(c) *Analysis* is a less superficial and also a more co-operative procedure than (a) or (b). The aim is to reveal the meaning and positive value of symptoms. A limitation is that a Freudian or Jungian analysis is time-consuming. The selection of patients (and analyst) is important. Broadly speaking, the Freudian procedure is more efficacious with younger patients and the Jungian with those over, say, 35, but no rigid line can be drawn.³

Locks of Grey Hair in a Child

Q.—Locks of grey hair, with about four hairs in each, are beginning to appear in a child of 9 years. Her mother first noticed grey hair in her own case at the age of 20. Can anything be done to arrest this condition?

A.—Locks of white or grey hair may appear in members of certain families soon after birth or during the first or second decades. It is an inherited characteristic transmitted as a dominant direct from generation to generation by males and females alike. An unaffected member of the family does not transmit the defect. Nothing can be done to arrest its appearance.

Books of "Any Questions?" and Refresher Course Articles.—The following books are available through booksellers or from the Publishing Manager, B.M.A. House. Prices include postage. *Any Questions?*, Volumes 2 and 3 (8s. each); *Refresher Course for General Practitioners*, Volumes 2 and 3 (26s. 6d. each inland, 26s. overseas); *Clinical Pathology in General Practice* (22s. 3d. inland, 21s. 9d. overseas).

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 4499. TELEGRAMS: *Alitology, Westcent, London*. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors overseas should indicate on MSS. if reprints are required, as proofs are not sent abroad. ADVERTISEMENTS should be addressed to the Advertisement Director, B.M.A. House, Tavistock Square, London, W.C.1 (hours 9 a.m. to 5 p.m.). TELEPHONE: EUSTON 4499. TELEGRAMS: *Brimedads, Westcent, London*. MEMBERS' SUBSCRIPTIONS should be sent to the SECRETARY of the Association, TELEPHONE: EUSTON 4499. TELEGRAMS: *Medisecra, Westcent, London*. TABLETS

- anti-inflammatory action 3 to 5 times that of cortisone or hydrocortisone.
- gastro-duodenal side effects minimised by protective coating of individual hormone crystals.

PRESENTATION: Bottles of 30 tablets of 1 mg. or 5 mg.

NO PURCHASE TAX APPLICABLE ON HYDRODELTALONE TABLETS

Available under N.H.S. prescription (Form E.C.10.)

On local application, Hydrodeltalone has a rapid and powerful anti-inflammatory and anti-allergic effect.

In intra-articular and peri-articular injections, the anti-inflammatory effects of hydrocortisone are obtained with a smaller quantity of Hydrodeltalone.

HYDRODELTALONE

intra-articular injections

for local articular and peri-articular inflammatory conditions

PRESENTATION:

5 ml. vials containing 25 mg. of prednisolone acetate per ml. in saline suspension.

HYDRODELTALONE

skin ointment with neomycin

for infectious and non-infectious inflammatory and allergic disorders of the skin.

PRESENTATION:

tube containing 5 g. or 15 g. Each gramme contains 5 mg. of prednisolone and 5 mg. of neomycin sulphate.

PARENTROVITE

Injectable B complex with vitamin C

A massive dose of injectable B complex with vitamin C . . . to restore normal cerebral functions in toxic states due to narcotic or barbiturate drugs, alcohol, or acute infections.
In boxes of 3 pairs of ampoules. Hospital pack also available.

A preparation **OROVITE**, containing the same B complex vitamins in high concentration for oral administration, is also available. *In tablets and elixir.*

Two groups of preparations containing the vitamin B complex in less massive concentration are: **BECOVITE & BEFORTISS**. *In tablets, ampoules and elixirs.*

(DEPT. A.4.), UPPER MALL, LONDON, W.6.

an unusual degree of tolerance

The partnership of the hermit crab and the sea anemone is one of the best known and most spectacular examples of symbiosis — mutual tolerance by which both parties stand to gain.

The crab augments his second-hand defensive armour by the offensive protection of the anemone's tentacles; the anemone in turn receives priority transport to ready-made feeding grounds, curving its tentacles downwards to sweep the sea floor for the crab's left-overs.

Most patients who are unable to take aspirin find that they can accept it in the form of Paynocil. Not only are Paynocil tablets usually well tolerated by the stomach (even on the heavy dosage needed for rheumatoid arthritis), but they are extremely palatable, disintegrate instantly on the tongue without water, and cause no discomfort or unpleasant after-sensation.

**NON-IRRITANT
PALATABLE
quick-dispersing aspirin**

SIR VICTOR HORSLEY, 1857-1916 CENTENARY LECTURE*

BY

Sir GEOFFREY JEFFERSON, C.B.E., M.S., F.R.C.P., F.R.C.S., F.R.S.
Emeritus Professor of Neurosurgery, University of Manchester

A hundred years ago was born a man who would bear one of the most famous names in surgery. What may have been the ambitions of John Callcott and Rosamund Horsley for this third son we cannot know. It is most improbable that they could have seen him as a colossus of scientific medicine. Very likely they thought of him as a future artist of some kind—a painter like his father, already an Associate Royal Academician. Or perhaps he would be like his grandmother's brother, the Sir Augustus Wall Callcott whose landscapes were valued only after those of Constable and Turner and are still known to collectors. Or perhaps, again, he might be a musician like his paternal grandfather, William Horsley, one of England's most famous composers of glees and rounds, the friend of Mendelssohn, who thought highly of these compositions. Victor's father later became a close friend of Felix Mendelssohn. A relation, Lady (Maria) Callcott, was the authoress of *Little Arthur's History of England* (1835), a book so perfectly attuned to the spirit of the times, so edifying, that it was a best seller for more than one generation. It was into this family with its strong artistic associations that the young Victor came.

Antecedents and Social Background

His father was known to the Prince Consort through his designs, one a winning one, for the new Houses of Parliament. Also Miss Scarratt, the Queen's companion, was a close friend of the Horsleys, and this strengthened their slender Palace association. Miss Scarratt had only to come across the announcement in *The Times* of the birth of a son to that family when reading the news to Her Majesty (confined on that same April 14, 1857, the year of the Indian Mutiny, by the

birth of her daughter Beatrice) for there to ensue a discussion from which the names Victor Alexander emerged as those the Queen would like the Horsley boy to have. One year later Horsley senior was commissioned to paint the Princess Beatrice, and Victor was brought to the Palace for the Queen's inspection. Victor

was inspected, as it were, by a host of people afterwards and impressed them by his rather deep-set eyes, wide forehead, his pronounced features, by the energy and alertness of his manner, quickness of decision, and the indefatigability of his frame.

His father before him had been exceptionally gifted and good-looking. The snapshot portrait of John Callcott Horsley which graces his *Recollections of a Royal Academician* (1903) shows a figure at ease in an outsize silk hat, braided cut-away coat and trousers—a figure elegant: one recognizes at once a man economically and socially secure. According to Stephen Paget, Victor's father was friendly, impulsive, hot-tempered, and restless. Like his son after him, he too had a crusade. This was the result of his once-famous address to the Church Congress at

Victor Horsley

[Swaine, London]

Portsmouth in October, 1885, protesting against the use of the nude model, especially when female, in art schools. His address was called "Art Schools and Art Practice in Their Relation to Moral and Religious Life." "Where," he said, "is the justification in God's sight for those who induce women so to ignore their natural modesty and quench their sense of shame as to expose their nakedness to men and thus destroy all that is pure and lovely in their womanhood?" He himself, though greatly dependent on models, had never required them to remove their clothes. This address, *The Times* said, caused a painful sensation. No doubt that was the speaker's intention, but it brought on his head the same sort of criticism, badinage, and hostility

that would come his son's way in due time. There were those who held that John Horsley would have been a better painter if he had been a better anatomist. Amongst his critics was Whistler, as can be read in *The Gentle Art of Making Enemies*. But make no mistake about it, Horsley was a sincere and highly competent painter. It was deep Christian reverence and concern for the welfare of the model that moved the father to protest against the nude.

Religion, by contrast, was not the basis for Victor's crusades, for he was an agnostic, a Huxleyite, but, like his father, a reformer. The motivations of Victor's anti-alcoholic crusade were physiological: alcohol was a toxic substance, a dangerous drug that was too freely available. It was an unpopular thesis, but not for that the less true, especially at that time.

This much has been said about Victor Horsley's parents and forebears because it is necessary, if his work is to be recalled and reappraised, that we should know not only his antecedents but the social background against which he grew to manhood. Social security he evidently had. What he had inherited from his Northumberland artist ancestors might well have been creativeness, inventiveness, and energy. As to this last, we may well be astonished at the great amount of scientific work of quality which Victor Horsley so soon achieved. By the time he was 30 he was well known in Berlin; in another ten years he was a world figure.

Personal Qualities

It seems that Victor Horsley's teachers, and later his fellow students, quickly realized that they were in the company of a person quite exceptionally talented. He learned without effort, he had an exceptional memory, he was skilful with his ambidextrous hands, he had daring, he had energy, he had integrity—in short, he had from early days the qualities of leadership. He shone even in such intelligent company as that group who entered University College Hospital as students with him in 1875—Gotch, Mott, Beavor, Dawson Williams, C. J. Bond. He qualified M.R.C.S. in 1880, M.B., B.S. in 1881, when he was 24, winning the gold medal in surgery with a London University Scholarship. He was elected surgical registrar next year, and took rooms in Gower Street—as Stephen Paget reminds us, in those days the registrar was permitted private practice, though history does not say with what success. However, as Paget charmingly remarked, "Gower Street had been helpful to many young physicians and surgeons of the hospital by making them comfortable till they could make themselves eminent." He was appointed assistant professor of pathology in 1882; in 1883 he was admitted to the F.R.C.S., and the following year was appointed Director of the Brown Institution, where so much of his experimental work was to be done. Horsley became assistant surgeon to University College Hospital in 1885; five years later he was full surgeon, remaining so until he retired from the staff in 1906.

He continued his hospital work at the National Hospital, Queen Square, while he pursued his researches still at University College. He must also conduct his very considerable private practice, operating at what I am told was a singularly comfortable and efficient nursing-home, 9, Mandeville Place. This, in short, is the official story of his life in the barest of outlines, yet the synopsis does mention some things that we still wish to inquire into. What, for instance, was this Brown Institution, and what can have been the pressures or possibly the ambitions that made a man already internationally famous retire from one of London's premier teaching hospitals when he was only 49? He had been elected a Fellow of the Royal Society at the age of 29. By what means had he won the prestige that was so liberally allowed him in the world of science?

It is this story on which I particularly wish to dwell. His researches gradually came to show that the anatomical approach which a surgeon's training is traditionally based must have life breathed into it by physiology. No clinician has ever conducted experimental laboratory research with such energy and without serious interruption over so long a period of years. We shall most admire in him not only his tenacity but his unwillingness to be halted by the technical difficulties that almost all neurophysiological problems present.

The Brown Institution

An excellent short account of the history of this Institution has been given in Stephen Paget's *Life* (1919). The Institution no longer exists, having been destroyed in an air-raid in 1944 at a time when Dr. Twort, famous, like d'Herelle, for the discovery of bacteriophage, was its director—its last. The Institution was built by the University of London, which had accepted a bequest from a Mr. Thomas Brown, of Dublin. The objects were to study and attempt to cure maladies, distempers, and injuries of quadrupeds and birds. The University founded it with these ends in view, but, at the same time, with great wisdom and foresight made it a centre for advanced research in physiology and pathology. The names of its successive superintendents are a sufficient guarantee of the quality of the work done there—Burdon-Sanderson, Greenfield, Roy, Horsley, Sherrington, Rose Bradford, Brodie. Sherrington's own appointment came, as he once told me, like manna from heaven, because the small salary attached as well as the living quarters there allowed him to marry. But there was something more—this Institution was the only place in those days at which recovery experiments could be done on animals of any size, and this had widened Horsley's scope greatly.

It seemed odd to many—it drove anti-vivisectionists to fury—that this institution for the welfare of animals should be used for experiments upon them.

Victor Horsley's tenure of the professor-superintendentship (1884-1900) was signalized with his first experiments on the nervous system, on the thyroid and pituitary glands, on myxoedema and infections in animals, on rabies and hydrophobia. During this period he performed and reported his first group of brain operations at Queen Square (1887) and had recorded with Gowers a world-famous case—the first successful recognition and removal of a spinal-cord tumour (1888).

Early Researches—the Pituitary

The account of Horsley's thyroid researches given by Stephen Paget, which were links in the chain of the cachexia strumipriva and myxoedema stories, is so complete that we may usefully pay attention to something else—the other ductless gland that attracted him, the pituitary. In the paper which he wrote with Handelsmann in 1911, "A preliminary note on experimental investigations of the pituitary body," the following sentence appears concerning partial or complete removal of the gland: "The first to perform such experiments was Horsley in 1886, after whom a series of authors (about 20) repeated the experiments with results which were not uniform." In some investigations the animals succumbed soon after the operation, in others they survived for long periods. Reference was made to the work of Cushing and his collaborators leading to the establishment by them of the experimental condition known as cachexia hypophyseopriva. This clumsy title served a useful purpose by drawing a parallel between the effects of total loss of the pituitary and of the thyroid. Cushing concluded from his own experiments that the pituitary was absolutely and urgently necessary to life, animals dying in a state of lethargy and drowsiness, slow respiration, lowered temperature after three to five days in adult dogs, 10 to 30 in puppies. Horsley criticized this statement and brought in proof three animals—a cat, a dog, and a monkey—which "survived a long time" in spite of proved complete pituitary extirpations.

In 1911, Horsley and Handelsmann reported experiments on 24 animals (20 cats, 21 dogs, and 13 monkeys). Some of the survivors were shown at a meeting of the Physiological Society in March, 1911. The gland had been removed by either the temporal or palatal route, the latter only in the cat. Incidental damage to other intracranial structures was shown in about half the animals by hemiparesis, hemianopia, and, in monkeys, by temporary ipsilateral ophthalmoplegia. This last is a possible disadvantage of the temporal route: third-nerve palsy occurred, as we shall see, sometimes in his human pituitary operations. In 15 animals (2 cats, 9 dogs, and 4 monkeys) the gland was totally removed. In a few others some fragments remained, but, unlike Cushing, Horsley did not include those cases, and thereby missed making some useful observations on chronic hypopituitarism. One of their animals was killed on the 115th day, though in good health; one monkey survived to the 39th day. No important changes were observed in the other organs of the animals that died naturally. They "died of asthenia as animals in captivity do." He did not know that the cause of death might have been adrenal or polyglandular failure. Glycosuria occurred in two out of seven examples where it was specially looked for.

Horsley remarked that he had cut the pituitary stalk in some experiments without causing death. This important paper is sadly lacking in the details that we should like to know, and the figures quoted in one place do not always tally with others elsewhere. Nor is it clear how much of this publication was based on the old work of 1886 or the horizon enlarged by recent experiments. However, the promise was made that Handelsmann would publish all the data in detail, but, so far as can be discovered, he never did. Turning back to the 1886 papers, we find the abstracts of the Brown Institution lectures in the *Lancet* are very bare. Whilst he says that "the cause of myxoedema and cretinism had been shown by Horsley to be due to the loss of the thyroid gland," there is little else exciting except the statement that he had twice successfully removed the pituitary and that the animals had lived five and six months respectively. During life no nervous or other symptoms were noticed. The excitability of the cortex was found to be raised in hypophysectomized animals; and that reminds us that the monograph of the brothers Wenzel (1811) on the association between epilepsy and the pituitary gland was almost the only known "fact" about it 75 years ago.

It was not until 1895 that Oliver and Schäfer discovered the unexpected properties of posterior lobe extracts, and not until 1900 that Benda demonstrated the acidophil adenomatous basis of Marie's acromegaly (1886). What this amounts to, in brief, is that when Horsley was in 1886 experimenting on the pituitary gland he was assisting at the birth of endocrinology, but the endocrines and steroid chemistry lay too far ahead in time for him to be able to see much more clearly what the uses of pituitary were than Claude Bernard had done. Horsley established the fact that the gland could be removed and that rapid death was not necessarily the result. And in this conclusion Horsley has been fully supported by large-scale experimenters. Animals deprived of their pituitaries do not die in a few days; their expectation of life is reduced by about a half. No urgent disaster faces them; Cushing was wrong about that. It will be recalled that P. Bailey and Bremer eventually showed that many of the supposed sequels of the hypophysectomies of Cushing and his school were due to damage to the floor of the third ventricle.

Pituitary Tumours

This may be a convenient place to introduce the subject of Victor Horsley's operations upon pituitary adenomas. It has often been complained that he left no full account (which is true), though he is known to have given lectures about the pituitary and its surgery; for example, Sheffield, 1910. What he may have said is not to be discovered. However, it is now possible to get a sufficiently clear

picture. Four of his cases are given briefly by H. H. Tooth in his report on brain tumours to the 17th International Medical Congress (1913) in London. In 1906, at Toronto, Horsley mentioned 10 pituitaries operated on by him—the cream, however, is contained in Verga's monograph (1911), and I am most grateful to my old friend Dr. Ernest Sachs for directing my attention in this direction. This book from Pavia on the pathology of pituitary tumours contains copies of the notes either at the National Hospital, Queen Square, or from Horsley's private files. Here are to be found the records of 10 patients and references to two more; of these eight recovered and four died. One private case came from South Africa, one from Chicago. With the assistance of Mr. Julien Taylor and Mr. John Hankinson, registrars at Queen Square, who helped in searching through the old notes, some of these cases were found. It is possible, therefore, to reproduce a description of the operative steps from one of these. I referred to this particular case in a former publication (Jefferson, 1955), but at that time it could not be identified.

William Knapp, aged 45, admitted to Queen Square, under Dr. Risien Russell, notes by house-physician, Gordon Holmes, and by clinical clerk, Grainger Stewart. The patient complained of severe pain in the left face and of loss of sight in the left eye, which he was unable to open. Temporal hemianopia was present in the other eye. He had been in hospital before, but was sent home to return if the pain got worse. The first symptom two and a half years previously had been drooping of the left upper lid, which progressed during the next 15 months to closure of that eye. In 1903 he began to suffer from "giddy turns" in which his wife said he had a vacant look—probably minor epilepsy. He began to have pain in the whole left trigeminal area, severe and somewhat paroxysmal, and now upsetting the patient badly. No sensory changes were noted in the left trigeminal distribution. The third nerve was paralysed but the sixth was not. His sight had deteriorated so that he could no longer read. V.A.R. 6/36, V.A.L. nil; bilateral optic atrophy was present.

December 2, 1904.—Operation first stage—Sir Victor Horsley. A large semicircular scalp flap was made from slightly behind the left external orbital process to the base of the mastoid, convex upwards. There was not much bleeding. An area of bone was then removed from the left lateral surface of the skull by trephine, saw, and bone forceps. The dura was found to be tense, but was not incised. The patient stood the operation very well.

December 6, 1904.—Operation, second stage. The flap was turned down and the dura incised and finally cut away where it was exposed. The brain did not bulge to any great extent nor did the convolutions seem flattened. The brain was then slowly lifted up by retractors placed under the temporal lobe, pressure being only slowly exerted so that the brain could mould itself to its altered position. In this way it was soon possible to see into the region of the sella turcica. There was not much haemorrhage, but what there was was controlled by hot irrigation.

An attempt was then made to cut the sensory root of the fifth nerve, but in doing so the superior petrosal sinus was injured and had to be compressed. Attention was next directed to the pituitary body; the dura in the lateral surface of the sella turcica appeared bulged out, and it was then incised by a knife; some tumour mass at once protruded and the greater part of it was then scraped out with a sharp spoon; it came away in small pieces.

A small rhinoscopic mirror was then inserted into the sella turcica so that it might be seen if all the tumour was removed. The small amount of bleeding which followed the operation was easily checked by hot irrigation, and a gauze plug was finally inserted, which reached down to the sella turcica.

(Horsley spoke in 1906 of inserting sometimes this small laryngological mirror into the capsule, and said what an excellent view he got of the second and third nerves, of the crus cerebri, and of the cavernous sinus. With a good headlight he could see the interior of the sella well.)

The patient stood the operation very well. An hour later he was quite bright, said he was quite comfortable, and moved both right and left limbs freely. There was, however, slight paraphasia, the use of wrong words, and occasionally some difficulty in finding words to express himself. He was discharged home on January 12, 1905.

The operation evidently failed to cure this patient's pain, and in March, 1905, we find him back in hospital to be operated upon again, this time for the removal of his left Gasserian ganglion. The notes are very brief.

March 28, 1905.—The previous trephine opening being utilized, Sir Victor Horsley removed the ganglion in the usual way by Krause's method. The fold of the dura covering the ganglion was raised up and incised. The sensory root was drawn from the pons varolii and the ganglion dissected forwards and removed after the nerves had been cut. There was not much haemorrhage. The lids were sewn together at the close of the operation. He lived for eight years.

Horsley's Gasserectomies

This case gives a chance for a brief comment on Horsley's operations for trigeminal neuralgia. Morriston Davies (1907) wrote an admirable paper on the sensory changes in the face as studied in Horsley's 48 cases. By the time of Horsley's death he had probably done more gasserectomies than anyone else, and was well known to share with Krause the reputation of being quite exceptionally expert at it. Observing with what ease apparently, in the case of the patient Knapp, Horsley reversed Krause's method and pulled the sensory root off the pons before he cut the divisions, the reader must wonder why he was not content with the root avulsion alone—why it was left to Spiller to suggest this as not only enough but sufficient. And yet did not Horsley (Horsley, Taylor, and Coleman, 1891) propose and carry this out when he went through the tentorium and cut the nerve in the posterior fossa? The patient, a feeble old lady, died post-operatively. What a pity it was that the case had that end, for otherwise he might have developed a good technique. It must be confessed that without the help of electrocoagulation the transtentorial operation was beyond the resources of Horsley's time as a routine procedure.

Any neurosurgeon reading through the accounts of Horsley's operations to-day will recognize that the operator must have been extremely dextrous. Why—we may repeat a question that has often been asked—why did Horsley use the temporal approach to the pituitary rather than the frontal that everyone used after him? The answer can be guessed fairly accurately. The most important influence must have been his experimental work at the Brown Institution. In the dog and monkey the temporal route is the natural and easiest way in. Familiar with this approach in the animal, it would be natural for him to follow a path that he knew so well. Then there is something else. He had evidently had a nasty experience with the frontal route. It is mentioned in his Toronto Address in Surgery (1906). He said that in 1889 he had been asked to operate on a tumour pressing on the front of the optic chiasma. It proved to be a "cystic adenocarcinoma." In order to get access Horsley tied some of the frontal veins so that he could displace the hemisphere. After the death of the patient some years later it was found that considerable softening of the frontal lobe had occurred. I imagine that a good deal more softening than he knew followed Horsley's elevations of the temporal lobe, but he was careful not to ligate Labbé's vein.

The impression obtained from reading the operation notes reprinted by Verga and from Horsley's own comments on technique is that he was an extraordinarily gentle, skilful, and knowledgeable surgeon. Certainly the testimony of his surgical pupils is that he was unsurpassed. It was the speed of his operating that shocked Cushing, bred in Halsted's school.

Experimental Neurology

Horsley had two main collaborators in his neurological work—Charles Beevor and Richard H. Clarke. Important experimental work was carried out also with his sister's husband, Professor Francis Gotch, with Sir Felix Semon, and with A. E. Schäfer. Some he had done by himself. Eight papers were printed in the *Philosophical Transactions of the Royal Society* between 1886 and 1891. The last of these was the Croonian Lecture presented by himself and Gotch on "The Mammalian Nervous System, its functions, and their localization determined by an electrical method." This paper is 260 folio pages long, and has to do with the

galvanometric pick-up of impulses in the cord and nerves set going by either central or peripheral stimulation. To take one example, stimulation of the motor cortex gave rise to electrical effects chiefly in the opposite half of the spinal cord, a little on the same side. Would it not be a good critical test if the spinal cord was vertically split for two or three inches at its lower end into two halves so that the electrical changes could be more easily kept separate? Very well—it was done and the result confirmed (Fig. 1). Again the sciatic nerve was stimulated and electrical impulses were picked up in the spinal cord and traced by dividing different spinal tracts. The cord itself was stimulated and the resulting discharge followed along it. All this was pioneer work of the first order and a huge undertaking; the results were accurate within the mechanical error of the recording instruments then available. It remains to this day highly important work.

The experiments with Beevor were mainly refinements of the experiments which Ferrier had done on the motor cortex. There is no room for mention of more than three: (1) the exploration of the motor area on the medial surface of the brain; (2) the mapping of the excitable fibres in the crus cerebri and in the internal capsule both in the macaque monkey and in the orang outang; and (3) the plotting of the motor cortex on the latter animal (1890), the first time that a primate had been so investigated.

A description of the furrow formation in the orang is given and the motor points are recorded by a series of 27 photographs—an expensive method, but one leaving no topographical doubt in the reader's mind. Horsley was struck by the similarity of the results of stimulating the orang's brain with what he had already seen in the human being and with what W. W. Keen had reported in his case of cortical excision for epilepsy (1888). With Semon, Horsley sought the cortical motor innervation of the larynx. They went on to explore the floor of the fourth ventricle, a structure that had not been explored electrically previously to 1889, when Horsley had first done this. Sharp closure of the glottis invariably followed stimulation of the calamus scriptorius, but higher up abduction of the vocal cords was the rule (Fig. 2). In parenthesis, no observations on consciousness could be made because the animals were anaesthetized.

As Horsley grew older his experiments, as might be expected, grew in maturity of thought and presentation. We may single out the work he did with Colin Russel, Otto May, and Arthur MacNalty, and with his second great collaborator, Richard Clarke. This work had to do with the cerebellum and brain stem. Moruzzi (1950) has said that the discovery by Horsley and Lowenthal as well as by Sherrington, that stimulation of the anterior median cerebellar cortex inhibited decerebrate rigidity, equalled in its revelation of cerebellar function the discovery of the excitability of the motor cortex.

FIG. 1.—From *Philosophical Transactions of the Royal Society*, 1891.

We may pause a moment here to comment on the excellence of the illustrations in Horsley's papers. The photographs are of admirable quality; they were made by him and his groups at U.C.H. or else at his home, 25, Cavendish Square, in the evenings. Also in his papers with May and MacNalty we may well admire the operative dexterity which allowed him to make small cuts into the mid-brain after sliding in above the tentorium or excursions elsewhere with so many survivals.

The cerebellar discovery came about as part of the investigation of the relative significance of the cerebellar cortex and its deep nuclei, and the inquiry whether any efferent

FIG. 2.—Sites on floor of fourth ventricle for movements of the vocal cords. Semon and Horsley. (From *Philosophical Transactions of the Royal Society*, 1890.)

tracts left the cerebellar cortex to enter directly into the spinal cord or brain. Lesions of the cerebellar cortex were traced by Marchi's method; no such fibres were seen. On the other hand, it was difficult to damage the deep cerebellar nuclei in a precise way without injuring the cortex as well. It was to solve this particular technical problem that R. H. Clarke set to work to produce what came to be known as the Horsley-Clarke stereotaxic machine.

Richard Henry Clarke

And here we should say a few words about this remarkable man. Clarke, who was born in 1850 and was therefore the older of the two, had been at Cambridge and taken his M.B. at St. George's Hospital—in his day and later a medical school which received a disproportionately large number of Cambridge men. Clarke must have had private means; he never practised, but was well known as an expert all-round athlete—cricketer, golfer, first-class shot, fox-hunter, and judge of a horse. He may have been a shade hypochondriacal, because he spent, Dr. Sachs tells me, some years in Egypt curing himself of some chest trouble. All who knew him agree about his popularity and say that his gifts as a sportsman were signs of his extraordinary skills married to a first-class intelligence—in short, that he could do anything—so that if anyone could have invented an accurate piece of machinery Clarke would be just that man. He had demonstrated anatomy in Glasgow and physiology at St. George's (1885-7), then worked for many years with Horsley

in the laboratories at University College. It was there that the first square apparatus was finally completed and later a second oval version made.

The stereotaxic instrument is one of the most beautiful tools ever introduced into a physiological laboratory. These instruments were admirably described and illustrated in long papers in 1908 and 1912, and again in the Baltimore (1920) monograph that Clarke finally published with E. E. Henderson from the Laboratory of Pathological Chemistry, University College.

As Clarke said in 1920, without such help it was "impossible to expose the deep ganglia without serious mutilation, haemorrhage, and shock, which not only hinder the attainment of our object but rob it of much of its value when secured." The principles of the instrument are as simple as they are ingenious. Clarke realized that it would be hopeless to base measurements on the shape and external surfaces of the brain and skull. They were too variable. But if one took the equator and meridians as zero planes and measured the brain from inside out much greater accuracy should follow. The sites of deep nuclei and tracts were calibrated by comparison with slices of the brain of cat, dog, and rhesus monkey 2 mm. thick cut in a frame most efficiently designed to ensure complete accuracy. The serial photographs were published in the papers named. Most unfortunately the real results of their electrolytic lesions and deep stimulations were promised but not published. Descriptions of this revolutionary instrument being necessarily very lengthy, they absorbed all the available space.

Something new has, however, recently come to light, for has not Professor Robin Pilcher found in the Department of Surgery at University College Hospital a bound thick folio volume that contains details, including many photographs of the brain, from Horsley and Clarke's cerebellar experiments during 1906? It covers some 70 of the early electrolytic lesions and stimulation of cerebellar cortex and deep nuclei. There is a gap in the dates from May 4 to October 29, 1906, when a rhesus monkey's cerebellum was stimulated. In the right hand at the top of the paper is written in Horsley's hand, "First time of using new instrument and mode of record." It is probable that the new plotting of small squares in the animal's head was under trial before this date. Just now no further comment can be made than to say that most of the stimulations produced movement of the eyes or pupillary changes if they produced anything. One thing might be briefly singled out—stimulations of the posterior longitudinal bundle in the floor of the fourth ventricle. In a cat, on March 29, 1906, they observed twitches of the face and not only conjugate movements of the eyes usually to the same side but, further, sometimes movement of one eye alone and to the same side. This was very new indeed, a refinement on the experiments made with Semon in 1889 and already mentioned.

In Clarke's monograph written after Horsley was dead he permitted himself to make some very unflattering observations on brain surgery. He thought it mutilating and a most unsatisfactory pursuit. If Ferrier's estimate of 7% of cures was the best one could hope for, he would be a strange fellow, Clarke thought, who could call this a triumph of surgery. This acerbity is unhappily a sign of the estrangement that had grown finally between these life-long friends, naturally grieving the friends of both. Clarke had long been the adored friend of the Horsley children. His bearded face, his twinkling blue eyes, his humour, and his ghost stories captivated them. He had for years been the constant companion of the family.

Clarke claimed that really elegant results could be produced by his machine—he hoped that even brain tumours could be cured by electrical means or by the placement of radium. Besides this Clarke thought that it should be possible to relieve pain better than in any other way by coagulation of intracerebral tracts—all these things through a 5-mm. trephine hole. And he was sure that time would show that there were other ways in which the stereo-

taxic instrument could achieve results far in advance of anything then available. Time would show. Allowing for some very pardonable special pleading, Clarke was right and time has vindicated him. His was very real prevision.

Although it is only too clear that Horsley's part in the instrument's actual design was negligible, it was he who had conceived its necessity. It is not too much to say that Clarke would never have thought of stereotaxis had it not been for Victor Horsley's curiosity about the roof nuclei of the cerebellum and his dissatisfaction with the method which he and Clarke had had to use in 1905 and earlier to explore the intrinsic fibres of the cerebellum.

In his flattering but no doubt well-deserved obituary notice on Clarke, Sir G. R. Turner (1926) said, what many must have thought, that this modest man did not receive the credit for his many researches that he deserved. He had left behind a manuscript on the divisions of the cerebellum and their relation to function. It is unpublished still. Time, that proved him right in his foresight of the uses of stereotaxis, has done him much but perhaps not yet enough honour.

Fig. 3.—Photograph of a traumatic epileptic with the coronal sutures and the cerebral fissures drawn on the skull.

Fig. 4.—Sketch from the operation notes of same case as Fig. 3. Queen Square, 1886.

good marginal sketch from the operation notes shows the state of the traumatic epileptic (Figs. 3 and 4). The tumour from another case in the first series operated upon immediately after the Brighton Meeting, although grossly it looks benign, was proved to have been malignant when the patient succumbed four or five months later.

Victor Horsley as a Neurosurgeon

It should be very plain that no neurological surgeon has ever turned his hand to the practical therapeutics of nervous diseases so well prepared by laboratory experimental work. And none has, as yet, continued, as Horsley did all through his life, to spend so much time in devising and conducting new experiments.

The pleasure felt by Victor Horsley can well be imagined when in August, 1886, he took down to Brighton for the 54th Annual Meeting of the British Medical Association three patients recently operated upon by him. All were examples of Jacksonian epilepsy

Charcot, who was present at Brighton, congratulated Horsley, adding how clearly clinical experience was illuminating the doctrine of cerebral localization as arrived at by animal experiments. Hughlings Jackson, in a characteristically brilliant commentary, ventured that all epilepsies were due to small lesions could they but be found. He said further and most wisely that he felt sure that it was important to cut out more than the lesion "which produced fits by altering the portion of the brain in which it was seated." Horsley had in fact done exactly that. Fortified by his recently acquired familiarity with operations on the animal's brain, he did not hesitate from the first to excise portions of the human cortex. Many surgeons—and in those days remember that all were general surgeons—were encouraged by Horsley's novel human experiments to operate for epilepsy and to report successes after removing trephine disks and bone splinters from old cranial injuries or supposed injuries; they did not often open the dura. Few except W. W. Keen did what Horsley did.

Unfortunately Horsley, except in his famous Linacre Lecture, never reported the later results of his cortical excisions for epilepsy or athetosis. That he made a considerable number is certain. The Surgical Reports of University College Hospital lent me by Professor Pilcher show that in the years 1900-6 30 cases were operated upon—more would be done at Queen Square—yet we do not know how they fared. Horsley published his first 10 brain operations in 1887, and in 1888, with Gowers, the account of the first correct localization and removal of a spinal tumour, the patient recovering from paraplegia. Naturally this case caused a stir. Two major events in combined neurology and surgery had now occurred—the localization and display at operation of both a brain tumour (Hughes Bennett and Rickman Godlee, 1884) and now a spinal.

Brain Surgery

No time shall be lost in discussing the real priority of the first case.

I have already dealt with that matter in a discussion of Macewen's neurological surgery (Jefferson, 1950). It is only fair to allow Macewen to speak again now, taking his words from the discussion on brain surgery at the International Medical Congress (1913). Macewen said: "Mr. President, I believe it was somewhere in the 'seventies when you visited my clinic in the Glasgow Royal Infirmary and asked me three questions—whether I had ever diagnosed a lesion of the brain from the localization of symptoms alone, and, if so, if I had operated upon such a case and had found a lesion in the part where it was expected to be, and, thirdly, if any of those cases so operated upon had recovered, and I was able to answer each of those questions in the affirmative." The logic of this sequence is perfect. It is the story of brain surgery. What was better was that Macewen was perfectly correct in what he said. He proceeded to say that if he were asked what most needed development, it was the physiology of the brain apart from the motor area. How right he was! But in fact it was just these subjects which had been engrossing Victor Horsley in his laboratory for some years, and, latterly, increasingly so. Perhaps it was these preoccupations that prevented Horsley from giving what I imagine was expected of him—a full account of his own experience of brain tumours. Disappointingly, whatever he may have said, the published report is maddeningly brief.

Percy Sargent gave an account of his first 100 cases, with 14.5% recovery in non-comatose patients. Byrom Bramwell spoke of his 225 cases, 42 operated upon, Krause his 154 tumour operations; and von Eiselsberg analysed his 166 cases, including 16 pituitary tumours. He concluded by saying: "Sir Victor Horsley geprägt hat: 'Bei Hirntumoren nicht zu operieren ist inhuman.'" All that Horsley had to say in effect was that it was unnecessary to talk about technique to surgeons—haemorrhage was unimportant, for it was easily controllable, "if it were capillary hot water stopped it, if it were venous then oxygen

stopped it, and if it were arterial the judicious use of chloroform would suffice to lower the blood pressure and so put an end to the haemorrhage." Too simple? Maybe. But it is a physiologist speaking. And, interestingly enough, the modern tendency in neurosurgery is, by means of deliberate hypotension, to return again to the advantage of chloroform anaesthesia without most of its dangers. Horsley, like Macewen, made a demand on the future; what he thought was most needed was a proper understanding of the structure and histological types of brain tumours. That was to be Cushing's main and lifelong preoccupation for which he needed much help, notably, predominantly, from Percival Bailey.

Possibly Victor Horsley at that 1913 Congress thought that Howard H. Tooth's very complete analysis of 500 cases that had come under observation at Queen Square in the years 1902-11 inclusive made it unnecessary for him to make any large communication. Of the cases operated upon—and only half the number were—most had been attended to by Horsley, and the immediate mortality and the survival periods of the patients were recorded. Tooth's was a major work of the first class, and nothing comparable appeared again until W. B. Van Wagenen (1934) and then Hugh Cairns (1935) each analysed the results of the cases of a different single year in Harvey Cushing's service.

The two things which most impress the modern reader when reading through the Queen Square material are: first, the oversimplicity of the pathological diagnosis, and indeed the now patent error of much of it; and, second, the frequency of death from shock after what should have been a highly successful tumour removal. If Horsley had had blood transfusion and blood banks the cases would have had happier endings. Then there was the sad frequency of infection that was a killer. Its incidence was multiplied and became more agonizing still during the first world war. It was 30 years after the date of Tooth's paper that intracranial infection began to come under control. Another failure was the incorrect diagnosis, the mistakes in localization, chiefly in the case of frontal and cerebellar tumours. This difficulty that had serious results was not resolved for many years, and then only by mechanical diagnostic means, not by neurological refinements. Horsley (1906) pointed out the risks of an incorrectly placed attack. Of 79 cases with a correct diagnosis, the post-operative mortality was a little over 8%, but of 16 where the localization was wrong the mortality was 37%. Notwithstanding, many of Horsley's patients were alive and well seven and eight years afterwards.

Horsley had one bee in his bonnet—that papilloedema (Parsons's new name for optic neuritis) always first appeared on the same side as a tumour, and hence had great localizing value. Leslie Paton and Gordon Holmes failed to persuade him of his error. The rest of his work on the nature of papilloedema was first-rate; he was ahead of Hughlings Jackson and Gowers there, having at once accepted the mechanical theory of Manz and made excellent preparations of Schwalbe's sheath and its ampulla. He illustrated his papers with photographs, taken by himself, I suppose, with the German camera that Sir Arthur MacNalty tells us of. One other piece of surgical pathological work should not be overlooked. It was the experiments that he had carried out with Walter Spencer in 1891 on the mode of death in cerebral compression and its prevention. They for the first time used the mercury-filled bag to raise the pressure and noted the same effects on respiration and blood pressure that Harvey Cushing reported in his much more interestingly written paper. Cushing did not refer to the Spencer and Horsley paper in the *Philosophical Transactions of the Royal Society*, which is fully documented, but to a later popular version.

Mention has already been made of Victor Horsley's dexterity; it is impressively evident in the description of his survival experiments on animals. He had stimulated the fifth, seventh, ninth, eleventh, twelfth, and upper third cervical nerves in the monkey; working with Otto May,

it is mentioned that in three cases Horsley had cut the fibres of the hypoglossal nerve off its nucleus by slipping a knife under the tubercle of Rolando parallel with the floor of the fourth ventricle. The animals recovered. Little wonder that Sir William Osler (1919), reviewing the Paget *Life*, said that Horsley was the outstanding surgeon of his generation, that he had acquired a technique hitherto unequalled.

The Man

The work and writings of a man can be properly assessed by anyone whether he has been personally acquainted or not. But to speak of a personality from hearsay is dangerous and almost impertinent. That Victor Horsley was a giant amongst men I have no doubt at all. That he excited admiration and devotion in those who worked with him in their youth can be confirmed because several of them are still alive to testify. Outside his scientific work his reputation was in some directions less secure. Stephen Paget dealt with this with fine discrimination and honesty. Perhaps in his fifties his creativeness was at last on the wane. Stephen Paget quotes him as remarking without complaint that his mind did not "boil with ideas" the way it once did. But that was late. Until then his life had been a fury of research and practice, hospital and private; on top of all were his crusades, first and always the famous anti-alcohol affair, later against treating the suffragettes as criminals, and finally politics, medical and national. He was a Liberal, but nowadays would surely have been a Socialist.

It is not greatly to be wondered at that Harvey Cushing found little to admire and nothing to imitate in this great Englishman. Their lines of interest diverged too far. Horsley's preoccupation was in the intimate structure and physiology of the nervous system. Cushing's was not, it was more practical. Horsley grew up a young man in the company of the great founders of clinical neurology: Hughlings Jackson, David Ferrier, William Gowers, C. K. Mills, Spiller, and Weir Mitchell in America; Sherrington, Gotch, Schäfer were his contemporaries. Horsley could bring to bear operative skills that these men did not have, and so he came actively to explore functions—and that, be it remarked, when 99 out of 100 surgeons thought that anatomy was the only proper study for a practical man. Horsley's eye was on the future. The details of operative surgery Horsley thought important, but not important enough to deserve much publication. Cushing, on the other hand, was much more interested in the immediate present, in technical improvements in a field which was ripe, if mortality was to be reduced and the rate of cure raised, for a change in method. His great gifts were better canalized than Horsley's, but had he been more generous to the older man it would have been more seemly and more just.

Horsley never, it seems, worried overmuch about what people thought of him, nor about the collecting of honours. He had work to do, absorbing work. In 1906 he was in the full flood of his work with Clarke. It was because of this that he gave up his professorship and charge of beds at University College Hospital. He must have found the responsibility of the care of general surgical patients and the routine of student teaching too much an interference with what he really wished to do. Furthermore, the clinical work he really enjoyed was mainly at Queen Square, and he was in great demand as a consultant. In those days a successful London specialist had many long-distance calls. The country was rich, the number of people who could afford to summon the best opinion north, south, east, and west was considerable. Horsley's counsel was often sought on cases which turned out not to be surgical. This was regarded as quite dreadful by some of his medical neurological colleagues. It was, on the other hand, quite all right for them to see surgical cases; that was traditionally correct since Linacre's day, and put the surgeon in his proper place.

There is rarely unanimity as to the shape reforms should take even when their necessity is agreed. This showed up

in his work for the British Medical Association, into the affairs of which he threw himself with his accustomed vigour, and there his professional and scientific reputation gave great weight to his counsels. He was one of the founders of its new constitution, and Chairman of its Representative Body (1903-6). Muirhead Little in his *History of the British Medical Association* (1932) spoke of Horsley's radicalism tempered though it was by a strong belief in constitutional methods. But, he says, "whatever opinions he held, whether on experiments on animals, on total abstinence or medical reform, he held them very strongly, and it was difficult for him to realize that those who differed from him were actuated by as honourable motives as he was himself." Those who differed were ruffians, scoundrels; he did not mince words. The fact that Lloyd George turned to him for advice in drafting his Insurance Act did him great harm in the estimation of the more conservative members of our profession.

In his letters home after he had had time to look around as consulting surgeon to the Army in Mesopotamia, he wrote of the "drunken misdirection of our military affairs," of the "apathy and indifference of the whiskey drinkers." He was, he said, "trying to make the aged and incompetent realize that the British Soldier is a human being" (Paget, 1919, p. 305). Off he went to India to lay the state of medical affairs before the Viceroy, Lord Willingdon, and the Commander-in-Chief, who had already had disturbing reports and were now so impressed that inquiries and reforms were quickly set on foot. Nothing in Horsley's life does him greater credit than the tearing and characteristically unselfish energy of his work for the Army in the field in the last months of his life. It was superb. His disregard, his open contempt even, for bigwigs would have brought only derision had it not been for the force of his personality, his absolute integrity, and the passionate logic of his arguments.

There is a story, now traditional, that Horsley had an almost imbecile belief in the immunity of a total abstainer from heat or disease. It is time that that fable was destroyed. Dr. Anthony Feiling, who was a young medical officer in the hospital to which Horsley was admitted, there to die on July 16, 1916, has kindly given me his impressions of Horsley's last illness. It is true, he says, that he died of heatstroke, but the cause was an infection, probably paratyphoid, though that was never proved. The lack of proof was not very surprising, since their bacteriology was, Dr. Feiling says, by no means reliable. Nor did differentiation become so anywhere, I believe, until some years later. Horsley perhaps did not wear the regulation topee and spinal pad that was so wrongly supposed to prevent sunstroke. But Horsley did not die of sunstroke, but of heatstroke following an infection, the atmospheric temperature near Bagdad in July making body thermostasis difficult even for the young. His opposition to alcohol did not, by the way, prevent him, I am told by Sir Archibald Gray, from permitting his house-surgeons to give alcohol in emergencies to his patients at their discretion. It was a common constituent of the nutrient enema then in such use; Horsley's patients were not exempt.

It was perhaps not always easy to catch enough glimpses of nobility in this man's character. They were often obscured by the mantle of his "extracurricular" activities, in which he roused such passionate devotion or such dislike. Maybe he fished too much in troubled waters, but had he not followed his bent he would have denied his genetic inheritance. Time has shown, annoyingly for his opponents, that the causes to which he devoted his life were good causes—the creation of neurological surgery, the necessity for experiments on animals, temperance if not abstinence, universal women's suffrage, the liberalism of his political opinions, the need for some reforms in our profession, and Government provision of free treatment for the working-man. Such variety suggests a kaleidoscopically colourful personality and makes us feel pale and desiccated beside him. Violent in expression Victor Horsley might at times have been, but he was a fastidious man as well as generous and humorous too.

Well might he say now, "Praise me for virtues, excuse me for my faults, which were never mean."

I wish to acknowledge the help which has been generously given me by many people. My thanks are particularly due to Sir Victor's daughter Pamela (Mrs. Stanley Robinson), to Sir Arthur MacNalty, Dr. Ernest Sachs, Sir Archibald Gray, Professor Robin Pilcher, Mr. Morriston Davies, Dr. Anthony Feiling, Sir Gordon Holmes, Dr. Purdon Martin, Dr. Golla, Dr. Z. Mennell, and to Mr. Julien Taylor and Mr. John Hankinson, of Queen Square, who helped in the search for old case records. Lastly, my debt to Stephen Paget's biography of Sir Victor Horsley is immense.

SIR VICTOR HORSLEY: HIS LIFE AND WORK*

BY

Sir ARTHUR MacNALT, K.C.B., D.M.
F.R.C.P., F.R.C.S.

Fellow of University College, London

Victor Alexander Haden Horsley was born at No. 1, High Row, Kensington, on April 14, 1857. His father was John Callcott Horsley, R.A., a famous artist of his day; his mother Miss Rosamund Haden, sister of Sir Francis Seymour Haden, surgeon and etcher. Horsley's first two names were given him by Queen Victoria, and we note how appropriate they were. Victor, "a conqueror," and he was to conquer in the battle against disease; Alexander, "a helper of men," and he was to be a benefactor of mankind.

Early Days and Education

Horsley was educated at Cranbrook Grammar School, and became a medical student at University College in 1874. In October, 1875, he entered University College Hospital. It was a vintage year, for several of his fellow students achieved distinction in later life. Of these may be mentioned: Francis Gotch, later professor of physiology at Oxford, who married Rosamund Horsley and became Victor's brother-in-law; Sir Frederick Mott, physician and neuropathologist; Sir Dawson Williams.

*A Holme Lecture delivered at University College Hospital Medical School on October 28, 1955.

Editor of the *British Medical Journal*; Sidney Martin, physician and professor of pathology; C. E. Beevor, the neurologist; Bilton Pollard, surgeon; C. J. Bond, surgeon, of Leicester; and J. E. Hine, afterwards Bishop of Northern Rhodesia. Most of these men remained Horsley's lifelong friends.

At the hospital his chief teachers were: Ringer, Bastian, Russell Reynolds, Gowers, and Wilson Fox in medicine; and John Marshall, Marcus Beck, R. J. Godlee, and A. E. Barker in surgery. Sir Leander Starr Jameson, the future prime minister of Cape Colony, was demonstrator of anatomy and subsequently resident medical officer. Sir Victor told me that Jameson in those early days was somewhat reserved and aloof, but that all the residents in the hospital valued his advice. He worked and read assiduously, and his only relaxation was whist in the evenings. In later years this led on to bridge, which proved a link of friendship between him and his former foe, General Botha.

Very early in Horsley's hospital career his teachers and contemporaries realized that he was a genius and had a brilliant future before him. They admired, too, his forthrightness, his integrity, and his readiness to help others. "He shunned delights and lived laborious days," and already was a vigorous advocate of total abstinence from wine, spirits, and tobacco.

In 1878 Horsley was awarded the Filliter Exhibition in Pathological Anatomy. In November, 1880, he qualified M.R.C.S., and in December became house-surgeon to John Marshall. In 1881 he became M.B. and B.S. London, securing the gold medal in surgery with a university scholarship, and during 1882-4 was surgical registrar to the hospital. He made a series of observations of the action of anaesthetics on his own brain at this time. In November, 1882, he put up his plate at 129, Gower Street, where he shared rooms with his friend and future brother-in-law, Whitelegge, who as Sir Arthur Whitelegge, K.C.B., H.M. Chief Inspector of Factories, was to do so much to advance industrial hygiene and to safeguard the health of the industrial worker. Outstanding events of the year 1883 were that Horsley took his F.R.C.S., became engaged to Miss Eldred Bramwell, a daughter of Sir Frederick Bramwell, the engineer, and made a communication to the Physiological Society, "On four cases of injury of the brain, illustrating the position of the motor centres."

Myxoedema

Horsley was appointed professor-superintendent of the Brown Institution, 149, Wandsworth Road, London, S.W., in 1884, and held the post until 1890. The University of London in 1871 had established this institution as a centre for advanced physiological and pathological research as well as a veterinary hospital for study and treatment of the diseases and injuries of animals. It was the first of its kind and did most important and valuable work in medical research, as will be apparent from the list of its professor-superintendents—Burdon-Sanderson, Greenfield, Roy, Horsley, Sherrington, Rose Bradford, Brodie, and Twort. Its financial resources were meagre, and Horsley repeatedly showed in his annual reports how difficult it was to maintain the institution. To-day research workers aided by endowments, benefactors, and an enlightened Medical Research Council live in better times.

During Horsley's six years of office at the Brown Institution the following researches were done by him:

(1) the localization of function in the brain, and the pathology of epilepsy and of canine chorea. The work on localization is dealt with below. (2) The thyroid gland and myxoedema and cretinism. (3) The protective treatment against rabies.

In 1873 Sir William Gull in a brief paper, "On a cretinoid state supervening in adult life in women," gave the first description of myxoedema. Curling and Fagge had previously noted cases of sporadic cretinism in which the thyroid gland was "atrophied" or even "absent." In 1877 Dr. Ord described further cases and gave the disease the name "myxoedema," for post-mortem evidence showed the thickening of the subcutaneous tissues by excessive formation of a gelatinous or mucinoid substance. The thyroid gland was markedly diminished, but Ord did not appreciate the true significance of this. Endemic cretinism in the Swiss valleys was known to be associated with goitre, but the function of the thyroid gland was unknown.

Reverdin, of Geneva, and Kocher, of Berne, in 1882-3 had been treating goitre by surgical operation (removal of the thyroid gland). In certain of their cases myxoedema had developed. On November 23, 1883, the Clinical Society of London discussed a case of myxoedema, and Sir Felix Semon suggested that cretinism, myxoedema, and "cachexia strumipriva" (Kocher's name for the condition) were allied conditions due to absence or degeneration of the thyroid gland. On December 14 the Clinical Society appointed a committee of investigation. Ord was chairman, W. B. Hadden, honorary secretary, and Horsley one of the members. Horsley, using monkeys, began experimental work on the thyroid with Rickman Godlee in Professor Schäfer's laboratory in October, 1884, continuing it single-handed at the Brown Institution. Removal of the thyroid was followed by muscular tremors and then by symptoms of myxoedema. He was able to record some of these findings in two lectures on the thyroid gland, which he gave at the University of London in December. He extended and continued his experiments in 1885 and 1886. In 1888 the Investigation Committee of the Clinical Society published the Report on Myxoedema. Horsley's report argued for the identity of myxoedema, cretinism, and cachexia strumipriva, and proved that these conditions were due to destruction of the thyroid gland.

As a surgeon Horsley now applied the results which he had obtained in the laboratory. On February 8, 1890, he published in the *British Medical Journal* (p. 287) a "Note on a possible means of arresting the progress of myxoedema, cachexia strumipriva and allied diseases." Schiff and von Eiselsberg had tried transplantation of thyroid gland in thyroidectomized animals. Horsley transplanted the thyroid gland into patients suffering from myxoedema and showed the treatment was specific although not always successful. In 1891 he contributed a critical and historical review of the subject to Virchow's *Festschrift*. In this year came George Murray's hypodermic injection of thyroid gland (*British Medical Journal*, 1891, 2, 796). Murray was also a U.C.H. man and had been Horsley's pupil. In 1892 Hector Mackenzie showed that feeding the patient with fresh thyroid gland was equally beneficial. Stephen Paget observed truly that Horsley founded in this country the modern study of the thyroid gland, and was the first in this country to suggest the rational method of treatment of myxoedema. I may mention here that in 1905 or 1906

Horsley introduced me to Kocher, and I was in the operating theatre of U.C.H. when Horsley performed a thyroidectomy in Kocher's presence, after which Kocher removed the thyroid in a second patient.

Rabies

Horsley had hardly finished his experimental work on the thyroid gland when he was summoned to a fresh field of research. In 1886 the Local Government Board appointed a commission to inquire into Pasteur's method for the treatment of rabies. The members of the commission were Sir James Paget (chairman), Sir Lauder Brunton, Dr. George Fleming, Lord Lister, Sir Richard Quain, Sir Henry Roscoe, and Sir John Burdon-Sanderson, with Horsley as secretary with a remuneration of £50! Horsley was not only the author of the report, but the active investigator and moving spirit of the investigation both in Paris and in London. The Report of the Commission was published in June, 1887, and was presented by Pasteur on July 4 to a meeting of the Académie des Sciences. It states that Horsley's experiments, begun in May, 1886, "entirely confirm M. Pasteur's discovery of a method by which animals may be protected from the infection of rabies. . . . It would be difficult to over-estimate the importance of the discovery whether for its practical utility or for its application in general pathology."

Horsley also investigated a serious outbreak of rabies among the deer in Richmond Park in 1886-7, when no fewer than 264 deer died, and he had some of the animals under observation at the Brown Institution. In 1886 he examined and showed the non-efficacy of the "Buisson bath treatment" for the prevention and cure of hydrophobia.

Rabies was formerly a menace in Great Britain. In 1881 it was responsible for 34 deaths and in 1885 for 60 deaths in England and Wales. As a result of the action taken by the Local Government Board under the presidency of Mr. Walter Long in rigidly enforcing the Muzzling Order of 1896 with the enforcement of a six-months quarantine for any dog introduced into Britain from abroad, human rabies has disappeared from the Registrar-General's statistics. It was Pasteur who suggested this method to Horsley.

In 1886, in recognition of his experimental studies, Victor Horsley had been elected a Fellow of the Royal Society.

The Physiologist

To-day the lessons of neurophysiology and neurology, the anatomy of nerve centres and nerve fibres, the localization of a cerebral tumour or abscess, and the results of cerebral or spinal paralysis are so much a part of medical teaching and practice that it is difficult for us to realize that at the time when Horsley began his experimental work on the subject at University College much of the anatomy and physiology of the brain was unknown territory. More wonderful still, not a few of us are still alive who have walked and talked with the founders of British neurophysiology, "the first who ever burst into that silent sea."

Progress of knowledge of the nervous system has been indissolubly linked with the determination of function in it, since Bell and Magendie discovered the difference of function in the two spinal roots and Flourens delimited the respiratory centre in the bulb.

Broca in 1861, by clinical and post-mortem evidence, localized speech in the third frontal convolution. Hughlings Jackson and Bastian supplied further clinical and pathological evidence of cerebral localization. In 1870 Fritsch and Hitzig, using a weak galvanic current, were able to map out certain centres in the cerebral cortex for movements of the neck, the limbs, and the face. Then in 1873-5 came the original research by Ferrier, which, as Sherrington observed, ranks among the classics of experimental neurology and physiology. Using the faradic current at minimal strength, Ferrier localized many more centres of movement and also of certain acts of perception and

charted them precisely. The suggestion of this work came to Ferrier from that great pioneer in neurological research, Sir James Crichton-Browne, as both Sir David Ferrier and Sir James informed me.

In January, 1884, Horsley began with Professor Schäfer in the physiological department of University College a series of researches upon the brain of the monkey, with a view to testing and, if possible, extending the work of Ferrier and Yeo. This was continued for two and a half years, until July, 1886. For much of the time Horsley was also pursuing allied researches at the Brown Institution with Dr. Charles E. Beevor. It is only possible here to outline the results obtained. In experiments on the external surface Schäfer and Horsley confirmed Ferrier's results and added to them with a finer analysis of certain groups of movements. The work with Beevor was more specialized. Localization was studied in one species of monkey, not only at the level of the surface of the brain but at the level of the nerve fibres passing from the surface of the brain towards the spinal cord. Horsley and Beevor also made an intensive study of localization in the cerebral cortex of the orang-outang.

With Sir Felix Semon, Horsley studied and described the central motor innervation of the larynx. Semon (*Archives of Laryngology*, 1881) had noted that in cases of organic disease involving the motor nerves of the larynx the abductor muscles failed before the adductors; in cases of functional disease the adductors fail before the abductors. Ferrier had discovered the cortical centre for adduction, but Horsley and Semon defined it more exactly at the lower end of the ascending frontal convolution in the monkey. In contradistinction to the monkey and the dog they found abduction well represented in the cat, and also that abduction in all young animals had a much stronger cortical representation than adduction. "Thus, the central motor innervation of the larynx is adjusted not only for phonation, but also for respiration, and adapts itself, in each species of animal, to the change from early life to adult life."

In these localization experiments the area to be studied was mapped out into subdivisions of about 4 mm. square, and a very weak secondary current was employed to obviate the fallacy of diffusion. The investigators used electrodes 2 mm. apart. As in all Horsley's experimental work, the experiments were performed with strict antiseptic precautions. The wound, after being closely stitched, was dressed with antiseptic gauze, and this again overlaid and rendered firmly adherent to the scalp by a layer of thick collodion. All the operations were performed under anaesthesia, either chloroform or ether being used, and usually supplemented by hypodermic injection of one-half to one grain of the acetate of morphine.

These experiments advanced the knowledge of cerebral localization and are memorable. In certain points of anatomical detail regarding the localized areas, and, more especially, regarding the excitability of the post-central convolutions and the existence of intermediate inexcitable zones, these results have been corrected or modified by subsequent work, in particular, by the more exact studies of Sherrington and Grünbaum. Horsley's work marks a great step forward, and his genius and industry made plain paths of research for those who came after him.

In 1890 Horsley and Walter Spencer read a paper to the Royal Society "On the Changes produced in the Circulation and Respiration by Increase of the Intra-cranial Pressure or Tension." In 1891 Horsley and Francis Gotch gave the Croonian Lecture to the Royal Society "On the Mammalian Nervous System, its Functions and their Localisation determined by an Electrical Method." The full text occupies 250 pages of the *Transactions*. Much of the work was done by the brothers-in-law in the physiological laboratory at Oxford. They used a capillary electrometer, and studied the passage of nerve impulses not only between the cortex and the cord but between many other levels of the nervous system.

Horsley's fame was now international, as was shown by the great reception he received at the International Medical Congress in Berlin in August, 1890, when he demonstrated the chief results of his work in cerebral localization. "Dem gehört die Zukunft," "To him belongs the future," said his Teutonic admirers.

In addition, a vast amount of experimental work on the tracts of the spinal cord was carried out by Horsley either alone or in collaboration with other investigators. All his experimental work after 1896 was done in his small laboratory behind the old anatomical theatre at University College. It was a Mecca to neurologists from all parts of the world, who came to see him there and to discuss his findings—for instance, Hughlings Jackson, William Gowers, William Macewen, Harvey Cushing, and L. F. Barker. Any keen resident at U.C.H. or Queen Square was sure of an invitation to the laboratory. As already observed, Sir Victor had many collaborators. I can mention only a few additional names—Risien Russell, Sir Francis Teale, Sir Gordon Holmes, Page May, Donald Armour, Wilfred Harris, Colin K. Russel, Otto May, and Ernest Sachs. Dr. Charles Beevor remained a devoted disciple, and he and I spent many hours side by side at the laboratory bench cutting and examining microscopical sections for Sir Victor.

Work on the Cerebellum

Although Horsley made the whole of the central nervous system his province, in the closing years of his scientific researches he devoted chief attention to work on the cerebellum, principally with R. H. Clarke. With special apparatus, devised by Clarke, they were able to produce a minimal electrolytic lesion of a cerebellar nucleus without involving the cerebral cortex. This was the first use of electrolysis in experimental physiology. Horsley and Clarke concluded that the cerebellar cortex is practically inexcitable, but this has been disproved by subsequent investigation with the use of a stronger electrical current. I remember one experiment in which I slightly increased the strength of the current and detected a cerebellar response, but Horsley attributed this to diffusion of stimulation to the cerebral cortex. I had the privilege of assisting Horsley in his researches from October, 1904, until 1909. The results of certain of these researches were incorporated in a joint paper published in *Brain* in 1909, with the somewhat lengthy title of "Cervico-Spinal-Bulbar and Spino-Cerebellar Tracts and On the Question of Topographical Representation in the Cerebellum."

So far as possible, Sir Victor set aside Thursday afternoons and Saturday mornings for experimental work. He sat at one end of the experimental table, arrayed in a long white coat and wearing a head mirror, which directed reflected light on to the exposed brain of the animal. Opposite him sat the anaesthetist, while I usually wrote notes from Sir Victor's dictation. Apart from these stated hours, at odd moments Sir Victor would appear in the laboratory, often in the early morning, and cut sections for about half an hour. I think the mere mechanical work of using the microtome rested him. At such times he would talk to one on all sorts of subjects, and at intervals whistle tunes out of the Gilbert and Sullivan operas.

At No. 25, Cavendish Square, the large skylighted room at the back of the ground floor was Sir Victor's workshop. It had been built as an anatomical theatre in the days when surgeons held private classes in anatomy, and Horsley said it was taken by R. L. Stevenson for his description of Dr. Jekyll's chemical laboratory in *The Strange Case of Dr. Jekyll and Mr. Hyde*, with which, indeed, it closely corresponded. Here in any spare time Horsley worked with tools, microscope, and camera, dissecting, cutting sections, photographing and developing, making drawings and diagrams. I went with him to purchase an excellent and costly apparatus for photomicrography (Zeiss); and we spent many Sunday afternoons and evenings in the workshop together taking photomicrographs, developing them, and trying the effect of different coloured solutions to act as filters for the light from a strong electric arc. Shelves lined

the walls of the workshop; they were stacked with lecture diagrams, photographs and negatives, lantern slides, trays of microscopical slides, and notes and papers. These last were the result of work which can never be put on record, for the master interpreter is gone. As Wilfred Trotter wrote (*British Journal of Surgery*, October, 1916): "Horsley was always more interested in the carrying out of his researches than in the record of them." He also looked forward to a period of leisure in which to garner up the fruit of past researches, but this was never granted to him.

It has been possible here to mention only the salient facts of Horsley's researches; to describe them fully and to indicate their material contribution to our knowledge of the anatomy, physiology, and pathology of the central nervous system would demand several volumes; furthermore, many of the publications under other names that issued from Horsley's laboratory represent investigations initiated and directed by him. Sir Victor Horsley was remarkable as a practising surgeon in London who maintained interest in pure scientific investigation in days when professional and other duties encroached considerably on his scanty leisure. His amount of scientific output in those precious hours snatched from other work would have amply sufficed for the whole time of many a research professor of physiology. Only a man of Sir Victor's exceptional enthusiasm and energy could have done it.

The Pathologist

Victor Horsley clerked for Dr. H. Charlton Bastian, one of the founders of our present knowledge of the diseases of the central nervous system. In 1880, while still a medical student, he published his first paper in *Brain* with Bastian on "Arrest of development in the left upper limb, in association with an extremely small right ascending parietal convolution." He also made two of the drawings for Bastian's book, *The Brain as an Organ of Mind*, published in 1880. At the same time he was working with F. W. Mott on bacteriology. In 1882 these two great sons of U.C.H. published their results in a paper in the *Journal of Physiology*, entitled: "On the existence of bacteria, or their antecedents in healthy tissues," then a controversial subject. Horsley was early associated with the research work of the Local Government Board, and in 1881 his paper "On Septic Bacteria and their Physiological Relations" appeared as an appendix to the 11th Annual Report of the Board. He wrote the articles on "Bacilli" and "Zyme" in Quain's *Dictionary of Medicine*, and also did work on the transplantation of tumours from man to animals, a subject of much interest to-day.

Thus early distinguished as a pathologist, Horsley was made assistant professor of pathology at University College in 1882, and in 1893 succeeded Bastian as professor. He rearranged the department for research work in pathology and bacteriology, with a subdepartment of pathological chemistry for Dr. Vaughan Harley. Under Horsley's direction the department became a definite and well-known centre for research in experimental pathology. As Dr. Charles Bolton, one of his pupils, observed: "He did not teach from the examination point of view in the very least; but his aim was to give an account of the processes of disease as ascertained by experimental inquiry; and he illustrated all his statements of fact by experiments on every possible occasion." He published excellent reports, and with Rubert Boyce, the assistant professor, he set the high standard of the department which has ever since been maintained. In January, 1893, Horsley and Boyce published in the *British Medical Journal* (p. 111) their "Preliminary Report on Oedema," which showed how complex was the condition—no mere oozing of blood serum into the tissues under mechanical conditions of pressure, but a result of actions and interactions of living tissues.

Owing to increasing pressure of work, in 1896 Horsley resigned the professorship and was succeeded by Dr. Sidney Martin. In the three years in which Horsley had held the chair he had accomplished great things, but it cost him more than it paid him, and the department, to fulfil his

aims, had to be run at a financial loss. He retained his private laboratory at University College under the aegis of the new department of chemical pathology. He was always ready to give advice to his colleagues and research students on pathological problems, and when the Medical School separated from the College a special "Department of Experimental Neurology" was instituted for him, a convention to link him with the College and to enable him to retain his laboratory.

The Surgeon

Horsley was soon known to the medical profession and the world at large as "the brain surgeon," and it was his experimental work on cerebral localization which led to his appointment at the National Hospital, Queen Square. Further, it was the fruit of these researches which he applied to the diagnosis of tumours of the brain and spinal cord, and which enabled him so quickly to evolve his masterly operative technique in cerebral and spinal surgery. He often regretted that the law prohibited students from learning their operative surgery on anaesthetized animals. He naturally saw and operated on many cases of thyroid disease. He did not restrict himself entirely to his special field. He had general surgical cases in his wards at University College Hospital. These he usually handed over to his assistant surgeon, but in private he did general as well as neurosurgery, "to keep my hand in," as he would remark. He was an assistant surgeon to University College Hospital from 1885 to 1893; a "full surgeon" from 1893 to 1900; and a "surgeon in charge of hospital beds" from 1900 to 1906; he then retired and was made a consulting surgeon.

Primitive man trephined. Horsley lectured in 1887 on "Brain-surgery in the Stone Age." Ambroise Paré operated on wounds of the head and laid down rules for their treatment. But the brain could not successfully be touched by the surgeon's scalpel until anaesthetics and antiseptic surgery were discovered and cerebral diagnosis was possible.

William Macewen, of Glasgow, operated on an abscess in the left temporo-sphenoidal lobe in 1881, but it had already infected the lateral ventricle and the patient died. The first successful operation in this country for temporo-sphenoidal abscess was by Arthur Barker, surgeon to University College Hospital, in 1886. The first operation for cerebral tumour in this country was performed by Sir Rickman Godlee, Lister's nephew, in University College Hospital in 1884. The diagnosis had been made by Dr. Hughes Bennett and was confirmed at the operation, the tumour being successfully removed. Lister and Hughlings Jackson were present at the operation. Unfortunately, septic complications occurred from which the patient died. Horsley practised antiseptic surgery and relied on perchloride of mercury rather than carbolic to prevent wound infection. He gave particular care to the anaesthesia of his brain cases. To stop bleeding from the cut edge of the bone he used his antiseptic wax. In operating he was bold and resolute, and his scalpel grazed the springs of life, the recesses of the brain where no other surgeon had dared to explore. At the same time his superb self-confidence never led him into rashness. On the historic occasion, June 9, 1887, when he removed an intradural tumour from the spinal cord (the first operation of its kind), the tumour was small and higher up in the spinal cord than had been diagnosed. Horsley hesitated at first to extend his incision, and did so only at the urgent request of Sir Charles Ballance, who was assisting him. The patient made an excellent recovery and died from another cause twenty years later.

At University College Hospital and at Queen Square Horsley soon had a lengthy list of successful operations for cerebral tumour and Jacksonian epilepsy, ranging from improvement to complete recovery. All the time he was pursuing his researches at the Brown Institution and at University College on the central nervous system, and made many experiments on epilepsy. He also studied "the

accurate use of such lines and angles of measurement as give the relations between the surface of the skull and the surface of the brain, and enable the surgeon to visualize the motor area of the brain in its exact position under the skull" (*International Journal of Medical Sciences*, April, 1887). This had never been done previously, and was a valuable guide for the cerebral surgeon. He found time also for researches in archaeology and anthropology, and lectured on his discoveries in this new field at the Royal Institution and the Anthropological Institute.

Private Practice

Horsley married Miss Bramwell at St. Margaret's, Westminster, on October 4, 1887. They lived at 80, Park Street, Grosvenor Square, where Victor Horsley already had a large and increasing private practice. Not only were head and spinal cases sent to him, or he was asked to see them in consultation all over the United Kingdom, but he often had to diagnose cases of obscure nervous disease, such as myasthenia gravis and progressive muscular atrophy, and to refer them to the neurologist. His name became one to conjure with. He gave equal care to his hospital as to his private patients, and as one of them in Queen Square said: "I do believe if one of us were to die, and Sir Victor got him within half an hour, he could bring him to life again."

