patient is necessary throughout all stages of rehabilitation. By this the Council means that the patient is always under the close personal care of the medical practitioner appropriate to the particular stage of rehabilitation, confidential information about the patient being passed on as one medical practitioner takes over the responsibility from another.”

As so many non-medical persons and official bodies are concerned in rehabilitation the role of the medical practitioner is apt to be overlooked, hence the importance of the Council's statement: “Indeed, there is no stage short of complete recovery at which the doctor could hand over all responsibility to non-medical personnel.”

SMOKING AND LUNG CANCER

Further evidence that tobacco smoking plays some part in causing lung cancer is given in the opening pages of the *Journal* this week by Dr. Richard Doll and Professor A. Bradford Hill, F.R.S. Gained by means of a different approach from that hitherto taken, it confirms in two important respects the conclusions already drawn.¹⁻³ These are, first, that the death rate from lung cancer is higher among smokers

(particularly of cigarettes) than among non-smokers, and, secondly, that the death rate from lung cancer among smokers increases with the amount smoked.

Previous studies of this problem were carried out by comparing the smoking history of lung-cancer patients with that of patients suffering from other diseases. The present study is distinct in that the subjects—members of the medical profession in the United Kingdom—were first sorted by smoking history, and the occurrence or not of lung cancer in the various groups of smokers and non-smokers was and is still being investigated. In October, 1951, Doll and Bradford Hill sent a short questionnaire to doctors in the United Kingdom asking them to give certain replies about their smoking habits. By this means sufficient information was obtained to classify into non-smoking or various smoking categories about 40,000 of the nearly 60,000 medical men and women to whom the questionnaire was sent. Since the questionnaire was issued the Registrars-General have informed Doll and Bradford Hill of the cause of death of every doctor. Thus it has been possible to compare the cause with the smoking history, the comparison being restricted to male doctors aged 35 and over, since lung cancer is uncommon in women and rare in young men. Of the 789 deaths considered, 36 were due to lung cancer. The death rate from this cause among non-smokers was nil, for smokers 0.66 per thousand. The death rates in the three smoking groups defined were as follows: 1-14 g. daily (1 cigarette=1 g. of tobacco), 0.48; 15-24 g. daily, 0.67; 25 g. or more daily, 1.14. The number of deaths from lung cancer in the last group, the heavy smokers, is twice the number expected if the deaths had been distributed evenly among all categories of smokers and non-smokers. There is also some confirmatory evidence, though not technically significant, that cigarette smoking is a greater hazard than pipe smoking. Among the other causes of death which Doll and Bradford Hill have studied in relation to smoking category only coronary thrombosis shows a notably increasing death rate with increase of amount smoked. But the upward trend is not so marked as that for lung cancer, and these workers conclude merely that there may be some causative relation between smoking and a subgroup of the coronary-thrombosis cases.

The figures are rather surprising in showing no considerable increase in deaths from respiratory diseases (other than cancer) with increase of smoking. It might have been supposed that the

¹ Doll, R., and Hill, A. B., *British Medical Journal*, 1950, 2, 739.
² *Ibid.*, 1952, 2, 1271.

³ Wynder, E. L., and Graham, E. A., *J. Amer. med. Ass.*, 1950, 143, 329

severe “smoker's cough”—which the smoker so often attempts to palliate by lighting another cigarette—would predispose to fatal respiratory conditions, but this inquiry has shown no evidence of it yet. In an article on p. 1473, however, Dr. K. N. V. Palmer records that bronchitis was found to be significantly commoner in adult male smokers than non-smokers. He too found not only that the incidence of bronchitis was higher among the smokers than among the non-smokers in his group of patients, but that among smokers the incidence increased with the amount smoked. He found clinical evidence of bronchitis in 32% of the smokers as compared with 18% of the non-smokers. When the smokers were classified into light, moderate, and heavy, the percentages in each group showing clinical evidence of bronchitis were respectively 23, 31, and 69. The figures for history of bronchitis and radiological evidence of it point the same way.

According to a report in the *Manchester Guardian* of June 23 Dr. Cuyler Hammond, of Yale, has just given a preliminary account of an investigation on similar lines to that of Doll and Hill. Some of the conclusions reported are that after the age of 50 cigarette smokers have almost twice as high a death rate as non-smokers from all causes, that coronary disease is higher in cigarette smokers than in non-smokers, and—what Dr. Hammond describes as “a most unexpected discovery”—that there is a “cause and effect relationship between cigarette smoking and all kinds of cancer.” Cigar and pipe smokers come out of his survey unscathed. We await with interest the publication of Dr. Hammond's findings.

THE GLASGOW MEETING

The 122nd Annual Meeting of the British Medical Association will be held in Glasgow next week, and from the programme published in last week's *Supplement* it is evident that our hosts of the Glasgow Division have spared no effort to give members of the Association a real Scottish welcome to one of the principal cities and university towns of Britain. According to precedent the first part will be devoted to the business of the Annual Representative Meeting, “the doctors' Parliament,” as it has been so aptly described. The A.R.M. is the policy-making body of the Association, and this is a prerogative that can be assumed by no other unit within the B.M.A. The A.R.M. has proved itself over many years as the sound testing ground for the policies advocated by the various committees through the Council of the

Association, and the assembled Representatives have invariably shown a shrewd appreciation of the facts of any situation presented to it.

The agenda, published in the *Supplement* of June 19, shows that the Divisions have scrutinized carefully the Annual Report of Council and its Supplementary Report. The large number of motions and amendments under “Hospital and Consultant Services” is a sufficient reminder, if any were needed, that the A.R.M. is not principally concerned with matters relating to general practice—a reminder, too, that we are one profession and not two, three, or more professions with conflicting interests. It was said by some in the time preceding the N.H.S. Act and the appointed day of 1948 that the N.H.S. was something that chiefly affected general practitioners. But events have shown that the hospital and consultant world has equally been caught up in the machinery of the State, and, with little precedent to guide it, has had to carry out negotiations of extreme complexity. If some consultants are sensitive in detecting a critical note in the motions and amendments on the agenda they may yet reflect that open argument is their greatest safeguard now and in the future, and that the A.R.M. is a most fair-minded body with a traditional respect for facts and an Anglo-Saxon distaste for theory. If there is some disquiet over the remuneration of consultants, specialists, and hospital medical staff, this necessary aspect of professional life is also of much concern to our colleagues in the Public Health Service, whose interests the Association has always done its best to promote. General practitioners will watch with interest and sympathy the debate on the scheme for the restoration of the right to buy and sell goodwill, and the motions under “General Medical Services” show how closely Divisions follow the wide-ranging activities conducted for general practitioners by the G.M.S. Committee. Among other matters may be noted the progressively important work of the Occupational Health Committee, and the first account of work in progress by the Constitution Committee.

The B.M.A., coming to the end of another successful year's work under the continued guidance of Dr. E. A. Gregg, the Chairman of Council, moulds and is moulded by the varied scientific and professional forces of a great profession which by its nature can never remain static. The interests of the Association are the interests of the whole profession, and the unity of the whole must accommodate within it diversity if the unity is to be other than a dull unison. And as a meeting place for diverse and critical minds the A.R.M. is a remarkable illustration of how diversity with unity can be maintained in a spirit of free inquiry.

DESENSITIZATION TO ANTIBIOTICS

When a person develops cutaneous hypersensitivity to a substance he uses at work the easiest course is to remove him from the hazard and to prevent re-exposure. This is the usual practice when the work is unskilled and when the worker does not lose much in prospects or wages through being moved to another job. It is more serious when a person who is highly trained and in specialized work becomes sensitized to some substance that must be handled every day in the course of the work. Avoiding the hazard may entail wrecking a career after years of training: for instance, a nurse trained in the treatment of venereal diseases may find it impossible to continue with this work if she develops cutaneous sensitivity to penicillin; or a nurse wishing to specialize in the treatment of tuberculosis may find her ambition thwarted if she becomes sensitive to streptomycin. Similar difficulties arise with doctors and veterinary surgeons. It is no use continuing to expose the sensitized individual to the hazard in the hope that "hardening" may occur. Hardening may seem to occur in some cases of acquired general hypersensitivity, but in many of these cases the hypersensitivity is linked with some temporary lowering of psychophysical well-being. Hardening does not occur in cases of specific hypersensitivity, including the forms due to penicillin or streptomycin: on the contrary, repeated exposure to the sensitizer leads to an ever-increasing degree of hypersensitivity, and in the end the sufferer finds that it is impossible to continue in the work.

A recent report from the Ministry of Health¹ has emphasized the extent of the problem. It has been shown that the wearing of gloves, masks, and gowns does not prevent reactions in people sensitive to streptomycin, though scrupulous attention to the avoidance of mist-production by all streptomycin handlers may reduce the incidence. Contamination may occur when preparing or giving injections, or when cleaning used syringes. The vigorous ejection against the side of a sink of the water used to clean a syringe may produce enough mist to cause a reaction.² Can these people be desensitized to penicillin and to streptomycin? Recent papers by Alexander³ and Crofton⁴ suggest that they can be and that the procedure is not unduly tedious, causing little or no distress. Alexander describes the desensitization of a nurse whose duties entailed giving injections of penicillin to patients suffering from syphilis. The nurse suffered from dermatitis of the hands, and patch tests with penicillin were positive. The initial dose used was 50 units of aqueous penicillin given every three hours, the dose being doubled every day, unless reactions occurred, until a dose of 200,000 units per injection could be taken without reaction. The dermatitis of the hands healed during the desensitizing course, except for minor exacerbations, which necessitated temporary reductions of the doses. The whole course lasted twenty days, the nurse being able to continue at work all the time. Alexander used the intramuscular route, regarding this as logical because penicillin is given therapeutically in this way. Peck *et al.*⁵ described desensitization of seven people to penicillin by the subcutaneous route and one by the oral route. So long ago as 1946 O'Donovan and Klorfajn⁶ reported complete desensitization of a penicillin-sensitive patient by oral administration of penicillin. Actinic sensitivity which was also present faded with the penicillin sensitivity.

Sensitization to streptomycin is often much more intense than sensitization to penicillin. Sometimes a nurse is unable to enter a room where streptomycin is handled without developing redness and itching of the eyelids, a phenomenon usually regarded as indicating air-borne transference of the sensitizer. Wheeler⁷ described the desensitization of a nurse by a course of injections, at first subcutaneous, later intramuscular, starting with 50 µg. and rising to 0.8 g. of streptomycin. The dose was doubled every other day when possible. Crofton reported⁴ the desensitization to streptomycin of a nursing sister by a course of intramuscular injections lasting thirty-five days; the dosage began at 10 µg. and rose to 1 g. A course of injections of dihydrostreptomycin, from 50 µg. to 0.5 g. over a period of fifteen weeks, failed to desensitize another nurse against streptomycin, but a subsequent course of streptomycin, from 50 µg. to 1 g. over another period of eight weeks, was successful, intradermal and patch tests to streptomycin becoming negative. Russell⁸ reported partial desensitization of a nurse to streptomycin following the intradermal injection of streptomycin in doses from 0.1 mg. to 2.2 mg. over a period of twenty-six days.

It seems from these observations that desensitization to penicillin or streptomycin can be carried out in a few weeks without much difficulty and that the intramuscular, subcutaneous, intradermal, or (with penicillin) the oral route can be used. Whether the immunity so induced is permanent remains to be seen.

PROTEIN SYNTHESIS

Our early training in chemistry impressed on us the importance of the elements constituting a substance: sulphuric acid was different from hydrochloric acid because it was H_2SO_4 and not HCl . But as we proceeded to organic chemistry elementary constitution lost its importance, most of the substances that we learnt of being built up from three or four elements only. Instead, we were impressed with the importance of the arrangements of atoms to form specific groupings, and it was these groupings that determined the peculiar characteristics of any compound. Organic chemistry was bewildering because of the multiplicity of the

possible groupings of just a few elements. In the field of protein chemistry we are presented with enormous possibilities of variation; a single molecule may be built up of chains of thousands of amino-acid residues of a dozen or more types; the possibilities of varying the sequence of amino-acid residues along the chains are immense; different sequences will impose different physical and chemical properties on the molecule and will determine the manner in which it is possible to fold the chains into specific configurations. Hence, although the number of different atom species on which we can ring the changes is small, we are at no loss to explain the number of proteins that must exist—a very great number indeed, as is clearly shown by species specificity. For human serum albumin differs from bovine albumin, which differs from rabbit albumin, and so on. Thus, individuality in the protein components of an organism is apparently determined by a pattern of amino-acids condensed to form polypeptide chains. The living organism reproduces itself, so that the species characteristics are retained in the offspring. It would be absurd to suggest that all the different proteins in the organism are represented in the reproductive cells, like so many animals in Noah's Ark, and that these reproduce themselves; instead, it seems probable that the power to synthesize these proteins, and to develop the various other species and individual characteristics, is bound up in the nucleus and possibly also in the distinct regions of the cytoplasm, the plasmagones. The substance of the chromosomes and plasmagones must therefore be such as to permit of a very wide range of variation in its physical and chemical properties. It is here that the nucleic acids become of interest, first, in being essential components of the gene substance, and secondly by their close connexion with the synthesis of protein—the dominant feature in cell multiplication.

Deoxyribonucleic acid (D.N.A.) is found exclusively in the nucleus and is almost certainly a fundamental constituent of the gene substance. Ribonucleic acid is found in both the nucleus and the cytoplasm and becomes prominent during phases of protein synthesis. Both of these nucleic acids, therefore, because of their special functions, must exist in a wide variety of forms. Like the proteins, they are built up of long chains, not of amino-acids, however, but of alternating molecules of sugar, purine base, and phosphate. Variations in chemical and physical properties could doubtless be achieved by variation in the order in which the different purine bases are built into the chains, but the difficulty in establishing experimentally whether this is indeed the case lies in the problem of separating the different nucleic acids from each other. In a recent paper¹ an ingenious application of chromatography to the problem has been described; with its aid several fractions have been separated from a preparation of nucleic acid, and there is good reason to believe that these fractions represent only a gross separation, so that ultimately it may be shown that "the deoxyribonucleic acid of a particular species consists of a continuous distribution of molecular species with varying ratios of the purine bases."

The synthesis of protein may be observed in its most pronounced form in the multiplication of a virus. The tobacco mosaic virus is apparently no more than a protein linked to nucleic acid. Rob the virus of its nucleic acid and it can no longer multiply; hence it is the presence of nucleic acid that determines the power of the organism to reproduce itself. Moreover, if the modern viewpoint is correct, it is the peculiar arrangement of the purine bases in the nucleic acid which determines that the virus will reproduce itself and not synthesize some new type of protein. How the nucleic acids can exert their influence is not known; presumably they enter into the synthetic reactions as catalysts, influencing, by virtue of their own structure, the sequence in which amino-acids are condensed to form polypeptide chains.

THE MINISTER ON GENERAL PRACTICE

The Minister of Health, opening extensions to the East Ham Chest Clinic on June 21, gave his views about the future of general practice in an important speech which is reported in this week's *Supplement* (p. 358). Many of those working in the Health Service may be tired of hearing pleas for improved co-operation, but Mr. Macleod's sensible, well-informed, and friendly remarks will surely be welcomed by all general practitioners. He said that in his two years of office he had not introduced a single health Bill, for he was convinced that it was more important to make existing legislation work than to introduce new Acts. In what he called "good" areas there was excellent co-operation between all branches of the Service, but that sort of co-operation could not be achieved by circular or regulation. "What I want to see," he said, "is the spirit of team-work in general practice devoted to the service of the patient such as we have already in hospital." The Minister agreed that the same pattern of general practice would not do for every area: health centres and group practice might be suitable for some areas but not for all. The soundness of the links between the general practitioner and the hospital was of the first importance. Not only should ordinary hospital facilities be open to him, but he should be welcome and know that he was welcome in all the local hospitals. The Minister emphasized that hospital reports on patients should not be regarded as routine form-filling, but should be considered statements from a senior member of the staff. If the link between the general practitioner at the hospital was continued through the work of the health visitor, then we might be getting somewhere near the ideal of the general practitioner as the head of a clinical team as diverse in its own way as the team which looked after the patients in hospital. Mr. Macleod also spoke about improving co-operation between the general practitioner and the medical officer of health. Because of the great demands on the curative medical services it might be difficult at present to concentrate on the preventive side, but, he concluded, the National Health Service ought to be designed to promote health.

CLINICAL PATHOLOGY IN GENERAL PRACTICE POLYCYTHAEMIA, LEUKAEMIA, AND CYTOPENIA

BY

RONALD BODLEY SCOTT, M.A., D.M., F.R.C.P.

Physician to H.M. the Queen; Assistant Physician, St. Bartholomew's Hospital

In most branches of medicine the excellent advice to "define one's terms" is neglected, but in haematology the necessity is inescapable, more particularly because the meaning of a term cannot always be derived from a study of its etymology. "Polycythaemia" is an example of this difficulty; it might well be expected to indicate an increase in number of all the cells in the blood, but by accepted usage its meaning is restricted to an increase above normal in the number of erythrocytes per cubic millimetre. It is qualified sometimes by the adjective "rubra," an illicit union of Greek and Latin, which, if distasteful to the classicist, gives it greater precision.

By derivation the word "leukaemia" means white blood, and this was exactly what Virchow intended to indicate when he devised it in 1845. The morbid anatomists have since shown us that its basis is an unexplained and uncontrolled proliferation of primitive leucocytes throughout the haemopoietic organs; leukaemia in the sense of white blood is an inconstant epiphenomenon, but the term is too well established to be replaced by one more logical.

"Cytopenia" means a reduction below the normal in the number of cells per cubic millimetre of blood; it is used in a non-specific sense and is applicable to erythrocytes, leucocytes, or platelets. Sometimes it is qualified by the prefix "pan," when it indicates a simultaneous reduction in all three of these elements.

POLYCYTHAEMIA

The significance of an erythrocyte count cannot be appreciated without knowledge of the limits of normal. Discombe, in an earlier article in this series,* has given the normal ranges as follows: erythrocytes 4,300,000-6,400,000 per c.mm.; haemoglobin 12-17 g. per 100 ml. (100% Haldane=14.8 g. per 100 ml.); and the packed red cell volume 42-48%. Polycythaemia rubra, therefore, may be defined as a state in which the erythrocyte count exceeds 6,400,000 per c.mm. This increase is almost invariably accompanied by a parallel increase in the packed cell volume and usually by a rise in the haemoglobin level.

Relative Polycythaemia

An increase in the erythrocyte count does not necessarily indicate an increase in the total number of circulating erythrocytes. It may be due to a reduction in the plasma volume and is then to be observed when dehydration occurs from a reduced intake of fluid, diarrhoea, vomiting, or profuse sweating; or when there is a sudden effusion of plasma into damaged tissues as in the shock of thermal burns and the crush syndrome. In all these conditions the increase in the erythrocyte count is transient and the cause evident; diagnosis is not in doubt, but blood examination often affords a useful index of the degree of blood concentration and thus of the reduction in plasma volume. This type of disturbance is sometimes described as "relative polycythaemia."