From 1892 onwards No. 25, Cavendish Square, was the Horsleys' home. As pressure of work increased with growing fame—he was knighted in 1902—he devoted less time to ward work at his hospital and clinical teaching. This meant increased responsibility for his house-surgeons, but he chose them wisely and trusted them. In my day Sir Archibald Gray and Sir Thomas Lewis, for example, held that coveted post. Another former house-surgeon, Dr. Wigmans, said of Sir Victor: "I never knew one who was more careful to lessen suffering and to avoid causing pain. His dressers were soon taught that the dressings had to be soaked until they came away of themselves; or they got a sharp telling-off. To his patients he was kindness itself; and for those who went to him for advice there was always full and careful help in every way possible."

In private he was assisted by Mr. Rupert Bucknall, assistant surgeon, and later by Wilfred Trotter, already in those days bearing the stamp of greatness. As a rule, Horsley liked to do his first dressings of head wounds himself. Sir Archibald Gray often gave anaesthetics for him in private work.

Because Sir Victor had little time for teaching, some have doubted his ability as a lecturer. In reality he was a great teacher. I well remember his lucid exposition of the diagnosis of cerebral tumours in a clinical lecture he gave in University College Hospital. Writing scientific papers was always a burden to him. His communications were often brief to the extent of curtness. He was an excellent critic of other men's writings. In a paper I drafted for him he struck out five pages of historical introduction, saying truly that if the references alone were given they could be looked up.

His surgery went hand-in-hand with research. In 1893 he made a long series of experiments on the effect of bullet wounds in the brain which showed that the immediate cause of death in such cases is failure of the respiration, not of the heart. In 1906 his address on surgery at the Toronto meeting of the British Medical Association surveyed the whole field of cerebral surgery, and is regarded as one of his most important contributions to the subject.

Horsley had a curious contempt for the surgical technique of which he was so masterly an exponent. He would throw back his head and laugh, saying: "Anyone can be a surgeon; it is only a question of mechanical skill easily acquired." Watching him, for example, removing a cerebellar tumour, how his deft and steady hands refuted this statement. He made up his mind that he would not operate after 60 years of age, which he regarded as the limit of the surgeon's active life.

Sir Victor devoted particular attention to the subject of anaesthesia. He served on a committee of the British Medical Association to study chloroform anaesthesia with Waller, Sherrington, Vernon Harcourt, and Dudley Buxton. Horsley concluded that the percentage of chloroform vapour ought to be exactly controlled, and liked to have the Vernon Harcourt inhaler used in his operations. Other surgeons objected to the time it took to get the patient anaesthetized. I remember once beginning an anaesthetic for Trotter with this inhaler. He pointed to a lint mask and dropping-bottle beside me. "I think this would be a more expeditious method," he observed.

Horsley was a very rapid operator, in contradistinction to Harvey Cushing, who was a most deliberate one. In J. Fulton's *Harvey Cushing* an account is given of Horsley showing Cushing how to operate on the Gasserian ganglion in 1900. "Horsley dashed upstairs, had his patient under ether in five minutes, and was operating fifteen minutes after he entered the house; made a great hole in the woman's skull, pushed up the temporal lobe—blood everywhere—gauze packed into the middle fossa, the ganglion cut, the wound closed, and he was out of the house less than an hour after he had entered it." Such rapidity did not appeal to Cushing, yet Horsley obtained excellent results. Modern methods of cerebral surgery are different, but the successors of Horsley—Harvey Cushing, Hugh Cairns, and Geoffrey Jefferson—have acknowledged their debt to Horsley's pioneer work.

The Medical and Social Reformer

After becoming the greatest of all cranial surgeons, Horsley found himself impelled to sociological and political work in the years preceding the first world war. He strove to serve his profession and womanhood and childhood above all. When the Medical Defence Union was threatened with failure he became its president and threw himself heart and soul into its work. He attended every council and executive meeting, and gave many other hours of his valuable time to its service, making it a bulwark of defence for doctors exposed to attacks from unscrupulous people.

Throughout his professional life Horsley worked hard for the British Medical Association. "He wrote in its Journal, took a chief part in its Annual Meetings, was one of the founders of its new constitution, served on its Council and Committees, was Chairman of its Representative Meetings, and Chairman of the Marylebone Division of its Metropolitan Counties Branch." He strove to make the Association the one great power between the State and the medical profession, a power in which the doctors would be united to defend themselves against injustice, to provide a complete service for the nation, and to obtain proper rates of remuneration for their work. He led the way in forming the policy of the Association in regard to reform of Coroners' Laws and death registration, medical inspection and treatment of schoolchildren, the constitution of a future Ministry of Health, State registration of nurses, and suppression of unqualified practice and quack advertisements. He saw the advantages of the National Insurance Act, that it would give better service for the insured and more favourable conditions for the general practitioner. This excited unjust opposition from those whom he was trying to help. But he took praise and blame with equal serenity, except that he expressed his appreciation of his true friends' sympathy and concern in the bitter attacks made upon him.

Sir Victor served as a direct representative on the General Medical Council from 1897 for nearly ten years, and took an active and useful part in its work.

A campaign in which he was much maligned was his crusade against alcohol. Those were the days when 90% of the injuries admitted on Saturday nights to hospitals might be attributed to drink. Like Benjamin Ward Richardson, it was on scientific grounds that Horsley became a temperance reformer. He was a vice-president of the National Temperance League and president of the British

Medical Temperance Association. As he said in his Lees and Raper Memorial Lecture on "The Effect of Alcohol on the Human Brain," the practical argument for total abstinence is based on the irrefutable proof derived from physiological investigation. In 1907 he and Dr. Mary Sturge published their book, *Alcohol and the Human Body*, which is a great store of medical and scientific evidence on the subject. He gave numerous lectures and addresses in support of temperance, and he attacked the issue of the rum ration in the first world war. He opposed tobacco smoking both on medical and on aesthetic grounds.

Sir Victor gave a number of brotherhood addresses to a non-sectarian group which arose in the Free Churches. Many a Sunday afternoon was devoted to these talks. "There is something of the spirit of Kingsley in them, and of Ruskin," wrote Stephen Paget. They covered a wide field—Christian ethics and unity, public health and sociology.

He was a strong advocate in the cause of female suffrage, and Lady Horsley and he worked hard together to this end. He scathingly criticized the Temporary Discharge of Prisoners Act, the "Cat and Mouse" Act, and denounced the forcible feeding of the militant suffragettes. He foresaw a splendid future for the emancipation of women, but he only saw the Promised Land from afar.

Sir Victor felt so keenly upon these questions of medical and social reform that he desired to enter Parliament as a Liberal in order to extend his service to mankind.

In 1910 he contested the University of London seat and was defeated by his former tutor, Sir Philip Magnus, the Unionist candidate. In June, 1911, he was adopted by the North Islington Liberal and Radical Association; and during 1911-12 did much work in the constituency, as well as speaking on behalf of Liberal candidates elsewhere. From 1910 onwards politics claimed much of his time. In 1912 he resigned his candidature for North Islington, and in January, 1913, was adopted instead by the Liberal Council of the Market Harborough Division. His outspoken views, especially on female suffrage, frightened the Executive Committee, and in November he resigned. Between January, 1914, and May, 1915, he was "approached" on behalf of four constituencies, and, finally, the Huddersfield Liberals were about to adopt him as their candidate.

Many of Horsley's scientific friends regretted his absorption in political warfare when he still had so much to teach mankind in cerebral physiology and other branches of knowledge. They shrank from seeing his motives misjudged, his words misinterpreted, and himself exposed to the hurly-burly of the market-place. His advocacy of National Health Insurance and of female suffrage lost him friends and patients. In those later years his practice fell off, as William Harvey's did when he discovered the circulation of the blood. Horsley made sacrifices of time, leisure, and money for the betterment of mankind. But he could do no other. He was "a bonny fighter" in any cause he believed to be a righteous one. Whether, if elected to Parliament, he would have held high office is doubtful, for he was no trimmer. He detested the *via media*. Compromise was hateful to him, and he always said straight out what he thought. Worthy of Cabinet rank, a government might have been afraid of giving it to him. But he would have made his mark in the Councils of the Nation at Westminster.

The Last Crusade

Sir Victor as a boy had wished to be a soldier, and for many years was a devoted member of the Artists' Corps. He nevertheless hated the wastefulness and folly of war, but when war came in 1914 he put everything aside so that he could render service in the national cause. He had been a captain in the Territorial Force since 1910, and was on the staff of the 3rd London Hospital, where he immediately began work. His great longing was for active service overseas, where there would be scope for his cerebral surgery, and where he could do so much for the sick and wounded. His two sons, Siward and Oswald, were in the Territorials, and afterwards received commissions in the Gordon Highlanders. He besieged the War Office with

appeals for employment, and at length, early in 1915, he was appointed in charge of the Surgical Division of the 21st General Hospital. Pending this hospital's organization, for six weeks he was surgeon to the British Hospital established at Wimereux by Sir Henry and Lady Norman. In May Sir Victor was gazetted Major R.A.M.C.(T.), and on May 20, 1915, he left Southampton with the staff and nursing staff of the 21st General Hospital for Egypt, the hospital being located at Alexandria. Nothing was ready, and, as Horsley wrote: "We shall be frantically busy licking into shape the rotten old barracks which has been handed over to us to convert into a hospital. The Israelites in Egypt were not in it *re* making bricks." On July 14 he was appointed consultant to the Mediterranean Expeditionary Force with the rank of full Colonel, A.M.S. He was in Egypt from June, 1915, to March, 1916. In August, 1915, Lady Horsley joined him, and later their daughter Pamela (Mrs. Stanley Robinson). In October Horsley visited Mudros and Gallipoli, inspected field ambulances and casualty clearing stations, as well as dressing-posts in the trenches and firing-line, and reported on medical conditions. In Egypt, after operating and visiting patients all day, he would work through the hot evenings writing letters and notes of his cases.

There was much public concern about the inefficiency of the medical arrangements in Mesopotamia, and, when Horsley volunteered for the campaign, the authorities were only too glad to have a surgeon of his eminence and standing to report on the matter. He reached Bombay on March 25, 1916, and visited Delhi and Simla: he left Bombay on April 9 and reached Basra on April 16. Here again he worked indefatigably under a hot tropical sun, operating on head injuries, investigating the medical conditions, and collating and preparing notes for his report which he intended to write in India.

Colleagues who worked with Sir Victor at Amara—the late Professor Grey Turner, Sir Zachary Cope, and Dr. Feiling—have told me that he worked too hard for a man of his age in a hot climate. He was frequently urged to curb his extraordinary energy and not to put too severe a strain upon his physical capacity. But to Horsley the work was all, the man nothing.

Sir Victor was working on July 14, when the shade temperature was over 110° F. (43.3° C.), and his last call was on a sick officer whom he knew. On the 15th he became ill and was moved to No. 2 British General Hospital. On July 16 his temperature rose rapidly, he became unconscious, and died of heat-stroke that evening.

Palms were laid on his grave. Later, a cross of white marble was placed over it. He had fought the good fight, he had finished his course, and so Mr. Valiant-for-Truth "passed over and all the trumpets sounded for him on the other side."

I am indebted to the late Mr. Stephen Paget, the author, and to Messrs. Constable and Company, Limited, the publishers, for permission to use certain material in the preparation of this lecture contained in *Sir Victor Horsley: A Study of His Life and Work*, Stephen Paget, London, 1919.

A short pamphlet entitled "The Doctor and his Patients, the Parish Priest and his People" has been published by the Guild of St. Raphael. The Guild consists of clerical and lay members of the Anglican Communion who are anxious to "restore the Ministry of Healing as part of the normal functions of the Church." The pamphlet discusses "the Christian view of Medicine, the Church's Ministry to the Sick, and the practical issues that stem from these considerations." The practical issues include the ways in which doctors and priests can co-operate to provide "a service to the sick which will be truly adequate to all their needs." Three doctors and three priests have jointly written the pamphlet, which is obtainable from the Guild of St. Raphael, 77, Kinnerton Street, London, S.W.1, price 6d., post free.

REMINISCENCES OF AN AMERICAN STUDENT

BY

ERNEST SACHS, M.D., F.A.C.S., F.I.C.S. (Hon.)

It is a great pleasure as well as a very great privilege to have this opportunity to pay tribute to Sir Victor Horsley. Unquestionably he was the father of neurological surgery, for, although sporadic attempts at brain surgery had been made before him, he was the first man to devote himself exclusively to this work.

It is my good fortune to have received my training with him. In 1907 no one in the United States was doing this work. While I was a student at Johns Hopkins, Harvey Cushing was just beginning his first efforts in neurological surgery, but the only place to obtain training was with Sir Victor. I applied to him and was given an opportunity to work in his laboratory in University College. He immediately took me under his wing and very promptly gave me every opportunity to learn his methods and follow his work from every angle. He withheld nothing and gave me most generously of his time. He treated me like a son in his home, and Lady Horsley was equally cordial.

Horsley at Work

I had been trained in surgery under Dr. Halsted at Johns Hopkins and was thoroughly imbued with the methods he taught; therefore it was something of a shock when I first saw Sir Victor operate. He practised antiseptic surgery while I had been trained in aseptic surgery. He worked under a stream of antiseptic solution with which the wound was constantly irrigated by an assistant. His opening of the skull was crude. He always sacrificed his bone flap, but I soon learned that this was unimportant, and that what really counted was his superb knowledge of anatomy and physiology. As soon as the brain was exposed, his handling of the tissues was exquisite and very delicate, and his knowledge of brain anatomy with all its possible variations was outstanding. I recall one occasion when he exposed the occipital lobe and remarked he would make an incision, avoiding Genari's streak. I doubt whether there are many neurosurgeons to-day who know their brain anatomy so thoroughly that they could do that.

Sir Victor spent every afternoon in his laboratory, and the only time I ever knew him to give up that session was when he had an opportunity to deliver an address on the subject of alcohol. He was an uncompromising teetotaler, and I have seen an audience spellbound by his wonderfully well documented discussion of the harmful effects of alcohol. He was convinced of this, and I frequently heard him say that no one could have heat-stroke who did not take alcohol. It is, of course, well known that this conviction of his was responsible for his death from heat-stroke while serving with the troops in the first expedition in Mesopotamia. A medical officer who was with him told me that Sir Victor absolutely refused to wear the helmet or spine pad required of all personnel, and as a result died of a heat-stroke.

Sir Victor was in his element when he was with a group of physiologists. I recall a meeting of the Physiological Society at which were Sherrington, Bayliss, Starling, Page May, and Gotch. Someone brought in a chicken that was ataxic, and Horsley, who with Clarke had just completed his experimental work on the cerebellum, upheld the thesis that the attacks were cerebellar in origin. There was considerable animated discussion and some difference of opinion. What the final outcome was I never learned, but the way Sir Victor stood his ground I shall never forget.

Animal Experiments

Sir Victor was much interested in comparative anatomy and would go to any lengths in order to obtain the brain of some unusual animal. When a walrus died at the Zoological Gardens, the first time in years, he gave up all his consultations that morning in order to take out the brain. When I remarked about this, he said: "If people want me to learn they must be willing to wait." Whenever any of his former students went to the Tropics or Far East he urged them to send him brains of wild animals. One day while I was with him a huge barrel arrived from India. In it, packed in salt, was an elephant's head. One of his former assistants had taken with him on an elephant hunt formaldehyde and injection bottles to inject the carotids after decapitating the animal. The specimen was accompanied by a letter and photographs showing the natives standing around gaping while this performance was going on. Sir Victor got a great thrill from these pictures and immediately took out the brain. In this way he collected a large amount of material and had innumerable photographs of various brains. These he photographed himself in his laboratory in his home in Cavendish Square, but, so far as I have heard, none of this material has ever been worked up or published.

Sir Victor was one of the most prominent vivisectionists at that period; consequently when Parliament was reviewing the laws about vivisection he was one of the important witnesses. A disgruntled former laboratory boy testified before the commission that he had seen Sir Victor pull the heads off living cats. The next day, when Sir Victor appeared in the laboratory, he told the laboratory assistant to bring up a cat, killed it with chloroform, and then told the boy and me to pull at one end of the cat while he pulled at the other. Of course we all knew nothing would happen, but Sir Victor

had to have positive proof before he would testify before the commission. The episode illustrates one of his fundamental characteristics—every statement he made had to be backed up by incontrovertible evidence.

Wide Interests

In the autumn he always rented a place for the shooting rights and went at the shooting as strenuously and enthusiastically as he did everything else. But the first thing he did when he rented a new place was to familiarize himself with the surrounding country. By the time I went down for my Christmas holiday he took me around in his high-powered Daimler, which he loved to drive, and showed me an interesting chancel in one church, a beautiful rose window in another, and a Roman ruin in another place. His interest in art he came by quite naturally, for his father had been a Royal Academician and his uncle was the famous etcher Sir Francis Seymour Haden.

Of Sir Victor's many admirable qualities, not the least was his generosity towards his younger colleagues. Of this I had striking proof. When I had completed the research I had been carrying on in his laboratory, I presented him with the manuscript and, naturally, had put his name and mine on the title-page. He crossed out his name, with the remark: "As long as it is customary, when two men publish a paper, to give credit to the one who is better known, I shall not allow my name to appear." No amount of persuasion could make him change this decision.

As I look back upon the years I spent with Victor Horsley, I feel he gave me the best possible insight into the life of a broadminded, generous scientist of his generation.

He will always be remembered as one of the great figures in medicine.

GLUCOSE TOLERANCE IN PERIODIC PARALYSIS

BY

G. A. MacGREGOR, M.D., M.R.C.P.

Hypokalaemia and muscular paralysis were first associated clinically in patients with familial periodic paralysis (Biernond and Daniels, 1934; Aitken *et al.*, 1937). Although the association has since been observed in several other conditions (Jackson and Oakley, 1955), the identity of the original disease remains distinct. Clinically it is characterized by a familial incidence in at least 80% of cases, by a tendency for the paralytic attacks to begin during sleep, and by the fact that the individuals affected are otherwise healthy (Talbot, 1941). Biochemically it is unique because the hypokalaemia is intermittent and evidence of potassium depletion is lacking (Gass *et al.*, 1948). The pattern of the disease is definite enough for "sporadic" cases without family history to be recognized, and exceptional cases without hypokalaemia are also described (Watson, 1946; Tyler *et al.*, 1951; Ecker, 1953).

The metabolic defect in this disease is not understood, but the response to stimuli which lower the plasma potassium level tends to be exaggerated (Aitken *et al.*, 1937). After the administration of glucose or insulin, for instance, hypokalaemia is often excessive, and paralytic attacks may sometimes be induced in this way to confirm the diagnosis. No undue external loss accompanies the fall in level of the plasma potassium, which is accounted for quantitatively by a transfer of extracellular potassium into the intracellular phase (Danowski *et al.*, 1948). In other words, hypokalaemia is

excessive either because too much potassium leaves the extracellular fluid or because too little returns to it. Which mechanism is operative and why it should occur is uncertain, but fortunately oral potassium controls the symptoms.

A sporadic case of periodic paralysis in which glucose tolerance appeared to be abnormal is described.

Case Report

A 33-year-old engineer complained of attacks of paralysis for 13 years. In the intervals between attacks his health was excellent and he often took part in weight-lifting contests. None of his relatives was similarly affected, nor was there a family history of migraine. The paralysis first occurred in 1943, when he was serving in the Royal Marines. At the end of an evening film show he was unable to rise from his seat because both arms and both legs were weak. All subsequent attacks began between 3 and 7 a.m. In a moderate attack he awoke unable to turn over in bed because his arms were weak and his legs were paralysed but he was able to move his head. Coughing and swallowing became difficult only in the most severe attacks, and speech, breathing, and eye movements were never affected. Micturition was impossible early in an attack, and he was constipated afterwards. Sensation was not disturbed, but his muscles were often painfully stiff next day. Consciousness was never impaired, although he became irritable and apprehensive when paralysed. Nothing was known to precipitate the attacks, but they were sometimes predictable from "a feeling

of stiffness" a few hours beforehand. They could not be "worked off," rarely followed undue exertion, and were unaffected by cold weather or a hot bath.

Most of the attacks were of mild-to-moderate severity, and the patient gradually recovered from them in from four to ten hours. With assistance he was able to eat meals and smoke a cigarette while paralysed, and after a few hours he was able to sit propped up in a chair even though his legs were useless. At first he suffered only three or four attacks a year, but their frequency increased, and in 1955 he had more than a dozen. Shortly before admission he gave up drinking beer (which contains potassium) and instead often ate sweets in the evenings. Attacks then occurred two to three times a week. He had no other complaints apart from infrequent unilateral headaches.

A provisional diagnosis of familial periodic paralysis was made when he was in the Services, but the only treatment he received was psychotherapy. In 1953 his complaint was again thought to be hysterical after brief investigation in hospital. He was later advised to take "Kruschen salts" (potassium 0.12 g. per drachm, or 3%) by a local chemist, but derived no benefit from this.

On examination after admission on March 5, 1956, the patient looked well, his physique was excellent, and no abnormal physical signs were found. The blood pressure was 120/80 mm. Hg, there was no proteinuria or glycosuria, and the specific gravity of the urine was 1016.

Investigations.—Haemoglobin, 15.7 g. per 100 ml.; blood urea, 24 mg. per 100 ml.; blood cholesterol, 200 mg. per 100 ml.; plasma bilirubin, 0.6 mg. per 100 ml.; alkaline phosphatase, 9 units; thymol turbidity, 6 units; zinc sulphate, 1 unit. Plasma electrolytes: potassium, 4.5 mEq/l.; sodium, 146 mEq/l.; bicarbonate, 29.7 mEq/l.; chloride, 90 mEq/l. Urinary steroids: 17-ketosteroids, 19 mg./24 hours; 17-ketogenic steroids, 20 mg./24 hours; aldosterone: normal by chromatographic technique (Dr. Ivor Mills). Radio-iodine excretion test: normal thyroid function. X-ray examination of chest and pituitary fossa: normal. Electrocardiogram: sinus rhythm, normal complexes. Urinary potassium: on a daily intake of 100 mEq of potassium, the urinary excretion was 47 mEq and 53 mEq/24 hours, with a normal diurnal variation. During the first induction of paralysis the excretion fell to 19 mEq/24 hours.

Description of Attacks

1. When first seen as an out-patient on February 23, 1956, eight hours after the onset of a moderate attack, the patient said that his arms and legs were paralysed. Muscle tone, however, appeared normal, all tendon reflexes were obtained, and with persuasion slight movement of the shoulders occurred. When asked to sit up the patient was unable to do so, although his abdominal muscles were seen to contract and his face flushed with the effort. These findings and the patient's indifference to them suggested a diagnosis of hysteria. This false impression was quickly corrected when the plasma potassium was found to be 2.1 mEq/l., and the E.C.G. showed absent T waves and slight depression of the ST segments.

2. On being told that a balance diet was to start next day, he ate a quantity of fruit and sweets on his second evening in hospital. He awoke next morning (March 7) in a minor attack, during which he was unable to stand up straight or climb stairs. Proximal weakness of all four limbs, most obvious in the hip extensors, was found, although all tendon reflexes were present. The weakness lasted five hours, and three hours after its onset the plasma potassium was 3.7 mEq/l., and the E.C.G. showed slightly decreased amplitude of the T waves.

3. On March 13 the first attempt to induce an attack was made. After a 12-hour fast the patient was given 150 g. of glucose orally at 9 a.m. No weakness developed and he was given 150 g. of lactose with lunch three hours later. At 3.10 p.m. he "felt weak," but the only evidence of this was inability to adduct the extended fingers of the right hand. The plasma potassium fell to 2.9 mEq/l. (see Chart, A), and

the T waves of the E.C.G. became progressively flatter. Weakness of both arms persisted for eight hours, but the tendon reflexes remained brisk.

4. An attack was induced more successfully on March 14. The patient was given 250 g. of lactose with supper at 7.15 p.m. Before going to sleep three hours later he noticed weakness of his left hand and shoulder. At 1.30 a.m. on the 15th he awoke with a partial quadriplegia, affecting his arms more than his legs. Slight movement of his right shoulder was possible and he was still able to move both feet. He

was unable to sit up but could move his head and face normally. His limbs were flail-like and only the ankle-jerks were obtained, although the muscles appeared to retain their tone. The plantar responses were flexor, but the abdominal reflex was present only in the right upper quadrant. The blood pressure was 135/90 mm. Hg. Half an hour later his condition was unchanged and he was given 1 g. of ammonium chloride orally. This was given as a control for his later treatment, because its taste resembles that of potassium chloride. Within the next hour the paralysis of his limbs became complete and the ankle and abdominal reflexes were no longer obtainable. He was therefore given, at 3 a.m., 5 g. of potassium chloride orally. His condition was unaltered 20 minutes later, but after 30 minutes his knee and triceps jerks returned. At 3.35 a.m. he was suddenly able to raise his right elbow from the bed, at 3.50 a.m. he could lift his left leg, at 4.20 a.m. he could move his right foot, and at 4.30 a.m. his left arm suddenly became responsive and stronger than the right one. Although hip extension was weak, he was able to stand unsupported at 5.30 a.m., and two hours later recovery was complete. In this attack the plasma potassium fell to 2.7 mEq/l., and it rapidly rose to normal after the potassium chloride was given (see Chart, B).

5. On March 22 an attempt was made to induce one further attack. The patient was given 300 g. of lactose with supper. On waking next morning his arms were weak and he was unable to move his hands, but his trunk and legs were unaffected. The weakness disappeared in two and a half hours and an E.C.G. showed T waves of normal amplitude. He was then given 150 g. of glucose with breakfast, and, because no weakness followed, a subcutaneous injection of 40 units of soluble insulin was given with lunch three hours later. Again no paralysis occurred, and two hours after the injection the plasma potassium was found to be 3.1 mEq/l. During the night, however, the patient noticed slight weakness of the shoulders and hips, and at 8.30 a.m. next day he was unable to extend the fingers of his right hand. There was demonstrable weakness of hip and elbow extension, but all tendon reflexes were present and the plasma potassium was 3.6 mEq/l. The patient was depressed and irritable and he was noticed to be sweating freely. He was given 5 g. of potassium chloride orally and 45 minutes later he was able

to extend all the fingers of his right hand except the third. His strength recovered fully and he was no longer moody half an hour later. The plasma potassium and blood-sugar changes during recovery are shown (Chart, C).

The Electrocardiogram

Serial E.C.G.s were obtained during the attacks, and the plasma potassium was estimated simultaneously with 22 of them. Flattening, and occasionally disappearance of the T waves with slight ST depression (best seen in Leads II and V5), always accompanied a decrease in the plasma potassium. Although in general the amplitude of the T waves followed the plasma potassium level, there was no exact correspondence between them. The reason for this was apparent in the serial records, which showed that the T-wave changes lagged behind alterations in the plasma potassium level. The time-lag was much shorter than that which often occurs in potassium-depleted subjects (Schwartz *et al.*, 1954), since it lasted only about an hour. A similar delay was observed in the recovery of muscular power after the plasma potassium was restored to normal.

There was no evidence that the E.C.G. was abnormally sensitive to changes in the plasma potassium, whether these were induced by carbohydrate, adrenaline, or insulin. An intravenous injection of 2 units of insulin, for example, produced the same degree of T-wave flattening and ST depression as it did in a control subject, and when the patient was fasting no alteration occurred.

Because hypokalaemia was recognizable from the E.C.G., a half-hourly record of Lead II was made throughout one night in order to discover whether the patient's plasma potassium level decreased significantly during sleep. No change in the T waves was observed, although the patient remained asleep for six hours.

Glucose Tolerance

Various tolerance tests were performed while the patient was on a diet containing 300 g. of carbohydrate, supplemented by the extra amounts used to induce paralysis. The true blood glucose was estimated by the method of King (1951), and the results are shown in the Table in the order in which they were obtained.

In the first test, a delayed rise from a low fasting blood sugar was observed after 150 g. of glucose was given orally. A week later 50 g. of glucose orally produced a "lag" curve; and when this amount was later given intravenously the response was normal. "Hypoglycaemia unresponsiveness" was revealed by a standard intravenous insulin-tolerance test; and when only 2 units of insulin was given intravenously the blood sugar again remained depressed longer than in a control subject. Since neither the intravenous glucose-tolerance test nor a 36-hour fast provoked hypoglycaemia, hyperinsulinism appeared to be excluded.

Two abnormalities are apparent in these results. There was initially a suggestion of increased glucose tolerance, and

there was also prolongation of the response to intravenous insulin. While the difficulty of interpreting tolerance tests is recognized, these findings are thought to be significant because they both independently imply that the storage of glucose was increased. The subsequent tests failed to show an increase in glucose tolerance, but the patient had by then received large amounts of extra carbohydrate and his attacks had become more difficult to induce. Few glucose-tolerance tests are reported in the published cases of periodic paralysis, and it is therefore particularly interesting that an apparent increase in glucose tolerance was also incidentally observed in cases described both by Aitken *et al.* (1937) and by Tyler *et al.* (1951). Their results are included in the Table for comparison. Painter (1955) reported a case with decreased tolerance, but as the patient required large amounts of potassium for several days to restore his plasma level we consider that he was suffering from potassium deficiency and not periodic paralysis. Decreased glucose tolerance is a feature of potassium depletion (Mahler and Stanbury, 1956) as shown by the example in the Table.

The plasma potassium levels observed during the carbohydrate tolerance tests are also shown in the Table. Acute fluctuations in level between estimations were excluded by serial E.C.G.s recorded throughout each test. The results show that in this patient the plasma potassium responded normally both to 50 g. and to 150 g. of glucose. Orally and intravenously, 50 g. failed to induce hypokalaemia, while the depression which followed 150 g. was not significantly greater than was found in the healthy control. It is of interest that the fall in plasma potassium after 150 g. of glucose was more profound in the case of potassium-losing nephritis than in either the patient or the control subject.

Progress

On discharge from hospital the patient was advised to restrict his carbohydrate intake and to take 1 g. of potassium chloride orally every night. Within a fortnight two attacks occurred, both of which were promptly relieved by 5 g. of potassium chloride. He has since remained free from attacks for three months on an unrestricted diet, while taking 2 g. of potassium chloride daily. If the potassium supplement is omitted for only one day attacks are apt to occur after sweets are eaten.

Discussion

The history and the biochemical findings in this case are typical of sporadic periodic paralysis. Hypokalaemic paralyses followed ingestion of carbohydrate, and the attacks were both relieved and prevented by small doses of potassium chloride. Muscle function, the E.C.G., and the plasma potassium were normal between attacks, and there was no evidence of hyperthyroidism, which occasionally precipitates the onset of the disease (Linder, 1955). During induction of an attack the excretion of potassium and creatinine in the urine decreased in the characteristic manner.

Results of Glucose- and Insulin-tolerance Tests

	Blood Sugar in mg. per 100 ml. at:													Comments

Figures in parentheses are plasma potassium in mEq/l.

Chronic potassium depletion was indirectly excluded by finding a normal plasma bicarbonate, no increase in urinary aldosterone, and a diurnal variation in the urinary excretion of potassium, which was itself within the normal range (Evans *et al.*, 1954). The depression of the plasma potassium by moderate doses of glucose was within normal limits, and it was less than that which occurred in a patient with potassium depletion. Large amounts of carbohydrate were required to induce paralysis, and with repeated attempts both the severity of the paralysis and the depression of the plasma potassium diminished. Talbott (1941) and Gass *et al.* (1948) also noted that attacks became more difficult to induce after repeated attempts.

The physical signs which appeared when the patient was paralysed were somewhat misleading. The paralysis was extremely variable in extent and severity, ranging from weakness of one finger to complete quadriplegia. The tendon reflexes were absent when paralysis was severe, but they returned during recovery before voluntary movement was possible. Furthermore, in slighter attacks the reflexes were retained despite widespread weakness. Sporadic periodic paralysis is often confused with hysteria, and in making the correct diagnosis the typical history is more helpful than the physical signs.

Gass *et al.* (1948) failed to establish an exact relationship between the severity of the paralysis and the plasma potassium level. Although the two severe attacks in our patient were associated with considerable hypokalaemia, in one of them the paralysis and the E.C.G. changes persisted for some time after the plasma potassium was restored to normal. Minor paralytic attacks occurred at low normal potassium levels, while levels lower than these were sometimes found when the patient was not paralysed. These findings make the occurrence of exceptional cases without hypokalaemia less remarkable, and, since the actual level of the plasma potassium is thus relatively unimportant, another factor must be responsible for the muscular dysfunction.

The abnormal mobility of potassium in this disease may be due to altered cellular permeability, to an unrecognized deficiency of tissue potassium, or to an increased demand for potassium in carbohydrate metabolism (Gass *et al.*, 1948). Of these alternatives the last-mentioned is perhaps the most likely, since paralysis follows carbohydrate ingestion, and potassium is known to participate in carbohydrate metabolism. Although carbohydrate metabolism is apparently qualitatively normal in this disorder, a quantitative disturbance may exist. The finding of increased glucose tolerance in our case and in those of Aitken *et al.* (1937) and Tyler *et al.* (1951) is thus relevant, since more potassium will be utilized if the normal process of glucose storage is exaggerated. The fact that a steadily falling blood-sugar level was twice found during attacks in our patient is in keeping with this suggestion, particularly since very low values were recorded on the second occasion.

Possibly, then, hypokalaemic paralysis follows ingestion of large quantities of carbohydrate simply because the mechanism for dealing with glucose is over-efficient, at the expense of the available potassium. When a small daily supplement is added to the pool of available potassium undue hypokalaemia is avoided and attacks no longer occur. Gass *et al.* (1948) thought that paralysis occurred because the contractile systems in muscle were deprived of adequate potassium, and this view is supported by the findings of Beccuau *et al.* (1955). These workers showed that attacks of periodic paralysis were relieved by adenosine triphosphate. This substance is the immediate source of energy in muscular contraction, and potassium is essential for its formation (Boyer *et al.*, 1943). The hypokalaemic paralysis may thus be analogous to that which is occasionally seen a few hours after glucose and insulin are given to patients with diabetic ketosis (Nabarro *et al.*, 1952). Admittedly the available potassium is already depleted in the diabetic cases before glucose storage is accelerated, but in attacks of periodic paralysis relative depletion may eventually develop. The fact

that hypokalaemia and paralysis become less easy to induce when large amounts of carbohydrate are repeatedly given suggests that the storage mechanism can become saturated. Conversely, patients are often more susceptible to attacks after exertion, when muscle glycogen is depleted.

Although the evidence on which it rests is scanty, several features of the disease support this theory. Periodic paralysis is relieved by limiting carbohydrate intake, and the potassium needed to prevent attacks is quantitatively related to the carbohydrate in the diet (Ziegler and McQuarrie, 1952). The condition is said to improve after middle age (Talbott, 1941), when a decrease in carbohydrate tolerance commonly occurs (Himsworth and Kerr, 1939). Attacks usually begin in the early morning, and since symptoms also tend to occur at this time in spontaneous hypoglycaemia it would appear that glucose storage is particularly active during the night. Irrespective of the time of day, the attacks are apt to start during sleep (Couston, 1955), when anabolism exceeds catabolism in the inactive muscles. Genetic disorders of carbohydrate metabolism are not unknown, and a similar familial incidence is found in idiopathic infantile hypoglycaemia (McQuarrie, 1954). Hypokalaemic paralyses have not been observed in this condition or in hyperinsulinism, but in the latter disorder (Conn, 1947) and in glycogen-storage disease (Crevel, 1939) muscular weakness occurs.

Zierler and Andres (1956) showed that there is a diurnal variation in potassium exchange between skeletal muscle and the extracellular fluid in normal subjects. Potassium tends to move into muscle during the night, and to leave muscle during the day. During the spontaneous development of a nocturnal attack of periodic paralysis, they observed a similar but much more extensive transfer of potassium into the forearm muscles. They therefore suggested that exaggeration of the normal diurnal variation in potassium exchange, due to unusual permeability of muscle membrane, is a fundamental defect in this disease. In the present case, however, there was no electrocardiographic evidence that hypokalaemia occurred spontaneously during the night, nor was the diurnal variation in urinary potassium excretion exaggerated. Hypokalaemic attacks were always related to carbohydrate ingestion, and only then was the excretion of potassium in the urine considerably reduced.

Since potassium normally moves into cells during glucose assimilation, the increased migration in periodic paralysis is again most simply explained by assuming that glucose assimilation is excessive. Zierler and Andres (1956) detected a disturbance of glucose metabolism in their cases, but no details of it were given in the brief report of their work. Grob *et al.* (1956) showed that after glucose administration the uptake of potassium by the muscles was greater than normal in periodic paralysis. They also found that in this condition insulin produced a migration of potassium into the muscles, which did not occur in normal subjects. In our patient insulin produced an abnormally prolonged depression of the blood sugar.

Many facts thus support the earlier suspicions of Allott and McArdle (1938) that "the activity of a normal mechanism involving hexosephosphate may be excessive in periodic paralysis." Our investigations suggest that the potassium migration, the hypokalaemia, and the paralysis are all secondary effects of overactive glucose storage. The qualitative response of these patients to influences affecting glucose assimilation seems to be normal, but the rate of assimilation, particularly in muscle, is apparently increased.

Summary

A sporadic case of periodic paralysis is described and the features of this condition are outlined.

A glucose-tolerance test in this patient revealed an apparent increase in tolerance, and an intravenous insulin-tolerance test showed "hypoglycaemia unresponsiveness."

The significance of these findings is discussed, and it is suggested that in this disease the rate of glucose storage is excessive following the ingestion of large amounts of carbohydrate.

We thank Dr. C. L. Cope for his interest and advice, and for allowing us to investigate this patient; Dr. M. D. Milne for helpful comment; and Dr. M. E. MacGregor for anticipating the diagnosis by 13 years. We are indebted to Miss Margaret Mathew for performing the biochemical estimations, and to our patient for his willing co-operation.

MODIFICATION OF HYPOGLYCAEMIA WITH HEXAMETHONIUM BROMIDE*

BY

EDWARD MARLEY, M.D., M.R.C.P.Ed., D.P.M.
Senior Registrar, Bethlem Royal and Maudsley Hospitals;
formerly at Severalls Hospital, Colchester

It has been shown by Schachter (1951) that the combination of hexamethonium with insulin results in an augmented hypoglycaemic response, this being attributed to the drug's blocking effect preventing compensatory sympathetic activity in response to the fall of the blood-sugar level. Laurence and Stacey (1951) also observed that the degree of hypoglycaemia produced by a given dose of insulin was greater in the presence of hexamethonium, but that, paradoxically, the ensuing hypoglycaemic symptoms were either reduced or abolished.

In this investigation the effect of the administration of hexamethonium bromide on the response to both large and small doses of insulin is reconsidered, but with particular emphasis as to how far the findings are influenced by alterations in posture.

The reaction to small doses of insulin was assessed by insulin-tolerance tests. Blood-sugar levels were also estimated after injections of large doses of the hormone, but as their values bear no precise relation to the clinical levels of hypoglycaemia (Himwich, 1951a) the response to large doses was therefore determined by attempting to overwhelm the extreme insulin resistance occurring in some schizophrenics during insulin therapy.

*Abstracted partly from a thesis accepted for the degree of M.D. Cantab., 1953.

Methods

The insulin-tolerance tests were performed in the manner advocated by Fraser *et al.* (1941), and as the previous diet influences the response to the hormone (Himsworth, 1935) the patients were given at least 300 g. of carbohydrate daily for three days before each of the tests. The blood sugar was estimated by the method of Herbert and Bourne (1930). The reaction of the blood sugar in these tests can be differentiated into two phases: first, the initial decrease of the blood sugar, then the secondary rise which is indicative of the responsiveness to hypoglycaemia. The difference between the fasting and the 30-minute blood-sugar value was adopted as an index of the first function, the mean value of these being determined for the group. As suggested by Fraser and Smith (1941), a measure of the hypoglycaemia responsiveness was obtained from the product of the percentage blood-sugar values at 45, 60, 90, and 120 minutes after the beginning of the test and the time interval of each of these from the previous sample, a quarter of an hour being taken as unity. These products were added together and termed the "hypoglycaemia responsive index" (H.R.I.), the mean value for the H.R.I. being determined for the group.

Patients were therefore subjected first to conventional insulin-tolerance tests; then after the lapse of at least a week they were retested, but in this instance the dose of insulin was supplemented by an intramuscular injection of hexamethonium bromide (25–50 mg.). A variation of this modification was to stand the patient erect after the concomitant injection of insulin and hexamethonium until a vasovagal response with syncope occurred. However, as insulin-tolerance tests were being performed on patients standing erect for approximately 15 minutes after the injection of hexamethonium, it was essential to perform control tests on the same patients who stood erect for a similar period. It is known that the injection of hexamethonium by itself has no significant consistent effect on the fasting blood sugar (Schachter, 1951).

The patients comprising this series were all male schizophrenics, but Hemphill and Reiss (1948) have pointed out that if biochemical investigations are repeated frequently on such patients much day-to-day variation in findings becomes evident. Therefore, as it was intended to compare the results of insulin-tolerance tests repeated at short intervals, it was essential to ensure that sequential tests under standard conditions showed no significant statistical dissimilarity. This was done, and it was seen that although the results of such tests repeated at short intervals on schizophrenics revealed considerable variability, if the mean values of these were assessed for the group the results showed no significant statistical disparity (Marley, 1953a).

No patient was accepted for testing if he was much underweight, if he had been treated within the preceding two months with either electroplexy or deep or modified insulin therapy, or if he had been receiving other drugs regularly within the previous two weeks, as it is known that in such circumstances there are alterations in the fasting blood-sugar levels, in the response to small doses of insulin, or in resting eosinophil counts (Tod, 1937; Gellhorn and Safford, 1948; Henneman *et al.*, 1951; Hunter and Merivale, 1954; Marley, 1955).

A total of 24 patients were given both standard and modified insulin-tolerance tests, each patient serving as his own control for the comparison of sequential tests.

The final part of the investigation comprised the attempted modification of extreme insulin resistance in six male schizophrenics. In three of these cases the patient remained recumbent after the injection of insulin and hexamethonium, whereas the other three patients were stood erect until syncope occurred after the administration of the two substances. In all instances the modified hypoglycaemias were preceded by and separated from the control reaction by a period of at least three rest days. In order that the transitions from one hypoglycaemic level to another could be formulated with precision, a slightly modified form of the classification of

hypoglycaemia proposed by Frostig (1940) was adopted. This includes five phases, the most important being stage 3 hypoglycaemia presenting with loss of consciousness, motor restlessness, clonic twitchings, and torsion spasms; and stage 5 hypoglycaemia, which corresponds to deep coma and is associated with much-reduced or absent corneal reflexes and pin-point pupils without a light reaction. The definition of insulin resistance was arbitrary, and was presumed to be present when no advance beyond a stage 3 hypoglycaemia ensued after the injection of approximately 500 units of insulin.

Eosinophil counts were performed both immediately before the insulin-tolerance tests and during the deep insulin treatments. The initial counts were made at 9 a.m., as the eosinophils tend to become stabilized about this time following the eosinopenia during the early hours of the morning (Rud, 1947). The eosinophils were also counted at 1 p.m., as hypoglycaemia is accompanied by an eosinopenia, which is most marked four hours after stress (Perlmutter and Mufson, 1951). The differences between the 9 a.m. and 1 p.m. counts were calculated, and were termed the mean eosinopenia. Capillary blood was used in eosinophil counting, and both the technique and the phloxine-urea diluent proposed by Manners (1951) were employed, the results being determined from the mean of two pipette counts.

In the attempt to produce syncope the patient would be stood erect immediately after the injection of the insulin and the hexamethonium, and would be supported by two attendants. It was usual for the patient to collapse within 15 minutes, and, following this, frequent estimations of the blood pressure and the pulse rate would be made. In order to record the cardiovascular changes accurately, Grant and Reeve's (1951) classification of circulatory patterns associated with injury was employed. The only patterns seen in the present investigation were the vasovagal and, in one instance, that of warm hypotension. Methylamphetamine hydrochloride was always immediately available for injection as it accelerates recovery after vasovagal collapse (McMichael, 1945).

Modification of Response to Small Doses of Insulin

The mean percentage blood-sugar values for the results of the standard insulin-tolerance tests and those modified with hexamethonium bromide in recumbent patients are depicted in Fig. 1, the other related findings being included in Table I, A and B. It can be seen from these that the combination of small doses of insulin with hexamethonium results in an augmented hypoglycaemic effect but a diminished response to hypoglycaemia with a decline in the mean eosinopenia. On further analysis of these figures it becomes clear that the increased fall in blood sugar after insulin and hexamethonium is statistically significant

($t=5.06$; $P<0.05$), as is the decrease in the mean H.R.I. ($t=3.22$; $P<0.05$) but not the decrease in the mean eosinopenia ($t=1.25$; $P>0.05$).

The results of the comparison of insulin-tolerance tests with those modified by the induction of syncope are considered next, the relevant data being presented in Fig. 2 and Table I, C, and D. It is apparent from these that the induction of syncope with hexamethonium leads to a significantly diminished fall of blood sugar ($t=3.85$; $P<0.05$), a significant increase of the mean H.R.I. ($t=2.28$; $P<0.05$), but an insignificant decrease of the mean eosinopenia ($t=1.17$; $P>0.05$). The assumption of the erect posture in the absence of syncope seems also to modify the test results, inasmuch that the standard deviations were consistently lower in this series (Table I, C) than those obtaining in the other tests.

Marked dilatation of the pupils occurred in the tests modified with hexamethonium, and was presumably due to the effect of the drug rather than to hypoglycaemia. Perspiration also seemed to be reduced by hexamethonium. All patients received their normal breakfasts after the completion of

the tests, and even in the case of those who had received hexamethonium with insulin there was no instance of later hypoglycaemic or hypotensive episodes.

Modification of the Response to Large Doses of Insulin

Only a précis of the findings will be presented, as the clinical results of the modification of the reaction to large doses of insulin are presented elsewhere (Marley, 1956).

The administration of hexamethonium bromide to recumbent insulin-resistant schizophrenics receiving deep insulin therapy led to more profound levels of hypoglycaemia than obtained with insulin alone. Thus in three patients doses of respectively 480, 480, and 560 units of insulin given intramuscularly led barely after 210 minutes to the appearance of a stage 3 hypoglycaemia. When the identical doses of insulin were combined in the same patients with 100 mg. of hexamethonium, injected subcutaneously or intramuscularly, a stage 5 hypoglycaemia developed within the same period.

The technique of inducing syncope with hexamethonium early in hypoglycaemia was more successful still. For instance, in another three patients doses of 520, 560, and 640 units of insulin injected intramuscularly failed after 210 minutes to produce even a stage 3 hypoglycaemia, whereas doses of 480, 480, and 520 units in the same patients, but combined with 100–150 mg. of hexamethonium and a syncope induced early in hypoglycaemia, resulted within 150–180 minutes in the emergence of a stage 5 hypoglycaemia.

In both types of modification with hexamethonium the hypoglycaemias differed from the conventional response to insulin in that the customary profuse salivation and perspiration were much reduced and even completely abolished in one patient. Comas tended to develop much more rapidly, and it was noted that the deepest level of hypoglycaemia was accompanied by widely dilated pupils in place of the pin-point pupils that are normally to be anticipated. It was found imperative to terminate the modified hypoglycaemias by the intravenous route, as the stomach appeared not to absorb substances following the combination of insulin with hexamethonium, and even after intravenous interruption the period for complete recovery was longer than that after insulin alone. It was also necessary to keep the patient in bed until the effect of the hexamethonium had worn off, for there was a marked susceptibility to further hypoglycaemic reactions, apparently determined by the assumption of the erect posture.

The blood-sugar levels for both the conventional and the modified hypoglycaemias are shown in Table II, and, although both pursue a very similar pattern, there is a tendency for the blood sugar to fall to lower levels at an earlier stage with the modified than with the orthodox insulin techniques.

In addition, the eosinopenias associated with both types of hypoglycaemia are included in Table III. It can be seen that the decline of the eosinophils in the modified techniques was sometimes greater and sometimes less than in the eosinopenias accompanying the control reactions.

TABLE II.—Reaction to Large Doses of Insulin: Blood-sugar Values (mg. per 100 ml.) for Conventional and Modified Insulin Techniques

Cardiovascular Responses Following Combination of Insulin with Hexamethonium

In the erect subject the radial pulse would increase in rate and decrease in volume until syncope occurred. The latter was vasovagal in character and usually brief in duration. In two patients this vasovagal pattern—that is, a systolic blood pressure below 100 mm. Hg, a pulse rate of 70 or fewer beats a minute, cold extremities with pallor of the facies—persisted for longer than 15 minutes. In another instance the brief vasovagal pattern was succeeded by that of warm hypotension, which by definition includes a systolic blood pressure below 100 mm. Hg, a pulse of 90 or more beats a minute, warm extremities, and a face that might be flushed or pale. No irregularity of the pulse was noted after syncope, and the peripheral circulation invariably improved without recourse to methylamphetamine hydrochloride.

Discussion

The finding of an increased hypoglycaemic effect of small doses of insulin following the administration of hexamethonium confirms, but is still merely a restatement of, the conclusions of Laurence and Stacey (1951) and Schachter (1951), although these authors make no mention of the subsequent delayed and reduced recovery from hypoglycaemia as was observed in the tests on recumbent patients. The increased resistance to the hypoglycaemic effect of small doses of insulin following syncope has, so far as is known, not been recorded, and seems reminiscent of the work of Selye and Dosne (1939), who demonstrated that insulin hypoglycaemia may be reduced although not completely abolished by the simultaneous administration of cortin. A similar diminished response to insulin has been recorded after the injection of toxin (Lawrence and Buckley, 1927), during artificial pyrexia (Ohtake, 1939), after short periods of anoxia (Gellhorn and Packer, 1939), and in association with electric shock (Delay and Soulaire, 1944).

It was Engel (1949) who suggested that an increased need for carbohydrate was the first effect of stress, and it is therefore topical that the induction of syncope with hexamethonium results in a significant hyperglycaemia and eosinopenia (Marley, 1953b). Previously, Engel (1945) had stated that the initial rise of blood sugar after stress was due to the hepatic glycogenolysis by adrenaline, and that it was only later that endogenous adrenal cortical hormone secretion

reached levels sufficient to initiate the protein catabolic impulse. Presumably it is the initial and exaggerated adrenaline response that accounts for the diminished hypoglycaemic effect seen in the insulin-tolerance tests modified by syncope. That this is not so paradoxical as it might seem is confirmed by Paton (1954), who mentions that vigorous adrenal medullary discharge can take place in the presence of ganglion block by hexamethonium.

An apparently different result accrued from the combination of hexamethonium with massive doses of insulin, for not only was there an increased depth of clinical hypoglycaemia in recumbent insulin-resistant schizophrenics, but also the induction of syncope with hexamethonium early in hypoglycaemia proved even more effective in overwhelming insulin resistance. Himwich (1951b) described three mechanisms to prevent the complete cessation of brain metabolism during hypoglycaemia. The most valuable of these was the release of hepatic glucose to the blood stream, for it not only acted over a longer period than the other but was quantitatively the most important. It would seem that the induction of syncope with hexamethonium so expedites this second mechanism that even in association with an augmented protein catabolic impulse the stored reserve of carbohydrate is not later available for implementing cerebral metabolism.

Laurence and Stacey (1951) were also at pains to point out that one of the practical applications of their investigation was the recognition of the additional risk incurred by diabetics receiving both insulin and hexamethonium, for such patients were very liable to develop hypoglycaemia in the absence of the usual signs and even to lose consciousness without warning. From the above investigations, this would seem a negligible hazard if the dose of insulin is small; however, in view of the increased sensitivity to insulin following the combination of large doses of the latter with hexamethonium, it is obvious that if large doses of the hormone are required for the satisfactory control of the diabetes, and particularly if the patient has also the tendency to develop hypotensive attacks after the injection of the ganglion-blocking drug, then the risk of hypoglycaemia is considerably augmented. In such an instance, great emphasis should be placed upon restricting the dose of either insulin or hexamethonium and insisting that these patients should remain recumbent until the likelihood of postural hypotension has worn off.

It would be no exaggeration to comment that the assumption of the erect posture in such patients is tantamount to a vastly increased liability to hypoglycaemic episodes further complicated by the fact that they are atypical in presentation. Moreover, while the oral administration of glucose is satisfactory for aborting early and minimal hypoglycaemic symptoms in a patient receiving both hexamethonium and small doses of insulin, once deeper hypoglycaemic levels have appeared, particularly coma, then the administration of sugared water either orally or by stomach tube is both valueless and dangerous. Interruption in this case must be by the intravenous route, a stricture endorsed by the work of Kay and Smith (1950) and Douthwaite and Thorne (1951), who reported that hexamethonium interferes with the motility and secretion of the stomach.

The fall of eosinophils was thought originally to be a specific if indirect index of adrenocortical activation, but this view has now been discarded, as in certain circumstances it proved to be misleading (Bayliss, 1955). Consequently it would be presumptuous to offer any categorical interpretation of the alterations in the values for the eosinophil counts. Speirs and Meyer (1949) had demonstrated that by increasing the amount of stress a greater fall of eosinophils ensued, but the eosinopenia following syncope and insulin was sometimes in excess and sometimes less than that recorded with conventional insulin techniques. The same was found for the combination of small doses of insulin and hexamethonium, although in the latter if the eosinopenia was determined for the group it was found to be diminished in

comparison with the eosinopenia associated with standard insulin-tolerance tests. It is therefore interesting that Gaarenstroom *et al.* (1953) noted that hexamethonium delayed the eosinopenia normally occurring in rats following blood sampling.

The decrease in salivation after hexamethonium is in accord with the experimental findings for animals, as Paton (1951) reported that the parasympathetic ganglion to the salivary glands was the most sensitive of all ganglia to the action of the drug. He also commented on the decrease of perspiration with hexamethonium.

Finally, it is worth alluding to the large values of the standard deviations for the test results, as they are a constant feature of investigations performed on schizophrenics (Hoskins, 1946) and not entirely attributable to the small size of the samples here under scrutiny.

Summary

The combination of small doses of insulin and hexamethonium in recumbent patients results in an augmented hypoglycaemic effect but a decreased response to hypoglycaemia with a decline in the eosinopenia.

The combination of large doses of insulin with hexamethonium in recumbent patients leads to more profound depths of clinical hypoglycaemia.

The combination of small doses of insulin with syncope induced by hexamethonium leads to the appearance of relative insulin resistance associated with an augmented hypoglycaemic response.

In contradistinction, the combination of large doses of insulin with hexamethonium and the induction of syncope early in hypoglycaemia is capable of significantly diminishing resistance to massive doses of this hormone.

The risks incurred by diabetics receiving both insulin and hexamethonium are re-emphasized.

I thank Dr. A. G. Duncan, medical superintendent, Severalls Hospital, Colchester, for permission to publish these findings.

UMBILICAL CORD AS RESERVOIR OF INFECTION IN A MATERNITY HOSPITAL

BY

JANET JELLARD, M.B., Ch.B., Dip.Bact.

From the Public Health Laboratory, Plymouth

Although much work has been done in recent years on *Staph. aureus* infections in maternity hospitals, the problem remains widespread and unsolved. Most hospitals experience outbreaks every few years, and sporadic cases occur at intervals in spite of all precautions. Minor infections such as spots and sticky eyes are a source of anxiety, and the occasional severe ones may cause death or prolonged illness. The fact that *Staph. aureus* is able to acquire resistance to antibiotic drugs means that treatment is likely to become more difficult and uncertain. Greater stress must therefore be laid on prevention.

From the bacteriological point of view there seem to be two aspects of the problem: (1) The ubiquity of *Staph. aureus* in a nursery as judged by the high proportion of positive samples from babies, the bedding, and other articles, and from the atmosphere. No other pathogenic organism is so widely distributed in the environment of a susceptible population. (2) The presence of some strains of increased virulence (Colbeck, 1949; Rountree and Freeman, 1955). At present there is no rapid or straightforward method of detecting virulent strains and excluding their carriers.

The problem which confronts us is therefore mainly one of cross-infection: how and where the staphylococci are maintained and how they spread from one patient to another.

The problem of cross-infection may be attacked from two angles: elimination of the reservoirs where the organisms flourish, and interruption of the routes by which they are spread. This paper is concerned mainly with the first of these points. There are many reservoirs of *Staph. aureus* in a nursery for newborn infants, but the nature of the umbilical cord suggests that it might be a particularly dangerous one. Cut off from its blood supply and separating by a process of dry gangrene, it must be an excellent medium for bacterial multiplication, as Cullen pointed out in 1916. The cord was described by Coventry and Isbister (1951) as an open wound with decreased powers of local resistance. Recent papers by Kwantes and James (1956) and Boissard and Eton (1956) on streptococcal infection support this analogy. The importance of such a wound has long been stressed by workers on hospital cross-infection. It has been shown how the dangers of spread from it may be decreased by the use of no-touch technique in a room supplied with filtered air, and by the protection of the wound with local applications under ample dressings. In contrast with this, it has become the custom recently in many maternity hospitals to do without cord dressings and binders, so that the cord stump is left in direct contact with the baby's clothes and bedding, and freely accessible to its hands. It is also handled every day by nurses who do not wear gloves. It thus seems to be ideally situated not only for the growth of organisms but also for their dissemination into the environment both by contact and by the air.

The umbilical cord has long been recognized as a site from which *Staph. aureus* may readily be recovered

(Cullen, 1916). Forfar *et al.* (1953) swabbed 120 babies at the time of separation of the cord (about the eighth day of life) and found an infection rate of 60%. Edmunds *et al.* (1955) recorded a rate of 40% in 604 infants of the same age. Coventry and Isbister (1951) found 54% of 50 babies to be carrying *Staph. aureus* on the cord by the third to fourth day and remarked on the special dangers of infection of this site. Isbister made further studies in 1951 and 1953. Her interest, however, was mainly clinical. She considered that infection of the cord might result in unsuspected liver damage, which in turn might be responsible for "physiological jaundice" and failure to thrive. The obvious complication of liver abscess and septicaemia is better known but rare.

The purpose of this paper is to draw attention to the cord as one of the main sources of staphylococci and to advance evidence that control of this reservoir more than others might be expected to lead to a diminished risk of virulent staphylococci being spread in a nursery.

Earlier Investigations

The investigations were made in a new maternity hospital, but earlier ones had been made in other maternity hospitals in the district to establish the extent of the problem. In these earlier investigations 74 babies out of 84, aged 4 days (88%), had given positive umbilical swabs in one hospital and 50 out of 59 (85%) in another. Nasal swabs had also been taken in these hospitals in an attempt to find out which was the more important reservoir of infection, nose or cord. In Table I are shown the results of the examination of swabs of cord and nose to determine which site was infected first, and it appears that the cord was almost always infected before or at the same time as the nose. It was rare for the nose alone to be positive.

TABLE I.—Number of Times that the First Positive Swab was Obtained From Nose or Cord

Hospital	Nasal Swab Pos. First	Cord Swab Pos. First	Both Swabs Positive	Total No. of Swabs
A	7	34	19	60
B	6	37	24	67

tion of swabs of cord and nose to determine which site was infected first, and it appears that the cord was almost always infected before or at the same time as the nose. It was rare for the nose alone to be positive.

It was also thought to be of some importance to make a rough comparison of the amount of growth obtained from nasal and cord swabs taken in the first four days of life. Cord swabs proved to give a heavy growth of *Staph. aureus* more often than nasal ones, and the organism was frequently in pure culture. The results are shown in Table II.

TABLE II.—Rough Comparison of Amount of Growth Obtained From Nasal and Cord Swabs Taken on First Four Days of Life

Age (in Days)	No. of Babies Swabbed	Growth from Nose			Growth from Cord		
		Heavy	Mod.	Light	Heavy	Mod.	Light
0	12	—	1	11	1	2	9
1	22	6	1	15	13	6	3
2	17	3	—	14	13	—	4
3-4	5	1	—	4	5	—	—

It was found also that 8 out of 22 babies with a positive nasal swab on the first day of life had become negative on the second. Only 5 out of 37 cord swabs showed a similar loss of the organism, and two of these were overgrown with *Proteus sp.* This suggests that the isolation of *Staph. aureus* from a nasal swab may not necessarily represent the multiplication of organisms there but merely that they have been filtered off from the air.

These preliminary investigations indicated that *Staph. aureus* infection of the umbilicus occurred early and in abundance.

Present Investigations

The investigations were carried out in a maternity hospital which had been opened only a few months previously. In controlled studies the cord stumps were painted with bactericidal dyes to see if this would influence the spread of infection.

The maternity hospital where this investigation was carried out was arranged conveniently on three floors, A, B, and C. There were five small wards and some single rooms for the mothers on each floor, and a nursery, which was divided into several large and small cubicles. The babies were kept in the nurseries during the night, but spent the day with their mothers in the wards. The number of babies varied between about 8 and 21 on each floor, and up to 10 or 12 slept in the same room in the nursery. The nurseries were well ventilated and had windows on three sides, so that much sunshine entered the rooms. They were cleaned with vacuum cleaners and dusted with wet cloths. The junior nursing staff on the different floors were changed every few weeks, but the medical staff and senior nurses remained the same, for the most part, on each floor.

Immediately after delivery the cord of a newborn baby was clamped by the accoucheur, ligated, and cut. The baby was put in a cot and any treatment or cleaning-up considered necessary was carried out with ungloved hands. The cord was inspected frequently to make sure that it was not bleeding; it was sometimes handled or squeezed during this inspection. About six hours after birth it was re-ligated and cut short to about an inch (2.5 cm.); surgical spirit was then applied and the cut end sealed with collodion. If the cord was thick, with an abnormal amount of Wharton's jelly, this was squeezed out before the second ligature was applied. Every day, between 7.30 and 9 a.m., the babies were cleaned, weighed, and bathed (if the cords had separated), and other routine nursing procedures were carried out. Cords were treated with spirit. The nurses' hands were washed with soap and water between the care of each baby and dried on a hand towel.

Bacteriological Technique.—Swabbing was done at the same time each day, just before the midday feed. At this time the babies had not been handled for several hours. Dry swabs were used for the nostrils, but for the skin they were moistened in nutrient broth. Skin swabs were taken from an area about 2 in. (5 cm.) in diameter at the lower end of the sternum. Three 4½-in. (11.5-cm.) settling-plates were put down daily on each floor, one in each of the two busiest nursery cubicles and one in the vestibule. They were not put down until all the babies had been removed from the nursery, so that the finer particles and droplets would be sampled rather than splashes and particles from blankets. There was little activity while the plates were exposed, which was between 9 a.m. and 1 p.m. Agar plates containing 2.5% sheep blood (Marks, 1952) were used both for swabs and settling-plates. They were incubated aerobically at 37° C. overnight and left on the bench for another 24 hours before being read. *Staph. aureus* colonies were identified by their colour and colonial appearance and by the zone of lysis which the majority showed on sheep-blood plates. They were all tested by the slide coagulase test of Cadness-Graves *et al.* (1943) and a tube test was done on all giving a doubtful result. The number of *Staph. aureus* colonies on each settling-plate was recorded. At the time of reading both sets of plates it was not known whether they belonged to the test or to the control group.

Treatment of Umbilical Cords with Triple Dye.*—For the purpose of the investigation, triple dye was applied to the cord of each baby immediately after its birth and every morning until separation took place. It was painted on to the whole of the cord stump and about an inch (2.5 cm.) of the surrounding skin. It appeared to be fixed to the tissues quickly, for it stained the clothes very little and did not spread to the rest of the baby's skin.

*Brilliant green 2.29 g., proflavine hemisulphate 1.14 g., crystal violet 2.29 g., water 1,000 ml.

Results of Triple-dye Treatment of Cords of all Babies on One Floor

(a) Between January 25 and April 14, 1956, triple dye was painted on the cords of all the babies born on floor A, while those on floor B were left untreated. A fortnight was allowed to pass before the investigations began so that there would be time for any effect to become apparent. The investigations were as follows: (1) Nasal and skin swabs were taken from all babies on both floors when they were 4 days old. (2) Settling-plates were put down in the nursery on both floors. The number of *Staph. aureus* colonies on the three plates was recorded. The results are shown in Table III.

TABLE III.—Treatment of Umbilical Cords with Triple Dye

Swabs	Treatment of Cord	No. of Babies	No. of Swabs Positive	Difference	Standard Error
Nasal	Dye (floor A)	91	46 (50.5%)	24.2%	6.95
	No dye (.. B)	91	68 (74.7%)		
Skin	Dye (.. A)	91	32 (35.2%)	25.2%	7.61
	No dye (.. B)	91	55 (60.4%)		

Average Number of *Staph. aureus* Colonies on Three Settling-plates

Treatment of Cord	No. of Days	Average Count	Difference	Standard Error
Dye (floor A) ..	62	4.77	4.93	1.14
No dye (.. B) ..	62	9.70		

(b) Between April 14 and June 1 this procedure was reversed, babies on floor B being treated and those on floor A being used as controls. A fortnight was again allowed before investigations began. These were exactly the same as before. The results are shown in Table IV.

TABLE IV.—Treatment of Umbilical Cords with Triple Dye

Swabs	Treatment of Cord	No. of Babies	No. of Swabs Positive	Difference	Standard Error
Nasal	Dye (floor B)	54	19 (35.2%)	36.2%	9.16
	No dye (.. A)	49	35 (71.4%)		
Skin	Dye (.. B)	54	17 (31.5%)	39.9%	9.03
	No dye (.. A)	49	35 (71.4%)		

Average Number of *Staph. aureus* Colonies on Three Settling-plates

Treatment of Cord	No. of Days	Average Count	Difference	Standard Error
Dye (floor B) ..	34	3.41	1.82	0.81
No dye (.. A) ..	34	5.23		

When the cords of all babies on floor A were treated with the dye, both the nasal and the skin infection rates were reduced by a significant amount when compared with those on the control floor. This difference may have been due to variations in nursing technique or to the presence of heavy nasal carriers on one floor and not on the other. However, this seems unlikely, because when the dye was introduced on floor B, and discontinued on floor A, after only a fortnight's interval, both infection rates fell on floor B and rose significantly higher on floor A. The number of colonies on settling-plates showed a similar distribution. Thus it appeared that treatment of all babies' cords on one floor was associated with a lower infection rate of nose and skin and with reduced contamination of the air.

Results of Triple-dye Treatment of Cords of Alternate Babies

Over this period a second type of investigation was being carried out on floor C. The cord of every second baby born in this unit was painted with the dye, but treated and untreated infants were kept in the same nursery and handled by the same staff, so that, apart from the dye on the cord, all conditions were similar for both groups. Swabs were taken from each treated baby when it was 4 days old and from an untreated one of the same age, which acted as a

control. The techniques used were the same as before, but settling-plates were not put down. This floor also contains the premature unit, so special precautions were used here which were not employed on the other floors, such as the wearing of masks and the application of chlorhexidine ("hibitane") cream after washing the hands. Premature babies were not included in the investigation. The results are shown in Table V.

TABLE V.—Treatment of Umbilical Cords with Triple Dye on Floor C

Swabs	Treatment of Cord	No. of Babies	No. of Swabs Positive	Difference	Standard Error
Nasal	Dye	50	20 (40.0%)	—	—
	No dye	49	19 (38.8%)		
Skin	Dye	50	10 (20.0%)	33.1%	9.1
	No dye	49	26 (53.1%)		

This investigation was carried out in order to eliminate the effect on the infection rate of nursing techniques and nasal carriers. The results, however, showed an unexpected pattern. While the skin swabs of treated babies gave a significantly lower infection rate than those of the control group, the nasal infection rates were the same. The babies on this floor all breathed the same air, so this finding suggests that, though organisms may spread from the cord on to the skin, nasal infection comes mainly from the air. The nasal infection rate in both groups was lower than usual; it is possible that the treatment of the cords of half the babies in this unit had decreased the level of airborne contamination, which was reflected in the number of organisms inhaled by the babies. The additional precautions mentioned before may also have contributed to this reduction.

Discussion

These results leave little doubt that the umbilical cord acts as a reservoir from which *Staph. aureus* may be spread. The importance of this depends on how far the second aspect of cross-infection may be brought under control—the transfer of organisms from one patient to another.

There are many ways in which this occurs in a maternity hospital, and the problem has been discussed in numerous papers. Most workers agree that the medical and nursing staffs are the chief source of the organisms (Parker and Kennedy, 1949; Forfar *et al.*, 1953; Rountree *et al.*, 1956). Once the organism has been introduced into the nursery, however, the spread seems to be mainly from one baby to another. Some workers stress the airborne route in this (Wallace and Duguid, 1952), while others consider that contact infection plays the greater part (Allison and Hobbs, 1947; Blaikley, 1952). In old-fashioned hospitals with poor ventilation and little sunlight the airborne route probably plays a large part in the spread of infection. It can be reduced considerably by methods such as treatment of blankets, oiling of floors, spacing of beds, etc. Even when all these procedures are carried out, however, organisms will still reach the air as long as infected patients are present. A limit is soon reached at which no further measures could be applied, in a place such as a nursery, without severe disorganization of the routine work. Clarke *et al.* (1954), for example, have shown that when applied alone these measures reduced the total numbers of organisms in the air in a surgical ward, but did not affect the cross-infection rate.

Contact infection is equally difficult to eliminate entirely, although it seems that better precautions could be taken than are in use at the moment. It does not seem to be appreciated, for instance, in many maternity hospitals, that soap and water will not remove staphylococci from the skin, although this is made clear by Colebrook (1930), Colebrook and Maxted (1933), and a Medical Research Council Memorandum (1941). Some findings which I obtained in the course of another investigation may illustrate this point. (1) A visit was paid to the nurseries while the morning routine of

changing and cleaning the babies was going on. The hands of 11 nurses were swabbed before and after they were washed in the usual way. Six were positive for *Staph. aureus* on both occasions, one acquired the organism and one lost it. The staphylococci isolated were of the phage-type endemic at the time, not the nurses' nasal strains. (2) Swabs were taken from door-handles of cubicles and hand-towels in the nurseries over a period of several months; 49% of 147 door-handles were positive for *Staph. aureus* and 47% of 53 towels. (Eight per cent. salt-broth enrichment was used for these swabs.) (3) The average time which a nurse was able to spare for hand-washing between the handling of each baby was 15 seconds.

Price (1938) found that, while hands were never completely sterilized by washing with soap and water, two minutes was the average time taken for the removal of "transient" organisms. Colebrook and Maxted (1933) reported that staphylococci could still be recovered from the hands after they had been washed for as long as five minutes. In order to limit this degree of hand contamination various skin disinfectants may be used, but many are not suitable for prolonged use. Chlorhexidine cream has not this disadvantage, and has been shown by Murray and Calman (1953, 1956) to be effective against *Staph. aureus* in laboratory tests. Colebrook (1955) suggested that gloves which could be disinfected on the hands might be used with advantage. It would certainly seem reasonable for nurses to wear gloves when handling the cord stump or when looking after babies with clinical infections.

It thus appears that at present the control of cross-infection by blocking routes of transfer is still imperfect. This makes it doubly important to eliminate, so far as is possible, the chief reservoirs of pathogenic organisms. It is necessary to distinguish between places where *Staph. aureus* can often be obtained, such as the air and fomites, and places where it actually multiplies. It will always be present because of the high nasal carrier rate; we must concentrate on reducing its numbers rather than attempt to banish it entirely from nurseries.

The main reservoirs are generally considered to be: (a) Any open lesion, whether in mothers, staff, or babies. These cases should be isolated. (b) The nostrils and skin of adult carriers. The work of Gould (1955) and Rountree *et al.* (1956) suggests that the use of nasal ointments containing antibiotics such as neomycin, gramicidin, and bacitracin may help to prevent the introduction and spread of organisms from this source. It would not be possible to use these continuously, however. (c) The babies themselves form the remaining reservoir of infection as well as its main target. After the first few days of life, *Staph. aureus* can usually be isolated from the nose, mouth, eyes, cord stump, faeces, and the skin as a whole. Of these, the cord is not only the site from which spread is most likely to occur, but it is also the easiest to treat. It would be difficult to eliminate *Staph. aureus* from the other sites without using antibiotic drugs, which is not to be recommended as a routine. Local treatment of the cord, on the other hand, appears to be effective and free from side-effects or complications. Whether cord dressings should be reintroduced instead of or as well as this procedure is a question that might well bear investigation.

This work was carried out during an inter-epidemic period, when there was very little *Staph. aureus* infection in the hospital. Where a large population of staphylococci has been allowed to accumulate, treatment of the cord by itself would probably make little difference to the cross-infection rate. All the known methods of control must be applied simultaneously if any impression is to be made on the prevalence of the organism. These may be summarized as follows: avoidance of overcrowding, isolation of cases, precautions against contact and airborne spread, and removal, if possible, of dangerous carriers. The purpose of this study has been merely to point out the similarity between the cord and an open wound, and to indicate how the danger of this as a source of infection may be reduced.

Summary

A study is described of the part played by the umbilical cord of the newborn infant as a source of infection in a maternity hospital.

The cords of one group of babies were treated with triple dye. Nasal and skin swabs were compared with those of an untreated group in another unit and counts made of *Staph. aureus* colonies on settling-plates put down in the two nurseries. After a fortnight, treatment was introduced into the unit which had previously acted as a control, and similar investigations were carried out.

There was a significant difference between the treated and untreated groups in respect of both the nasal and skin swabs and the numbers of *Staph. aureus* colonies isolated from settling plates.

In a second investigation, treated and untreated babies were kept together in the same nursery. Skin swabs again showed a significant difference, but the nasal infection rates were the same in both groups.

The practical value of these findings is discussed in relation to the prevention of cross-infection among newborn infants.

This work was done while I was working at the Public Health Laboratory, Cardiff, and I would like to thank Professor A. S. Duncan, Professor A. G. Watkins, and the matron and staff of Cardiff Maternity Hospital for their co-operation. I am also grateful to Professor Scott Thomson and Dr. G. S. Wilson for their help with the presentation of this paper.

In 1955 the British Council for Rehabilitation set up a working party to investigate "the gastric problem" in industry. The working party has now reported. Its chairman was Dr. F. AVERY JONES, and among its members were two professors of industrial health, six industrial medical officers, a physician, a psychiatrist, and a medical statistician. The report is very short (6 pages) and intended for lay readers. The principal conclusions are that gastric and duodenal ulcer are common among men to-day; that those prone to ulcer must avoid undue fatigue, anxiety, and irregular meals; and that both management and worker can help to reduce the problem. The report, entitled "Gastric and Duodenal Ulcer: A Modern Industrial Problem," can be obtained for 1s. 6d. from the British Council for Rehabilitation, Tavistock House (South), Tavistock Square, London, W.C.1.

BARBITURATE ANTAGONISTS TO SHORTEN DROWSINESS AFTER SEDATED B.M.R. DETERMINATIONS

BY

The reliability of determinations of the basal metabolic rate depends largely on the certainty of the patients being basal during the test. It has been shown that preliminary sedation to the point of sleep can ensure this in nervous patients (Bartels, 1949; Fraser and Nordin, 1955). This technique, however, may leave the patient drowsy and confused for a variable and sometimes prolonged period after the test. We have therefore conducted the clinical trial reported below to assess whether the drowsy period can be shortened with barbiturate antagonists.

Two substances, bemegride (β -ethyl- β -methylglutaramide; "megimide") and amiphenazole (2:4-diamino-5-phenylthiazole hydrochloride; "daptazole") have been advocated for the treatment of coma due to barbiturate overdosage (Shulman *et al.*, 1955). Bemegride is a specific barbiturate antagonist, while amiphenazole has a similar weaker action but also acts as a nervous and respiratory stimulant (Shaw *et al.*, 1954). It seemed likely that these drugs might also shorten the period of drowsiness and confusion following smaller doses of barbiturates.

Method

The trial was arranged on a series of 10 patients whose sedated B.M.R. was being determined in hospital on each of two successive days. After the B.M.R. determination on one day they received the antagonist bemegride, the other day being used as a control. On both days the rate of awakening was carefully assessed so that any consistent difference between rates of waking on the two days could be determined and perhaps attributed to the antagonist drug.

Drug Dosage.—On each day the patient was sedated with three oral doses of 200 mg. (3 gr.) of sodium amylbarbitone ("sodium amytal") at 7, 8, and 9 a.m. Subsequently, at 10.30 and 11 a.m. on one day, he or she received two oral doses of the antagonist bemegride (each of 150 mg. in a 0.5% solution), while on the other, or control day, he or she received two apparently similar doses containing only saline. In the case of four patients the observer also was unaware which was the control day.

Assessment of Wakening.—From 10.30 a.m. the patient's drowsiness was assessed at half-hourly intervals until fully awake, using the following criteria:

Appearance	Speech	Gait
Asleep 3	Incoherent 3	Gross impairment 4
Drowsy 2	Slurred 2	Moderate " 3
Normal 1	Normal 1	Slight " 2
		Normal 1

Occasionally, observations on a control day were not followed through until the patient was completely awake.

These patients have been graded as fully awake half an hour after the last observation, an assumption which would tend to weigh against any waking effect of bemegride.

We are at present testing by similar means whether the addition of amiphenazole to the present regime will influence the rapidity or degree of wakening. The results of this investigation are not yet complete.

Results

Time of Wakening.—In the accompanying Chart the average state of drowsiness at half-hourly intervals on all control days is compared with that on all bemegride days (10 control days, 13 bemegride days, 10 patients). This shows that on the control day normal speech was usually regained at 4½ hours, normal appearance at 5 hours, and normal gait at 6 hours, while after bemegride the corresponding times were much shorter: 3½, 3, and 3 hours respectively. The trial was planned so that the initial status of each patient should be as near the same as possible on each day. The

Average time in hours to reach normality on control days and bemegride days (13 patients).

mean initial values are seen to be very nearly equivalent, so that the more rapid waking after bemegride appears to be due to this drug.

Speed of Awakening After Bemegride Compared With Control Day

Cases*	Initial Status on Bemegride Day	Difference between Control Day and Bemegride Day (in Minutes) until Fully Awake as Judged by:		
		Appearance	Speech	Gait

* Numbers indicate patients tested. Letters in parentheses show where the same patient was tested on more than one occasion.
 † Blind assessments (observer unaware of which day was the control).
 Negative values record instances in which the patient took longer to reach normality on bemegride day than on control day.

The consistency with which this effect was observed is shown in the Table. Each patient's results are recorded separately, and the shortening of the time to reach normality after bemegride compared with the control day is shown for each of the three criteria. Any instances of lengthening of values. The patients have also been grouped according to their initial status—whether it was judged slightly deeper, equivalent, or slightly lighter than on the control day. This grouping does not seem to have influenced the shortening of waking-time observed, confirming that this effect was not merely a reflection of differing initial drowsiness. On nine of the bemegride days waking was more rapid by all criteria. On the other four days waking was judged slower by only one criterion and never by that of gait, the most precise assessment of all three. These apparent exceptions therefore probably reflect merely the crudeness of the assessments.

It should also be noted that the four patients tested "blind" show as much evidence of bemegride effect as the others.

The average shortening in waking-time attributable to bemegride is 135 minutes for appearance, 111 minutes for speech, and 192 minutes for gait. This acceleration in waking-time is clearly significant when the mean values for all these differences in waking-time are considered; for each criterion alone, $P < 0.01$ by t test.

Toxic Reactions

Of the 10 patients who were closely observed, two became nauseated. This was the only toxic effect, and occurred after the second dose of bemegride in both instances. Under normal circumstances the second dose would probably have been withheld from one of these patients, since he was already sufficiently awake after the first dose. That this would have lessened the incidence of toxicity is shown by a consideration of the toxic effects observed in a further 45 patients who were not so closely observed, and from whom the second dose was sometimes withheld if the patient was reasonably awake after the first. In this group, two patients became agitated, four were nauseated, and two developed a skin rash.

Mental.—During the early period of the trial one nervous thyrotoxic patient became confused and agitated after the standard dose of bemegride. The significance of this effect was misinterpreted and a further dose given, with worsening of her excitement. A second patient, with myxoedema, became agitated after the two doses of 150 mg. In both instances the excitement was controlled by sodium amylbarbitone, 200 mg. by mouth, and subsequent sedated B.M.R.s followed by smaller doses of bemegride were performed without incident.

Gastro-intestinal.—Three patients complained of nausea and one actually vomited after the two standard doses of bemegride. One further patient complained of slight nausea after the first dose but did not vomit. Single doses repeated on subsequent days on the first three patients were unaccompanied by gastro-intestinal upset.

Skin.—Two patients developed a diffuse irritating erythematous rash on the trunk and limbs within 48 hours of bemegride administration. In both instances the rash was controlled by antihistamines and disappeared within 48 hours. The cause of the eruptions remains uncertain, as both bemegride and sodium amylbarbitone had been given in each case.

We conclude that the overall incidence of possible side-effects is 15% and that this figure may be much lower if the second dose of bemegride is withheld in all instances where the patient appears sufficiently awake after the first 150 mg.

Discussion

Previous workers have used bemegride in the treatment of barbiturate overdosage (Shulman *et al.*, 1955; Montuschi and Wickenden, 1955; Holten, 1955; Perinpanayagam *et al.*, 1955). From their findings it seemed likely that the drug would shorten the waking-time after barbiturate anaesthesia. Bentel *et al.* (1956) have recorded their results in a series of 108 patients in whom bemegride was used to terminate thiopentone anaesthesia. The drug was given by intravenous injection in doses usually of 25 and 50 mg. All patients were awake five to nine minutes after the injection, and side-effects were noted only after doses subsequently believed to have been excessive. Harris (1955) reported a similar series of 73 patients with no side-effects. Unfortunately there were no controls in either of these trials.

It could not be inferred from the results in barbiturate coma or anaesthesia that bemegride would also shorten the drowsiness following smaller doses of barbiturate. Our results give clear evidence of the effectiveness of oral bemegride in shortening the drowsiness and confusion following moderate barbiturate sedation. It can be seen that sedation adequate for B.M.R. tests may be followed by four to six hours of drowsiness and mild confusion which can be

shortened by an average of two to three hours by the use of bemegride. We have gained support for these observations in another series of 20 patients without control observation and in a further 25 patients who were not so closely observed.

The dosage used in the present series was standardized for purposes of comparison, and in the great majority this proved to be satisfactory. In practice, it should suffice to give one dose and follow it with a second only if the patient is still drowsy (and not nauseated) half an hour later. Only very occasional patients have shown slight agitation or nausea after the first dose of 150 mg. and only 5 out of 55 have shown these toxic effects after the two doses used. As nausea or vomiting is likely to be one of the earliest toxic effects, there is advantage in giving the drug orally. There was no evidence that thyrotoxicosis or myxoedema predisposed to toxic reactions.

On the basis of the above findings, we can now recommend oral bemegride as a practical and safe means of shortening the period of drowsiness which follows barbiturate sedation. One oral dose of 150 mg. in 0.5% solution should be given, and be followed by a second in 30 minutes only if the patient is then still drowsy and not nauseated. In this series barbiturates had been given in order to carry out sleeping B.M.R. estimations. There are many other diagnostic and therapeutic techniques, however, which require sedation and have therefore usually necessitated admission to hospital. If such barbiturate sedation is terminated by bemegride these procedures can be simplified, and may then even be performed in the out-patients department.

Summary

A series of 13 patients sedated with barbiturates for the purpose of B.M.R. determinations were studied to evaluate the action of a barbiturate antagonist, bemegride. A two- to three-hour shortening of the drowsy period was noted after bemegride compared with a placebo.

Bemegride was given in two oral doses of 150 mg. in 0.5% solution at an interval of half an hour. Toxic reactions were few and related mainly to the second dose.

Bemegride appears to have considerable value in facilitating the performance of therapeutic and diagnostic procedures which need barbiturate sedation.

We thank the nursing staff of Hammersmith Hospital who co-operated in this trial; also Dr. Edmund Alcock, medical officer, A. & G. Nicholas Ltd., for generous supplies of megimide.

The British Council for the Welfare of Spastics has published a pamphlet containing four addresses on cerebral palsy. They were given at a conference for doctors in Birmingham last October, under Professor J. M. SMELLIE's chairmanship. Professor R. S. ILLINGWORTH discusses the "Early Diagnosis of Cerebral Palsy"; Dr. FRANCES BRAID "The Aetiology of Cerebral Palsy"; Dr. H. M. COHEN "Cerebral Palsy and the School Health Service"; and Mr. A. INNES, F.R.C.S., "The Management of Cerebral Palsy." The pamphlet (pp. 40) may be obtained from the council at 13, Suffolk Street, Haymarket, London, S.W.1, price 3s. 6d. (post free).

FATAL DUODENAL PERFORATION DURING PREDNISONE THERAPY

BY

Withington Hospital, Manchester

Prednisone, or Δ^4 -dehydrocortisone, is regarded as superior to cortisone both because of its greater potency and because, within the normal range of therapeutic doses, it has less sodium-retaining effect with little tendency to produce oedema. Bollet *et al.* (1955), however, reported the development of symptomless duodenal ulcers, identified radiologically, in 3 of 18 patients receiving prednisone or prednisolone (Δ^4 -dehydro-hydrocortisone) for rheumatoid arthritis.

The following report concerns the development during prednisone therapy of a symptomless duodenal ulcer which remained unsuspected until perforation and peritonitis were revealed at necropsy.

Case Report

A man aged 61 was first admitted to hospital on April 20, 1956, complaining of bilateral rib pain and a purpuric rash. On May 5 a diagnosis of multiple myeloma was made by sternal marrow examination, and was confirmed biochemically and radiologically. There was no history of digestive upset. Treatment was with urethane for 25 days and cortisone for 8 days. On June 14 prednisone, 5 mg. three times a day, was substituted for cortisone, while urethane therapy was continued. He was discharged from hospital somewhat improved five weeks later, and continued to receive these drugs at home. On August 14 he was readmitted complaining of vague abdominal pain, constipation, and dyspnoea, of one week's duration. By this time, he had received a total of 920 mg. of prednisone. He was pale, with a recurrence of the purpuric rash which had been observed intermittently for the past year, and there was evidence of considerable weight loss since his last admission. The abdomen was soft and was not distended. Tenderness was not elicited in any area, nor was there any guarding or rigidity. Bowel sounds were heard. The rectum was full of soft faeces, but there was no tenderness. Pulse rate 80 per minute; blood pressure 95/50 mm. Hg. He became comatose shortly after admission, and died four hours later.

Post-mortem examination showed that death had been due to generalized peritonitis following perforation of a duodenal ulcer. The peritonitis was maximal in the upper abdomen and right iliac fossa, and there was a frankly purulent exudate between liver and diaphragm. The ulcer, which measured 3 by 0.6 cm., was situated vertically on the posterior wall of the duodenum, immediately beyond the pyloric sphincter. Histologically, it was a peptic ulcer of acute type which, except at the site of perforation, was almost confined to the mucosa and submucosa, with a minimal degree of fibrosis and virtually no involvement of the muscle coat. The probable duration of the ulcer was two to four weeks. The remaining positive findings were those of multiple myeloma.

Discussion

While there have been reports of dyspepsia developing during prednisone or prednisolone therapy (Bunim *et al.*, 1955; Margolis *et al.*, 1955; Fisher, 1956), a more striking finding was that of Bollet *et al.* (1955), who observed radiological evidence of duodenal ulceration, without corresponding symptoms, in three previously ulcer-free patients on

prednisone and prednisolone therapy. In all three cases radiological evidence of healing followed the institution of routine ulcer treatment, without the need for discontinuing the drug. In contrast, in two patients treated by Hart *et al.* (1955) dyspepsia improved when prednisone was substituted for cortisone.

The case recorded here is a further example of symptomless duodenal ulcer developing during prednisone therapy. Although the patient experienced some abdominal pain during the seven days before his death, this was not localized and was never severe, and at no time were either the symptoms or the clinical findings suggestive of perforation. In the absence of symptoms and of radiological evidence it is not possible to state accurately the date of onset of the ulcer, but the histological appearances leave no doubt that its duration was substantially less than that of the prednisone therapy.

There have been several reports of massive haematemesis (Pechet, cited by Bollet *et al.*, 1955; Bickel, 1955) and of intestinal haemorrhage (Muller, 1955) occurring during prednisone therapy. Pickert (1956) recorded a case similar to ours in which perforation of a symptomless duodenal ulcer, histologically acute, was the cause of death. Fentress *et al.* (1956) and Hess and Macpherson (1957) described cases of perforation, which were not symptomless, complicating treatment with prednisone and prednisolone respectively.

It is clear that symptomless perforation must be added to symptomless ulceration as one of the possible complications of prednisone therapy.

It would seem advisable to carry out frequent examinations of the stools for occult blood, as well as repeated barium-meal examinations where possible, during prednisone therapy. Antacids probably have some prophylactic value. Estimation of plasma and urine pepsinogen levels (Hirschowitz, 1955; Hirschowitz *et al.*, 1956) might become a practicable method for detecting the onset of peptic ulceration. The occurrence of epigastric pain, however mild, should be regarded as a danger signal.

Summary

A case of fatal perforation of a duodenal ulcer following two months' prednisone therapy for multiple myeloma is recorded. The ulcer was histologically of acute type, and was probably of two to four weeks' duration. It was virtually symptomless, and the subsequent perforation and peritonitis were attended by a minimum of symptoms and a total absence of physical signs.

We wish to thank Dr. J. S. Parkinson for permission to publish this case.

The British Epilepsy Association gave a preview of its film "People Apart" at the Royal College of Surgeons this month. The film tells the public "the facts" about epilepsy. It was made by Guy Brenton, who won an "Oscar" for the best documentary film of 1955. The main actors are epileptics; there are no professionals. "People Apart" (35 mm. or 16 mm., 35 minutes, with sound) may be hired by private associations from the British Epilepsy Association, 136, George Street, London, W.1. (Hiring fee £2.)

Medical Memoranda

Intussusception and Acute Appendicitis

The association of acute intussusception with acute appendicitis in infancy and childhood is not a common one. The age incidence of the two conditions differs, intussusception being uncommon over 2 years and acute appendicitis uncommon under 2. In a small personal series of 12 consecutive operations for acute intussusception during the past year, only one infant was aged over 2 years; in a series of 75 operations for acute appendicitis during the same period, only one child was under 2.

Thompson (1955) records a case of caeco-colic intussusception complicating perforated appendicitis in an infant of 20 months, and gives reasons why the intussusception probably followed the appendicitis. He refers to a similar case of Lipin and Miller (1948): a man of 21 in whom acute appendicitis was complicated by intussusception.

The reverse sequence—acute appendicitis following intussusception—seems particularly uncommon. The following case is thought of sufficient interest to be recorded.

CASE REPORT

A healthy girl of 5 was admitted to hospital as an emergency case on March 13, 1955. The history was of attacks of colicky central abdominal pain and vomiting for the previous 36 hours. There had been no rectal bleeding. Examination showed her general condition to be satisfactory: she was neither shocked nor pyrexial. There was no tenderness or any other physical signs on abdominal examination.

She was kept under observation. Twelve hours later she developed another attack of severe abdominal colic and vomiting. Abdominal examination then revealed some central distension and a palpable mass in the right lumbar area. During this period her highest temperature was 99° F. (37.2° C.). The urine contained no pus cells on microscopy. A white cell count showed 28,000 per c.mm. (80% polymorphs). It was decided to operate. A diagnosis of intussusception was considered, but the leucocytosis was not explained.

A right paramedian incision was made and an intussusception found with its apex half-way up the ascending colon. This was reduced without difficulty and the gut was perfectly viable. The appendix appeared very slightly swollen, but did not seem acutely inflamed. In view of the leucocytosis, appendectomy was performed. After completion of the operation the appendix was opened and found to contain frank pus. Mucosal ulceration was present, and it was felt that perforation would soon have followed. Histological examination confirmed the acute inflammatory process. The patient made an uninterrupted recovery without antibiotics, and was discharged on the twelfth post-operative day.

It is thought likely that the first event occurring here was the intussusception. The acute appendicitis probably followed when the base of the appendix was drawn up by the intussusceptum, precipitated by the appendix becoming obstructed by the neck of the intussusciptum. The following features confirm this view: (1) the absence of pyrexia and abdominal tenderness, due to the inflamed appendix being buried in the intussusception; (2) the first physical signs noted were those of abdominal distension and a mass; and (3) the intussusception was of the common ileo-caecal type starting just proximal to the ileo-caecal valve.

COMMENT

After reduction of an intussusception the appendix is often seen to remain blue and even show incipient gangrene after the gut wall has returned to normal. For this reason,

in the series of 12 intussusceptions referred to above, appendicectomy was performed in five cases, with no deleterious effects on post-operative recovery. No reference has been found to intussusception precipitating acute appendicitis by obstructing the lumen of the appendix. In view of the outwardly innocuous appearance of the appendix in the case described, it is felt justified to urge appendicectomy in intussusception if the appendix shows the slightest abnormality. This should apply especially to children over the age of 2. Gross (1953) states that "mere engorgement and swelling of an appendix is not a sufficient indication for appendicectomy. . . . The cautious operator will not remove the appendix unless it is gangrenous and its vessels thrombosed." A plea is entered to modify this attitude.

I should like to thank Mr. A. Gourevitch for permission to publish this case.

Fatal Agranulocytosis During Treatment with Amodiaquine

Amongst the drugs more recently introduced both chloroquine and amodiaquine ("camoquin") have established a good reputation for safety in the treatment of malaria. In this disease, however, they are usually given in short courses. The extension of their use over long periods to treat chronic diseases such as lupus erythematosus and other skin diseases in which photosensitivity is an important factor introduces new hazards.

In the treatment of malaria, side-effects which have been reported include mild and transient headache, visual disturbances, gastro-intestinal upsets, and pruritus. After prolonged medication for suppressive purposes dermatitis, bleaching of the hair, and diminution of T waves in some or all leads of the E.C.G. have been reported (Goodman and Gilman, 1955). Side-effects are reversible on withdrawal of the drugs and only rarely become serious enough to contraindicate their use in this disorder.

In a recent review of the treatment with these drugs in lupus erythematosus (Dubois, 1956) two more potentially serious side-effects have been recorded—namely, thrombocytopenia and severe leucopenia—the former being encountered once and the latter three times in treating a series of 42 patients with chloroquine. In this series neither of these effects was encountered in treating 31 patients with amodiaquine. However, as these drugs are so closely allied chemically the following case of fatal agranulocytosis following treatment with amodiaquine seems worth reporting.

CASE HISTORY

A married woman aged 53 was admitted to hospital on September 26, 1956. Ten days previously she developed a sore throat and was presumed to have a quinsy. Three months earlier she had a rash on her face and forehead which appeared to be made worse by exposure to sunlight, and for this reason she was given amodiaquine. In all she received one tablet (200 mg.) of amodiaquine daily for nearly eight weeks, from July 24 to September 16. With the onset of the sore throat on September 16 the amodiaquine was stopped and "distaquaine penicillin," 300,000 units, was given systemically daily for three days and subsequently by mouth. The temperature, which was initially 102° F. (38.9° C.), never responded to treatment, and just before admission she became irrational, was unable to open her mouth, and was thought to have some neck rigidity. The presence of meningitis was suspected.

On admission she was obviously very ill, jaundiced, and toxæmic. Temperature was 99.8° F. (37.7° C.). With much difficulty the mouth was opened and a sloughing ulcer surrounded by a zone of erythema was detected on the right tonsil. The left tonsil was also inflamed. There was marked fetor of the breath. Neither the cervical lymph nodes nor the spleen were palpably enlarged. The other systems shared no significant abnormality.

Investigations.—September 26: Hb, 90% (13.3 g./100 ml.); C.I., 0.95; red count, 4,760,000 per c.mm.; white cells, 3,500 per c.mm. (lymphocytes 100%); E.S.R., 48 mm.; P.C.V., 40%; M.C.H. 28 µg.; M.C.V. 84 cubic microns; M.C.H.C., 33.2%. September 27: Direct bilirubin, 1.2 g./100 ml.; indirect bilirubin, 1 g./100 ml.; total bilirubin, 2.2 g./100 ml.; alkaline phosphatase, 22.3 K.A. units; thymol turbidity, 1 unit; zinc sulphate turbidity, 1.5 units; total protein, 5.15 g./100 ml. (albumin 3.6 g., globulin 1.55 g.); albumin:globulin ratio 2.38:1. Widal reaction negative in all dilutions of patient's serum against the following: *Salmonella paratyphi B* O and H, *Salmonella typhi* O and H, *Brucella abortus*, *Brucella melitensis*, and non-specific *Salmonella* H. Urine: reaction acid; albumin trace; sugar nil. Microscopical examination—light deposit of amorphous urates only. No growth on culture. A negative test for quinine derivatives. White count 600 per c.mm. September 28: Sternal marrow showed a very marked hypoplasia of the granular series; the red blood cells showed some anisocytosis and polychromasia; erythropoiesis did not appear to be much affected; myeloid-erythroid ratio 1:4. Right tonsil: culture—large number of Gram-positive cocci seen. Left tonsil: culture—several epithelial cells and a number of Vincent's organisms present. A few colonies of *Staph. albus* and *Str. viridans* were grown. White cells, 450 per c.mm. (lymphocytes 99%, large monos. 1%). September 29: Paul-Bunnell, unabsorbed weak positive at 1:20, absorbed weak positive at 1:10. White cells, 350 per c.mm.

The patient was given one million units of soluble penicillin six-hourly from the time of admission, and in addition tab. prednisone, 10 mg. four times a day. The following day she was also given pyridoxine, 200 mg. daily. This was later changed to 50 mg. twice daily intravenously and 100 mg. daily orally. The patient failed to respond to therapy; the temperature remained elevated and the white count low throughout. She went steadily downhill and eventually died on September 30 at 6.50 a.m.

Post-mortem Findings.—At necropsy the outstanding abnormal findings were as follows. The brain showed some congestion and much oedema, but the central nervous system was otherwise normal. The fauces and tonsils were ulcerated and there was slight erosion of the lower end of the oesophagus. The large bowel as far as the splenic flexure was thickened owing to oedema. The lungs were congested. Small haemorrhagic areas resembling infarcts were visible. Both lower lobes were dark and oedematous, but there was no pneumonic consolidation. The pericardial sac contained 1½ oz. (45 ml.) of clear icteric fluid. The heart was dilated and the cut surface of the myocardium revealed diffuse fine fibrosis. The kidneys were of normal size, but early arteriosclerotic changes were visible. The liver was enlarged and had a nutmeg appearance. The spleen was about double normal size. The lymph nodes in the porta hepatis and mesentery were enlarged. The bone marrow appeared normal.

I am grateful to Dr. F. Macdonald, of Parke, Davis and Co. Ltd., for drawing my attention to the relevant literature, and to my colleague, Dr. R. A. Garson, who carried out the special investigations.

LOUIS GLICK, M.D., M.R.C.P.,
Physician, Royal Halifax Infirmary.

Reviews

DERMATOLOGY

Dermatology. By Donald M. Pillsbury, M.A., D.Sc., M.D., Walter B. Shelley, M.D., Ph.D., and Albert M. Kligman, M.D., Ph.D. (Pp. 1,331+xix; illustrated. £7.) Philadelphia and London: W. B. Saunders Company. 1956.

This is an exciting book, and one of the most important on dermatology that has yet been produced. Had it not been so heavy, I should certainly have taken it to bed to read, or to church in anticipation of a dull sermon. Each one of the many eminent dermatologists working in the University Hospital at Philadelphia is an authority in some other discipline, as physiology, mycology, pharmacology, or art. It was thus inevitable that an important textbook should come out of this institute, and it is most welcome. It is of great interest to dermatologists, but is of importance to the medical student, the family doctor, and the physician, and perhaps chiefly to those who determine the balance of the curriculum in the medical school. Too often, as the authors remark, the skin is regarded as a veil which obscures the proper study of deeper organs instead of the guide which it should be.

The first portion of the work emphasizes the significance of normal function in the skin, and each chapter is ably summarized at the end. This is beautifully done and makes attractive reading. For the rest the authors have ventured on a new approach. There is first an important chapter on taking the medical history, and this section is expanded into a consideration of paediatric, gastric, and tropical problems. Similar space is then devoted to clinical examination of the patient and develops into a consideration of regional dermatology. There are many points of fundamental importance here for all practitioners. It may sound banal to stress the need for examination of the whole patient in a good light, yet often this is neglected even in high circles, with resulting errors in diagnosis. These sections are well conceived, though they sometimes fall a little short of their promise, as in those entitled "Distribution of patterns as an aid to diagnosis" and "Basic pathologic patterns." Great opportunities seem here to have been neglected. Other sections sometimes deteriorate into a catalogue of diseases or unimportant details which cause unprofitable duplication. It would seem better generally, when dealing with broad principles, to keep to this approach and to leave detail for the later clinical sections. A valuable section on therapy might be expanded on the general side, so much more important than local treatment, yet so commonly neglected. Attention here is chiefly directed to steroid hormonal therapy, which is a little out of proportion. The authors' views on radiotherapy will not receive general dermatological approval, although they are, in my opinion, unquestionably sound and essentially wise: Radiotherapy, though not without value, has taken too large a place in the treatment of skin disease. It has dangers, and is a measure that will surely be abandoned before many years are past. But steroid hormonal therapy is also dangerous.

Most of the remainder of the work is devoted to clinical dermatology with avoidance of elaborate and unnecessary terminology. There are few references to the literature, which is wise, for it is the authors' views that are of interest, and the allocation of priorities in description of disease or in the accidental discovery of useful therapeutic measures is not important. The clinical descriptions of disease are good and make easy reading, and the illustrations, all black-and-white, are generally excellent. I should feel that, to be in line with the general purport of the book, more space might be devoted to general and constitutional factors in aetiology—for example, in psoriasis—and treatment is too brief. Some diseases, though not common, are sufficiently important to merit more attention, as parapsoriasis and pityriasis rubra pilaris.

The pattern of the book makes some repetition inevitable, which is no great disadvantage, though it calls for careful editorial scrutiny. Contact dermatitis and the patch-test, for instance, figure extensively under allergy, under dermatitis and eczema, and under industrial dermatoses. The sections on fungous diseases, parasitology, hereditary diseases and psychodermatoses, lymphoma, and most of the field of eczematous dermatoses are very good. The section on tumours is good, but is not simplified by including such affections as sebaceous cysts, urticaria pigmentosa, milium, and naevi generally. There is a tendency to base generalizations on American experience and forget the rest of the world. It is not true in Britain that sycosis barbae is more common in the bearded, or that erythema nodosum is seen with rheumatic fever and is rare in tuberculosis.

These are small criticisms beside the major concept of this work, which is well set out in the preface. We shall look forward to further editions. The editors could usefully do some pruning, for there is a tendency to be a little prolix and there are a few illustrations and diagrams which are of no value. Though we must approve the editors' "inability to maintain an attitude of consistent solemnity throughout," the work is, it seems to me, of too high an order to contain the comic-strip cartoon.

ANKYLOSING SPONDYLITIS

Ankylosing Spondylitis. Clinical Considerations—Roentgenology—Pathologic Anatomy—Treatment. By J. Forestier, M.D., F.A.C.R., F. Jacqueline, M.D., and J. Rotes-Querol, M.D. Translated by A. U. Desjardins, M.S., M.D., F.A.C.P., F.A.C.R. (Pp. 374+xviii; illustrated. 81s.) Springfield, Illinois: Charles C. Thomas. Oxford: Blackwell Scientific Publications. 1956.

This well-produced monograph on ankylosing spondylitis is a welcome addition to high-class rheumatological literature. It is perhaps rather expensive, but it is very well produced. In America, where it is published, the general view is that ankylosing spondylitis and rheumatoid arthritis are merely variants of the same disease. It is possible that this volume may change opinion on this matter. It starts with a brief historical account of the disease, which points out, rightly, that Bechterew's eponymous connexion with this disease is unmerited. In further chapters incidence, diagnosis, spinal and paraspinal symptoms, involvement of the peripheral joints and organs, laboratory examinations, and differential diagnosis are all well dealt with, as is the subject of treatment, in which the authors differ from current practice in this country, mainly in their use of gold and copper salts, thorium X, and amidopyrine. Their orthopaedic approach is in line with our own.

The authors write of their personal experience with a group of 400 cases, and their description of the early symptoms is particularly useful, as these have been understressed in previous works. Early diagnosis is all-important in ankylosing spondylitis. They state rightly that iritis is commoner in this disease than in rheumatoid arthritis, but are wrong in their belief that this is contrary to English opinion. Their account of the x-ray changes to be found at various stages of the disease is clear and detailed, and the plates are well reproduced. The syndrome of ankylosis in the spine of old people, which they regard as a specific entity, is of special interest. The place of radiotherapy and of the steroid hormones in treatment is fully discussed. It is their opinion that the latter should be reserved for severe cases which have failed to respond to normal routine methods—an opinion which finds general acceptance in this country. It is surprising, however, that they do not mention the use of local intra-articular injections of hydrocortisone in the control of active peripheral joint lesions. There is a comprehensive and useful list of 270 references. This book should be read not only by rheumatologists, but by all general physicians who have, or should have, any interest in this disease.

LIVER DISEASES

Diseases of the Liver. Edited by Leon Schiff, M.D., Ph.D. Foreword by Cecil J. Watson, M.D., Ph.D. (Pp. 738+xix; illustrated. £5 10s.) London: Pitman Medical Publishing Co. Ltd. 1956.

This textbook contains 26 chapters written by 28 different authors. Most of the writers are American, but Britain is represented by N. F. MacLagan, W. B. Matthews, and Sheila Sherlock. It is a heavy book with 735 large pages printed in double columns, but it is not unpleasant to read, as the type is large, legible, and pleasingly spaced and there are numerous illustrations. It does not pretend to be encyclopaedic, though the chapters are well documented with references; it is rather a primer of current knowledge about the common diseases of the liver. It begins with accounts of the anatomy, physiology, biochemistry, and experimental pathology of the liver. There are then descriptions of liver-function tests and needle biopsy of the liver, and discussions of jaundice, portal hypertension, and hepatic coma. Ascites is not given a chapter to itself, but is discussed rather briefly in the chapter on cirrhosis. The various forms of hepatitis and cirrhosis are fully described. Infections, parasites, and tumours of the liver all receive attention, and there is a chapter on amyloidosis. Zuelzer has an excellent chapter on liver diseases in infancy and childhood, but there does not seem to be any mention of veno-occlusive disease in infancy or of Chiari's syndrome. Macfarlane Burnet's stimulating ideas on subacute hepatitis as an autoimmune disease due to failure of the self-recognition mechanism probably appeared too recently for inclusion. There is a long final chapter dealing with diseases of the gall-bladder and extrahepatic bile ducts. This is a book one can commend to the average postgraduate student, though more serious workers will probably find it lacking in brilliance.

A DOCTOR OF MANY PARTS

One Doctor in His Time. By Bethel Solomons, M.D., F.R.C.P.I., F.R.C.O.G., M.R.I.A. (Pp. 224; illustrated. 18s.) London: Christopher Johnson. 1956.

"One doctor in his time" (Solomons) "... plays many parts" (Shakespeare). Many doctors have proved this point, but none better than Dr. Bethel Solomons, who, in his time, has appeared in so many roles and in so many acts. In this one he rightly plays the lead in rapidly shifting scenes, and does so with buoyancy backed by an excellent memory for people and places. He creates for readers a vivid picture of the man himself. We see him at school, at Trinity College, and in practice in Dublin. We see him as the Master of the Rotunda (not to be mistaken for one of the Irish hunts); as a lecturer in the U.S.A.; as President of the Royal College of Physicians of Ireland; as a member of the Irish Rugby Football team and later as one of the Irish selectors. We see him at the bridge table, on the ski slopes, and in the hunting field—which he first invaded at the age of 46 years. We see him on the stage at the Abbey Theatre, and fraternizing with writers, actors, and artists of all kinds. We see him in his own home as a gracious host, and in many other homes as an entertaining guest. Last, but not least, we see him as an obstetrician and gynaecologist who, expecting—no doubt rightly—that his autobiography will appeal to lay as well as medical circles, indulges in asides to give popular advice on sundry medical matters. There is a forthrightness about this book which allows even frank mention of Jewry (Orthodox and Liberal) and anti-Semitism. It is pervaded by the atmosphere of old-time Dublin into which creeps for a few moments a galaxy of great people chosen from many spheres of life. Some readers may think that there are too many small parts and that these are too small—little more than a "walk on" in many cases. The named cast, given in the form of an index, is approximately 300. Mention of so many will have a special appeal for those who are familiar with Dublin and its folk. Those less intimately

associated may find themselves wishing that the author had done more than whet the appetite about certain people and events, even if this had meant the exclusion of others.

AN AMERICAN VOLUNTARY HOSPITAL

Hunterdon Medical Center: The Story of One Approach to Rural Medical Care. By Ray E. Trussell. (Pp. 237+xxii; illustrated. 30s.) Cambridge, Massachusetts: Harvard University Press for The Commonwealth Fund. London: Oxford University Press. 1956.

Hunterdon, a county in the State of New Jersey with 43,000 inhabitants, had no hospital, and this book tells the story of the provision of a hospital service. The hospital has several interesting and unusual features. It is closely connected with New York University-Bellevue Medical Center; the Hunterdon hospital junior staff appointments are included in the Bellevue rotating internships, and the directors of the various services in the local hospital have part-time teaching responsibilities in the Bellevue Medical Center. The hospital provides routine medical examinations and various public-health services in addition to the customary in-patient and clinical facilities. The patients are in the care of their general practitioner, but are under the control of the director of the appropriate service, who must approve the treatment of patients, which is routinely conducted by the interns. The specialists, of whom there are twelve, are whole-time and pool their fees, so that the salary of the paediatrician is equal to that of the surgeon. The initial capital outlay worked out at 50 dollars per head of the community and was raised by subscription. The fees, which are thought to be high by some of the rural patients, are fixed at the "Blue Shield" rates (which are not stated), and can therefore be fully covered by the "Blue Shield" hospital insurance. The indigent are treated free, and the cost of their treatment is borne by the community. The standard of hospital care provided in Hunterdon is comparable with that which can be purchased by the wealthy in this country; indeed, the payment of the "Blue Shield" hospital insurance would be beyond the capacity of the average British family budget.

It will be readily seen that there are some features of the scheme, such as the submission of the general practitioner to consultant control and the conflict of the group consultant with the private specialist outside, which must raise problems—administrative, ethical, and personal. Such experiments in the provision of hospital services in the United States and Canada will continue to be watched with great interest by all engaged in the National Health Service here.

SKELETAL ROENTGENOLOGY

Borderlands of the Normal and Early Pathologic in Skeletal Roentgenology. By Alban Köhler. Tenth edition by E. A. Zimmer. English translation arranged and edited by James T. Case, M.D., D.M.R.E. (Pp. 723+xiv; illustrated. \$24.50.) New York and London: Grune and Stratton Inc. 1956.

This English translation of the tenth German edition of Köhler's famous work will be welcomed by all who are interested in the detail of skeletal structure. It has been brought fully up to date by Zimmer, of Berne, and is a goldmine of accurate information. It is superbly produced, and the elaborate plates and diagrams are described so clearly that one is apt to forget the vast labour that must have gone to their production. An immense bibliography is included for those who are engaged in research. We would express our gratitude to the translator who has brought this great work within the reach of all of us, and we would hope that it will soon be available in every library where it can be consulted by surgeons as well as by radiologists, for to both it furnishes a work of reference unique in its value and importance.

MELANOCYTE-STIMULATING HORMONE
AND CORTICOTROPHIN

Melanocyte-stimulating hormone (M.S.H.) is one of the names given to a substance found in the pars intermedia of the pituitary gland. It was recognized as a hormone over thirty years ago as a result of the work of W. J. Atwell¹ and of L. T. Hogben and F. R. Winton² on the ability of pituitary extracts to cause darkening of the skin in certain amphibia, particularly the frog. The darkening of the frog's skin in dark surroundings and its paling in light surroundings are largely controlled by the secretion of M.S.H. The blackening of the skin appears to be due to a dispersion of the melanin in the melanocytes³ under the influence of the hormone. Other names given to M.S.H. are intermedin, melanophore-expanding hormone, and melanin-dispersing hormone. Although various types of action in influencing metabolic activity have been ascribed to M.S.H. from time to time, it has long been uncertain what part this substance plays in mammalian and human economy. The hormone is certainly present in the pituitary glands of species in which no simple activity of the type observable in the frog can be shown. There is now good evidence that in man and animals skin melanin can be formed in the cytoplasm of melanocytes⁴ and that extracts of pituitary tissue rich in M.S.H. activity can bring about an increase in the quantity of melanin in amphibian and human skin.⁵⁻⁷

For some time now the possibility has been considered that the darkening of the skin in Addison's disease might be due, perhaps in part, to the action of M.S.H. In 1952 S. Johnsson and B. Högborg⁸

showed that the blood of patients with Addison's disease is abnormally rich in M.S.H. activity. Their blood would be expected also to be rich in corticotrophin (A.C.T.H.) because of the low concentration of corticosteroids in the blood.⁹ A high level of M.S.H. activity is also found in the blood of patients with Cushing's syndrome, of those subjected to stress, and of pregnant women, where again a high concentration of corticotrophin in the blood is to be expected.¹⁰ In view of these observations, together with the fact that the most highly purified preparations of corticotrophin available possessed M.S.H. activity, the suggestion put forward in 1952 by S. Johnsson and B. Högborg⁸ and by F. G. Sulman¹¹ that M.S.H. and corticotrophin might be identical commanded some attention. Since, however, corticotrophic activity is destroyed by treatment with hot dilute alkali under conditions in which M.S.H. activity may be retained and prolonged,¹²⁻¹³ the two activities cannot be ascribed to the same chemical structure. This is not in itself evidence that the two structures are in different molecules; but evidence that the two activities do indeed reside mainly in different molecules was provided by the comparative ease of almost complete separation of corticotrophic and M.S.H. activities.¹²⁻¹⁴ Johnsson and Högborg¹⁴ accepted this evidence against their former suggestion of identity, while F. G. Sulman¹⁵ modified his hypothesis, proposing instead that M.S.H. is one "factor" in "the A.C.T.H. complex." This relationship was not closely defined, but suggested simultaneous secretion and perhaps also loose combination of two molecules. Such a suggestion is perhaps unexpected in view of the 100-fold difference in the ratio of corticotrophic and M.S.H. activities¹² between pituitary anterior lobes, which are rich in corticotrophin, and intermediate and posterior lobes, which are rich in M.S.H.¹⁶ An even clearer difference in the ratio of activities between concentrates from anterior and posterior lobes was found by F. W. Landgrebe and C. J. O. R. Morris.¹⁷

The fact that the two types of activity remain together during much of the process of purification

of corticotrophin¹⁸ can now be attributed to chemical similarities in the structures of M.S.H. and corticotrophin. These similarities became clear once the hormones had been isolated. In 1955 A. B. Lerner and T. H. Lee,¹⁹ J. O. Porath *et al.*,²⁰ and B. J. Benfey and J. L. Purvis²¹ all independently isolated apparently pure melanocyte-stimulating substances from the pituitary glands of pigs. All these workers used oxycellulose adsorption, which F. W. Landgrebe and G. M. Mitchell²² had first applied to the purification of M.S.H. T. H. Lee and A. B. Lerner²³ have since suggested that there exist two types of the hormone in pig pituitary glands, the α and the β types. Their β type appears to be identical with that isolated in 1955 by the other workers cited, and also with that isolated by I. I. Geschwind, C. H. Li, and L. Barnafi²⁴ in 1956. These purified preparations of M.S.H. appear to be lacking in detectable corticotrophic activity where they have been tested. Nevertheless corticotrophin does possess some melanocyte-stimulating activity—about 1/150 of that of purified M.S.H., according to F. W. Landgrebe (cited by H. B. F. Dixon²⁵). Dixon inactivated corticotrophin by treatment with hydrogen peroxide and subsequently partially reactivated it by treatment with sulphhydryl substances according to the method of M. L. Dedman, T. H. Farmer, and C. J. O. R. Morris.²⁶ In the mixture resulting from the partial reactivation the corticotrophic and M.S.H. activities could not be mutually separated under the conditions of the experiment, although the unregenerated inactive substance was separated from the reactivated material and was devoid of both activities. In other words, chemical alteration, followed by regeneration, of corticotrophin went hand in hand with the loss and recovery of both its corticotrophic and melanocyte-stimulating activities: this might be considered as evidence that both activities can be ascribed to the same molecule. That the M.S.H. activity of corticotrophin was an intrinsic property of the molecules and not due to contamination with M.S.H. itself had already been suggested by C. A. Winter *et al.*²⁷ and by P. H. Bell,²⁸ on the basis of the constancy of the small amount of melanocyte-stimulating activity still possessed by rigorously purified corticotrophin. This residual M.S.H. activity is much less than that to be found in the preparations of corticotrophin now generally available for clinical use, and this suggests that these preparations are significantly contaminated with M.S.H.

The possession of M.S.H. activity by both M.S.H. and corticotrophin might be expected to reflect a similarity in the order of amino-acid residues in their molecules. This similarity was revealed when their

structures were elucidated. The structure of corticotrophin was first determined by P. H. Bell and his colleagues.²⁸ Comparable findings were independently published by W. F. White and W. A. Landmann,²⁹ while C. H. Li and his colleagues³⁰ also found a similar structure. It is a peptide containing 39 amino-acids in a single chain. Recently J. I. Harris and P. Roos³¹ have completely elucidated the chemical structure of one type of M.S.H., that which corresponds with the β -M.S.H. of T. H. Lee and A. B. Lerner.²³ Harris and Roos find their M.S.H. to be a peptide of 18 amino-acids in a single chain, a sequence of seven amino-acid residues being common to their structure for M.S.H. and that of corticotrophin. In this way a chemical basis for the intrinsic M.S.H. activity of corticotrophin has almost certainly been revealed. Subsequently I. I. Geschwind, C. H. Li, and L. Barnafi²⁴ have come to similar conclusions about the structure of the M.S.H. which they have isolated.

H. B. F. Dixon³² has found that mild treatment of corticotrophin with periodate destroys the corticotrophic activity of the substance without discharging its small melanocyte-stimulating action. Under the conditions in which it was used periodate would be expected to attack only the amino-acid residue of serine at the end of the peptide chain of corticotrophin, and to leave unchanged the sequence of seven amino-acids common to β -M.S.H. and to corticotrophin. This evidence therefore strengthens the likelihood that this sequence is responsible for the M.S.H. activity of corticotrophin. There is the possibility that with M.S.H., as with corticotrophin,³⁰ insulin,³³ and vasopressin,³⁴ species differences in the chemical structure of a peptide hormone may exist.³⁷

Many problems remain. Why is the blood of patients with Addison's disease rich in both M.S.H. and corticotrophin? Why does treatment with cortisone appear to lower the concentration in the blood of both these hormones?³⁵ Why does such treatment nevertheless alter to different extents the amounts of these hormones found in the pituitary gland?³⁶ Investigation of the control of the secretion of corticotrophin and M.S.H. may disclose clinical, and perhaps evolutionary, relationships of these two hormones that are at present only vague possibilities. Certainly the investigations of the biochemists have opened up entrancing new fields of study. The growing inter-action of the clinical and biochemical aspects of this subject may be reflected in the notable contributions made by the dermatologist A. B. Lerner^{7 19 23 35} to the fundamental biochemistry of M.S.H. and of melanogenesis.

SIR VICTOR HORSLEY

The three opening articles in this week's issue of the *Journal* pay tribute to the centenary of the birth of Sir Victor Horsley. His is a name which will endure as the pioneer of neurosurgery, even though he was in point of fact not the first surgeon to remove a brain tumour. Horsley's physiological researches and his work upon the surgery of the brain and spinal cord broke fresh ground in a unique fashion. His early career was spent in the propitious intellectual atmosphere of University College, London, for he studied in close contact with such inspiring teachers as Bastian, Russell Reynolds, and William Gowers. In his Centenary Lecture, delivered last week in B.M.A. House, Sir Geoffrey Jefferson has painted a vivid picture of Horsley, his background, his career, and his place in the medical pantheon. Sir Arthur MacNalty, who had the great advantage of having known Horsley personally and having worked with him, has been able to give us a fascinating glimpse behind the scenes. He reminds us that Horsley was an artist of no mean ability: while still a young demonstrator of anatomy at University College Hospital he executed the drawing which has since become so familiar to all students, showing the morphological relationships of the spinous processes, the vertebral bodies, and the segments of the spinal cord.

Horsley will also be remembered as being the first surgeon ever to operate successfully upon a case of spinal tumour. In 1887 an Army officer aged 43, suffering from a spastic weakness of both legs, came under the medical care of William Gowers. The clinical diagnosis of spinal tumour was made. Already Gowers had toyed with the notion that such a type of lesion was surely one which would lend itself to successful surgery. Accordingly, with the moral support of his old chief, Sir William Jenner, Gowers invited his young surgical colleague Horsley, then 30 years of age, to see the patient and to operate. This was performed in the surgical theatre at the National Hospital, Queen Square, on June 9, 1887, in the presence of Gowers, Edmunds, and Percy Kidd. Dr. White was the anaesthetist on that great occasion, and Mr. Steadman and Mr. (afterwards Sir) Charles Ballance acted as surgical assistants. A tumour, which proved to be a fibromyxoma, was found attached to the 4th thoracic root on the left side of the spinal cord, and was removed successfully. In less than six months the patient was walking, and a year later he was back at full duty.

Inevitably there was somewhat of a clash of personalities between Horsley and that other neuro-surgical pioneer, Harvey Cushing. The latter first

visited Horsley in 1900, Cushing then being 31 years of age. But having seen Horsley at work, Cushing shied: he behaved rather like Walter Pater, who shrank from reading Stevenson or Kipling lest their stronger style might infect his own. Cushing felt that the refinements of neurological surgery could not be learned from Horsley, and he went elsewhere. None the less, in later years he maintained a friendly correspondence, and he even sent one of his pupils, Ernest Sachs, to work with Horsley. That this was a successful visit can be judged from Dr. Sachs's reminiscences (p. 916).

Horsley was a man of strong personality, overbearing perhaps, and impatient of criticism. His active mind and abundant energy could not be contained merely by his professional techniques. For the last twenty-five years of his life the B.M.A. was one of his main interests, and he left his mark on the history of the Association, for he was largely responsible for the reform of its constitutional machinery fifty-six years ago. He filled nearly every important office in the Association except those of President and Chairman of Council. His public activities went well beyond the boundaries of medicine, and as a politician and propagandist he became familiar to his contemporaries, even to the verge of unpopularity, by reason of his enthusiastic sponsorship of such causes as women's suffrage, teetotalism, and liberalism. As Sir Geoffrey Jefferson puts it, "Maybe he fished too much in troubled waters." But as a doctor he had all the admired virtues: in a tribute written at the time of his death, Wilfred Trotter wrote: "In dealing with his patients Horsley consistently showed a deep and tender humanity very much at variance with the picture of him which it is to be supposed the public allowed itself sometimes to draw." Horsley's great drive finally became canalized along patriotic lines. Despite his years, he volunteered for wartime service. He served in the Army at first in a ludicrously low rank, and died in 1916 on active service in the Mesopotamian desert.

RETIREMENT AND EMPLOYMENT

A recent Bill amending the national insurance provisions enables pensioners under 70 (65 for women) who have retired to return to work and become eligible for increases in the weekly pension they will eventually draw. It is thus a valuable incentive to older persons to resume working. But we know relatively little about the ways in which the newly retired adjust to their new conditions or about their willingness or otherwise to return to work if it is available. A careful study made by I. M. Richardson¹ is an interesting addition to our

knowledge of the subject. It was based on an examination of a sample of 244 retired men between the ages of 65 and 75. Its aims were to examine the reasons given for retirement and the use made of it, with special reference to possibilities of re-employment.

Two previous surveys, one made in 1950 by G. Thomas and B. Osborne² for the Social Survey, the other made by the Ministry of National Insurance in 1953,³ had already established that ill-health and the enforcement of a fixed retirement age by the employer are the main reasons given by workers for their retirement. Richardson's survey confirmed these findings, action by employers being a common reason at 65 but relatively unimportant over the age of 70, when ill-health predominated. He points out, however, that the significance of compulsory retirement at 65 may be exaggerated, since it is not known how many of the men affected would have retired in any event for some other reason, such as disability; hence the effectiveness of relaxing the age restriction to working life imposed by some employers cannot be estimated. Moreover, while Richardson accepts ill-health and action by the employer as the most commonly recurring factors in determining a man's time of retirement, he emphasizes that for the majority of the men interviewed it was a combination of factors that finally decided the question. For example, in a minority of cases at any rate it was evident that family opinions and circumstances had strongly influenced the individual's decision, and future studies might well pay attention to the role of the family here.

Richardson next considers the possibilities of re-employment when a man has once retired. Fitness for work is obviously a major factor, and as a result of an attempt to grade his subjects on this basis he reaches the tentative conclusion that more than 50% had a disability of occupational significance. The three leading causes of disablement discovered (cardiovascular disease, arthritis, and chronic bronchitis) all impose restrictions on mobility. If these conclusions can be regarded as generally valid, they would point to serious limitations on the size of the pool of retired workers from which new recruits to industry might be drawn. But if a man is to return to work after retirement he must not only be fit but also sufficiently keen to make the effort required to start again. As the result of careful investigation Richardson discovered that only 54% of the wholly retired men in his sample were "content" with their position, and about one-third said that they wanted to resume work. Not many of these had actually tried to find it, however, and he concludes, "it may well be that, at and soon after the time of retiring, there is a more active interest in opportunities for work, but as time passes the retired man's enthusiasm seems to wane." So it would appear essential to avoid any long interval

between retiring from one job and finding another. Once the routine of retirement is established, it is difficult to break.

In the final section of his study Richardson investigates some of the characteristics of the life of a retired person. He emphasizes the importance of the learning period when new habits are formed, a new daily routine established, new attitudes acquired, and suggests that in Great Britain we have thought little about the different ways in which help and encouragement might be given to men and women to use their retirement constructively. Finally, he also gives some consideration to the complex theme of family relationships during these years. Here the conclusions he draws are generally optimistic. Like the National Assistance Board in its study made in 1954 of a group much more likely to be dependent (men and women over 80 in receipt of assistance),⁴ he repudiates the tendency to regard all old people as problems: "the truth is that the majority live largely independent lives and only a minority present one or other kind of serious problem." This is worth emphasizing, as is the support he gives to the finding of several other investigations that in most cases old people are in close touch with their relatives and "family duty" is well done. Nevertheless, the socio-medical problems of old people needing the support of family and friends but either lacking it or rejecting it are sometimes serious and difficult, while the strains imposed by the older generation on the younger can be considerable. As Richardson points out in his concluding paragraph, "the complex dynamics of inter-generation relationships are only beginning to be understood," and the answers to many questions must await the outcome of further research.

DRUG COSTS

A scheme for regulating the prices of proprietary drugs was announced by the Minister of Health last week. The Association of British Pharmaceutical Industry has been working on it and arguing points with the Ministry for the last two and a half years. Stating that the Government has accepted the scheme in principle, the Minister said he hoped it would begin operating in the next two months. It covers over 4,000 products and has three main provisions which enable manufacturers to regulate maximum prices voluntarily. They are given in our Parliamentary report at page 955. When the scheme begins, existing prices will be brought down if necessary, but not brought up, to the levels determined by its provisions.

The background to all this is a rumbling barrage of Parliamentary questions to successive Ministers of Health ever since the Health Service began. The thought has often occurred to M.P.s of divers political creeds that the cost of the Health Service could easily be cut if doctors included a smaller proportion of

proprietary preparations in their prescriptions. The figures show that this idea has not made much headway in the medical profession, and there are several good reasons why it has not. One is that many proprietary preparations have no so-called official equivalent, because the pharmaceutical industry, by virtue of its research, has introduced most of the potent new drugs. Another is that, among those drugs which have an official equivalent, there are many whose equivalence is more apparent in official circles than in the doctor's surgery. Again, a considerable number of the proprietaries are cheaper than their official equivalents,¹ while among those which are not only a few can be found whose price seems to call for criticism. Consequently, as might be expected, the estimated saving under the new scheme is small—about £750,000 a year on a drug bill of over £50m. Nor is the need for drastic saving particularly evident. Between 1949 and 1956 the cost of prescribing in general practice, after allowing for the increase in the cost of living (or inflation), rose by 17%.² This figure might well be attributed to the introduction of new and more efficacious drugs, resulting in lives saved and earlier return to health and work.

A recent analysis of barbiturate tablets carried out by H. H. Bagnall and F. G. Stock³ provides some evidence of why the doctor's judgment in sometimes preferring a proprietary to its equivalent is sounder than the politician's. They took 343 samples of barbiturate tablets; these comprised 11 samples of various proprietary tablets and 332 samples of 14 different types of barbiturate supplied by the manufacturers as conforming to B.P. specifications. The 343 samples included the products of 36 manufacturers plus a few of uncertain origin. Tests to see whether the tablets were up to B.P. requirements revealed some striking discrepancies. All of the proprietary tablets were found to be correct. Of the 332 non-proprietary samples 79 were found to be incorrect. Differences between the firms were notable; four firms, for instance, had been the manufacturers of 83 correct samples, whereas 42 incorrect samples were found out of 67 made by two firms. Disintegration tests showed times ranging from 1 minute up to the indefinite: some tablets had not softened after a week's immersion in water. Shelf life, or speed of deterioration on storage, was found to differ greatly, and the authors suggest that "a very good case could be made out for requiring all drugs to be labelled with their dates of manufacture." Another possibility is that all drugs as supplied to the patient should be labelled with the manufacturer's name. Experience has shown time and again that the named product, whatever it may be, is more to be relied on than the unnamed; the manufacturer who takes care to maintain quality puts his name on his products. In the old days, when pills and mixtures were dispensed on the premises, the patient often had a shrewd idea of which chemist in his town did the job best, and chose accordingly. By contrast, it is not so easy for doctor or patient to discriminate between the boxes of anonymous tablets handed over the counter nowadays. However that may be, good prescribing will always be economical prescribing, and

doctors will no doubt continue to rely more on their own informed judgment than on the judgment of parties whose chief aim is either to promote sales or to restrict them.

INTRA-ARTERIAL OXYGEN

In 1934 W. H. Chase¹ noted a curious thing about the behaviour of blood vessels after intra-arterial injection of gases when he reported seeing the vessels of the rabbit's mesentery dilate after air embolism. M. Villaret and R. Chachera² further observed that, whereas solid emboli always provoked vasoconstriction, air bubbles never did—on the contrary, dilatation often ensued. Lately, F. Duff and his colleagues³ have examined the physiology of this response in detail in the healthy human forearm. They injected a few millilitres of various gases into the brachial artery and found that the blood flow through the forearm increased some three or four times, irrespective of the gas used and despite an initial slight fall in flow when the bubbles first entered and blocked some of the smaller vessels. The most remarkable feature of the response was its persistence; normal flows were not regained for 48 hours or more. Duff and his colleagues are inclined to believe that the gas emboli inflict some injury on the tissues, a product of which (not histamine) causes the vessels of the part to dilate. The nervous system was found not to be concerned in the response.

Such long-lasting dilatation might well be of therapeutic worth, and in France and Germany numbers of patients with arterial disease of the limbs have been so treated. A. Lemaire, J. Loeper, and E. Housset⁴ in Paris were the pioneers, and in 1953 reported 58 cases. From Germany, M. Ratschow⁵ and W. Fey and W. Boxberg⁶ between them reported over 200 cases in 1956. They used repeated injections into the femoral artery of oxygen gas in volumes of 40 to 100 ml. or more. In the arm much smaller volumes were used. Complications have been few. The chief danger is that bubbles may be carried proximally and find their way into viscera, including the brain; a death has been reported from cerebral air embolism. Slow injection and insistence upon the patient lying flat for three-quarters of an hour after injection prevent such mishaps. Generalized urticarial reactions and severe pain associated with intense vasoconstriction in the treated limb are also occasionally encountered. A spastic phase, during which the skin becomes white and the pulses disappear, is the normal initial response of the limb to the injection; noises due to the gas bubbles may be heard with the stethoscope. This is soon succeeded by a hyperaemic phase, and the skin temperature remains raised for the next day or two. Of the patients treated, those with the milder forms of arterial obstruction obtained most benefit. In Fey's series three-quarters of the patients with

exercise pain alone improved their walking distance, whereas of patients in whom necrosis was present only about one-quarter benefited. Indeed, if tissue damage is the mode of action of gas therapy, great caution is necessary in treating patients with tissues already anaemic. In a recent report published in this *Journal* R. J. Marshall and R. F. Whelan⁷ described the encouraging results they obtained with intra-arterial oxygen in the treatment of 18 patients with peripheral vascular disease (Raynaud's phenomenon, intermittent claudication, and ischaemic necrosis of feet). These authors believe that, rightly applied, it is a safe method of treatment, but warn against its use in patients with very low resting blood flows or in those with recent occlusion of a major vessel.

Generally speaking, chemical vasodilators have proved disappointing in treating occlusive arterial disease. Perhaps the mechanical effects of gas bubbles have something better to offer.

HUMAN TUMOUR TRANSPLANTS IN ANIMALS

Great efforts have been made in Britain and the U.S.A. to find a suitable testing-ground for chemotherapeutic substances believed to have a selective effect on cancer cells. The pioneer work on the transplantation of human tumours was carried out by M. T. Carrell and H. Burrows¹ in 1913: they showed that such tumours could be transplanted and grown in animal hosts. From then on little interest was taken in the technique until 1938, when Dr. H. S. N. Greene,² of Yale, published his results on transplantation of human tumours into the anterior chamber of the guinea-pig's eye and the rabbit's brain. Prompted by the idea that this might prove a useful technique for studying the efficacy and action of anti-cancer substances, Dr. Helene Toolan,³ of the Sloan-Kettering Institute in New York, devised her method of injecting a finely minced suspension of tumour below the skin of the abdominal wall in rats or of implanting a tiny fragment or suspension of tumour into the cheek pouch of the hamster. Transplants of this sort will not take in a normal animal, since the host's tissue reaction overwhelms the implant, which is very vulnerable, being without a blood supply or protecting stroma. For this stage of vulnerability to be overcome and for the tumour to be put in a position to survive and grow, the host reaction has to be modified by first treating the animal either with x rays to the total body or with cortisone injections, or with a combination of the two. Tumours growing in this way and used for chemotherapeutic trials can be easily palpated and measured with callipers, and change in their size thus assessed.

The advantages of the method were obvious, but its critics said that a human tumour treated in this way lost its human character and became an animal tumour. One way to refute this criticism would be to show that one of these tumours after passage through animals

could again be grown in the original host—but to find such a host would require very exceptional circumstances. By an extraordinary chance this test was able to be performed. A patient named Mrs. Fernandez was admitted to the Memorial Centre with cancer of the cervix which was pronounced inoperable. A piece of the tumour was taken for biopsy and part of this was taken for transplantation into an animal. The implant was successful. On hearing this, the patient, in spite of knowing her hopeless prognosis, took an intelligent interest in the animal experiments and indeed seemed to derive some consolation from it. From questioning the staff and reading of this sort of work in the lay press she realized that the final test ought to be reimplantation of the tumour, now growing in rats. At her suggestion and with her consent this was done: a piece of tumour was implanted below the skin of her forearm. That the implant took was proved when the nodule was excised and examined microscopically. Dr. C. P. Rhoads reported this unique experiment in his recent Imperial Cancer Research Fund lecture at the Royal College of Surgeons. Through the courage of the patient who offered herself for this experiment, the important biological fact has been established that a human tumour grown in animals retains its human character. Her example has been followed by the prisoners in Ohio gaol who volunteered to have living cancer cells implanted below their skin.⁴ In these experiments the tumour implants failed to grow, showing that the normal host was able to destroy the cancerous implant.⁵ This work marks another stage in the study of tumour-host relationships and of the problems of cancer growth and spread.

"PUBLIC HEALTH"

Public Health, the journal of the Society of Medical Officers of Health, was first published in 1888, and ever since it has kept members informed of the activities of the society and published work of interest to those working in the preventive medical services. Eighteen months ago the familiar utilitarian buff cover gave way to a more dignified design of black on green, and at the same time the paper was improved and a larger type-face used. It now turns out that these improvements were only a foretaste of better things to come, for this month *Public Health* appears in a completely new and much more readable form, with a single-column page, larger type, and a lay-out more in line with other monthly medical periodicals. No doubt the new publishers of the journal, Baillière, Tindall and Cox Ltd., are responsible for some of these agreeable changes, but the editors are also to be congratulated on the contents of the first number of this new volume. As a former editor of *Public Health* wrote not long ago: "The editor of a journal which is the official organ of a learned society must, we believe, always bear in the forefront of his mind that the journal he edits is the only regular link between its sponsoring body and many of the members."¹ *Public Health* in its new guise should do much to strengthen this link between the society and its members.

PSYCHOLOGY AND MEDICINE

BRITISH PSYCHOLOGICAL SOCIETY

[FROM A SPECIAL CORRESPONDENT]

The annual conference of the British Psychological Society was held at St. Andrews University from March 28 to April 2. A large number of the papers were of medical interest and some of them are summarized below.

Rehabilitation of Chronic Schizophrenics

Dr. N. O'CONNOR, Ph.D., an M.R.C. research psychologist, gave the first of the clinical papers. His subject was the rehabilitation of chronic schizophrenics. The magnitude of this problem will be realized from the fact that the best estimates reckon chronic schizophrenics as comprising 70% of all chronic mental patients. In mental hospitals there is increasing emphasis on the social and occupational treatment of chronic schizophrenics, not only as a means of preventing their further deterioration, but also to prepare even those severely affected for return to life outside. Although, over the years, enthusiasts have obtained good results from such rehabilitation, the factors that initiate and maintain improvement are still largely unknown. Dr. O'Connor's paper dealt with a study of chronic schizophrenics given a simple industrial task. Their performance was found to be very low, but they improved with practice and eventually achieved 85% of the level reached by a control group of normal subjects. Whereas most schizophrenics improved in a manner similar to normal subjects, a group of paranoid schizophrenics showed a type of improvement quite unlike the others. Instead of an initial rapid improvement, slowing down as it reached the maximum, these patients improved steadily and continuously to their maximum. On theoretical grounds it was suggested that this pattern of improvement was due to some difference in their motivation related to their particular psychological make-up. Their training might therefore require a rather special technique. A paper by Dr. ANNE BROADHURST, Ph.D. (Springfield Hospital, Tooting), on the mental functioning of chronic schizophrenics showed that, after practice tests for mental speed, they actually improved more rapidly than normal subjects, even though their final level was below normal. Ordinarily schizophrenics show abnormally slow mental functioning.

A Biological Approach to Child Development

From the medical point of view the most interesting part of the meeting was the symposium on child development. The symposium was opened by Dr. JOHN BOWLBY (Tavistock Clinic, London), who gave a simple account of ethology and its clinical implications. He defined ethology as the "study of species-specific behaviour-patterns." A central problem for both clinical and social psychology was, he said, the nature and development of the child's relationships with other people. Psycho-analytic theory was concerned with human instincts, their development, organization, and conflict, and these, it was held, were the determinants of human behaviour. Unfortunately, although clinical reports were voluminous, records of systematic observations were few, experimental methods were conspicuously absent, and hypotheses were often so framed that they were not susceptible of testing. It was here that the example of the ethologists, with their descriptive and experimental studies of the development of social behaviour, family relationships, and conflict and defence mechanisms in lower organisms, was able to offer a scientifically rigorous method of approach.