One variety demands special mention because it is often confused with polycythaemia vera. It is commonly seen

*British Medical Journal, 1954, 1, 326.

in middle-aged males in whom anxiety symptoms are salient; hypertension is present in at least half the patients and splenomegaly never occurs. The erythrocyte count is moderately raised, seldom exceeding 7,000,000 per c.mm.; the leucocyte count is below 10,000 per c.mm., and no immature forms are seen. Recent observations on the blood volume of such patients by J. H. Lawrence and his colleagues* have shown that the plasma volume is reduced and the total erythrocyte mass is not increased. The recognition of this disorder is important because treatment aimed at reducing the total erythrocyte volume is likely to be harmful. The condition is probably that described by Gaisbock in 1922 as polycythaemia hypertonica, although an attempt has been made to rename it, in the fashionable idiom, "stress erythrocytosis."

Secondary Polycythaemia

Polycythaemia, often termed secondary, occurs in anoxic states whatever their cause. The most striking examples are met with in cyanotic congenital heart disease in which the erythrocyte count may exceed 9,000,000 per c.mm. with a parallel elevation in the haemoglobin level. It is rare, but has occasionally been noted, in acquired (rheumatic) heart disease. In lesser degree it is common in pulmonary disease, particularly emphysema and fibrosis of the lung; it is a feature of diffuse atheroma of the pulmonary vessels. Its occurrence at high altitudes is well known, and it is seen when anoxia is due to decrease of the oxygen-carrying capacity of the blood in sulphaemoglobinemia and occasionally with cerebral tumour its occurrence is well attested but ill understood. In all these varieties of secondary polycythaemia there is an increase in the total erythrocyte mass, but the plasma volume is usually somewhat reduced; splenomegaly does not occur, unless for some unrelated reason, and the leucocyte and platelet counts are normal.

Polycythaemia Rubra Vera

Polycythaemia rubra vera is a disorder of the haemopoietic tissues characterized by a marked and persistent increase in the total erythrocyte count. It is, however, a disease in which all the elements of the bone marrow proliferate, and leucocytosis with thrombocytosis is the rule. The clinical features are a cyanosis, plum-coloured in winter and brick-red in summer, with splenomegaly. The erythrocyte count may be as high as 12,000,000 per c.mm., and in about 10% of patients normoblasts are observed. The haemoglobin reading may exceed 20 g. per 100 ml. The packed cell volume (haematocrit) is constantly above 50% and may reach 75%. Three-quarters of the patients have a leucocyte count above 10,000 per c.mm. Blood volume studies have shown the total mass of circulating erythrocytes to be increased, sometimes to three times normal; the plasma volume is normal or somewhat reduced.

Diagnosis requires a persistently raised erythrocyte count without other cause for its elevation; in the absence of blood volume estimations a diagnosis of polycythaemia vera should not be entertained when the figure is below 7,000,000 per c.mm. It is made likely by an increase in

*Lawrence, J. H., Berlin, N. I., and Huff, R. L., *Medicine*, 1953, 32, 323.

the leucocyte count, due to an excess of myeloid cells, particularly when immature forms are present, by a raised platelet count, and by splenomegaly.

LEUKAEMIA

The cellular proliferation of leukaemia "breeds true," and thus three cytological types—myeloid, lymphatic, and monocytic—can be recognized. The process may be acute or chronic; however, only three well-defined clinical varieties exist because the acute forms, in the main, differ only cytologically and chronic monocytic leukaemia is of extreme rarity. These clinical forms are acute leukaemia, chronic myeloid leukaemia, and chronic lymphatic leukaemia.

The proliferative process affects the blood in three ways. First, the proliferated cells may overflow into the circulation, causing alterations in the peripheral leucocyte count which may be qualitative or both quantitative and qualitative; when the total leucocyte count is not increased the unfortunate epithet "aleukaemic" is applied. Secondly, by a process of crowding out or by differentiation of primitive cells to the leukaemic type, the other elements in the bone marrow are reduced in number, and anaemia, thrombocytopenia, and leucopenia ensue. Thirdly, secondary effects, probably related to splenomegaly, may occur; of these the haemolytic anaemia, which sometimes complicates chronic lymphatic leukaemia, is the most important.

Acute Leukaemia

The patient with acute leukaemia usually comes under observation because of anaemia or a haemorrhagic state. The degree of anaemia is variable, but often intense, haemoglobin levels of 3-5 g. per 100 ml. being common; the erythrocytes are commonly of normal size and well filled with haemoglobin; thus the mean corpuscular volume (M.C.V.) and mean corpuscular haemoglobin concentration (M.C.H.C.) are normal. Occasionally some macrocytosis is noted but the M.C.V. seldom exceeds 110 μ^3 . In most instances regenerative phenomena, such as reticulocytosis, polychromasia, and normoblastosis are lacking. In the more acute varieties the platelet count is reduced when the patient is first seen; in all it falls progressively as the disease advances. Haemorrhagic phenomena, a prolonged bleeding time, diminished clot retraction, and a positive tourniquet test usually accompany its reduction.

The leucocyte count varies. It is probably true to say that normal or low figures are more common than high, particularly in the myeloid form. There may be a profound leucopenia of 500 cells per c.mm. or less or an extreme leucocytosis of 250,000 per c.mm. or more. The predominant cell varies with the type of leukaemia. In the acute myeloid form it is the myeloblast, and these cells may form 95% of the circulating leucocytes. In the leucopenic cases, however, the proportion of myeloblasts may be as low as 5%. It is noteworthy that the myeloid cells show no regular gradation from the most primitive to the most mature and that a "hiatus leukaemicus" (Naegeli) often separates the myeloblasts from the granulocytes (see Fig. 1). In acute lymphatic leukaemia again the total leucocytes count varies, but it is the rule for lymphoid elements to be present in obvious excess; in some cases these are easily classifiable as lymphoblasts, but frequently less primitive cells predominate. In monocytic leukaemia there is almost always a leucocytosis, although it is seldom above 30,000-40,000 per c.mm. Monoblasts and promonocytes predominate and usually form a high proportion of the total.

In the leucopenic forms, particularly when the proportion of primitive cells is low, firm diagnosis is impossible without examination of the bone marrow. The findings are usually characteristic; the marrow is richly cellular and 80-90% of the cells are primitive myeloid, lymphoid, or monocytic elements. In acute myeloid leukaemia the changes are sometimes less clear-cut, particularly when the

disease is not rapidly progressive; here the proliferation may be mainly at the level of the promyelocyte or less commonly affecting equally promyelocytes and myelocytes.

The diagnosis of acute leukaemia is not usually difficult when the results of blood and bone-marrow examinations are available. Aplastic anaemia may be suggested by the blood count; the leucoerythroblastic anaemia of skeletal carcinomatosis should not cause confusion, for the hiatus leukaemicus is lacking (Fig. 1). Leukaemoid reactions to infection or acute haemolysis seldom give rise to the preponderance of primitive cells seen in acute leukaemia. An exception to this is the myeloblastic response occasionally seen with generalized tuberculosis; it may be impossible on haematological grounds alone to distinguish this from acute myeloid leukaemia.

Chronic Myeloid Leukaemia

In chronic myeloid leukaemia there is seldom any difficulty in diagnosis. By the time the patient seeks advice the changes in the blood are usually fully developed and characteristic. Anaemia of moderate severity is the rule, the haemoglobin level lying most often between 6.5 and 7.5 g. per 100 ml.; the erythrocyte count is reduced in proportion, the anaemia being normocytic and normochromic; occasional normoblasts may be seen. The platelet count is normal or raised, sometimes to figures above 750,000 per c.mm. The striking alteration is, however, in the leucocytes: the total number is increased, most often perhaps to about 250,000 per c.mm., but counts of above 1,000,000 per c.mm. are sometimes seen. These high figures are due entirely to a great excess of myeloid cells; fully segmented neutrophils usually predominate, and if the cells are placed in grades it will be found that the numbers in each diminish with decreasing maturity. This dispersion is shown in Fig. 2, where the maturity of the myeloid cells of blood and bone marrow in a case of chronic myeloid leukaemia is compared.

Deviations from the picture described are rarely seen, except after treatment, when the blood may be indistinguishable from normal. Occasionally, however, chance

FIG. 1.—Histograms showing maturity dispersion of myeloid cells in the blood in aleukaemic myeloid leukaemia (left) and erythroblastic anaemia (right). Note the "hiatus leukaemicus" in the left-hand histogram. (Reproduced by permission of the editor of the *Proceedings of the Royal Society of Medicine*.)

directs that the blood count shall be made before the characteristic changes have developed, and in such instances a persistent and unexplained neutrophil leucocytosis is discovered; when such patients are followed the typical haematological features of the disease are found gradually to appear. It is unlikely that a true leucopenic, or aleukaemic, chronic myeloid leukaemia ever occurs. Such a label has often been attached in the past to patients now recognized as suffering from myelosclerosis in whom the blood changes are those of leuco-erythroblastic anaemia.

In many typical cases of chronic myeloid leukaemia increase in the eosinophil and basophil granulocytes is to be noted; rarely eosinophils, and much more rarely basophils, predominate; these varieties are spoken of as chronic eosinophilic or basophilic leukaemia. More common is a form in which the features of polycythaemia rubra vera and chronic myeloid leukaemia both exist; in such cases neither the erythrocyte nor the leucocyte counts usually reach the high levels which occur in typical examples of either disease. This disorder has been given the name "chronic erythromyelosis."

Chronic Lymphatic Leukaemia

In chronic lymphatic leukaemia the only constant feature of the blood count is a relative, and usually also an absolute, increase in lymphocytes. In the early stages the total leucocyte count is often below 20,000 per c.mm., with lymphocytes making up perhaps 60-80% of the total. As the disease progresses the total leucocyte count rises and may reach figures in excess of 300,000 per c.mm.; with this increase there is a parallel rise in the number of lymphocytes, which may surpass 99%. The type of cell varies: in the more chronic form it is the small lymphocyte; in others a larger cell with more abundant cytoplasm and an indented nucleus—"the lymphosarcoma cell" of some authors—may occur. In all a characteristic feature is the uniformity of cell type. Lymphocytes are more fragile than other leucocytes and often fragment when films are made, to leave numerous "basket cells," "smear cells," or "Gumprecht's shadows." This is particularly true of the less mature varieties.

In the earlier stages of many cases of chronic lymphatic leukaemia anaemia is absent and the platelet count unaffected. After months or years lymphoid infiltration of the bone marrow makes its appearance and there is a progressive fall in erythrocyte and platelet counts. Terminally, profound anaemia and thrombocytopenia are common.

In a proportion of patients with this disease a symptomatic haemolytic anaemia supervenes, imposing upon the haematological features of chronic lymphatic leukaemia those of excessive blood destruction. A rise in the serum bilirubin, urobilinuria, a sudden aggravation of anaemia with reticulocytosis, and a positive Coombs test mark this complication.

Bone-marrow puncture biopsy is of limited value in diagnosis because lymphoid infiltration of the marrow is seldom intense in the early stages, when extreme peripheral lymphocytosis is lacking and anaemia slight.

CYTOPENIA

Cytopenia has already been defined as a non-specific term indicating a reduction in some or all of the types of cell of the circulating blood. In the present discussion it is used in the restricted sense of leucopenia or reduction in the number of leucocytes per cubic millimetre; erythrocytopenia and thrombocytopenia are considered only when associated with it.

The lower limit of the leucocyte count in health is about 3,100 per c.mm. (Discombe), although it is rare to meet figures below 3,600 per c.mm. Leucopenia may therefore be said to exist when the count falls below 3,000 per c.mm. It will be appreciated that this figure refers to the sum total of the leucocytes, a term which embraces all five varieties of normal white blood cell. In the present con-

nexion the neutrophils are of outstanding importance, because leucopenia is virtually synonymous with neutropenia. Lymphopenia occurs rarely and in practical haematology is most frequently the result of radiotherapy. The lower limit of the normal neutrophil count may be taken as 2,500 per c.mm. and of the lymphocyte count as 1,000 per c.mm. When leucopenia is profound the neutrophils are most affected, but all other varieties of leucocyte are also greatly diminished in number.

Ex hypothesi neutropenia or any other cytopenia might be brought about by defective formation of the cells in question, by their excessive destruction, or by some impediment to their emigration from the bone marrow. Little practical help is gained by attempting to compress the causes of neutropenia into these categories, because in many instances the operative mechanism is not understood. The following classification does little more than group together the neutropenias by the disorders with which they are associated.

Infections

There are certain infections in which leucopenia is commonly stated to be a characteristic or even a diagnostic feature. These are the enteric group of fevers, brucellosis, virus infections such as influenza and sandfly fever, and the typhus fevers. Application of the criteria proposed by Discombe shows that these infections are marked rather by absence of leucocytosis than by leucopenia. It is relatively uncommon for the leucocyte count to fall below 3,000 per c.mm. in any of them. In the differential count neutropenia with "shift to the left" is the main feature, usually with an absence of eosinophils.

Leucopenia is the rule in malaria and kala-azar; in the latter it may be extreme and associated with necrotic angina or other secondary infection. In both these disorders it is possible that the neutropenia is "splenic" in the sense considered below.

Infections of overwhelming severity, particularly some examples of septicaemia and generalized miliary tuberculosis, may be accompanied by neutropenia. It is difficult to distinguish infections, the severity of which is enhanced by pre-existing neutropenia, from those intense enough to paralyse leucopoiesis.

Bone-marrow Failure

When the haemopoietic functions of the bone marrow are destroyed by physical or chemical agents, pancytopenia results. There is a normocytic normochromic anaemia without evidence of blood regeneration; the leucocyte count falls, perhaps to a few hundreds per c.mm., with disappearance of granular cells; the platelet count is similarly reduced. Such damage may result from exposure to radioactive substances or may be caused by a rapidly increasing number of drugs and other chemical products. The same picture is sometimes seen without apparent extrinsic cause, when it is termed "idiopathic aplastic anaemia."

It is more common for damage to the bone marrow, whether physical or chemical in nature, to be less overwhelming and to affect predominantly one cytological series, often the leucocytes. This sequence is well seen with therapeutic irradiation and after such drugs as the nitrogen mustards and triethylene melamine. There is an initial slow fall in lymphocytes which is followed by a sudden and precipitous drop in the neutrophil count when large doses are used.

Cytopenia is a sequel of bone-marrow failure due to other causes. Leucopenia is the rule with the functional disturbance of leucopoiesis which accompanies the erythroblastic hyperplasia both of pernicious and of hypochromic anaemia. It is common when the bone marrow is invaded or replaced by abnormal cellular proliferations as in leukaemia, myelomatosis, carcinomatosis, and myelosclerosis. The blood changes in leukaemia have already been considered. In the three last disorders pancytopenia with-

out qualitative changes may occur; in carcinomatosis, but especially in myelosclerosis, a leuco-erythroblastic anaemia is common. This is marked by a normochromic normocytic anaemia with a moderate reticulocytosis and normoblastosis; the leucocytes are commonly reduced in numbers, but the differential count shows a "shift to the left" of the granular cells from a high percentage of segmented neutrophils to an occasional myeloblast with a regular reduction in the proportions of the intermediate classes as their maturity diminishes (see Fig. 1); there is thrombocytopenia. Leuco-erythroblastic anaemia is considerably less common in myelomatosis; in this disease the leucopenia is often more striking than the anaemia or the thrombocytopenia, but occasionally the blood is flooded with the proliferating cells to cause a "plasma-cell leukaemia."

Associated with Splenomegaly

Leucopenia, often with thrombocytopenia, marks many diseases in which there is massive splenomegaly. Examples in which this association is common are congestive splenomegaly (Banti's syndrome), Felty's syndrome, and Gaucher's disease. It is occasionally observed in Hodgkin's disease, Boeck's sarcoidosis, and various forms of reticulosis and reticulosarcoma causing outstanding enlargement of the spleen. This symptom-complex is sometimes termed secondary splenic neutropenia; a primary variety has been recorded in which the excised spleen shows only non-specific reactive hyperplasia.

Although splenectomy is usually followed by restoration of the blood count to normal, the exact connexion between the spleen and the leucopenia is uncertain. Examination of the bone marrow shows hyperplasia of the myeloid series, and thus distinguishes these cases from those in which leucopenia is due to aplasia. It has been suggested that the spleen exerts some inhibitory influence upon discharge of leucocytes from the bone marrow.

Immuno-neutropenia

This ungainly term describes a variety of neutropenia apparently due to antineutrophil substances of the immune-body type. Moeschlin and Wagner established this mechanism as operative in agranulocytosis due to amidopyrine*; the leucocyte antibody acts in the presence of antigen as an agglutinin, and destruction of agglutinated neutrophils is thought to proceed in the lungs. In agranulocytosis of this type the leucocyte count falls precipitously within an hour or two of taking the causative drug; figures of 200-300 per c.mm. with absence of granular cells are not rare. Bone-marrow changes vary with the duration and the intensity of the leucopenia; when short and mild most of the myeloid series, except the mature granulocytes, are well represented; with increasing severity and duration there is progressive disappearance of this series, starting with the most mature elements and finally leaving the bone marrow depleted. These changes, formerly attributed to maturation-arrest, are now thought to be due to active depletion of the bone marrow by the intense peripheral destruction of granulocytes.

The importance of this cause of neutropenia is not yet known. It may well be responsible in acute diffuse lupus erythematosus in which pancytopenia is the rule; it has been recorded in primary atypical pneumonia. It seems probable that it explains the common agranulocytosis of explosive onset seen not only after amidopyrine but with sulphonamide, thiouracil, troxidone, tripeleminamine, and many other drugs.

Cyclical or Periodic Neutropenia

This is a rare disorder, often starting in infancy, in which periods of extreme neutropenia alternate with periods in which the leucocyte count is within normal limits. There is no anaemia or thrombocytopenia, and bone-marrow

*Acta haematol., Basel, 1952, 8, 29.

examination shows normal granulopoiesis. The leucocyte count will often show a pure neutropenia, sometimes with an absolute increase in lymphocytes and eosinophils. During the neutropenic phases infective phenomena are common. The cause is unknown and the course extends over many years; in some instances spontaneous recovery occurs.

PAEDIATRICS AND CHILD HEALTH IN FRANCE

BY

K. W. LOVEL, B.M., M.R.C.P.

Tutor in Child Health, University of Oxford; formerly Anglo-French Medical Exchange Bursar

AND

CYRILLE KOUPERNIK

Médecin-Assistant des Hôpitaux de Paris

In France, children's diseases occur against a background which is in most respects similar to that in this country, but there are certain differences of climate, race, and distribution of population, while social and economic factors are of even greater importance. The area of France is more than twice that of Great Britain, but the population is only 42 millions, of whom a considerably smaller proportion live in towns and suburbs; so the problems of rural medicine are important. Nevertheless, the highest infant mortality rates occur in the industrial and densely populated regions of the Nord and the Pas-de-Calais. Until 1941 the population had been declining, as a result of the low birth rate, for nearly a century, but this tendency has now been reversed by the generous maternity benefits and family allowances under social security, and in 1951 the birth rate was 19.4 and the natural increase in population 6.1 per 1,000. There is, in addition, a certain amount of immigration, and at present about two million foreigners are in the country, of whom the Algerians (400,000) form the largest group.