The pioneer of this approach was Darwin. In his chapter on instinct in the *Origin of Species* he noted that each species was endowed with as specific a repertoire of inherited behaviour-patterns as it had specific anatomical structure. Modern ethologists had identified a number of the specific stimuli—"sign stimuli"—that elicited these patterns of behaviour; they were often fairly simple visual or auditory

signals to which the organism was innately sensitive. Where these behaviour-patterns mediated social behaviour, much light had been thrown on the nature of social interaction. The concept of sign-stimuli able to release or suppress social behaviour—"social releasers" or "social suppressors," as they were called—would, Dr. Bowlby believed, prove valuable in the study of social relationships in man. Of course, internal conditions, such as hormone levels and the degree of maturation of the central nervous system, also played an important part in initiating and terminating behaviour. In the growing individual, species-specific behaviour-patterns often underwent critical phases of development, when certain of their characteristics were established either permanently or nearly so. These critical phases usually occurred very early in the life cycle, and during them were determined not only whether a particular response appeared at all, but also its form and intensity and the particular stimuli which activated or terminated it. It was essentially in these critical phases that modification of behaviour by learning occurred. In the animal kingdom conflicting impulses were a commonplace, and the outcome of such conflicts was very varied and sometimes as maladaptive as in man. Much could probably be learnt from studying the ways in which such conflicts were regulated in animals. He thought that here too critical phases would be found, and this might well provide a key to understanding the origin of neuroses.

An example of the ethological approach to clinical problems was the work on the social behaviour of babies. There was little doubt that a baby's smile acted as a social releaser: one of its functions was surely to evoke maternal behaviour in the mother. Although the earlier workers had discovered that the sign-stimulus for the baby's smile was the human face—or a representation of it equipped with two "eyes"—they had not recognized this smiling as an innate response. As the infant grew older a more complex stimulus was needed to evoke its smile. The fact that this behaviour was influenced by learning did not contradict the view that the response was originally innate. Crying, sucking, and smiling were, he suspected, some of our many "built-in" motor patterns, representing Nature's insurance against leaving everything in man to the hazard of learning. In this context it was relevant to recall Freud's belief of over forty years ago that, for a further understanding of instinct, psychology would have to look to biology. The biologically rooted science of ethology, said Dr. Bowlby in conclusion, would probably enable them to recast the psycho-analytic theory of instinct.

Other Theories of Child Development

Dr. C. B. HINDLEY (Institute of Education and Child Health, London) gave an account of the contribution of "associative learning" theories to the problems of child development. On the basis of the inherited tendencies of the infant, the various learning principles, including classical conditioning, trial-and-error learning, and the acquisition of secondary drives, could explain the formation and development of later characteristic modes of behaviour. In infants, conditioning had been found in the second week and was quite strong by six weeks. The first phase of learning was discriminative and abstractive, and restriction of perceptual experience had been found to be more damaging than restriction of motor experience. Work on chimpanzees, continued Dr. Hindley, had shown that critical periods were not as important as in the lower animals. The theory that reduction of anxiety acted as a reinforcement had already proved useful in clinical medicine, and the finding that enuretics had often had an exceptionally frustrating habit-training was a good example of the ability of frustration to "fix" behaviour. However, provided allowance was made for maturation, there was no essential contradiction between ethological and learning theories.

Dr. CECILY DE MONCHAUX, Ph.D. (University College, London), discussed the contribution of psycho-analysis. The original psycho-analytic formulations about child development had been based on the analysis of adult patients, she

said. But later they had been confirmed by studying children. While observation of adults in regressive states had led to deductions about children's unconscious fantasies, it had required the analysis of children to reveal the details of the defence mechanisms which were used to deal with these fantasies at different stages of development.

Dr. E. J. ANTHONY (Institute of Psychiatry, London) then gave a historical account of the development of Piaget's system, and contrasted it with the Freudian system.

First Social Relationship

Mr. J. A. AMBROSE (Tavistock Clinic, London) then described, from an ethological standpoint, a preliminary study forming part of a wide programme of research on the processes underlying the development of the infant's attachment to its mother—its first permanent social relationship. The study concerned the variations of the smiling response of babies to the stimulus of the sight of a motionless, unsmiling human face. The "smiling time," defined as the number of seconds a baby smiled in a total period of 30 seconds' exposure to the stimulus, was found to diminish rapidly from a maximum, but could be revived by moving, speaking, or smiling at the baby, or by removing the stimulus for a short period. If a constant stimulus was repeated intermittently the smiling response waned. This waning curve differed from infant to infant and was sensitive to a variety of external and internal conditions affecting the baby. However, smiling was only part of a baby's response. It engaged in a good deal of other forms of activity which Mr. Ambrose described and discussed.

Mr. T. MOORE (Institute of Education and Child Health, London) gave an account of a study of the sleeping habits of babies in their first year of life. At three weeks an infant slept for some 14 out of the 24 hours, and only slowly during the course of its first year did its sleeping tend to occur wholly at night. At the end of this year 10% of the babies he studied had never slept regularly through the night for four consecutive weeks, and half of those who had settled relapsed to waking at night later. Among the factors associated with this failure to settle at night were neonatal asphyxia, male sex, feeding difficulties, insufficient nursing, and inconsistent handling at night.

Separation from Home

Dr. C. M. HEINICKE, Ph.D. (Tavistock Institute, London), described a carefully designed clinical investigation on the effects of temporary separation from the home and a stay in a residential nursery on children, aged 15-30 months. A control group matched in all respects except for the absence from home were similarly studied. This work confirmed the damaging effect of separation from the home.

Dr. T. R. LEE, Ph.D. (St. Andrews University), had obtained assessments of the social and emotional adjustment of 883 infants attending 57 village schools from their teachers. He found greater maladjustment in those who went to schools far from home. Of possible explanations for this (including fatigue), the only one which satisfied the data was a situation where the child felt its mother to be inaccessible.

Mrs. KELLMER PRINGLE, Ph.D. (Birmingham University), reported that children who had been admitted to institutions early in life and had lost contact with their families, when tested at the ages of 8, 11, and 14 for range of vocabulary and intelligence, obtained lower scores than those admitted later and with persisting home contacts.

Other Medical Contributions

Mr. P. H. GLOW (University College, London) described the effect of a hallucinogen—lysergic acid—on the behaviour of rats. His experiments had shown that its effect was related to its concentration in the brain and was due to its action on the afferent system, not the motor system.

Dr. M. HAMILTON (Leeds University) gave an account of the application of psychometric methods to the assessment

of the symptoms of anxiety neurosis. Patients were assessed on 13 variables (symptoms), using a five-point scale, and simultaneous assessment by two psychiatrists showed that the method was more reliable than most psychological tests of personality. The method of factor-analysis had been used to study the relations between the variables, and it was shown that these could be ascribed to two independent factors, one accounting for "psychic" symptoms, and the other for somatic symptoms. German psychiatrists, he pointed out, classified the latter group as a distinct syndrome of "autonomic dysfunction."

Professor H. J. EYSENCK (Institute of Psychiatry, London) gave an account of a recent work in which excitatory drugs such as amphetamine and caffeine and sedatives such as amylobarbitone sodium were used to alter cerebral functioning. Previous work has shown the importance of excitation and inhibition on the personality. This paper was concerned with the effects of these drugs on the development of visual after-images.

No account of this meeting would be complete without some reference to Dr. E. B. STRAUSS's presidential address on "The Anatomy of Treachery." He gave a literary and sparkling address in which sound judgment of character, wisdom, and clinical acumen were nicely mingled. It made a fitting climax to a stimulating meeting.

Reports of Societies

MANCHESTER MEDICAL SOCIETY

"Perinatal Pneumonia" and "Hormones and Adrenalectomy in Metastatic Breast Carcinoma" were discussed recently by the Sections of Pathology and Surgery respectively of the Manchester Medical Society.

Perinatal Pneumonia

The discussion on perinatal pneumonia was opened by Dr. F. A. LANGLEY, senior lecturer in special pathology. In the years 1950, 1952, and 1954 they had found pneumonia *post mortem* in 10% of stillborn foetuses, in 25% of babies dying on the first day, in 33% of those dying on the second day, and thereafter in diminishing proportion. The still-born foetuses and infants dying under three days were on average larger than a control group of foetuses and infants dying without evidence of pneumonia, and birth injury and severe dystocia were commoner among them. Particularly striking was the high incidence of pneumonia in infants whose amniotic membranes had been ruptured more than 48 hours, although the duration of labour by itself seemed to play no part. Of stillborn foetuses whose placentas were available for examination, all the ones with pneumonia showed inflammation of the foetal surface of the placenta.

A clinical trial was carried out in 1955 in which women in labour with pyrexia, foetal tachycardia of 160 or more, or offensive liquor were separated into two groups. One group was treated with streptomycin and oxytetracycline, while the other received no antibiotic therapy. Five cases of pneumonia were found *post mortem* in the untreated and none in the treated group. In each case of pneumonia there was evidence that maternal infection had been present for 48 hours or more. And again a close correlation was found between the length of time the membranes had been ruptured and the occurrence of pneumonia.

Dr. R. F. JENNISON, lecturer in clinical pathology, said he had made bacteriological studies during the last two years of 330 lungs from infants dying in the perinatal period. He had isolated bacteria from 128. The commonest organisms were *Bact. coli* (15%), *Strep. faecalis* (9%), and non-haemolytic streptococci (6%). Of the 39 lungs showing pneumonia, 21 had given positive cultures, six of these being of *Bact. coli*.

Strontium-90 in Man

SIR,—Strontium-90 is now frequently being discussed all over the world, and your leading article (*Journal*, March 30, p. 752) will no doubt be quoted in lay fora as an expression of the best medical opinion of this country. It is important that some of the weaknesses of this, in most ways excellent, short summary of the situation should be noted.

"The main problem is how to assess the hazard from a given amount of strontium-90 in bone." Most would agree with this quotation.

Permissible Body Burden for the Occupationally Exposed.—This has been given by the International Commission on Radiological Protection and the Medical Research Council's Committee on Protection against Ionizing Radiation as 1 μ c of strontium-90 or approximately 1,000 S.U. (strontium units, μ c per gramme of calcium), and was derived as follows. From industrial experience in the luminizing industry it was considered that the minimum toxic body burden of radium—a chemical analogue of calcium and strontium—was 1 μ c. Early results with experimental rodents in Chicago had indicated that the toxic dose of strontium-89 relative to radium was about 10:1. Strontium-90 and its daughter yttrium-90 liberate per disintegration about twice the energy of strontium-89. Therefore the ratio of strontium-90 to radium should be about 5:1 as administered; but radium decays in the body to radon, a gas, much of which escapes in expired air, more in the case of recently deposited radium than from long-standing depots, and more in the case of experimental rodents than man. In terms of body burden of effective radioactive material in human bone it was fair to allow a factor of 2 for this, bringing the ratio strontium-90:radium=10:1. The calculated, minimum toxic permanent body burden for strontium-90 is thus 10 μ c. Allowing a safety factor of 10 a maximum permissible body burden of 1 μ c was derived.

The following uncertainties are relevant. (1) Industrial radium used in the luminizing industry was a mixture containing variable amounts of mesothorium and other radioactive elements, too short-lived for their contribution to the observed toxic manifestations to be assessed at the time when the body burdens of luminizers were estimated. However, a few subjects who had received injections of relatively pure radium for medical (sic) reasons have been discovered: in them the minimum toxic body burden appears so far to be about 3 μ c as compared with recent estimates of about half a microcurie of "radium" in ex-luminizers. The minimum toxic body burden of radium cannot therefore be indicated with precision. (2) The ratio of toxic doses of radium and strontium-89 was derived from injected animals. After more chronic administration these radioactive materials may be expected to be more widely distributed in bone. (3) The comparative metabolism of radium and strontium may differ significantly in man from the rodent because of different size and bone structure.

Permissible Body Burden in General Population.—In spite of the uncertainties the maximum permissible body burden for strontium-90 remains one of the best authenticated for strontium-90 for occupational purposes. However, because of the uncertainties it is not justifiable to use this figure as a yardstick when one is considering a general population as Libby² and Kulp *et al.*³ have done. Your leading article and the Medical Research Council⁴ have given the most cogent reason—the presence in a general population of foetal, neonatal, and adolescent subjects who have greater avidity for and greater sensitivity to radioactive strontium. On the other hand, with the homeopathic doses they receive daily the young will distribute strontium much more uniformly in bone than will the adult. How much this latter offsets the former is unknown.

A comparison of the bacteria isolated from the infants' lungs with those from their mother's vaginas during a controlled trial in 1955 had shown a similar distribution of pathogenic organisms. The number of pathogens increased with the length of time the membranes had been ruptured and also with the duration of maternal pyrexia. All the infants with pneumonia in this series had been born of mothers with a pyrexia of 99.4° F. (37.4° C.) or more for at least 48 hours and whose membranes had been ruptured for 36 hours or more. No cases occurred in mothers without pyrexia or who had been given antibiotics as soon as pyrexia developed. It appeared, therefore, that the majority of cases of perinatal pneumonia were caused by bacteria from the vagina, and were associated with a maternal reaction manifested by pyrexia.

Bilateral Adrenalectomy and Oophorectomy for Breast Cancer

Mr. A. F. ROBINSON (Burnley General Hospital) opened the discussion on "Hormones and Adrenalectomy in Metastatic Breast Carcinoma." Bilateral adrenalectomy and oophorectomy (or orchidectomy) could help control disseminated breast cancer only if the tumour was hormone-dependent, he said. To eliminate all oestrogenic hormones both adrenals and ovaries had to be removed, unless a hypophysectomy was done instead; a previous x-ray sterilization or menopause did not remove the need for oophorectomy. Operation was recommended if the disseminated cancer was active and advancing and simpler treatments had failed. Cases had to be selected with care. Those whom it was thought would not stand operation, those whose arms were grossly swollen, those over about 70, those with much hepatic or mediastinal metastasis, and those with irreversible vital damage, should be excluded. At operation accessory adrenals must be looked for and removed.

After the critical first six hours there was usually little cause for anxiety. In general more cortisone was the remedy for most ills at any stage after operation, and difficulty in cortisone management usually meant failure of response in the cancer. Postural hypotension was an indication for deoxycortone in the follow-up period. Response in the successful cases had been dramatic, bone pain often being relieved by the morning after operation. In 43 cases there had been 5 deaths associated with the operation, and 18 out of the 38 survivors had been greatly helped.

Dr. MARY COLE (Christie Hospital) gave more details of the operative results. Of the 43 patients 19 had been operated upon at least 12 months ago; of these, nine showed a measurable response, seven being still alive, three being well at 18, 17, and 13 months respectively. Including those operated upon six months ago, there were 38 cases; 19 had shown a response and 10 were still in remission after periods between 6 and 18 months.

At most sites there was some improvement, but bone metastases responded more consistently than others. Many of the patients had had a trial of hormones pre-operatively, and of 18 patients who responded to adrenalectomy nine had previously shown a response to hormones; of 14 who did not respond to adrenalectomy two only had shown a previous response to hormones.

Dr. Cole then compared these results with those from other methods of treatment. X-ray castration had resulted in improvement of the metastases in 21.5% of 79 pre-menopausal women, she said. Some 20% of 142 pre-menopausal women receiving testosterone propionate responded, but there was a gradual diminishing response in the older age-groups. Of 258 patients treated with stilboestrol the best response—19.2%—was obtained in those at least 10 years past their menopause, while of the pre-menopausal patients only 5% responded. In spite of the lower remission rate with hormones compared with combined oophorectomy and adrenalectomy, she made a plea for a trial of the appropriate hormone before operation—the final palliative measure—was considered. Some patients, she said, might have a remission with hormones, and subsequently again after adrenalectomy and oophorectomy.

This matter of distribution of strontium is worthy of stress. The values given by Kulp *et al.*⁹ for strontium-90 in human skeletons were not those directly measured but figures "normalized" for unevenness of distribution in different bones. Now, unless I am in error, the factor for normalization was derived from the single administration of strontium-85 to adults in the terminal phase of killing diseases. An ill adult patient, probably bed-ridden, given a single dose of a radioactive marker and dying 3 to 125 days later, is no criterion for the metabolism of a daily ingested calcium analogue, and to use this criterion to "normalize" observed data, particularly from children, is, to say the least, unscientific. In fact field studies on domestic animals⁵ indicate that gross radioactivity from strontium-90 is fairly uniformly distributed throughout the bones. Moreover, the analysis of stable strontium in human bones from subjects of all ages shows a similar uniformity.⁶ Strontium is a normal though apparently non-essential metabolite, and radioactive strontium will follow the same pathways.

Radioactive strontium-90, now universally distributed over the surface of the world, should be considered in comparison with the naturally occurring radium found in all bone, human and animal. Calculations of acceptable risks for a population from body-burdens of radioactive strontium are best made therefore using natural radium contamination as the criterion. This approach is being pursued with vigour.

Dose-response Relationship.—Meanwhile, "How does formation of bone tumours vary with dose?" Is there a relationship between natural radioactivity of bone and natural incidence of bone sarcoma? Though this has been carefully looked for, the only conclusion is that the evidence is too scanty.

Is there "growing evidence that the relation between the amount of exposure to radiations and the probability of developing long-term effects is of a linear nature"? In so far that formerly there was none at all, while recently a linear relationship has been suggested between dose to a point in the spinal marrow and the incidence of leukaemia in irradiated spondylitics (Appendix B*), this statement is true.⁷ But radiation-induced leukaemia is an odd thing. It has a much shorter latency than other radiation-induced malignant states. Some would even yet argue that it is not a malignant condition. In the experimentally induced lymphoma of the mouse the relation between total dose and fractionation of the dose is most complex and certainly not simply linear.⁷

It would be unwise therefore to use leukaemia as a model for all radiation-induced malignancies and as a justification of the thesis of somatic mutation as the cause of cancer. It is wrong, moreover, to attribute to the M.R.C. report⁴ opinions which it did not express. The statement, "Each unit quantity of radiostromium absorbed by bone confers a certain probability of bone tumour formation," was not in the report but one of its signed appendices. Furthermore, the statement would suggest a linear relationship only if each unit quantity conferred the same probability.

In point of fact, the quantitative evidence of the carcinogenic properties of radiostromium, and there is not much of it, suggests that the relationship is not linear and that there is some form of threshold, or effective latent period.⁸ Therefore your conclusion, "The consequence of a linear relationship is that every H-bomb test by causing an increase of the content of strontium-90 in bone will increase the frequency of bone lesions," is as yet without foundation. The correct conclusion in the present state of scientific knowledge is that a linear relationship sets the limit and indicates the worst possible conditions, so that it would be prudent to go easy until the real facts are ascertained.

Strontium in Animal Metabolism.—*Pari passu*, it is right and proper that investigations be made on the uptake of both natural radium and the now universal strontium-90. Your leading article notes that we derive most of our calcium and strontium from milk and certain of its products. A safety factor of about 7—the cow—is built into this route by which we ingest strontium-90. Your leading article

quotes a second safety factor of about 8 in going from food to the deposition of strontium in human bone. The combination 7×8 would indeed be impressive, but is unfortunately an overstatement. Sowden and Stith⁶ find the strontium content of human bones to be, in round figures, 100 p.p.m. of ash, of which about 40% will be calcium. The strontium:calcium ratio is thus about 1:4,000. In a general diet one can derive from the data of Harrison *et al.*¹⁰ that strontium:calcium is about 1:500. Here is the factor 8, but this includes the factor for the cow in so far as milk and its products are part of the diet of the average adult. Moreover, Harrison *et al.* calculate that the discrimination against strontium in favour of calcium by the human gut gives a factor of about 2. Unpublished observations from the same source suggest that the human bone absorbs calcium and strontium from the blood without discrimination. The best figure at the moment for the human safety factor is thus only 2. It is likely to be rather higher for alkaline earths of vegetable origin than for those derived from milk, since lactose and some amino-acids cause reduction in the factor of discrimination.¹¹

Strontium in Soil and Plant.—Your leading article infers that all the strontium-90 in plants is derived from the soil. But the leaf of the plant is a very good surface for the adhesion of small particles of "fall-out" and for the absorption of strontium as well as other mineral ions.^{12,13} Thus the present contamination may be much more related to the rate of fall-out than to integrated total "fall-out."—I am, etc.,

Didcot, Berks.

SIR,—Your leading article (*Journal*, March 30, p. 752) states that strontium-90 does not present genetic hazards since it emits only β -rays which do not penetrate to the gonads. In view of the great importance of this subject at the present time, it would be interesting to know whether this statement is based on experimental evidence or merely on supposition. If the latter, then it is difficult to accept the argument without further investigation. It may be that the writer assumed that all the available strontium-90 is deposited in the bone and therefore is unlikely to affect the gonads. However, even on this assumption the β -particles can traverse distances of up to about a centimetre in soft tissues¹: when the testes are in the inguinal canal, they must be less than one centimetre distant from bone at some stage in their journey. This may also apply to the ovaries during development.

A second possibility which may not be excluded is the effect of any strontium-90 prior to its deposition in the bone or after subsequent mobilization. If there is any similarity between the effect of strontium and lead it may be that strontium does in fact have an effect on the soft tissues in general. Lead is well known to have a special affinity for bone, but its main impact is on soft tissues, such as the nervous system and the gut. Until, therefore, these possibilities have been excluded by experiments of suitable length in mammals, such a statement as that in your leading article may convey a false sense of security.—I am, etc.,

Carcinoma of Oesophagus Associated with Tylosis

SIR,—Keratosi palmaris et plantaris (tylosis) has hitherto been considered a rather trivial disability, of interest chiefly to geneticists on account of its classical method of inheritance as a mendelian dominant. However, that the skin condition can sometimes have a sinister association is shown by a study of two tylotic Liverpool families, where, on no less than 16 occasions, patients with the skin abnormality have also developed cancer of the oesophagus. In one family there were 10 such cases in three generations, and in the other six in two generations.

The following points are relevant: (1) The association was first discovered in family S, but family C had been reported previously on account of the familial incidence of the carcinoma.¹ On reinvestigation the affected members of this family were also found to have been tylotic. It is possible that the two families are related, but definite proof of this is so far not forthcoming. (2) There were no cases of carcinoma of the oesophagus occurring in the non-tylotic members of either family, and there was no excess of cancer of other sites in these individuals. (3) It is important when investigating for tylosis to examine both the hands and feet of patients, as not infrequently in our families the lesion is only on the soles. (4) In the two families the average age at death of those who developed the carcinoma was 45 years, and males and females were equally affected. (5) The site of the growth was in the lower third of the oesophagus in 10 cases, in the mid-third in three, and in three cases the site was not known. (6) Of the tylotics investigated in these families, 30% developed carcinoma of the oesophagus. (7) The average age of onset of the tylosis was about 14 years—this is later than is usually described. (8) In two patients in whom the growth was removed the skin condition markedly improved after operation.

In a large survey of carcinoma of the oesophagus made in Denmark² it was firmly concluded that inherited factors played no part in the aetiology of this type of growth. The association, therefore, between tylosis and oesophageal cancer in our two families seems of particular interest, and as far as we know has not been described before. Pedigrees and full details of the families will be published later, but in the meantime we should be very interested to know if anyone has observed a similar association. We are also interested to find out the causes of death in patients who have been known to have tylosis.—We are, etc.,

Living with a Colostomy

SIR,—Your leading article (*Journal*, February 2, p. 274) and subsequent letters in the *Journal* quite rightly focus the attention of a new generation of doctors on the need of being informed about the management and care of a colostomy and of being competent to pass on this information in simple terms to their patients.

I think the impression has unfortunately been given that a colostomy needs either a washout or "drugs" to make it work efficiently. It is my contention that the success of a colostomy depends on how well it has been made. If it has been ill-fashioned, no method of management, no combination of drugs, diet, or bulk-forming substance will make it work efficiently. It should be possible to pass the adult male index finger covered with a lubricated finger-cot into a colostomy and through the layers of the abdominal wall without discomfort to the patient. If the colostomy is too tight this digitation will cause the patient pain.

The only concern to a patient who has to have a permanent colostomy is that, if it has to be, then it should be

efficient. The majority of permanent colostomies are an essential step in the treatment of cancer of the rectum, where a surgeon's attention is naturally focused on removing the growth and the fashioning of the colostomy is often left till the end of the operation, when the surgeon is tired and when complications arising during the operation may make it necessary to fashion it hurriedly without the care and attention it deserves.

Because of this, I have recommended that the colostomy stoma should be fashioned as the first step of an excision of the rectum before making the laparotomy incision. The advantages of this sequence are: (1) The colostomy is made when the surgeon is fresh. (2) Sufficient time can be spent on its detailed construction. (3) The stoma through the abdominal wall is made with the layers in anatomical superimposition. (4) If complications arise during the operation the colostomy has already been fashioned and need not be left to a hurried last-minute stab incision through the abdominal parietes. I have found that the best colostomies are those where a disk of abdominal wall 3 cm. in diameter (the size of a penny) is "trephined" through the outer third of the left rectus muscle just below the level of the umbilicus.¹

In conclusion, an unsatisfactory colostomy nearly always means that it has been badly made, or has become stenosed. A well-fashioned colostomy will act, usually twice a day, according to food intake and the physiological responses of the colon, without having to resort to medicines or washouts.—I am, etc.,

London, W.1.

REFERENCE

- Mainiot, R., *Management of Abdominal Operations*, 1957, Vol. 2, p. 1209. H. K. Lewis, London.

SIR,—I would like to refer to one point in your excellent leader on living with a colostomy (*Journal*, February 2, p. 274). The instructions which are given to a patient on the aftercare of his disability are usually adequate, but, as you rightly say, it is when the patients go home that they often run into difficulties. Many patients are elderly and in the early days at least will rely for help from their relatives, who have not received any instructions on the subject. How much better it would be if all hospitals issued to their patients a written guide on the day-to-day management of a colostomy. I am sure the lives of these people and their relatives would be made much easier. In this connexion, I would refer your readers to a most valuable little handbook, *The Home Management of a Colostomy* (published by Harker Stagg Ltd.), which is available free to doctors and hospitals for issue to their patients. I have used it with considerable success in my practice in the East End of London.—I am, etc.,

London, E.3.

Continuous Suxamethonium Infusion

SIR,—With due respect to Dr. C. Langton Hewer's vast experience, I beg to disagree with his reference to continuous suxamethonium (*Journal*, January 5, p. 45).

I have been fortunate in administering over 400 continuous suxamethonium anaesthetics with only one case of post-operative apnoea lasting 25 minutes with no ill-effects. This happened at the beginning of the series and it was my fault. Thereafter much the same rules were rigidly adhered to as prescribed by Drs. Godfrey Herington and E. James (*Journal*, January 26, p. 227). To exclude the possibility of overloading the patient with fluids, the concentration of the drip was increased to 1,500 mg. per 500 ml. of saline and the rate reduced to an absolute minimum by a "fine adjustment" screw, so that the patient was allowed to breathe spontaneously at intervals. Using a simple "rubber tubing-glass canula" modification¹ 500 ml. of suxamethonium solution was used for three or four successive cases on the list.—I am, etc.,

Inflammation

SIR,—Professor L. P. Garrod wrote a very interesting critical review of my book¹ (*Journal*, September 1, 1956, p. 518). There are, however, several points in this review which I think need some clarification.

Whenever attempts have been made to isolate leukotaxine by the methods which we described, its isolation has been confirmed from practically everywhere, starting from Cullumbine and Rydon² in England in 1946, and more recently by a number of Japanese investigators, notably Kimeo Yasuhira.³ In regard to Professor Garrod's comment, "whether substances produced by the chemical treatment of body fluids exist as such in nature and exert naturally the effects produced by the isolated substance," let me point out that in all our studies we have always used the untreated exudate as a base level. If a biological factor is found to be present in this body fluid which has biological effects, only then is chemical extraction begun. This has been repeatedly emphasized. In the concluding chapter on page 403 of *Biochemical Mechanisms in Inflammation* the statement is made: "These factors are first shown to exist in the whole exudate. Subsequently, biochemical analysis reveals these factors as further purified biochemical units." In regard to Miles's work, I have originally sent Dr. Miles some of our leukotaxine, and he himself states that his factor is not leukotaxine. I quote from my own footnote on page 51: "It appears to be neither leukotaxine nor histamine."

In regard to the comment concerning figure 78 on page 236, I think that the point is well taken, but this is a false impression, and it is essentially the artist's fault. The injections are always made immediately after taking the basal temperature. On that particular figure the artist should have had two arrows, because the arrow refers really to the time following the necrosin injection, and that was started later. At any rate, for the information of the reader, the local temperature prior to pyrexin injection was just over 104° F. (40° C.); and very soon after its injection it began rising until a peak of 107° F. (41.7° C.) was reached. Such experiments have been repeatedly confirmed. Nevertheless, I am to take the blame for this oversight, for I should have noticed it when the chart was returned to me by the artist.

In regard to the heterologous reaction, as a control, in all experiments we also use the blood serum and the fractions extracted from it from the same type of animal as is employed in the extraction of the factors from exudates. In this way it is shown that the effect is not referable to heterologous proteins, since the blood serum fails to give the same reactions as the exudate. Although this is not stated in the book as such, the blood serum controls are mentioned in several places in it.

I value considerably Professor Garrod's survey of my book, and it is only in the spirit of truth that I am calling attention to the aforementioned factual information.—I am, etc.,

Toxic Effects of Meprobamate

SIR,—In your annotation (*Journal*, November 24, 1956, p. 1227) you state that Friedman and Marmelzat¹ say that one 400-mg. tablet of meprobamate may produce skin lesions in less than four hours.

A dentist, aged 36, took his first and only 400-mg. tablet of meprobamate at 4 p.m. Around 8 p.m. he felt he was on the point of fainting, with general malaise and chills. The skin of the area of the pelvic girdle began to itch severely. He went to sleep. When he awoke next morning at 6.30 a.m. there was massive purpura with discrete and confluent lesions over the skin from mid-thigh to lower third of trunk, sharply demarcated from the normal skin, below and above. A full blood count was normal, platelets

normal in number and normal in morphology, as seen by routine stains; bleeding time, coagulation time, normal. The rash disappeared in four days without any treatment other than reassurance. It was neither feasible nor desirable to subject this patient to a further test dose of meprobamate.

This patient resembles case 2 and case 6 of Friedman and Marmelzat.—I am, etc.,

Jerusalem.

Acute Amphetamine Poisoning

SIR,—I was interested in a paper by Drs. R. Greenwood and R. S. Peachey (*Journal*, March 30, p. 742). A review of the literature reveals the very variable response of different individuals to overdosage with both dexamphetamine and its isomer DL-amphetamine. Symptoms may vary from mild excitability to acute psychotic states or even death. In a case cited by Ehrlich *et al.*,¹ a 27-year-old mechanic took 20 g. of amphetamine over a two-day period and, though he developed an acute paranoid state, he made an uneventful recovery following treatment with barbiturates. At the other extreme is the case of L. C. Smith,² quoted by Drs. Greenwood and Peachey, who died after taking 10 mg. of DL-amphetamine. The case described by Hertzog *et al.*,³ and mentioned by Drs. Greenwood and Peachey in their paper, cannot be accepted as having died from amphetamine overdose, as the symptoms and post-mortem findings were those of poisoning due to ferrous sulphate which Hertzog regarded as non-toxic.

The following case history illustrates the very mild symptoms that may occur following the ingestion of a fairly large dose of dexamphetamine.

An unmarried woman, age 20 years, who had had a baby two months earlier, became depressed and swallowed 42 15-mg. dexamphetamine "spansule" capsules (630 mg.). She was admitted to hospital nine hours later. On admission, she was mildly excited but she was easily calmed by reassurance. Her pulse rate was 110 per minute and B.P. 120/85 mm. Hg. She was given 1½ oz. (42.5 g.) of magnesium sulphate by mouth and phenobarbitone sodium 0.2 g. intramuscularly. Three hours later she complained of difficulty in sleeping and she was given sodium amytal 0.2 g. by mouth at 1 a.m. She slept well and the following morning she was quite calm and none the worse for her experience. The patient's first bowel action after taking the capsules was 13½ hours after admission. The whole 170 g. of semi-solid faeces was examined but only one dexamphetamine pellet was found. There are approximately 19,000 pellets in 42 15-mg. spansules, which suggests that she probably absorbed most, if not all, of the ingested drug.

It is possible that the absence of severe symptoms was partly due to the form in which the drug was taken. The construction of spansule capsules is ingenious. The dexamphetamine is divided between a large number of pellets contained in the capsules. About one-third of the active ingredient is incorporated into uncoated pellets which disintegrate as soon as the capsule dissolves. The remainder of the pellets are protected by digestible coatings of various thicknesses and they disintegrate constantly over a period of about eight hours.—I am, etc.,

Termination of Pregnancy

SIR,—May I draw attention to a number of inaccuracies in the article by Dr. James Arkle entitled "Termination of Pregnancy on Psychiatric Grounds" (*Journal*, March 9, p. 558)? Your contributor states that "the Christian opposition [to abortion] is based to some extent on a mis-translation of the abstract laws of the ancients." This is simply not true. The Christian attitude has always been determined by the principle that the child, though yet unborn, is a human being to the same degree and by the same title as its mother. As such it has an inalienable right to

life, a right which it receives immediately from God. The commandment "Thou shalt not kill" therefore holds good for the foetus as for all human beings (for a clear statement of Catholic teaching on this and related matters see the Papal Allocution to the Congress of the Catholic Union of Midwives).

The Hebrew text of Exodus, ch. xxi, v. 22, is interpreted by your contributor as referring to the deliberate procuring of an abortion. This is, in fact, a misinterpretation. The passage means: if two men are quarrelling, and one should happen to strike a pregnant woman (even by accident), so that a miscarriage results, two kinds of penalty are applied. If the woman lives, the guilty one must pay a fine, as shall be determined by the woman's husband. If, however, she dies, the punishment shall be inflicted in accordance with the principle "An eye for an eye." There is therefore no question of an operation for the purpose of deliberately terminating a pregnancy, nor is there any mention of the husband's agreeing to the operation. The last sentence translated by your contributor, "He shall pay for the miscarriage," is based on an amended Hebrew text. The probable meaning of the Hebrew text as it stands is: "And he shall pay it [the fine] before the judges." For almost exact parallels in Assyrian law, *The Assyrian Laws*¹ could be usefully consulted.

It is interesting to note that, whatever St. Jerome thought about the time of the infusion of the human soul into the foetus, he translated Exodus, ch. xxi, v. 22, correctly, avoiding the error of the Greek translators. He would therefore have understood that it was irrelevant to refer to this passage in a discussion of therapeutic abortion.—I am, etc.,

Dublin.

Hospital Confinement

SIR,—There is much to be said in favour of Professor W. C. W. Nixon's plea (*Journal*, March 30, p. 761) for hospital delivery of all primigravidae. But why stop there? Despite the lip service often paid towards the benefits, psychological and otherwise, of domiciliary midwifery, the only important consideration, surely, is that it is so much safer to have a baby in hospital than in the home; consequently, a majority of intelligent women will request hospital booking. If anyone may be said to enjoy a "right" under the Welfare State, then surely the pregnant woman has a right to demand the safest and best possible conditions for the birth of her baby. In my opinion, these conditions are only fulfilled in the modern maternity hospital or good nursing-home. Incidentally, it would be interesting to know how many doctors' wives are confined at home.

However, having had the baby, the sooner the normal parturient rejoins her family the better for all. Most patients are ready to leave hospital by their fourth or fifth post-partum day, and I have seen no harm result from such early discharge. If British obstetricians adopted the practice of their colleagues in America and Canada, and encouraged early ambulation and early discharge from hospital, there would be ample beds for all who desired them. It should not be difficult, by co-operation between hospital staff and family doctor, to arrange adequate puerperal attention on an out-patient basis.—I am, etc.,

Pinner, Middlesex.

J. P. O'DWYER.

Underfeeding of Babies

SIR,—I cannot agree with Dr. Ian G. Wickes (*Journal*, March 23, p. 702) and Mr. Albert Davis (*Journal*, April 6, p. 821) that all babies should be given as much milk as they can take. A baby who does not feel completely secure is likely to "want" more than it needs at any one feed, and if the doctor is relying on the baby to regurgitate what it is

unable to assimilate there is a risk of overtaxing the baby's digestive capacity, especially with artificial feeding. As in adults, one badly assimilated meal may be more difficult to recover from than hard manual labour.¹ Surely the inguinal hernia in Dr. Wickes's case is more likely to be the result than the cause of perpetual crying?—I am, etc.,

Enfield, Middlesex.

REFERENCE

- Emerson, W. R. P., *The Diagnosis of Health*, 1930. New York.

SIR,—I support Dr. Ian G. Wickes's views (*Journal*, March 23, p. 702) on the error and the evil of the over-feeding diagnosis. Like Mr. Albert Davis (*Journal*, April 6, p. 821), I teach that "you cannot overfeed a baby" (and usually the next baby to be seen in the clinic is the one overfed baby encountered every term).

I write, however, to disagree with Mr. Davis on two important matters. We do not want "baby doctors" in England. They bring many disadvantages. The proper solution is the training of family doctors who really know about normal babies. The second matter is the curious belief, not unique to Mr. Davis, that the consultant paediatrician is "too senior to bother about trivia." Many of us continue to work in infant welfare clinics to prevent ourselves from any chance of losing touch with "trivia," because we know that so many symptoms in infancy and childhood grow out of "trivia." In other words, every detail of management that influences the happiness and the healthy development and the family relationship of the new individual is of real importance. Put another way, for the paediatrician there are no such things as "trivia."—I am, etc.,

London, W.1.

ALFRED WHITE FRANKLIN.

SIR,—In addition to Mr. Albert Davis's timely suggestion (*Journal*, April 6, p. 821) that a "baby doctor" should be available to all mothers who are in despair over "trivia," might it also be suggested that the paediatricians who would instruct these doctors would also undertake to teach the nurses who, in the present scheme of things, cannot avoid advising on infant feeding? Thus, contradictory advice, so confusing for young mothers, would be less likely.

But why should senior nurses be cried down, in print or otherwise, so often and so severely by paediatricians when the paediatric professor is himself ultimately responsible for the training of these women? If doctors who hold teaching posts and who lecture on infant feeding not only to medical students but also to nurses do not give suitable and adequate instruction this surely suggests that they themselves have received inadequate or poor teaching in this field of child welfare is long overdue.—I am, etc.,

London, E.C.4.

ELIZABETH MORRISON.

Medical Ethics in Wartime

SIR,—It is of interest to read in your issue of February 16 (p. 397) that the World Medical Association's suggested "Code of Medical Ethics in Wartime" is now being submitted to national medical associations for their approval and support. The protection of civilian doctors in time of war would undoubtedly be strengthened by the universal adoption of such a code.

The changing character of warfare is changing the character of the problems of the protection of medical personnel. The Commonwealth Official Medical Historians' Liaison Committee has been considering this subject for some time in the light of experience of the working of the Geneva Convention during the second world war, and a joint memorandum is to be prepared on the subject. The historians are in a unique position to appraise the working of the Convention and to put forward suggestions concerning possible revisions.

New problems have arisen which indicate the need for bringing the provisions of the Geneva Convention up to date and, in view of the total nature of modern war, of extending them to embrace the whole field of medical ser-

vice in time of war, both military and civilian. The initiative of the World Medical Association and that of the Commonwealth Official Medical Historians' Liaison Committee may contribute greatly to this end.—I am, etc.,

W. FRANKLIN MELLOR,

London, W.1.

Secretary,
United Kingdom Official Medical History of the War
and of the Commonwealth Liaison Committee.

Massive Hypertrophy of the Breasts

SIR.—A 23-year-old Yoruba woman was admitted to the General Hospital, Abeokuta, in December, 1956, on account of increasing disability due to the huge size of her breasts (Fig. 1).

She was a primigravida in the 8th month of pregnancy, and the hypertrophy had started three years previously. There was no milk in the breasts. Owing to interference

FIG. 1

FIG. 2

with her movements and with respiration it was decided to amputate the breasts straight away and not wait for the birth of the child. The breasts were removed one at a time with an interval of three weeks between the operations. She gave birth to a stillborn child five days after the first operation. Split-skin grafts were used to cover small areas left bare by the amputations. Each breast weighed more than 15 lb. (6.8 kg.). The second photograph shows her appearance before her discharge from hospital (Fig. 2).

My thanks are due to the acting Director of Medical Services, Western Region of Nigeria, for permission to publish this note.—I am, etc.,

Abeokuta, W. Nigeria.

R. O. PARNIS.

The Hurt Brain

SIR.—As one who has been interested in the treatment of neurosyphilis in mental hospitals during the past twenty years, and who has had the opportunity of discussing the subject with many mental hospital psychiatrists interested in penicillin treatment of such cases over the past eleven years, I can assure Dr. E. E. Prebble (*Journal*, February 16, p. 399) that mental hospital psychiatrists do not accept the statement that syphilis of the brain could now be cured with ten injections of penicillin as stated in the television programme "The Hurt Mind." During the past ten years I have been treating patients with neurosyphilis by aqueous solutions of intramuscular penicillin alone, and have seen excellent results.

Early in my investigations two courses of treatment were prescribed, the second course to be given one month after the first.¹ In two patients who had improved clinically as well as serologically but died from other causes histological examination of the brain revealed inflammatory changes which were definitely less intense than in the average untreated general paretic.² This suggested that treatment by penicillin alone is capable of influencing the pathological progress of general paresis. Further research into the subject led me finally to advocate a scheme of dosage for the treatment of parenchymatous neurosyphilis—namely, first day, 20,000 units three-hourly for eight

doses; second day, 50,000 units three-hourly for eight doses; third day, 100,000 units three-hourly for eight doses; and fourth to tenth days, 500,000 units four-hourly for forty-two doses.³ I have used this scheme of treatment ever since with remarkable success, and many patients have been cured. The relative safety of penicillin and the shorter periods of time required to administer the penicillin are, in my opinion, definite advantages over the older methods of treatment of general paralysis of the insane.—I am, etc.,

Bilirubin

SIR.—In your annotation on bilirubin (*Journal*, February 16, p. 393) you state that direct reacting bilirubin has been shown to be a complex with glucuronic acid. It might be of interest to your readers to know that in 1905 P. J. Cammidge,¹ then of St. Bartholomew's Hospital, recorded that when bile was present in the urine glucuronic acid was also present in excess in those subjects whose jaundice was due to obstruction of the biliary passages.—I am, etc.,

B. P. BILLINGTON.

Sydney, Australia.

Bolus Obstruction

SIR.—Three cases of post-gastrectomy bolus obstruction have been described in the recent correspondence (Dr. B. N. Colabawalla, *Journal*, February 23, p. 465; Dr. J. T. Corbett, March 2, p. 524; Dr. L. Goodman, March 30, p. 764). We have had a similar case in a man, aged 63, who had had a partial gastrectomy several years before and developed acute intestinal obstruction two days after eating an orange. He insisted that he had eaten it in single segments, but at operation the obstructing bolus, which was removed from the ileum two feet (61 cm.) from the ileo-caecal valve, was found to consist of half an orange. He was edentulous, and in spite of this obstructive accident still persists in eating without dentures.

It seems that orange is a poorly digested article; it was also the obstructive agent in two of the three post-gastrectomy cases quoted above, and it has been described as causing obturation obstruction in the normal gastrointestinal tract.¹ As Dr. Corbett suggests, the post-gastrectomy patient should be warned about adequate mastication and, we should add, proper fragmentation of oranges, especially in the edentulous.—We are, etc.,

Hydrocortisone in Sunburn

SIR.—With the impending advent (we hope) of the sunny season, I should like to record my very satisfactory experiences with hydrocortisone 1% (usually in the form of the lotion) in the treatment of severe sunburn. In several cases, especially of people with fair complexions who require only relatively small doses of sunlight to redden and "burn" their skin badly, I found that one or possibly two applications of the lotion at, say, four-hourly intervals were sufficient dramatically to relieve the pain and almost visibly to reduce the rapidly progressive erythema which otherwise would have resulted by next day in an acute "solar dermatitis," and its concomitant general malaise. I found this treatment equally useful in the crews of open cars, where, I believe, the moving air stream enhances the effect of ultraviolet light.

One patient presented herself at my surgery on her return from her seaside holiday, by which time her legs in particular were seriously affected by extensive oedema of the skin, blistering, and weeping. The pain was wellnigh unbearable. I treated her with hydrocortisone lotion, and she also improved at a rate I had never before witnessed—or, indeed, considered possible.

In retrospect, I began to wonder about the rationale (I must confess it was experimental inquisitiveness which caused me to hand the first patient a sample bottle of the lotion I had with me), and it occurred to me that it was quite reasonable, for the complaint is due to an acute inflammatory reaction of the skin and hydrocortisone is probably the best anti-inflammatory agent in our armamentarium. This could be one instance of a theory working out in actual practice.

It seems quite clear that the cost of this preparation precludes its routine use as a sunburn lotion (my next experiment, if an opportunity should present itself, will be to see whether application of the lotion before exposure will help to prevent or at least delay the onset of symptoms), but I consider its use well justified in selected severe cases, where it will save untold suffering.—I am, etc.,

K. E. JOLLES.

West Bromwich.

Police Evidence Preferred

SIR.—While agreeing with Dr. Charles Worthington's statement (*Journal*, March 16, p. 643) that the purpose of medical examination of persons accused of driving while under the influence of drink should be to exclude illness, accident, or infirmity which might be mistaken for alcoholism or contribute to its effects, not everyone would agree that the medical witness should be allowed to confine his evidence to such matters.

The doctor's examination often reveals signs of a cerebellar lesion which if transient is likely to be toxic in origin. Toxic substances causing cerebellar impairment are alcohol and phenytoin. Surely it is the doctor's duty to report such a finding and state "consistent with . . ." The rest of the evidence and the final decision as to "whether he is under the influence of drink or drugs to such an extent as to be incapable of having proper control of a motor vehicle" may not seem to be in the doctor's province. In view of the 15 people a day who die on the roads and the 750 who are injured, I would submit that any evidence of neurological dysfunction resulting from toxicity should be equated with being incapable of having proper control. The emergencies that arise demanding a high level of performance from a sober driver seem far too frequent to me (not only when I am driving) to permit tolerance of any degree of neurological impairment; especially as the mental attitude of the driver is at times more dangerous than his lack of physical skill.—I am, etc.,

St. Albans.

RUSSELL BARTON.

Safety Factor in Car Design

SIR.—There is one respect in which a three-wheel car is more dangerous than a small four-wheel car, and that is the danger of overturning. Six months ago I witnessed one of the small three-wheel cars completing a perfect somersault. The driver was a teenager and he was fortunate in having his car hood up. Just as it is essential for motor-bicycle drivers to wear helmets, it is presumably essential for drivers in small cars to be similarly protected when the car hood is down. Most of the three-wheel cars have these rather flimsy car hoods and obviously appeal to teenagers on fine days. In the U.S.A. an increasing proportion of schoolchildren drive their own cars to school, so that the problem of car parking makes small cars popular with the authorities. This problem, of course, does not yet exist in this country, where bicycles are used and take up little room. However, it must be reckoned with in years to come.—I am, etc.,

Wolverhampton.

GARETH R. DAVIES.

Rectal Foreign Body

SIR.—Dr. H. Pratap's interesting letter (*Journal*, March 30, p. 763) prompts me to record another unsuspected rectal foreign body. A Dutch engineer who had been referred to me originally because of a residual urethritis complained at a subsequent attendance of a sudden attack of severe pain in the anal region when passing a motion earlier that

day. The pain had gradually lessened, but discomfort still persisted. Suspecting an anal fissure, I cautiously introduced a well-lubricated finger into the rectum. Immediately beyond the anal sphincter it came in contact with an elongated object with its long axis at right angles to the anal canal. I was able to extract it without difficulty and identified it as a fish bone. Its wickedly sharp point was intact and it measured just over 1½ in. (3.8 cm.) in length. The patient recalled eating a fish meal two days previously. One can only marvel at its uneventful passage through the alimentary canal prior to its being held up at the exit.—I am, etc.,

Liverpool, 3.

C. D. ALERGANT.

Material of Early Contraceptive Sheaths

SIR.—As an Australian, I have been brought up to believe that by far the most important product to be obtained from the sheep is wool. I was therefore interested to read in Professor Julian Huxley's letter (*Journal*, March 9, p. 581) of the earlier use of the caecum of this animal for contraceptive sheaths, as shown by Professor J. Z. Young's examination.

I felt it might be of interest to know that in this atomic age the same use is still being made of this portion of the sheep's gut, in the U.S., if not elsewhere. In the eleventh edition of the *Physician's Desk Reference*,¹ under the manufacturer's name, prophylactics are described which "are produced from the caecum of the lamb." The influence of the twentieth century is seen, however, when one reads further down the column that they are supplied not only dry, "to be moistened before use," but also "pre-moistened, each in a plastic capsule."—I am, etc.,

Boston, Mass., U.S.A.

C. A. RIGG.

Sherrington Centenary

SIR.—This is the centenary year of the birth of Sir Charles Scott Sherrington, O.M., a founder and main architect of the physiology of the nervous system. The Royal Society of Medicine, wishing to pay tribute to his life and work, proposes to raise a fund towards a Sherrington Lecture, for the furtherance of knowledge on the nervous system, to be delivered from time to time in the Society's rooms in London.

It is felt that many will wish to contribute: both those who were his friends, pupils, and colleagues, and those, more numerous, who, as patients, doctors, and scientists, have benefited indirectly from his work. We wish to take this opportunity to commend the endeavour of the Royal Society of Medicine to establish this memorial to a great pioneer in scientific medicine.

Donations should be made payable to the Secretary, The Royal Society of Medicine, 1, Wimpole Street, London, W.1, and cheques crossed "Sherrington Memorial."—We are, etc.,

RUSSELL BRAIN,

President, Royal College of Physicians.

LINDOR BROWN,

Foreign Secretary, Physiological Society.

JOHN FULTON,

Stirling Professor of the History of Medicine, Yale University.

London, W.1.

Obituary

G. R. MATHER CORDINER, C.V.O., M.B., D.M.R.E.

Dr. G. R. Mather Cordiner, honorary radiologist to St. George's Hospital, died suddenly at his home in London on April 8. He was 58 years of age.

George Ritchie Mather Cordiner was born at Dundee on July 28, 1898, and was educated at Harris Academy and at Dundee University College, graduating M.B., Ch.B. from St. Andrew's University in 1922. Coming south shortly afterwards he held the appointment of house-surgeon at Gravesend Hospital, and then practised for a time in North London. In 1924 he obtained the Cambridge D.M.R.E., and three years later gave up general practice in order to specialize as a radiologist. He quickly made a name for himself in his specialty and at one time or another was on the staff of numerous hospitals in the London area, including the Middlesex Hospital, the Evelina Hospital for Children, the Royal Northern Hospital, the Victoria Cottage Hospital, Barnet, St. Paul's Hospital, the Hospital for Tropical Diseases, and Oldchurch Hospital, Romford. His connexion with St. George's Hospital began in 1935, with his appointment as assistant radiologist, and in 1937 he became consultant radiologist. He was a lecturer in radiology at the medical school at St. George's and also at the London School of Hygiene and Tropical Medicine. Most of his published work was on the radiology of the stomach and duodenum, and when he was elected president of the Hunterian Society in 1948 he chose as the subject for his presidential address, "The Role of Radiology in Relation to the Peptic Ulcer Problem." In 1951 Dr. Mather Cordiner was called in to join the medical advisers who were attending King George VI prior to his operation for resection of lung, and he signed a number of the official bulletins. In the Birthday Honours of the same year he was appointed C.V.O. for his services. He leaves a widow and one son and one daughter.

We are indebted to Dr. J. W. D. BULL for the following appreciation: George Cordiner's sudden death at the relatively early age of 58 will come as a great shock to all those who knew him. In his earlier years he was honorary radiologist to several hospitals, but with increasing commitments was forced to give up active work in them all, save St. George's. Until the end he offered his services free at this hospital, never joining the Health Service, which he disliked intensely. Cordiner will be best remembered for his work on the radiology of the gastro-intestinal tract. Some twenty-five years ago he went to study under Berg in Germany, who had followed the work of Åkerlund, of Stockholm, on gastro-intestinal radiology, with special reference to the compression technique of the duodenal cap. Generally speaking, in most countries at that time the radiological diagnosis of peptic ulcer was crude and haphazard. Cordiner immediately saw the great value of Åkerlund and Berg's work and applied it scrupulously in this country.

His rise to fame was meteoric. Physicians, surgeons, and general practitioners who consulted him were astonished to see duodenal ulcers, time after time, demonstrated on the x-ray films. Prior to this they were often compelled to guess at diagnosis from the results of test meals, occult-blood tests, and the doubtful value of what was seen or not seen on the x-ray fluorescent screen. As a result, Cordiner's opinion was sought by doctors up and down the country and he rapidly developed a large practice. Throughout his professional career the alimentary tract was his main interest. His ability to demonstrate minimal lesions continued to astonish his colleagues. Sceptical surgeons after being bullied—for

it was necessary—to open the abdomen, frequently had to eat their words. Sometimes, indeed, they thought they were right until humbled by the histologist's evidence which supported Cordiner's diagnosis.

In recent years overwork told on him and he was seen at scientific meetings less and less. He seldom contributed papers and had never been interested in medical politics. His practice of medicine was essentially personal, and very many patients and doctors will feel his loss an irreparable void.

He was devoted to his family, was an excellent host, and cherished the beautiful things he had in his house. His knowledge of old furniture and old clocks was considerable and was his chief hobby. For his widow, son, and daughter, all will feel the deepest sympathy in their loss.

A. E. MORTIMER WOOLF, M.B., F.R.C.S.

Mr. A. E. Mortimer Woolf, consulting surgeon to Queen Mary's Hospital for the East End and emeritus surgeon to Lord Mayor Treloar Orthopaedic Hospital, Alton, died at his home at Loughton, Essex, on April 6, aged 72.

Albert Edward Mortimer Woolf was born in London on October 3, 1884, and educated at Clifton College and Emmanuel College, Cambridge. He went on to the London Hospital, qualifying in 1908, taking the F.R.C.S. in 1909, and graduating M.B., B.Chir. a year or two later. At the London he was house-surgeon, house-physician, and receiving-room officer. During the first world war he served in the R.A.M.C. with the British Expeditionary Force in France, and later in Mesopotamia, India, and Serbia. After the war he was appointed demonstrator in anatomy at King's College and set to work to help students from many hospitals. His first honorary appointment was to the staff of Queen Mary's Hospital for the East End, and later he became senior surgeon there. Among other hospitals he served were the East Ham Memorial Hospital, the Forest Hospital, Buckhurst Hill, the Epping and District Cottage Hospital, St. Margaret's Hospital, Epping, and Lord Mayor Treloar's Home, Alton. He was always ready to help nurses, and for many years he gave lectures to the nurses in training at Queen Mary's Hospital. Apart from his very active professional life, Mr. Mortimer Woolf retained his connexion with the family business of Yeatman and Co. Ltd., Watford, of which he had been chairman for the past 20 years.

C. P. G. W. writes: The death of Mr. Mortimer Woolf removes from the medical profession a well-known personality who will be missed by a wide circle of his friends. He was a great disciple of John Hunter and was largely responsible for the rejuvenation of the Hunterian Society. He more than trebled the membership of the society and insisted that it should continue as a medical society in the City of London. He served as its honorary secretary and librarian for many years and was president on two occasions, delivering the Hunterian Oration in 1931 on "Some Personalities of the Hunterian Epoch." Up to the time of his death he acted as editor of the society's *Transactions*.

Woolf was a general surgeon in the real meaning of the term, and he published many articles on a variety of surgi-

DONALD WATSON, M.B., F.R.C.S.

Mr. Donald Watson, consultant surgeon at the Royal Eye and Ear Hospital, Bradford, died at his home at Bradford on March 28. He was 69 years of age.

Donald Watson was born on July 7, 1887, in the North Island, New Zealand, and received his early education there. Leaving college, he first entered the Civil Service, but, finding the atmosphere stultifying to a rugged and robust individualist, he embarked on a career in medicine and was trained in the Edinburgh medical school, graduating M.B., Ch.B. in 1911. He served as a medical officer in India and the East during the first world war. Returning to Edinburgh, he became assistant to the late Sir Harold Stiles, whose teaching had a profound influence upon him, and much of his undoubted success as a laryngologist he attributed to his basic training in general surgery. Becoming a Fellow of the Royal College of Surgeons of England in 1920, Watson was appointed to the honorary staff at the Royal Eye and Ear Hospital in Bradford in 1922, and this hospital he served most devotedly until his retirement in 1952. His fame spread widely, and he came to be recognized as one of the outstanding surgeons in the North of England.

Always an enthusiastic member of the British Medical Association, Donald Watson was chairman of the Bradford Division for three periods between 1939 and 1947 and its treasurer for many years. An original member of the Leeds Regional Hospital Board, he was appointed chairman of the medical services committee and represented the regional board on the board of governors of the United Leeds Hospitals, honours which he earned by the recognition from both lay and professional colleagues of his absolute integrity of purpose. Among the numerous other offices he held were the first chairmanship of the Group of Otolaryngologists of the B.M.A., chairmanship of the Leeds regional consultants' committee, and the presidency of the North of England Otolaryngological Society. Perhaps the appointment which gave him most pleasure was the election to the chair of the Section of Otolaryngology of the Royal Society of Medicine. Always a doughty champion of consultants not associated with teaching schools, he was specially gratified by this appreciation of his status by his fellow otologists, for he regarded it not only as a personal tribute but as a recognition of the value of the work done in the non-teaching hospitals. When the B.M.A. held its Annual Meeting at Bradford in 1924 he acted as one of the honorary secretaries of the Section of Laryngology and Otolaryngology, and at Cambridge in 1948 he served as a vice-president of the Section of Otorhinolaryngology.

Donald Watson was a man of very wide interests, and whatever he was doing, whether in the hospital, in the committee room, or in the countryside, he really did it with all his considerable might, and neither at work nor at play did he ever allow matters to drift. It is a measure of the affectionate regard in which he was held that he numbered among his closest friends those with whose opinions he did not always agree. Like many of his fellow countrymen he excelled at games and field sports. A fine shot, a first-class golfer, and in later years a keen fisherman, he brought to each a boyish enthusiasm which made him such a delightful companion. His passing still further reduces the ranks of the great characters in medicine who, nurtured in different conditions, have contributed so much to the upholding of our great traditions in present-day circumstances. He is survived by his wife and his daughter, to whom the deep sympathy of his many friends is extended.—F. E. C.-W.

C. E. SCOTT, M.B., F.R.C.S.Ed.

Dr. C. E. Scott died at Edinburgh on April 3, after some months of illness, at the age of 61. He was the senior practising otolaryngologist in Edinburgh, and at the time of his death was surgeon in charge of the ear, nose, and

cal subjects. But he had time for his many hobbies. He was a keen and able golfer, a well-travelled man who knew the surgical clinics in Europe and America. He was also a keen musician, and many of his friends have happy memories of some of the musical evenings spent at his house in Harley Street. Mortimer Woolf will be greatly missed, for he was a genuine, happy character. He was upright in all his actions and incapable of any mean one. He leaves a widow and two daughters, to whom we extend our deep sympathy.

Sir RATANJI DALAL, C.I.E., M.R.C.P.

Sir Ratanji Dalal, who had a distinguished career in public health in India, died at his home at Belgaum in the Bombay Presidency on April 6. He was 88 years of age.

Born at Broach, Bombay, on July 27, 1868, Ratanji Dinshaw Dalal was educated at high schools in Broach and Bombay and then received his medical training at the Grant Medical College, Bombay, qualifying L.M.&S. at the University of Bombay in 1894. He continued his medical studies at University College, London, and at St. Bartholomew's Hospital, taking the M.R.C.S., L.R.C.P. in 1895. For two years he was resident medical officer to the Finsbury Dispensary, being the first Indian doctor to hold a public appointment in England. In 1897 he was assigned by the India Office for plague duty in India, and quickly distinguished himself by his efficient and outstanding work.

In 1905 his report on the saving of life among the employees of the Empress Mills in Nagpur, Central Provinces, resulting from the use of anti-plague vaccine was published by the Bombay Government and distributed widely for the information of employers of labour and the public generally in India. From 1904-6 he conducted some important investigations at the Bombay Bacteriological Laboratory on anti-plague vaccine. For three years (1908-11) he carried out research on methods of preventing plague, and in 1909 was the first to introduce in India the use of barium carbonate as a rat poison. This proved an effective measure and helped to save innumerable lives. During the famine of the early 'twenties in the Bijapur district he selected sites for famine relief camps and so organized and supervised the sanitary arrangements and vaccination work that no cases of cholera or other epidemic disease occurred in the camps, although cholera was prevalent outside. As director of the Vaccine Institute, Belgaum, from 1923 to 1925 Sir Ratanji carried out many important changes in the manufacture of vaccine lymph. He was the author of a *Manual of Vaccination*, published in 1930 by the Bombay Government. On his retirement from Government service in 1925 Sir Ratanji worked for the Red Cross and lectured on public health subjects.

From 1930 to 1945 he was a member of the Indian Central Legislative Assembly, and he bore much of the burden of the debate on the Indian Medical Council Bill. During the second world war he raised funds for defence loans and war gifts and also recruited officers for the Indian Army.

Sir Ratanji was the first Indian to be awarded the diploma of Membership of the Royal College of Physicians of London without examination. This was in 1931, just after the publication of his *Manual of Vaccination*. In 1916 he took the D.P.H. of the English Royal Colleges. He was knighted in 1942. Previously he had, in 1923, received the Kaisar-i-Hind medal for public service in India, in 1935 King George V's Silver Jubilee medal (awarded to him both by the Government of Bombay and the Government of India for distinguished services), the Companionship of the Order of the Indian Empire in 1936, and in 1937 King George VI's Coronation Medal "for unimpeachable loyalty to the British Government." Among the various governing bodies of which he was a member were the British Empire Leprosy Relief Association (Indian Council), the Lady Hardinge Medical College and Hospital, Delhi, the Countess of Dufferin's Fund, and the Pasteur Institute, Kasauli.

throat department of the Royal Hospital for Sick Children and of the Northern Group of Hospitals in Edinburgh.

Charles Ernest Scott was born on November 3, 1895, and was educated at Selkirk High School and Fochabers Academy. His medical studies at Edinburgh University were interrupted by service in the Royal Navy during the first world war, and he graduated M.B., Ch.B. in 1921. After holding resident posts at Edinburgh Royal Infirmary, and quickly deciding upon the line which he would follow, he obtained the appointment of senior clinical assistant and university clinical tutor to Dr. J. D. Lithgow's unit in the infirmary. During this period he passed the examination for the Fellowship of the Royal College of Surgeons of Edinburgh in 1926, and when an appointment fell vacant in the Royal Hospital for Sick Children in Edinburgh he became assistant surgeon to Dr. Douglas Guthrie. Dr. Scott held other local appointments, being assistant surgeon to Leith General Hospital, and quickly took a prominent position among the specialists in his chosen subject. Apart from his work within the city he had the responsibility for the ear, nose, and throat services in his native Border country, and he will be greatly missed in the Border towns.

Dr. Scott was known to a very wide circle of friends as a man of great ability and a surgeon of the first rank. His quiet and modest manner covered and to some extent concealed the fact that he possessed one of the most skilful and dexterous pair of hands in his profession, and his many patients will greatly miss his gentleness and his kind and considerate ways. He took a keen interest in his profession, and outside his normal work acted as secretary of the Scottish Otolaryngological Society from 1933 to 1946, except for the year (1935) in which he was president of the society. Curling was a favourite pastime and he was at his best when enthusiastically skipping one of the Edinburgh medical rinks. In his younger days, following Border traditions, he took a keen interest in athletic pursuits, in particular Rugby football, at which he proved himself an excellent full-back. A lovable, unassuming man, he will be sadly missed from the medical scene in Edinburgh. For many years a widower, he is survived by a son, to whom the sympathy of his friends is extended.—I. S. H.

FLORENCE M. S. THOMAS, M.B., Ch.B.

Dr. Florence M. S. Thomas died at her home at Canford Cliffs, Bournemouth, on March 3, at the age of 77.

I. C. H. writes: Florence Margaret Sarah Price was born at Carmarthen on December 30, 1879. Her life was intensely medical. She was brought up in the atmosphere of a large general practice; her father, Dr. Rees Price, combined ability with immense enthusiasm for his profession, giving to it his best energies, both his sons, and his daughter. His desire, one gathered, was that his daughter should remain, like her great Victorian namesake, dedicated and single: this was, most happily, unfulfilled. Nevertheless, her marriage was far from being a loss to medicine, for after marrying a doctor she continued to work as one; both her sons are doctors and her daughter is a doctor's wife. She graduated in 1904 with the M.B., Ch.B. of Edinburgh, where she spent the first half of her student life, completing the course at Birmingham. In those days, when the "lady medical" had not been so thoroughly accepted, she vanquished all prejudice with her complete modesty, despite a personal charm which was irresistible to both sexes and all ages, and an ability which took her through the medical course without a failure and at maximum speed. Moreover, during much of this time she kept watch, by parental injunction, over the studies of her elder brother—a charming youth, but ill-armed against the distractions of life—coaxing, helping, and scolding him as required, for all of which, when qualified, he was duly grateful.

After taking her degree she became a house-physician at the Swansea General and Eye Hospital, where she met the rising young oculist, Frank Thomas, whom she married.

As his practice grew she helped him more and more with his hospital work, and after several years of this experience was appointed consulting ophthalmic surgeon to the Port Talbot Hospital. It was a marriage full of happiness. Frank Thomas was a jewel among men, both as an oculist and in his warm humanity, and his wife gave to both an ideal reinforcement. She knew just how to distribute energy between her home and her profession. The nursery years of their four children were indeed privileged. Near the end of a life, long, useful, and happy, the deepest sorrow fell upon her. Frank Thomas, who had worked in failing health till the end of the war, retired and left Swansea for Canford Cliffs, where both his son and son-in-law were in practice. In 1949 he died. The loss was overwhelming, though the nearness of her children much helped her. Soon her own health began to fail. She bore many troubles most bravely, including the rigours of an operation for glaucoma. Then, last August, her younger daughter died suddenly. The shock to her intense maternal feeling, with a seriously impaired heart, might have been immediately fatal but for her other children: through them she again found some happiness before the end, with heart failure, sudden and painless.

Her personality was unique, with a charm difficult to convey in words. Her voice was a delight, soft, musical, and very characteristic. It was always a pleasure to look at her; she had a neat, small figure, a face vividly expressing her essential beauty, and we have never known so much of a fascinating girl carried on into the seventies. Her outstanding quality was a sincerity that fairly shone. Her intense human sympathy never willingly stopped at words; she always longed to help, and when possible she did. Her patients adored her. She had a wonderful sense of humour and a superb gift of entertaining narrative. A beautiful and rare spirit has taken flight. We grieve with her devoted children for all they have lost, and humbly share their thankfulness for all she has given.

L. L. McMAHON, M.B.

Dr. L. L. McMahon, of Whitchurch, Glamorgan, died at his home there on March 10 at the age of 68. Leo Luke McMahon was born on October 31, 1888, and studied medicine at the University of Melbourne, where he graduated M.B., B.S. in 1915. After the first world war he came to Britain and settled in general practice at Whitchurch, where he remained until his death.

C. W. S. writes: Dr. L. L. McMahon was one of the large army of general practitioners who shun the limelight, do their duty, and leave behind them a sweet-smelling memory. "Mac" was always a joy to his patients and friends—solid, four-square, uncompromising, and kindly. Uprightness and common sense were the twin poles of his being, and in his last long illness his courage was amazing. He made no concession to the enemy, worked to the last day, and died, as he wished, in harness. For the lighter side of life, golf was his passion: unorthodox in style, he was a dangerous opponent because he never recognized defeat. He leaves a widow and one son, who is a medical student.

R. E. H. PARTINGTON, M.R.C.S., L.R.C.P.

Dr. Robert Edward Heap Partington, who practised in Sheffield, died suddenly on March 10 at the age of 51. He had an unusual career, for before beginning the study of medicine at Sheffield in 1938 he served for seventeen years in the Merchant Navy and the Royal Naval Reserve. When the second world war began in 1939 he rejoined the Royal Navy and was actively engaged throughout most of the war, taking part in the North African landings and in convoy work across the Atlantic and to and from Murmansk. For his services he was awarded the Reserve Decoration and promoted to the rank of commander. Sent home in 1944 to finish his

medical studies at Sheffield University, he qualified M.R.C.S., L.R.C.P. in 1949.

After a year's resident work at the Royal Hospital, Sheffield, he started in practice at Beighton as partner to Dr. L. A. de Dombal. He combined mature judgment and powers of leadership with an up-to-date medical knowledge, and his patients came to rely on him and to love him. They will miss him as a counsellor as well as a doctor. He was a staunch and active churchman all his life, and for the past two years had been lay reader at Eckington church. He leaves a widow and one son, aged 5 years.

T. Y. BARKLEY, O.B.E., M.B., M.R.C.P.Ed.

Dr. T. Y. Barkley died at his home at Weybridge, Surrey, on March 11 at the age of 65.

Born on December 28, 1891, Thomas Yuille Barkley was a Scot, and studied medicine at Edinburgh University, where he graduated M.B., Ch.B. in 1915. He qualified for the Annandale Gold Medal, which was not awarded during the first world war. He at once joined the R.A.M.C., serving in France, Salonika, and the Balkans. He attained the rank of lieutenant-colonel and commanded a casualty clearing station. Mentioned in dispatches on three occasions, he was appointed O.B.E. in 1919 for his distinguished services. The war over, in 1919 he went into general practice at Weybridge, and carried on there until his death nearly 38 years later. He devoted his life to his practice, and worked so hard in the service of his patients that he had little time for other interests. Apart from his annual holiday, he rarely went "off duty," and latterly, when he had painful warnings of serious cardiac trouble, refused to retire from work. His clinical judgment was exceptional, and his ready sympathy and understanding of their problems made him a much-loved friend of his patients, as well as their trusted medical adviser. It was typical of the man that in 1931, despite a busy and successful practice, Dr. Barkley made time, by working in the early hours of the morning, to read for the M.R.C.P. of Edinburgh, obtaining this diploma at the first attempt. When the National Health Service was instituted in 1948 Dr. Barkley did not enter it, but continued in private practice as strenuously as ever. He leaves a widow, a son, and a daughter, his elder son having been killed when flying a bomber in 1944. At a memorial service at Weybridge, St. Mary's Church, Otland, was filled almost to capacity. There could have been no more sure sign of the love and esteem in which Tom Barkley was held. Truly he was "an helper of many," and he will be sadly missed by the many of whom he was physician, friend, and counsellor.—S. S. B. and R. G. H.

J. G. STEBBING, M.B.

Dr. J. G. Stebbing died at the Royal Marsden Hospital on March 23 at the age of 32. For the past three or four years he had been in practice in Bermondsey.

John Garvin Stebbing was the younger son of the late Mr. G. F. Stebbing, who was a surgeon at Lambeth Hospital and a well-known pioneer in radiotherapy. After leaving Dulwich College he went on to Guy's Hospital, graduating M.B., B.S. in 1947. He had a fine record as a student, and after graduation was house-surgeon to Sir Russell Brock. Thereafter he worked for a time as junior lecturer in physiology, and then became assistant director of research in the department of surgery. He had unusual gifts, inheriting much from his remarkable father, and he continued to work in his practice in Bermondsey, though suffering from a disease he knew was incurable. Since 1955 he had been a member of council of the Medical Protection Society, of which his father had been chairman. His death at such an early age is a great loss to the profession. He leaves a wife and daughter.

Sir RUSSELL BROCK writes: Dr. J. G. Stebbing's early death marks the end of a courageous although short professional life. A routine radiograph before entering the Services at

the end of his house appointments disclosed a serious lesion. In spite of this knowledge, his cheerfulness was unimpaired and he embarked on a busy life as a general practitioner in one of the poorer districts of London and rapidly established a position as an able and sympathetic doctor. He did not allow repeated relapses to interfere with his work and efficiency. One can have nothing but admiration for a professional life carried on so doggedly and successfully under such a grave handicap. The fine spirit with which he faced his final illness was characteristic of his nature.

FREDERIC DURAN-JORDA, M.D.

Dr. Frederic Duran-Jorda, pathologist at Booth Hall Children's Hospital, Manchester, died on March 30 in the Manchester Royal Infirmary, at the age of 52.

Frederic Duran-Jorda, a Catalan by birth, graduated M.D. from the University of Barcelona in 1928. He decided to specialize in pathology, and in 1934 was appointed clinical pathologist to the public health department of his home town. With the outbreak of the Spanish Civil War he organized the blood transfusion service of the Republican Army, using, for the first time on a large scale, the civilian population as donors. In 1937 he officially took up the post as chief of the service. In this capacity he obtained the highest medical award of the Catalan Government, and was invited to various European countries to lecture and advise on the organization of national blood transfusion services. The British Red Cross Society helped him to come to England in 1939. After a short stay in London he decided to work as a technician in the clinical laboratory of Ancoats Hospital, Manchester, where, after his admission to the British Medical Register, he was soon appointed first as assistant pathologist and then as pathologist. In 1950 he became director of the department of pathology at Booth Hall Children's Hospital and Monsall Hospital, Manchester.

A. H. writes: Duran-Jorda loved his work, and, as with so many medical men, it was the purpose and hobby in his life. A wide range of problems attracted his interest, and he approached them with originality of method and conception. In spite of an unusual liveliness, he would pursue with infinite patience and energy the most intricate details of any problem that engaged his fertile mind. Partly as a result of his training, but also due to an innate ability, he had become a master of laboratory technique. This was particularly evident in his histological studies of the gastric and intestinal mucosa, the Bellini ducts, and pulmonary hyaline membrane in the newborn. His paper on the histopathology of the semi-squamous epithelial layer in the colon was awarded the first prize and a certificate of merit by the American Gastro-enterological Association in 1947, as well as a first prize of the Institute of Catalan Medical Studies in Barcelona. He had his own ideas on blood formation, ideas not generally accepted, but which he supported by a number of fascinating investigations, not only in man but also in different animal species. Another subject which had attracted him early in his medical career and to which he returned quite recently was parasitology. A study on the relationship of *Oxyuris vermicularis* to appendicitis in children is in the press. During the past two years he introduced a new and promising treatment for scalds and burns in children.

Duran-Jorda was a man of striking good looks but modest and gentle. Although he had decided views on most subjects he was exceedingly tolerant and respected the opinions of others. In his kindness he would always willingly offer help where help was needed and took a fatherly interest in all his subordinates and assistants. They responded with an affection bordering on devotion. For some time he had been fully aware of his incurable illness, but he continued bravely with his daily duties and his research work until the final phase of his disease, hoping that fate would grant enough time to complete some of the tasks he had set himself. All his colleagues were his friends, but he had many outside the professional circle, and all will extend their deep-felt sympathy to his widow and his two children.

Medico-Legal

ACQUITTAL OF DR. J. BODKIN ADAMS

JUDGE'S SUMMING-UP

The jury found Dr. John Bodkin Adams not guilty of the murder of Mrs. Morrell, who died at Eastbourne on November 13, 1950. They reached their verdict in 44 minutes on April 9, the seventeenth day of the longest murder trial recorded in Great Britain. In his summing-up the Judge referred to "a most curious situation, perhaps unique in these courts," that the act of murder had to be proved by expert evidence; and again: "the medical evidence is the essential part of the case, and perhaps the crucial part."

Sir Reginald Manningham-Buller, Q.C., appeared for the prosecution with Mr. Melford Stevenson, Q.C., and Mr. Malcolm Morris. Mr. Geoffrey Lawrence, Q.C., appeared for Dr. Adams with Mr. Edward Clarke and Mr. John Heritage. The Medical Defence Union instructed Messrs. Hempsons, solicitors, to act for Dr. Adams.

Mr. Justice Devlin began his summing-up on April 8 by defining murder as "an act, or a series of acts, done by the prisoner which were intended to kill and did in fact kill." It did not matter for this purpose that the patient's death was inevitable and her days were numbered. If her life was cut short by weeks or months it was just as much murder as if it was cut short by years.

"You have heard a good deal of discussion during the evidence about the circumstances in which doctors might be justified in administering drugs which would shorten life. Cases of severe pain were suggested and also cases of helpless misery. The law knows of no special defence of this category. But that does not mean that a doctor who is aiding the sick and dying has to calculate in minutes or even hours, perhaps not in days or weeks, the effects on a patient's life of the medicines which he will administer."

"If the first purpose of medicine—the restoration of health—can no longer be achieved, there is still much for the doctor to do, and he is entitled to do all that is proper and necessary to relieve pain and suffering even if the measures he takes may incidentally shorten life. There are cases in hospital where a doctor prolongs or shortens life by hours or perhaps even longer. The doctor who decides to administer the drug or not is not thinking in terms of hours or months of life. He could not do the job if he were. If, for example, a doctor has done something or omitted to do something and death occurs, say on the 11th or 12th or on the Monday instead of the Tuesday, no one with common sense would say the doctor caused the death. They would say the cause of death was the injury or whatever it was that brought her to hospital. It remains a fact and remains the law that no doctor, nor any man, has the right to deliberately cut off life. I say it to you so there can be no mistake."

Proper Treatment

Counsel for the defence was saying, said the judge, that the treatment given by Dr. Adams was designed to promote comfort, and if it was the right and proper treatment the fact (if it was) that it shortened life did not convict him of murder.

He directed the jury that as a matter of law there was no evidence on which they could conclude that any drugs were administered to Mrs. Morrell over and above the injections recorded in the nurses' books.

He then digressed to comment on the public hearing in the magistrate's court: "I would like to say this—I say it with the approval and authority of the Lord Chief Justice—I think it would have been wiser in this case if those preliminary proceedings before the magistrates had been held in private; because, when you have a case of this character which arouses widespread discussion, it is inevitable reports should appear in the press. And, as I reminded you at the beginning of this case, the proceedings before the preliminary magistrates were quite different from the proceedings that emerged in this court. They should be read by the public consequently and by members of the public who might be asked to serve on the jury." He did not criticize the magistrates, who had a difficult decision to make, nor did he

make any criticism of the general rule that except for good and special reasons criminal processes should be conducted in open court.

After telling the jury that the burden of proof was on the prosecution, the judge said that they had to decide between the medical opinions as they would in getting conflicting medical opinions over a relative who was ill. They had to make up their mind which was most likely to be right. Referring to Mr. Lawrence's advice that Dr. Adams should not go into the witness-box, the judge said: "It would be utterly wrong if you were to regard Dr. Adams's silence as contributing in any way towards proof of guilt. It does not, and it cannot. The prisoner who goes into the witness-box goes there for his own benefit and his own defence." Turning to Mrs. Morrell's will, the judge pointed out that what Dr. Adams got was the oak chest and silver valued at £276, which compared with £300 to the night nurse and £1,000 to the chauffeur. The jury might bear in mind that the usual mark of undue influence was that the influencer was able to extract something which he ought not to have got.

"When you find that the bequest, so far from being something in the opinion of the relatives that Dr. Adams ought not to have got, Mr. Morrell thinks it fair to add something to that which his mother had bequeathed, it may help you to decide whether this was really a case of undue influence exercised by Dr. Adams."

Discussing the discrepancies between the amounts of drugs prescribed and the amounts shown in the nurses' note-books as administered, the judge said it seemed clear that the special injections could not possibly account for the difference between them. Was there a channel, he asked, down which drugs which were prescribed were improperly disappearing? The jury might think or suspect that someone was dealing dishonestly with them, and that that someone must either be Dr. Adams or one of the nurses.

"If you were ever to get so far in your investigations as to begin to wonder which of the people is most likely you will, in fairness to Dr. Adams, bear in mind that two of the nurses have told lies about this matter in the witness-box. One of them lied about where the drugs were kept locked up—that was Nurse Stronach—and one of the others, either Nurse Mason-Ellis or Nurse Randall, lied about the conversation in the train in which Nurse Randall is alleged to have said: 'Don't say that, or you will get me into trouble.'"

The prosecution had to satisfy the jury that death was not due to natural causes. "It is a most curious situation, perhaps unique in these courts, that the act of murder has to be proved by expert evidence," and of the doctors' evidence he commented: "Men of science cannot always give precise, clear, and unqualified answers, particularly if they are dealing with an illness which occurred years ago at which they were not present."

Question of Intent

The court adjourned, and on its resumption the following day, April 9, the judge said the medical evidence was the essential part of the case, and perhaps the crucial part. The jury were entitled to accept the evidence of Dr. Douthwaite and not to attach much to the contrary opinions of Dr. Harman, and they were entitled to say that Dr. Ashby's real conclusion was that the drugging was an unjustified act in the medical sense which accelerated death. That was the issue on this point which they had to determine. If they decided certain points in favour of the prosecution, then they would have to deal with the question of intent. Intent was something that existed in a man's mind. Apart from his own evidence it could only be proved by inferences that were drawn from his own acts, but his own evidence must be welcome. People did not normally intend things unless they were going to benefit from them. Therefore the jury must examine what was the motive in this case. Mr. Lawrence had said that the suggestion that the doctor had anticipated Mrs. Morrell's death by a few days or few weeks for a chest of silver valued at £270 was ludicrous.

"'Ludicrous' is a strong word. But it is a strong point, and it is a point which requires an answer. I listened carefully to the Attorney-General to see what the answer was. I didn't hear the answer."

The judge said a further point for the jury to consider was the false filling up of the cremation form. "I say 'false' advisedly, for it is a matter for you. But it seems to me that it is false." The answer which Dr. Adams had given on the form—"Not so far as I am aware"—had to be set side by side with the answer given to Superintendent Hannam, and that answer made it plain that he knew, or thought, he was going to get the oak chest and the car.

As to the nurses' note-books, the judge said that the Attorney-General in his address had asked where they had come from, and in whose interest it was to keep them. While the judge would not say that there was a mystery about it, it was something which one would have liked to have known the answer to.

Finally, the judge said there were three points that the jury would have to consider. The Crown must satisfy them that Mrs. Morrell did not die of natural causes; that, from the medical evidence, the act of killing was something that was capable of being murder; and that the act was committed by the accused with the intent to murder. "Not infrequently I have heard the case presented by the prosecution that seems to me to be manifestly strong, and sometimes I have felt it my duty to tell the jury so. I do not feel I should hesitate to tell you here the case for the defence seemed to be manifestly a strong one, and you must not find for the Crown until you have weighed and subjected and ruled out all the evidence and the arguments put before you on behalf of the defence. It is always the same question—is the case for the Crown strong enough to carry conviction to your mind? It is your question and you have to answer it."

Medical Notes in Parliament

Protection in Atomic Plant

Mr. SOMERVILLE HASTINGS (Barking, Lab.) asked the Prime Minister on April 9 whether, in view of the danger resulting from accidents, malicious or otherwise, in connexion with the processes in which nuclear energy was applied, he would institute an inquiry into the best first-aid treatment, and arrange that such information was made available wherever it might be required.

Mr. H. MACMILLAN replied that the Atomic Energy Authority took the most exhaustive precautions against accidents, and there were extensive measures for detecting radioactivity in all laboratories and plants where radioactive or toxic material was used. Emergency arrangements to deal with accidents which might occur were tested regularly in exercises designed to cover every foreseeable contingency. A draft code of regulations covering the protection of workers in factories against ionizing radiations was in preparation. A code of practice for the protection of workers in hospitals in the Health Service was also being published. He was satisfied that there was no need for the inquiry suggested.

Mr. HASTINGS thought that, as the results of heavy and even fatal doses of ionizing radiation were not at once apparent, it was especially important that in every area where such accidents could occur there should be a definite statement, easily read by all who might be affected, about danger involved and what should be done. Mr. MACMILLAN said he appreciated the anxiety of Mr. Hastings, but he thought the Authority were taking every possible precaution. In the laboratories and plants everything was done to ensure that high standards of protection against absorption of radiation were general, and continuously observed. Personal records of radiation received during occupational exposure were kept for all persons whose work exposed them to such radiation.

Dr. EDITH SUMMERSKILL (Warrington, Lab.) suggested that as the greatest authorities agreed that there were aspects that were obscure, this was the time to institute an inquiry. What were the objections? Mr. MACMILLAN replied that

he would certainly consider an inquiry if he thought it would help the work of the Authority in its care of those it employed. But he was satisfied that everything possible was being done, and he did not think an inquiry would help its work; it might even at present impede it. If at any time he felt an outside inquiry by experts not available to the Authority would be valuable he would discuss it with the Authority and consider whether it would be useful.

Proprietary Preparations Agreement

Mr. R. RUSSELL (Wembley, South, Con.) asked the Minister of Health for a statement regarding his negotiations about the price of proprietary preparations. Mr. D. VOSPER, replying on April 8, said the Government had accepted in principle a scheme proposed by the Association of British Pharmaceutical Industry, and modified in the course of discussions with the Health Ministers, for regulating the prices of certain proprietary pharmaceutical products. The scheme provided a method of establishing reasonable maximum prices for most of these products.* There would also be cases where firms negotiated prices directly with the Departments. The Government's acceptance of the scheme was subject to the completion of some points of detail and to the working out of suitable administrative machinery, but he hoped it could be brought into operation within the next two months. The scheme would be on trial, and subject to review. He was grateful to the industry for the co-operation they had shown throughout these negotiations.

Information Refused

Mr. N. DODDS (Erith and Crayford, Lab.) asked on April 8 what intelligence quotient examination had recently been given to Miss Mary Betteridge, a patient at St. Margaret's Mental Hospital, Birmingham; who supervised the examination; and with what result. Mr. J. K. VAUGHAN-MORGAN, the Parliamentary Secretary, replied: I do not think it would be right to give this information, which is confidential.

Expenditure on Vaccinations

Mr. S. P. VIANI (Willesden, West, Lab.) asked the Secretary of State for Scotland what payments had been made, either out of the rates or from Exchequer funds, to cover the cost of vaccination against smallpox since the operation of the Health Service Act in July, 1948; how payments were made for inoculating against diphtheria, whooping-cough, and for any other inoculations; what was the total amount of payments for the materials used in these inoculations; and how much had been paid out of State funds for carrying out these inoculations or for supplying local authorities with a record of the inoculations performed. Mr. J. S. MACLAY stated on April 5 that vaccinations and inoculations carried out by general practitioners in the Health Service were covered by their remuneration from capitation fees, etc. In addition they received 5s. from the local health authority for each record submitted. No special fee was paid for

*The scheme contains three main provisions which enable manufacturers to regulate their prices voluntarily:

(a) Under the first, the price in the U.K. will not exceed that which the product commands in adequate volume in overseas markets in face of international competition.

(b) The second, which applies when a product is not exported in significant quantity, provides that if an identical non-proprietary standard drug is available in the U.K. the price of the proprietary shall not exceed the price of the standard drug.

(c) If it is impossible to apply either of these two provisions, a maximum price may be determined by using a detailed formula comprising (i) an ingredient allowance based on recognized trade prices and (ii) processing and packaging allowances according to a schedule covering different types of product.

The prices determined by the three formulae will be maximum prices. Immediate effect will be given to price reductions that result from the application of the scheme. On the other hand, if in any case the permitted maximum under the appropriate formula is higher than the existing price, the existing price will not be increased on that account. The scheme also provides that in special cases, and where a manufacturer prefers this course, a fair and reasonable price may instead be negotiated with the Health Departments.

vaccinations and inoculations carried out by medical practitioners employed full-time by local health authorities; those employed part-time were paid on a sessional basis. The gross expenditure incurred by local health authorities in Scotland in respect of vaccinations and inoculations carried out under the Health Service from July, 1948, to the end of March, 1957, was £598,000, half of which fell on the Exchequer and half on the rates. This expenditure was in respect of record fees, staff costs, and materials not supplied centrally. In addition, during the same period the Scottish Office incurred expenditure for vaccines and other immunizing materials issued free to local health authorities amounting to £111,000. Separate figures in respect of the different vaccines were not available. Nor was the cost of vaccines dispensed by chemists on the prescriptions of general medical practitioners separately recorded.

Doctors' Lists of Patients

Mr. D. VOSPER told Mr. SOMERVILLE HASTINGS on April 12 that in July, 1956, the number of general practitioners with lists of between 2,500 and 3,500 patients was 5,385; the number with lists between 1,500 and 2,500 was 5,218; and the number with lists of 1,500 or under was 5,500, of which about 540 had lists of 500 or under.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

Dr. B. Towers has been reappointed a University Demonstrator in the Department of Anatomy with tenure from April 1, 1957, for two years. Dr. R. T. Sims has been appointed a University Demonstrator in the Department of Anatomy and Dr. J. G. Cruickshank a University Demonstrator in the Department of Pathology, both with tenure from April 1, 1957, for three years.

In Congregation on February 23 the degree of M.B. was conferred (by proxy) on R. H. Lavelle.

In Congregation on March 9 the following degrees were conferred:

M.B.—C. C. Gunn (by proxy).
M.D.—J. R. Seale, T. M. D. Gimlette, J. O. Robinson, K. E. Halnan, H. B. L. Williams, A. S. Herington,
M.Chir.—C. H. Kinder (by proxy).

D. S. H. W. Nicol, M.D., formerly Scholar of Christ's College, has been elected into the Josephine Rebecca Wolf Fellowship at the College for research in biochemistry.

UNIVERSITY OF DUBLIN

SCHOOL OF PHYSIC, TRINITY COLLEGE

At a recent examination the following medical practitioners were awarded the Diploma in Gynaecology and Obstetrics:

N. K. Allahbadia, B. H. Marten, S. Madan, S. Khosla, S. K. Ghosh, P. J. Kaur, S. Froman.

UNIVERSITY OF LONDON

Dr. A. J. M. Rees has been elected and Dr. A. Talbot Rogers re-elected to membership of the Standing Committee of Convocation, as the representatives of Medicine.

The William Julius Mickle Fellowship for 1956-7 has been awarded to Elfrida L. G. Hilton, M.B., F.R.C.S., F.F.R., in respect of her work on the care and cure of cancer.

The degree of M.D. was awarded by the Senate to D. Rowley on February 27.

UNIVERSITY OF LEEDS

The following candidates have been approved at the examinations indicated:

M.D.—Mary McMillan (with distinction).
M.B., Ch.B.—C. D. Holdsworth, *P. H. Smith, *Brenda Thiede, J. S. W. Brierley, Dorothy C. Campbell, J. H. Chippendale, H. M. Chung, J. E. Cox, N. Cross, A. Darnborough, Eileen M. Gillespie, P. Goodwin, L. L. Hemis, P. H. Holmes, D. Jarratt, D. T. Jones, Vera E. Lawton, J. W. Lewis, M. Mahloudji, J. W. A. Moxon, D. T. Price, B. E. Roberts, Audrey Sarfas, Margaret Sawyer, Marion Sherman, J. N. Smith, R. I. Swires, R. J. Taylor, D. L. Thiede, F. E. Tomlinson, Barbara F. Turner, R. W. Turner, B. Whitaker, Dorothy M. Wootton.

DIPLOMA IN PUBLIC HEALTH.—E. W. G. Birch, †C. Burns, G. Cust, J. A. G. Graham, J. Harkness, M. E. O'Neill, J. Pemberton, †W. Turner, J. A. G. Watson, Marianne H. Witt.

*With second-class honours. †With distinction.

UNIVERSITY OF SHEFFIELD

At a meeting of the University Council held on March 15 Dr. I. B. Sneddon was appointed part-time Lecturer in Dermatology.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

At a meeting of the Council of the College held on February 14, with Sir Harry Platt, President, in the chair, Sir Henry Dale was admitted as a member of the Court of Patrons.

The Hallett Prize was awarded to Darrel Felix Weinman, of Ceylon, on the result of the Primary Fellowship examination held recently in that country.

Diplomas of Fellowship in the Faculty of Anaesthetists were granted to the following successful candidates:

J. K. Trotter, T. R. Bomonji, H. M. C. Corfield, P. Dinmore, A. Thorogood, Morag J. R. Bastable, June E. Brett, J. B. Montgomery, J. D. Holdsworth, D. I. Chisholm, C. Moss, R. H. Bolton, Wendy A. Clark, M. Rosen, F. Wilson, A. R. Boutros, T. D. W. Davies, W. J. Glover, R. P. Holmes, R. T. Pettigrew, H. G. Saunders, K. B. Holloway, J. Moore, R. G. Waterhouse, I. E. Purkis.

The diploma of M.R.C.S. was granted to J. R. Anthony and to the 84 other successful candidates whose names were printed in the report of the meeting of the Royal College of Physicians of London in the *Journal* of March 2 (p. 530) as recipients of the diploma of L.R.C.P.

Diplomas in Public Health and in Industrial Health were granted, jointly with the Royal College of Physicians of London, to the successful candidates whose names were printed in the report of the meeting of the Royal College of Physicians of London in the *Journal* of March 2 (p. 530).

A Diploma in Child Health was granted to U. S. Ellis and a Diploma in Radiodiagnosis to B. W. A. Leeming, both jointly with the Royal College of Physicians of London.

At a meeting of the Council of the College held on March 14, with Sir Harry Platt, President, in the chair, the Hallett Prize was awarded to Dr. S. K. Nair, of Agra, and the Macloghlin Scholarship to F. R. Jackaman, of Queen Elizabeth's School, Barnet.

The death of Dr. Everts A. Graham, an Honorary Fellow of the College, was reported.

Vital Statistics

Marriages in 1955

In England and Wales in 1955 the most popular age for men to marry was 23 and for women 21. In 14 marriages both bride and groom were aged over 85, and in 48 both were aged 16. Of the 28,016 men aged under 21 who married, 3 were widowers and 7 divorced; while, of the 108,464 women under 21 who married, 21 were widows and 27 divorced. In response to the income-tax laws, the most favoured month for marriage was again March, when 60,532 took place; May had the fewest number, with 16,474. The downward trend in divorces continued, there being 26,262 as compared with 58,444 in 1947, the post-war peak. About 500-600 annulments a year have been granted in the 1950's.—*Registrar-General's Statistical Review of England and Wales for the Year 1955*, Part 2, Tables, Civil (H.M.S.O., 7s. 6d.).

Week Ending April 6

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 878, whooping-cough 2,768, diphtheria 9, measles 25,280, acute pneumonia 466, acute poliomyelitis 37, dysentery 1,051, paratyphoid fever 3, and typhoid fever 2.

Infectious Diseases in First Quarter

Notifications of infectious diseases in England and Wales during the first quarter of this year were in general below the average of the preceding first quarters. The exceptions were acute poliomyelitis and whooping-cough. The number of notifications of acute poliomyelitis was the highest ever recorded for a first quarter, the previous highest figure was 512 in 1950. The incidence of whooping-cough, though relatively high, has been exceeded in earlier March quarters. Notifications of dysentery were below the level of the two preceding March quarters, but the incidence is still very high. Diphtheria notifications were the lowest ever recorded for any first quarter; the average number per week was 4.5, compared with 1,611 in the first quarter of 1938. The incidence of acute pneumonia was very low, and the number of deaths from influenza in the great towns was the lowest for many years.

Returns of the great towns suggest that the infant mortality rate for the whole country will be the lowest ever recorded for a March quarter and the general death rate will be the lowest for recent first quarters.

The uncorrected notifications for the first quarters of the past five years are:

England and Wales	1953	1954	1955	1956	1957
Scarlet fever	20,550	15,868	9,121	11,400	10,315
Whooping-cough	34,207	28,985	25,020	16,870	38,251
Measles	350,836	23,340	251,486	35,164	233,826
Acute poliomyelitis	345	332	208	366	516
Diphtheria	264	246	173	89	59
Meningococcal infections	595	515	499	436	385
Dysentery	4,449	10,808	14,551	19,297	13,594
Acute pneumonia	20,005	10,507	13,430	12,905	8,491
Enteric fevers	123	244	113	98	94
Great Towns: Deaths from influenza	2,995	398	1,181	921	204
All deaths	97,150	85,783	95,780	95,191	77,292

Graphs of Infectious Diseases

The graphs below show the uncorrected numbers of cases of certain diseases notified weekly in England and Wales. Highest and lowest figures reported in each week during the nine years 1948-56 are shown thus ———, the figures for 1957 ———.

Except for the curves showing notifications in 1957, the graphs were prepared at the Department of Medical Statistics and Epidemiology, London School of Hygiene and Tropical Medicine.

Infectious Diseases

Infectious diseases were less prevalent in England and Wales during the week ending March 30. The falls in the notifications included 1,994 for measles, from 27,179 to 25,185, 150 for acute pneumonia, from 695 to 545, 95 for dysentery, from 1,317 to 1,222, 88 for food-poisoning, from 298 to 210, and 83 for whooping-cough, from 2,932 to 2,849.

The largest falls in the incidence of measles were 614 in Essex, from 2,046 to 1,432, 402 in Lancashire, from 3,866 to 3,464, 310 in London, from 2,034 to 1,724, 242 in Middlesex, from 1,576 to 1,334, 214 in Yorkshire West Riding, from 2,852 to 2,638, and 210 in Northumberland, from 879 to 669; the largest rises were 162 in Nottinghamshire, from 443 to 605, 105 in Durham, from 1,488 to 1,593, and 92 in Lincolnshire, from 450 to 542. The notifications of scarlet fever numbered 812, being 10 fewer than in the preceding week, and there were no large fluctuations in the local trends. The largest variation in the trends of whooping-cough was a rise of 55 in Kent, from 173 to 228. 6 cases of diphtheria, 3 more than in the preceding week, were notified, and 2 of these cases were from Plymouth C.B.

28 cases of acute poliomyelitis were notified during the week, and these were 8 fewer for paralytic and 1 fewer for non-paralytic cases than in the preceding week. The largest returns were Sussex 3 (Brighton C.B. 3), Middlesex 3 (Ealing M.B. 2), Gloucestershire 3 (Bristol C.B. 2), and Essex 3.

The largest centres of dysentery were Yorkshire West Riding 301 (Leeds C.B. 72, Rotherham R.D. 57, Rotherham C.B. 53, Bradford C.B. 30, Sheffield C.B. 21, York C.B. 15), Lancashire 167 (Blackburn C.B. 25, Liverpool C.B. 24, Ashton under Lyne M.B. 19, Blackpool C.B. 16, Stretford M.B. 11), Durham 95 (Blaydon U.D. 26, Gateshead C.B. 20, South Shields C.B. 15, Whickham M.B. 15, Boldon U.D. 10), Cheshire 83 (Hyde M.B. 32, Stalybridge M.B. 24, Dukinfield M.B. 12), London 71 (Wandsworth 20), Kent 53 (Deal M.B. 44), Surrey 50 (Surrey M.B. 15, Esher U.D. 12), Nottinghamshire 44 (Mansfield M.B. 11, Basford R.D. 11), Bedfordshire 36 (Luton M.B. 25), Devonshire 29 (Plymouth C.B. 29), Middlesex 28 (Hayes and Harlington U.D. 11), Staffordshire 27 (West Bromwich C.B. 24), Shropshire 25 (Oswestry R.D. 16), Hertfordshire 20 (Welwyn Garden City U.D. 15), Northumberland 20 (Newcastle upon Tyne C.B. 12), Essex 20 (Romford M.B. 10), and Yorkshire East Riding 20.

INFECTIOUS DISEASES AND VITAL STATISTICS

Summary for British Isles for week ending March 30 (No. 13) and corresponding week 1956.

Figures of cases are for the countries shown and London administrative county. Figures of deaths and births are for the 160 great towns in England and Wales (London included). London administrative county, the 17 principal towns in Scotland, the 10 principal towns in Northern Ireland, and the 14 principal towns in Eire.

A blank space denotes disease not notifiable or no return available. The table is based on information supplied by the Registrars-General of England and Wales, Scotland, N. Ireland, and Eire, the Ministry of Health and Local Government of N. Ireland, and the Department of Health of Eire.

CASES in Countries and London	1957					1956

* Measles not notifiable in Scotland, whence returns are approximate.
† Includes primary and influenza pneumonia.
§ Includes puerperal pyrexia.

Medical News

Chalmers Medal.—The council of the Royal Society of Tropical Medicine and Hygiene has awarded the 1957 Chalmers medal to Dr. A. J. HADDOW. The award is made every two years to a worker under 45 for research of outstanding merit in tropical medicine or hygiene. Dr. Haddow is director of the Virus Research Institute at Entebbe, Uganda, and his work on the entomology of yellow fever in East Africa is cited as particularly meritorious. Not only did it solve the initial problem of the transmission of sylvan yellow fever there, but it exposed "fundamental problems in mosquito behaviour." The presentation is expected to be made at the society's annual general meeting in June.

Australian Doctors on Visit to China.—A party of 20 Australian doctors left Sydney on April 8 for a month's lecture tour of China. They had been invited by the Chinese Medical Association. The party is led by Dr. LEONARD COX, president of the Australian Association of Neurologists, and among its members are the deans of the faculties of medicine at the Universities of Sydney and Melbourne, Professor E. FORD and Professor S. SUNDERLAND, and the chairman of the Australian Red Cross Society, Sir PETER MACCALLUM. They are to visit Peking, Shanghai, Canton, and Hankow, according to Radio Australia.

National Association for Mental Health.—The annual conference was held at Church House, Westminster, on April 11 and 12. The general theme was "The Maladjusted Child," and the Underwood Committee's report on the subject was taken as the basis for discussion. The conference debated the causes of maladjustment and the factors that predispose to it, and considered practicable measures in prevention and management. Among the medical speakers were Dr. KENNETH SODDY, Dr. JOHN BOWLBY, and Dr. MILDRED CREAK. The conference was opened by the Lord Chancellor, VISCOUNT KILMUIR.

Association of Occupational Therapists.—The association celebrated its 21st anniversary with a reception at the Goldsmiths' Hall in London on April 12. There is a particularly close link between the association and the Goldsmiths' Company, which has supported them for many years. When the association was originally formed there were only a few occupational therapists practising in England; now there are nearly 1,800 full members of the association and seven recognized training schools—in London, Oxford, Liverpool, Chertsey, Derby, Exeter, and Northampton. The association conducts its own examinations and awards a diploma which at present is the sole qualification in this specialty available in England. With the Scottish Association of Occupational Therapists the English association works closely in a joint council, through which both countries are represented on the World Federation of Occupational Therapists. The World Federation was formed at a meeting in Liverpool in 1952.

Polio Vaccine from Britain.—Distribution in the Federation of Rhodesia and Nyasaland of 38,000 doses of British re-processed polio vaccine was completed last month. The vaccine arrived there on March 23. A further 20,000 doses were expected to arrive on March 30. This is stated in the official *Newsletter* of the Federal Information Department, dated April 6, which adds that an order for an additional 40,000 doses has been placed "with the United Kingdom manufacturer" by the Federal Ministry of Health. The Federation has also received 5,900 doses from the Poliomyelitis Research Foundation in South Africa. This gave rise to questions in the South African Senate, as the Union Government was then making arrangements to import 300,000 doses of polio vaccine from the United States (*South African Medical Journal*, March 2, p. 204).

COMING EVENTS

Association of Clinical Biochemists.—Southern regional meeting at St. Bartholomew's Hospital, London, E.C.1, on May 11 at 2 p.m. Four papers on chemical toxicology will be read.

Indian Medical Service Dinner Club.—Annual dinner at the East India and Sports Club, St. James's Square, London, S.W.1, June 7, at 7 p.m. Details from the hon. secretary, I.M.S. Dinner Club, Medical Board Room, Commonwealth Relations Office, Matthew Parker Street, London, S.W.1.

National Association for Maternal and Child Welfare.—Annual conference, June 26-28, at Church House, Westminster, London, S.W.1.

International Poliomyelitis Conference.—Fourth conference, organized by the International Poliomyelitis Congress, in Geneva, July 8-12. Details from the secretariat of the conference, Hôtel du Rhône, Geneva, Switzerland. Early registration is advised.

Institute of Social Psychiatry.—Course in Group and Social Psychotherapy, July 22-29, at Moor Park College, Farnham, Surrey. Details from Institute of Social Psychiatry, 9, Fellows Road, London, N.W.3.

Control of Chemical Additives in Food.—A joint meeting of the U.S. Food Law Institute, the division of food, drug, and cosmetic law of the American Bar Association, and (from Britain) the food group of the Society of Chemical Industry, the Society for Analytical Chemistry, and the Association of Public Analysts, will be held at the Royal Institution, 21, Albemarle Street, London, W.1, on July 26, 10 a.m.-4.30 p.m. The conference is open to the public, free of charge.

NEW ISSUES

British Journal of Pharmacology and Chemotherapy.—The new issue (Vol. 12, No. 1) is now available. The contents include:

THE ACTION OF TRIETHYLENEMELAMINE ON THE FERTILITY OF MALE RATS. Marion Bock and H. Jackson.
EFFECTS OF RESERPINE ON BLOOD-PRESSURE RESPONSES EVOKED FROM THE HYPOTHALAMUS. B. K. Anand, S. Dua, and C. L. Malhoira.
PHARMACOLOGICAL EFFECTS PRODUCED BY INTRACEREBRAL INJECTION OF DRUGS IN THE CONSCIOUS MOUSE. T. J. Haley and W. G. McCormick.
THE INHIBITORY ACTION OF SOME ANTIMALARIAL DRUGS AND RELATED COMPOUNDS ON THE HEXOKINASE OF YEAST AND OF PLASMODIUM BEPHELI. Dorothy M. Fraser and W. O. Kermack.
THE EFFECT OF ESERINE AND NEOSTIGMINE ON THE BLOOD PRESSURE OF CONSCIOUS RATS. M. Medaković and V. Varadić.
THE INHIBITION BY SODIUM SALICYLATE OF OEDEMA OF THE HIND-PAW OF THE RAT INDUCED BY 5-HYDROXYTRYPTAMINE. E. Kelemen.
SOME ASPECTS OF THE PHARMACOLOGY OF AN HOMOLOGOUS SERIES OF CHOLINE ESTERS OF FATTY ACIDS. R. Schneider and A. R. Timms.
HISTAMINE RELEASE INHIBITION IN VITRO AND ANTIAPHYLACTIC EFFECTS IN VIVO OF SOME CHEMICAL COMPOUNDS. F. C. McIntire, R. K. Richards, and L. W. Roth.
EXPERIMENTS WITH THE TRYpanocidal COMPOUND "528" IN WEST AFRICA. R. L. Chardler.
PHARMACOLOGICAL ACTIONS OF PURE MUSCARINE CHLORIDE. P. J. Fraser.
THE ASSAY OF ANTI-ACETYLCHOLINE AGENTS FOR ANTAGONISM OF PILO-CARPINE-INDUCED SALIVATION IN RABBITS. D. M. Brown and R. M. Quinton.
THE RELEASE OF CATECHOL AMINES FROM ISOLATED CHROMAFFIN GRANULES. N. R. Eade.
THE ANTIVIRAL ACTION OF THREO-β-PHENYLSELINE. Lois Dickinson and Mildred J. Thompson.
THE INFLUENCE OF POTASSIUM CONCENTRATION ON THE ACTION OF QUINIDINE AND OF SOME ANTIMALARIAL SUBSTANCES ON CARDIAC MUSCLE. A. K. Atmizac.
THE ACTION OF MORPHINE ON THE SUPERIOR CERVICAL GANGLION AND ON THE NIGHTMARE MEMBRANE OF THE CAT. U. Trendelenburg.
THE TRANSMITTER RELEASED BY STIMULATION OF THE BRONCHIAL SYMPATHETIC NERVES OF CATS. Mary F. Lockett.
ANALOGIC ACTIVITY OF DIPIPANONE HYDROCHLORIDE IN STUDENT VOLUNTEERS. D. A. Cahal.
SEASONAL VARIATIONS IN THE RESPONSE OF RATS TO THE ANTIDIURETIC HORMONE. H. Heller, G. Herdan, and S. M. A. Zaidi.
THE EFFECT OF ETHER AND PENTOBARBITONE SODIUM ON GASTROINTESTINAL FUNCTION IN THE INTACT RAT. P. C. Reynell and G. H. Spray.
LOCAL EFFECTS AND MECHANISM OF ABSORPTION OF IRON PREPARATIONS ADMINISTERED INTRAMUSCULARLY. C. R. Beresford, L. Golberg, and J. P. Smith.
INHIBITION BY MORPHINE OF THE RELEASE OF ACETYLCHOLINE FROM THE INTESTINE OF THE GUINEA-PIG. W. Schaumann.
THE ACTION OF MORPHINE AND RELATED SUBSTANCES ON CONTRACTION AND ACETYLCHOLINE OUTPUT OF COAXIALLY STIMULATED GUINEA-PIG ILEUM. W. D. M. Paton.
SOME PHARMACOLOGICAL ACTIONS OF CHOLINE 2:6-XYLyl ETHER BROMIDE. G. L. Willey.

Issued quarterly; annual subscription £4 4s.; single copy 25s.; obtainable from the Publishing Manager, B.M.A. House, Tavistock Square, London, W.C.1.

Recruitment of Nurses and Midwives.—From May 1 the Ministry of Health and the Department of Health for Scotland are to take over from the Ministry of Labour and National Service the general oversight of the recruitment of nurses and midwives. In view of this change the national advisory council concerned will be reconstituted and henceforth advise the Health Ministers instead of the Ministry of Labour. The nursing appointments service of the Ministry of Labour will continue, however. It has 166 local offices which assist those wishing to train, or obtain employment, as nurses, midwives, or nursing assistants or auxiliaries.

Central Midwives Board.—Mr. ARNOLD WALKER and Professor ALAN MONCRIEFF were re-elected respectively chairman and deputy chairman of the Board at a meeting on April 4.

Apartheid in Medicine.—On April 8 the South African Government introduced its revised Bill to enforce university apartheid; the Durban Medical School is expected to be dealt with later (see this *Journal*, April 13, p. 899). The South African Government has also been concerned with the principle of apartheid in nursing and blood transfusion practice. According to a *Reuter* dispatch, the Government has decided not to enforce apartheid for blood transfusions. Mr. J. H. VILJOEN, the Minister of Health, told the House of Assembly recently that the blood transfusion regulations requiring the race of the donor to be shown clearly on each bottle would not in any way prohibit the use of blood interracially. Last September the South African Medical and Dental Council accepted a recommendation that blood for transfusion should be so labelled. Dr. M. SHAPIRO, director of the Blood Transfusion Service, who was present, declared at the time: "It is tragic that there should be discrimination in South Africa between the blood of whites and non-whites." But, while the South African Government has now decided against apartheid in blood transfusion, it is pressing forward with measures to ensure racial segregation in the bodies which control nursing in South Africa. Notice of a Bill aimed at debarring non-European nurses from the Nursing Council and the South African Nursing Association was given in the Speech from the Throne at the opening of the new session of the South African Parliament in Capetown in January.

Collegium Internationale Allergologicum.—The Collegium's third annual meeting was held on March 28 in London, and the following officers and council were elected for 1957-8: *president*: Dr. D. Harley (London); *vice-president*, Dr. J. Duchaine (Brussels); *hon. secretary*, Dr. P. Kallós (Helsingborg); *treasurer and executive secretary*, Dr. A. Cerletti (Basle); *members of council*: Dr. R. R. A. Coombs (Cambridge), Professor H. A. E. van Dishoeck (Leyden), Dr. W. Feldberg (London), Professor W. Hansen (Lübeck), Dr. R. Hoigné (Berne), Professor C. Jimenez-Diaz (Madrid), Dr. W. Kaufman (Bridgeport, U.S.A.), and Professor H. R. Olivier (Paris).

Professor A. C. Frazer, professor of pharmacology at Birmingham University, has been appointed a member of the W.H.O. expert panel on food. The appointment is for five years. Professor Frazer is also president of the British Food Manufacturing Industries Research Association, a Government-sponsored organization concerned with problems of food processing and preservation.

Sir Geoffrey Jefferson, F.R.S.—A proposal to confer the honorary degree of D.Sc. on Sir GEOFFREY JEFFERSON, emeritus professor of neurosurgery at Manchester University, will be considered in Congregation at Cambridge on May 4.

Professor J. M. Robson, professor of pharmacology at Guy's Hospital, London, has arrived in Australia on a lecture tour. He is visiting Sydney, Brisbane, Canberra, and Melbourne.

British Journal of Ophthalmology.—The new issue (Vol. 41, No. 4) is now available. The contents include:

THE FELLOW EYE IN ACUTE CLOSED-ANGLE GLAUCOMA. W. E. S. Bain.
DARK-ROOM TEST AND ITS MECHANISM. Wallace S. Foulds.
CHRONIC CLOSED-ANGLE GLAUCOMA. Wallace S. Foulds and Calbert I. Phillips.

NATURAL HISTORY OF ONCHOCERCIASIS. F. H. Budden.
CAVERNOUS SINUS THROMBOPHLEBITIS. P. J. Taylor.
OXYPHENONIUM AS AN ATROPINE SUBSTITUTE IN OPHTHALMOLOGY. M. J. Roper-Hall.

ACCIDENTAL VACCINIA. Charles Taylor.
SYNCHETIC LID RETRACTION. N. S. Jain.

CORRESPONDENCE.

British Heart Journal.—The new issue (Vol. 19, No. 2) is now available. The contents include:

THE SYNDROME OF THE SUSPENDED HEART. By William Evans and H. G. Lloyd-Thomas.

EPILEPSY AND MITRAL STENOSIS. By C. G. Baker and T. R. L. Finnegan.

OBSCURE CARDIOPATHY. By Byron Evans.

DIFFUSE ENDOMYOCARDIAL SCLEROSIS. By J. B. Lynch and J. Watt.

FIBRO-ELASTOSIS OF THE HEART IN ADOLESCENCE. By W. H. R. Auld and H. Watson.

ENDOCARDIAL FIBRO-ELASTOSIS WITH GENERALIZED LYMPHADENOPATHY, OEDEMA, AND RASH. N. M. Gibbs, J. C. Haworth, and John Rendle-Short.

THE AORTA AND PULMONARY ARTERIES IN FALLOT'S TETRALOGY. By J. Norman Pattinson and Richard W. Emanuel.

DILATATION OF THE AORTA DUE TO GRANULOMATOUS (GIANT-CELL) AORTITIS. By J. V. O. Reid.

THE ANATOMICAL APPEARANCE OF RHEUMATIC TRICUSPID VALVE DISEASE. By Arthur Hollman.

PULMONARY ARTERIAL PRESSURE AFTER PRISCOLINE IN MITRAL STENOSIS. By K. Braun, G. Izak, and S. Z. Rosenberg.

HAEMODYNAMIC STUDIES DURING AURICULAR FIBRILLATION AND AFTER RESTORATION OF SINUS RHYTHM. By Ole Jacob Broch and Otar Müller.

PROGNOSIS OF CORONARY HEART DISEASE IN MEDICAL PRACTITIONERS. By J. N. Morris and J. A. Heady.

SEPTAL INFARCTION WITH RECOVERY OF THE ELECTROCARDIOGRAM. By D. Gordon Abrahams.

ELECTROCARDIOGRAPHIC CHANGES DURING PRESSURE BREATHING. By R. J. Shephard.

COMPLETE HEART BLOCK IN AN EXPERIENCED PILOT. By Francis A. L. Mathewson and Fred H. Harvie.

PRÆCORDIAL BALLISTOCARDIOGRAPHY. By Patrick Mounsey.

INFLUENCE OF ACETYLCHOLINE ON PULMONARY ARTERIAL PRESSURE. By P. Harris.

THE EFFECT OF ACETYLCHOLINE ON PULMONARY VASCULAR RESISTANCE AND LEFT ATRIAL PRESSURE IN MITRAL STENOSIS. By Paul Wood, E. M. Besterman, M. K. Towers, and M. B. McIlroy.

CASE REPORTS

BALL-VALVE MITRAL OBSTRUCTION BY A SARCOMA OF A PULMONARY VEIN. By A. A. R. Cumming and A. J. Shillitoe.

KAPOST'S HAEMANGIOSARCOMA OF THE HEART. By Michael Gelfand.

REPETITIVE PAROXYSMAL VENTRICULAR TACHYCARDIA WITH FUSION BEATS. By Ruston Jal Vakil.

DUPPLICATION OF THE MITRAL VALVE. By E. D. Wigle.

INCREASED CARDIAC OUTPUT CAUSED BY SECONDARY HYPERNEPHROMA. By Geoffrey Bourne.

Issued quarterly; annual subscription £2 2s.; single copy 12s. 6d.; obtainable from the Publishing Manager, B.M.A. House, Tavistock Square, London, W.C.1.

SOCIETIES AND LECTURES

A fee is charged or a ticket is required for attending lectures marked ●. Application should be made first to the institution concerned.

Wednesday, April 24

BIRMINGHAM MEDICAL INSTITUTE: SECTION OF PSYCHIATRY.—8 p.m., Dr. J. A. Harrington and Dr. K. W. Cross, Ph.D.: Survey of Chronic Patients in a Mental Hospital and its Implications. Discussions to be opened by The Hon. W. S. Maclay.

INSTITUTE OF DISEASES OF THE CHEST.—5 p.m., Dr. J. G. Scadding: Clinical Significance of Tuberculin Tests.

LONDON ASSOCIATION OF THE MEDICAL WOMEN'S FEDERATION.—8.30 p.m., Dr. G. F. Abercrombie: College of General Practitioners.

MIDLAND CENTRE FOR NEUROSURGERY, Holly Lane, Smethwick, near Birmingham.—8 p.m., Dr. J. N. Cumings: Biochemical Abnormalities in Hepatolenticular Degeneration.

SCOTTISH EASTERN ASSOCIATION OF THE MEDICAL WOMEN'S FEDERATION.—At Adam House, Chambers Street, Edinburgh, 8.30 p.m., Dr. Joy Patrick: Demonology.

Thursday, April 25

HILL END HOSPITAL MEDICAL SOCIETY, St. Albans.—8.45 p.m., Sir Francis Walshe, F.R.S.: Traumatic Neuroses.

LONDON JEWISH HOSPITAL MEDICAL SOCIETY.—At Medical Society of London, 8.30 p.m., Sir Archibald McIndoe: Scope of Plastic Surgery.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—3.45 p.m., Arnold Demonstration by Dr. B. D. Wyke: Surgical Considerations of the Temporal Lobes.

ROYAL NORTHERN HOSPITAL.—2.45 p.m., Mr. A. E. Roche: Some Genito-urinary Problems.

Friday, April 26

INSTITUTE OF DISEASES OF THE CHEST.—5 p.m., Dr. F. H. Young: clinical demonstration.

INSTITUTE OF LARYNGOLOGY AND OTOTOLOGY.—3.30 p.m., Mr. G. H. Howells: Sinusitis.

Saturday, April 27

KENT PEDIATRIC AND CHILD HEALTH SOCIETY.—At Royal Star Hotel, Maidstone, 3 p.m., annual general meeting.

APPOINTMENTS

HOSPITAL FOR SICK CHILDREN, Great Ormond Street, London, W.C.—C. V. Peterson, M.B., B.S., F.R.C.S.Ed., Resident House-surgeon; N. J. O'Doherty, M.D., M.R.C.P., M.R.C.P.I., Resident House-physician.

HOSPITAL OF ST. JOHN AND ST. ELIZABETH, 60, Grove End Road, London, N.W.8.—A. Giordani, M.R.C.S., L.R.C.P., D.M.R.D., Honorary Assistant Radiologist; J. R. Cooper, M.R.C.S., L.R.C.P., L.D.S., Honorary Dental Surgeon.

LIVERPOOL REGIONAL HOSPITAL BOARD.—A. C. Barry, M.B., Ch.B., D.P.M., Assistant Psychiatrist at Sefton Mental Hospital; M. J. Cosgrave, M.B., Ch.B., D.P.M., Assistant Psychiatrist at Deva Hospital; R. Fairhurst, M.B., Ch.B., B.D.S., Consultant Dental Surgeon to Birkenhead Group; G. W. Bamber, M.D., F.R.C.P., Consultant Dermatologist to Bootle Hospital and the Liverpool Radium Institute.

MANCHESTER REGIONAL HOSPITAL BOARD.—E. L. Trickey, M.B., B.S., F.R.C.S., Consultant Traumatic and Orthopaedic Surgeon, Ashton, Hyde, and Glossop Hospitals; G. T. Johnson, M.D., F.F.A.R.C.S., M.R.C.O.G., Consultant Obstetrician/Gynaecologist, West Manchester Hospitals; E. Sherrah-Davies, M.B., B.Chir., F.R.C.S., D.M.R.T., Whole-time Assistant Radiographer, Christie Hospital and Holt Radium Institute, Manchester; L. G. G. Jones, M.R.C.P.Ed., M.R.C.S., L.R.C.P., Whole-time Assistant Venerologist, Manchester Area.

NORTH-WEST METROPOLITAN REGIONAL HOSPITAL BOARD.—Joan Martinez, M.B., Ch.B., D.A., Consultant Anaesthetist, Highlands General Hospital; K. R. Dempster, M.B., B.S., Consultant Morbid Anatomist, King Edward VII Hospital, Windsor; R. T. D. Emond, M.B., Ch.B., M.R.C.P., D.T.M.&H., Consultant in Infectious Diseases, and Physician Superintendent, Coppetts Wood Hospital; E. K. Gardner, M.B., B.Chir., F.R.C.S., F.F.A.R.C.S., Consultant Anaesthetist, Barnet Group of Hospitals; F. H. Edwards, M.R.C.S., L.R.C.P., D.P.M., Consultant Psychiatrist, Portman Clinic; P. J. F. Walsh, M.B., B.S., D.P.M., Assistant Psychiatrist (S.H.M.O.), St. Bernard's Hospital; W. O. Heffernan, L.R.C.P.&S.I., D.P.M., Assistant Psychiatrist (S.H.M.O.), Hill End Hospital; C. O. Kennedy, M.B., Ch.B., M.F.Hom., and L. R. Twentyman, M.B., B.Chir., M.F.Hom., Senior Hospital Medical Officers, Royal London Homoeopathic Hospital.

SOUTH-WESTERN REGIONAL HOSPITAL BOARD.—R. A. J. Baily, M.B., B.Chir., F.R.C.S., Consultant Orthopaedic Surgeon to Weston-super-Mare Group of Hospitals; S. S. Knappe, M.D., Deputy Medical Superintendent, Sandhill Park Hospital, Bishops Lydeard; A. K. Banerjee, M.B., B.S., F.R.C.S., F.R.C.S.Ed., Surgical Registrar at Southmead Hospital, Bristol; S. D. Bulos, M.D., F.R.C.S.Ed., Registrar in Orthopaedic and Traumatic Surgery in Exeter Clinical Area; M. F. Bethell, M.D., D.P.M., Consultant Psychiatrist and Deputy Medical Superintendent at Tonic Vale Hospital, near Taunton; E. W. Moore, M.B., Ch.B., M.R.C.P.Ed., D.P.H., D.M.R.D., Consultant Radiologist to Bath Clinical Area.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

May.—On March 8, 1957, at Prince Albert, Saskatchewan, Canada, to Jean, wife of Malcolm J. May, M.B.E., M.B., F.R.C.S., a brother for Martin—Nigel Malcolm.

Rohatgi.—On April 3, 1957, at Queen Charlotte's Maternity Hospital, London, W., to Malti, D.R.C.O.G., wife of J. N. Rohatgi, M.S., F.R.C.S., a daughter—Nira.

DEATHS

Billinghurst.—On March 22, 1957, at 24, Fairway, Merron, Guildford, Surrey, Walter Brinsmead Billinghurst, M.B., B.Ch.

Cooper.—On March 22, 1957, in London, Henry Cremer Cooper, M.R.C.S., L.R.C.P., L.D.S., aged 85.

Craig.—On April 1, 1957, at Bognor Regis, Sussex, William James Forsyth Craig, L.R.C.P.&S.Ed., L.R.F.P.S., of 137, Wheelwright Road, Erdington, Birmingham, Warwick.

Duran-Jorda.—On March 30, 1957, at the Manchester Royal Infirmary, Frederick Duran-Jorda, M.D., of Broughton House, 139, Marsland Road, Sale, Cheshire, aged 51.

Hanson.—On March 24, 1957, at 11, Egerton Gardens, London, S.W., David Cochrane Hanson, M.C., M.B., Ch.B.

Hudson.—On March 21, 1957, at Ashford Hospital, Kent, Bernard Hudson, M.D., M.R.C.P., of Castleton Oak Cottage, Biddenden, Kent.

Johnston.—On March 26, 1957, at Rothesay, Clyde Road, St. Leonards-on-Sea, Sussex, Robert Macfie Johnston, M.B., aged 85.

Jones.—On March 24, 1957, at St. Thomas's Hospital, London, S.E., Isaac Eastwood Jones, M.D., F.R.C.P., aged 74.

Kidd.—On March 29, 1957, at the London Hospital, Beatrice Mary Kidd, M.B., of Brooklands, Blackheath Park, London, S.E., aged 80.

O'Donnell.—On March 29, 1957, at The Avenue, Stone, Staffs, James Roderick O'Donnell, M.B., B.Ch.

Oster.—On March 25, 1957, at Capetown, South Africa, Robert Douglas Oster, M.B., Ch.B., formerly of Edinburgh.

Quinn.—On March 25, 1957, at Cork, Francis B. Quinn, M.B., B.Ch., Surgeon Captain, R.N., retired, of Thornton Hall, Jersey, Channel Islands.

Read.—On March 24, 1957, at Addenbrooke's Hospital, Cambridge, Harold William Read, T.D., M.R.C.S., L.R.C.P., of Long Sutton, Lincs.

Relf.—On March 25, 1957, Herbert John Relf, M.R.C.S., L.R.C.P., L.D.S., of 6a, Fairfield Road, East Croydon, Surrey, aged 84.

Scott.—On April 3, 1957, in a nursing-home, Edinburgh, Charles Ernest Scott, M.B., F.R.C.S.Ed., of 33, Palmerston Place, Edinburgh.

Stebbing.—On March 23, 1957, John Garvin Stebbing, M.B., B.S., of 1, Liskeard Gardens, Blackheath, London, S.E., aged 32.

Turner.—On March 28, 1957, at his home, Oundle, Peterborough, Northants, Bernard Roworth Turner, M.B., B.Chir., aged 85.

Watson.—On March 28, 1957, at 3, Park Drive, Heaton, Bradford, Yorks, Donald Watson, M.B., F.R.C.S., aged 69.

Watts.—On March 24, 1957, at Hampton Dene, Hereford, Hilbre Hamilton Watts, M.B., Ch.B., aged 41.

Weir.—On March 20, 1957, at 4, Little Anglesey Road, Alverstoke, Hants, Hamish McDonald Weir, M.B., Ch.B., formerly of The Moorings, Lee-on-Solent, Hants.

Wilson.—On March 23, 1957, at his home, Redvales House, Bury, Lancs, William Webster Watt Wilson, M.B., Ch.B., aged 78.

Any Questions?

We publish below a selection of those questions and answers which seem of general interest. It is regretted that it is not possible to supply answers to all questions submitted.

Underwriting Substandard Lives

Q.—Dr. K. Shirley Smith in his presidential address to the Assurance Medical Society mentioned the existence of special "pools" for those with coronary disease, diabetes mellitus, or hypertension. What steps must a person with one of these conditions take in order to obtain life cover by inclusion in one of these pools?

A.—The formation of special "pools" to deal with conditions such as coronary disease, diabetes mellitus, and hypertension has in recent years become a feature in the handling of difficult life assurance cases. These pools are administered by a Re-assurance Company which will undertake the whole or part of a life assurance risk submitted by any one of the ordinary Life Assurance Societies. It does not follow that all such Societies make use of the special pools, but their services are available to any Life Office which seeks their aid.

So far as a sufferer from one of these conditions is concerned the normal procedure is for him to make a proposal for life assurance to the Society of his choice, which will arrange all the necessary details and undertake a medical examination. The Society will then indicate to the applicant whether it can, of itself, offer life assurance at all, and, if so, on what terms. On the other hand, it may decline the proposal outright. In the latter case the applicant may then ask the Society to submit his proposal to the special pool for consideration, and this it will do on the applicant's behalf. Equally it is open to the individual to say from the outset that he would like his proposal to be considered not only by the Life Assurance Society but by the special pool concerned, so that he can see which of the two offers the better terms and place his assurance accordingly.

Gynaecomastia as an Industrial Hazard

Q.—A young man who has worked for a number of years on the production of stilboestrol has recently complained of pain and tenderness of his breasts. The pain has become less since transferring to a different job two weeks ago. (1) Is this a recognized hazard of those working with oestrogens, and, if so, what is the portal of entry of the oestrogen to the body? (2) What is the prognosis after cessation of exposure? (3) If acquired as a result of a man's occupation, does the condition attract compensation, and what powers exist to compel an employer to take adequate precautions to eliminate this hazard?

A.—(1) The occurrence of mammary hyperplasia among those working with oestrogens is a hazard which is recognized at least by endocrinologists and those interested in industrial medicine. Fitzsimons¹ reported 20 cases of gynaecomastia among 38 men engaged in the manufacture of stilboestrol and dienoestrol. The portals of entry are probably through the skin and, if the worker does not wash his hands before meals, by the mouth. The lungs are an important portal of entry for the dust of oestrogens, and in fact precautions in the factories handling these substances are directed towards keeping the dust out of the atmosphere and avoiding their contact with the skin. The condition usually subsides gradually after cessation of exposure.

(2) Gynaecomastia as a result of an excessive dose of stilboestrol is not included in the list of prescribed diseases under the Industrial Injuries Act. In certain circumstances diseases

would be due to an overdose of sex hormones might be accepted as being due to "injury by accident," but each case is considered on its merits. There are no factory regulations covering the manufacture and handling of oestrogens, but Section 47 of the Factories Act requires the removal of "any dust or fume or other impurity of such character and to such extent as it is likely to be injurious or offensive to the persons employed, or any substantial quantity of dust of any kind. All practical measures shall be taken to protect the persons employed against inhalation of the dust or fume or other impurity and to prevent its accumulation in any workroom, and in particular, where the nature of the process makes it practicable, exhaust appliances shall be provided and maintained, as near as possible to the point of origin of the dust or fume or other impurity, so as to prevent its entering the air of any workroom." In practice the work with oestrogens is usually done under exhaust ventilation in enclosed cabinets, and the workers are provided with overalls, gloves, head-coverings, and dust respirators. They also undergo periodic medical examination. All these measures, however, are voluntary except the exhaust ventilation.

Antivenin for Adder Bites

Q.—Should antivenin always be given for adder bites in Britain? If so, how soon must it be given and in what dosage, and where may it be obtained?

A.—The adder or common viper (*Vipera berus*) is the only species of poisonous snake indigenous to Great Britain. Fatalities following its bite are rare, though small children may be severely affected. A tourniquet should at once be applied well above the bite, which is almost invariably on an extremity, and it should be loosened for 5 to 10 seconds every 10 to 15 minutes. The encouragement of bleeding may also help.

Specific venom antiserum, or antivenin, is highly effective and should always be administered if it can be obtained before the expected recession of symptoms commences. Dosage is dependent on the potency of the preparation, and should be in accordance with the instructions on the leaflet provided by the manufacturer. The dosage for children should never be less than the adult dose. It is always safer to give a larger dose to young children because of the smaller blood volume. Antivenin is not manufactured in Great Britain, but can be obtained by application to certain hospitals and other centres (for a list see *Monthly Bull. Minist. Hlth (London)*, 1955, 14, 70). Before giving serum, ideally one should make sure by means of a "trial dose" that the patient is not sensitive to it; but in practice, owing to the emergency, it is unusual to delay the main dose for a sensitivity test.

Apart from the special measures recommended above—namely, a tourniquet and antivenin—the treatment of the shock should be on general lines.

BCM: A New Nitrogen Mustard

Q.—A recent report from Budapest¹ records the clinical trial of a nitrogen mustard compound called BCM (1,6-bis (β-chlorethyl-amino-1, 6-desoxy-D-mannitol) dichloride). Is anything further known about the value of this compound?

A.—There are four other references to BCM in the literature. A paper by Vargha² briefly describes its preparation. Kellner, Németh, and Sellei³ report on its biological, haematological, and tumour-inhibiting activity. In a much more detailed paper Kellner and Németh⁴ report their studies of the tumour-inhibiting effects of several nitrogen-mustard-carbohydrate combinations and have established that BCM surpassed HN2 (methyl dichloroethylamine) in its tumour-inhibiting and haematological effects. The substance is less

toxic and has a wider range of clinical use than HN2. Animal experiments show that BCM has an inhibiting effect on metastases, so that it could be used prophylactically in surgery. The authors in this paper recommend that clinical tests be carried out not only in blood dyscrasias but also in carcinomas and sarcomas. There is also the original Hungarian publication.²

Susceptibility to Belladonna

Q.—What accounts for the great differences between species in their susceptibility to belladonna poisoning? I understand hens and rabbits can eat the leaves and berries with apparent impunity. Why can children stand relatively much greater doses of belladonna than adults?

A.—The question contains two statements both of which are generally accepted as true, but both are open to doubt. According to Willberg¹ the lethal dose of atropine per kg. for a rat or a hen (750 mg./kg.) is four times as great as the lethal dose for a cat or finch. Hedgehogs, guinea-pigs, mice, rabbits, ducks, dogs, pigeons, and crows are intermediate. The range of doses is not very great. The lethal dose for man is not accurately known, but it is probably much less than in any of the species tested by Willberg. Unna *et al.*² studied the effect of atropine on salivary secretion in children under 12 and found little or no variation with age: the effective doses were proportional to body weight and comparable to those effective in adults.

Differences in susceptibility depend, in part at least, on differences in the rates of elimination of the alkaloids. Some rabbits possess an enzyme which hydrolyses both atropine and hyoscyne; the presence of the enzyme is controlled by genetic factors. Rabbits fed on belladonna acquire tolerance, and several generations have been reared on a diet consisting exclusively of belladonna, hyoscyamus, and stramonium.³ This tolerance is also due to more rapid elimination, and the story, which appears in some textbooks, about a whole family, plus cat and dog, being killed by eating the flesh of resistant rabbits is most improbable.

Sleep Paralysis

Q.—What is the nature of sleep paralysis, and how is it explained?

A.—Brief and infrequent episodes of sleep paralysis can occur in normal people. The subject finds that he is lying in bed and, although awake, cannot move or speak. In its full clinical form the symptom may be associated with hallucinations, either visual or more often auditory, which may be pleasant or unpleasant. Attacks of cataplexy in the day, and even at times narcolepsy, may occur in these patients. The syndrome of sleep paralysis, hallucinosis, and cataplexy was described by L'Hermite.¹ The condition is not related to epilepsy or psychosis, but many sufferers are neurotic subjects. There is little evidence that the condition is the result of damage or disease of the brain, but appears to be a functional disturbance of the sleep-waking mechanism. The condition, which occurs usually in young adults, tends to improve spontaneously with time, and often responds to a simple barbiturate hypnotic and reassurance that the condition is not a mental illness. Psychotherapy may have some place in the treatment of these patients.

Premedication for Hypnosis

Q.—Is there any drug which is useful in preparing a patient for hypnotic suggestion?

A.—It is not usual to prepare a patient for hypnosis by giving him a drug in advance. In the relatively few instances when hypnotic suggestion is at all useful, it is a technique to be employed deliberately and without haste. The difficulty about giving any drug in advance would be that the patient might sleep.

It has of course been customary for many years to use the injection of a sedating drug instead of hypnosis, and this technique is called narcoanalysis. The drug employed is usually thiopentone or amylbarbitone, which in either case must be injected slowly, the object being to produce a state of maximum suggestibility short of sleep.

Aetiology and Prevention of Coronary Thrombosis

Q.—What is definitely known about the aetiology of coronary thrombosis? Has there been a genuine increase in its frequency, and how far can this be blamed on "modern life"? What precautions, in dietary or other habits, may a professional man reasonably adopt in order to reduce his chances of developing the disease?

A.—In a great proportion of cases, atheroma of the coronary arteries underlies coronary thrombosis. The aetiology of coronary thrombosis is thus in large measure the aetiology of atheroma. The consensus of opinion is that this disease of the arteries is connected with derangements of fat and cholesterol metabolism. A familial influence in causing coronary disease in younger men has been proved. Sex and age incidence point also to involution of sexual organs as a contributory circumstance. There has unquestionably been an increasing incidence of coronary heart disease. While nothing is definitely known as to the influence of factors under the heading "modern life," mental and physical stress, frustration of ambition, and exceptional fatigue and high responsibility have been regarded as contributing to this disease. However, most authorities agree that a sedentary life with little exercise and over-indulgence in rich foods is a more likely basis of coronary thrombosis than a physically strenuous habit of life coupled with a simple moderate diet.

The precautions that a professional man may reasonably adopt to minimize his chance of coronary disease may be adduced as follows: (i) maintenance of the habit of walking and/or golf or other outdoor sport; (ii) avoidance of putting on weight; (iii) avoiding, as far as possible, rush and hurry; (iv) keeping to strict moderation in animal fats and rich foods in general in the diet; (v) observing a reasonable moderation in the use of tobacco and alcohol.

Books of "Any Questions?" and Refresher Course Articles.—The following books are available through booksellers or from the Publishing Manager, B.M.A. House. Prices include postage. *Any Questions?*, Volumes 2 and 3 (8s. each); *Refresher Course for General Practitioners*, Volumes 2 and 3 (26s. 6d. each inland, 26s. overseas; *Clinical Pathology in General Practice* (22s. 3d. inland, 21s. 9d. overseas).

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 4499. TELEGRAMS: Aitiology, Westcent, London. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors overseas should indicate on MSS. if reprints are required, as proofs are not sent abroad. ADVERTISEMENTS should be addressed to the Advertisement Director, B.M.A. House, Tavistock Square, London, W.C.1 (hours 9 a.m. to 5 p.m.). TELEPHONE: EUSTON 4499. TELEGRAMS: Britmedads, Westcent, London. MEMBERS' SUBSCRIPTIONS should be sent to the SECRETARY of the Association. TELEPHONE: EUSTON 4499. TELEGRAMS: Medisecra, Westcent, London. B.M.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

Clinically proven

SPARINE

(PROMAZINE HYDROCHLORIDE)

the new
phenothiazine derivative

Sparine has already brought decisive and dramatically effective relief to many hundreds of patients. It calms the troubled seas of the mind. Most of the published clinical reports are concerned primarily with its use in the management of psychiatric conditions. But evidence is accumulating rapidly in support of the many other indications for this drug in everyday medical practice.

Sparine not only controls psychomotor overactivity—it is also synergistic with analgesics, hypnotics and anaesthetics, and is a potent anti-emetic. Little wonder, therefore, that the predictions of the pharmacologists have been amply justified by the successes of Sparine treatment in such diverse conditions as terminal carcinoma and nausea of pregnancy. Full details of indications and dosage will be supplied on request.

PACKS:

For parenteral administration—

5% solution (50 mg. per ml.) in 2 ml. ampoules. Boxes of 10.

For oral administration—

Coated tablets of 25 mg. (yellow).
50 mg. (orange).
100 mg. (red).

Bottles of 50 and 250.

Wyeth

The word "Sparine" is a trade mark

JOHN WYETH & BROTHER LIMITED

Clifton House, Euston Road, London, N.W.1.

WARD, CASSENNE LTD.

3 to 5 times more
active than hydrocortisone
or cortisone.

DELTALONE

BUFFERED TABLETS

REGD.T.M.

MAJOR INDICATIONS:
*Rheumatoid Arthritis,
Severe allergies.*

The antacids and the protective coating covering the Deltalone crystals increase therapeutic advantages by lessening the risk of gastric disorders.

DELTALONE

REGD.T.M.

BUFFERED TABLETS: At 5 mgm. or at 1 mgm.

ADVANTAGES:

—Better gastric tolerance,
due to the addition of
antacids. These counteract
the gastric hyperactivity
often caused by these
corticoids.

—a protective coating which
covers each hormone
crystal individually.

*No sodium or water
retention when usual
therapeutic doses are prescribed.*

FORMULA:

Prednisone (Delta-1-Cortisone)
Aluminium hydroxide
Magnesium trisilicate

WARD, CASSENNE LTD.

*When fluid contents
exceed requirements*

DIAMOX
REGD. TRADE MARK
ACETAZOLAMIDE
Lederle

In conditions where excess fluid accumulates in body tissues, prompt dispersal measures are called for. In such cases, by inhibiting carbonic anhydrase, DIAMOX acetazolamide produces prompt copious diuresis. It has proved its ability to control body-fluid balance in cardiac oedema, glaucoma and epilepsy. Published reports also show satisfactory results from DIAMOX in toxæmia and oedema of pregnancy, premenstrual tension, renal oedema, emphysema and drug-induced oedema. DIAMOX is a welcome departure from the mercurials and is well suited to long-term maintenance of ambulant and out-patient cases.

TABLETS of 250 mg.

Bottles of 25, 100 and 1,000

PARENTERAL Vials of 500 mg.