Wages are low, and the cost of living is higher than in this country, but wage-earners with children are greatly helped by the "allocations familiales," which often exceed the father's wages. There is a fixed payment for a child born within two years of marriage, a monthly allowance which reaches its maximum for the second and third children, and an additional payment if the father is the only wage-earner in the family. Examples of the family allowances are:

No. of Children	Mother Working	Mother at Home
1	—	1,725 fr. per month
2	4,385 fr. per month	11,285 " " "
3	11,000 " " "	19,625 " " "
4	17,610 " " "	26,235 " " "

Nutrition and Diet

Since the war food has been plentiful, and a high proportion of the family income is spent on it, so that malnutrition and deficiency diseases are uncommon, but the French children are shorter and considerably lighter than British children of the same age (see Table I). No doubt racial

TABLE I.—Average Heights and Weights of Boys and Girls

Age	Height (cm.)		Weight (kg.)	
	French	British	French	British
3 years ..	87	92	12.6	15.0
6 " ..	106	113	17.0	20.3
10 " ..	129	135	25.2	29.6
15 " ..	151	161	44.4	51.0

factors account in part for these differences, at least in height, but the figures suggest that either British children are unduly fat or there is a considerable amount of sub-optimal nutrition in France. If this is so, it may be because children of school age spend more time indoors and less on games, because the national dietary (with a high proportion of bread and meat, and large infrequent meals) is not so suitable for children, and because the consumption of milk is lower in France. Milk is not provided free in schools, and its hygienic quality leaves much to be desired in many districts, so that it is customarily made safe by boiling, with consequent loss of palatability. It has recently been made compulsory in towns of more than 20,000 inhabitants for milk to be pasteurized and sold in sealed bottles.

Social Factors

The standard of housing accommodation is generally lower than in this country, and serious overcrowding exists. This and alcoholism are the greatest social problems in France to-day, and they lead to a large number of broken homes and a high incidence of psychiatric disorders.

Education is compulsory between the ages of 6 and 14, and school subjects are similar to those taught in this country, but there is less physical education, and no milk or subsidized meals are provided. Children go to school on Saturdays, but have a half-holiday on Thursdays, because it is thought that a break in the middle of the week is better for them than a long week-end.

Incidence of Disease

It is difficult to judge the relative incidence of disease in the two countries in the absence of morbidity figures, but it is the impression of clinicians who have worked in both countries that the general pattern is the same. However, it seems that juvenile rheumatism and coeliac disease are more frequent in Great Britain, as are respiratory infections of all kinds. The latter are no doubt due largely to climatic and atmospheric differences, but the better heating of buildings in France may also be a factor. Tuberculosis, on the other hand, is more frequent in France, where, in 1951, the death rate was 60 per 100,000, compared with 31.5 here. Although it is difficult to be certain, because tuberculosis is not notifiable in France, the morbidity rate is probably higher also, and this and overcrowded living conditions account for the higher death rates from tuberculosis among children (Table II).

TABLE II.—Death Rates from Tuberculosis in 1951, per 100,000

Age	France	England and Wales
0-1 year ..	65	14.7
1-5 years ..	25	15
5-10 " ..	8	4.7
10-15 " ..	7.5	4.4

The infant mortality was 41.5 per 1,000 live births in 1951, compared with 29.7 in England and Wales, and analysis of the causes shows that "prematurity" takes first place in both countries and pneumonia comes second, but congenital malformations account for 4.34 per 1,000 in England and Wales and only 2.89 per 1,000 in France.

Another interesting comparison is given by the figures for fatal accidents in 1950 (Table III). The much higher road

TABLE III.—Fatal Accidents in 1950

Cause	France (Population 42 m.)			England and Wales (Population 44 m.)		
	0-1 Year	2-5 Years	6-15 Years	0-1 Year	2-5 Years	Years
Motor vehicle ..	5	47	77	3	265	430
Poisoning ..	15	21	19	8	53	15
Other accidents ..	307	937	551	750	565	464
Total ..	327	1,005	647	761	883	909
		1,979			2,553	

deaths in this country are no doubt due largely to the fact that a greater proportion of children live in built-up areas, but straighter roads and the absence of ribbon development in France are contributory factors.

Medical Arrangements

Sick children are first treated either by the family doctor or by a paediatrician, to whom the family have direct access and of whom there is one in most towns of 20,000 or more inhabitants. There are approved scales of fees, and patients insured under the social security scheme can claim back 80% of these fees and the same proportion of the cost of medicines; but the fees actually charged are usually somewhat higher than those approved. Also 80% of the cost of hospital treatment is reimbursed, except in case of maternity, infectious diseases, and illnesses lasting more than six months, when it is 100%. People who are not insured pay according to their means, assessed by the hospital's social service, up to the full cost, which is between £2 and £3 a day in the public hospitals. This figure includes drugs and operations, but laboratory and radiological examinations and consultations are extra. Children's hospitals and the children's services of general hospitals provide 0.24 bed per 1,000 of the population, and private clinics 0.019; the main differences from the hospitals of this country are that they admit children up to the age of 16, and that a greater proportion of the accommodation is in children's hospitals, many general hospitals having no children's wards. Daily visiting is the rule.

The hospitals have for many years ceased to depend on voluntary contributions, but they have not been "nationalized" and are not controlled in any way by the Ministry of Health. Instead, they are administered by the "Assistance Publique" of each town or département, and are generally self-supporting by virtue of the contributions they receive from their patients, though in some cases they may be subsidized by the municipality. The medical staff are unpaid, or receive only a small honorarium, and they attend in the mornings only, except for one or more "internes de garde," who are on duty all day and sleep in the hospital. Nurses are already trained and have obtained their State diploma when they come to work in a children's hospital, but the training lasts for only two years and the course is the same as for general nursing. There is, however, an additional "Diplôme d'Etat de Puéricultrice," instituted in 1947, which may be taken for a further year's study. Hospital nurses are usually non-resident, and their duties are arranged not in two shifts but in three. Otherwise, the personnel of a hospital is much the same as in this country, except that there is perhaps a smaller proportion of auxiliary workers such as physiotherapists, speech therapists, orthopodists, and clerical staff.

Convalescent homes number 300, with more than 9,000 places, and there are nearly 34,000 beds in establishments concerned with the fight against tuberculosis. Provision for chronic sick and handicapped children is not as good as in this country, and only a few of them, in institutions like the Hôpital Raymond-Poincaré, at Garches, Seine-et-Oise, receive formal education.

Preventive Services

The preventive and public health services, which have been greatly extended since the war, include antenatal, postnatal, and infant welfare clinics; additional maternity bene-

fits are paid to those who attend regularly and to mothers who breast-feed their babies. There are, however, no dietary supplements provided free or at reduced prices. Expectant fathers may attend antenatal clinics in many areas, to undergo chest fluoroscopy and a blood test; the same investigations are included in prenuptial medical examinations, which are compulsory throughout the country.

To combat further the infant mortality, of which prematurity is such an important cause, a network of premature-baby units, with a total of more than 1,800 cots and possessing 720 incubators, has been set up to cover the whole country. Transport arrangements are such that a premature baby may be quickly taken in a portable incubator, from wherever it may have been born, to one of these centres. The principal centre, at the École de Puériculture de Paris, has 55 cots, and in 1951 achieved the remarkable result of rearing 152 out of 198 babies weighing between 2½ and 4 lb. (1.2 and 1.8 kg.) at birth.

Infant welfare clinics now number 8,200 and fulfil much the same functions as in this country, but there is no distribution of welfare foods. The clinics are taken mainly by doctors who are also in practice locally, but there are 45 full-time medical officers, who are mainly occupied travelling with mobile "consultations itinérantes," which visit villages where it may be difficult to have a fixed centre. Corresponding to not large enough to have a fixed centre. Corresponding to health visitors are the "assistantes sociales," whose training consists of one year's medical study (unless they are already trained nurses) and two years' social study. Preventive inoculations are given at these clinics, and also by private doctors and at hospitals, against smallpox, diphtheria, tetanus, typhoid, pertussis, and tuberculosis. The first three are obligatory, and B.C.G. vaccination is now compulsory for the following categories: (1) All children born in 1938 and 1939 who are still tuberculin-negative. (2) Children admitted to residential or day nurseries. (3) Those exposed to infection in the home (where the source of infection is receiving sickness benefit). (4) Teachers and other persons employed in schools. (5) Medical and dental students, nurses, and all other hospital personnel. (6) Entrants to the armed Forces.

It is intended gradually to extend the age groups for compulsory B.C.G. vaccination until in 1957 all children will be vaccinated in the year in which they reach their sixth birthday. Removal from infectious surroundings to a foster-home or to a "préventorium" or "aérium" is arranged two months before vaccination, and the children remain away until the tuberculin test becomes positive, or until after they have been vaccinated a second time if it is still negative after three months.

The vaccine is prepared at the Institut Pasteur in Paris, where Dr. Guérin is happily still living.

Homeless Children

In consequence of the housing shortage, alcoholism, and other causes, there are a large number of broken homes, and many children are abandoned by their parents, either permanently or temporarily, and have to be taken into care by the State. In 1951, in the Département de la Seine alone, there were 27,263 such children, of whom 12,591 had been abandoned permanently (Lelong, 1953). Homeless children are received first at a "dispensaire de triage," where they undergo a full medical and psychiatric examination (the latter is particularly important, for many of the children are abandoned at a relatively late age, consequently there is difficulty in readaptation). Those who are not adopted privately are boarded out, where possible, under a "centre de placement familial surveillé," which is a group of foster-mothers, usually in a country district, round a centre of supervision. Foster-mothers are, in any case, subject to close surveillance by "assistantes sociales," who visit them at intervals of from one to six months, according to the age of the children.

Medical Education and Training

There are a number of important differences between the training of doctors in France and in this country. There is

not so much competition to enter medical schools, and in consequence less selection on entry, but about 50% fail the examinations in anatomy and physiology. Clinical subjects are studied from the beginning, and the minimum duration of the course is six years. After the end of their third year, students are eligible to compete for posts as "externes," when they are responsible for keeping the case-notes and carrying out such procedures as lumbar puncture in the wards of one of the teaching hospitals. From among the "externes," "internes" are chosen by competitive examination, and the duration of internship is four years. These posts are highly valued, and to have held one almost counts as a higher qualification, but their number is such that, at least in Paris, only 4% of students achieve internship. The time is divided into eight periods of six months each, which may be spent in as many different hospitals, and in as many different specialties, but students who have already decided to follow a special subject usually spend at least two years of their internship in that specialty. The duties of "internes" are similar to those of senior residents in this country, but they do not necessarily live in hospital, except when it is their turn to act as "interne de garde." There are no compulsory hospital appointments, and most students qualify without having been either an "interne" or an "externe," but all have to write a thesis. They are then granted the degree of "Docteur en Médecine"; the abbreviation Dr. is used, but not the letters M.D.

All the students spend six months studying paediatrics, followed by an examination, in their third clinical year, and there is a further optional term in the sixth year. Those who wish to specialize in paediatrics take a postgraduate course lasting four years which leads to the "Certificat d'Études Spéciales de Pédiatrie et Puériculture"; but those who have been "internes" or "chefs de clinique" (a higher hospital post corresponding to registrar) in an approved paediatric service are allowed to count that time towards the four years.

There are paediatric teaching departments in nine of the Paris hospitals, the principal ones being at the Enfants Malades, Trousseau, and St. Vincent de Paul. They are attended by students of the Paris Faculty of Medicine, and also by postgraduates from many European countries, as well as from the French colonies. The main provincial teaching centres are at Lille, Lyons, and Strasbourg. In Paris there is also the École de Puériculture, which trains doctors, nurses, students, and "assistantes sociales" in the various aspects of child health, has a large premature-baby unit and a breast-milk bank, and a ward for babies who are "feeding problems."

The International Children's Centre, founded in 1949 and supported by Unicef, is concerned with "all the problems pertaining to childhood with the exception of education." It holds conferences and postgraduate courses; conducts research into growth, vaccination, and immunization; has an excellent library; and publishes a monthly journal, the *Courrier*. There are six other paediatric journals published in France, and flourishing paediatric societies, which meet once a month, in Paris and other large centres, while the "Association des Pédiatres de la Langue Française" holds a congress every two years.

History

France has played a large part in the development of paediatrics, perhaps the greatest of any country. The Hôpital des Enfants Malades, Paris, founded in 1676, was the first children's hospital in the world, and now has 1,200 beds. The infant welfare movement is attributed to Budin, Professor of Obstetrics in Paris, who held his first clinic in 1892. The discoveries of Louis Pasteur led to the prevention of infectious diseases, and the principle of preventive isolation was established by Grancher. In the present century, perhaps the greatest advance has been the preparation of B.C.G. vaccine by Calmette and Guérin. France lagged behind other European countries in some aspects of public health between the two wars, but since 1945 great efforts have been made by the Ministry of Health and Population,

and the results are shown in the greatly improved infant and child mortality figures.

We acknowledge with pleasure the help we have received from Professors Debré and Lelong and members of their staffs, from Drs. Alison and Lotte, of the Institut National d'Hygiène, Dr. Frank Falkner, and the Librarian of the Centre International de l'Enfance. Above all, we are grateful to Dr. J. J. Kempton, who first suggested this study to us, for his constant help and encouragement. One of us (K. W. L.) wishes to thank the staff of the Hôpital des Enfants Malades for all the kindness shown to him during the tenure of his bursary, given by the Ciba Foundation and the Institut National d'Hygiène; and the Board of Governors of the Hospital for Sick Children, Great Ormond Street, for granting him leave of absence.

REHABILITATING THE DISABLED

A B.M.A. REVIEW OF THE POSITION

At the invitation of the Interdepartmental Committee on Rehabilitation and Resettlement of Disabled Persons, the Council of the British Medical Association set up a special committee to prepare a memorandum of evidence. The committee of 17 members, under the chairmanship of Professor R. E. Tunbridge, of Leeds, was a highly expert body, including orthopaedic surgeons, directors of university or hospital departments of industrial health, medical officers to industrial rehabilitation units, a medical officer of health, medical officers to large industrial concerns, a regional psychiatrist, and four general practitioners from industrial areas. The committee also had the assistance of certain experts from specialized fields. The result of the committee's labours is now published as a report of Council. It is a thesis of 80 pages covering the whole subject and with many recommendations.¹

The Nature of Rehabilitation

The size of the problem cannot be gauged, but it is assumed in the memorandum that 25% of the patients passing through acute general hospitals could be helped by planned rehabilitation. Rehabilitation is an indivisible process; the whole man must be rehabilitated, including his emotional life and moral values. It is a question of team-work, involving not only medical but industrial and social skills, and especially the co-operation of the patient himself. The stages of acute illness, convalescence, and resettlement merge into one another. Nor can there be any real distinction between medical and industrial rehabilitation.

"In the opinion of the Council it is a special medical responsibility to ensure that the degree of invalidism during and after the illness, accident, or operation is minimal, and that the final degree of functional capacity attained should match the full potentialities of the individual. . . . Medical supervision continues to be necessary after active medical treatment has been completed. Indeed, there is no stage, short of complete recovery, at which the doctor could hand over all responsibility to non-medical personnel."

In the stage of acute illness the doctor will undertake active treatment; in the industrial rehabilitation unit he will supervise the patient's progress and advise on medical matters while other members of the team carry out their technical procedures. Social rehabilitation of the patient

¹ *The Rehabilitation and Resettlement of Disabled Persons*. London: British Medical Association. Free to members of the B.M.A. Price 1s. 6d. (inclusive of postage) to others.

also is important, and this is a medical responsibility, though the help of a social worker is invaluable.

The Resettlement Clinic

A comprehensive system in which the existing facilities are integrated is set out in the memorandum. The hospital or general practitioner may refer the patient to a resettlement clinic, through which the patient will proceed either to the industrial rehabilitation unit or some form of convalescence and back to his own work, or to different work, or to sheltered employment, or, if he remains seriously incapacitated, to home work. This resettlement clinic, within the N.H.S., should be an integral part of all major hospitals or hospital groups, and available alike to general practitioner or hospital staff. Its main function would be as a point of co-ordination for rehabilitation services and agencies inside and outside the hospital, a medico-social sorting centre, and a clinic for reference of cases. It would be staffed by a consultant, a general practitioner, an almoner, and a disablement officer, and the patient's doctor would be invited to attend the review of patients he had referred to the clinic.

Medical supervision is essential for giving purpose to convalescence. It is believed that some form of planned convalescence is needed by some 50,000 individuals every year. Planned convalescence will have a background of discipline. A patient normally engaged in heavy physical employment should receive during his convalescence a gradual reorientation of his outlook from that of an invalid to that of a responsible worker. At the resettlement clinic psychiatric advice should be available, as well as physical treatment, which must embrace medical gymnastics at this stage. The patient who needed still more specific post-operative measures would be prescribed a course at the industrial rehabilitation unit. "If the patient's rehabilitation has been satisfactory, he will be eager for resettlement."

The Return to Work

The assessment of the patient's ability to work must be a medical responsibility, undertaken in consultation with technical experts. Resettlement becomes more difficult with the segregation of industries in particular areas, so that there is no suitable alternative employment in the patient's neighbourhood; also with the increase in mechanization, which compels the individual to proceed at the pace of the machine. It is often found that a man can return to his old work if some readjustment of machinery is made. More imagination and initiative might be shown in this respect. Some account is given of sheltered employment, such as the Papworth Village Settlement, the Bargoed factory set up by Austin Motors for disabled ex-miners, and the Scottish enterprise "Haven Products," a socio-medical experiment in industry. Day-occupation centres are also desirable for severely disabled persons too handicapped to be employed in sheltered industry. Work for the home-bound has two aspects, diversionary and productive, both of therapeutic value. A word is said about the disabled housewife who could be assisted through the welfare services of the local authority on a medical practitioner's recommendation.

The memorandum also deals with the special problems of resettlement in cases of tuberculosis, dermatitis, rheumatism, epilepsy, blindness, and deafness. Certain recommendations are made concerning certification. There should be a certificate of partial fitness. The D.P. forms might be simplified. The disabled persons register should be constantly reviewed. More disablement resettlement officers should be employed. The role of the physiotherapist, the occupational therapist, and the social worker is discussed. On the question of incentives it is recommended that the receipt of statutory benefits should be dependent on regular attendance for whatever form of treatment may be prescribed. Research is called for into methods of follow-up, classification of disabilities, and the like, as well as education for doctors (in the form of special courses), industrialists, and the general public. "Rehabilitation is not merely physical treatment but a regeneration of the spirit."

In man the morning drop in eosinophils was associated with a fall in lymphocytes, but because of a concomitant neutrophilia the total white cell count usually rose during the morning.

The daily changes in the circulating eosinophils in rats and mice appeared largely to be related to light. If the lighting rhythm were reversed, and the rats were kept in the dark during the daytime but exposed to light at night, the eosinophil cycle became reversed in about nine days, irrespective of any dietary changes. Under conditions of restricted diet the daily feeding time could also influence the eosinophil cycle. However, even if there were no periodic synchronizers of the eosinophil cycle, and both lighting and feeding times were irregular, a cycle was present. Moreover, in blinded mice a new and shorter cycle might become apparent, with reversal of rhythm, after 20 to 30 days. Observations on the effects of adrenalectomy, both in man and in animals, suggested that the adrenals were an important part of the mechanism which controlled the daily eosinophil cycle, and possibly other functions with a periodicity of 24 hours. The adrenal cycle developed earlier in life than the sex cycle, and might persist under some circumstances which abolished the latter.

Dr. HOWARD R. BIERMAN (Medical Centre, Duarte, California) then described investigations in man upon the sequestration of leucocytes. He pointed out that eight sites had been shown in man to play a part in the mechanism of leucocyte sequestration—that is, withdrawal from the circulation for a varying period of time. These sites were the lungs, not lymphocytes. Dr. Bierman concluded the in the lungs, not lymphocytes. Dr. Bierman concluded the in the lungs, not lymphocytes. Dr. Bierman concluded the in the lungs, not lymphocytes.

The pulmonary circulation in particular had shown a remarkable capacity for the rapid removal from the blood, over prolonged periods, of transfused leucocytes. On the other hand, the administration of adrenaline resulted in the rapid discharge of leucocytes into the circulation. It was predominantly granulocytes which underwent sequestration in the lungs, not lymphocytes. Dr. Bierman concluded the in the lungs, not lymphocytes. Dr. Bierman concluded the in the lungs, not lymphocytes.

Dr. KENNETH M. RICHTER (University of Oklahoma School of Medicine) showed a film illustrating the formation of droplets in leucocytes, and their subsequent discharge into the surrounding medium.

Leucopenia and Hormone Control

Dr. F. J. HECK (Mayo Clinic) discussed the different ways in which depression of leucocytes might occur. One type of leucopenia was that which was produced by benzene or irradiation, in which the leucopenia could be of gradual onset, with slow and prolonged recovery. On the other hand, there was the agranulocytic angina first noted by Schultz in 1922, in which in so many cases there was an acute febrile response, with angina and ulceration of mucous membranes. The leucopenia in these cases was usually precipitous, and recovery depended upon the removal of the cause, which might be one of 50 or more drugs, of which amidopyrine was the first to be noted in 1934.

Dr. ALBERT S. GORDON (New York University) reviewed the influence of hormones upon the numbers, fate, and distribution of leucocytes. The secretions of the pituitary and adrenal were those most concerned, and in the intact animal either the administration of adrenal cortical hormones (11-oxysteroids) or A.C.T.H., or exposure to stress, induced a characteristic blood picture in the intact animal, the main features being lymphopenia, eosinopenia, and neutrophilia. Eosinopenia occurring within a few hours was not due to diminished formation in the bone marrow, though when it followed the prolonged administration of cortical steroids the total number of marrow eosinophils was reduced. A method was described for the determination of the number of cells in the marrow of a single long bone.

Professor J. M. YOFFEY then gave an account of the quantitative studies of the nucleated cells of the bone marrow which were being made by a group of workers at Bristol. After describing the technique employed, he said that in the guinea-pigs employed the bone marrow as a whole contained (a) 10–20 times the number of lymphocytes present in the blood, and (b) something like 100 times the number of the circulating granulocytes. He reported the observations of Dr. R. S. Harris upon the effects of anoxia on the marrow content of erythroid cells and lymphocytes, and of Dr. R. J. Ancill on the quantitative changes in the marrow following the administration of bacteria. He also cited experiments by Dr. F. J. Ensell which showed that splenectomy was followed by a marked increase in the nucleated cell content of the marrow.

Chemotaxis and the Inflammatory Response

Dr. MORTON MCCUTCHEON (University of Pennsylvania) discussed the chemotactic properties of leucocytes. He first described the general phenomena of chemotaxis, and noted that the lymphocytes alone among the white cells showed no chemotactic properties. The granulocytes, on the other hand, displayed the most marked chemotaxis, both positive (moving towards) and negative (moving away). The mechanism of chemotaxis was still in many cases obscure. Quite strong chemotaxis could occur in the apparent absence of diffusible material, and other possible explanations involved either electrical forces or the differential absorption of plasma constituents to the test particles.

Dr. VALY MENKIN (Temple University School of Medicine, Philadelphia) reviewed some of the factors concerned with the mobilization of leucocytes during inflammation. Leucotaxine was concerned largely with the local migration of leucocytes. The cytological picture in inflammation depended to a large extent on changes in the hydrogen-ion concentration. From alkaline exudates a leucocytosis-promoting factor (LPF) could be isolated, and its active principle appeared to be a polypeptide. Its effect upon the bone marrow was to cause a discharge of immature granulocytes into the circulation, and also to stimulate hyperplasia of the remaining granulocytic elements. In acid exudates, on the other hand, a thermostable leucocytosis-promoting factor could be identified. Similarly, two leucopenic factors had been isolated, one from acid and one from alkaline exudates. Compound F (hydrocortisone) inhibited the formation both of leucotaxine and of the leucocytosis-promoting factor by injured cells.

Dr. ALBERT H. COONS (Harvard Medical School) gave a brief review of the evidence he had obtained, with the aid of fluorescent media, on the cells concerned in antibody formation. A large part of the antibody was formed by young and multiplying cells, of which the plasma cell was a mature end-form. Lymphocytes as such played a very small part if any in antibody formation, except in so far as the immature antibody-forming cells were closely related to the reticular lymphocytes or their precursors.

In Vitro Cell Differentiation

On the last day of the Conference the morning session was devoted to a consideration of the enzymes and other chemical constituents of leucocytes both in health and in disease. The final session in the afternoon took the form of a round-table discussion. Dr. O. A. TROWELL introduced the discussion with an account of his recent findings concerning the growth of lymphoid tissue in a synthetic culture medium, which contained Tyrode solution, glucose, 19 amino-acids, 2 of the B vitamins, co-carboxylase, and para-aminobenzoic acid. This gave much better results than serum. In this synthetic medium cell differentiation occurred, and small lymphocytes hypertrophied to become monocytes and macrophages. This change consistently occurred, and on a large scale, in every culture. The reticulum cells also grew more actively, the nucleus enlarging and the cytoplasm becoming basophilic. Many of the reticulum cells became phagocytic, but even these could transform into lymphocytes.

Correspondence

Because of the present high cost of producing the Journal, and the great pressure on our space, correspondents are asked to keep their letters short.

Drinking Sea-water

SIR,—I should like to reply to Dr. R. A. McIlraith's letter (*Journal*, May 29, p. 1264), which calls for an explanation of the present teaching that castaways should not drink sea-water. The reasons why they should not are as follows.^{1,2,3} A man deprived of an adequate intake of water continues to lose water through his skin, lungs, and kidneys. As a consequence the osmotic pressure of his body fluids rises, and this, rather than the change in their volume, eventually causes death. Ingestion of salt, or of fluids such as sea-water which contain salt in a concentration higher than is found in human urine, increases the hypertonicity and so hastens death. This is so whether the salt is retained in the body or excreted with expenditure of body water. Sea-water also causes water to move from the cells to the extracellular compartment. This probably explains the apparent benefit which has been reported after sea-water drinking for periods of up to four days,⁴ since most of the signs of dehydration actually depend on the state of the extracellular compartment only. Intracellular dehydration is, however, the cause of death and of the signs of failure of the central nervous system which apparently precede death.⁵

Dr. McIlraith's contention that salt lost in sweat should be replaced is not relevant to castaways. Sweat is a very dilute solution, and its loss leaves the body hypertonic. Only if the water lost is replaced by copious drinking can the concentration of body fluids fall below normal, and only then is salt beneficial. Unlike the crew of the *Kon-Tiki*, castaways would seldom have adequate supplies of fresh water. The foregoing account is based on a substantial weight of evidence, and Dr. Bombard has produced no evidence which casts doubt on it, either in his book⁶ or his technical report.⁴ He has based his argument simply on statements that a certain quantity of salt is "permissible," and that the effects of giving sea-water early or late in water deprivation are different (experimentally no difference has been found). No one wishes to discredit his achievement of crossing the Atlantic, but as scientific evidence it must be seen in its context. A number of other long voyages have been made in similar latitudes with little in the way of equipment or rations. The testimony of survivors in the past has been overwhelmingly against sea-water drinking. Moreover, a study of information collected from survivors of sinkings during the war shows a much higher death rate, under otherwise comparable conditions, in boats in which sea-water is known to have been drunk.⁷ As would be expected, this is most marked where the supplies of fresh water were smallest. That Dr. Bombard should have been able to survive for as long as 23 days drinking only sea-water and fluid obtained from fish is certainly remarkable, but we have no information as to how he was able to do this, and his voyage is at best an observation by one subject on himself, without "controls" or detailed measurements.

The Services' recommendations for castaways are based on a careful study of all the available practical information and on thorough laboratory trials. They can hardly be reversed on account of the teaching of one man, however sincere and enthusiastic, when this is not supported by any comparable evidence.—I am, etc.,

Cambridge.

Iodide in Goitre Due to P.A.S.

SIR.—We were interested to read the article by Dr. J. A. Balint and his colleagues (*Journal*, May 29, p. 1234) on the results of radio-iodine tests of thyroid function in patients receiving para-amino salicylic acid (P.A.S.). Four of their patients developed a goitre, and after P.A.S. had been withdrawn the goitre subsided in two of them, an effect ascribed to the potassium iodide given for a period of a week. It is not clear from their text whether any change occurred in the goitre of the other two patients, who were presumably also given iodide, although the radio-iodine tests were not subsequently repeated.

No evidence has been adduced in support of the assertion that a weekly dose of iodide is sufficient to counteract the antithyroid effect of P.A.S. We have studied over 30 cases of goitre following the use of P.A.S., six of the patients being markedly hypothyroid. In our experience, and in that of most other workers, there is a spontaneous regression of the goitre as soon as the P.A.S. is withdrawn, a regression which is accelerated by the administration of thyroid extract. If a patient continues to take P.A.S., remission of the goitre, and of symptoms of hypothyroidism, occurs if thyroid is given. One of our cases failed to respond in any way to the use of iodide in large doses, but the goitre disappeared as soon as thyroid was given instead. It is of interest that Brinkman and Coates¹ also found that iodide is quite ineffective in preventing the antithyroid effect of P.A.S.

The statement that iodide is effective implies that the antithyroid action of P.A.S. is upon the iodine-concentrating, rather than the iodine-binding, function of the thyroid gland. Such an effect would be similar to that of thiocyanate or perchlorate, and can be readily overcome by large doses of iodide. The efficacy of potassium iodide in these circumstances can only be proven by showing the effect while the P.A.S. is still being administered. The restoration of a normal radio-iodine excretion pattern only indicates that the previously existing iodine depletion of the gland has been abolished by the iodide. This is an effect which is demonstrable when iodide is given following the use of any goitrogenic agent, and does not imply any therapeutic result due to the iodide.—We are, etc.,

Vaporizing Fluids Containing Phenols in the Treatment of Whooping-cough

SIR.—A recent tragic experience has reminded us that vaporizing fluids containing phenols are still being used in the home for the treatment of whooping-cough.

A child aged 20 months had had the disease for a fortnight when, on the recommendation of a friend, the parents bought a vaporizer. This consisted of a perforated metal cylinder which supported a shallow pan containing the vaporizing fluid. The latter contained 98% cresol and was warmed by a night light placed within the metal cylinder. The fluid was supplied in a fluted bottle which plainly stated that the contents were capable of producing severe burns if they came into contact with the skin. On the morning in question the child, who had been sleeping with her parents, climbed out of bed, pulled the vaporizer off the adjoining dressing-table, spilling the remaining cold undevaporized fluid over herself. Although admitted to hospital within half an hour she was already deeply unconscious. Whitish-brown burns covered the lower face, neck, upper part of the chest, and the front of both arms—about 20% of the body surface. The mouth was normal, but there was already alarming oedema of the larynx and widespread pulmonary oedema as well. In spite of immediate tracheotomy and careful resuscitation with intravenous fluids the child never regained consciousness and died suddenly, apparently from central respiratory failure, 26 hours after the accident.

The vaporizer on this occasion was obtained without the knowledge of the family doctor, but we know of occasions where it has apparently been used with his consent. It is perhaps not so well known as it should be that severe and fatal poisoning can occur from the absorption of phenol

through quite small areas of unbroken skin. On the other hand, there is not, so far as we know, any reliable evidence that cresol inhalations, or indeed inhalations of any kind, have the slightest effect on the course or outcome of whooping-cough. We realize that the treatment of whooping-cough is often tedious and unrewarding, but it is surely desirable that the dangerous and useless procedure described in this letter should be rejected by the profession and ultimately discarded by the public.—We are, etc.,

MARION BETHUNE.
DONALD COURT.

Simple Thyroid Retractors

SIR.—With reference to Sir Heneage Ogilvie's description of a pair of thyroid retractors (*Journal*, June 5, p. 1319), Sloan's goitre retractors are even more useful when the retracting arms are made of unequal length, as the elbow of the appliance then falls more easily to the side of the neck. Sloan's own retractors have arms 5 in. and 6 in. (12.7 cm. and 15.2 cm.) long. A mirror-image pair is required. Sloan himself gave a pair to Mr. H. Frankling, who in turn gave them to me in 1932, and this pair has been in use ever since.

In Harrogate and Ripon we have used a set of similar equal-armed spreaders of differing sizes and strengths of spring in all sorts of operations for 22 years.—I am, etc.,

Harrogate.

T. V. PEARCE.

Cytodiagnosis of Bronchial Carcinoma

SIR.—Dr. Raymond Whitehead's remarks (*Journal*, May 29, p. 1254) about the place of exfoliative cytology in the diagnosis of bronchial cancer cannot be allowed to go unchallenged. He gives a most misleading impression of its value in this field, and his statement that he is unable to make positive diagnosis with confidence is hard to understand. I commenced the examination of sputum and bronchial washings for malignant cells by the Papanicolaou technique in 1952 after spending some months in Dr. Papanicolaou's laboratory. I have examined 875 specimens of sputum or bronchial washings by this technique and of 58 of them as malignant. In no case, so far as I am aware, has a false positive result been given; in one case which was reported as suspicious the lesion was finally proved to be non-malignant. False negatives there have been and always will be: a negative result is to be regarded as without significance; but false positive results should not occur. The method has proved its value to clinicians earlier diagnosis than would otherwise have been the case. In a few proved positive cases, cytological evidence was the only positive laboratory evidence of malignancy, and in more than one case the finding of malignant cells in sputum provided the first grounds for suspicion in cases where the possibility of malignancy had not been seriously considered.

Many tumours are beyond the reach of the bronchoscope, but such cases will be just as likely as the more accessible ones to give positive cytological preparations. I would go so far as to state that examination of sputum and bronchial washings by cytological methods will provide more positive results in cancer cases than will bronchoscopy. It is relevant to quote here the findings presented by two speakers at a symposium on exfoliative cytology held in New York City in October, 1951.¹ Herbut, of Philadelphia, referred to 500 malignant cases in 29% of which cytology provided the only positive laboratory evidence of malignancy, and Benioff, of San Francisco, reported on 162 proved cases in 24% of which cytology alone gave positive laboratory findings. The latter speaker stressed the value of the method in increasing the clinician's awareness of the possibilities of early diagnosis in lung cancer. The method is simplicity itself so far as the patient is concerned, and repeated examinations are easily arranged. Much tedious laboratory work is involved in negative cases, but surely this should not weigh against the proved value of the

method. It would be a great pity if Dr. Whitehead's remarks should deter clinicians from seeking the aid of a method of diagnosis which is long past the experimental stage and which has proved its usefulness in many parts of the world.—I am, etc.,

Grimsby.

Psychiatry and General Medicine

SIR.—I was greatly interested in the article entitled "Psychiatry and General Medicine" by Sir David Henderson (*Journal*, April 17, p. 889), which has just reached me. I am glad that he mentions malarial infection and anaemia as possible causes of personality disturbances, since I once had the unfortunate experience of suffering from both of these and becoming suspicious, irritable, aggressive, and acutely fear-stricken as he describes, and of being rendered incapable of treating myself. The purpose of this letter, however, is to draw Sir David's attention to his statement under "The Art of Case-Taking": "Very modestly it is suggested that our psychiatric case-taking methods may be of considerable value to our general medical colleagues. They will help them to remember that physical symptoms are often purely a face-saving device to maintain the *amour propre* of the patient. If this is forgotten, then examinations and treatments are introduced which often obscure the clinical picture."

Sometimes I think it can be the other way about. My own general medical colleague who first called in the alienist was "more psychiatric than the psychiatrist." True, in my case, on first examination in West Africa, no malaria parasites were found in my blood, and my temperature was only very slightly elevated, perhaps because I was still on suppressive doses of proguanil. However that may be, after examination by a psychiatrist colleague I was flown back to England with a diagnosis of schizophrenia, which stuck firmly even when about three weeks later, while I was a voluntary patient at a mental hospital, I developed a pyrexia of 105° F. (40.6° C.) and a *P. falciparum* parasitaemia (it seemed to be nobody's business to ensure that my prophylactic antimalarial was continued), and despite the fact that the admitting doctor who carried out a routine general examination said: "We are getting a lot of mental cases from the Tropics." Useless for my sister to inform the psychiatrists that I had always been mentally normal before and that there was no history of mental illness in our family, and useless for me to protest against being given quinine because of the possible danger of blackwater fever (I think they thought I was just being difficult).

So far from physical "examinations and treatments being introduced which often obscure the clinical picture," the staff doggedly attempted psychological examinations and treatments of just such a nature. My wife was told that I might have to be certified, psychotherapy was begun, and they tried unsuccessfully to persuade me to undergo a long course of insulin therapy. I thought that perhaps a proper course of antimalarial treatment would be better, gave three days' notice, and took my discharge against advice. I have never ceased to be thankful that I did. At home severe parasitaemia and anaemia were confirmed by the pathologist at the local hospital, and so I entered an institution where they knew all about the peculiarly virulent falciparum malaria that occurs in West Africa, but no more about psychiatry than any general hospital. Within two days I began to feel mentally normal again, and after about ten days I returned home perfectly fit.

The staff of the mental hospital contended that the malarial infection had little to do with the mental condition, and, like Sir David Henderson, probably think that the various bizarre physical symptoms that I produced were "a face-saving device to preserve my *amour propre*." They may be right, but such a theory must account for the facts that (a) I received virtually no psychiatric treatment, yet (b) my symptoms, both mental and physical, cleared

serious? Journalists have enough responsibilities of their own to bear without the burden of the sin-eater.

You, Sir, have in your leader columns encouraged the hope of better understanding between the medical and journalistic professions. It is earnestly to be hoped that this unfortunate affair—in which, I respectfully suggest, the fault was primarily Mr. Dickson Wright's—will not discourage this understanding.—I am, etc.,

RITCHIE CALDER,
Chairman of the Association of
British Science Writers.
Sutton, Surrey.

SIR,—I feel sure that Mr. Dickson Wright is right (*Journal*, June 12, p. 1350). If the heart goes into asystole, or the ventricles start to fibrillate during an operation, then each minute's delay in rectifying the defect must lessen the patient's chances of survival very greatly. The important thing is to know the precise moment at which the heart stops. To rely upon an occasional examination of the temporal pulse for this information strikes me as being completely archaic.

Therefore, I would say, anaesthetists should rely more on machines, not less, for have not machines proved themselves more accurate and reliable observers than men in many spheres? Being interested in the design of such a machine, I hope that Mr. Wright's requirements may soon be met.—I am, etc.,

Newcastle-upon-Tyne.

P. HEX VENN.

Varicocele and Male Subfertility

SIR,—The correspondence in the *Journal* (May 29, p. 1231, and June 12, p. 1378) reminds me of the violent change of surgical opinion about varicocele which has occurred in my lifetime. Formerly operation was obligatory for the Indian Civil Service, the Colonial Service, and was strongly recommended for the fighting Forces. Now it is generally condemned because in many cases atrophy follows. But there were excellent clinical reasons why it should have been recommended in the Services, for varicocele can be a most painful condition in tropical countries.