LATENT INFECTIONS WITH VIRUSES AND RICKETTSIAE*

BY

M. G. P. STOKER, M.D.

Huddersfield Lecturer in Special Pathology, Department of Pathology, Cambridge University

[WITH SPECIAL PLATE]

The laboratory diagnosis of virus diseases is to-day somewhat complicated by the embarrassing number of new agents which have been isolated through increasing use of human and monkey cells in tissue culture. One of the principal problems is to establish a causal connexion between these new viruses and particular clinical syndromes. A number are still unattached and continue to deserve the name "orphan virus" originally used by Melnick (1955).

Some of the newly discovered viruses are clearly transient visitors, whether or not they are associated with disease. Certain types, however, appear to persist as latent infections in the tonsils and adenoids (Rowe *et al.*, 1953). Latent infection raises special problems, not only in its relationship to illness, but also in the mechanism by which obligate intracellular organisms can survive for long periods in one host. A review of this topic should not be limited to latent virus infections of man, however, because there is much to be learnt from similar conditions of animals, birds, and even bacteria.

In this paper "latent infection" will be used to mean the persistence of a virus or rickettsia in the tissues for long periods, during most of which there is no obvious manifestation of disease. This will not be taken to include the incubation period even when it is long, as, for example, in infective hepatitis.

Our knowledge of latent viral and rickettsial infections of man is, of course, limited by our inability to search the tissues for the hidden organism. We are dependent upon the reappearance of virus in the blood or vesicle fluid or in some other situation where it can be isolated and detected by laboratory methods, or where its presence can be deduced through secondary infection of contacts. An inevitably different approach has, however, revealed the presence of latent viruses in the tissues of wild and laboratory-bred animals.

Latent Infections of Animals

Attempts to isolate the causative organism from suspected virus diseases of man often involves inoculation of experimental animals by various routes with a number of so-called "blind" passages of tissue suspension from one group of inoculated animals to the next. After one or more such passages the animals may sicken

*The Lock Lecture delivered before the Royal Faculty of Physicians and Surgeons, Glasgow, November 14, 1956.

and a filterable agent be obtained from the tissues which will cause reproducible disease in other animals of the same species. A great many organisms isolated in this way have turned out to be viruses lying dormant in the stock animals, which are activated by passage of tissue suspensions. Sometimes salt solutions or other simple diluents will activate these viruses, rather like the non-specific stimuli which activate herpes simplex in man. These latent infections of laboratory animals naturally add to the difficulties of virus research. Eaton (1950), in his attempts to isolate the causative agent of primary atypical pneumonia by intranasal inoculation of cotton-rats and hamsters, identified three different latent viruses in the lungs alone of his stock animals. A number of latent virus infections have also been found in the lungs of mice and guinea-pigs. Such infections are not confined to the respiratory tract, however. There is, for example, spontaneous encephalomyelitis of mice, sometimes called mouse poliomyelitis, and originally investigated by Theiler (1937).

Mouse Encephalomyelitis

Theiler's virus is almost universally present in the intestinal wall of laboratory mice between the first and sixth months of life and sometimes longer; in fact it is difficult to obtain for experimental work a line of mice which are free of the virus. Infection apparently occurs through exposure of the baby mice to faecal contamination, and not *in utero* or through the milk. When carrying Theiler's virus the mice are healthy, and it may be regarded for the most part as a harmless commensal infection, but occasionally the virus invades the central nervous system and produces a paralytic disease.

Lymphocytic Choriomeningitis

Another condition of mice which has considerable bearing on our problem is lymphocytic choriomeningitis, which, of course, can occasionally spread to man. Traub (1939) at the Rockefeller Institute studied a stock of mice in which this virus was originally absent but gradually became established naturally over several years. At the end of the period of study all the mice, including the newborn, carried the virus in large numbers in their tissues and, except for an occasional illness in young animals, remained perfectly healthy. Infection was transmitted to the young *in utero* and persisted throughout life. Of special interest was the complete absence of antibody development in animals infected with the virus *in utero*, although antibodies appeared in the usual way after infection of older virus-free mice from another stock. It was suggested by Burnet

and Fenner (1949) that this was due to failure to recognize as antigenically foreign substances previously present in foetal life. The work of Billingham *et al.* (1953) with skin grafts in mice has led to the full confirmation of this important principle of "immune tolerance."

The adaptation of lymphocytic choriomeningitis virus to the mouse is the most complete that has been identified. The discovery depended, however, on the availability of other stock mice which were free of this virus and susceptible to infection. If such an agent was universally present in mice, and if no other host were susceptible, it might never be detected even if it occasionally produced obvious disease.

Latent infections are not confined to small rodents. The virus of swine influenza, whose complicated life history would surprise even the students of parasitic worms, was shown by Shope (1941) to lie dormant in a lungworm in the pig tissues, and it is only activated by a stimulus such as a superadded bacterial infection with *Haemophilus influenzae*. Monkeys are known to suffer from their own variety of herpes which persists in the same way as human herpes, while the recent large-scale use of monkey cells for growth of poliomyelitis virus has yielded a number of other viruses from the tissues of apparently healthy animals.

Rickettsial Infection

Rickettsiae, which resemble viruses in their intracellular habitat, characteristically persist in their natural or laboratory hosts long after the original infection. When rats or mice are inoculated with typhus rickettsiae the organisms can be re-isolated from the brain for periods up to at least a year despite the presence of antibody.

Rickettsia burneti, the causal agent of Q fever, also remains alive in the tissues of animals for long periods after the initial acute infection, and this has considerable bearing on the natural history of Q fever. Unlike other rickettsiae, this organism is maintained in large domestic animals such as cows and sheep. Its spread between these animals and to man depends not on ticks or other arthropods, but upon massive excretion at parturition in the placenta and birth fluids, and then in the milk. Animals are susceptible to infection at any time whether pregnant or not, but after a short generalized infection the organism becomes quiescent. Although it can be isolated from the spleen and kidneys, no transmission occurs. This latent state continues perhaps for years, until the animal becomes pregnant. Towards the end of pregnancy the infection is activated and the rickettsiae multiply in enormous numbers in the placenta until at parturition they are shed and are potentially able to infect other animals and occasionally man.

Psittacosis

This virus also persists as a latent infection in a great variety of wild and caged birds in a rather similar way: shedding of virus in the excreta occurs at certain periods of physiological stress, and particularly at nesting time, thus causing infection of the young birds. Some of these die, but the survivors develop latent infection and the cycle is continued. Many of the latent viruses in the lungs of laboratory animals, which have been mentioned above, also belong to the psittacosis group.

The Tumour Viruses

It is not the purpose of this paper to consider the part played by viruses in the aetiology of tumours. In certain neoplasms of mice, however, a virus-like agent clearly plays some part in a fashion which implies long-continued latent infection. In strains of mice with a high incidence of cancer of the breast the milk factor, or Bittner factor, is transmitted to the offspring by suckling and carries with it the predisposition to develop cancer of the breast in middle life. The agent is filterable and particulate, and present in the breast and other tissues as well as the milk from mice of the high-cancer strain before the age at which cancer normally develops. It has many of the characteristic properties of viruses, but like lymphocytic choriomeningitis

it remains quiescent in the cells of the mouse throughout most of its life, in the meanwhile infecting its offspring.

According to Gross (1952), mouse leukaemia is transmitted in a similar fashion. He found that leukaemia could be transmitted to a strain of mice which was free of the disease, by inoculating filtrates of tumours from high-leukaemic strains. As with the milk factor, transmission was possible only in the first few days of life. Thereafter the mice developed normally, but by the end of a year about half developed leukaemia. The leukaemic factor was subsequently found at all ages in other tissues of healthy mice from the high-leukaemic strain, and it is thought to be continuously transmitted from generation to generation, possibly *in utero*.

This work on animals suggests that there are a large number of viruses which lie dormant in the tissues, perhaps gaining entry when the animal is very young and persisting throughout its life. In some circumstances the balance between host and parasite is upset, cells are damaged, and clinical manifestations may result, perhaps long after the initial infection. It should, however, be noted that, purely on clinical grounds, there would be little to suggest that such an illness was due to an infectious agent.

Latent Infections of Man

When a patient recovers from a virus disease such as measles or smallpox the virus disappears from the tissues. It has admittedly been suggested that the subsequent life-long immunity implies continued survival of the virus, but there is as yet no clinical, epidemiological, or experimental evidence to support this hypothesis. In other conditions such as poliomyelitis the cells of the alimentary tract support the virus for several weeks, but prolonged carriage has not been reported.

Herpes Simplex

The only common disease of man which is generally acknowledged to be due to life-long persistence of a virus is, of course, herpes simplex. The vesicular eruption or cold sore which appears on the lips or nostrils during acute fevers is one of the most familiar of the minor nuisances of medicine. Many individuals are subject to recurrent attacks throughout their life, and these develop in response to non-specific stimuli such as sunburn, fever, or trauma, and not through exposure to another source of herpes virus. There is no doubt that the virus is present during each of these recurrent attacks, because it can invariably be isolated in the early stages by inoculation of vesicle fluid into some susceptible tissue such as that of the rabbit cornea or chick embryo. Individuals who are prone to repeated herpes have specific antibody in their blood between attacks, which neutralizes the virus in laboratory tests, and probably prevents wide extension of the lesions; but the antibodies do not seem able to prevent either the life-long persistence of the virus or the onset of the attack. Paradoxically, the individuals who do not have herpes are the ones without herpes antibody.

This is only one aspect of this disease, however. With increased facilities for virus isolation it has become clear that in infants and children, and occasionally young adults, several entirely different illnesses are caused by the same herpes virus. The most common is herpetic stomatitis, a mild vesicular eruption of the oral mucous membrane with fever and constitutional disturbance. More severe, but rarer, examples are eczema herpeticum, a type of Kaposi's varicelliform eruption, and meningoencephalitis due to herpes virus. These conditions as such do not recur, and they follow the more usual pattern of an acute infectious disease. They affect individuals who have no antibodies initially but who develop them during the attack, and it is often possible to show that infection was exogenous through contact with another patient suffering from herpes.

Burnet and Williams (1939) suggested that these infections in childhood constituted the primary attacks due to first exposure to herpes virus, but that the virus established

itself permanently in the cells in some latent form, causing the usual recurrent manifestation in later life. It was supposed that the virus remained within the cells, dividing with them, normally causing no damage, and unexposed to antibody. This comfortable symbiosis was presumably upset by a number of non-specific stimuli which led to cell breakdown with the release of a large number of virus particles.

This idea of the natural history of herpes, which was later more fully developed by Burnet (1946), is now widely accepted, but a good many unsolved problems remain. Where, for example, does the latent virus reside? The recurrent attack is most often in a place contaminated by saliva, and herpes virus is known to be present in the saliva of carriers, both between and during attacks. Furthermore, Stalder and Zurukzoglu (1936) have shown that areas of facial skin subject to recurrent herpes no longer develop the disease if transplanted to another part of the body. This suggests that the virus persists in some other cells, perhaps those of the buccal mucous membrane at the site of the primary attack, passing in the saliva or nasal secretion to the site of the recurrent attack. If this were the sole explanation, however, it would imply some rather curious dribbling habits. The recurrent attack usually occurs in roughly the same place every time, and this is not the only place likely to be contaminated with saliva. It is therefore necessary to postulate that one particular area of skin is sensitive to reinfection. This brings us back to the other idea that the virus lies dormant at the site of the recurrent attack and is activated by saliva. Others favour the central nervous system, dorsal root ganglia, or cutaneous nerve endings as the permanent home of the virus, but there is little supporting evidence.

Herpes virus from humans does not cause a similar recurrent infection which can be studied in animals, although Good and Campbell (1948) showed that rabbits given an anaphylactic shock long after recovery from an acute herpetic infection may die of herpes encephalitis. Perhaps investigation of natural monkey herpes might give a further lead in the study of human herpes.

Brill-Zinsser Disease

There are other, less familiar but well established forms of long-continued infection, and a notable example is Brill-Zinsser disease. This is a sporadic form of typhus which occurs principally in the Eastern United States, but it has also been recently reported in Britain (Hawksley and Stokes, 1950; Steel and Lawy, 1956). For many years it was assumed that it was contracted locally, but it was difficult to explain why it was chiefly confined to Jewish immigrants to the U.S.A. from South-Eastern Europe. It was then shown that the rickettsia from patients with Brill's disease was not of the endemic variety present in the United States but was of the classical epidemic type from Eastern Europe, and Zinsser (1934), after a prolonged study, was forced to the conclusion that the disease was a recrudescence of epidemic typhus contracted in the typhus foci of South-Eastern Europe. Some of the patients had not visited Europe for many years, and the rickettsia can presumably persist in the tissues throughout this period even in the presence of antibody. Price (1955) has recently confirmed this by isolating the organism from the lymph nodes of healthy individuals who have previously had typhus. These observations are of wide importance because they also explain how the epidemic typhus rickettsia can survive in the intervals between typhus epidemics in Eastern Europe and Asia.

Other pathogenic rickettsiae can sometimes persist in man. Smadel *et al.* (1952) isolated *R. tsutsugamushi* from the lymph nodes of a patient one year after scrub typhus which had been treated with chloramphenicol. Q fever can be a long-continued relapsing illness, and Huebner has found *R. burneti* in the blood and urine one year after an attack (see Marmion *et al.*, 1953). Psittacosis virus has been isolated from the same patient over a period of eight years by Meyer and Eddie (1951).

Herpes virus, pathogenic rickettsiae, and the psittacosis virus grow well in a variety of laboratory animals and eggs, and so are relatively easy to isolate and identify. We come now, however, to other viruses which are apparently host-specific and able to grow only in man. These are, of course, much more difficult to study, and depend upon the use of volunteers or, alternatively, cultures of human cells *in vitro*.

Serum Hepatitis

One virus which has been discovered unintentionally by using man himself as an experimental animal is, of course, the virus of serum hepatitis. It is now known that a proportion of apparently healthy adults carry in their blood a virus capable of causing hepatitis in non-carriers. Transmission occurs by parenteral inoculation alone during blood transfusion or from inoculation of blood products such as serum or plasma. The large outbreaks which occurred during the last war were due to human serum used as a preservative in yellow-fever vaccine. The amount of virus in the blood of carriers must be quite appreciable, because transmission may occur with minute amounts of blood such as that contaminating the needle of an imperfectly sterilized syringe, and large pools of serum and plasma can be infected from one contributor to the pool. Potentially the virus might be transmitted by blood-sucking insects simply by contamination of the proboscis, although there is no evidence that this in fact occurs. Little is known about serum hepatitis virus because it has been studied only by inoculation of human volunteers, and the substantial mortality rate does not exactly encourage this means of investigation. Attempts to use human cells in culture from liver or elsewhere have not been successful. In recent months Richtsel *et al.* (1956) have described a strain of human cells apparently susceptible to a similar virus, that causing infectious hepatitis, but it is not yet known if serum hepatitis will also infect these cells.

It is difficult to see how the virus gains access naturally, and it has even been claimed that this is an example of spontaneous generation from the cells of the carrier. The account of hepatitis in newborn infants by Dible *et al.* (1954), however, suggests the possibility that transfer may normally occur from mother to child *in utero* with consequent development of immune tolerance—that is, loss of ability to develop antibodies to the virus. This might then lead to a permanent latent infection, persisting for life, in the same way as lymphocytic choriomeningitis in mice, and, like the latter, detectable only by inoculation of susceptible non-carriers.

Serum hepatitis may not be the only latent virus which manifests itself in this way by parenteral inoculation. Beutler and Dern (1955), when working on the survival time of transfused red cells, discovered that the blood of one healthy donor produced an acute feverish illness in nearly all recipients about 12 days after inoculation. The agent causing this illness was filterable and could be transmitted from these recipients to others during the acute stage and up to at least nine weeks later, causing similar symptoms. The fever, lasting about a week, was accompanied by headache and muscle pain, sometimes with nausea and vomiting or respiratory symptoms, and 6 patients out of 38 developed arthritis one to five weeks after the end of the acute illness. The agent producing this disease was present in the blood of the donor in repeated tests over a 13-month period, during which he remained perfectly well. The authors point out that this rather mild illness could easily be missed after the usual transfusion of a single recipient from a donor who was a carrier.

The Adenoviruses

The development of tissue-culture methods for the study of viruses, stimulated by Weller *et al.* (1949) in their work on poliomyelitis, showed the great potential advantages in the use of human and monkey cells growing *in vitro*. This has not unnaturally led to the uncovering of new viruses previously undetected through lack of pathogenicity for laboratory animals and eggs. These viruses are in roughly

two groups: (1) a heterogeneous collection from faecal specimens mostly isolated during attempted isolation of poliomyelitis virus; and (2) a single family of related viruses largely from the upper respiratory tract and eye, now known as the adenoviruses or A.P.C. viruses (adenoido-pharyngo-conjunctival viruses). Rowe *et al.* (1953) isolated the first of these agents when growing cultures of tonsils and adenoids removed at operation. They found that epithelial cells from these tissues grew well for about two weeks, but degeneration then appeared in some of the cultures. A virus could be isolated from the degenerating cells, which would then cause similar changes in the remaining adenoid cultures which had remained normal, as well as in certain other cultures of human epithelium, such as the HeLa strain of carcinoma cells. The virus could not so easily be obtained from swabs or even ground suspensions of adenoids, although it regularly became unmasked after growth of the cells in culture. This could perhaps be due to the elimination of antibody or other inhibitory substances originally present in the extracellular fluid.

Since then at least 14 closely related viruses have been isolated, some from adenoids removed at operation and some from patients with acute respiratory disease, while two members of the same group have been found in monkey and chimpanzee tissues respectively (Rowe and Huebner, 1956).

Some members of this group of viruses—notably Types 3 and 4, 7 and 8—cause acute diseases such as pneumonia, pharyngitis accompanied by conjunctivitis, and other upper respiratory syndromes in patients of all ages. It is not known if these viruses persist after the initial infection. Certain other adenoviruses, however—Types 1, 2, and 5—are found only in association with febrile respiratory illnesses in young children, but they are present in the majority of adenoids removed at operation from both children and adults, and antibodies against one or other type are also present in the blood of nearly all adults. This suggests that widespread infection with these types occurs at an early age and is associated with the typical hyperplasia of tonsils and adenoids seen in young children. Despite the development of antibodies after first infection, the virus apparently persists, perhaps indefinitely, in the lymphoid tissue.

This resembles latent herpes except that adenovirus may be more widespread. The latent herpes virus, however, at intervals damages the cells and gives rise to disease. The similarly latent adenovirus would have practical importance only if there was also some clinical manifestation of its presence after the initial infection. There may be a number of unexplained illnesses due to recrudescence of latent viruses in lymphoid tissue. It is tempting, for example, to suspect some of the recurrent spontaneous afflictions of the throat and nose, especially in children, and lymphoid hyperplasia caused by a virus of this sort might even initiate attacks of acute appendicitis.

Proof of a causal connexion is not likely to be an easy matter, however. If such illnesses were accompanied by release of virus from damaged cells the virus would probably not be detectable in practice through immediate neutralization by antibody already present. In recurrent herpes the virus conveniently presents itself in an easily recognized superficial vesicle from which it can be isolated before antibody filters in as well. Apart from the difficulty of sampling the lymphoid tissue sufficiently early in an illness, neutralization of adenovirus is likely to be much more rapid in what is the probable site of antibody production.

Demonstration of a rise in serum antibody after the illness might be suggestive, but there is little alteration after recurrent herpes. Perhaps it would be possible to show an increase in viral antigen (even if infectivity was neutralized) by injecting exudates, or tissue suspensions where available, into rabbits, and comparing the antibody rise with that resulting from injections of control material; but the variability of antibody response in different rabbits might be prohibitive. Nevertheless, a fresh approach of some sort will be needed to study this type of aetiological relationship.

Mechanism of Latent Infection

Having considered some examples of latent viral and rickettsial infection in man and animals, it would now be appropriate to discuss the mechanism by which these parasites can survive so successfully in their hosts. This review is confined to the viruses and rickettsiae, but bacteria and even larger parasites can persist for long periods as well. Most of these organisms live on an internal surface of the host, however, and they avoid the immunological problems involved by prolonged sojourn inside the tissue. Furthermore, most of the larger organisms, even inside the tissues, retain their morphological identity, whereas some viruses probably develop a much more intimate relationship with the cells of the host.

Once a virus or rickettsia has gained access to the susceptible cells initially, one may suppose the following requirements if it is to establish a persistent latent infection: (1) the virus must produce no damage to the cells, or at least the rate of damage must be less than the rate of production of new cells; (2) it must have some mechanism for getting from cell to cell, particularly if the cell concerned has a short life; and (3) it must not be affected by the immunity mechanism of the host.

It is admittedly possible to imagine an equilibrium with a low-grade immunity, in which a small proportion of virus released is always left unneutralized and is thus able to infect a small number of new cells and so on. One could hardly expect such a system to remain stable for long, however, without some sort of over-all control mechanism. Our consideration of some examples of latent infections indeed suggests that there may be more than one way in which viruses persist. After all, there are certain infections, such as lymphocytic choriomeningitis in mice and possibly serum hepatitis in man, in which antibody never develops and virus can pass unhampered throughout the body. On the other hand, herpes virus is presumably maintained in cells which are surrounded by antibody.

It would be convenient, at the risk of oversimplification, to consider three main groups of persistent viruses, which probably have different mechanisms for survival.

1. *No Development of Antibody.*—In lymphocytic choriomeningitis of mice, mouse mammary cancer, mouse leukaemia, and possibly serum hepatitis of man, infection occurs *in utero* or within the first few days of life. Antibodies probably never develop against these viruses even though they persist for life. This is presumably due to the phenomenon of immune tolerance. Lymphocytic choriomeningitis virus, and probably the agent of mouse leukaemia, are widely scattered in various tissues and present in high concentration, while it is also probable that serum hepatitis virus is plentiful at least in the blood of human carriers. The only limitation to the growth of these viruses is the supply of susceptible cells. Since a large number of cells are infected, one would assume that these are not damaged during virus multiplication. This immediately leads to difficulty in explaining why serum hepatitis virus causes necrosis of liver cells when transmitted to non-carriers. Perhaps the liver damage in non-carriers is connected with a normal immune reaction to the virus. This might help to explain the very long incubation period, allowing for growth of the virus and development of immunity before onset of clinical manifestations.

Theiler's virus may fall into this first group, but, since infection of young mice is sometimes delayed for two or three weeks, the immune tolerance is not complete and latent infection generally persists for only about six months, after which antibody appears and the virus is eliminated.

2. *Antibody Present but Ineffective.*—In persistent infection of man and animals, or of birds, with rickettsiae or viruses of the psittacosis group, antibody to the organism is normally present, and can be detected by various *in vitro* methods such as agglutination or complement fixation. These antibodies will neutralize the toxic effects of the organisms

and prevent fever or other clinical signs of infection in animals, but it is difficult to show any effect on the actual growth of the organisms. For example, *R. burneti* grows just as effectively in eggs in the presence of high-titre immune serum as with normal serum. Growth of smaller viruses is probably neutralized because antibody prevents their entry into the cells. Perhaps the large viruses and rickettsiae have a different method of entry and one which is not blocked by antibody. Some grow in phagocytic cells, and here the opsonic action of antibody might actually help. Anyway, it seems likely that the long persistence of these organisms in the tissues of naturally infected individuals is connected with a similar failure of antibody to prevent multiplication and dissemination.

Several of us at Cambridge have investigated this phenomenon with *R. burneti*, the causal agent of Q fever. Dr. Fiset and I have found that organisms freshly isolated from animals, either in the acute stage or after long persistence, fail to react in certain *in vitro* tests even with their homologous antibody (Stoker and Fiset, 1956). This was subsequently found to be due to a polysaccharide of low antigenicity on the surface of the naturally occurring rickettsiae which prevents the main protein antigen of the organism from combining with its antibody (Fiset, unpublished). It was suggested that the surface layer allowed *R. burneti* to survive in the host in the presence of this antibody. An *in vivo* neutralization test developed by our colleagues Abinanti and Marmion (1956) added some confirmation, but there is not yet sufficient evidence to conclude that this phenomenon is entirely responsible for long persistence under natural conditions.

Morgan's (1956) studies with psittacosis suggest that, with this virus at least, other factors may also be involved. Thus the psittacosis virus remains latent in chick cells cultured on deficient medium, but multiplies normally when the cells are given certain amino-acids. Studies of this sort with other latent viruses and rickettsiae are now needed.

3. *Antibody Present and Effective, but No Contact with Virus.*—In the third group of latent infections, which includes herpes and the adenoviruses, antibody is also present in the circulating blood of the host. Unlike the rickettsiae and psittacosis group, however, growth of the virus can easily be neutralized by antibody. When herpes virus or adenoviruses are mixed with antibody in laboratory tests and brought into contact with susceptible cells they are prevented from entering the cells and multiplying. This seems to imply that under natural conditions the latent virus, once established, can pass from cell to cell without exposure to antibody. How could this take place?

If there is no damage to the cells during virus growth there would, presumably, be no inflammatory reaction with exudate of plasma protein, including antibody globulin, in the extracellular fluid. Thus a virus such as herpes could pass from cell to cell quite freely, provided it remained outside the blood stream, particularly where the cells are closely packed as in the basal layer of epithelium. In lymphoid tissue, where the adenoviruses persist, however, antibody may be in much closer contact with the infected cells.

An alternative is passage from cell to cell along cytoplasmic connexions. Black and Melnick (1955) observed that when sheets of monkey cells in culture are infected with B virus, the monkey herpes, spread was at first confined to cells adjacent to the initial focus of infection and was not affected by antibody in the medium. With human herpes virus growing in human carcinoma cells (HeLa strain) a similar focal spread is observed. Under ordinary experimental conditions the cells release virus into the surrounding medium, secondary foci appear, and the lesions soon become confluent, with the development of giant cells (Special Plate, Figs. 1 and 2). If antiserum is added to the medium a few hours after first infection the change does not become confluent. The primary foci continue to enlarge, however (Plate, Fig. 3), suggesting that the virus is passing to contiguous cells without coming into contact with antibody.

One of the most striking changes is the development of a web of cytoplasmic connexions between cells, but these are most easily seen in unneutralized cultures in the neighbourhood of giant cells (Plate, Fig. 2), and are not visible between the tightly packed cells of the foci which develop in the presence of antiserum. My colleague Dr. Ross, who has stained herpes-infected cells with fluorescent antibody by the technique devised by Coons and Kaplan (1950), has found some fluorescence in these cytoplasmic extrusions, but it is not certain if this is due to the presence of the infective virus particles themselves.

An alternative would be the transfer of the virus to the descendants of the originally infected cells at mitosis. This is unlikely in the cultures of carcinoma cells, because we have found that they stop multiplying immediately they are infected, but we must seriously consider this possibility under natural conditions, where absence of histological change in the quiescent phase implies a lack of damage to be expected if cell division were proceeding normally. It is perhaps noteworthy that herpes and adenovirus are the only two animal viruses for which there is unequivocal evidence of multiplication in the nucleus. If such viruses could divide at the same rate as the host cell, the progeny might pass with the chromosomes to the nuclei of the daughter cells and might almost be considered cell constituents. It is in the latent virus infections of bacteria, however, that this type of relationship has been most fully investigated, largely following the work of Lwoff and Gutmann (1950).

Lysogenic Strains of Bacteria

When two closely related strains of bacteria—for example, two strains of staphylococci—are grown together, one strain may grow normally but cause lysis of the bacteria in the other strain. The apparently normal strain is called lysogenic, and the property is due to the presence of latent virus in each bacterium. The virus does no damage to the bacterial host, and divides with it so that the strain is permanently infected but its physiological functions are unimpaired. A small proportion of the cells release virus, which has no effect on the remainder of the infected bacteria, but which will cause lysis of other susceptible strains of bacteria not already carrying the latent infection. These uninfected strains which undergo lysis can therefore act as indicators of virus from the apparently normal carrier strain. Provided one can find a suitable indicator, it is now possible to show latent virus infection in a large number of strains of various bacterial species.

This symbiotic relationship between the virus and bacterial cell can be upset by certain physical stimuli and chemical agents. If a lysogenic strain is irradiated with ultraviolet light, for example, all the bacteria undergo lysis and release large amounts of virus. One is immediately reminded of the transformation of latent into active herpes by sunlight and other apparently non-specific stimuli.

State of the Latent Virus

It is well to remember that the mature virus particle, as shown in electronmicrographs of purified virus suspensions, is probably only one stage in the life cycle, allowing transport to and penetration of the virus into new cells. The work of Hershey and Chase (1952) on bacteriophage has led to the conclusion that the characteristic tadpole-shaped particle does not enter the bacterial cell, but acts as a sort of syringe to introduce nucleic acid, which is apparently the organizer of new virus and which carries its genetic characters. Work on human and animal viruses, and especially influenza virus, also suggests that the virus particle, after penetration of the cell, is broken down into its constitutive genetic elements, or, at least, completely altered into a vegetative state during multiplication.

If in some latent infections the virus lies permanently within the cell and its descendants, it may consist solely of the genetic material of the virus dividing in time with the hereditary constituents of the parent cell. It is in this form, called prophage, that the virus persists in lysogenic bacteria.

This adds to the problem, because if latent animal viruses exist in this state they would not be detected by ordinary isolation procedures, because virus material would not be in a form which could infect new cells. Some inducing agent would be needed which would upset the equilibrium and allow the virus to mature to a fully infectious form, as in the induction of lysogenic bacteria by ultra-violet light. There is no clear evidence at present, however, that latent virus infection of human or animal cells resembles that of bacterial cells. Further progress awaits a suitable model of latent infection in tissue culture which could be studied by the quantitative techniques which have been so fruitful with lysogenic bacteria.

A more or less undetectable latent virus which persists indefinitely without damaging the cell in the ordinary sense may anyway seem rather an academic nicety. Absence of recognizable histological change, however, does not mean that the continued presence of viral material in a cell will not alter some of its functions. For example, the tumour viruses change the potentiality of the cells they infect without necessarily causing necrosis. Latent virus infection of a bacterium may confer entirely new characters, such as the development of flagella or toxin production, on the otherwise normal host. We have yet to see whether viruses may cause long-standing alterations of cell function in man.

Conclusion

We have now indulged in a good deal of speculation and have come some way from practical medical problems, but, judging by the numbers of latent viruses found in animals, our own tissues may harbour more unobtrusive guests than we imagine. For the survival of a virus or any other parasite it is, of course, the most satisfactory arrangement. No damage to the house—no trouble with the landlord.

When symbiosis is complete, especially if early infection leads to immune tolerance, we may expect few medical problems. These will arise only when artificial procedures, like blood transfusion, carry the virus to someone who has escaped early infection. Nevertheless, this risk will call for great care if virus vaccines are ever made from human cell cultures, which are more likely than blood to carry these hidden agents.

With other infections, like herpes and Brill's disease, the balance may occasionally be upset with a sudden acceleration of virus production and cell damage, causing illness in the carrier. Some sporadic afflictions of tonsils and adenoids, or even other lymphoid tissue, may eventually prove to be due to recrudescences of infection with adenoviruses. Such conditions lack many of the usual attributes of an infectious disease, and their recognition as latent virus infections will involve subtle problems for the virologist as well as the clinician. It is to be hoped that investigation of the more fundamental problems of the mechanism of latency, as outlined, may ultimately be of practical value in the elucidation of these diseases.

ADULT HYPERTROPHY OF THE PYLORUS

BY

A. M. DESMOND, M.B., F.R.C.S.

Surgeon

AND

B. F. SWYNNERTON, D.M., M.R.C.P.

Physician and Research Assistant

St. James's Hospital, London

[WITH SPECIAL PLATE]

Pyloric hypertrophy in adults has in the past ten years been found 25 times during laparotomy at St. James's Hospital. Fewer than 200 cases have been recorded in the literature since the condition was first described by Cruveilhier over 100 years ago, and many of these were discovered only at necropsy. Horwitz *et al.* (1929) found that the normal thickness of the pyloric muscle varied from 3.8 mm. to 8.5 mm.; in all our cases it has been 1 cm. or more (see photograph). Furthermore, in all cases the hypertrophy was mainly confined to the circular muscle.

Only once has a confident pre-operative diagnosis of the condition been made, but increasing experience has enabled us to form a strong suspicion of its existence from the radiographs after a barium meal in a few

Resected stomach from Case 6, showing incised thickened pylorus (1.3 cm.).

other cases. The majority of patients have had co-existent duodenal or gastric ulcers, and it is the symptoms of these which have brought them under our care.

Treatment has therefore been directed to cure of the ulcer. The accompanying table summarizes the findings in these cases.

History

In no case were we able to obtain a clear-cut history of vomiting in infancy suggestive of congenital pyloric stenosis. One or two patients stated that in childhood they had suffered from bilious attacks with vomiting, and one gave a history of migraine with vomiting dating back to childhood. It may be significant that in this case the migraine has been

cured, at least temporarily, by partial gastrectomy. In 15 of the 25 cases vomiting was a prominent symptom, and it was profuse in four, two of which had a duodenal ulcer and two a gastric ulcer. In 18 cases concomitant peptic ulcers were confirmed at operation, and all but one of these presented with ulcer-type dyspepsia. It is interesting that five of the remaining seven cases also gave typical ulcer histories. In another case the condition was an incidental finding at an emergency operation for obstruction due to bands; and the last case had a history of vague discomfort, waterbrash, and a sensation of choking. In short, ulcer-type dyspepsia was the main feature whether or not the presence of an ulcer was confirmed, and vomiting was frequently a symptom.

If there is an aetiological connexion between peptic ulceration and adult hypertrophy of the pylorus, it might be expected that the site of the ulcer would be fairly constant, but this does not appear to be so, since in 11 cases it was gastric, in four duodenal, in two both gastric and duodenal, and in the other pyloric.

We have been unable to discover any symptom or group of symptoms which would help in establishing a confident diagnosis. A history of profuse vomiting for many years associated with an atypical history of ulcer dyspepsia, without gross gastric retention, might lead one to suspect the condition.

Physical Signs

Here again no diagnostic facts have been elicited. Epigastric tenderness has been a constant sign in cases with or without ulcer. A tumour has never been felt on clinical examination, but in Case 18 the radiologist felt a pyloric tumour during screening. In seven cases a succussion splash was noted, and in these a large gastric residue was apparent on x-ray examination. Four of them had a gastric ulcer, and in three the hypertrophy was the only finding. Curiously, none of the cases associated with a duodenal ulcer had a splash or showed gross gastric retention on x-ray examination.

Radiological Findings

The x-ray findings are reported in two ways: as original reports and as reports in retrospect. Two cases were not examined radiologically, the diagnosis of gastric ulcer being made in each case by gastroscopy. In nine cases a retrospective examination of the radiographs has not been possible.

Although duodenal ulcer was found at operation in only six cases, a pyloric or duodenal ulcer was reported in 17. The reports on the remainder are in summary as follows: no lesion seen, 2; hyperperistalsis, 1; gastric ulcer with retention, 1; gastric ulcer with duodenitis, 1; probable adult hypertrophy of pylorus, 1. Thus the diagnosis was suggested with confidence in one case only, though in another two it was mentioned as a possibility.

Retrospective examination of the barium-meal radiographs has been interesting. In the two cases in which it was reported that the condition might be present it is now obvious that the report could have been given with confidence (see Special Plate, Figs. 1 and 2). In seven cases no reason could be found to modify the original report. Two of these had a duodenal or pyloric ulcer, three others a gastric ulcer with gross mucosal stenosis and in which no cap could be demonstrated, and one both gastric and duodenal ulcers. In five other cases revised reports were as follows:

Case 4.—There is narrowing of the pyloric canal with a slight duodenal bulbar impression; the canal is not elongated. Operative findings: gastric ulcer and duodenal ulcer with hypertrophy.

Case 5.—The canal is normal but there is a slight duodenal bulbar impression. Operative findings: duodenal ulcer and hypertrophy.

Case 16.—There is elongation and narrowing of the pyloric canal with a duodenal bulbar impression. Operative findings: pyloric hypertrophy only.

Case 17.—There is elongation but no narrowing of the pylorus with a deformity of the duodenal cap. Operative finding: pyloric hypertrophy only.

Case 20.—There is slight peaking of the pylorus with a very small cap.

Gastroscopy

This was performed in eight cases. Results in two were inconclusive and in one normal; five had gastric ulceration or scarring. In only one was narrowing of the pylorus noted, but blood-clot in the antrum prevented close examination of the mucosa.

Operative Findings

In all cases at laparotomy the diagnosis was reasonably obvious. In an early case, to exclude the possibility of carcinoma, a small incision was made in the pylorus. This manoeuvre removes all doubt. The white, regular, glistening muscle cannot be confused with the grey, irregular infiltrative type of carcinoma. The serosa is normal, and the submucosa loose and lax and easily defined. At the same time a small piece can be taken for microscopical examination (Tanner, 1950).

In 11 cases there was no evidence of a concomitant lesion of the stomach or duodenum on thorough inspection and palpation. In five of these a gastrectomy was performed, and the excised specimen revealed scarring or shallow ulceration in either stomach or duodenum in all but one case. In four cases a Heineke-Mikulicz pyloroplasty was performed, in one a Ramstedt operation, and in one a gastro-jejunostomy. The last patient was a man aged over 70; his general condition was not good and the operation was carried out under local analgesia. In the 14 cases where a peptic ulcer was found a suitable gastrectomy was performed to cure this.

The state of the pyloric mucosa excited interest in five cases, three of which had such a degree of mucosal stenosis that only a moderate-sized probe could be passed; two of the three also had a gastric ulcer, but in the third no ulcer was found. The other two cases presented small protrusions through the pylorus into the duodenum, about 2.3 mm. in diameter. In both instances these were thought to be polypi, but section showed normal musculo-mucosal tissue. The exact nature of this is doubtful, but we think it is an abnormal form of mucosal prolapse due to the hypertrophied pyloric muscle preventing normal reduction. The cause of mucosal stenosis is obscure, but we feel that it must be inflammatory in origin, possibly from an acute pyloric or duodenal ulcer. It may be due to some degenerative change secondary to mucosal prolapse.

An associated congenital lesion was found in Case 6—namely, non-rotation of the gut. This patient had a gastric ulcer and was subjected to a Billroth-I gastrectomy.

There were no deaths in the series, and post-operative convalescence was uneventful in all cases. Two of the earlier ones have not been contacted recently, but the remainder are all known to have satisfactory relief of their symptoms.

Discussion

Various theories concerning the aetiology of pyloric hypertrophy in adults have been advanced, of which the most probable is that it is a persistence of the infantile form. Considering the amount that has been written on the immediate results of treatment of congenital hypertrophic pyloric stenosis, there is remarkably little information on the ultimate fate of the tumour. In careful follow-up studies of babies treated medically Runström (1939) has shown that the condition tends to resolve slowly and an abnormality may be detected for many years.

There seems to be fairly general agreement that a Ramstedt operation is followed by complete disappearance of the tumour (Wollstein, 1922). The very few "failures" have all required a second operation within a few days or weeks of the first, and have usually been attributed to

incomplete division of the circular muscle fibres. In no case, so far as we have been able to ascertain, has the tumour been shown to have persisted for more than a few weeks after this type of operation. Two patients at St. James' Hospital who had Ramstedt's operation in infancy have undergone laparotomy in adult life, one for gastric ulcer and the other for recurrent appendicitis. In both the pylorus felt normal and there appeared to be no persistence of the hypertrophy.

If the infant is treated by gastro-jejunostomy the tumour frequently remains unaltered (Holt, 1917), even well into adult life (Donovan, 1946; Walters, 1946; Armitage and Rhind, 1951; and others). Indeed, the cases recorded suggest that the tumour nearly always does persist after gastro-jejunostomy, though this may be an erroneous impression, as the absence of a tumour at a subsequent operation may be overlooked or not regarded as worthy of record. Be this as it may, it is difficult to imagine why a short-circuiting operation will lead to persistence of the tumour while other forms of treatment will cause its disappearance. We agree with McCann and Dean (1950) that the tumour will persist in a proportion of medically treated or subclinical cases and will be discovered only at necropsy, at operation for some other condition, or when some additional mechanical or inflammatory factor leads to increased stenosis with the production of symptoms.

The frequent finding of a peptic ulcer in association with the condition indicates that there may be some relationship between the two. It has been postulated that stasis is conducive to peptic ulceration: several papers have drawn attention to the incidence of duodenal ulceration in duodenal ileus, and recently Johnson (1955) has suggested that gastric ulceration may follow pyloric stenosis. The hypertrophy, then, may explain the gastric ulcers, but would not account for the duodenal ulcers.

Kirklin and Harris (1933), reviewing the literature and describing 81 cases seen at the Mayo Clinic, list the following radiographic appearances which may be aids to diagnosis: (1) lengthening of the pyloric canal (normal does not exceed 1 cm.); (2) a narrowing of the pyloric canal, though this is variable; (3) a narrow crevice or a longer depression about the mid-point of the lower edge of the canal; and (4) concavity in the base of the duodenal bulb—that is, a duodenal bulbar impression. They considered that the only definite pathognomonic feature was the last of these. While it is of interest, and occasionally of importance, to make a pre-operative diagnosis, we would emphasize that all filling defects in the region of the pyloric canal in adults should be regarded as neoplastic until proved at operation to be benign.

It has been stated (Morley, 1949) that it is difficult to distinguish this condition from a carcinoma of the pylorus, but we have found that, when it has been met with once and diagnosed at operation, recognition of the innocent nature of the tumour is relatively easy. If in doubt, a small incision with diathermy into the tumour will render the diagnosis more obvious, as the glistening, bulging cut surface of the muscle is quite characteristic and in no way resembles the cut surface of an infiltrative type of neoplasm.

Having identified the lesion, we have dealt with it along the following lines: (1) If a peptic ulcer is present a gastrectomy is performed. The presence of hypertrophy is no contraindication to the Billroth-I type of reconstruction, as the duodenum is never involved in the hypertrophy. (2) If there is no obvious ulcer on examination of the serosal surfaces of stomach and duodenum and after careful palpation, we consider the history, and where there is a good clinical history suggestive of peptic ulcer we perform a Billroth-I gastrectomy, since on occasions ulcers have been found only after examination of the resected specimen. (3) If the clinical history is atypical and the diagnosis has been mainly based on radiological findings, we advise a pyloro-duodenotomy, biopsy, and resuture transversely to make a Heineke-Mikulicz pyloroplasty. This is most likely to prove satisfactory where there is coexistent mucosal stenosis (Tanner, 1950).

It is very inviting where no other lesion is found to perform a Ramstedt operation, and this was done in Case 16. The result so far has been most gratifying, but as the patient had no gastric symptoms before laparotomy for intestinal obstruction it is hardly a fair test.

In conclusion we would like to add that since we started to make a particular study of this condition in 1953 we have identified it with greater frequency than we had done before, and are sure that it is a far more common condition than is generally realized.

Summary

In the past ten years 25 cases of pyloric hypertrophy in adults have been seen during laparotomy at St. James' Hospital. In no case was a confident diagnosis of the condition made before operation, though in three cases the radiologist had suggested this possibility. All but two cases presented with symptoms suggesting peptic ulceration, and a peptic ulcer was in fact found in 18.

The radiological findings are reviewed and the aetiology is discussed. Where an ulcer is found or there is a history suggesting peptic ulcer a Billroth-I partial gastrectomy is advocated as the best form of treatment. In other cases, after exclusion of gastric carcinoma by biopsy, a lesser operation may suffice.

We acknowledge with thanks the kind co-operation of Mr. Norman Tanner in allowing us to use his cases. Our thanks are also due to Dr. R. V. Quilliam for his helpful suggestion with the radiographs.

LOCAL ANALGESIA AND KIELLAND'S FORCEPS

BY

J. S. SCOTT, M.B., M.R.C.O.G.

AND

R. L. GADD, M.B., M.R.C.O.G.

From the Department of Obstetrics and Gynaecology,
University of Liverpool, and Mill Road Maternity
Hospital, Liverpool

[WITH SPECIAL PLATE]

The dangers of general anaesthesia in operative obstetrics have been repeatedly emphasized in recent years (Jeffcoate, 1953; Parker, 1954, 1956). Forceps delivery is by far the commonest operation performed, and is probably the most dangerous from an anaesthetic point of view. To avoid this risk some have advocated a return to operating with the patient in the lateral position, while others have advised the use of local analgesia wherever possible. Up to the present it has, however, been the general experience and opinion (Parker, 1956) that pudendal block and local infiltration of the perineum is applicable only to about 60% of all forceps deliveries—that is, those in which the head is at the outlet and favourably rotated.

This paper describes the methods and presents the results of an attempt to extend beyond this limit the use

of local analgesia for forceps delivery. The work was carried out at Mill Road Maternity Hospital, Liverpool, during the 12 months April 1, 1955, to March 31, 1956. Lignocaine (1%) up to a maximum of 50 ml. was the agent used, by a technique similar to that described by Gate and Dutton (1955).

Over-all Results

During the year in question 3,553 babies were born in the hospital, and 410 of these (11.5%) were delivered by forceps. Of these operations, 94% were successfully conducted under local analgesia. The operations consisted of 266 outlet forceps without rotation of the head and 144 cavity forceps with rotation of the head. The proportion of primigravidae to multigravidae in the forceps series was 7:1, whereas for all deliveries it was 10:13. The mortality was as follows:

Maternal.—One mother died, but death was in no way related to the operation. She had extensive bronchiectasis and contracted pneumonia shortly before the onset of labour. The foetus died from asphyxia early in the first stage, and an easy low forceps delivery was performed under local analgesia when the head reached the perineum. The patient died 36 hours later from cardiac failure secondary to the lung condition. (Table I, Case 7.)

Foetal.—Table I shows the foetal loss with forceps delivery. Nine babies were stillborn, and two died in the neonatal period from gross malformations. Of the still-

born babies, 4 (Cases 3, 4, 8, and 11) died *in utero* before the onset of labour and 3 (Cases 5, 6, and 7) during the first stage of labour. If the grossly malformed babies and those which died *in utero* before operation are excluded there were two stillbirths, a mortality of 0.5%. In both these cases an easy low forceps operation was carried out because of foetal distress, and necropsy showed asphyxial changes only. There were no foetal deaths from intracranial injury. That these results were not obtained by an over-ready resort to caesarean section in cases of potential difficulty is shown by the caesarean section rate of only 2.8%, despite the fact that the hospital serves a poor-class area where contracted pelvis, even rachitic in origin, is still prevalent.

Rotation of the Foetal Head

The need to rotate the foetal head is generally regarded as the largest single factor calling for general anaesthesia. Local analgesia is said to be unsuitable for these cases

because: (a) it does not permit the introduction of the whole hand into the vagina and the slight disimpaction of the head usually necessary for manual rotation; (b) it does not allow free abdominal manipulation of the trunk; and (c) it does not produce the uterine relaxation thought to be necessary to allow rotation of the foetal trunk with the head (Kerr and Moir, 1949).

In planning our work it seemed that the use of Kielland's forceps for head rotation offered a possible answer to the first difficulty. The second and third arguments appeared to be based on a belief that general anaesthesia is needed to produce sufficient uterine relaxation for trunk rotation, this having been handed down through generations of textbooks without its truth ever being seriously questioned. It was decided to investigate this by studying the behaviour of the foetal trunk radiologically during the course of rotation of the head by means of Kielland's forceps under local analgesia, 14 cases, in all of which a persistent posterior or transverse position of the head called for operative intervention, being so examined. In each case rotation of the head was easily achieved and was accompanied by rotation of the trunk without any abdominal manipulation whatever, and before traction was applied. (Special Plate, Figs. 1 and 2.)

This finding was clearly of importance. It led to the abandonment of manual rotation in favour of the routine use of Kielland's forceps for head rotation, and an immediate extension of the scope of local analgesia.

Kielland's Forceps

The techniques for the use of Kielland's forceps have been fully described by Parry Jones (1952) and Donald (1955), but certain points in their use under local analgesia deserve comment.

The successful application of the blades of the forceps under local analgesia demands extreme gentleness and the most careful attention to details of technique. For applying the anterior blade in cases of transverse arrest the classical method seemed unsuited for use without general anaesthesia; thus either the wandering or the direct method was employed, depending on the operator's preference.

Parry Jones has stated that the use of the direct method is limited to those cases in which the head is arrested at a low level in the pelvis, but we have found that by careful attention to the patient's position it can be employed in nearly all cases of transverse arrest at ischial-spine level. To do this the patient is placed in the lithotomy position on an operating-table or suitable hard bed, with the convexity of her sacrum resting on the edge and her buttocks overhanging slightly (Fig. A). Providing her buttocks are well clear of the end of the table, the handle of the forceps can be depressed beyond the vertical, and this allows the direct introduction of the anterior blade between the palmar surface of two fingers inserted anteriorly and the foetal head (Special Plate, Fig. 3).

FIG. A.—Patient in lithotomy position on operating table for direct application of anterior blade of Kielland's forceps. If position is achieved by lowering a folding leaf at foot of table this should be removed, to allow depression of handle of blade beyond the vertical.

It is next necessary to emphasize that for success with local analgesia it is essential that all manipulations be performed *between* contractions. This applies to application of the blades, rotation of the head, and also traction. This is contrary to the general recommendation that traction should be restricted to the period of uterine contraction, but it is necessary because, since the analgesia does not relieve the contraction pain, the patient is bound to be disturbed and may become uncooperative. By applying traction only between pains it is possible, in a large proportion of cases, to deliver the child without the mother realizing it has been born.

Among the 144 cases in which Kielland's forceps were used for rotation there was no case of urinary fistula, third-degree tear, or other maternal injury (Table II). This can

TABLE II.—Morbidity with Forceps Operation (Including Four "Trial of Forceps" Cases which Came to Caesarean Section)

Morbidity	Local Analgesia		General Anaesthesia	
	Forceps (Simpson's or Wrigley's) without Rotation (264 Cases)	Kielland's Forceps (125 Cases)	Trial of Forceps (11 Cases)	Other G.A. (14 Cases)
A. Maternal:				
Notifiable pyrexia	16	8	1	2
Post-partum haemorrhage	7	3	2	2
Secondary post-partum haemorrhage	3	Nil	Nil	Nil
Transient haematuria	2	2	"	"
Third-degree tear	2	Nil	"	"
Perineal breakdown	3	1	"	"
B. Foetal:				
Cephalhaematoma	2	1	"	1
Cerebral irritation	2	Nil	"	"
Facial paresis (all transient)	2	2	"	Nil
Fractured clavicle	1	Nil	1	"

be attributed to the conduct of the majority of the operations (125) under local analgesia, with resultant gentleness and delicacy in the handling of the instrument. There was no attributable foetal loss in the group, and this aspect is discussed later. The effectiveness of local analgesia for the Kielland's operation is shown in Table III. There was only one case in which local analgesia had to be abandoned in favour of general anaesthesia. Inhalation analgesia ("trilene" or gas-and-air) was administered only if the patient complained of discomfort.

TABLE III.—Effectiveness of Local Analgesia for Kielland's Rotation and Delivery

	No. of Cases
Very effective; patient undisturbed	105 (83%)
Satisfactory except for slight discomfort at some stage for which gas-and-air or trilene was given	20 (16%)
Unsatisfactory or impossible to inject	1 (1%)

While it is realized that the assessment of comfort is individual and open to question, we are convinced that none of the patients experienced any distress comparable to that associated with the passage of a stomach tube in the second stage of labour, which is usually regarded as an essential preliminary to any general anaesthetic in the circumstances.

Supplementary Sedation

Cases where the patient is apprehensive and uncooperative or where discomfort is experienced during injection of the analgesic present a special problem. In the earlier part of the investigation general anaesthesia had to be resorted to for two simple low forceps deliveries on this account, and following this we tested the effect of an intravenous injection of a mixture of pethidine hydrochloride, 100 mg., and chlorpromazine ("largactil"), 12.5 mg., diluted with 10 ml. of normal saline solution. The purpose of the small quantity of chlorpromazine is to counteract the emetic effect which the rapid injection of pethidine usually produces, but it also potentiates the sedative action. This combination of drugs proved so effective that nervousness and lack

of maternal co-operation ceased to be regarded as contra-indications to local analgesia. In fact, it is probable that a considerable number of forceps operations could be performed under this injection alone.

The question obviously arises as to the effect of these drugs on the foetus. Judging from the small number of cases in which we used them, they do not have a significant respiratory depressant effect. In reaching this conclusion we assessed the results against those obtained when local analgesia was used alone, and when general anaesthesia was used for a comparable series of forceps operations in 1951. (See Graph 1.)

Legend:
 [Hatched bar] Cried or established regular respiration within 1 minute
 [White bar] Apnoea for 1-5 minutes (asphyxia livida)
 [Dotted bar] Apnoea for over 5 minutes (asphyxia pallida)

GRAPH 1.—Incidence of apnoea neonatorum. The last group is of comparable cases of forceps delivery conducted under general anaesthesia in the same practice during 1951.

Contraindications to Local Analgesia

Although the use of local analgesia was widely extended, there remained a small group of cases (amounting to only 6% in our series) where general anaesthesia seemed necessary or advisable. The factors calling for general anaesthesia were as follows.

1. **Unsatisfactory Local Analgesia** (3 cases).—In two of these cases, occurring early in our series, lack of maternal co-operation prevented injection of the local analgesic. In the light of our subsequent experience with supplementary pethidine and chlorpromazine injection it seems likely that general anaesthesia could have been avoided in these cases.

2. **"Dangerous Uterine Contractions"** (3 cases).—In these cases strong uterine contractions were hazardous to mother or baby. Two were cases of deep transverse arrest in patients with previous caesarean section scars, while the third was a case of prolapsed cord.

3. **"Complicated Forceps"** (7 cases).—This group included mento-lateral and posterior face presentations (2 cases), forceps application before full dilatation of the cervix (4 cases), and gross foetal abdominal distension (1 case).

4. **Eclampsia** (1 case).

5. **"Trial of Forceps"** (11 cases).—The indications for this procedure were second-stage arrest in the pelvic cavity with (a) the biparietal diameter not completely down to the ischial spines; (b) so little room at the level of the arrest that application of the forceps blades seemed likely to be extremely difficult; or (c) evidence of marked outlet contraction. Of the 11 cases in this category, four came to caesarean section. No foetal loss occurred, and the only foetal morbidity was a fractured clavicle in a case where shoulder dystocia was encountered.

Management of General Anaesthesia Cases

Our policy was to conduct in the operating theatre these few cases requiring general anaesthesia. Parker advocated this and stressed its anaesthetic benefits. The electric suction apparatus and all the other equipment of the anaesthetist are always readily available, while the fact that the patient is on an operating-table facilitates laryngeal intubation and ensures that the Trendelenburg position can be easily obtained. In our experience it also presents certain advantages to the obstetrician. The ability to proceed immediately to caesarean section is essential in the "trial of forceps" cases,

and also in cases of face and brow presentation in which the best results can be obtained only if attempts at vaginal delivery can be abandoned when the difficulties prove greater than anticipated (Morris, 1953).

FIG. B.—Operator seated on 6-in. (15-cm.) stool and with operating-table slightly elevated, allowing traction in true axis of pelvis.

Local Analgesia, Kielland's Forceps and the Foetus

The principal aim of our policy was to combat the maternal anaesthetic hazard, but in its actual operation it appeared to be beneficial to the foetus as well. Graph 2 gives the corrected results for all forceps deliveries during the 12 months' operation of the policy, compared with those of the previous five years, similarly corrected. Graph 3 shows the foetal mortality of the forceps series compared with that for spontaneous cephalic delivery in the same year, 1955-6, similarly corrected. The striking thing is that four foetal deaths attributable to cerebral trauma occurred in the spontaneous group, while there were no such deaths in the forceps group. The use of local analgesia was probably the most important factor in achieving these improved foetal results. A parallel might be drawn between the increased safety of delivery with forceps, particularly Kiel-

YEAR	FORCEPS INCIDENCE	FOETAL MORTALITY (CORRECTED) PER 1,000 FORCEPS BIRTHS
1950-4	8.4%	11
1955-6	11.5%	22

□ = DEATHS DUE TO CEREBRAL TRAUMA
■ = DEATHS DUE TO ASPHYXIA, ETC.

GRAPH 2.—Comparison of forceps delivery incidences and foetal results in 1950-4 and present series. Figures for foetal mortality are corrected in each case for: macerated foetuses; babies weighing under 4 lb. (1.814 kg.); gross foetal abnormalities; severe erythroblastosis foetalis; and foetal deaths in labour before delivery was embarked upon.

GRAPH 3.—Comparison of foetal mortality for forceps and spontaneous deliveries in cephalic presentations. The same correcting factors applied as in Graph 2.

land's, under local analgesia, and the safety of external version without anaesthesia compared with version performed under a general anaesthetic. The other possible factor was the replacement of manual rotation by Kielland's forceps rotation (see Graph 4). Assessment of this would clearly involve a complex discussion of the merits of the manual method versus the forceps method of rotating the head. Brief mention will be made, however, of several aspects of the controversy on which we have new evidence to offer.

GRAPH 4.—Foetal loss in relation to forceps technique in cases of malposition of occiput. The same correcting factors applied as in Graphs 2 and 3.

First, the traction force with Kielland's forceps is applied directly to the base of the skull and there is a negligible amount of biparietal pressure. That this is so is clearly seen in Fig. 4 of the Special Plate. In this case the head was so extended in the pelvic cavity that the brow was presenting. Kielland's forceps were applied (Fig. 4a) and simple downward traction exerted. When this reached 60 lb. (27.22 kg.), flexion of the head to a vertex occurred (Fig. 4b) followed by easy delivery. The site of the forceps force was marked by bruising of the pinnae, which lay on the mastoid regions. This finding has been confirmed in another similar case, and it is clear that such movement could not occur if there was any appreciable biparietal pressure. This freedom of movement of the foetal head within the blades, which is not widely recognized, may also account, in part at least, for the diminished traction force said to be needed with Kielland's forceps as compared with the orthodox axis-traction instrument. Kielland (1916) was so convinced of this that he stated categorically that measurement of it was unnecessary!

However, to try to obtain accurate measurements of the force employed, a pair of Kielland's forceps were adapted so that a dynamometer fitted into two slotted pins on the distal shoulders. The lower bar of the dynamometer is elliptical, and can be attached by opening and then closing the handles slightly after the blades have been applied and any asynclitism corrected (Fig. C). Graph 5 shows the results obtained in 55 cases. The range of the traction forces was 15-75 lb. (6.8-34 kg.)—the majority of the readings being between 35-50 lb. (15.9-22.7 kg.). Baxter (1946), who measured the traction force with axis-traction forceps, gives 70 lb. (31.8 kg.) as the critical force beyond which cerebral damage is likely to be sustained, but he does not report a large series. In the "trial of forceps" cases in our series, not more than moderate traction (35-50 lb. or 15.9-22.7 kg.) was employed.

Another factor affording a mechanical advantage with Kielland's forceps is the lack of upward displacement of the head during rotation, which is well shown in Fig. 2 of the Special Plate. In this case it can be seen that once the occiput has been rotated to the anterior position the head is practically delivering itself. This is a common clinical experience.

Summary

It has been found possible to extend the scope of local analgesia to 94% of all forceps deliveries. This has been achieved by the routine use of Kielland's forceps for rotation of the head, and the supplementary injection of a mixture of pethidine and chlorpromazine in certain cases. In addition to the great reduction in the maternal anaesthetic hazard, this policy has produced an improvement in foetal results. The possible factors concerned in this are discussed. It seems likely that the most important fact is that the great majority of the

operations were performed under local analgesia. This, incidentally, leads to gentleness and accurateness while precluding the use of excessive force.

We are grateful to Mr. C. H. Walsh and Professor T. N. A. Jeffcoate for the opportunity to perform this work and also for their encouragement and advice; and to Professor Jeffcoate we are further indebted for constructive criticism and help in the preparation of this paper. Our thanks are also due to Mr. W. Jennings and his colleagues for the radiographic work, and to Messrs. Kidd, Greenough, and Lee for the photographs and tables. Mr. Price, of Alexander and Fowler, Liverpool, constructed the dynamometer attachment on the Kielland's forceps.

DIFFERENTIAL DIAGNOSIS OF ANKYLOSING SPONDYLITIS

BY

JAMES SHARP, M.D., B.Sc., M.R.C.P.

Assistant Clinical Director, University of Manchester
Rheumatism Research Centre, Manchester Royal
Infirmary

[WITH SPECIAL PLATE]

The last 25 years have seen two notable advances in the management of ankylosing spondylitis—namely, the use of deep x-ray therapy, and recognition of the importance of active movement in preventing loss of motion in the spine and limbs. Both the beneficial effects of x rays (Smyth, Freyberg, and Lampe, 1941; Hilton, 1943; McWhirter, 1945; Hart *et al.*, 1949) and the extensive loss of mobility which commonly results from prolonged immobilization (Swaim, 1939) appear to be relatively specific features of ankylosing spondylitis (Smyth, Freyberg, and Peck, 1941; Desmarais, 1953; Sharp and Easson, 1954). Serious complications of x-ray treatment of spondylitis are rare, but the possibilities of aplastic anaemia (Goodman, 1956; Sharp and Easson, 1954) and perhaps leukaemia (Brown and Abbott, 1955) resulting from such treatment make it very desirable that patients who are unlikely to benefit should not be treated with x rays. From the practical point of view it is therefore important, before advising treatment, to establish the diagnosis as certainly as possible in a patient in whom ankylosing spondylitis is suspected.

"Atypical" Spondylitis

The excellent accounts of Polley and Slocumb (1947), Mowbray *et al.* (1949), and particularly Hart *et al.* (1949) and Hart (1955), render a further detailed description of the clinical and radiographic features of classical ankylosing spondylitis superfluous; the emphasis placed by these authors on the significance of such symptoms as recurrent "lumbago," "sciatica," or "fibrositis," particularly when they occur in young men, are aggravated by immobility, or are associated with diminished chest expansion or iritis, and on the importance in diagnosis of radiographic changes in the sacro-iliac joints (Special Plate, Fig. 1a), has led to more frequent diagnosis at a stage where treatment is likely to be effective.

In a study of 530 patients attending a special clinic for investigation and treatment of spondylitis it was found that

FIG. C.—Views of Kielland's forceps showing dynamometer fitted to pins on posterior aspect of distal shoulders.

GRAPH 5.—Traction force as measured by dynamometer in 55 deliveries with Kielland's forceps.

the majority conformed to the classical picture of ankylosing spondylitis, but that about one in five presented unusual clinical or radiographic features; these patients were labelled "atypical" spondylitis, although most of them had bilateral radiological changes in the sacro-iliac joints. Analysis of the results of x-ray treatment in these patients (Sharp and Easson, 1954) showed that those with straightforward ankylosing spondylitis were mostly much improved, while the majority of the "atypical" cases were unimproved. This suggested that "atypical" spondylitis might in part be due to other spinal conditions simulating ankylosing spondylitis but unresponsive to x rays. Some of the "atypical" spondylitis had features suggesting rheumatoid arthritis, such as involvement of the hands and feet and of tendons, and gave positive reactions to the differential sheep-cell agglutination test (D.A.T.) (Ball, 1950); others had valvular heart lesions, and from their histories it appeared that the spinal changes had followed recurrent attacks of rheumatic fever. In some patients the spinal changes were associated with psoriasis, and they also usually had involvement of the hands and feet but negative D.A.T. results; and in still others the onset of the illness seemed to be clearly related to an attack of urethritis or of dysentery, so that the possibility of Reiter's disease came into the picture.

We therefore investigated other patients who had attended the centre with rheumatoid arthritis, rheumatic fever, psoriasis and arthritis, or Reiter's disease with the object of assessing the extent and nature of the spinal involvement in these conditions and the features which might help to distinguish these forms of spondylitis from typical ankylosing spondylitis.

Rheumatoid Arthritis

The frequency and the pattern of spinal involvement in rheumatoid arthritis were obtained from a study of a random selection of 100 patients who attended the centre with rheumatoid arthritis over a two-year period; the proportion of males to females proved to be almost exactly one to two. Other adult patients selected because of marked spinal disease and the 36 who had attended with juvenile rheumatoid arthritis—that is, starting at or below the age of 15—since the centre was established were also studied.

Involvement of the spine was rarely a prominent feature of the disease picture, but evidence of spinal involvement in the rheumatoid process was found in exactly half of the randomly selected patients and was slightly commoner in males. In contrast to ankylosing spondylitis, the cervical region was much the commonest site affected, being involved in four-fifths of those with spinal involvement, whereas the dorsal and lumbar regions were involved in less than one-third. In over half the patients with spinal involvement the cervical region only was affected; involvement of the cervical region alone was never observed in ankylosing spondylitis.

Painful limitation of neck movement was the commonest symptom, and the main pain was often referred over the "shoulders" but rarely down the outer border of the upper arm, where the pain from subdeltoid bursitis, which was also commonly present in these patients, was referred on movement of the shoulder, particularly through the "painful arc" in abduction. Pain from the lower spine was usually less severe than that from the cervical region.

Severe deformity of the spine was unusual, but often there was decrease in lumbar lordosis and increase in dorsal kyphosis, as illustrated in the accompanying photograph of a woman of 46 with severe rheumatoid arthritis of 13 years' duration. This patient was chosen as an example as she also had subcutaneous nodules over several lower dorsal and lumbar spinous processes, the elbows, and occipital region, such nodules over spinous processes being a source of considerable discomfort in several bed-fast patients.

Although in exceptional cases the spine had been rendered completely rigid, there was usually only moderate restriction of movement of an affected region of the spine; the chest expansion was rarely reduced. In some of the most severe,

although often relatively painless, forms of cervical-spine involvement, abnormal mobility and cervical kyphosis had developed but neurological complications were uncommon.

Radiographic Changes.—Abnormalities of the sacro-iliac joints occurred not uncommonly in patients with severe and extensive rheumatoid disease. Occasionally the joints were fused, but in the earlier stages erosions of the joint surfaces were usually smaller than in ankylosing spondylitis and the fluffy juxta-articular bone sclerosis was absent (Special Plate, Fig. 1b). Moreover, extensive spinal involvement often occurred in patients whose sacro-iliac joints appeared normal.

Radiographic changes in the spine were often absent in patients with clinical spinal involvement, and when present were most easily demonstrable in the cervical region (Plate, Figs. 2b and 3b). They were characterized by narrowing of the intervertebral disks, often with relatively little osteophytosis of the vertebral bodies, and by erosion, narrowing, and sometimes ankylosis of the apophyseal joints. The vertebral plates adjacent to the narrowed disks often appeared irregular, and occasionally faint ossification was visible within the disk spaces; subluxation of vertebrae, usually forward, was not uncommon in severe cases.

In children the spine was rather more frequently involved than in adults, particularly in the dorsal and lumbar regions. The process appeared to be similar to that in adults, apart from a greater tendency to bony ankylosis of apophyseal joints and to complete disappearance of the margins of the disks and fusion of the rims of adjacent vertebral bodies. Arrest or slowing of vertebral growth was common when the disease had started in early childhood (Plate, Fig. 2c).

Rheumatoid arthritis of the spine was therefore distinguished from ankylosing spondylitis by the predominant involvement of the cervical region and retention of normal chest expansion; by frequent involvement of the sacro-iliac joints, without radiographic abnormalities of those joints, which in any case rarely resembled those in ankylosing spondylitis; by a strong tendency to narrowing of multiple disk spaces and not infrequent cervical subluxation; and by the absence, even in advanced cases, of the "bambooning" and of "squaring" of vertebral bodies (Rolleston, 1947) commonly seen in ankylosing spondylitis (Plate, Figs. 2a and 3a).

Treatment.—The wearing of a padded cardboard collar for some weeks or months was usually most effective in relieving symptoms from the cervical spine. In patients with unstable cervical subluxation more effective support was supplied by means of a plastic or leather collar, and even in some of these it was found that the support could be discarded after some months without recurrence of symptoms; surgical spinal fusion was rarely required. Symptoms from the lower spine usually responded well to bed rest and analgesics of the aspirin type.

Rheumatic Fever

It has been known for many years that permanent joint changes may result from rheumatic fever (Jaccoud, 1867;

Female aged 46 with severe rheumatoid arthritis involving the spine, showing spinal deformity and subcutaneous nodules over several spinous processes and other bony prominences.

Bywaters, 1950), but Thomas (1955) was the first to call attention to the frequency of spinal involvement in this form of arthritis.

The condition is rare, and only ten males and nine females suffering from this form of arthritis have been seen at the centre in a period during which over 2,000 patients have attended with rheumatoid arthritis; 5 of the 19 had been referred to the spondylitis clinic. Ten of these patients were reported previously by Thomas (1955). All the patients were adults with valvular heart lesions, and they gave a characteristic history of repeated attacks of severe and prolonged rheumatic fever, usually following throat infections and starting in childhood and continuing into adult life. Almost all of them had developed ligamentous laxity, abnormal mobility, and sometimes effusions in the limb joints, notably the hands, where ulnar deviation of the fingers was common; the deformity was usually correctible, but in very advanced stages was permanent. One-third of the patients had nodules on tendons, sometimes of considerable size.

The spine had been involved in one or more rheumatic attacks in almost all the patients, but, in contrast to the findings in the limbs, two-thirds of them had residual limitation of spinal movement, particularly of the lower spine; occasionally the whole spine was rigid. None of them had severe spinal deformity and the chest expansion was usually normal. In one man the residual changes were confined to the sacro-iliac joints and spine, and in another to the sacro-iliac joints only.

The D.A.T. was negative in the 16 patients tested and there was an almost complete absence of bony erosions on radiographs of the limb joints—a further point of difference from rheumatoid arthritis. The sacro-iliac joints were radiographically abnormal in over half the patients, and occasionally the appearances were indistinguishable from those of ankylosing spondylitis (Plate, Fig. 1c), but the advanced spinal changes were distinctive (Plate, Figs. 2d and 3c). These comprised antero-posterior narrowing of some vertebral bodies, narrowing of multiple disks without vertebral osteophytosis, bony ankylosis of apophyseal joints, and, when the disease had started in childhood, hypoplasia of the vertebrae.

Differentiation of this condition from ankylosing spondylitis with coincident rheumatic heart disease rested, first, on the characteristic history, particularly the precipitation of the attacks of rheumatic fever by throat infections; secondly, on the presence in the greater number of them of the peripheral joint changes and in some cases large tendon nodules, the latter being very rare in our patients with ankylosing spondylitis; and, finally, on the characteristic radiographic changes in the spine in advanced cases.

Treatment.—Almost all of these patients derived great symptomatic relief from calcium aspirin in a dosage of 60 gr. (4 g.) or so daily; three of them received x-ray therapy, but since none was much improved we no longer prescribe x-ray therapy for these patients. In their long-term management, prevention or prompt treatment of streptococcal infections would appear to be indicated with the object of preventing recurrences of rheumatic activity, and progression of the heart lesions which form an important part of their disability.

Reiter's Disease

The main features of this syndrome, which is of unknown but probably infective aetiology, are non-specific urethritis, arthritis, and inflammatory eye lesions, most commonly conjunctivitis but sometimes iritis (Paronen, 1948; Zewi, 1947). In this country the infection is usually of venereal origin (Harkness, 1950), but a probably identical condition may follow dysentery (Reiter, 1916; Fiessinger and Leroy, 1916; Paronen, 1948). Other less constant features of the syndrome are skin rashes, of which the most characteristic is keratoderma blennorrhagica, although this may be indistinguishable from pustular psoriasis (Auckland, 1951). Stomatitis, cystitis, and haematuria (Piora, 1953) are occasional features.

The three main features of the disease had all been present during the illness of the 20 patients, all males, in whom this diagnosis had been made at the centre; three-quarters had started with a urethral discharge. In 14 of the cases three, and in the remainder two, of the main features had occurred simultaneously, usually at the onset, and keratoderma blennorrhagica had also been present in two. Relapses of the eye inflammation and arthritis were common, sometimes after remissions of up to ten years' duration; the urethritis recurred less frequently.

The arthritis involved the joints of the feet or ankles in all the patients, and almost half of them had tender heels, but the hands were involved in only one-third. Occasionally the feet showed a rather characteristic deformity with dorsal dislocation and outward deviation of the extended toes, first described in this condition by Launois (1899). The knees were involved in three-quarters and the spine was affected almost as frequently, particularly the lumbar region, which was involved in half the patients. One-fifth of the patients had developed gross restriction of spinal movement, particularly in the dorsal and lumbar regions, with little deformity but usually with reduced chest expansion.

In patients with advanced spinal changes both the clinical picture and the x-ray appearances of the spine were often difficult or impossible to distinguish from those of advanced ankylosing spondylitis. The sacro-iliac joints were radiographically abnormal in almost half of all the patients, and were always abnormal, and sometimes fused, when there were extensive spinal changes (Plate, Fig. 1d). There was a striking tendency to proliferation of new bone at any affected site. In the pelvis and spine this was evident in the form of bony proliferation around the acetabula and femoral heads, much new bone formation on the margins of the pelvis, and heavy bony bridging of the intervertebral spaces, usually through ossification of spinal ligaments, but sometimes also of the disk margins (Plate, Figs. 2e and 3d).

The diagnosis of Reiter's disease is suggested by the characteristic history, the involvement of the feet—which are involved in less than one-fifth of our patients with ankylosing spondylitis—and the radiographic evidence of much ligamentous ossification.

Treatment.—The acute phase of the arthritis subsided in most cases following bed rest, analgesic and in some cases artificial fever therapy, and plaster splintage when indicated. The duration of the acute attacks varied from a few weeks to many months, and residual anatomical changes were the rule in severe or relapsing cases. In one case in which both wrists and two others in which both feet were involved with about equal severity x-ray therapy was given to one side and, unknown to the patient, "mock" therapy to the other side. In each case both the treated and "mock" treated lesions were improved at the completion of the course, and there was no evidence of any greater improvement on the treated side.

Psoriasis and Arthritis

The incidence of psoriasis in patients with polyarthritis is said to be unduly high (Dawson and Tyson, 1938; Bauer *et al.*, 1941). Most authorities maintain that the arthritis is rheumatoid arthritis, perhaps modified in some cases by the presence of psoriasis; but others, such as Sherman (1952), consider that it is a distinct entity.

Evidence of psoriasis was found in 34 males and 32 females referred to the centre with a polyarthritis; 11 of them had been referred to the spondylitis clinic. In 58 cases the rash was present at the time of examination, in 29 the nails being involved; six gave a history of psoriasis which had cleared up apart from persistent nail changes in two; and in the remaining two the psoriasis was confined to the nails.

The hands or feet, usually both, were almost invariably involved in the arthritis, and in over one-third of the cases the distal interphalangeal joints of the fingers were affected. The proximal limb joints were also involved in two-thirds of the patients. Only four, however, had subcutaneous nodules, and 12 others involvement of tendons. The D.A.T.

was positive in only 11 (28%) of the 39 patients tested, whereas in the random series of 100 rheumatoid patients mentioned earlier, subcutaneous nodules were present in 23 and tendon lesions in 56, and 24 (73%) of the 33 patients tested gave positive D.A.T. results. These findings suggested that the majority were not suffering from straightforward rheumatoid arthritis.

Painful limitation of spinal movement was present in three-quarters of the patients; the three spinal regions were involved with equal frequency, and in over one-third the whole spine was affected and was virtually rigid in four, only one of whom had been referred to the spondylitis clinic.

Radiographically, the sacro-iliac joints were often normal in patients with clinical spinal involvement. Except that cervical subluxation was not observed, the changes in the spine combined the other features observed in rheumatoid arthritis with a strong tendency to ossification of spinal ligaments. In the limb joints and particularly in the feet, the arthritis was often of a very destructive type, but a tendency to proliferation of new bone, less striking than in Reiter's disease, was also evident.

Ankylosing spondylitis merited serious consideration in the diagnosis of very few of these patients. Extensive spinal involvement was almost invariably associated with florid and widespread arthritis in the limbs and atypical radiographic changes in the sacro-iliac joints and spine. The differentiation from Reiter's disease was sometimes more difficult, and only made in some cases through the absence of the ocular and genito-urinary features.

Treatment.—The best results appeared to have been obtained from management along the same lines as for rheumatoid arthritis. Only 2 of the 11 patients treated by x rays appeared to derive worthwhile benefit; one patient died from aplastic anaemia five years after treatment.

Review of the "Atypical Spondylitis" Group

On reviewing the atypical group seen in the spondylitis clinic in the light of these findings it was found that approximately half of the atypical cases could be fitted into these categories. A few had radiographic appearances in the spine of "senile ankylosing hyperostosis" (Forestier and Rotes-Querol, 1950) (Plate, Fig. 3e) associated with bony enlargement of multiple limb joints. There were two members of a family, who have been described elsewhere (Sharp, 1954), who suffered from a heredo-familial form of spondylitis associated with extensive calcinosis of joint structures and blood vessels in the limbs. In some of the remainder the spinal changes appeared to be due to osteoarthritis or degenerative disease, and there were a few patients probably suffering from ankylosing spondylitis in whom the picture was complicated by such conditions as metabolic or Paget's disease of bone. In addition there was a small number of cases in which the diagnosis still remained obscure.

Discussion

The findings in this study suggest that bilateral sacro-iliac joint changes as seen radiographically cannot be accepted as certain evidence of ankylosing spondylitis or as a definite indication that deep x-ray therapy is likely to be beneficial. If a patient has symptoms and signs suggesting ankylosing spondylitis, the possibility of other diseases of the spine should be borne in mind, and the following features should be specially looked for: (1) evidence of rheumatoid arthritis, such as predominant involvement of the cervical region, widespread polyarthritis affecting particularly the distal joints of the limbs, subcutaneous and large tendon nodules, or a positive result in the differential sheep-cell agglutination test; (2) evidence of rheumatic fever, such as a valvular heart lesion and a history of recurrent acute rheumatism; (3) evidence of Reiter's disease, such as a history of urethritis or dysentery, conjunctivitis, or keratoderma; and (4) evidence of psoriasis. If any of these features are present the patient is probably not suffering from ankylosing spondylitis and is unlikely to derive much

benefit from deep x-ray therapy. Furthermore, bed rest and immobilization may be indicated instead of the active mobilization which is so necessary in the management of typical ankylosing spondylitis.

Summary

In approximately one-fifth of the patients attending a special spondylitis clinic the clinical picture differed in various ways from that of classical ankylosing spondylitis, although most of them had bilateral radiographic changes in the sacro-iliac joints. Some of them had psoriasis, and others had features suggesting rheumatoid arthritis, recurrent rheumatic fever, or Reiter's disease with spinal involvement.

A study of these conditions in other patients revealed certain features by which they can usually be distinguished from ankylosing spondylitis.

On review, many of the atypical cases from the spondylitis clinic appeared to fit into the above categories, suggesting that bilateral sacro-iliac joint changes cannot be accepted as certain evidence of ankylosing spondylitis. Some others had radiographic changes of "senile ankylosing hyperostosis," and two had a heredo-familial form of spondylitis associated with calcinosis of limb joints and blood vessels. A few cases remain undiagnosed.

The differential diagnosis of ankylosing spondylitis appears important, since patients with these other forms of spondylitis do not usually appear to benefit from deep x-ray therapy, and they may be helped by bed rest and immobilization rather than by encouragement of active movement as in the management of ankylosing spondylitis.

I am indebted to Professor J. H. Kellgren for much advice and assistance; to Dr. J. Ball, who performed the sheep-cell differential agglutination tests; and to Dr. Robert Ollerenshaw and his staff for the illustrations. I am grateful to Dr. A. E. Thomas and the editor of the *Annals of the Rheumatic Diseases* for permission to reproduce Figs. 2d and 3c (Special Plate).

The spondylitis clinic is conducted in collaboration with the Christie Hospital and Holt Radium Institute, and Dr. Ralston Paterson provided facilities for, and Dr. E. C. Easson supervised, the x-ray treatment of these patients.

THYROID DISORDERS IN THE NEWBORN

BY

IAN D. RILEY, M.D., M.R.C.P., D.C.H.

Paediatrician

AND

G. SCLARE, M.B., Ch.B.

Formerly Registrar in Pathology

Stobhill General Hospital, Glasgow

[WITH SPECIAL PLATE]

Disturbances of thyroid function in the newborn have been recorded at three periods in the history of thyroid disorder. The first cases were described before the discovery of the value of iodine prophylaxis in endemic areas, the second after its employment, and the third following the introduction of thiouracil. Three cases of this third type are described in the present paper.

Case 1

Male born normally at term on June 27, 1955. The mother, aged 28, was a primigravida and had had thyroidectomy for thyrotoxicosis in 1946. She was treated with 200 mg. of thiouracil daily for a recurrence in the same year. On January 5, 1955, she was not fully controlled on 100 mg. daily, and was admitted from March 31 to April 10 for stabilization. She was receiving 100 mg. daily at the time of her admission on June 9, and this was continued up to term.

The infant weighed 5 lb. 1 oz. (2.296 kg.) at birth. Nothing abnormal was detected, there being no goitre. On the eighth day, when there was very slight thyroid enlargement, he was noticed to be sweating profusely and to have developed a sweat rash. He was irritable, his conjunctivae were suffused, and there was no increase in weight for the first 13 days. He was pale and his skin was hot to the touch, but his appetite was good. The irritability increased and the temperature showed an intermittent fluctuation between 97° and 100° F. (36.1° and 37.8° C.). Lugol's iodine, 5 minims (0.06 ml.) twice a day, was given with phenobarbitone, $\frac{1}{4}$ gr. (8 mg.) twice daily, and the weight then rose steadily. He was sent home on the twenty-sixth day weighing 6 lb. 3 oz. (2.807 kg.).

Case 2

Male born six weeks prematurely on December 16, 1954. The mother, aged 34, a primigravida, had been treated for thyrotoxicosis with methyl thiouracil, 100 mg. daily, and laevothyroxine, 0.1 mg. daily. Seven days before delivery, in spite of a tachycardia of 90 per minute, it was decided not to increase the thiouracil for fear of the effect on the foetus.

The infant weighed 4 lb. 4 oz. (1.927 kg.), and was cold and cyanosed with visible enlargement of the thyroid (Special Plate, Fig. 1). Next day the blood urea was 30 mg. and the blood cholesterol 104 mg. per 100 ml. By December 24 there was a tachycardia and the skin was moist and clammy. The baby was tremulous and hyperactive and had an irregular fever, mainly from 97° to 99° F. (36.1°–37.2° C.), but reaching 102° F. (38.9° C.) on one occasion. Cyanotic attacks developed with diminished air entry in the right lung, thought to be due to aspirated feeds. A week later, although no weight had been gained, he was no longer hyperactive and the thyroid was a little smaller, but he regained the hyperactivity and became very thin. The blood cholesterol on January 8, 1955, was 124 mg. per 100 ml. Lugol's iodine, 5 minims (0.3 ml.) three times a day, was

started on January 21, but death occurred next day, when the infant's weight was 4 lb. 1½ oz. (1.856 kg.).

Necropsy showed the thyroid to be uniformly enlarged and to weigh 10 g. (see photograph). The gland was firm and its cut surface of fleshy appearance.

Histology.—Although the interval between death and necropsy was 60 hours, autolytic changes were inconspicuous. The thyroid follicles varied little in appearance from one part of the gland to another. They were small, of irregular outline, and had a scanty colloid content which, in a very few instances, showed a solitary central vacuole. The lining cells were uniformly cuboidal, but there was marked variation in the size of their nuclei (Special Plate, Fig. 2). The stroma was unusually prominent (Special Plate, Fig. 3).

The uniformly enlarged thyroid found at necropsy in Case 2, compared with a normal gland.

Case 3

Male born normally at term on June 26, 1944. The mother, aged 29, a primigravida, developed thyrotoxicosis during pregnancy and was treated with 200 mg. of thiouracil five times a day from April 27, 1944, reduced to three times daily on May 25 and to twice a day on May 30. For three weeks before delivery thiouracil was discontinued.

The infant weighed 6 lb. 1½ oz. (2.764 kg.) at birth. There was visible enlargement of the right lobe of the thyroid at this time, and it was remarked that the baby was "hypothyroid" in appearance. Tube feeding was employed, but frequent vomiting occurred, and on July 3 loose stools began to be passed. Death ensued on July 9.

Necropsy showed the body to be emaciated, with loss of nearly all subcutaneous and body fat. Histologically the thyroid was devoid of colloid, and the follicles were partially or totally occupied by desquamated epithelial cells. Nuclear variation of the type seen in Case 2 was not present.

Discussion

Endemic goitre in the newborn was first described by Fodere in 1796, and since that time many cases have been reported. In 1935 the condition was present in 50% of all newborn babies in Switzerland and accounted for 10% of the neonatal mortality in Freiburg im Breisgau (Aschoff, cited by Parmelee *et al.*, 1940). It is probable that both heredity and iodine deficiency are factors in the production of the condition, as it has become less common since prophylaxis with iodine came into use. Sporadic cases have also been reported with some frequency, and the clinical picture is similar. The mother usually, but not always, has a simple goitre, and the infant, as a rule, a nodular goitre. This may be so large as to cause death from respiratory obstruction (Peterson, 1911; Williamson, 1933; Mitchell and Struthers, 1933; Davies, 1943; Kunstadter, 1948; Seligman and Pescovitz, 1950; Schiffrin and Hurwitt, 1951; Jones, 1951).

Thyrotoxicosis in the newborn was first described by White (1912); he had suspected the condition to be present before birth in the foetus of a thyrotoxic mother. Such cases are rare (Margetts, 1950). Goitre in the offspring of mothers who have received iodine either for goitre (Vérel, 1949; Skinner, 1924) or for some other condition (Parmelee *et al.*, 1940) has been reported. These goitres were transitory and diffuse rather than nodular.

Since the introduction of thiouracil it has been found that mothers treated with this drug may give birth to babies with goitres (Hubble, 1956). The babies may be otherwise normal or show signs of either myxoedema or hyperthyroidism. The condition usually subsides in a few weeks without treatment, but subsequent myxoedema has been reported (Elphinstone, 1953; Morris, 1953) and death has been known to ensue (Keynes, 1952). Such a goitre has been found in a six-months foetus at necropsy (Davis and Forbes, 1945), and it has also been seen in twins (Saye *et al.*, 1952). The goitre is usually diffuse, and on section hyperplasia with absence of colloid is seen. It is noteworthy that the histological appearances in our Case 2 are comparable in many ways with those seen in adult thyrotoxicosis, whereas many previous reports described hyperplasia of a type that commonly occurs in the normal newborn infant (Sclaire, 1956). A raised level of protein-bound iodine was found by Bongiovanni *et al.* (1956). There does not appear to be any relation between the type of lesion in the mother and that in the child. Normal or goitrous mothers may give birth to normal or goitrous infants, and signs of toxicity may be present or absent in either (Eaton, 1945; Fischer, 1951; Salm, 1954; Koerner, 1954; Scarizza, 1954).

Investigations related to the problem include the discovery that the serum iodine level rises during pregnancy (Man *et al.*, 1951; Cooke and Man, 1956) and that the foetal thyroid has a greater affinity for iodine than that of the adult. It has also been shown that maternal thyrotropic hormone cannot pass the placenta (Nikitovitch and Knobil, 1955), but that thyroid hormone and thiouracil can do so (Freiesleben and Kjerulf-Jensen, 1947; Frisk and Josefsson, 1947). From these facts it would appear that thiouracil acts by depressing foetal thyroxine formation, thus inducing production of foetal thyrotropic hormone which in a few days leads to thyrotoxicosis. It is, however, probable that a hereditary factor also operates, and this might explain instances of identical disorders in mother and child.

The most important clinical question is to what extent the mother's thyrotoxicosis may be controlled without producing damage to the foetal thyroid. This is probably best answered by maintaining the protein-bound iodine above the normal level, and by substituting iodine for the thiouracil some weeks before delivery (Keynes, 1952); but the evidence for the value of this manoeuvre is not conclusive, as the third case of the present series would suggest. Certainly if the condition of the mother demands thiouracil, the drug should not be discontinued.

Two of the three cases described here ended fatally, which suggests that the danger to the infant is substantial. Despite its failure in Case 2, iodine is probably the best drug to administer to the infant. Studies of the radioactive iodine uptake would help to elucidate the condition, but the danger at such an age renders the method inadvisable.

Summary

Three cases of goitre in the newborn are reported. In all three cases the mother had during pregnancy received treatment with thiouracil for thyrotoxicosis. Two of the infants died. The post-mortem appearances are described and illustrated.

The aetiology is discussed, and the question of treatment is reviewed in the light of cases described previously.

ADDISON'S DISEASE IN A NINE-YEAR-OLD GIRL

BY

R. G. WELCH, M.D., M.R.C.P.

Senior Registrar to the Children's Department, St. Thomas's Hospital

[WITH SPECIAL PLATE]

The purpose of this paper is to record a further example of Addison's disease in a child—a very rare occurrence—and to draw attention yet again to the great change in the nature of the usual underlying pathological process that has taken place in the past ten years, coincident with, and probably resulting from, the high degree of control of tuberculosis now achieved.

Report of Case

The patient was a girl aged 9½ years, the second of four children, the parents and the other children all being healthy. A few weeks after a mild attack of mumps she gradually became listless, felt weak, and lost her appetite. There were frontal headaches, especially on waking, and occasional epigastric pains. Giddiness on standing, stiffness and aching of the limbs, vomiting, and occasional double vision followed in a month or so with loss of weight. After four months, too weak even to get out of bed, she was admitted to hospital. She was ill, pale, and thin, but the only other findings were a slight evening pyrexia and a rapid sleeping pulse rate (about 110 per minute). B.P. 100/60 mm. Hg; E.S.R. 7 mm. in one hour; Hb 102%; W.B.C. 8,900 per c.mm. (lymphocytes 65%, monocytes 2.5%, neutrophil polymorphs 25%, and eosinophil polymorphs 6.5%). Mantoux 1:1,000 negative. Chest radiograph clear (a small heart shadow). Cerebrospinal fluid normal except for a chloride value of 670 mg. per 100 ml.

An intracranial tumour was considered and the patient was transferred to St. Thomas's Hospital. At this time a general increase in pigmentation was noticed, including a pigmented spot on the lip. She was very miserable, and lay curled up in her bed, moaning quietly. She drank fluids, but refused nearly all solids (in retrospect, the only foods she enjoyed throughout her illness were salty), and vomited daily. B.P. 105/80 mm. Hg. The electroencephalograph (E.E.G.) was abnormal; there were theta waves at 7 c.p.s. and fast activity at 20 c.p.s., seen in leads from all areas, but the record was dominated by asymmetrical irregular high-voltage (150–200 μ V) slow waves at 2–3 c.p.s., of greatest amplitude in leads from the left cerebral hemisphere, and of lower frequency posteriorly. The E.S.R. was now 32 mm. in one hour.

The pigmentation increased rapidly over the next few days, and Addison's disease was considered. The day before

she died her blood pressure was 100/70 mm. Hg. Three hours after this was taken she collapsed and became pulseless. The plasma electrolyte values (in mEq per litre) were: sodium 119, potassium 5, chloride 94, and bicarbonate 24; blood sugar 80 mg. per 100 ml.; P.C.V. 44 c.cm. per 100 ml. She was given glucose saline containing hydrocortisone and noradrenaline intravenously and deoxycortone acetate (D.C.A.) and cortisone intramuscularly, but despite the administration of 120 mg. hydrocortisone, 100 mg. cortisone, 3 mg. D.C.A., and nearly 5 mg. noradrenaline in the next 23 hours the blood pressure never rose above 70/40 mm. Hg and she never became conscious. Three hours before death the plasma electrolyte values (in mEq per litre) were: sodium 124, potassium 5.2, chloride 100, bicarbonate 18; the P.C.V. was now 32 c.cm. per 100 ml. and the blood sugar 158 mg. per 100 ml.

Necropsy (Dr. H. Spencer) showed leaflike adrenals (30×10×1 mm.) each weighing about 0.75 g., which on cutting had no recognizable cortex. Histologically they showed adrenal atrophy (see Special Plate). No inclusion bodies could be seen. Apart from two small areas of perivascular lymphocytic cuffing on the outer part of the lentiform nucleus of the brain and chromatolytic changes in a few nerve cells of the pons and medulla, there were no other histological or anatomical changes of note.

Comment

This history of increasing weakness and loss of energy, of vomiting, loss of appetite, and wasting, and the development

of pigmentation, is characteristic of the condition which, untreated, progresses to a fatal crisis, precipitated perhaps by infection, trauma, surgery, or drugs such as morphine or the barbiturates, to which these patients are particularly sensitive. An increased liking for salt is often found—it occurred in 13 of the cases quoted in the accompanying table. The blood pressure may, as here, remain normal until the onset of the crisis. Lymphocytosis and eosinophilia, reflecting perhaps the low secretion of glucosteroids, are noted occasionally. The E.E.G. record showing diffuse high-voltage slow activity waves is typical.

Discussion

Jaudon (1946) found reports in the world literature of 62 proved cases of Addison's disease in children under 15 years, all but 13 of them being over 10 years. The underlying condition was tuberculosis in 53, atrophy in five, and "not demonstrated" in one, whilst in three the symptoms complicated hyperplasia of the androgen-secreting cells of the foetal cortex—mixed adrenal disease, a relatively more common condition best considered apart. Since then reports of a further 29 cases of uncomplicated Addison's disease have appeared, 22 in boys. The details are shown in the table.

Thus, including this present case, adrenal atrophy was the cause in 11 (55%) of the 20 proved cases, hypoplasia in four, and tuberculosis in only two (10%). In the 10 cases where the aetiology was less certain, only one had definite evidence of tuberculosis. Talbot *et al.* (1952) found tuber-

Summary of 29 Cases of Addison's Disease in Children Reported since 1946

	Sex	Age at Onset	Length of Illness	Pathology	Associated Conditions	Comments
Sikl (1948)	M	3 weeks	2 weeks	Hypoplasia (P.M.)		Treated from 7 months
Geppert, Spencer, and Richmond (1950)	M	Birth	20 months	" "		
Deamer and Silver (1950)	M	" "	10 "	" "		Survives. "Treated" from 18 months
Moore and Cermak (1950)	M	Few months	4 years +	Probably hypoplasia		Treated with D.C.A.
Provenzano (1950)	M	2 weeks	7 months	Adrenal cysts (P.M.)		Responded to A.C.T.H. at first
Garraban, Sampayo, and Di Pietro (1952)	M	Birth	24 days	Hypoplasia (P.M.)		
O'Donnell (1950)	M	16 months	5 months	Atrophy (P.M.)		
White and Sutton (1950)	M	20 "	7 "	" "		
Mautner (1954)	F	2½ years	2 days	Fibrosis and calcification (P.M.)		Negro child. Septicaemia aged 1 month; normal then until crisis precipitated by otitis media
Russell and Potter (1951)	M	4½ "	12 hours	Calcification, cause not known (P.M.)	Internal hydrocephalus	Mentally and physically retarded. Sudden death in crisis precipitated by mild illness
Bickel and Stamm (1948)	F	7 "	7 months	Atrophy (P.M.)	Followed severe impetigo	Pigmented scar aged 4 months after vague febrile illness at 2 months. Retarded growth. Crisis at 9 years. Survives on treatment
Beasman (1948)	M	5 "	3 "	" "		Presented as hypoglycaemia
Burdick, Warthen, Cassidy, and Welsh (1950)	M	5½ "	6 "	" "		Sister has thrush and Addison's disease
Craig, Schiff, and Boone (1955)	M	6½ "	3 "	" "	Monilia; 7 hypoparathyroidism; pneumonia, empyema	Brother with monilia, coeliac disease, and hypoparathyroidism
Leonard (1946)	F	10 "	2 years	" "	Monilia at 2½ years; 7 coeliac disease at 4½ years; hypoparathyroidism at 6 years	No parathyroids found at necropsy
Broch (1946)	F	10½ "	18 months	" "	Monilia at 3½ years; 7 hypoparathyroidism from 5½ years	
Laplane and Fritel (1948)	M	14 "	6 "	" "		Pigmentation only for 18 months and then fatal crisis
Correa and Piers (1952)	F	12 "	18 "	Tuberculosis (P.M.)		
Mouriquand, Dechavanne, and Laugel (1951)	F	11½ "	4 "	" "	Heart failure	After 4 months' treatment developed faintly positive Mantoux reaction, shortly before death. No other evidence of tuberculosis
Demirag (1947)	M	13 "	9 "	Unknown; probably non-tuberculous		
Mathiesius (1947)	M	11 "	2 years +	Unknown; no evidence of tuberculous infection	Chronic malaria	
Briggs, Goodwin, and Wilson (1951)	M	8 "	3 "	" "		Presented at age 10 with 3-year history of illness. Stunted growth
Patzrowa (1953)	M	12 "	6 months +	Unknown; probably atrophy, possibly tuberculosis		One year later 17-year-old brother died in 5 weeks of adrenal atrophy. Calcified abdominal glands
Papadatos and Klein (1954)	M	10 "	" "	Unknown; no evidence of tuberculosis	Hypoparathyroidism at 5½ years	
Bernheim and François (1953)	F	12 "	3 "	Unknown; no evidence of tuberculous infection		
Stanton, Jones, and Marble (1954)	M	10 "	2 years +	Probably tuberculosis	Diabetes mellitus at 2½ years	Aetiology not considered at all by authors

culosis to be a factor in only one of nine cases known to them. In so far, therefore, as can be judged from the evidence of published case reports, tuberculosis has now been displaced from its position as the commonest cause of Addison's disease in childhood, and atrophy must account for at least half the cases of this condition. A similar trend has been seen in adults in recent years. In adults atrophy is more common in the female, yet in these recently reported cases in children the reverse is true, a fact Jaudon (1946) also noted.

As to the cause of adrenal atrophy (adrenocortical contraction) nothing definite is known. The histological picture is clear-cut (Guttman, 1930): the parenchymal cells degenerate and disappear, shrinking away from the undamaged reticulum framework, which in time collapses, leaving no trace of the columnar zonal pattern. Both cortex and, to a lesser extent, medulla are infiltrated with lymphocytes, and there is usually no cicatricial or productive fibrosis. The condition has occurred in members of the same family—definitely in one case (Craig *et al.*, 1955), probably in two more (Briggs *et al.*, 1951; Smith and Higgins, 1952). It can be associated with disorder in other endocrine glands. Of these 11 proved examples of adrenal atrophy, clinical hypoparathyroidism was present in two and strongly suspected in two more. In two of the surviving cases where atrophy was suspected there is a further example with associated hypoparathyroidism and one with diabetes mellitus, the 47th example in the literature (Stanton *et al.*, 1954). In adults Addison's disease, particularly (but not always) when due to adrenal atrophy, has been found in association with both hypothyroidism and hyperthyroidism (Sorkin, 1949). Changes in the pituitary are found in Addison's disease from all causes, being secondary to the adrenal hypofunction. The adrenal changes in hypopituitarism are quite distinct from those of adrenocortical contraction (Crooke and Russell, 1935).

In the particular instance reported here the onset after mumps is of interest when one considers the effect of the mumps virus on testis, ovary, and pancreas. No inclusion bodies, however, can be seen on microscopy. The only other suggestions that this selective destruction of parenchymal cells might be viral in origin are from Weiner (1936), who found intranuclear inclusions in a case of atrophy in a middle-aged woman, and Friedman (1948) and others, who have noted a resemblance between the changes in this condition and those of certain liver diseases, particularly hepatitis—allowing for the different natures of the organ—and that there was some correlation in the rise in incidence of both conditions as seen at the United States Army Institute of Pathology. Yet, on the whole, it seems more likely that the relationship in time between the mumps and the onset of the child's final illness is only a coincidence.

Summary

A fatal case of Addison's disease due to atrophy of the adrenals in a girl of 9 years is reported. The picture of progressive weakness and listlessness, of vomiting and anorexia, and the development of pigmentation is typical of the condition. Until the onset of crisis her blood pressure was normal.

The recent literature on Addison's disease in children is reviewed. In the past ten years more than one-half of the cases reported with a known pathology have been due to atrophy of the adrenals (adrenocortical contraction) and only one-tenth to tuberculosis—a great change from the findings in a previous review of this subject. Over one-third of the cases showed evidence of a craving or increased liking for salt.

I wish to thank Dr. J. Forest Smith and Dr. John Anderson for permission to publish details of this case admitted under their care; Dr. H. Spencer and Dr. J. D. Pollitt for permission to quote from their reports; and my colleagues who gave their help and advice.

AN UNUSUAL CASE OF CAROTID-BODY TUMOUR

BY

MAXWELL ELLIS, M.D., M.S., F.R.C.S.

Surgeon, Royal National Throat, Nose and Ear Hospital,
 London; Ear, Nose, and Throat Surgeon, Central
 Middlesex Hospital, London

AND

P. WINSTON, M.B., F.R.C.S., D.L.O.

 Laryngology and Otolaryngology, London

[WITH SPECIAL PLATE]

Aberrant parasympathetic nervous tissue often occurs near the great vessels of the neck. From this tissue a tumour called non-chromaffin paraganglioma may arise, sometimes near the bifurcation of the common carotid artery, where it is known as a carotid-body tumour, or occasionally near the exit from the skull of the internal jugular vein, where it is given the name of glomus jugulare tumour. These tumours are characteristically extremely vascular, and the carotid-body tumour is, in addition, closely attached to one or other of the carotid vessels by vascular connexions as well as adhesions, often simulating an aneurysmal dilatation. Excision of such a tumour may be impossible without also resecting a length of the adherent vessels.

As the tumour increases in size, pressure on neighbouring structures may occur, particularly the vagus and hypoglossal nerves and the sympathetic nerve trunk. The internal jugular vein is more often pushed aside than invaded. Harrington *et al.* (1941) state that 40–50% of carotid-body tumours become malignant, but Lahey and Warren (1947) consider this estimate is much too high. Metastases to cervical lymph nodes may occur, and very occasionally distant metastases.

The interesting and unusual features of the case now recorded are the extent of invasion and destruction of the internal jugular vein together with pressure atrophy of the vagus nerve, without any close relationship or adherence to the carotid vessels.

Case Report

A married woman aged 37 had two years previously, possibly following an attack of influenza, noticed a swelling develop in the left side of her neck. There were no other symptoms. She attended a local hospital, where in May, 1953, an enlarged lymph node was removed. Histological

FIG. A.—Vertical section of tumour.

FIG. B.—Diagram showing anatomical relations of tumour.

examination showed sinus catarrh, and there was no evidence of granulomatous or malignant disease. At the same time nothing abnormal was found in the upper respiratory tract. Within two weeks the swelling recurred under the scar, and the patient thinks that her voice became husky at about the same time.

She first attended the Royal National Throat, Nose and Ear Hospital on September 24, 1954. Her voice was then weak and very slightly hoarse. Under a puckered scar 3 cm. long and running obliquely in the left side of the neck at the level of the upper border of the thyroid cartilage was a swelling about the size of a large walnut. It was smooth, firm, and painless on palpation, and not pulsatile, although it transmitted pulsation. There was no bruit. The lump was partly overlapped by the anterior margin of the left sternomastoid muscle, and was mobile laterally but not in a vertical plane. There were no other palpable swellings in the neck. The tonsils were healthy, and the remainder of the upper respiratory tract was normal except for the left vocal cord, which was completely paralysed and was situated close to the mid-line at a lower level than the right vocal cord. Tomograms of the larynx showed the relaxed condition of the left vocal cord (Special Plate, Fig. 1), but no other abnormality. A radiograph of the chest was normal. A very slight secondary anaemia and also a slight rise in the erythrocyte sedimentation rate were present, but neither was considered significant. Bronchoscopy and oesophagoscopy revealed nothing abnormal.

An exploratory operation was performed on November 1, 1954. The swelling was found in the anterior triangle, partly covered by the sternomastoid muscle, which was adherent to it. A smooth, pale grey swelling was then clearly defined lateral to the bifurcation of the common carotid artery and very slightly adherent to it and to the external carotid artery. The mass was ovoid in shape, and measured 5 by 3 cm., with its long axis in the vertical plane (Fig. A). There was a communicating vessel between the tumour and the external carotid artery. The striking feature, however, was the absence of a definite internal jugular vein. This was replaced by several small vessels

which entered and left the tumour, as shown diagrammatically in Fig. B, but this position was not disclosed until after considerable dissection. The vagus nerve was not identified. The artery of supply and all the venous connexions were ligated and divided and the tumour removed. A small lymph node adherent to it was also excised. The wound healed soundly, convalescence was uneventful, and the patient left hospital ten days later. The histological report (Dr. I. Friedmann) was: "A large gland-like tumour. Sections show a well-encapsulated vascular tumour consisting of groups of epithelial cells with poorly defined boundaries closely associated with the vascular spaces and stroma (Special Plate, Fig. 2). The growth belongs to the paragangliomata, and in view of its site is a so-called carotid-body tumour." The lymph node contained no evidence of neoplasm or tuberculosis.

There has been no sign of recurrence of the growth (April, 1957), though the vocal cord has remained paralysed (Plate, Fig. 3).

Comment

The paragangliomata associated with the great vessels of the neck differ markedly in their characteristics and natural history, depending on their site. In the middle of the neck the tumour is usually well defined and encapsulated and adherent to the carotid arteries; higher in the neck it is more diffuse and related to the internal jugular vein and jugular bulb. In the case described above a half-way position has been observed in which the tumour was situated in the middle of the neck and encapsulated, although related almost entirely to the internal jugular vein.

There seems to be no reason why it should not sometimes assume this character, but curiously enough no previous record has been found in the literature. The absence of the usual dense adherence to the carotid vessels facilitated excision, but the close connexion with the internal jugular vein leading to its disruption as an entity was probably responsible for the early onset of pressure on the vagus nerve and paralysis of the vocal cord.

Summary

A case of carotid-body tumour is described in which there was extensive invasion and destruction of the internal jugular vein but no close relationship or adherence of the tumour to the carotid vessels. The left vocal cord was completely paralysed. After surgical removal of the tumour there has been no recurrence, but the left vocal cord remains paralysed.

Our thanks are due to Mr. D. J. Connolly, of the Institute of Laryngology, for the preparation of the illustrations.

The smoking habits of English schoolboys were discussed at a recent meeting of the Royal Society of Health. Mr. RONALD W. RAVEN, F.R.C.S., had analysed material collected by the Marie Curie Memorial Foundation from the heads of 141 schools. "The problem is a serious one," he said, "and the habit is widespread in secondary and grammar schools. The habit starts as early as 8 years and a few of these boys tend to become regular smokers. In some primary schools smoking is a difficult problem with the 9- and 10-year-old group, but the more 'inveterate addicts' are in the 13- and 15-age group. The percentage of regular boy smokers is increasing; one headmaster found that at 14 and over half the boys are confirmed smokers."

PULMONARY ASPERGILLOSIS

REPORT OF A CASE

BY

C. S. DARKE, M.D., M.R.C.P.

Consultant Physician, City General Hospital, Sheffield

Sheffield

[WITH SPECIAL PLATE]

A century has elapsed since Virchow (1856) first reported the post-mortem findings of pulmonary aspergillosis, and many cases of this disease have subsequently been described. While pulmonary aspergillosis as a primary infection remains a rare and mainly occupational disease, its occurrence as a fatal complication of bacterial infections of the lung treated with antibiotics has become important with the increasing use of these agents for the treatment of pulmonary diseases. Fatal cases have recently been described by Abbott *et al.* (1952) and by Rankin (1953), although in the latter instance agranulocytosis and a monilial infection were also present. The object of this report is to describe another case of aspergillosis which proved fatal, and to suggest that it is an example of secondary rather than primary infection.

Case History

A male road worker aged 63 was admitted to hospital on the 18th day of a respiratory infection. The illness began acutely with fever, cough, and left pleuritic pain, and initial treatment was with sulphonamides. There was some response, but later a relapse set in with increasing breathlessness and right-sided pleurisy. A routine chest radiograph taken two years previously during investigation for schizophrenia showed calcified tuberculous lesions, moderate emphysema, and pleural thickening at the base of the right lung.

Clinical examination now indicated bronchopneumonia with a severe bilateral pleurisy, and a radiograph showed mottled opacities in the right lower lobe and base of the right upper lobe. Culture of the sputum, which was mucoid, yielded a heavy growth of *Streptococcus viridans* and a scanty growth of *Neisseria catarrhalis*. Pneumococcus Type XXVII was isolated by mouse inoculation. Blood culture was sterile.

Tetracycline, 0.5 g. six-hourly for 4 days and then 0.25 g. six-hourly for 8 days, was given. Despite this therapy the temperature ranged from 97.6 to 102° F. (36.4 to 38.9° C.) for the next 14 days. The general response was poor and quite unlike that expected in the ordinary case of pneumococcal infection. A chest radiograph taken eight days after admission showed the appearance of bronchopneumonia throughout the whole of the right lung with excavation in the upper lobe. Weakness, delirium, and a flushed facies developed, and 14 days after admission the sputum, which had remained essentially mucoid, became russet-brown and later black in colour. A further radiograph at this time showed progressive bronchopneumonic consolidation in the right lung with spread to the left upper lobe. Chloramphenicol, 2 g. followed by 0.5 g. six-hourly, was given by mouth for the next three days, and finally one intramuscular injection of 200 mg. of pentamidine as

well as potassium iodide by mouth. Mental confusion and early heart failure developed shortly before the patient's death 19 days after admission and on the 37th day of the disease.

A leucocyte count showed a polymorphonuclear leucocytosis rising in 20 days from 12,000 to 29,000 per c.mm. A radiograph taken on the day before death showed extension of the disease to the whole of both lungs with multiple abscess formation, particularly in the upper lobes. Culture of the sputum at intervals showed little change in the bacteriological flora, which throughout remained sensitive to tetracycline and chloramphenicol. No acid-alcohol-fast bacilli were found on several examinations. Complement-fixing antibodies to influenza virus A and B, to the psittacosis-LGV group of viruses, and to *Rickettsia burneti* were not detected. Cold agglutinins and agglutinins against *Streptococcus M.G.* were not found.

In view of the lack of clinical response, and unusual radiological course, and the colour of the sputum, a secondary fungus infection of the lung was suspected. Direct examination of the sputum for yeast or mycelial fragments was consistently negative, but a specimen taken two days before death yielded, after 48 hours, a growth of a fungus which was identified as *Aspergillus fumigatus*.

Post-mortem Examination.—Positive findings were confined to the respiratory system. The larynx, trachea, and main bronchi showed congestion only. There were old pleural adhesions on the anterior surface of both upper lobes. Both lungs showed extensive pneumonic consolidation with a scattered cystic appearance. This was particularly marked in the left lower lobe, where there were small, ragged abscess cavities. Thrombosis of the small pulmonary arteries was evident in the left lung. Wet preparations of scrapings from the abscesses revealed the fruiting heads of an *Aspergillus*. Cultures taken under sterile precautions from the main bronchi and from two separate lung lesions yielded a heavy growth of a mould of the genus *Aspergillus*, which was kindly identified for us as *A. fumigatus* by Dr. Jacqueline Walker, of the Mycological Reference Laboratory. A scanty growth of this mould was also obtained from the spleen.

In the lungs the general histological picture was that of a resolving pneumonia with abscess formation. In the left upper lobe there was an acute inflammatory exudate, mainly cellular, but fibrinous in some places. Other areas showed similar pneumonic changes with abscesses but with evidence of some resolution. Most of the abscesses were lined by a layer of fungal mycelia about 10 μ thick, and in one cavity the characteristic fruiting bodies of *A. fumigatus* were found (see Special Plate). The bronchial mucosa was mainly intact, and the bronchioles contained pus but no fungal mycelium.

Discussion

Although death was due to a diffuse bacterial pneumonia and pulmonary arterial thrombosis, there was histological evidence that resolution of the pneumonia had begun. Antibiotic therapy had, however, failed to limit the spread of pneumonia, and was complicated by the growth of a fungus which had invaded necrotic areas in both lungs. The eradication of a fungus infection in these circumstances is difficult, although in this instance specific therapy was employed only terminally.

In cases of pulmonary aspergillosis, iodides in full doses and neoarsphenamine have been used (Conant *et al.*, 1954), although they were found by Hinson *et al.* (1952) to be of no value in two of their cases. The latter authors state that *A. fumigatus* was inhibited *in vitro* by "M. and B. 938" (4:4'-diamidinodiphenylamine dihydrochloride) in a concentration of 1 in 100,000. This substance was used by them in one case with equivocal results, and unpleasant hypotensive symptoms followed intravenous injection.

In the present case the strain of *A. fumigatus* was found to be resistant to the commonly used antibiotics and also to

BRONCHO-PULMONARY ASPERGILLOSIS

REPORT OF A CASE

BY

J. G. STEVENSON, M.D., F.R.F.P.S.

AND

J. M. REID, M.B., M.R.C.P.Ed.

From the Thoracic Unit, Mearns Kirk Hospital,
Renfrewshire

Fungal infections of the lungs were first described in a variety of animals early in the nineteenth century, birds and horses being the commonest victims. The credit for the first account of this infection in human beings is given to Hughes Bennett (1842), but some doubt exists as to the validity of his description of the infecting fungus. The earliest definite identification of the aspergillus came from Sluyter (1847). Since that date the world literature on this subject has grown progressively, but contributions from this country have been sparse.

In 1952, however, broncho-pulmonary aspergillosis was admirably reviewed in this country by Hinson *et al.* In their paper eight new cases were reported, the mycology and literature considered exhaustively, and reference was made to both medical and surgical treatments for the condition. Resection measures were applied where the infection was confined to a lobe or a lung. In the medical management of more general disease "M. and B. 938" (4:4'-diamidinodiphenylamine dihydrochloride) was used both as an inhalant and an intravenous medication.

The case now described is of interest in that (1) it arose in a man working in close proximity to a cotton-mill; (2) the initial diagnosis was that of possible lung cancer; and (3) the correct diagnosis became obvious when *Aspergillus fumigatus* was grown on pure culture from aspiration material obtained at bronchoscopy. This led to the intravenous use of hydroxystilbamidine with considerable and sustained improvement in the clinical and radiological pictures.

Case History

The patient, a man of 62 years, had worked from the age of 26 onwards as a brass-dresser in a foundry. For many years before this present illness developed the premises adjacent to his place of employment had been used as a cotton-mill. His position while working exposed him to heavy clouds of cotton dust which emanated from the mill. Bronchitic afflictions, according to him, were common amongst his co-workers.

In August, 1955, he sustained a back injury when a heavy beam fell on him from a moderate height. No skeletal damage resulted, but he dates his symptoms of cough and sputum production from this event. In the next few weeks the cough became increasingly troublesome and was accompanied by progressive exertional dyspnoea. The coughing was so severe that vomiting occurred on several occasions. The sputum was copious and mucopurulent, but never blood-stained. Lassitude was marked, but there was neither chest pain nor undue weight loss. These symptoms led to radiological examination of the chest with the discovery of an excavated lesion in the left lung, and his admission to the Thoracic Unit, Mearns Kirk Hospital, on November 29, 1955.

Clinical examination showed a pale, thin, lethargic man, with slight finger clubbing, but no cyanosis or dyspnoea at

isoniazid and *p*-aminosalicylic acid. In carrying out the sensitivity tests there was no evidence that the growth of the mould was stimulated *in vitro* by low concentrations of the antibiotics.

Active research is at present being carried on in many centres to develop fungistatic agents, and certain information is now available on the new antifungal antibiotic nystatin, which has been used in certain fungus infections, particularly intestinal moniliasis (Newcomer *et al.*, 1954-5). With the possibility of similar agents becoming available for the treatment of fungal infections, it is clear that an aspergillus infection should be considered in every case where a respiratory infection fails to respond to antibiotics, particularly if lung destruction is present. In such cases special attention should be paid to examination of the sputum for moulds both by direct means and especially by culture. In direct wet preparations the mature conidiophores of *A. fumigatus* have a pale-brown colour, and their resistance to 4% caustic soda permits the use of this substance to digest the sputum and so facilitate their recognition. Mycelial fragments may also be detected by the periodic-acid-Schiff reaction, which is invaluable for the detection of fungi in paraffin-wax sections of sputum or tissue, although we have had no experience of its use in direct wet preparations.

The strain isolated from this case produced an abundant growth on blood agar after 48 hours' incubation at 37° C. When there is heavy bacterial contamination of the sputum, penicillin and streptomycin may be added to the medium to inhibit other organisms (Conant *et al.*, 1954). The fungus is identified by its colonial appearance and its microscopical morphology. For the latter purpose a portion of the growth may be mounted in a drop of lactophenol cotton blue, or, to obtain better preparations, agar block culture should be used.

Although there is no evidence that the antibiotics caused the patient's death, it seems likely that they favoured the saprophytic development of a fungus which led finally to direct invasion of the tissues and death.

Summary

A case of pulmonary aspergillosis complicating a diffuse bacterial pneumonia is described. Although there is no evidence that antibiotic treatment caused the patient's death, it seems likely that the antibiotics favoured the saprophytic development of a fungus which finally directly invaded the tissues and led to a fatal outcome.

Methods of investigating and treating similar cases are put forward.

We would like to thank Mr. C. A. Lambourne for technical assistance and photography.

Minerva Nucleare, a new addition to the group of medical journals published by Edizione Minerva Medica, Turin, is a bi-monthly devoted to nuclear biology and medicine. It is the official organ of the Società di Biologia e Medicina Nucleare. Annual subscription is 4,000 lire, and the journal is obtainable from 83, Corso Bramante, Turin.

rest. A chest radiograph revealed a large abscess cavity with a fluid level occupying the greater part of the left lower lobe, and scattered infiltrative changes throughout the remainder of both lungs. The two possibilities of neoplasm with abscess formation and of tuberculosis were considered, and bronchoscopy under local analgesia was performed. There were copious purulent secretions, and the mucosa of the left main bronchus was severely congested. A random mucosal biopsy from the origin of the apex of the left lower lobe bronchus showed only severe non-specific inflammatory change.

A diagnosis of pyogenic lung abscess was made, and tetracycline therapy was instituted without improvement. Serial cultural examinations of the sputum failed to reveal tubercle bacilli; instead *A. fumigatus* was grown in almost pure culture. This finding being insufficient to establish a diagnosis of aspergillosis, bronchoscopy was repeated on January 3, 1956, with aspiration of bronchial secretions. The specimen was reported on as follows: "One fungus only was present, and on microscopic examination it was identified as an *Aspergillus* species. Careful examination of the microscopic characteristics and of the colonies on Czapek's solution of agar were carried out. The form and measurements of the smooth conidiophores and flask-shaped vesicles with the single series of crowded sterigmata conformed to those given by Thom and Raper (1945) for *A. fumigatus* Fresenius. The colonies were of the velvety strain described by the authors, at first white, becoming dark green to almost black with age, and with the reverse, which was at first colourless, becoming pale brown in two to three weeks."

Intravenous hydroxystilbamidine therapy was thereupon instituted, and two ten-day courses of 0.15 g. daily were administered, with a seven-day rest between courses. Progressive clinical and radiological improvement resulted. Oral nystatin therapy in a dosage of 500,000 units thrice daily followed the second course of hydroxystilbamidine and was continued for eight weeks. During this time albuminuria was noted, and a mid-stream specimen contained numerous pus cells and red blood cells, with only a very light growth of neisseriae on culture. No yeast-like structures were discovered, and no further renal investigations were undertaken.

The patient was discharged from hospital on March 3, 1956, much improved. He continued to report at intervals for out-patient supervision. At his last attendance on August 30 x-ray examination showed further clearing and the abscess cavity had almost totally disappeared. There was corresponding reduction of the infiltrative changes. His general condition, however, had deteriorated in the previous two months, and he complained of lassitude, some weight loss, and frequency of micturition. One month later he died at home after a rapid terminal illness in which urinary symptoms with incontinence and lower limb oedema were prominent. No post-mortem examination was carried out.

Discussion

Isolation of *A. fumigatus* from the sputum is of quite frequent occurrence. In the past such a finding has been the basis of a diagnosis of broncho-pulmonary aspergillosis in some cases, but, as Hinson *et al.* (1952) pointed out, such diagnoses are tenuous. These authors indicated more rigorous diagnostic criteria, the corner-stone of which was histological examination of the diseased tissue, which they were able to carry out in all three of their cases. In our case such examination was impossible, as necropsy was not performed, and resection treatment was not feasible in the earlier part of the illness. Instead the sputum findings were confirmed by cultural isolation from bronchial secretions of a solitary fungus identified as *A. fumigatus* Fresenius. In addition the response to hydroxystilbamidine therapy, although temporary, was gratifying, and seemed to support the diagnosis. The patient showed progressive radiological improvement over the space of nine months. Riddell (1956) mentions the efficacy of inhalations of nystatin, brilliant

green, or hydroxystilbamidine in *A. fumigatus* infections, but his paper was not published until after the death of our patient.

Aspergillosis may be a primary infection, or, probably more frequently, it may involve tissues already damaged by disease—for example, bronchiectasis, bronchial carcinoma, or tuberculosis. In the present case the initial diagnosis rested between a tuberculous excavation, and a lung abscess either of primary type or secondary to lung neoplasm. Serial bacteriological culture ruled out the former, while bronchoscopy coupled with the progressive nine-month period of radiological improvement excluded the latter. This infection was therefore felt to be primary in origin. Marshall and Perry (1952) described three types of primary involvement: (1) acute tracheo-bronchitis or (2) bronchopneumonia, both of which are rare; and (3) a chronic process simulating either tuberculosis or neoplasm. The third category would appear to cover our case.

An interesting feature of the case, and one which must remain a matter of conjecture, is the possibility of a secondary renal involvement by the fungus, presumably due to haematogenous spread, which has been reported in the literature. Death resulted in circumstances which suggested renal failure, although previous examination of the urine while the patient was in hospital failed to reveal the fungus. Presumably, too, if renal involvement had been present it would appear that the stilbamidine therapy had been ineffective.

A final point concerns the occupational history and requires little stressing. The disease occurs predominantly in those handling infected grain, flour, etc. (Norris and Landis, 1920; Davidson, 1948). Heppleston and Gloyne (1949) mentioned its occurrence in coal-miners.

Summary

A case of primary broncho-pulmonary aspergillosis which ended fatally despite a temporary favourable response to hydroxystilbamidine and nystatin therapy is described. Death occurred in circumstances suggesting renal failure, though *Aspergillus fumigatus* had not been isolated from the urine.

We acknowledge with pleasure the assistance afforded us by Mr. R. S. Barclay, thoracic surgeon, in whose ward the patient was treated. We are indebted for the careful bacteriological investigations to Dr. L. G. Bruce, consultant bacteriologist, and also Mr. J. C. Gentles, medical mycologist, at the Western Infirmary, Glasgow.

Milk can now be frozen and stored for at least a year without deterioration, it is claimed. A method of doing this has been developed by the National Institute for Research in Dairying, with financial support from the National Research Development Corporation, and is discussed in the corporation's annual report published last month (H.M.S.O., price 1s. net). Pasteurized milk is treated with ultrasonic waves, poured into polythene bags, and quickly frozen in a brine bath. The report mentions "the commercial possibilities of frozen milk, which include the provision of fresh milk for passengers throughout long sea-voyages, storage of milk during times of over-production, and shipment to countries where good-quality fresh milk is unobtainable." The corporation, to whom the patent rights have been transferred, has licensed two British firms, who expect to go into production shortly.

FIBROSARCOMA OF RIGHT AURICLE

BY

S. COPE, M.D., M.R.C.P.

Senior Medical Registrar, Royal Southern Hospital,
Liverpool

[WITH SPECIAL PLATE]

The following case of cardiac tumour is reported as showing a clinical picture which, although unusual, should not be impossible of recognition. If this case had been diagnosed during life surgical intervention might have had a successful outcome, and for this reason it is proposed to describe the case in some detail.

Case Report

The patient, a woman aged 40, was admitted to hospital on March 1, 1956. In September, 1954, she had been in hospital suffering from biliary colic, for which cholecystectomy was performed. The gall-bladder was thickened and fibrosed and contained several gall-stones. Subsequently she had remained in good health until the end of 1955, when she became listless and tired. In January, 1956, she complained of generalized aches and pains in the limbs, and, although she was afebrile, mild influenza was diagnosed and she was confined to bed. On January 10 severe pain in the right hypochondrium and epigastrium associated with nausea developed. During that day she had three further such bouts, but findings on physical examination were negative apart from the suspicion of slight jaundice. Four days later she was still suffering from bouts of pain and nausea, and diarrhoea and severe weakness had also developed. There were no abnormal signs in any of the major systems. In particular the heart sounds were normal, there was no tachycardia or arrhythmia, and the blood pressure was 100/80 mm. Hg. A surgical opinion was that there was no acute abdominal condition requiring emergency treatment. An electrocardiogram was normal, as also was a radiograph of the dorso-lumbar spine.

Nausea with vomiting and diarrhoea persisted, together with pain in the right hypochondrium. In addition the patient had two alarming attacks in which she almost collapsed, complaining of feeling cold and faint and a sense of impending death. Examination was again negative apart from slight, but now definite, jaundice, and on the advice of the surgeon the patient was transferred to hospital. On admission she was afebrile and in good general condition. There was no anaemia, wasting, or dehydration, but moderate jaundice was present. Examination of the abdomen was negative. Blood pressure 130/90 mm. Hg; pulse regular; heart sounds normal and no murmurs heard. Lung fields clear and no abnormality detected elsewhere. Results of blood examination: haemoglobin 89%; mean corpuscular (increase due to a polymorphonuclear leucocytosis). Non-protein nitrogen, 30 mg. per 100 ml. Stools normal. Urine contained bile but no other abnormal substances. Serum bilirubin, 5 mg. per 100 ml. Thymol turbidity, 2 units; serum flocculation and zinc sulphate flocculation, negative. Serum alkaline phosphatase, 9 units; serum proteins, 6.6 g. per 100 ml. On the following day examination by screen x-ray of the chest and a barium meal showed normal results. The abdominal pain and jaundice persisted, oedema of the ankles developed, and albumin appeared in the urine. There was no fever, but a repeat white blood count showed a leucocytosis of 19,000 per c.mm.

I first saw the patient on March 7. At this time her general condition was reasonably good. There was moderate jaundice, with now an extensive oedema of the legs, abdomen, and back as far as the lumbar region. The liver was enlarged to about three fingerbreadths below the costal margin, soft, tender, and with overlying muscular rigidity. There was no engorgement of the jugular veins, and the

lung bases were clear. The blood pressure was 125/85 mm. Hg, and the heart appeared normal in all respects. Oedema, albuminuria, and leucocytosis with no congestive signs above the diaphragm indicated a thrombosis of the inferior vena cava. The cause of this was in some doubt. In view of the previous gall-stones, the present pain, jaundice, and tenderness in the right hypochondrium, the liver appeared to be the primary site of disease. It was postulated that there had been a recurrent stone with subsequent infection and the development of hepatic-vein thrombosis spreading back to involve the inferior vena cava. This somewhat tortuous mechanism seemed to cover all the facts better than a primary hepatic-vein thrombosis. Further investigation showed: serum albumin 3.4 g., serum globulin 3.1 g. per 100 ml.; Wassermann reaction negative; blood coagulation time normal; non-protein nitrogen, 65 mg. per 100 ml.; blood culture negative; in the urine a large quantity of albumin, a few epithelial cells, and hyaline casts.

During the next few days the patient's condition deteriorated. The jaundice fluctuated and she had repeated attacks of pain with profuse sweating and a feeling of weakness; nausea was troublesome, though vomiting was only occasional. The rigidity and tenderness in the right hypochondrium were constant, the liver was unchanged in size and consistency, and there was some ascites. The oedema was gross and the patient complained of cramp-like pains in the legs, thought to be due to accumulation of fluid. The temperature was subnormal. Blood pressure, pulse, heart, and lungs were normal. The leucocyte count was still 20,000 per c.mm. and liver-function tests gave normal results.

On March 17 small purpuric spots were seen on the lips, palate, and diffusely over the skin. A harsh to-and-fro murmur was heard over the praecordium, and though its curious quality was noted it was presumed to be a pericardial rub. There were several points against the diagnosis of hepato-renal failure, but even so a more satisfactory explanation of these various signs was not forthcoming.

Over the next 48 hours the patient's condition deteriorated further, and she died in coma on March 20.

Post-mortem Examination

At necropsy the relevant findings were as follows.

A number of dilated veins were present at the lower end of the oesophagus.

The lungs showed gross congestion and oedema. There were several pulmonary infarcts; these were of recent origin and due to the presence of masses of thrombus in the major and minor branches of the pulmonary artery. The thrombi appeared to be embolic in nature.

There were numerous petechiae on the surface of the heart, and about 2 oz. (57 ml.) of straw-coloured fluid was

Photograph of the tumour.

found in the pericardium. The right auricle and ventricle were distended by a large, rounded, somewhat gelatinous tumour arising from the upper part of the medial wall of the auricle (see photograph). The tumour measured about 2½ by 1½ in. (6.4 by 3.8 cm.) and passed through the tricuspid valve into the right ventricle. Over the surface of the tricuspid valve and endocardium of the auricle was an area of roughening on which were numerous fibrin vegetations, apparently caused by friction between the tumour surface and the endocardium. The aorta, great vessels, and coronary arteries were normal.

A considerable quantity of slightly turbid yellow fluid was present in the abdomen.

The liver was enlarged and showed gross changes of chronic venous congestion. There was no thrombus in any of the hepatic veins. The inferior vena cava was obliterated by a fairly recently formed thrombus. This appeared to have originated at a point near the orifices of the hepatic veins, and it extended throughout the entire length of the inferior vena cava and iliac veins. The thrombus passed across the openings of the hepatic and renal veins, but did not extend into them. The portal and splenic veins contained no thrombus. No indication of the cause or origin of this thrombus other than venous stasis due to back pressure by the tumour could be detected.

Histology of the Tumour (see Special Plate)

A cellular tumour, the cells being spindle in type and showing pleomorphism and an occasional mitosis. No infiltration of surrounding tissues was noted in the sections examined. Special staining methods revealed no evidence of cross-striations to suggest a myomatous origin, but did reveal a moderate amount of intracellular collagen. The tumour therefore appeared to be of fibroblastic origin, and was considered by the pathologist to be most probably a low-grade sarcoma.

Discussion

In a review of tumours of the heart Prichard (1951) states that such tumours are rarely diagnosed before necropsy, largely because there is little knowledge of their natural history. The total number of sarcomata Prichard was able to find in the literature was 113, of which the majority were infiltrative or sessile, but some 20% were polypoidal. Whorton (1949), who also analysed the types of cardiac tumour, classified 41 as "spindle-cell neoplasms" of the type described in the present case. Hurst and Cooper (1955) state that primary sarcomata occur most frequently in the right auricle and right ventricle—a point also noted by Prichard. Of Yater's (1931) series of 48 sarcomata, 18 were in the right auricle—an extension of Mandelstamm's (1923) series of 11 primary malignant tumours in this site out of a total of 26.

There are several types of clinical picture arising from tumour of the right auricle. In a discussion of myxoma Bahnson and Newman (1953) mention four possible syndromes: (a) obstruction or regurgitation at the auriculo-ventricular valve, varying with time and the position of the patient; (b) syncope and reactional tachycardia with positional changes; (c) dyspnoea; and (d) a syndrome resembling subacute bacterial endocarditis. Weller (1940) emphasizes the symptoms of respiratory involvement and also describes two cases with superior vena caval block. Hurst and Cooper mention that inferior vena caval obstruction may be the presenting feature. Whorton also notes this and quotes four cases from the literature. In one of these (Raw, 1898), although the fibrosarcoma had infiltrated directly into the inferior vena cava causing thrombosis of the upper third, the clinical picture was rather that of dyspnoea due to haemorrhagic pleural effusion.

In the present case the original two episodes of collapse may well have been due to temporary impaction of the tumour in the A.V. ring. Subsequently intermittent obstruction of the inferior vena cava occurred, giving rise to acute hepatic congestion and pain. Eventually, as a result of this repeated obstruction, thrombosis of the inferior vena cava

occurred, producing oedema, albuminuria, and enlargement of the liver. The next stage would appear to have been impaction of the tumour in the tricuspid orifice, when the harsh to-and-fro murmur was discovered, the patient dying within three days. The fact that the liver was soft and tender in the presence of slight jaundice, normal liver-function tests, and the absence of fever might have suggested that it became congested only when the signs of inferior vena caval obstruction were noted. An acute obstruction as anatomically high as this should then lead to consideration of a tumour of the right auricle as a possible cause, particularly as collapse with a sense of impending death is so frequently a symptom of an intra-auricular mass.

In the present case, although the tumour is regarded as a fibrosarcoma, the polypoidal appearance and the absence of infiltration suggest that, if it had been diagnosed, surgical removal might have been feasible.

Summary

A case of fibrosarcoma of the right auricle in which the tumour gave rise to the clinical picture of acute obstruction of the inferior vena cava is described.

The relevant points in the literature are briefly reviewed.

It is suggested that this type of case, if diagnosed, may be amenable to surgical treatment.

I should like to thank Dr. Monica Hurst for her detailed notes on the patient's progress before entering hospital. The pathological reports were prepared by Dr. Charles St. Hill, and the slides by Mr. Elliot, senior laboratory technician. I am also grateful to Mr. R. Doyle and Dr. R. W. Brookfield for permission to publish this case.

ALEUKAEMIC MYELOBLASTIC LEUKAEMIA

EFFECT OF CORTISONE THERAPY

BY

R. B. THOMPSON, M.D., M.R.C.P.

Department of Medicine, Royal Victoria Infirmary and
King's College Medical School, Newcastle upon Tyne

AND

S. G. M. MACKAY, M.B., B.S.

General Practitioner

[WITH SPECIAL PLATE]

That cortisone may have an adverse effect on at least some cases of myeloblastic leukaemia is not generally accepted; the course of the illness described in this paper, however, provides evidence that such therapy may sometimes be disastrous. The case is also of interest in that it supports the suggestion that certain cases of "aleukaemic myelosis" and "myeloproliferative syndrome" bear a close relationship to frank myeloid leukaemia.

Case Report

The patient was a woman aged 51 years. Her initial complaints of lethargy, exhaustion, and shortness of breath for one month had by the time of her first clinical examination become extreme. Increasing pallor had been observed

for the same period; there was also loss of appetite and a fall in weight by over 8 lb. (3.629 kg.). Apart from increased frequency and amount of menstrual loss over the previous year there had been no history of bleeding. From childhood until the age of 32 she had been treated from time to time with iron preparations. Two years before the present illness she had probably suffered from methaemoglobinemia following sulphonamide therapy; at this time her blood count was normal. This was the only history of exposure to any potentially toxic substance. The patient's mother was known to have received regular treatment following a clinical diagnosis of pernicious anaemia. Physical examination revealed marked pallor without any hint of icterus. The liver, spleen, and lymph nodes were not enlarged; there were no skin lesions, no purpura, and no sternal tenderness. There were occasional spikes of fever up to 100° F. (37.8° C.).

The initial blood count showed: R.B.C. 2,890,000 per c.mm.; haemoglobin 7.6 g. per 100 ml. (51%); P.C.V. 22 c.cm. per 100 ml.; M.C.V. 76 c.μ; M.C.H. 26.0 μg.; M.C.H.C. 34.6%. The reticulocyte count averaged 0.4%. The white cell count averaged 3,000 per c.mm.; initial differential counts were neutrophil polymorphs 60%, lymphocytes 37%, monocytes 2.5%, and plasma cells 0.5%. Platelets appeared scanty on smears and counts averaged 80,000 per c.mm.; no abnormal forms were seen. Bilirubin was less than 0.1 mg., iron 152 μg., and urea 47 mg. per 100 ml. of serum. Alkaline phosphatase was 7.8 units (Jenner and Kay). There was histamine-fast achlorhydria. Radiological appearances of chest and upper gastro-intestinal tract were normal. A very small amount of marrow was aspirated with difficulty from one iliac crest; the specimen was too poor for detailed differential counting, but erythropoiesis was clearly normoblastic and no abnormal cells were found. A rib biopsy showed normal bone; the marrow spaces, however, were largely filled by proliferating fibroblasts (Special Plate, a) and scattered among these were normal marrow cells, with a predominance of the granulocytic series; there were many reticulin fibrils (Special Plate, b). Repeated differential counts were made on the peripheral blood during the first ten weeks of observation. Occasional primitive myeloid cells were found and, more rarely still, normoblasts (see Graph). These findings were not considered surprising, in view of the fibrosis of the bone marrow. During this period the haemoglobin level was maintained by transfusion; the clinical picture did not change.

Because of the clinical findings and the diffuse fibroblastic proliferation in the marrow, together with a pancytopenia, treatment with cortisone was discussed. It was felt that such therapy might raise the haematological values and produce clinical improvement as well as possibly checking the fibroblastic proliferation. The possibility that the disorder might be related to myeloid leukaemia, and so might be made worse by cortisone therapy, was thought to be remote, and treatment was started on the 72nd day of observation. At first the effect was gratifying; the patient's clinical condition improved and she felt stronger than for some weeks. Within eight days a remarkable outpouring of primitive myeloid cells began, however, and the cortisone dosage was reduced. The initial clinical improvement was not maintained on this reduced dosage, however, and the patient began to complain of weakness and severe pain in the limbs. After much discussion the dosage of cortisone was raised, and there followed a return of well-being and disappearance of the limb pain. An even more remarkable rise in total white cell count then occurred with an increase in

production of primitive myeloid cells; indeed, the peripheral blood picture became frankly leukaemic. The spleen became palpable for the first time, the tip reaching two to three fingerbreadths below the costal margin. Cortisone was then withdrawn and a course of 6-mercaptopurine was given with a very satisfactory haematological response. The total white cell count fell and the leukaemic cells almost disappeared. Transfusion was required less frequently; indeed, the haemoglobin level began to rise spontaneously. Clinical improvement was not so satisfactory, and after a period of intense weakness the patient died suddenly on the 175th day of observation. Unfortunately, necropsy was not performed.

Discussion

There seems no doubt that the patient was suffering from an unusual variant of myeloid leukaemia. This type of case has been well discussed in recent years by Heller *et al.* (1947), Merskey (1949), Dameshek (1951), Hutt *et al.* (1953), and Black-Schaffer and Stoddard (1953). These authors have stressed the close relationships which these cases have to chronic myeloid leukaemia on the one hand and polycythaemia on the other. It has been suggested that proliferation of marrow cells is the common factor which in some cases leads to the production of excessive granulocytes and in others to excessive erythrocyte formation. Either condition may be accompanied by a thrombocytosis and by fibrosis of the marrow, or the latter may be the predominant feature. The true nature of the underlying process in cases showing mainly myelofibrosis is usually very difficult to determine. The course of the case here described would certainly support the contention that some at least of these cases are very closely allied to myeloid leukaemia. This concept of myelofibrosis excludes, of course, those cases secondary to granulomatous deposits in tuberculosis, sarcoid, and Hodgkin's disease, secondary to carcinomatous deposits, and resulting from various chemical and physical agents. The case described here differed from most published cases of "myeloproliferative disorder" or "aleukaemic myelosis" in having no splenomegaly until the terminal leukaemic phase. A similar case (Case 2) was recorded in the series reported by Hutt *et al.*

Graph showing haematological findings and treatment.

(1953); here, however, the fibrosis was more pronounced and there was no leukaemic phase comparable to that seen in the present instance.

We have been unable to find a record of any similar case treated with steroids. Gray and Taylor (1953) have, however, reported a patient with an acute systemic reticuloendotheliosis who developed a frank monocytic leukaemia while on A.C.T.H. therapy. That steroid therapy might be harmful in at least some cases of acute myeloblastic leukaemia, in contrast to the remarkable though temporary remissions often obtained in lymphoblastic leukaemia, has been suggested by several authors (Rosenthal *et al.*, 1951; Fessas *et al.*, 1954; Björkman, 1956). Very recently Joseph and Levin (1956) have described a very interesting case of monocytic leukaemia in which cortisone made the leukaemia worse. One of us (R. B. T.) has further unpublished evidence pointing to the same conclusion. On the other hand, steroid therapy is recommended for both lymphoblastic and myeloblastic leukaemias by Scott (1955), and by Hayhoe and Whitby (1955), although it is clear that the responses in myeloblastic leukaemia are poorer. It seems likely, therefore, that not all myeloblastic cases show acceleration of the leukaemic process under the influence of steroids. At present there is no method of distinguishing one type of case from the other except by clinical trial of steroids. It is, admittedly, often difficult to distinguish acute lymphoblastic from acute granulocytic leukaemia. With care, however, such a distinction is usually possible with the exception of occasional very acute cases showing no evidence of differentiation. In these a diagnosis of stem-cell leukaemia must be made; most of them seem to react as lymphoblastic leukaemia. In view of the disastrous effect of steroids in the case described above it does seem important to make as accurate a diagnosis of the type of leukaemia as possible and to bear in mind the possibility that an adverse effect may be obtained in the myeloblastic type.