It must be admitted, however, that atrophy can occur after the usual operation, and the reason is mainly anatomical. If the spermatic artery is carefully isolated and the veins of the pampiniform plexus clamped and divided, what follows is that the arterial supply is undiminished but the venous return is heavily impeded. In consequence the testis swells at first, but eventually it atrophies. If a few veins are retained undivided around the artery this generally does not happen, but it is a matter of luck. If, however, a surgeon has the courage to ligature and excise the artery with the veins the congestion of the testis does not occur, but what does happen is that the artery to the vas rapidly hypertrophies and takes the place of the spermatic. The testis is not congested primarily, and in consequence no atrophy occurs as a sequela.—I am, etc.,

London, W.1.

J. JOHNSTON ABRAHAM.

Pancreatico-duodenectomy

SIR,—We have read with interest Mr. Gordon Ferguson's article (*Journal*, May 29, p. 1243) in which he describes two successful cases of pancreatico-duodenectomy. While agreeing with much that he says, and in particular with his enthusiastic attitude to the radical operation and his condemnation of the so-called palliative procedures in operable cases, there are two comments which we would like to make.

The first of these concerns age. In our recently published series¹ the age incidence in 49 cases was: 30–40, 2 cases; 40–50, 2; 50–60, 6; 60–70, 22; 70–80, 14; 80–90 3. Thus, one-third of our cases were over 70, and two of our patients over 80 both survived the radical operation. Age alone does not seem to be an important factor.

The second and much more important comment concerns early diagnosis, and this, we believe, can and should be reached in almost all cases long before the "month of painless jaundice" suggested by Dodd.² We believe that

all cases of jaundice over 30, whether painless or not, should be investigated by all clinical and laboratory methods, and a diagnosis reached within at most a fortnight. Once the diagnosis of obstructive jaundice is made, operation is indicated as a matter of urgency. Cattell and Warren state in their recent book³ that they, and most other American surgeons, now favour a one-stage operation, but that they feel that a two-stage operation is necessary in any patient who has a severe obstructive jaundice, "particularly if it has been present for several weeks." A two-stage operation means a delay of several weeks before the actual resection is done, and operability is further reduced thereby.—We are, etc.,

Origin of Pilonidal Sinus

SIR,—The present trend of opinion towards regarding pilonidal sinus as acquired rather than congenital in origin is leading to the usual searches in the literature for earlier expressions of this view. Aird in your columns¹ has recently called attention to an important paper by Hodges, of Boston, written in 1880² as well as other earlier papers. The question arises whether John of Arderne possibly recognized the condition, but there is no real evidence in his writings that he did. It is interesting to note, however, that the late Sir D'Arcy Power, in the foreword to his collection of Arderne transcripts in the library of the Royal College of Surgeons of England, wrote (vol. 1, p. 8): "Arderne's attention was no doubt called to the subject of fistula by the actual cases which came to him for relief. . . . Wet, cold, long hours in the saddle weighted down by the heavy armour of the time would readily lead to this condition in the knightly class."

If D'Arcy Power's historical interpretation be accepted, it is tempting to speculate that John of Arderne in his extensive experience of suppuration around the anus may have seen many cases of pilonidal sinus; and that what may be called the "knight's bottom" of the fourteenth century was the direct historical precursor of the "jeep disease" of the twentieth. If so, the theory of the acquired origin of the pilonidal sinus has a long and distinguished ancestry, and the condition may even have come to England with the cavalry of the Conqueror.—I am, etc.,

London, W.1.

The Sensitivity of the Respiratory and Circulatory Centres

SIR,—When one is present at a patient's death it is not uncommon to hear the heart sounds by auscultation for some minutes after the termination of respiration. A patient died recently and the heart continued to beat for over an hour after respiration had ceased.

A woman aged 38 was admitted under certificate on May 16, 1954. The patient exhibited some confusion and cerebral tumour was considered, but there was no confirmatory evidence nor any localizing signs. About 5 p.m. on May 24 she quietly went into coma after being restless during the earlier part of the day. Methods were instituted to bring her round—i.e., intravenous glucose 33%, picrotoxin intravenously and intramuscularly—with no response. Picrotoxin was later repeated up to a total of 48 mg. and shortly before midnight an intravenous drip was set up. The patient's breathing for the two or three hours preceding her decease was alternately cog-wheel and Cheyne-Stokes. About 10 minutes after midnight respirations ceased and she gradually became cyanosed, but the carotid pulse was observed to be beating strongly and regularly. Artificial respiration was applied by gentle rhythmical pressure on the epigastrium and the lower part of the chest and gradually the patient's colour became normal. Oxygen was then delivered by a face mask while no spontaneous breathing occurred the patient's colour remained good and the heart sounds normal in quality and regular at 70/80:

per minute; blood pressure was not measured. The patient continued in this state for about an hour, when the heart began to fail, the pulse weakened in quality and volume and finally ceased at 1.20 a.m. on May 25. Examination at this stage revealed the heart to be silent—that is, a little over an hour after respiration had terminated completely.

At necropsy there was one large and three small cerebral tumours not yet identified.—I am, etc.,

Bromsgrove.

Cortisone and Aspirin in Rheumatoid Arthritis

SIR,—It is unfortunate that the clinical trial conducted by the Medical Research Council and Nuffield Foundation comparing cortisone and aspirin in the treatment of early cases of rheumatoid arthritis (*Journal*, May 29, p. 1223) has been interpreted in the press as meaning that cortisone is no better than aspirin, as the trial does not prove this. Insensitive trials improperly analysed will always tend to confirm the null hypothesis. The null hypothesis in this trial was, "Cortisone is no better than aspirin." Such trials do not prove and cannot prove the null hypothesis to be true. The results of clinical trials are only useful and worth reporting when they destroy the null hypothesis. "Every experiment may be said to exist only in order to give the facts a chance of disproving the null hypothesis."¹

In this trial the tests of function cannot be regarded as sensitive and the analysis of the figures is fallacious. We have shown by experiment that the grip test is insensitive compared with measurements of joint range and speed of joint movement (if accurately measured), and given reasons for thinking that such tests of dexterity as tying knots and climbing steps are insensitive, unless they can be and are related to arbitrary standards of normality.² The faulty analysis has made these tests still more insensitive and so given the trial little chance of demonstrating any difference there might be between treatment with cortisone and aspirin.

The error in analysis should be obvious to anyone with an elementary knowledge of arithmetic. It is easily illustrated by an example. The average range of wrist movement with cortisone treatment increased from 99° to 120° and with aspirin from 78° to 103°, which is erroneously interpreted in the report as a 21% improvement with cortisone and a 32% improvement with aspirin. The absurdity of this conclusion becomes obvious if one exaggerates the discrepancies between the cortisone and aspirin averages. Let us suppose that the average range of wrist movement of the cortisone-treated cases at the outset was 120°, and of the cortisone-treated cases at the outset was 125°—i.e., an that after a year's treatment it improved to 125°—i.e., an improvement of 5/120 × 100 = 4.2%, and let us also suppose that the change with aspirin was from 60° to 120°—i.e., 100%. This gives aspirin an apparently enormous advantage over cortisone. This means that for the change with cortisone to be the same as that with aspirin it would have had to have been from 120° to 240°, which, as the normal range of movement of the wrist joint is 130°, is clearly absurd. As long ago as June, 1952, we pointed out that this difficulty can largely be overcome by expressing results as a percentage of that possible up to an arbitrary standard of normality.²

We will now examine the figures quoted in Tables III and IV of the report from this more realistic and less erroneous point of view. They show that the range of wrist movement improved by 68% with cortisone and 48% with aspirin, taking the average normal range of wrist movement as 130°; the improvement in grip of the left hand with cortisone was 57% and with aspirin 38%; the improvement in grip of the right hand with cortisone was 46% and with aspirin was 37%; assuming that the normal average grip is 250 mm. of mercury; on the knot-tying test the improvement with cortisone was 50% and on aspirin was 33%, assuming that the average normal time for tying six knots is 20 seconds, which we have found to be roughly true by experiment; and that the improvement with corti-

sone in the stepping test was 75% and on aspirin was 63%, assuming that the average normal time to go up and down ten steps is approximately 10 seconds, which we have shown to be roughly true by experiment. It is clear that in all five tests cortisone showed an improvement greater than that of aspirin. It is a thankless task to subject the results of insensitive and ill-planned experiments to a statistical analysis; but we have subjected the mean of the differences between these figures to Student's test, and find the mean to represent a significant difference between cortisone and aspirin in favour of cortisone ($P < 0.01$).

If this trial had been properly planned, using sensitive tests, which could quite easily have been done with a little thought, and properly analysed, the conclusion that for practical purposes there is little to choose between cortisone and aspirin might have been acceptable; but this conclusion is clearly invalid, and it seems that the exactly opposite conclusion should have been drawn.—We are, etc.,

GEOFFREY E. LOXTON.

Gorleston Holiday Camp for the Physically Handicapped

SIR,—I should like to thank the 78 doctors who kindly sent me medical details of their patients attending our holiday camp at Gorleston last week, in answer to my circular letter and for the benefit of the camp doctor. Most of the letters were very helpful and courteous, and some even contained words of appreciation of our efforts which were most encouraging. As there were nearly 240 disabled guests altogether, it was disappointing to get no response from the rest of the family doctors concerned. Possibly the patients mislaid my circulars and they never reached the doctor's hands. Curiously enough, the only guests needing medical attention during the week were among the group about whom we had no clinical information. Our gallant general practitioner was therefore manfully working in the dark and we are very grateful to him for his devoted services.

The camp was organized by the Norfolk Voluntary Association for the Care of the Physically Handicapped and open to all handicapped people who can be got there from anywhere in the country. This year we had large contingents from Yorkshire, Essex, Norwich and Norfolk, and smaller groups from as far away as Bedford, Carlisle, Tyneside, and London. It was an unqualified success, and everyone seemed happy in spite of many forms of severe disability. Indeed, one man walked for the first time for 20 years and several carried out manoeuvres they had never tried before, fired by the example of equally disabled people. All types of disability were seen, including rheumatoid arthritis, poliomyelitis, disseminated sclerosis, paraplegias, Friedreich's ataxia, and tuberculosis of bones and joints, to mention only a few. At least 34 were helpless and had to be washed, dressed, taken to the toilet, and pushed in chairs, and all this work was carried out by volunteers either resident or part-time.

The camp itself is used by ordinary holiday-makers from Whitsun to October, but, through the courtesy of the directors and management, has opened a week earlier these last two years in order to cater for these special guests. We should be glad to have comments or suggestions from doctors whose patients attended this year, and specially to know whether they feel that the camp fulfilled its purpose in giving a really happy holiday to those whose disability normally prevents them from enjoying such a luxury. We hope to make this an annual event, and we should be glad to send details of how it was organized and run to interested people who may be considering similar ventures.—I am, etc.,

Norwich.

Vice-chairman, Norfolk Voluntary
Association for the Care of the
Physically Handicapped.

Obituary

Dr. A. L. P. PEENEY, M.R.C.S., L.R.C.P.

Dr. A. L. P. Peeney, Director of the Clinical Pathological Services of the Queen Elizabeth Hospital and General Hospital, Birmingham, died on June 11 at the age of 50, after a short illness.

Angelo Louis Peter Peeney was born on May 7, 1904, a son of the late John Peeney, of Blackpool, and was educated privately. He received his medical training at Manchester University, and qualified M.R.C.S., L.R.C.P. in 1928. After being house-physician to Professor F. E. Tylecote at the Manchester Royal Infirmary, and for 18 months in a similar post at the Brompton Hospital, London, he became assistant director of the clinical laboratory at the Manchester Royal Infirmary. In 1934 he was invited to join the staff of the Public Health Laboratory in Manchester, where he remained until 1936, when he was appointed clinical pathologist to the Queen's Hospital, Birmingham. With the closing of this hospital he became the first clinical pathologist at the Queen Elizabeth Hospital and, with the retirement of Dr. Hillier, the director of the clinical pathological services of the General Hospital in addition. He was elected an honorary lecturer in bacteriology of Birmingham University in 1946.

In the 18 years in Birmingham, Dr. Peeney built up a bacteriological and haematological service which can hardly be surpassed in the United Kingdom. His standards were high and he was able to impart them to his staff. It was not surprising that his laboratory gradually became the most important unit in the hospital; and the volume of work demanded from it continually increased, but it never fell from the high standard he demanded. Dr. Peeney never spared himself, putting in very long hours and frequently returning to the laboratory in the evening. The increasing complexity of antibiotic therapy led to his advice being sought by all members of the hospital staff; again, this was so willingly and effectively given that many will feel keenly the loss of his guiding hand in their clinical problems.

In many respects haematology was his most favoured subject and his opinion was much sought throughout the region. His interpretation of the morphology of the red cell and diagnostic suggestions often appeared uncanny in a decade where morphology does not claim the eminence it once held. He was one of the first adequately to describe the haematological changes in the steatorrhoea syndrome, and his accurate interpretations of blood films were often the first clue to the eventual diagnosis of this condition. Though he had no hospital beds under his direct responsibility, such was his clinical judgment and such the esteem in which he was held by his colleagues that large numbers of patients could attribute their treatment to his care; he brought the services of the laboratory right to the bedside.

It is not perhaps surprising that in view of the great demands upon his services he published relatively little in comparison with his great knowledge of the specialty. Beyond his clinical and scientific ability will stand his character. He became the repository of everybody's troubles and the advice he dispensed was good and sound. "The onlooker sees most of the game" was his oft-quoted remark, and he applied his observations

as a beneficent catalyst in all the problems that arise in an active hospital and medical school.

His friendliness and charm will not be forgotten. He has set a high standard for his successors to emulate. To his widow and son we extend our sympathy.

W. M. A. writes: In this harsh competitive age it can be said of few that they were loved by all; of such was A. L. P. Peeney. Others have borne eloquent testimony to his high qualities as a physician and a pathologist, to his devotion to duty, and his gentle unobtrusive guidance which so often led us to the solution of a clinical problem. But it was memories of Peeney the man that overwhelmed me on the evening of the day we bade him farewell. We went to him not only for professional help but for administrative advice and for comfort when perplexed and dispirited. Although he must often have been desperately tired, for he worked long hours, he was never too busy to listen patiently. Houseman or senior consultant all alike were received with the same friendly courtesy and left with renewed hope. Completely unselfish himself, he never imputed base motives to others. We will not see his like again, but we can best serve his memory by trying to emulate his chivalrous charity.

W. D'A. SILVERA, M.B., F.R.C.P.Ed.

Dr. W. D'A. Silvera, senior lecturer and head of the department of pathology of University College, Ibadan, Nigeria, died at Ibadan on May 19 at the age of 40.

Walter D'Aguilar Silvera was born in Jamaica on August 2, 1913, and was educated at Edinburgh University, where he graduated M.B., Ch.B. in 1937. He was elected a Member of the Royal College of Physicians of Edinburgh in 1941, becoming a Fellow four years later. After graduation he was appointed to the pathology department at Edinburgh Royal Infirmary and Leith Hospital. In 1945 he entered the Colonial Medical Service and was posted to Jamaica, where he remained until 1949, when he accepted the appointment of senior lecturer in pathology at Ibadan.

We are indebted to Sir KOFO ABAYOMI for the following appreciation: The death of Dr. W. D'A. Silvera has created a gap which will be very difficult indeed to fill. I first met him at Edinburgh in 1941, when he was working under a great friend of mine, Dr. R. F. Ogilvie, in the pathology department. One day I suggested that, should there ever be a university college in Nigeria, he might like to join the staff. He at once said that should such an opportunity occur he would willingly accept the offer. This promise was later fulfilled when Dr. Kenneth Mellanby approached him in Jamaica, and he came to Ibadan as one of the earliest pioneers at the University College. At first he had many difficult problems to overcome, for lack of materials, men, and money made the project seem one of making "bricks without straw." However, he faced the problems very cheerfully, working almost round the clock to build up the department which to-day reflects great credit on the College. It was a great pleasure to Dr. Silvera when all of the first group of medical students sent to the United Kingdom to complete their course did well in the pathology examinations, one student succeeding in winning the coveted first prize in pathology at his hospital in London. At Edinburgh Dr. Silvera's house was thrown open to all Colonial students, whom he entertained with lavish hospitality. Gentle and affable, he acted as an inspiration to those students who tended to neglect their studies, and as a great scholar himself always stressed the value of hard work. Although taciturn in committee or at board meetings, his views carried weight and were to the point when he did speak. He was convinced that Nigeria had a wealth of material for research work, on which he intended to concentrate, and he had a profound faith in the future of the country. In spite of a very busy life, he found time to play cricket occasionally. A congenial companion, we mourn deeply one who did much to help lay a solid foundation to

our College, and we give a "great salute" to his revered memory. Deep sympathy goes to his devoted wife, formerly Miss Betty MacEwan, of Kinross, and his children, and to his family in Jamaica.

ROBERT AITKEN, M.D., F.R.C.P.Ed.

Dr. HUGH C. W. STRINGER writes from New Zealand: Dr. Aitken's passing, recorded in the *Journal* of April 3 (p. 822), will leave a gap in the memories of those who worked in the skin department of the Royal Infirmary, Edinburgh. A clinician of the older school, he was an Edinburgh "identity," notably kind to scholars from the Dominions. On tuberculosis of the skin he held tenacious views, which derived from much sound experience gained over the years. Few understood the disease better, and he insisted that new remedies be severely tested. Robert Aitken was a keen yachtsman who did his own cruising, even in bad weather. No cardiac ever faced an exercise machine to equal the old Kelvin engine in his cabin cruiser when it declined to start, and he fought a guerrilla campaign with it over years. Our sympathy goes to his family in their loss.

The death of Dr. ADAM GILCHRIST on April 9 at the age of 68 has deprived Burslem of one of its oldest and most respected general practitioners. Born at Wells, Aberdeenshire, on November 4, 1885, Adam Gilchrist received his early education at Badenscoth Public School and Aberdeen Grammar School, from which he entered Aberdeen University as a medical student. After graduating M.B., Ch.B. in 1908, he held resident posts at Aberdeen Royal Infirmary before settling in practice at Burslem in 1909. During the war of 1914-18 he served in the R.A.M.C., first as a recruiting medical officer in this country and then in East Africa from 1917 to 1919. After the war he returned to his former practice, in which he found the surgical work of particular interest. For many years he was a member of the honorary staff of the Burslem, Haywood, and Tunstall War Memorial Hospital, and he acted as police surgeon, Admiralty surgeon and agent, medical adviser to the Post Office and the Treasury, and medical adviser to the Pottery Manufactory Federation. Much of his spare time was devoted to the British Red Cross Society, and the enthusiasm for its work shown by the local detachments was largely due to his efforts; he became assistant county director of the society for North Staffordshire, and was also a divisional surgeon of the St. John Ambulance Brigade. An early member of the North Staffordshire Caledonian Society, he was its honorary piper and president in 1921 and again this year. A member of the British Medical Association for forty-four years, Dr. Gilchrist was chairman of the North Staffordshire Division in 1935-6. Until recently he enjoyed a game of golf, but the work of his profession held his main interest, and he continued in practice, as he would have wished, to the end. He married Dr. Mary Sampson in 1927, and she survives him together with two sons, one of whom is also in the medical profession.

Dr. A. O. M. FEHRSEN, for many years surgeon for the Potgietersrust district of the Northern Transvaal, died at his home on the Zoedveld Estates in that province on April 20 at the age of 79. Alexander Olof Malcolm Fehrser was born at Cradock, Cape Province, on February 9, 1875, and had a medical background, both his father and grandfather being doctors. His grandfather had attended President Kruger when the President was a boy. From Bishops College, Rondebosch, he entered Cambridge University, where he graduated B.A. with honours, in 1897. Proceeding to the study of medicine, he qualified M.R.C.S., L.R.C.P. in 1901, having received his clinical training at St. George's Hospital. Two years later he obtained the degrees of M.B., B.Chir., and in 1905 the Cambridge D.P.H. While a student

at Cambridge he played Rugby football for the Barbarians, and for the rest of his life never neglected an opportunity to show his club colours to visitors, so proud was he of having played for such a famous club. After qualification, he held the appointments of house-physician and house-surgeon at Birmingham General Hospital. Returning to South Africa in due course, he became surgeon to the Potgietersrust district in 1912, and there he was the only doctor in an area of thousands of square miles, embracing practically the whole of the Northern Transvaal. In those days visits to patients at a distance had to be made on horseback, or by mule-cart or ox-wagon, with the fording of flooded rivers an added excitement; and he would frequently sleep in the veld. Life in a town held no attractions for Dr. Fehrser, for he loved the wild country in which he lived and worked. He became a well-known figure in that vast territory and was soon recognized as a highly capable all-round physician and surgeon, greatly loved by his patients. The profession is the poorer for the loss of a fine personality and his death is mourned by all who knew him. He is survived by a widow.

Dr. T. J. JENKINS died at his home, Vron Iago, Henllan, Cardiganshire, on May 20 at the age of 75. His long illness had already deprived the West Wales family and hospital practitioners of a most colourful personality. Thomas Jones Jenkins was the son of a sea captain, and was born at Cwrcoed, Henllan, in 1879. He received his medical education at the University College, Cardiff, and at St. Mary's Hospital. After qualifying with the conjoint diploma in 1906 he became a resident at the Cardiff Royal Infirmary. He soon made up his mind to return to his native Cardiganshire, and started in general practice in Henllan. The practice was truly rural. His patients came from the farming community in the middle reaches of the beautiful Teify Valley and from the hill farms on the Cardiganshire-Carmarthenshire border. His reputation as a first-class family doctor was quickly established, and it was not long before he found himself deliberately limiting the extent of his practice. His patients appreciated his intense and sincere interest in all their troubles. They loved his keen sense of humour. His complete honesty sometimes perplexed them, but they always trusted him. In any profession a man's true value is assessed by his colleagues rather than by the lay public. "Jenkins Henllan" was a name respected by the whole profession in West Wales. In the group of practitioners in and around the Teify Valley he had a profound influence in maintaining a happy spirit of comradeship. Nobody in any medical community could have done more in this respect than he did. Jenkins was in 1908 one of the four founders of the Vale of Teify Medical Society. The other three (who had long predeceased him) were Sir John Lynn Thomas, Dr. J. Powell, of Newcastle Emlyn, and Dr. J. W. Stephens, of Cardigan. T. J. Jenkins was secretary of the society for years, and later became its chairman. He was an active member of the B.M.A. Although he could not raise any enthusiasm for medical politics he was always present at the clinical meetings. Until the last war he would surprise his younger colleagues by going off on a postgraduate course every few years. His passion for new books (especially in general medicine and obstetrics) kept him well informed over the years. He liked to talk of new ideas and advances in medicine, and took great pride in applying new methods and drugs in his practice. He held several appointments, and greatly esteemed his attachment to the Cardigan and District Memorial Hospital and the coronership of South Cardiganshire, which he held for many years. Outside medicine he had many interests. He was particularly keen on perpetuating the Welsh language and its culture. He was a first-class shot and at one time a very keen angler. Seldom would he miss a home Rugby international match, where he would be unashamedly partisan. He shunned the footlights of public life, but he did a great deal for his fellow men, aside from his work; his public service was unheralded and unsung.

Vital Statistics

Psittacosis in Kent

In March this year a man of 34 was admitted to the Southern Hospital, Dartford, suffering from chest symptoms. On investigation it was found that his blood gave a positive complement-fixation test with psittacosis antigen to a titre of more than 1:128. Inquiry revealed that in his back garden, near Dartford, the patient kept about 80 budgerigars for breeding. He made a special hobby of buying sick birds and treating them, but some had died. A detaining notice under the Psittacosis Order, 1953, was served by the Ministry of Agriculture and Fisheries on the owner, who allowed five apparently healthy birds to be killed and sent to the Virus Reference Laboratory, Colindale, for examination. However, virus was not isolated from the birds and the detaining order was subsequently lifted. The remaining five members of the patient's family were symptom-free. Complement-fixation tests were carried out on them; two gave negative results, but the remaining three showed results positive in the following titres:

April 14, 1954	April 30, 1954
1:64 (wife)	1:64
1:32 (child)	1:16
1:32 (child)	1:16

In addition, the patient's general practitioner, who was admitted to hospital a few weeks after the patient, showed a complement-fixation test positive to a titre of 1:64, and later to 1:32. A complement-fixation test on the bird-breeder done on June 3 gave a positive result at 1:320.

Graphs of Infectious Diseases

The graphs below show the uncorrected numbers of cases of certain diseases notified weekly in England and Wales. Highest and lowest figures reported in each week during the nine years 1945-53 are shown thus -----, the figures for 1954 thus ————. Except for the curves showing notifications in 1954, the graphs were prepared at the Department of Medical Statistics and Epidemiology, London School of Hygiene and Tropical Medicine.

Infectious Diseases

In England and Wales during the week ending June 5 the number of notifications declined by 218 for whooping-cough, from 2,207 to 1,989, 119 for dysentery, from 1,136 to 1,017, and 118 for scarlet fever, from 911 to 793, while the only large increase was 788 for measles, from 2,046 to 2,834.

A rise in the incidence of measles occurred in every region of the country except the south-west, though it was the experience of the northern section of the country that was mainly responsible for the large rise. The largest increases in the number of notifications of measles were 95 in Cheshire, from 132 to 227, 90 in Yorkshire North Riding, from 83 to 173, 89 in Lancashire, from 464 to 553, 86 in Norfolk, from 167 to 253, 73 in Durham, from 176 to 249. The largest declines in the incidence of whooping-cough were 50 in Staffordshire, from 120 to 70, and 47 in Yorkshire West Riding, from 156 to 109. A small decline in the incidence of scarlet fever occurred throughout the country. The largest fall was 33 in Lancashire, from 138 to 105. 18 cases of diphtheria were notified, being 5 more than in the preceding week. The largest centres of infection were Warwickshire (Birmingham C.B. 4), Lancashire (Huyton with Roby U.D. 4), and Devonshire (Plymouth C.B. 3).

34 cases of acute poliomyelitis were notified. These were 15 more for paralytic and 3 more for non-paralytic cases than in the preceding week. The largest returns were Staffordshire 7 (Walsall C.B. 4, Smethwick C.B. 2), Lancashire 5 (Walton-le-Dale U.D. 2), Yorkshire West Riding 4 (Ripon and Pateley Bridge R.D. 2), and Durham 4 (Sunderland C.B. 4).

The largest returns of dysentery were Lancashire 187 (Haydock U.D. 22, Bolton C.B. 18, Liverpool C.B. 18, Farnworth M.B. 15, Kearsley U.D. 13, Manchester C.B. 12, Irlam U.D. 12, Middleton M.B. 11), Yorkshire West Riding (Sheffield C.B. 51, Leeds C.B. 47, Dewsbury C.B. 15, Bingley U.D. 11, Otley U.D. 11), London 112 (Islington 35, St. Pancras 12), Leicestershire 64 (Leicester C.B. 63), Sussex 51 (Brighton C.B. 32), Surrey 49 (Croydon C.B. 37), Middlesex 47 (Southgate M.B. 10), Staffordshire 42 (Cannock U.D. 14, Newcastle-under-Lyme 10), Kent 41 (Penge U.D. 11), Essex 34 (Burnham-on-Crouch U.D. 15), Cheshire 28 (Dukinfield M.B. 12), Durham 25, and Nottinghamshire 22 (Beeston and Stapleford U.D. 14).

Quarterly Return for Scotland

The birth rate for the March quarter of 1954 was 18.6 per 1,000 population, being 0.5 above the rate for the corresponding quarter of 1953 and 0.1 above the average of the five preceding first quarters. The infant mortality rate was 38 per 1,000 registered live births, and was 4 above the rate for the preceding March quarter. The stillbirth rate was 25 per 1,000 total births, and was the lowest rate recorded in a first quarter. The death rate was 14.3 per 1,000 population, an increase of 0.6 upon the rate for the first quarter of 1953 but 0.8 below the average rate for the five preceding March quarters.

The death rate was 31 per 100,000 for all forms of tuberculosis and 28 for respiratory tuberculosis; the former was 1 below and the latter 1 above the rate for the preceding first quarter, but they were respectively 25 and 21 below the five-years average. Only 91 deaths were attributed to the principal epidemic diseases. These were 64 from influenza, 14 from meningococcal infections, and 13 from whooping-cough. No deaths were due to scarlet fever, diphtheria, or measles. 719 deaths were attributed to violence; of these, 133 were due to road transport accidents; these deaths were respectively 18 fewer and 3 more than the number recorded in the corresponding period of last year.

Week Ending June 12

The notifications of infectious diseases during the week included pneumonia 335, scarlet fever 731, whooping-cough 1,686, diphtheria 8, measles 2,801, dysentery 772, acute poliomyelitis 26, paratyphoid fever 12, and typhoid fever 6.

Medical News

Nuffield Chair of Surgery at Oxford.—Mr. PHILIP ALLISON, the Leeds thoracic surgeon, has been appointed to the Nuffield field professorship of surgery made vacant by the death of Sir Hugh Cairns two years ago. In the interval Professor POMFRET KILNER, Nuffield Professor of Plastic Surgery, has been carrying out the duties of the Chair. Mr. Allison's appointment is from October 1.

Welfare Foods.—On June 21, at a press conference, Dr. CHARLES HILL, M.P., parliamentary secretary to the Ministry of Food, explained the new arrangements for the distribution of Welfare Foods which come into force on June 28. The arrangements were announced jointly by the Ministries of Food and Health and the Department of Health for Scotland. Liquid milk will continue to be supplied by the retail dairies, but National Dried Milk, orange juice, cod-liver oil, and vitamin A and D tablets will be distributed by local health authorities. Maternity and child-welfare clinics will be used for distribution more than in the past, but in some areas it will be necessary to establish new distribution centres in place of the Food Offices, which will cease distribution on July 14. Addresses of the new centres can be obtained from Food Offices (until they close), agency offices of the Ministry of Labour and National Service and the Ministry of Pensions and National Insurance, and from

local welfare clinics or their council offices. Documents of entitlement to welfare foods will be obtainable from offices of either the Ministry of Labour and National Service or the Ministry of Pensions and National Insurance. From November 1 the latter Ministry will be the only issuing authority for documents of entitlement. The present arrangements for the supply of liquid milk under the Welfare Foods Service will continue until October 30, when books of "Tokens for Welfare Milk" will be supplied to beneficiaries. Application forms for these books will be sent by post to existing beneficiaries in time for applications to be made before the scheme starts.

"Recovery Homes" and "Special Diets."—The King Edward's Hospital Fund for London continues to place the profession in its debt. Its latest pamphlets, "Recovery Homes: A report of an inquiry into the working of Recovery Homes and their value to the Hospital Service" and "Memorandum on Special Diets," will be warmly welcomed. The first describes the actual working of certain recovery homes, their functions, possibilities, and limitations. A recovery home is defined as a place "for patients in whom the disease has definitely begun to abate, or the risk of complications after operation is only slight, so that with proper care and nursing the patient is likely to progress to recovery," in contrast with a convalescent home which is for patients who need only rest before returning to normal work. The report is intended as a guide to hospital authorities which may be planning such homes. The memorandum on special diets is written with the needs of the smaller hospital without a dietitian particularly in mind. It starts by describing the essentials of a balanced diet, and then goes on to give details of the various special diets that may be ordered in hospital. Both pamphlets are obtainable from the Fund's offices, 10, Old Jewry, London, E.C.2 (price 1s. each, post free).

British Association of Plastic Surgeons.—The summer meeting was held on May 27, 28, and 29, at the Royal College of Surgeons and the Hospital for Sick Children, Great Ormond Street, London. Papers were read on "Experimental Approaches in Plastic Surgery," "Storage and Use of Arterial Grafts," "Prognathism," "Repair of Palate Defects with Pedicle Flaps," and "Problems of Maxillary and Mandibular Deformities." The social programme included a cocktail party given by the president of the association, Mr. D. N. MATTHEWS, and Mrs. MATTHEWS, a luncheon at Great Ormond Street by the Board of Governors, and a dinner at the Royal College of Surgeons.

Association of Sea and Air Port Authorities.—The 55th annual meeting of the Association of Sea and Air Port Authorities of the British Isles was held at Kingston-upon-Hull on June 9, 10, and 11, under the presidency of Councillor E. G. BRINT, of Hull. In his presidential address Councillor Brint reviewed the activities of the association during his year of office. Papers read at the meeting included "The Reconditioning of Food" (Dr. STUART I. A. LAIDLAW), "A Quarter Century of Port Health Work" (Professor R. H. PARRY), "The Hull Deep Sea Trawling Industry and Some of its Health and Medical Problems" (Dr. J. BURNS), and "Some Aspects of the Health of Trawl Fishermen" (Dr. P. A. G. MACQUEEN). Mr. DONALD E. ERLEBACH, representing the Port of London Authority, was elected president for 1954-5.

Scottish Society of Anaesthetists.—At the annual meeting in April Dr. I. M. CAMPBELL DEWAR (Glasgow) was elected president, Dr. F. G. GIBBS (Edinburgh) vice-president, and Dr. A. G. MILLER (Glasgow) hon. secretary. Dr. Campbell Dewar's presidential address was entitled "Wells, Morton, *et al.*," and in it he discussed the many problems and responsibilities of the anaesthetist in the National Health Service. Professor R. R. MACINTOSH, of Oxford, was a guest of the Society and gave a talk entitled "Experiences Abroad." The prize which the Society awards annually for the best paper submitted by an anaesthetist of or below the grade of senior registrar was won by Dr. J. B. STIRLING (Glasgow).

Memorial to William Smellie.—The William Smellie Maternity Hospital at Lanark will be the scene of a memorial celebration on August 18 in honour of the great obstetrician after whom it is named. At 3 p.m. Professor MILES PHILLIPS, emeritus professor of obstetrics of Sheffield University, will deliver an address on William Smellie's achievements. This will be followed by the unveiling of a statue of Smellie by Dr. T. HONEYMAN, Lord Rector of the University of Glasgow. The statue, designed by DENIS PEPLIE, is a gift from Professor S. J. CAMERON, emeritus professor of midwifery of Glasgow University, to the townspeople of the Royal Borough of Lanark. It was at Lanark that Smellie was born in 1697, and he practised there for 19 years before going to London, where he gained fame as a teacher of midwifery. He died at Lanark in the year 1763.

"Vox Sanguinis," now in its fourth year, is a bi-monthly journal published from the Central Laboratory of the Netherlands Red Cross Blood Transfusion Service, and edited by Dr. J. J. VAN LOGHEM, jun., and others. Its papers, which are of a high standard and come from all parts of the world, appear in English or French, and cover all aspects of blood transfusion and immuno-haematology. They are a striking reflection of the development of these subjects since the discovery of the Rh factor and the war-time needs of blood-transfusion services. The contributors include haematologists of international standing. Subscription costs 5.50 florins per annum (10s. 6d.), and the journal may be obtained from the Central Laboratory, Binnen-gasthuis, Amsterdam C.

Treacher Collins Prize.—Dr. ROBERT LEISHMAN, of Glasgow, has been awarded the 1954 Treacher Collins Prize by the Ophthalmological Society of the United Kingdom for his essay on "The Eye in General Vascular Disease: Hypertension and Arteriosclerosis." This is a triennial prize valued at £100.

Frances Wood Memorial Prize.—A prize of £40 is offered by the council of the Royal Statistical Society for the "best investigation, on statistical lines, of any problem chosen by the competitor, which bears directly or indirectly upon economic or social conditions." This includes problems of health or nutrition. The competition is open to anyone under the age of 35 on October 1, whether a Fellow of the Society or not. Entries should be sent to the honorary secretaries of the Royal Statistical Society, 21, Bentineck Street, London, W.1, not later than September 30.

Chair of Psychiatry at Leeds.—As a temporary measure the Council of Leeds University are instituting a part-time Chair of Psychiatry to which Professor D. R. MACCALMAN, the present Nuffield Professor of Psychiatry, is to be appointed. This change is in deference to medical advice given to Professor MacCalman, and will relieve him of much administrative responsibility. It is hoped to appoint a successor to Professor MacCalman in the whole-time Chair, but in the interval Dr. MARY BURBURY, the senior lecturer in child psychiatry, will act as head of the department.

Honorary Degrees at Glasgow.—Among the recipients of the honorary degree of Doctor of Laws of Glasgow University on June 16 were Professor J. A. G. BURTON, formerly St. Mungo Professor of Surgery at Glasgow; Professor J. H. DIBLE, Professor of Pathology at the Postgraduate Medical School of London; Sir JOHN MCNEE, formerly Regius Professor of Practice of Medicine at Glasgow; and Professor G. I. STRACHAN, Professor of Obstetrics and Gynaecology at the Welsh National School of Medicine, Cardiff.

Captain D. R. Boyns, R.A.M.C., has been awarded the M.B.E. for gallantry in Malaya. After a parachute descent in which he sustained a fractured spine he continued his duties without food or rest until ordered to stop work.

Dr. B. F. Martin has been appointed senior lecturer in anatomy at Sheffield University.

S.M.A. Library.—The Library will be closed and the library service suspended from July 30 to August 16 while redecorating is being done.

COMING EVENTS

Polio on Television.—At 10 p.m. on Monday, June 28, there will be a half-hour programme on infantile paralysis, presented by Jeanne Heal. It has been arranged in association with the Ministry of Health, the Infantile Paralysis Fellowship, the National Federation for Polio Research, and the British Red Cross Society, and is concerned with the danger signs that parents should look for.

Courage Laboratory of Ophthalmology.—The Duchess of Gloucester will open the Courage Laboratory of Ophthalmology at the Royal Eye Hospital, St. George's Circus, London, S.E.1, on July 6 at 3 p.m.

The Handicapped at School.—London County Council is organizing an exhibition of the work of London's special schools for handicapped children. It will be open daily from July 6 to 10, admission free, from 1 to 7 p.m. on July 6, and from 11.30 a.m. to 7 p.m. on other days, at the County Hall, Westminster Bridge, S.E.1.

Bertram Louis Abrahams Lecture.—Professor E. B. S. VERNEY, F.R.S., will speak on "Some Aspects of the Renal Excretion of Water and Salt" at the Royal College of Physicians on July 8 at 5 p.m.

Silver Jubilee of R.C.O.G.—The Royal College of Obstetricians and Gynaecologists will celebrate its silver jubilee on July 13, 14, and 15. On July 14 Sir WILLIAM FLETCHER SHAW will deliver the William Meredith Fletcher Shaw Memorial Lecture on "The College: its Past, Present, and Future," and on July 15 Professor BRUCE T. MAYES, Sims-Black Professor, will deliver the William Blair-Bell Memorial Lecture on "The Making of an Obstetrician." These lectures, which will be delivered at 11.30 a.m. in the Barnes Hall of the Royal Society of Medicine, are open to non-members of the College.

Joint Services Medical Surgical Diagnostic and Therapeutic Conference.—The U.S. Third Air Force is sponsoring a medical conference at the U.S. Embassy Theatre, 5, Grosvenor Square, London, from July 22 to 24 (9 a.m. to 5 p.m. each day). Speakers will be drawn from the Medical Services of the American and British armed Services, and will also include several British civilian surgeons and physicians. The conference is open to all members of the profession who would care to attend. Further information may be obtained from the Office of the Surgeon, Headquarters Third Air Force, Victoria Park Estates, South Ruislip, Middlesex (Telephone: Waxlow 4300, Ext. 206).

Claude Monet Exhibition.—An exhibition in aid of the British Empire Cancer Campaign is being held until July 30 at the Marlborough Gallery, Old Bond Street, London, W.1.

NEW ISSUES

British Journal of Venereal Diseases.—The new issue (Vol. 30, No. 2) is now available. The contents include:

NON-GONOCOCCAL URETHRITIS. P. Durel, V. Roiron-Ratner, A. Siboulet, and C. Sorel.
SYSTEMIC DONOVANIASIS. R. V. Rajam, P. N. Rangiah, and V. C. Anguli.
NON-SPECIFIC URETHRITIS: IS MYCOTIC INFECTION IMPORTANT? G. Auckland and W. J. Preston.
DISSECTING ANEURYSM OF THE AORTA. DIFFERENTIAL DIAGNOSIS FROM SYPHILIS. G. O. Horne.
PREVALENCE OF SYPHILIS IN CEYLON: REPORT BASED ON THE RESULTS OF SEROLOGICAL SURVEYS MADE BY THE W.H.O. V.D. CONTROL TEAM. Sydney M. Laird.
TRYPSIN DIGESTING MEDIUM ADDED WITH HORSE PLASMA FOR THE CULTURE OF THE GONOCOCCUS. V. Roiron-Ratner.
RECENT CHANGES IN FRENCH POLICY ON VENEREAL DISEASES AND PROSTITUTION. Cicely Watson.

Issued quarterly; annual subscription £2 2s., single copy 12s. 6d. Obtainable from the Publishing Manager, B.M.A. House, Tavistock Square, London, W.C.1.

Archives of Disease in Childhood.—The new issue (Vol. 29, No. 145) is now available.

Issued six times a year, annual subscription £3 3s.; single copy 12s. 6d.; obtainable from the Publishing Manager, B.M.A. House, Tavistock Square, London, W.C.1.

SOCIETIES AND LECTURES

A fee is charged or a ticket is required for attending lectures marked ●. Application should be made first to the institution concerned.

Monday, June 28

●WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—At Apothecaries' Hall, Blackfriars Lane, E.C., 7.30 for 8 p.m., annual banquet.

Tuesday, June 29

INSTITUTE OF DERMATOLOGY.—5.30 p.m., Dr. H. J. Wallace: Endocrine Disorders Affecting the Skin.

●INSTITUTE OF NEUROLOGY.—5.30 p.m., Dr. E. A. Blake Pritchard: Spontaneous Intracranial Haemorrhage.

Wednesday, June 30

BRITISH ASSOCIATION OF PAEDIATRIC SURGEONS.—At Hospital for Sick Children, Great Ormond Street, London, W.C.1, 5 p.m., Simpson-Smith Lecture by Dr. O. Swenson (Boston, U.S.A.): Congenital Defects in the Pelvic Sympathetic System.

INSTITUTE OF DERMATOLOGY.—5.30 p.m., Dr. J. O. Oliver: Mycobacteria in Skin Disease.

POSTGRADUATE MEDICAL SCHOOL OF LONDON.—2 p.m., Professor T. F. Hewer: Gastritis.

Thursday, July 1

INSTITUTE OF LARYNGOLOGY AND OTOTOLOGY.—At Royal College of Surgeons of England, 5.30 p.m., Mr. J. E. Piercy: Diseases of the Thyroid, Parathyroid, and Thymus Glands.

●INSTITUTE OF NEUROLOGY.—5.30 p.m., Dr. P. H. Sandifer: Traumatic Paraplegia (1).

POSTGRADUATE MEDICAL SCHOOL OF LONDON.—4.30 p.m., Dr. R. I. S. Bayliss: Adrenal Function in Health and Disease.

Friday, July 2

INSTITUTE OF CHILD HEALTH.—5 p.m., Dr. T. Ehrenpreis (Stockholm): Hirschsprung's Disease.

POSTGRADUATE MEDICAL SCHOOL OF LONDON.—2 p.m., Professor C. G. Robt: Present Status of Blood Vessel Grafting.

Saturday, July 3

SOCIETY OF ANAESTHETISTS OF SOUTH WALES.—At Plastic Surgery Centre, St. Lawrence Hospital, Chepstow, 9.30 a.m. to 4 p.m., clinical meeting.

APPOINTMENTS

MACFARLANE, DAVID A., M.B., B.Ch., F.R.C.S., Research Fellow in Surgery, Harvard Medical School, and Assistant in Surgery, Peter Bent Brigham Hospital, Boston.

MCGRATH, S. DESMOND, M.R.C.P.I., D.P.M., Physician in Charge of Clinical Research, St. Patrick's Hospital, Dublin.

NEWCOMBE, JOHN, M.B., B.S., D.P.M., Whole-time Consultant in Psychiatry for the Mental Deficiency Hospitals and Associated Hostels in the Hull and East Riding areas.

TAYLOR, ELLIS, M.B., Ch.B., D.P.H., Divisional Medical Officer, Lancashire County Council, Health Division No. 11, and Medical Officer of Health, Leigh Municipal Borough, and Urban District Councils of Atherton, Horwich, Tyldesley, and Westhoughton.

WOOD-WILSON, JAMES, M.D., D.P.H., County Medical Officer, West Riding of Yorkshire.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Barlas.—On June 11, 1954, at Queen Victoria Cottage Hospital, Tonbridge, Kent, to Pam (formerly Coutanche), wife of Dr. John Barlas, of Tudely Hale House, Tonbridge, a sister for Jane—Shena Rozel.

Gordon.—On June 16, 1954, at Chase Farm Hospital, Enfield, Middlesex, son, to Nonette (Dr. Harris-Wright), wife of Dr. Ian J. Gordon, a second son.

Jones.—On June 7, 1954, at Edinburgh, to Dr. Elizabeth (formerly Hislop), wife of Dr. James Jones, a daughter—Sheila Margaret.

Pavillard.—On June 8, 1954, at Singapore, to Irene, wife of Dr. Stanley S. Pavillard, a daughter, Anita June. Sister for Linda.

Pilcher.—On June 17, 1954, at the Military Hospital, Catterick Camp, to Elizabeth Margaret (formerly Smedley), wife of Major R. K. Pilcher, R.A.M.C., a brother (Richard) for Anne.

Turner.—On June 9, 1954, at Berkeley, California, U.S.A., to Joan, wife of Robert G. Turner, M.D., F.R.C.S., a son—John Edward.

DEATHS

Brown.—On June 11, 1954, at Newton Abbot Hospital, Thomas Brown, M.D., D.P.H., of 3, South Road, Newton Abbot, Devon.

Butter.—On June 3, 1954, at his home, 139, Palmerston Road, London, N., Andrew James Moyes Butter, M.M., M.D.

Challenor.—On June 4, 1954, at 40, Ripon Road, Harrogate, Yorks, Lionel Thomas Challenor, M.R.C.S., L.R.C.P.

Cooke.—On June 10, 1954, at Putney Hospital, London, S.W., John Bow-Cooke, of 400, Upper Richmond Road, London, S.W., aged 75.

Cooke.—On June 7, 1954, Richard Alphonso Cooke, M.R.C.S., L.R.C.P., of Ashfield House, Aspull, near Wigan, Lancs, aged 59.

Cosham.—On June 4, 1954, at Jersey, Channel Islands, William Lorymer Cosham, M.B., Ch.B., of Bristol.

Davidson.—On June 11, 1954, at the Duke of York Home, Bradford, Yorks, Richard Davidson (senior), M.B., Ch.B., of Woodgate, King Cross, Halifax, Yorks.

Fergusson.—On June 5, 1954, at Barn House, Eltham, London, S.E., Norman Mello Fergusson, O.B.E., T.D., M.B., B.Ch.

Fothergill.—On June 5, 1954, Leopold Fothergill, M.B., B.S., of 41, Grosvenor Place, Jesmond, Newcastle-upon-Tyne, aged 88.

Freeman.—On June 9, 1954, Sidney Lionel Freeman, M.R.C.S., L.R.C.P., of 572, Green Lane, London, N.

Hickey.—On June 4, 1954, in a nursing-home, Dublin, William Hickey, M.C., M.B., B.Ch., B.A.O., of Fort William Cottage, Black Rock, Dublin, Eire, formerly of Bombay, India.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Cholinergic Urticaria

Q.—A boy of 16 years gets urticaria every time he takes part in the cross-country run at school. Is this phenomenon known and what is the explanation? What treatment is advised?

A.—The urticaria appears on exertion, and it suggests the type known as "cholinergic." Cholinergic urticaria is provoked by exercise and by strong emotion. It can also be produced experimentally by the injection of carbachol. It is intensely itchy and can often be distinguished from other types of urticaria by the fact that the individual lesions are quite small—a fraction of an inch in diameter.

No satisfactory treatment for cholinergic urticaria is known. There is sometimes some response to antihistamines, but in most cases this response is not sufficient to prevent the eruption or to give a satisfactory degree of relief.

Inguinal Hernia and Fitness for Work

Q.—As a factory medical officer I often come across candidates for employment who suffer from a more or less severe degree of inguinal hernia. Often they make no complaint of it and have thought of no treatment by truss or operation. Can you give me any guidance on the following problems? What type of work are these men capable of? Is there any foundation for the statement that increase in size or strangulation may follow exertion? What proportion and what types of hernia are likely to develop complications? It has been my impression that, in the past, we have perhaps laid too much stress on suggesting treatment, or alternatively light work, for a man who is not complaining in any way, nor incapacitated by this condition.

A.—It is difficult to give a comprehensive answer to the first question and much will depend on the type of work done. While strangulation of an inguinal hernia may occur in a patient at rest there is no doubt whatever that irreducibility and strangulation often follow some violent exertion. Most hernias grow bigger relatively slowly, but the constant increase of intra-abdominal pressure in a heavy occupation certainly accelerates this process.

Direct hernias due to diffuse bulging of the posterior wall of the inguinal canal rarely, if ever, give rise to complications. The funicular direct variety, in which there is a small defect in the posterior wall of the canal, does occasionally become obstructed.

Indirect inguinal hernia is much more liable to complications. In general those with broad necks are less likely to become obstructed than those with narrow ones. There are so many variable factors to be taken into consideration that any reliable statistics are lacking. It is, however, doubtful whether such figures would really help in persuading a reluctant patient to accept operation. The advice a doctor gives must depend on the type of hernia, its size, the size of the defect through which it emerges, its rate of growth, and the occupation of the sufferer. It is quite unnecessary to persuade the majority of patients with direct hernias to have something done. To those with indirect ones the examiner can truthfully say that the risks of an untreated hernia are far greater than those of operation.

Most surgeons would agree that those conducting routine medical examination tend to be over-cautious in advising the patient. The facts should be simply explained and coercion avoided. It is regrettable that certain firms and organizations do compel a man to have an operation as

a condition of his employment. Those who do their work without complaint or apparent incapacity should be allowed to continue as they are. In the writer's experience it is best to give such men an explanation on the lines outlined above and to tell them to report back in the event of any worries or difficulties.

Air-locks During Transfusion

Q.—What is the best way of preventing and removing air-locks during a drip transfusion?

A.—Air-locks are prevented by expelling all the air from the transfusion apparatus before setting up the transfusion. After the giving set has been inserted, the clamp is tightly closed and the bottle suspended at a height of 3 to 4 ft. (1 metre) above the site selected for venepuncture. The set is then hung full length and the distal length of the rubber tubing held up in a "U" so that the needle tip comes just below the level of the drip counter. The clip is slowly opened, and not closed again until the blood has expelled all the air from the distal tubing. When the air has been expelled it is important that the drip chamber should remain vertical, particularly when inserting the set into another bottle, otherwise air may enter the distal tubing and create an air-lock.

Once an air-lock has developed the only satisfactory procedure is to disconnect the apparatus and expel the air by the method outlined above. Disconnecting the set or changing to a fresh one is greatly simplified, and carries no risk of dislodging the needle, if the transfusionist has taken the precaution of using, between the needle and the giving set proper, the short length of rubber tubing included with every giving set prepared by the National Transfusion Service.

Trichlorethylene in Industry

Q.—What are the toxic effects of trichlorethylene ("trilene") when used in industry? In my experience, inhalation of the vapour produces a feeling of sleepiness which quickly passes off on exposure to fresh air after leaving work. Some workers complain of an embarrassing flushing of the face when enjoying the evening pint of beer. Can this flush be prevented?

A.—An excellent account of the toxic effects of trichlorethylene in industry can be obtained in *Toxicity of Industrial Organic Solvents*, by Ethel Browning.¹ Degreasing operations are the most frequent cause of industrial intoxication in this country, and cases of acute poisoning usually arise during the cleaning of the apparatus. Acute poisoning is manifested by sudden loss of consciousness without any profound effect on the respiratory or vascular system. Recovery without after effect is usual if the sufferer is removed soon enough from the fumes, but death occasionally occurs when suitable precautions are not taken.

Chronic exposure to sublethal concentrations of trichlorethylene produces drowsiness and consequently a loss of alertness which may render the worker more liable to accidents. Not infrequently this drowsiness is not appreciated and may persist for some time after leaving work. Instances have been encountered of workers falling asleep in the 'bus and going on long past their stop, and of falling off their bicycles on the way home. This drowsiness during the working day is often associated with an inability to sleep at night. Vague nervous symptoms of a neurotic type are often encountered. Headaches, dyspepsia, ill-defined aches, and sometimes paraesthesiae are common.

It seems likely that trichlorethylene is fixed in some organ where it is metabolized into trichloroacetic acid, which is slowly excreted for several days after exposure.² This forms the basis of a test of exposure to trichlorethylene by the measurement of the trichloroacetic acid excretion in the urine.³

It is recognized that alcohol and trichlorethylene have a synergistic effect and that workers who have been exposed to trichlorethylene find that they become easily drunk if they indulge in alcohol in the evening. The symptom of

face flushing comes into this category. There is apparently no way of avoiding this effect except by reducing the exposure to trichlorethylene.

NOTES AND COMMENTS

Treatment of Leukoplakia of the Tongue.—Mr. P. A. LANE-ROBERTS (London, S.E.1) writes: I would suggest with deference that the answer to the question on treatment of leukoplakia of the tongue ("Any Questions?" June 5, p. 1336) is more optimistic in its tone than the facts justify. The patch has been steadily progressing in size from being "quite a small area to being almost the size of a halfpenny." Although the age of the patient is not stated, the suspicion arises that this may already be neoplastic and not merely hyperplastic; and this suspicion would be stronger if the patient were over the age of 45. In a recent short study of the records of Guy's Hospital 22 cases were found in which leukoplakia buccalis was associated with carcinoma of the oral cavity. Of these cases 6 had only recently (within 12 months) developed a patch or patches of leukoplakia, of which one was proved to be carcinomatous on examination by biopsy. It seemed that their leukoplakia was cancerous from the first. Of these cases none had a positive Wassermann reaction. The size of the lesion is of importance. A halfpenny measures 2.5 cm. Sturgis and Lund¹ found that 16 (22%) of 71 cases with lesions of more than 2.1 cm. in diameter developed cancer in the course of five years. Surely in a case of this nature biopsy is obligatory, and diathermy removal is justifiable.

OUR EXPERT writes: This criticism certainly demonstrates the truth of the statement in the answer that "some surgeons have always been inclined to more radical measures than others." With the great decrease in the numbers of late syphilitic lesions of the tongue, leukoplakia is nowadays nearly always due to other causes, but, apart from impressions, I do not know that there is any definite evidence that this either increases or diminishes the incidence of malignant change. One can "play for safety" and submit all cases to biopsy or adopt a more discriminating attitude, with, of course, the precautions mentioned in the answer. So many cases followed over the years have turned out to be benign (even sometimes despite a pathological report to the contrary) that I still think the more conservative attitude is justified.

Corrections

At the end of Mr. W. S. Hanna's letter on undergraduate education (*Journal*, June 19, p. 1438) his address was given as Ballymena, Eire. This should, of course, have read Ballymena, N. Ireland.

The honorary degree which Sir Rudolph Peters, F.R.S., is to receive on November 26 is that of Doctor of Science of London University, not of Oxford (*Journal*, June 19, p. 1448).

"Any Questions?" Book.—The second book of selected "Any Questions?" is available, price 7s. 6d. (postage 6d.). Copies may be obtained either direct from the Publishing Manager, B.M.A. House, Tavistock Square, London, W.C.1, or from booksellers.

All communications with regard to editorial business should be addressed TO THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 4499. TELEGRAMS: *Medicorum Lond.* ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. House, Tavistock Square, London, W.C.1 (hours 9 a.m. to 5 p.m.). TELEPHONE: EUSTON 4499. TELEGRAMS: *Britmedads*, *Westend, London*.

MEMBERS' SUBSCRIPTIONS should be sent to the SECRETARY of the Association, TELEPHONE: EUSTON 4499. TELEGRAMS: *Medicorum Lond.*

— Adrenalectomy in advanced cancer, 1257
— Aldosterone (electrocortin): occurrence in human urine, 1290

ADRENAL GLANDS (continued):

Cortex: assessment of activity (F. T. G. Prunty), 751
— *Ciba Foundation Colloquia on Endocrinology, Volume VII: Synthesis and Metabolism of Adrenocortical Steroids* (Editor: G. E. W. Wolstenholme), 368
— function in burned patients with special reference to A.C.T.H. and adrenaline tests (S. Sevi), 541 (O); 572 (A); 763 (C); 986 (C)
— response to corticotrophin: effect of A.C.T.H. on plasma adrenal steroid levels (R. I. S. Bayliss and A. W. Steinbeck), 486 (O)
— Hyperplasia: treatment with cortisone, 5
— Medulla: insulin resistance following removal, 1287
Adrenaline: use in determination of adrenocortical function in burned patients, 541
Adrenocorticotrophic hormone. See A.C.T.H.
Adrenogenital syndrome, 1375
ADRIAN, E. D.: The basis of sensation: some recent studies of President of British Association, 165
— induced as President of British Association, 165
Aerosol detergents, 323 (A)
Africa: Medical and social problems of the African in industry, 93; 334 (C); 455 (C); 818 (C)
— medical needs in the Gold Coast, 157 (C); 214 (C); 383 (C); 519 (C); 580 (C); 1041 (C)
— problems of malaria control (L. J. Bruce-Chwatt), 169 (O); 201 (L)
Age and Achievement (H. C. Lehman), 1309
Age, old. See Old age
Agerne in flour (parliamentary note), 405
— substitute (parliamentary note), 1216
AGERHOLM, Margaret: Poliomyelitis, 877 (C)
Aggression and Its Interpretation (Lydia Jackson), 1363
Agranulocytosis, fatal, following phenylbutazone (I. H. Wood), 802
— treatment with A.C.T.H., 2
Agricultural chemicals, residues in food, 445 (L); 465 (parliamentary note)
Aherne, John Maurice, obituary of, 402
AINSWORTH, N. J.: Teeth, extraction, facial disfigurement after, 224
Air pollution, 1367
— parliamentary notes, 711, 767
— power station flue gases (parliamentary note), 939
Aircraft, spread of disease by, 670
AIRD, I.: Conjoined twins of Kano, 831 (O), 863 (L)
— Press publicity, 153 (C)
— MELROSE, D. G., CLELAND, W. P. and LYNN, R. B.: Assisted circulation by pump-oxygenator during operative dilatation of the aortic valve in man, 1284 (O); 1310 (L)
Aitken, Robert, obituary of, 822, 1501
Albahr, C.: *Maladies Médicamenteuses d'Ordre Thérapeutique et Accidental*, 1364
Alcohol and antihistamines (medico-legal note), 403
— and road accidents, 749 (A)
— use and abuse of, 1439 (C)
Alcoholism, management of, in general practice, 270
— methylpentynol as hypnotic, 760 (C)
— Recognition of Intoxication, 753; 749 (A)
Aldosterone: Occurrence in human urine (C. L. Cope and J. Garcia-Llanudo), 1290 (O); 1311 (L); correction, 1450
Algae as food, 1085 (A)
ALLAN, T. M.: Fitness, fertility, and blood group, 1437 (C)
ALLEN, A. W.: Cancer of the colon, 1257
ALLEN, C.: Definition of male and female, 816 (C)
— Change of sex, 1040 (C)
— Homosexuality, 1442 (C)
Allergy: See also Asthma; Urticaria
— *Clinical Allergy* (F. K. Hansel), 139
— *The Eczemas* (Editor: L. J. A. Loewenthal), 1478
— incidence of allergic diseases in general practice (N. J. T. Hamilton and B. Bendkowski), 1069 (O)
— urticaria, cholinergic, 1307
ALLISON, A. C.: Protection afforded by sickle-cell trait against subtertian malarial infection, 290 (O); 320 (L); 871 (C); 988 (C)
Allison, P., appointed to Nuffield professorship of surgery, University of Oxford, 1505
Almoners, Institute of: annual meeting and dinner, 827
Alopecia totalis, 1390
Ambulance Service, London: accident section statistics, 1350
American College of Surgeons, meeting in London, 343, 1106, 1251 (L); 1256
— Three-day sectional meeting at Royal College of Surgeons of England, 1208

Amidopyrine: two cases of "novalgine" agranulocytosis (D. Patuck), 919
p-Aminobenzoate, milk, and malaria of rats and monkeys (F. Hawking), 425 (O); 447 (A)
p-Aminosalicylic acid, sensitivity to, 153 (C)
— in tuberculosis; radio-iodine measurements of thyroid function during and after treatment (J. A. Balint and others), 1234 (O); 1494 (C)
Amoebiasis in Britain: diagnosis, 1082
Amphetamine: acute psychotic reaction after inhalation of methylamphetamine (R. B. Carr), 1476
— in "pocket" inhaler, 616
Ampoules, sterilization of, 100 (C); 335 (C); 455 (C), 581 (C)
Amputation and arteriosclerosis (parliamentary note), 404
— elastic stump socks, 873 (C)
Amputees, mortality in (parliamentary note), 404
ANAEMIA:
— Aplastic: treatment with A.C.T.H. and cortisone, 2
— Diagnosis: copper sulphate test, 771
— laboratory investigations in iron-deficiency and simple chronic anaemia (G. Discombe), 886
— Haemolytic, investigation of (J. F. Wilkinson), 1490
— treatment with A.C.T.H. and cortisone, 1
— Hyperchromic: laboratory investigation (J. F. Wilkinson), 1870
Megaloblastic, resistant to vitamin B₁₂ and parenteral liver extract, 983 (C); 1284 (C)
Megaloblastic Anaemias (L. J. Davis and A. Brown), 199
— treatment with oral vitamin B₁₂ without known source of intrinsic factor (J. N. M. Chalmers and Zaida M. Hall), 1179 (O)
Pernicious, estimation of intrinsic factor of Castle by use of radioactive vitamin B₁₂ (Sheila T. Callender and others), 10 (O)
— treatment with very small quantities of pyloric mucosa and vitamin B₁₂ (E. Meulengracht), 838 (O)
Sickle-cell, 276 (C)
— incidence in Uganda, 1440 (C)
— protection afforded by sickle-cell trait against subtertian malarial infection (A. C. Allison), 290 (O); 320 (L); 871 (C); 988 (C)
— variability of sickle-cell rates in tribes of Kenya and Southern Sudan (H. Foy and others), 294 (O); 320 (L)
Spherocytic, congenital, crises in (J. L. Emery and D. W. Lemmon), 737 (O); 833 (C)
Symptoms as guide to anaemia (W. T. C. Berry and F. A. Nash), 918 (O)
Treatment: effect of purchase tax on medications, 999 (C)
ANAESTHESIA: See also Analgesia
Airway, pharyngeal (A. H. Galley), 516
Anaesthesia, three-dimensional illustrations in, 886
Anaesthetic explosions caused by reservoir bag, 701 (C)
Anaesthetic management of patients with poliomyelitis and respiratory paralysis (E. W. Andersen and B. Isben), 786 (O)
— Anaesthetics: Ministry of Health inquiry, 894 (C)
— disposal of, 279 (C)
Auscultation during thoracic operations, apparatus for (J. D. Laycock), 151
Carbon dioxide retention simulating curarization (C. F. Scurr), 565; 820 (C); 931 (C)
Contaminated spinal anaesthetics (medico-legal note), 940
Distention pressure in rebreathing bags, 1040 (C)
Endotracheal: acute post-operative laryngeal obstruction (J. B. Prendiville and H. G. Middleton), 1126 (O)
— tubes, storage cabinet for (M. J. Harker), 930
Ether and chloroform, keeping qualities, 716
Faculty of Anaesthetists: elections to Board, 714; dinner, 769; diplomas granted, 1217
For children, 1427 (A)
General anaesthesia for out-patients, 462; 505 (L); 641 (C); 702 (C); 818 (C); 873 (C); 874 (C), 937 (C)
Hibernation anaesthesia, prolonged hypotension after, 645 (C); 759 (C); 931 (C)
Hypothermia, 44 (C)
In hospital breech delivery (R. G. Law and Shila G. Ransom), 562 (O); 758 (C); 932 (C)
Inhalation Therapy and Resuscitation (M. Saklad), 441
Methyl α -propyl ether as anaesthetic for children (H. G. Middleton and D. K. W. Picken), 1192
Protection of Animals (Anaesthetics) Bill (parliamentary note), 466
Scottish Society of Anaesthetists, 1505
Standard in Britain, 1267 (C); 1326 (C); 1380 (C), 1497 (C); 1498 (C)

ANAESTHESIA (continued):

- Succinylcholine chloride for casualty anaesthesia, 46 (C)
 Succinylmonocholine iodide; neuromuscular activity in anaesthetized man (F. F. Foldes and others), 907 (O)
Synopsis of Anaesthesia. Third edition (J. A. Lee), 1024
 Trichlorethylene inhaler of constant strength utilizing a new principle (T. H. S. Burns), 329
 Wasp venom and anaesthesia, 1204
 Whither anaesthesia? 42 (C), 159 (C), 212 (C), 278 (C), 396 (C), 588 (C)
- Analgesia, continuous caudal; experiences in management of disordered uterine function in labour (G. T. Johnson), 827 (O); 759 (C)
 — extradural, simple indicator for (G. A. Jackson), 152
 — *Management of Pain: With Special Emphasis on the Use of Analgesic Block in Diagnosis, Prognosis, and Therapy* (J. J. Bonica), 1248
Analytical Abstracts, 489
Anatomy: Atlas der Systematischen Anatomie des Menschen (G. Wolf-Heidegger), 804
 — Dissection; procedure for bequest of body, 771
 — *Gynaecological and Obstetrical Anatomy and Functional Histology* (C. F. V. Smout and F. Jacoby), 200
- ANDERSEN, E. W. and ISSEN, B.: The anaesthetic management of patients with poliomyelitis and respiratory paralysis, 786 (O)

- ANTICOAGULANTS:
 Anticoagulant therapy at sea, 285
 — death after (medico-legal note), 1045, 1828 (C)
 Heparin and ethyl biscoumacetate in prevention of experimental venous thrombosis (Pamela Jewell and others), 1018 (O)
 Vitamin K₁ in anticoagulant therapy (M. Toohy), 1020 (O)
- ANTHISTAMINES:
 Chlorcyclizine hydrochloride poisoning in an infant (M. C. Gill-Carey), 687
 Diphenhydramine in treatment of vomiting, 976 (A)
 Influence of alcohol on (medico-legal note), 408
 Side effects, 1067
 Therapy, with special reference to skin disorders (R. F. Warin), 1066 (O); 1084 (A)
- Antiseptic, golden jubilee of, 1199 (A)
 Ants, eradication of, 471, 772 (C)
- ANY QUESTIONS?:
 Acid-forming food, 472
 Acne, treatment with oestrogen ointment, 1450
 Anaemia; diagnosis, copper sulphate test, 771
 Anaesthesia, deep, for domiciliary midwifery, 857
 Antibiotics, stability of, 1108
 Anticoagulant therapy at sea, 285
 Ants, eradication of, 471
 Appendicitis, white cell count in, 410
 Arsenic; danger of liquor arsenicals, 1889
 Ascorbic acid, synergistic effect on phenylbutazone, 286
 Asthma, inheritance of, 1440
 Bell's palsy, infectivity of, 54
 Blackheads, treatment of, 409
 Bladder; decompression technique, 1380
 Blood picture in children, 716
 — pyruvate estimation, uses of, 107
 — transfusion; air-locks during administration, 1508

ANY QUESTIONS? (continued):

- Blood transfusion, intraperitoneal, of infants, 1278
 — massive, causing haemorrhagic state, 581
 — precautions against transmission of syphilis, 1166
 Bone development in treated cretins, 1440
 — regeneration after mastoidectomy and antrostomy, 1222
 Breast milk, excretion of drugs in, 897
 Bromide rashes; effect of arsenical treatment, 1060
 Carbon dioxide bubbles on acidifying urine, 1278
 Chalices, infection from, 1107
 Cheirpompophylx; dangers of repeated x-ray treatment, 944
 Childbirth and cataract, 224
 Children, European, advisability of removal from Tropics during adolescence, 830
 Chlorbutol in nasal disease, 410
 Chloroform, metal containers for, 595
 Chloronaphthalene wax, dermatitis due to, 1221
 Cholera, treatment with borax, 596
 Circumcision in infancy, indications and contra-indications, 944
 Colds; role of central heating in outbreaks, 167
 Compression chamber, fitness for work in, 472
 Coronary disease and dental analgesia, 107
 — occlusion, clotting time in, 846
 Creatinine content of urine and accuracy of 24-hour specimen, 1222
 Crickets, transmission of infection by, and eradication of, 223
 Cyanosis after tattooing, 846
 Cysts, sebaceous, multiple, 716
 Dead, regulation governing burial of, 286
 Deodorants in general practice, 900
 Dermatitis, ammoniacal, in infants, 847
 Detergents; composition, nature and phytotoxic effects, 716
 Diabetes mellitus; liability of diabetics to peptic ulceration, 1221
 Diarrhoea in travellers, 286
 Disinfectants in the lavatory pan, safety of, 168
 Dissection; procedure for bequest of body, 771
 Drowsiness in an old man, 1330
 Encephalitis risk after immunization, 943
 Enemas, nutrient, 108
 Epilepsy; epileptic relative and marriage, 1389
 Episcopes, diascopes, and epidiascopes, 889
 Ether and chloroform, keeping qualities, 716
 Eyes; bags under the eyes, 995
 — bleary; causes and treatment, 1278
 — colour changes, 846
 — colour inheritance, 107
 Feet; bare feet in all weathers, 829
 Ferrous gluconate in iron deficiency, 472
 Fibrositis; definition and relation to emotional stress, 1277
 Fowl pest in man, dangers of, 715
 Furunculosis, scarring due to, 1336
 Glycerin in obesity, 54
 Glycosuria, renal, as cause of hypoglycaemic attacks, 846
 Growth and its control, 108
 Hair, cause of sudden loss, 1390
 — superfluous; electrolysis at home, 54
 Hernia, inguinal, and fitness for work, 1507
 — repair, artificial, 108
 — treatment by exercises, 345
 Herpes, corneal, recurrent, treatment of, 1222
 Huntingdon's chorea, management of, 223
 Hypertension and nocturnal frequency, treatment of, 472
 — in pregnancy, treatment of, 409
 Incest; marriage to a sister-in-law, 54
 Infants: Should mothers leave their babies? 658
 Intravenous therapy in infants, 1106
 Iodine sensitivity tests before radiological investigations, 1049
 Iron carbonyl, toxic hazards of, 221
 Leg raising test, 695
 Lipuria and chyluria; investigation and management, 887
 Malaria prophylaxis, 107
 Male and female symbols, 596
 Masturbation in married woman, 1335
 Meibomian cysts, multiple, in children, prevention of, 772
 Menopause, correlation with length of menstrual cycle, 506
 Mepacrine stains, removal from clothing, 608
 Mercury poisoning in dentists, 658
 Mouth-breathing in children, correction of, 285
 Mucous membranes, sterility at birth, 1386
 Mumps oophoritis value of oestrogen therapy, 808
 Myopia in motorists, 596
 Obstetrics; risks of late child-bearing, 1165
 Oestrogens administered to cockerels; effects on humans, 1166
 Ophthalmia, sympathetic, 346
 Oxygen cylinders; method of storage, 1277
 Paint, luminous, harmful effects of, 906
 Parapertussis, 592
 Parotid enlargement in primitive peoples, 64
 Penicillin lozenges; therapeutic uses, 167
 Penis, infantile, diagnostic significance and treatment, 595
 — causes of irritation, 880
 Phenylbutazone in pulmonary tuberculosis; possible side-effects, 471
 Photofluorography in diagnosis, 608

ANY QUESTIONS? (continued):

- Pica in pregnancy, 409
 Pneumectomy, vascular effects of, 1335
 Potassium estimation in plasma, 1336
 Priapism, nocturnal, 108
 Prickly heat; aetiology, diagnosis and treatment, 54
 Procaine, idiosyncrasy to, 1108
 Protein and resistance to tuberculosis, 1050
 Purpura, anaphylactoid, effect of pregnancy on; treatment and prognosis, 829
 Radiology; hazards of fluoroscopy, 532
 Reticulosis, definition of, 995
 Rheumatism; treatment with counter-irritant ointments, 592
 Rosehip syrup recipe, 1277
 Saline, hypertonic, for lightning pains, 829
 Salivary gland swelling; treatment, 531
 Salt, craving for, 532
 Scaphocephaly; prognosis and treatment, 223
 Scarlet fever; school precautions, 1222
 Schizophrenia, inheritance of, 531
 Sclerosis, disseminated, effect on susceptibility to other diseases, 472
 Scrotum, testosterone injections into, 596
 Sepsis among butchers, 715
 Serum-sensitivity, 471
 Sex education, 531
 Sodium glutamate in food, 1108
 Spermatorrhoea, investigation and treatment of, 1050
 Spinal cord; neuronal pathways in decerebrate rigidity, 1450
 Splenectomy for leukaemia, value of, 410
 Spots before the eyes; causes and treatment, 943
 Sterilization by dry heat in general practice, 658
 Stilboestrol for prostatic cancer; dosage, 596
 Still's disease, treatment of, 772
 Streptomycin, deafness due to, 410
 — during pregnancy; effects on foetus, 286
 — ocular side-effects, 472
 T.A.B., intradermal, 657
 T.A.B.T. vaccine in children, 1050
 Teeth; value of toothbrush, 1019
 Television; where to sit for viewing, 1390
 Testicles, abdominal, effect on fertility, 409
 Tetanus risks in sport, 167
 — toxoid and combined prophylactics, 888
 — development of immunity after, 888
 Thallium poisoning; symptoms and treatment, 592
 Thiopentone, accidental extra-venous injection, treatment of, 345
 Threadworms; efficacy of ammoniated mercury ointment, 410
 Thundery weather, vasomotor effects of, 224
 Thyroid extract dosage, 531
 Tobacco smoking, 471
 Tongue, leukoplakia, treatment of, 1336
 Trichlorethylene in industry, toxic effects, 1608
 Tuberculosis; tubercle bacillus in house dust, 1449
 Tumours; exposure to sunlight as predisposing cause, 167
 Uric acid gravel, prevention of, 1390
 Urine, cloudy, after acetic acid, 1390
 Urticaria, cholinergic, 1507
 Uterus, bicornuate, operative treatment of, 223
 Vaccines, damage by hot syringes, 167
 Varicose venues, treatment of, 53
 Veins, varicose; effect of cycling in man aged 69, 1450
 Vertebrae, wedge-shaped, with arachnoidactyly, 944
 Vertigo, laryngeal, 224
 Veterinary medicine, practice by medical practitioner, 1278
 Visual development in infants, 1450
 — standards for the Navy, 1165
 Vitamin K; indications in dental haemorrhage, 168
 Vitiligo, treatment of, 846
 Water; chlorination in camp, 830
 — softener for a sterilizer, 1222
 Whooping-cough; vaccine trial in general practice, 1107
 Wounds, contaminated; treated with penicillin alone, 53
 Yellow fever vaccination for children, 1165
- Aorta: Case of complete atresia with dissecting aneurysm (H. K. Meller), 1245
 — organs of Zuckerkind, 385 (A)
 Aortic valve, assisted circulation by pump-oxygenator during operative dilatation in man (I. Aird and others), 1284 (O); 1310 (L)
 Aphonia and deafness in hyperparathyroidism (J. A. Simpson), 494 (O)
 Apocrine gland function, 1198 (A), 1441 (C)
 Apothecaries' Hall of Ireland: Diplomas awarded, 1108
 Apothecaries, Society of. See Society of Apothecaries of London
- APPENDIX:
 Appendicitis in the course of measles, 156 (C); 397 (C), 454 (C), 1098 (C)
 — masked, 279 (C)
 — white cell count in, 410
 First removal, 101 (C)
 In hernial sac, 46 (C), 396 (C)
 Lymphosarcoma of (F. A. Henley and W. W. Slack), 878
 Mucocoele of (J. H. Johnston), 135 (O), 458 (C)
 Appointments, 106, 285, 345, 408, 470, 595, 657, 715, 887, 1221, 1276, 1335, 1388, 1507

A.P.T. and poliomyelitis; effect of diphtheria-pertussis inoculation on susceptibility, 215 (C)
 Arachnoidactyly and wedge-shaped vertebrae, 944
 Arber, Agnes: *The Mind and the Eye: A Study of the Biologist's Standpoint*, 689

ARMED FORCES: See also Military medicine; Naval medicine
 Appointments and retirements, 48, 283, 990, 1385
 Awards and decorations, 341, 990, 1085, 1506
 National Service men medically unfit, 1102
 Porritt, Sir Arthur, appointed consulting surgeon to the Army, 1387
 R.A.M.C. dinner, 1275
 R.A.M.C. pay (parliamentary note), 1390
 Royal Navy: Honours, 1394