Summary

An unusual case of aleukaemic myeloid leukaemia with fibroblastic proliferation in the marrow is presented which, on treatment with cortisone, became frankly leukaemic and ended fatally in spite of a haematological remission with 6-mercaptopurine therapy.

Acknowledgments are due to the Departments of Pathology and of Photography, King's College, Newcastle upon Tyne, for sections and photographs respectively.

Manchester Royal Infirmary

[WITH SPECIAL PLATE]

Haemangioma of the gastro-intestinal tract is a very uncommon condition, rarely diagnosed without laparotomy. Like Guy and Cooper (1950), we believe that this warrants the reporting of all cases. The case we now describe is instructive in that the diagnosis was not suspected before operation, and the result of exploratory laparotomy and excision of the lesion was dramatically favourable.

Case Report

A man aged 46 was admitted to hospital in the early hours of April 29, 1955. On the previous evening, while driving his car, he suddenly felt faint and had a desire to defaecate. He managed to drive home—a few miles—and then passed a stool mixed with bright red blood. Six days previously he had had a brief spell of nausea, vomiting, and diarrhoea which he attributed to something he had eaten, but he had felt perfectly well on the day of onset of the rectal bleeding. He had always been a healthy man, though five years previously there had been a little rectal bleeding, said to be due to haemorrhoids. There had been no weight loss and no dyspepsia.

On admission he was not shocked, though his own doctor had found him to be in a state of shock about an hour before. Abdominal and rectal examination revealed no abnormality except the presence of fresh blood in the rectum. Next morning he was passing dark fluid blood; his haemoglobin was 74%. There was no evidence of any abnormal bleeding tendency.

Over the next seven days three attacks of melaena associated with shock occurred, and on each occasion blood transfusion was required. During this week the haemoglobin level was never above 60% in spite of the infusion of a total of 6 pints (3.4 l.) of whole blood and 2½ pints (1.4 l.) of packed red cells. On May 2, after the second attack of bleeding, he was seen by one of us (A. F. R.), and it was decided that any further bleeding would necessitate urgent operation. Thereafter his progress was observed jointly by the medical and surgical units concerned. Operation was finally performed on May 6 after the third attack of bleeding, which, like the others, led to a rapid deterioration in the patient's general condition. At no time had there been abdominal tenderness or any sign of a local lesion in the abdomen, and a definite pre-operative diagnosis was not made. The following possibilities were considered (in order of likelihood): ulcerated Meckel's diverticulum; proximal colonic neoplasm; duodenal ulceration.

Exploration through a right paramedian incision centred opposite the umbilicus revealed distension of the lowest 6 ft. (180 cm.) of the ileum and of most of the proximal colon by an accumulation of blood. Just below the upper limit of the distended length of ileum there was a dimpling of the antimesenteric border with an underlying hard,

APRIL 27, 1957

HAEMANGIOMA OF SMALL BOWEL

BRITISH
MEDICAL JOURNAL 991

globular, intramural nodule about ½ in. (1 cm.) in diameter (see accompanying drawing). The stomach, duodenum, and jejunum appeared normal, and no Meckel's diverticulum was found; the nodule was therefore judged to be the source of the bleeding. Accordingly a generous resection of over 8 in. (20 cm.) of ileum and its mesentery was carried out, being planned to allow for possible malignancy. Repair was effected by end-to-end anastomosis.

There was no more bleeding after the operation and the patient went home on the 15th post-operative day after an uneventful convalescence. He was seen again four weeks later, when he felt in normal health and showed no evidence of anaemia.

Pathological Report

The specimen consists of a loop of ileum 20 cm. long, together with part of its mesentery. On the mucosal surface, on the antimesenteric border, is a firm, blue, sessile polyp 1 cm. in diameter, at the apex of which is a cup-shaped depression 3 mm. in diameter. The cut surface shows the bulk of the polyp to consist of a blood clot surrounded by grey tissue, the whole covered by mucosa except at the apex, where the clot protrudes through the central depression (see Fig.). The muscularis is intact deep to the lesion.

Drawing of tumour. Note central depressed area.

Microscopically, in the submucosa there is a large, solitary, saccular vascular dilatation which has ruptured through the surface mucosa; its wall consists of smooth muscle and fibrous tissue with a small amount of elastic tissue externally; its lumen is plugged with recent thrombus. In serial sections the dilatation appears to arise from the artery to the right (see Special Plate). The vascularity of the submucosa around the lesion is no greater than that seen elsewhere in the specimen.

The lesion is clearly a vascular hamartoma; there is no evidence of a progressive neoplasm.

Discussion

Life-saving emergency operations often have to be performed to stop bleeding from duodenal and gastric ulcers. Operations for bleeding Meckel's diverticulum and bleeding oesophageal varices are also familiar, but operations for bleeding haemangiomas of the intestine must be rare, either in emergency or otherwise.

Haemangiomas may be found either in the small or the large bowel, the former being the commoner site. According to Raiford (1932) they form only 0.3% of all gastrointestinal tumours and 3.4% of tumours of the small bowel themselves rarities. They are almost always benign, there

being only two recorded instances of malignancy, both affecting the small bowel. Brown (1924) and Kaijser (1936) consider and classify the intestinal haemangiomas in detail, and Hansen (1948) gives a most useful review of the 85 cases he found described in the literature between 1860 and 1948. His figures show that in the small bowel the tumours are often multiple, though single lesions as in the case here described, generally cavernous and polypoid in nature, are found in about 40% of cases.

The clinical presentation may take one of the following forms: (1) chronic haemorrhage, causing an unexplained anaemia with occult blood in the stools; (2) acute haemorrhage, as in this instance; (3) obstruction, acute or chronic, and sometimes the result of intussusception; (4) inflammation of the lesion itself, simulating appendicitis. In presentations (3) and (4) laparotomy is likely to be carried out without delay and the nature of the lesion soon discovered. But in (1) the diagnosis is often not made until the anaemia has been unsuccessfully treated medically for many years. In (2) the diagnosis of haemangioma will seldom be made. Even if it is considered, the alternatives of duodenal or Meckel's diverticulum ulceration are certain to appear much more likely sources of haemorrhage. This could even apply at laparotomy, much as in an operation reported by Smith *et al.* (1944) in which a radiologically detected duodenal ulcer was thought to be the source of bleeding; in actual fact the bleeding arose in an undiscovered leiomyosarcoma of the jejunum.

Associated angiomatous lesions in the skin and visible mucous membranes may suggest the diagnosis to the clinician, as in the cases reported by Rickham (1952) and by Heycock and Dickinson (1951). This association emphasizes the fact that the vascular lesions are developmental anomalies and not true neoplasms. In the present case there were no visible lesions.

In these days there is no need to stress the value of surgical treatment in cases of recurrent acute gastrointestinal haemorrhage. In reporting this case we hope to show that the diagnosis haemangioma should be considered before operation and that a search should be made for haemangiomas at the time of operation, even in the presence of an obvious peptic ulcer. This search is even more necessary before embarking on the usual empirical gastrectomy in those cases where no peptic ulcer is found.

The surgeon should not have a difficult task at operation unless the lesions are multiple. Bentley (reported by Heycock and Dickinson) in a two-stage operation, had to make 23 separate mural incisions and resect 5 cm. of bowel in a patient with 30 haemangiomas of the small bowel. The more usual difficulty will be one of diagnosis.

Summary

A case of acute intestinal bleeding in which an urgent operation became necessary because the bleeding persisted in spite of repeated blood transfusion and other medical treatment is reported. Owing to the absence of any significant previous history and any abnormality on abdominal examination, no precise diagnosis could be made pre-operatively, although duodenal ulceration, ulceration in a Meckel's diverticulum, and colonic neoplasm were thought to be likely causes. The source of the bleeding proved to be an angiomatous lesion in the ileum, and resection of a short segment of ileum led to complete cure.

The literature is reviewed and the various syndromes produced by angiomata of the intestine are discussed. It is suggested that this type of lesion should be considered as a possible diagnosis in cases of chronic anaemia with occult blood in the stools as well as in cases of acute intestinal haemorrhage. It is also pointed out that if these latter come to operation it is as well to

bear in mind the possibility of angioma even when a peptic ulcer is actually found at laparotomy, and especially when no such ulcer can be found.

We are grateful to Dr. C. S. D. Don and to Mr. R. L. Holt for permission to publish this case. Miss D. Davidson, Medical Artist, Manchester Royal Infirmary, kindly provided the drawing of the specimen.

Medical Memorandum

Death following Injection of Paraffin into the Breast

Up to 20 years ago in Hong Kong it was considered indecent for Chinese women to have even a suggestion of a figure, and it was common for them to wear tight clothing to flatten their busts. But the advance of modern ideas, particularly through the medium of Western films, has changed this attitude. One method of improving the figure is the injection of liquid paraffin into the mammary glands, based on the use of such injections into the tissues in plastic operations, such as for the correction of nasal deformity. This has been practised indiscriminately, in some cases causing severe pain and leading to infection and sloughing.

In the following case the injection of paraffin into the breast for cosmetic reasons resulted in death from fatty embolism in the brain and lungs.

CASE REPORT

A Chinese woman aged 32, the mother of four children, who had been in poor health for some time, had arranged with a nurse to have a total of eleven injections of paraffin into her breasts to improve her appearance. She received the first three injections into the right breast at 3 p.m. on May 5, 1954. During and soon after the injections she experienced extreme pain and discomfort. Four hours later she felt giddy and faint and complained of severe headache. Her husband applied some Chinese medicinal oil to her face, forehead, and temples, and this seemed to relieve her. By 10.30 that evening she appeared to be asleep. About midnight she cried out, apparently in great pain, and this continued at intervals throughout the night. Early next morning her condition was worse, and a doctor was called in. He found her semicomatose and restless, with closed eyes; she was afebrile, but had a pulse rate of 100 per minute, regular but weak. Pupils were slightly dilated and reacted to light, more sluggishly on the left. Knee-jerks were exaggerated, but there was no neck rigidity or paralysis of extremities. Nothing significant was found in heart and lungs. There was no sweating. After prescribing for her he left.

As her condition did not improve another doctor was summoned at about 12.30 p.m. She was still semicomatose and with dilated pupils, but her right breast had become swollen and tender. Immediate removal to hospital for observation and treatment was advised.

By midnight the patient's condition had not improved despite energetic care, and a third practitioner was called in in consultation. She was then unconscious, with a temperature of 102° F. (38.9° C.) and incontinence of urine and faeces. The pupils were dilated and reflexes still present. The right breast was hot to the touch and swollen, and three puncture marks were noted. A diagnosis of cerebral paraffin embolism was suspected; ice packs were applied and nikethamide and nicotinic acid injections prescribed.

The patient was transferred next day to Queen Mary Hospital under the care of Professor A. J. S. McFadzean.

She was still unconscious, but her temperature had fallen to 100.5° F. (38° C.). She reacted to painful stimuli, and both pupils were small and reacted sluggishly to light. On auscultation there was diminished air entry with rales over both bases. Her condition progressively deteriorated and the coma deepened in spite of treatment, and she died 24 hours after admission. Necropsy was performed 20 hours later.

Post-mortem Findings.—The lips and nail-beds were cyanotic. The right breast was swollen and had three puncture marks, at 2, 5, and 9 o'clock, each about 5 in. (12.7 cm.) from the nipple. On reflecting the breast from the surface of the pectoralis major muscle about 10 ml. of clear oily fluid exuded from the under surface of the mammary gland. Incisions into the breast just under the puncture marks, and particularly in the lower medial quadrant, revealed globules of clear oil, which exuded from the yellow, semi-solid fatty tissue. A small haematoma mixed with oily fluid was present in the gland under the puncture mark at 9 o'clock. In the heart a thick layer of fat was visible under the visceral pericardium. The myocardium was soft and flabby. Petechiae were present on the endocardial lining and papillary muscle of the left ventricle and on the left interventricular septum. The bronchi contained frothy sanguineous fluid. The lungs were red and soft, with numerous petechiae on the surface. The cut surface was intensely congested. On squeezing the lung, frothy fluid mixed with oil globules exuded. Section of the kidney revealed a pale cortex and a slightly redder medulla. In the brain nothing abnormal was found in the basal arteries and soft meninges, but the cortical vessels were congested. The cut surface showed numerous minute petechiae spread over the white matter of the cerebrum.

Staining frozen sections prepared from brain and lung tissues with Sudan III resulted in red droplets appearing in the capillaries. These were considered by Professor P. C. Hou to be droplets of neutral fat, on the basis of an experiment in which he stained with Sudan III a mixture of liquid paraffin with human (neutral) fat, the fat droplets taking the stain but not the paraffin droplets.

DISCUSSION

When adipose tissues are lacerated, fat globules may enter ruptured venules and veins at the site of injury and be carried to the lungs. Most of the globules which reach the lungs are held up initially in the small arterioles, but by a process of moulding many of them ultimately pass through the pulmonary capillaries into the systemic circulation, in which they are carried to all tissues of the body and become lodged in the arterioles of such organs as the brain and kidneys.

The way in which fat globules enter lacerated or ruptured veins has not yet been established. In the case here described a blood vessel was ruptured, resulting in haematoma; in addition the high force needed to inject the liquid paraffin into the breast caused some displacement of the patient's own fat globules into the blood stream.

In cases of bone fracture it has been claimed that haematoma formation and inflammatory reaction at the site of fracture create a positive pressure in the marrow cavity which forces damaged fat cells into the veins. It has also been claimed that there is a negative pressure in the marrow cavity and that this has the effect of "sucking" damaged fat cells into the veins.

It is of interest that at the inquest on this patient the jury returned a unanimous verdict of manslaughter, and a warrant for the arrest of the nurse was issued by the magistrate sitting as coroner.

I am grateful to Professors A. J. S. McFadzean and P. C. Hou, of the University of Hong Kong, for their help; to the Honourable Director of Medical Services, Hong Kong, for permission to publish this report; and to the Commissioner of Police, Hong Kong, for access to his files.

Police Surgeon, Hong Kong.

Reviews

FORENSIC MEDICINE

Practical Forensic Medicine. By Francis E. Camps, M.D., and W. B. Purchase, C.B.E., M.C., M.B., D.P.H. Foreword by H. Edmund Davies, LL.B., B.C.L. (Pp. 541; illustrated. 75s.) London: Hutchinson's Medical Publications Ltd. 1956.

This book represents the active collaboration of a medical practitioner and a barrister who is also one of H.M. coroners. Since they are both highly experienced, practical men, it is to be expected that something good would result from their co-operation. The reader will not be disappointed. The first occasion, I think, on which such a combination occurred was in 1823 when Paris and Fonblanque wrote a three-volume treatise on medical jurisprudence. That work was rightly acclaimed as an elaborate and scholarly production. Since that date, although lawyers have contributed to several publications, there have been few if any examples of close co-operation between the two professions of law and medicine in the preparation of a textbook.

This book by Camps and Purchase makes excellent reading, although the space allotted to different subjects is very uneven. The article on identification, for example, which is very good, takes up about an eighth of the book excluding toxicology, whereas the sections dealing with the medico-legal necropsy, the examination of blood, semen, hairs, fibres, etc., are much too brief. Similarly, in a most informative article on the barbiturates, with a wealth of interesting cases, there is little if any advice about the treatment of a case of poisoning due to a barbiturate, and no instructions about how to wash out the stomach. The absence of an index is a defect which should be remedied in the next edition. The book is excellently printed and bound and is a credit to the publishers. It should be in the library of all those interested in forensic medicine. Its usefulness to the general practitioner in an out-of-the-way place and who is not likely to have more than one book on the subject is not so clear.

SYDNEY SMITH.

SCIENCE AND CRIME

The Scientific Investigation of Crime. By L. C. Nickolls, M.Sc., A.R.C.S., D.I.C., F.R.I.C. (Pp. 398 + xiii; illustrated. 50s.) London: Butterworth and Co. (Publishers) Ltd. 1956.

The author of this book is the director of the forensic police laboratory at New Scotland Yard and has drawn on a vast experience of forensic work to produce a book which is informative, instructive, and eminently readable.

"Contact traces" is an expression frequently used to indicate the trail which a criminal may leave on his surroundings, or which the surroundings may leave on the criminal. The most obvious example of a contact trace is a fingerprint. There are, of course, many others such as blood, semen, dust of botanical or mechanical origin, and marks made on or by instruments and weapons. In this book the author describes first the lay-out of an up-to-date police laboratory, with an enumeration of the more important apparatus necessary for the identification of contact traces. This chapter will be of great interest to any laboratory worker, irrespective of his specialty. There follows a chapter on the type of material which is likely to be available at the scene of a crime and a description of the various methods of recovery of such evidence, with practical advice on storage and transport. The following chapters deal in detail with the identification of soils, paint, wood fragments, body fluids, and a host of other materials. Further information of a highly technical character is given on such subjects as the restoration of obliterated marks and impressions and the deciphering of damaged and altered documents. A chapter on alcohol determination in blood and urine gives the precise details of the modern methods of such analysis, and in the final chapter

on toxicology the author wisely confines himself to a discussion of the broad principles entailed in the identification of common poisons.

The book is particularly well illustrated with a wealth of photographs and many simple but informative diagrams. In some cases the captions are not sufficiently clear to readers who are not constantly practising forensic science, and recourse to the text is necessary for clarification. The price of 50s. places this book somewhere between an ordinary textbook and a reference book, which is probably its proper place. The author would, I am sure, be the last person to describe his work as a medical textbook. It will, however, be of great value to members of this profession who are obliged to carry out forensic investigations because of the absence of local forensic science laboratories. And, without belittling the book in any way, the numerous amateur detectives in the medical profession will find it most absorbing reading.

DONALD TEARE.

MENTAL DEFICIENCY

A Textbook of Mental Deficiency. First compiled by the late A. F. Tredgold, M.D., F.R.C.P., F.R.S. Ed. Ninth edition by R. F. Tredgold, M.D., D.P.M., and K. Soddy, M.D., D.P.M. (Pp. 480 + xv; illustrated. 40s.) London: Baillière, Tindall and Cox. 1956.

It is sometimes overlooked that mental deficiency is a field in which a number of major advances have been made in recent years and in which current views have undergone a great deal of revision, especially those concerned with aetiology and the social aspects of backwardness and defect. Recognition of several new syndromes with a simple genetic determination and of a number of new pre- and post-natal noxae which can disturb the maturation of the nervous system has bitten deep into the formerly large group of "simple amentia," and theories such as those of blastophoria and neuropathic taint have become obsolete in the face of increased evidence of inheritance through single and multiple unitary traits. When A. F. Tredgold's textbook was published in 1908, it documented the accumulated experience of a very original observer, and for many years it was rightly considered the best introduction to the subject. Many of Tredgold's views have stood the test of time, but by the seventh edition the text was beginning to fall behind, some of the case reports and illustrations were not representative of the defective as now seen, and notable new research was not recorded. In the present edition, while much of the original form has been retained the whole text has been revised and the results of new work incorporated without overloading.

The presentation of the subject at the outset is clear and systematic. There is sometimes an unnecessary tendency to preserve the form laid down by the original author, especially in classification, and to ensure that he is still given personal credit for ideas which are by now common property, but with this the reader will readily sympathize. The sections on the pathology and chemistry of defect rather lag behind the rest, and R. F. Tredgold's original drawings of neurones will surely have to be left out or replaced by modern photographs in the next edition, as will a few of the older illustrations. The chemistry of the defective brain is discussed in less than half a page, and the discussion of cerebral function generally lays an almost exclusive stress on the cortex, which is out of keeping with the present interest in basal structures. In spite of this, the more striking new work on neurones, blood vessels, and fibre-systems in defect receives adequate mention. A valuable feature is the attention given to environmental factors and to the special characteristics of the defective psyche in conditions of maladjustment. In a long chapter on disorders of relationship formation the frame of reference and classification are of psycho-analytic origin, but, if the relevance of this may be disputed, the case histories carry conviction and illustrate well the total approach to the defective which is essential if the best use is to be had from his meagre wit. One will be sorry to lose the detailed

description of J. H. Pullen, the "genius" of Earlswood Asylum, but this must be positively his last appearance.

Teachers of psychiatry whose hesitation to recommend "Tredgold" to beginners in the field of mental deficiency has increased with the last few editions will be much reassured by the radical revision which has been undertaken, and it is probable that this venerable text will now take a new lease of life and add itself to the few exceptions to the usual rule that "they never come back."

ALEXANDER KENNEDY.

PROGRESS IN HAEMATOLOGY

Progress in Hematology. Volume I, 1956. Edited by Leandro M. Tocantins, M.D., with 27 contributors. (Pp. 336+ix; illustrated. \$9.75.) New York and London: Grune and Stratton, 1956.

In his editorial introduction to this first volume of *Progress in Hematology* Tocantins refers to the remarkable expansion of investigations and knowledge that has taken place during the last 20 years in haematology, and explains that the intention of this publication is to provide a periodical survey of the existing position in fields where substantial advances have been made. The frequency of future volumes in the series will depend on the response to the first and on the number and state of advance of current topics as they develop.

The standard of the 16 contributions making up this work is high, and together they undoubtedly go a long way towards achieving the editor's expressed intention. No haematologist who wishes to maintain a broad acquaintance with work in the many subdivisions of his subject would fail to welcome this book and to look forward to future volumes. The articles which offer critical reviews of fairly broad subjects are particularly valuable. "Abnormal Hemoglobins" (39 pages, 211 references) by Zuelzer, Neel, and Robinson, "Chemotherapy of Human Leukemia" (20 pages, 146 references) by Burchenal and Ellison, and "The Biochemistry and Enzymatic Activities of Leukocytes in Health and Disease" (15 pages, 66 references) by Valentine, exemplify this excellent aspect of the work. Valuable though they are, all these articles suffer from the inevitable disadvantage that the processes of publication in book form, however fast, render each review to some extent outdated by the time it appears. The same criticism applies to several otherwise admirable reviews of more restricted fields, such as Ungley and Thompson's "Gastric Intrinsic Factor and Vitamin B₁₂ Interrelationships" (15 pages, 127 references), Brown and Moore's "Parenterally Administered Iron in the Treatment of Hypochromic Anemia" (18 pages, 158 references), and Strumia's "Life Span of Erythrocytes and their Post-transfusion Survival" (14 pages, 42 references). In general all these review articles give satisfactory summaries of the position in the latter half of 1955.

Apart from one or two articles of very restricted range which might more appropriately have been published in some current haematological journal, the surveys presented here emphasize the rapid growth of haematology and endorse the need for the kind of periodical review envisaged in this projected series.

F. G. J. HAYHOE.

IN HONOUR OF NISSEN

Chirurgische Indikationen. Dedicated to Rudolf Nissen. (Pp. 299+xii; illustrated. D.M.42.) Stuttgart: Georg Thieme Verlag, 1956.

This birthday offering to Professor Nissen from more than fifty of the leading surgeons of the world, his friends and colleagues, is a worthy recognition of what surgery owes to one whose career must have been unique. A pupil of Sauerbruch both at Munich and Berlin, he was sent by him to Constantinople, there to create the first great surgical school in Turkey. In 1940 he was called to New York, and after twelve years of brilliant work he was called four years ago to the professorship of surgery at Basle. In every field

of surgery he excelled, and as a teacher he was equally at home in German, French, or English.

These contributions in his honour come from the chiefs of great surgical centres all over the world; they are throughout of a very high order, and each of them represents some special interest of its author. We can mention only a few, but all are worthy of close study. Professor Jentzer, of Geneva, gives in French his wide experience of indications for operation in many different fields. Papper, of New York, discusses anaesthesia in the aged. Bing, of Alabama, describes the contribution of physiology to the surgery of the heart, and Bayer, of Düsseldorf, the surgical treatment of stenosis of the cardiac valves, while Mason, of Newcastle, discusses mitral valvotomy in pregnancy. Brunner, of Zurich, writes on the surgery of bronchiectasis, Welch, of New York, on splenectomy, and Bergmann, of New York, on prosthetic replacement of the femoral head. These few notes will at least show the range covered by these contributions from the leaders of surgery all over the world, but they can give no idea of the wealth of material here collected. This book should be made available to every surgeon in the country and every surgical library should possess it. We would all like to share in the honour so well paid to Professor Nissen.

HENRY SOUTTAR.

BONE STRUCTURE AND METABOLISM

Ciba Foundation Symposium on Bone Structure and Metabolism. Editors for the Ciba Foundation: G. E. W. Wolstenholme, O.B.E., M.A., M.B., B.Ch., and Cecilia M. O'Connor, B.Sc. (Pp. 299+xii; illustrated. 45s.) London: J. and A. Churchill Ltd., 1956.

Since its inauguration in 1949 the Ciba Foundation has arranged a series of symposia on various subjects of medical interest, and at each of these a number of selected research workers have been able to meet informally in order to exchange ideas and information on a particular subject. In July, 1955, such a symposium was devoted to bone structure and metabolism and was attended by about 25 distinguished workers from Europe and North America. The present volume, edited by Dr. Wolstenholme and Miss O'Connor of the Ciba Foundation, is designed to bring the substance of the meeting to the attention of a wider audience. It takes the form of a series of papers, together with a more or less verbatim account of the informal discussion that followed each contribution. The book makes an interesting introduction to the considerable amount of very active research that is at present being carried out in the field of bone biology. Important topics discussed include chemical studies of bone salt and bone mucopolysaccharides, studies of isotope uptake and localization in bone and cartilage, the bearing of microradiographic and electron-microscopic techniques on the investigation of bone structure, the action and fate of vitamin D in the experimental animal, and the part played by vascular factors in bone pathology. From a clinical viewpoint, the symposium is notable for its discussions on the relations between parathyroid function and bone, "vitamin-D-resistant rickets," and the rare disease "hypophosphatasia." No outstanding synthesis of knowledge emerges from the discussions, but the book gives us an idea of the way skeletal research is developing, and lets us see something of the techniques it employs and the problems it encounters.

H. A. SISSONS.

The Approach to Mental Health, by Dr. David T. MacLay, has the great virtue of being written with exceptional clarity. Intended for the educated lay reader, the book offers a review of how the mind normally works; the emphasis is on the healthy mind, but the author aptly illustrates the normal by brief case-histories of the pathological. Though he introduces the reader to the work of the psycho-analysts and their allies, he pays his respects also to McDougall. The book is written with some delicacy; indeed, the discussion of sexual desires and their fulfilment, normal and abnormal, comes under "Social Aspects of Psychology." Not only the adult layman but the adolescent might find that this book suits his needs. It is published by Thorsons Publishers Ltd. for 12s. 6d.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY APRIL 27 1957

A CHANGING PICTURE

Two events in particular claimed the attention of the Council and the G.M.S. Committee when they met last week. The Central Consultants and Specialists Committee decided on April 10 to support the decision of the G.M.S. Committee, of the Public Health Committee, and of the B.M.A. Council not in present circumstances to co-operate with the Royal Commission. Immediately following this there was an exchange of letters between the chairman of the Joint Consultants Committee and the Prime Minister. Sir Russell Brain's next move was to summon a special meeting of the Comitia of the Royal College of Physicians of London four days before his successor was elected. After hearing the letters exchanged between the Prime Minister and the President of the College this poorly attended assembly thereupon decided to co-operate with the Royal Commission, thus departing from the recommendation of the four other bodies mentioned above, which represent the consultants and specialists, the general practitioners, and the medical officers of health of Britain. The next event, which likewise came as no surprise, was this announcement in the House of Commons by the Prime Minister on April 16: "The Government have now decided to increase the basic remuneration of senior hospital medical and dental staff, including consultants and specialists, and all dentists engaged in general dental service by 5% from May 1 next, and from the same date to add 5% to the aggregate net remuneration of general practitioners—that is, remuneration after the deduction of practice expenses. We propose to consult representatives of the profession as to the best method of distributing this sum between individual practitioners." This particular figure had been round the whispering galleries for some time, and had been mentioned in several newspapers a few days before Mr. Macmillan informed the medical profession of his arbitrary decision in the House of Commons, without any previous consultation with representatives of a profession which, in accordance with a covenant it had entered into with the Government of 1946 and 1948, submitted over a year ago a claim for increased pay. As the cost of living had gone up by 24% since the previous adjustment was made in the remunera-

tion of general practitioners, the claim was for an increase of 24%. In the face of the Government's No! under the present and the recent Ministers of Health, Dr. S. Wand, chairman of the B.M.A. Council—and in this capacity the key professional figure in the present dispute—has made it quite plain that the profession is willing, even anxious, that the present claim should go to arbitration, the results of which would be accepted. But Mr. Macmillan refuses this just as he denies to the profession the use of the customary avenues of direct discussion, negotiation, and, if necessary, arbitration. On behalf of the Government he dictates to doctors working in the health service an important part of their terms of employment, brushing aside all the customary conventions, not to mention courtesies, in this kind of human transaction.

The B.M.A. Council and the G.M.S. Committee had emergency meetings last week to discuss the significance of these events. The attitude of these two important bodies to the exchange of letters between Mr. Macmillan and the Chairman of the Joint Consultants Committee reflected that of the debaters in the House of Lords when it recently discussed this matter. Once the Government has got into the position of having to explain by means of letters what the terms of reference of a Royal Commission mean, it has really got to the point of admitting that the terms should be revised. It appears not to be impossible to have second thoughts about the terms of reference of a Royal Commission, and surely it would be much better to do this, and more dignified, than to pursue a course utterly distasteful to one side in the present dispute—unless, of course, the Government wants such a course. But in any event a Royal Commission is not the right body to settle a dispute over terms of service. In a letter to *The Times* the Chairman of Council, Dr. Wand, recently reiterated the profession's wish to get round the table, through its own representatives, with representatives of the Government, with the Minister of Health and his Department. This is a matter of principle. That is why the G.M.S. Committee last week passed a resolution against accepting the 5% award arbitrarily made last week by Mr. Macmillan, without any prior consultation whatsoever with the medical profession. The Committee is recommending to the Conference of Local Medical Committees that the amount of the award be put into a suspense account.

In the meantime support grows in meetings of the profession for the plan of withdrawal of general practitioners from the National Health Service. The C.C. and S. Committee of the B.M.A. have heartened their colleagues in general practice by their recommendation that consultants and specialists should give

them financial support in the coming struggle, a struggle which the Government could bring to an end to-morrow if it decided to negotiate a settlement or submit the claim to arbitration. In a letter to *The Times* last Saturday a group of doctors implied that the matter has shifted from the crude question of being paid the rate for the job to a question of principle. It is good that more doctors are beginning to realize this, but it has been a question of principle from the very beginning—the principle of contract, though that contract cannot be legally enforceable at law. It appears to us to be essential to stand unshakably firm by principle, and to avoid the quicksands of expediency. In the House of Lords a fortnight ago Lord Moran, in an able if bitter speech—and understandably bitter—seemed to hint that the B.M.A. regarded the two Spens Reports as a professional sacred cow. But he knows as well as anyone that the profession entered the N.H.S. in 1948 largely because it felt that the two Spens Reports gave it a guarantee of its future status in a state medical service. If the Government invited the medical profession to discuss with it an alternative formula—and discuss it on an equal basis and on agreed terms—surely it would meet with a favourable response. And what could be simpler or more reasonable? When the Conference and the Representative Body come to discuss the question of co-operating or not with the Royal Commission they will no doubt bear in mind Lord Moran's warning that the findings of the Royal Commission will be "taken seriously only if they are in the Government's favour."

MATERNAL AND FOETAL THYROID

The foetal thyroid accumulates radioactive iodine from the twelfth to the fourteenth week of gestation.^{1,2} After that time the thyroid is assumed to be capable of synthesizing thyroxine and of supplying the needs of the foetus. The infants of hypothyroid mothers are not cretinous at birth; this suggests that the infant is not dependent on the provision of maternal thyroxine. Nor does maternal thyroxine reach the foetus in sufficient concentration to prevent hypothyroidism occurring in the athyroid foetus, as judged by the retarded skeletal development of some cretins diagnosed during the first few weeks of life. It has sometimes been assumed that the presence of maternal thyroxine is responsible for the fact that cretinism is not obvious in the newborn infant, but a progressive failure of the infant's thyroid remnant provides an equally acceptable explanation. Placental passage of ¹³¹I-labelled thyroxine has, however, been proved to occur.³ Passage was slow, and 169 hours had passed

before the concentration in the foetal serum had reached 49% of that in the maternal serum.

E. B. Man⁴ has recently reported that the thyroxine-like iodine (butanol-extractable iodine) in the serum of pregnant women rises to 7.0 $\gamma\%$ (normal 3 $\gamma\%$ to 7 $\gamma\%$) at the tenth week of pregnancy and stays at this level, or above, until term. Pregnant women with B.E.I. levels below these normals frequently abort or bear infants with various abnormalities. Man concluded from these facts that this "hypothyroidism" in the mother produces disease in the foetus and that such women should be treated with thyroid in their pregnancy. Clinical maternal hypothyroidism has not yet been shown to produce disease in the child, and S. Ingbar,²¹ in the discussion that followed her paper, put a very different construction on these facts by stating that the serum protein in the plasma of pregnant women has an increased capacity to bind thyroxine. Moreover, by giving 30 mg. of stilboestrol daily to a variety of non-pregnant subjects, Ingbar found that the thyroxine-binding capacity was enhanced.

If the maternal thyroxine passed the placenta in any quantity it would prevent not only the development of the foetal thyroid but also the production of the thyrotropic hormone (T.S.H.) by the foetal pituitary. If the T.S.H.-thyroid mechanism is established in the foetus, the placental passage of either T.S.H. or the thyroid hormone would interfere with its full development and function. Even if such a passage does not normally occur, it might take place in disease in which, for example, an excess of either T.S.H. or thyroxine is circulating in the maternal blood. It has been shown^{5,6} that the highest levels of T.S.H. are found in hypothyroidism, and though the birth of children to hypothyroid women is by no means uncommon (assessed, it is true, by retrospective history-taking) only one baby with an abnormal thyroid condition (hyperthyroidism) has so far been reported as born to a hypothyroid mother.⁷ These clinical facts

speak strongly against the passage of T.S.H. across the placenta, and they are supported by experimental evidence, for thyroidectomy in the pregnant rat does not cause hyperplasia of the foetal thyroid.⁸

Thyrotoxicosis has been described in infants born of thyrotoxic mothers.⁹⁻¹⁵ Some of these authors have taken this as evidence that T.S.H. has passed the placenta in excess and stimulated the foetal thyroid to the production of thyrotoxicosis in the infant. This might be accepted as a possible explanation, despite the evidence already cited that this is unlikely to be a normal mechanism, if it were not for the fact that the levels of T.S.H. circulating in thyrotoxicosis are either undetectable or low by the histological methods of assay used.^{5,6} However, I. C. Lewis and A. G. Macgregor¹⁵ point out that in the reported cases of congenital hyperthyroidism exophthalmos has been present (not in all¹⁴), and in their case and in those of M. O. Skelton and B. Gans¹³ severe exophthalmos was present in the mother. Sir Geoffrey Keynes¹⁰ has recorded a remarkable case in which a woman developed exophthalmos after thyroidectomy and subsequently became pregnant. Her baby was born without thyrotoxicosis but with exophthalmos and with lid retraction, which persisted for one year. Patients with exophthalmos have been shown to have a high level of circulating T.S.H.,^{5,6} but before conclusions are drawn about the passage of T.S.H. across the placenta it is well to remember that the pathogenesis of both thyrotoxicosis and exophthalmos is still the subject of much debate and speculation.

When antithyroid drugs have been given for maternal thyrotoxicosis, goitres in the baby have been described and the baby's thyroid condition has been reported as toxic,¹⁴ hypothyroid,¹⁶ and euthyroid.¹⁷ Three further cases are reported in the *Journal* this week (p. 979) by Drs. I. D. Riley and G. Sclare. Propylthiouracil given to the pregnant rat⁸ leads to hyperplasia of the foetal thyroid, and in the human cases it is usually assumed that the goitrogen passes across the placenta and inhibits the synthesis of thyroxine by the foetal thyroid. This results in increased production of thyrotrophin, with thyroid hyperplasia; after birth, when thiouracil no longer reaches the baby, a phase of neonatal hyperthyroidism may occur. The birth of goitrous babies to mothers who have been treated with antithyroid drugs emphasizes the need for care in the treatment of thyrotoxicosis in the pregnant woman. Keynes¹⁰ reported twenty-one successful cases of subtotal thyroidectomy in pregnancy, with only one stillbirth, and recommends that the operation should be done between the third and the seventh month of gestation.

Most physicians and obstetricians will prefer to give antithyroid drugs for thyrotoxicosis in the pregnant woman, and, if hypothyroidism is carefully avoided and if the drug is stopped three to four weeks before delivery, no harm to the infant thyroid should ensue. It is reasonable to treat thyrotoxicosis in the infant with both iodine and thiouracil¹⁵ (or neomercazone); occasionally severe respiratory obstruction by a large thyroid may require subtotal thyroidectomy.¹⁴

Where goitre is endemic, deficiency of iodine (possibly associated with genetic and other unexplained environmental causes) will produce neonatal goitre. In areas where goitre is not endemic, a neonatal goitre may be associated with the administration of iodine or iodide to the mother.¹⁸ This action of iodine is unexplained; it may be due to an inhibition of hormone synthesis¹⁹ or to an interference with T.S.H. activity in the thyroid gland and a consequent slow discharge of thyroxine.²⁰ Though much uncertainty still surrounds the exact pathogenesis of these hazards to the foetal thyroid, we can say that both neonatal goitre and thyrotoxicosis (but not cretinism) may be preventable.

SURGERY OF CORONARY ARTERY DISEASE

In the year that has elapsed since the surgical treatment of coronary artery disease was discussed in these columns¹ a few operations have been performed in Great Britain and experience in the U.S.A. has continued to enlarge. In particular, C. S. Beck, of Cleveland, Ohio, has carried out thousands of experimental operations during more than two decades, and recently many operations on human patients. With B. L. Brofman he has reported² 100 consecutive cases with no operative mortality. These authors point out that theoretically there are two ways of increasing the blood supply to an area of myocardium in which it is deficient owing to arterial disease—firstly by adding to the total blood flow to the heart, and secondly by altering the distribution of that flow within the heart muscle. Many operations aimed at increasing the entering flow may in fact have no such effect, but nevertheless be successful by acting in the second way. This was the result of the difficult operation of anastomosis of the aorta to the coronary sinus, now abandoned; the reversed flow of arterial blood lasted only a few weeks, but by then inter-coronary anastomoses had developed, with benefit that lasted much longer. T. M. Zoll and colleagues³ investigated the frequency of naturally occurring anastomoses between terminal branches of the coronary arteries, and found they are present in fewer than one in ten healthy hearts; when coronary arteries are narrowed to less

¹ *British Medical Journal*, 1956, **1**, 503.

than one-quarter the normal diameter, the incidence is increased to more than one in two; and, when total occlusion occurs as a chronic process with survival, intercoronary anastomoses are always found. If these anastomoses can be artificially produced or increased, the likelihood of survival with further progress of coronary disease is enhanced. This is the aim of Beck's present operation. It consists in four manœuvres: abrasion of the lining pericardium and epicardium to cause inflammation; instillation of powdered asbestos to maintain it and stimulate the formation of vessels; application of mediastinal fat as a graft, for the same purpose; and partial ligation of the coronary sinus, since this, like the other measures, has been shown to cause the formation of intercoronary anastomoses and to protect the experimental animal against the effects of coronary ligation. The present indications accepted for the operation are coronary insufficiency and angina pectoris, and one or more infarcts; but it is advised that at least six months should have elapsed since the last infarct. Congestive heart failure, marked enlargement of the heart, and rapidly progressive symptoms are contraindications.

This operation, like present-day medical treatment, does nothing to restore the lumen of the obstructed coronary artery. Though anticoagulant therapy may perhaps prevent the spread of thrombus, it too has no effect on the causative intimal lesion. Attempts have been made, even as an emergency operation, to evacuate clot and cholesterol deposits and so restore the coronary lumen; but, since even in large arteries like the femoral such disobliteration operations are not at all reliable, success can seldom be expected in the appreciably smaller coronary vessels. As the occluded segment of artery is often limited, its replacement by a graft is an attractive conception. When with the aid of the mechanical pump-oxygenator more experience has been gained in operations on the dry, arrested heart, this will no doubt become practicable. At present technical difficulties seem insuperable. Meanwhile an emergency operation may be of value in another way. Death from coronary thrombosis is often due to cardiac arrest from ventricular fibrillation, occurring in a heart which is well able to continue beating adequately if this disorder of function can be reversed. As in cardiac arrest occurring during surgical operations, normal beat can often be restored by prompt massage of the heart. If aid is at hand, and the condition recognized within two minutes, lives could be and have been¹ saved in this way. The only instrument required is a knife.

A simple operation which perhaps merits further trial has been reported from Italy.⁴ This consists in bilateral ligation of the internal mammary artery in the second intercostal space, a little below the origin of the pericardiophrenic branch, so that the total blood flow is directed into this artery. There are normally anastomotic vessels between pericardium and myocardium at the root of the aorta, and it is said that these are greatly increased by this ligation. The hazard is relatively small and the operation has been safely done very soon after infarction—when an increased blood supply is most especially needed.

INTESTINAL LIPODYSTROPHY

In 1907 G. H. Whipple, then an instructor in pathology at Johns Hopkins University, wrote an account of "a hitherto undescribed disease characterized anatomically by deposits of fat and fatty acids in the intestinal and mesenteric lymphatic tissues."¹ The subject of his report was a 36-year-old physician who had suffered for five years from attacks of arthritis, loss of weight and strength, cough and, later, diarrhoea, with the passage of three or four bulky stools a day containing an excess of fat. He was diagnosed clinically as suffering from sarcoma or Hodgkin's disease of the mesenteric glands and was therefore explored surgically. At operation the mesenteric glands were very much enlarged and hard; a diagnosis of mesenteric tuberculosis was made and the abdomen was closed. The patient was reasonably well for two days but then developed dyspnoea which became extreme and terminated suddenly in death. At the post-mortem examination Whipple found the villi of the small intestine swollen, the submucosa thickened, and the mesenteric glands enormously enlarged by deposits of neutral fats and fatty acids. Both in the mucosa and in the mesenteric glands he found numbers of large mononuclear cells surrounding the fatty deposits. He proposed the name intestinal lipodystrophy for the disorder, which is often called Whipple's disease.

Though a rare disease, intestinal lipodystrophy has always aroused the interest of gastro-enterologists, and in 1956 Chun-I. Wang, H. D. Janowitz, and D. Adlersberg² reported the 55th published case-history. The great interest of their case is the response shown to corticosteroid therapy. The diagnosis had been made beyond all reasonable doubt by intestinal biopsy at laparotomy in 1951, when an ileo-transverse colostomy was carried out because the terminal ileum bore some suspicious evidence of regional ileitis. After the operation the diarrhoea increased and the patient was then treated with oral cortisone for four months with marked improvement, both symptomatically and as shown by tests of intestinal absorption. The patient relapsed one week after stopping this treatment. Soon afterwards she was treated with corticotrophin gel for 6½ months, also with good results, but again she relapsed soon after treatment ceased. She was then given hydrocortisone (free alcohol) by mouth for five months with both subjective and objective improvement. Thereafter she did not relapse during a follow-up period of twenty months.

Wang and his colleagues are not alone in having used corticoids in this disease, and they summarize the results of this form of treatment in six previously published cases as well as in their own. Several of the patients responded initially to cortisone or corticotrophin, although relapse, either after stopping treatment or even during it, was liable to occur. So far as can be deduced from the very small number of cases treated, hydrocortisone (free alcohol) by mouth may be the most effective

¹ Whipple, G. H., *Bull. Johns Hopk. Hosp.*, 1907, 18, 382.
² Wang, C.-I., Janowitz, H. D., and Adlersberg, D., *Gastroenterology*, 1956, 30, 475.

⁵ Russo, F. R., *ibid.*, 1952, 89, 600.

treatment, and intramuscular corticotrophin probably gives better results than oral cortisone. Wang and his colleagues recommend in addition a high-protein, low-fat diet with restriction of sodium intake and added potassium.

With the finding that Whipple's disease is sometimes amenable to treatment, its early recognition becomes important. Its clinical features have been well reviewed during recent years.³⁻⁵ The disease occurs chiefly in middle-aged men, and is characterized by polyarthritis, dyspepsia, cough, loss of weight, diarrhoea, and steatorrhoea. Brown pigmentation of the skin, resembling that of Addison's disease, is not uncommon. Death always used to occur between one and five years from the onset of symptoms. As the diagnosis cannot be made on clinical grounds, laparotomy should be advised when the disease is suspected so that biopsy specimens can be taken of the intestinal mucosa and of the mesenteric lymph nodes for microscopical study. How necessary this is for correct diagnosis can be seen from the fact that J. P. Hendrix and his colleagues,³ when reporting four cases in 1950, had made the diagnosis in one of them by mesenteric lymph-node biopsy, and they believed that this was the first reported case to be diagnosed during life.

DANGERS OF STRONTIUM-90

Recent discussion on the hazards of releasing nuclear energy has centred about the dispersing of radioactive strontium into the environment. As was said in these columns recently⁴: "The main problem is how to assess the hazard from a given amount of strontium-90 in bone." The issue may be narrowed by considering whether there is such a thing as a safe dose of strontium-90 in the human body, with the corollary that every addition to this threshold dose increases the risk of malignant disease developing. An important contribution to the debate from a committee of the Atomic Scientists' Association is reported at p. 1003 of the *Journal* this week, and its short answer is that the evidence is as yet inconclusive.

The fundamental difficulty, says the report, is that the relationship between damage produced and amount of radiation is not known. If there is a threshold dose below which cancer cannot be induced, "then it can reasonably be inferred that the small amount of strontium-90 which will accumulate in bone from the current H-bomb tests would not result in any harm." But if a linear relationship exists between amount of strontium-90 in the body and risk of developing a bone tumour, and if various other assumptions detailed by the committee are made, then "the number of bone sarcomas from one nominal high-yield nuclear test may amount to 20,000 all over the world." The type of test referred to is the one carried out with an H-bomb at Bikini in 1954 and with a fission-yield equivalent of 20 megatons. Whether or not such a linear relationship exists has not yet been determined. If it does, the consequence

of it is that "every H-bomb test by causing an increase of the content of strontium-90 in bone will increase the frequency of bone lesions."⁴ Some evidence^{5,6} that the relationship may be of a different kind was referred to in this *Journal* last week by J. F. Loutit,⁷ whose views command great respect. He wrote: "In point of fact, the quantitative evidence of the carcinogenic properties of radiostrontium, and there is not much of it, suggests that the relationship is not linear and that there is some form of threshold, or effective latent period." The research being carried out to elucidate these issues is unlikely to provide clear-cut conclusions for some time. Meanwhile, the situation is well summed up in these words of Loutit's: "The correct conclusion in the present state of scientific knowledge is that a linear relationship sets the limit and indicates the worst possible conditions, so that it would be prudent to go easy until the real facts are ascertained."

ANIMAL EXPERIMENTS AND PROTECTION FROM DISEASE

The Research Defence Society generally chooses for the annual lecture commemorating its founder, the late Sir Stephen Paget, a speaker guaranteed to carry the battle into the opponents' territory. In the twenty-fourth lecture (1955) Sir Henry Dale, with the vigour still characteristic of this stimulating octogenarian, had given a devastating exposition of the untold suffering among men and women and children, to say nothing of domestic animals and pets, that the anti-vivisectionists would have inflicted if they had had their way.¹ Last year the twenty-fifth Memorial Lecture was delivered by Professor A. A. Miles, director of the Lister Institute of Preventive Medicine. His title, "Resistance to Infection—the Experimental Approach," suggested that he was going to be philosophical rather than polemical: none the less he had many shrewd hits at those who wish to prohibit the use of animals in the laboratory. He made a scrupulously careful analysis of what animal experiments cannot and—far more important—of what they can in fact help to achieve. He dwelt at some length, after a historical introduction ranging from Galen to Koch, on the dual concepts of host susceptibility (or lack of resistance) and virulence of the invading organism, showing that the resulting intensity of an illness or infection is due to the joint, and ever-changing, operation of both factors together. He explained further how the late Professor W. W. C. Topley's studies of epidemiology in laboratory groups of mice had thrown fresh light on this joint action, revealing, for example, what might be expected from bringing a new group of uninfected animals into a colony in which an epidemic is already under way. One of the unexpected results—that this might even cause a waning infection to flare up again—has immediately practical applications in the domain of human health. Professor Miles also carefully expounded just how little the experimental method had so far been able to tell us of the complex relationship between nutrition and infection and of the even more complex one between heredity

and resistance to disease. Opponents of the experimental method no doubt will be eager to cite this in their propaganda and will ignore Professor Miles's demonstration that without it we should to-day not merely know even less of these important relationships than we do, but should almost certainly be pursuing will-o'-the-wisps through the gloomy quagmires of what he calls "notional biology."

Professor Miles dealt in some detail with the major line of attack on animal experiments—an attack relying for the most part on the argument that they are unnecessary or irrelevant or unjustifiable. And he distinguished all three of these from what is often confused with them—namely, the attack for so-called ethical reasons. This can only be met, according to Professor Miles, by our recognizing "a clear-cut hierarchy in the animal kingdom" that causes us to "conceive our first duty to be to man." On this point, moreover, he neatly turned the tables on the critics of animal experiments. "The contention," he said, "that what happens in an animal is irrelevant to what happens in man can be made only by insisting on the differences between one animal and another; and ignoring the similarities. To do so is to deny on biological grounds the very kinship that is invoked to forbid the use of animals altogether."

Professor Miles is far from advocating the indiscriminate or extravagant use of animals in the laboratory. Indeed, he cited as one of the "beautiful" features about Topley's experiments that their planning and analysis permitted the maximum certainty of result to be got with the minimum number of mice; he also said that "the respect we accord to the living animal . . . is a very real thing to most of us. . . . We acknowledge it in any consideration of animal experiment not only by avoiding the brutal, but by doing our best to avoid the unnecessary." The whole lecture is an admirable example of honest philosophical thinking clearly expressed, and will give in the reading, now that it has been published* by the Research Defence Society, even more food for thought, and incidental pleasure, than it did in the hearing.

EMMETROPIA

The problem of the refraction of the eye has excited the interest of the physicist and physiologist since the early part of the seventeenth century, and in more recent years the ophthalmologist has added his attention to the subject. While a mass of detail has emerged from these studies, there is still no complete understanding of the factors which contribute to the development of the emmetropic eye or of the deviations from normality which lead to the state of ametropia. Until the beginning of the present century only the variations in the axial length of the eye were considered, a normal axial length being associated with emmetropia, a decreased length with myopia, and an increased length with hypermetropia. In 1913 this simple philosophy was upset by

A. Steiger,³ who showed that in emmetropia the axial length could vary widely, and he found also much variation in corneal dioptric power. Steiger concluded that the different forms of ametropia seen in clinical practice are the result of a free association of these two variable components, axial length and corneal dioptric power. This conclusion was proved to be untenable by E. Tron,⁴ who obtained a correlation rather than a random association between these two components.

Now in a Medical Research Council report⁵ Professor A. Sorsby and colleagues have shown that axial length and corneal dioptric power are correlated when the refractive error is less than ± 4.00 D, so that a subnormal axial length tends to be correlated with an increased corneal dioptric power, and vice versa. In this way emmetropia is the result of perfect correlation, and minor degrees of ametropia follow a slight failure in this correlation. On the other hand, high degrees of ametropia (more than ± 4.00 D) are the result of anomalous components with values falling outside the range of normal variations, and axial length is without doubt the main determining factor. Fewer than 5% of eyes fall into the category of high ametropia. The two other components which contribute to the total refraction of the eye are the depth of the anterior chamber and the lens dioptric power, but these play a less significant part in the production of ametropia. It is likely that in the normal eye the correlation between axial length and corneal dioptric power is a simple and self-regulating process whereby, during any increase in the axial length of the eyeball, the cornea, which is part of a sphere, naturally becomes less curved. The retina may act as the organizer of the refractive components of the eye in the process tending towards emmetropization.

PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS

Dr. Robert Platt, Professor of Medicine in the University of Manchester, was elected last week President of the Royal College of Physicians of London. Professor Platt was educated at Sheffield University, where he took his M.D., and was physician to the Royal Infirmary in Sheffield before moving to Manchester in 1945. He is widely known as an authority on renal disease. His writings on medical education and other aspects of medicine, thoughtful and penetrating in their analysis, have commanded the deep respect of his professional colleagues. Since 1948 he has been an editor of the *Quarterly Journal of Medicine*. Professor Platt's election as President of the Royal College of Physicians will be welcomed on these and on many other grounds. Coming from the provinces he breaks what has been almost a London monopoly of one of the high offices in the world of medicine. He carries his learning and his culture without ostentation, and his approach to the position and problems of his new office will, we may be sure, be refreshingly direct. Apart from his medical appointments, Professor Platt is on the Council of the Royal Manchester College of Music and is Chairman of the Manchester Chamber Concerts Society: he is himself a 'cellist of no mean distinction.

ASTHMA AND HAY FEVER

SYMPOSIUM FOR G.P.s

[FROM A SPECIAL CORRESPONDENT]

A symposium on allergy and the respiratory tract was held at the Institute of Diseases of the Chest, London, on April 9. It was designed specially for the general practitioner.

Management of Asthma

Dr. J. L. LIVINGSTONE began by defining asthma as a clinical syndrome marked by periodic dyspnoea with wheezing, mainly expiratory, associated with temporary narrowing of the smaller bronchi and bronchioles throughout the lungs. In long-standing cases the wheezing might become permanent. Asthma was a common condition, affecting at least 1% of our population, or around 750,000 persons in England and Wales, he said. Although it was generally accepted as a relatively benign though trying condition, this was not strictly so, for 3,000 individuals were certified each year as dying from "asthma," and even this was probably an underestimate.

What was the prognosis? It was very difficult to dogmatize, as the course depended on so many interrelated factors. In a 20-year follow-up of almost 500 children under 13 years of age Rackemann and Edwards had found that 70% either were "cured" or were almost completely unaffected by asthma, so long as they avoided allergens; that 25% were still suffering from asthma, 11% of these being severely affected; and that 1% had died. There was therefore a natural tendency towards a spontaneous "cure" during adolescence.

In discussing therapy and management it was well to have some simple system of classification. Dr. Livingstone suggested the following as practical: allergic asthma, with mucoid sputum; infective asthma, with purulent sputum; mixed asthma, a combination of the two preceding groups; psychological asthma; drug sensitivity, especially to aspirin; asthma due to nasal causes; and a miscellaneous group such as that associated with menses, exertion, and foods. Treatment must always be a serious matter and not just a question of prescribing antispasmodics. The main features in any plan of management should include: (i) early and accurate diagnosis of the type of asthma, as already defined, and the application of appropriate therapy; (ii) a "hardening regime" including fresh air, cold baths, and general toughening up, especially in children—this regime was based on the good results when children entered boarding schools and youths joined the Forces; (iii) avoidance of allergens, especially in bedrooms, where attention to pillows and mattresses would yield rewards, as would removal of dust; (iv) physiotherapy, which had twofold psychological and functional benefits; (v) treatment of nasal defects; (vi) treatment of any infection with appropriate antibacterial measures; and (vii) hyposensitization.

Hormone Therapy in Asthma

Dr. HOWARD NICHOLSON spoke on the use of the corticosteroids in the control of asthma, basing many of his comments on the results of the recent Medical Research Council trial.* In status asthmaticus a good proportion of patients would respond to the simpler well-established treatment with adrenaline and aminophylline, he said. The more potent and more dangerous corticosteroids should be reserved for those more severely affected who did not respond to the simpler remedies after 24 hours of energetic treatment. This applied more particularly to the first attack of status asthmaticus. However, discretion must be used in each case, and in a very severely ill patient who was in danger of his life corticosteroids were indicated at once.

Cortisone or one of its delta derivatives were the oral preparations most often used. Dr. Nicholson expressed a preference for prednisone. The dosage recommended for cortisone was 350 mg. on the first day, 200 mg. on the second, followed by a reduction of 25 mg. over each suc-

*Lancet, 1956, 2, 798, 803.

ceeding day for the next 8-10 days. The dosage for prednisone was one-fifth of that for cortisone.

In the infective group, with a purulent sputum, the infection should be energetically treated with antibiotics such as the tetracyclines or penicillin and streptomycin if catapnoes were to be avoided.

In chronic asthma the corticosteroids were much more disappointing, in the vast majority the condition relapsing when the drug was discontinued. They did have their place, however, in a small group of cases who were very severely incapacitated, and in these patients the drug had to be continued more or less permanently in a dosage of 75 mg. daily for cortisone or 15 mg. for prednisone. It must be strongly emphasized that this was a potentially dangerous therapy which should be reserved for the very severe and intractable case, properly selected and with a full appreciation of the risks involved.

Hay Fever

Mr. P. F. MILLING spoke as an E.N.T. surgeon on the differential diagnosis of hay fever. The signs and symptoms of hay fever were common to a number of other conditions. Even the everyday coryza had to be remembered when examining a new case. Vasomotor rhinitis was a confusing group of cases with almost identical clinical features but without the characteristic seasonal patterns. Allergic rhinitis was a more definite group in which a history of association of symptoms with contact with dust or animals was obtainable. With the increasing use of hypotensive drugs it was becoming more common to see patients with stuffy noses and sneezing attacks as a direct effect of these drugs. Nasal polypi and infected sinuses which might result as complications from any of the already mentioned conditions could also produce symptoms of "hay fever."

In the treatment of hay fever prophylactic therapy with antihistamines was not usually successful, and it was better to wait till symptoms appeared before using these drugs.

Assessment of the Allergic Factor

The allergist's views were presented by Dr. J. PEPYS, who stated that the incidence of allergic disorders had been calculated to be 10% in those countries where studies had been made. This high incidence made it all the more necessary to approach the problem in a proper scientific fashion.

The diagnosis of allergy must be based on a careful history and examination. The pale boggy appearance of the nasal mucosa together with the presence of eosinophil cells in the nasal secretions was typical. Itching of the nose was common, and in children particularly the vigorous rubbing of the nose, the "allergic salute," was a very frequent sign. Repeated episodes of "bronchitis," "pneumonia," and "colds" should be regarded with suspicion, since they could all be part of the allergic clinical manifestations. These incidents could be all the more confusing because of associated pyrexia, which, whilst its cause was not clear, might nevertheless disappear on control of allergic factors.

Classification of respiratory allergic disorders was difficult. The simplest method was to group cases as extrinsic or intrinsic. The extrinsic group presented a long history of skin and other allergic manifestations, often starting in infancy with eczema. External allergens could be found, and the prognosis for this group was good. The intrinsic group started symptoms later in life; the prognosis was poor, and, except for their frequent and remarkable sensitivity to aspirin, other allergens were seldom identified.

Management was based on identification of the causal allergen, and the removal of the patient from the cause from the patient. If this was not possible, the course of desensitization should be considered. Identification of the cause should be based on a careful history. It was essential to ask the questions as to possible specific causes. Were there seasonal variations? Allergy to tree pollens produced symptoms early in the year, grass pollens produced symptoms towards the end of June,

and in the autumn moulds were often responsible for allergic reactions. Were symptoms related to house dust? Here one had to ask specifically about the effects of sweeping and dusting in the home. Were the attacks nocturnal? If so, then they might be related to the dust in, or the composition of, the mattress and pillows. Were there associations with animals, foods, or drugs? All these possibilities had to be explored, and a careful history was much more valuable than any of the ancillary tests. Skin tests were very difficult to assess, and, unless they were carefully executed with reliable materials and the results carefully interpreted by an expert, they were apt to be misleading. A positive skin-reaction did not necessarily imply that the test allergen was, in fact, the real cause of the clinical disorder. Skin tests could, however, be most useful in confirming allergic sensitivity to moulds and grass, flower, or tree pollens.

Control of Allergy

Environmental control—i.e., the removal of allergens—was based on long experience of the results of identification of allergens, continued Dr. Pepys. A common approach to such patients, modified by individual findings, included advice on the removal of animals; the changing of mattresses or pillows or providing suitable plastic covers for them; and the control of house dust by vacuum cleaning, damp dusting, and the wearing of masks when dusting.

Desensitization was indicated only if control by other means was not possible. It consisted of carefully graduated courses of injections which might have to be continued for many years. It was a nice point to decide whether the trouble involved was worth while.

The corticosteroids had a very small place in the treatment of the common respiratory allergic disorders. They were useful, however, in the very severe seasonal asthmas, and in these they could be used prophylactically during the season.

Dr. Pepys stressed the very real dangers of "nasal addiction," with severe aggravation of rhinitis, caused by the use of some of the currently popular nasal drops—"fenox" and "privine" being, in his view, the worst offenders.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM

[FROM A SPECIAL CORRESPONDENT]

The 77th annual congress of the Ophthalmological Society of the United Kingdom was held at the Royal Society of Medicine from April 11 to 13, under the presidency of Mr. J. J. HEALY. A record number of members and their guests attended and a wide variety of papers were read.

The Bowman Lecture was delivered by Sir STEWART DUKE-ELDER on "The Aetiology of Simple Glaucoma." This lecture is the highest honour the Society can bestow, and this year's exposition was outstandingly interesting and informative.

Diabetic Retinopathy

The principal discussion was on the eye changes in diabetes. Professor G. I. SCOTT, of Edinburgh, opened it by referring to the difficult problem of the aetiology of diabetic retinopathy. The evidence about this was still inconclusive, he said, but he could confirm that the retinopathy occurred in the absence of general hypertension or local retinal arteriosclerosis, and that its development depended primarily on the duration, not the severity, of the diabetes. He also drew attention to the two different types of retinitis proliferans that characterize its later stage, one being the typical product of vitreous haemorrhage and the other manifesting itself by the gradual development of vascular loops which often result in a retinal detachment. Although the tendency to diabetes can be inherited, there seems to be no genetic predisposition to the retinopathy, and Professor Scott quoted a personal case in which it occurred in diabetes following

a pancreatic lesion. He also mentioned an unusual family who regularly developed an optic atrophy in association with their diabetes, but not a retinopathy. Capillary fragility also failed to account for diabetic retinopathy, but the retinopathy was always accompanied by a disturbance of carbohydrate metabolism of the diabetic type. Was the retinopathy commoner in the well-controlled type of diabetic, he asked in conclusion, and did it show any altered frequency in those with a high renal threshold? These were questions he was now in the process of investigating.

Relationship to Glomerulosclerosis

Dr. NORMAN ASHTON, director of pathology at the Institute of Ophthalmology, London, then discussed the relationship between diabetic retinopathy and glomerulosclerosis as seen in man and in experimental animals. In a post-mortem series of 203 diabetic patients he had found retinopathy in 67.4% and glomerulosclerosis in 36.9%. His main conclusions from this study were: (a) that retinopathy precedes glomerulosclerosis, and in its early stages may exist without the renal lesion; (b) that diabetic glomerulosclerosis, on the other hand, is always associated with retinopathy; and (c) that, although practically all stages of the two lesions can coexist, severe retinopathy is almost always associated with glomerulosclerosis, the proportion of cases with severe glomerulosclerosis increasing with the severity of the retinopathy. The close relationship between the incidence of the two lesions suggested a common cause, which was further borne out by their histological similarity. Indeed, a hypothesis could be advanced which explained their histogenesis on the same basis—namely, the seepage of lipoproteins and mucopolysaccharides from the circulation through foci of capillary degeneration. However, as Volk had recently pointed out, this comparison between the two lesions in terms of histogenesis was not completely acceptable, for there were several points difficult to explain, and the relationship between the two lesions might not in fact be as close as previously supposed.

On the experimental side, no worker had yet succeeded in reproducing a retinopathy which could be accepted as analogous to that seen in human diabetes, although isolated components of the retinopathy had been produced by a variety of experimental procedures. In contrast, lesions resembling diabetic glomerulosclerosis had been repeatedly demonstrated experimentally, the most noteworthy results being those of Becker and his colleagues, who had obtained such glomerular lesions in 96% of rabbits deficient in vitamin B₁₂ treated with cortisone. There was considerable evidence to show that these lesions might be due to lipaemia, for cortisone was known to induce lipaemia in rabbits, and the lesions could be prevented by the simultaneous administration of heparin and reproduced by other forms of experimental hyperlipaemia. However, Cook had shown that fat emboli alone were insufficient to produce characteristic retinal and renal lesions, but in man it seemed possible that a complex macromolecular substance consisting of fat, protein, and mucopolysaccharide, by impeding or obstructing the capillary circulation or by forming intramural deposits, might give rise to the various manifestations of diabetic micro-angiopathy.

Clinical Factors

Finally, Dr. J. D. N. NABARRO (London) gave a general assessment of the picture from the physician's point of view, discussing the incidence of diabetic retinopathy and its possible relation to a relative increase in adrenal cortical activity. After reviewing the two groups, insulin-deficient and insulin-resistant diabetics, he concluded that the clinical evidence pointed to "prolonged sustained hyperglycaemia, or something closely related to it, as the cause of the retinitis." Discussing the management of the insulin-resistant group, he felt that the principal concern should be in controlling their obesity. He also mentioned the danger of carbutamide (BZ 55) in promoting the risk of retinal damage.

Subsequently he had tried tolbutamide, which was slightly different chemically and not a true sulphonamide, and here the results had been satisfactory with negligible side-effects. However, prolonged trial of these new drugs would be necessary before they could be recommended for widespread use, and even then they would be suitable for only a small proportion of cases. More radical measures included hypophysectomy, which carried a considerable mortality and whose effects although generally favourable were difficult to assess.

STRONTIUM HAZARD FROM NUCLEAR EXPLOSIONS

STATEMENT BY ATOMIC SCIENTISTS' ASSOCIATION

If there is no threshold dose with strontium-90 below which malignant bone tumours do not occur, then some 50,000 such cases may result from the radioactive strontium already liberated into the atmosphere from nuclear explosions. In addition there would probably be a number of cases of leukaemia. This admittedly rough estimate is given in a statement by the radiation hazards committee* of the Atomic Scientists' Association. The statement was published on April 16. The committee thinks it quite possible that for strontium-90 no threshold does exist.

The Atomic Scientists' Association was founded in 1946, mainly by scientists who had taken part in the wartime atomic energy projects. One of its principal aims is to keep the public informed about the effects of the release of atomic energy on human welfare. Its president is Professor H. S. W. MASSEY, F.R.S., Quain professor of physics, University College, London; there are 20 vice-presidents, all save one fellows of the Royal Society, and including among their number Sir JOHN COCKROFT; Professor J. ROTBLAT is executive vice-president.

The statement begins by recording that the association's council had earlier appointed a committee to study radiation hazards "and to follow up the implications of last year's report of the Medical Research Council† in the light of more recent information." In view of the present concern about the H-bomb tests, continues the statement, the council asked the committee to prepare a public statement on its current assessment of the hazard from radioactive strontium.

Committee's Statement

"When," says the committee, "an H-bomb is exploded at a high altitude, and in an area in which there are no inhabitants—as is said to be the case with the forthcoming British tests—there is very little likelihood of immediate injury to people, or of substantial local contamination of the oceans, even if a large amount of radioactivity is produced in the explosion. This radioactivity would be taken up into the upper regions of the atmosphere from where it would spread all over the globe and gradually descend to the ground over a period of some years. By that time only the long-lived radioactive products of the bomb would remain, and it is with the possible effects of these that we are concerned.

"If H-bomb tests continue at the present rate, the dose of radiation to the reproductive organs, which may cause damage to future generations, has been estimated in the M.R.C. report to be of the order of 1% of that resulting from the natural level of radiations. Of greater import, however, is the damage which may result to the present generation, mainly from one radioactive substance—strontium-90. This substance enters into our food, chiefly in vegetables and dairy products, and it accumulates in the human body in the bones, where it remains for a long time.

*Membership of Radiation Hazards Committee: Professor J. Rotblat (chairman), Dr. J. W. Boag, Professor A. Haddow, Dr. W. M. Levitt, Dr. Patricia J. Lindop, Mr. S. B. Osborn, Professor L. S. Penrose, F.R.S., Professor P. A. Sheppard, Dr. G. Simon, and Dr. A. J. Salmon.
†The Hazards to Man of Nuclear and Allied Radiations. Cmd. 9780, 1956. H.M.S.O., London.

Depending on the assumptions made about the distribution of strontium in bone, we calculate (see appendix) that by the year 1970 the radiation dose to bone from all the tests carried out up to the autumn of 1956 will range from 9% to 45% of the dose received from all natural sources, including the radium which is normally present in bone.

"It is known that radioactive substances concentrated in the bone may give rise to bone cancers and other damage, and that the irradiation of bone marrow may result in leukaemia, a type of cancer of the blood. The induction of bone cancers by the action of strontium-90 in the bone has been demonstrated in animals; in human beings the same effect has been observed with radium, which in some ways behaves like strontium. In all these cases, however, the amounts of radioactivity present in the bone were far greater than those that are likely to accrue from H-bomb tests. The question then arises how to apply these findings to very small doses. There is here a fundamental difficulty, in that the relationship between the damage produced and the amount of radiation is not known. If this relationship is such that there exists a threshold dose below which cancer cannot be induced, then it can reasonably be inferred that the small amount of strontium-90 which will accumulate in bone from the current H-bomb tests would not result in any harm. If, however, the number of additional bone tumours resulting from radiation is directly proportional to the dose, then even a very small dose will give rise to a small but definite probability of bone cancer. This means that in a very large population a certain number of people would contract this disease as the result of their having a small amount of strontium-90 in their bones."

Evidence on a Threshold Inconclusive

"The evidence is as yet inconclusive. Some animal experiments have been interpreted as indicating the existence of a threshold dose. On the other hand, in man the occurrence of leukaemia caused by radiation suggests a simple proportional relationship. Unfortunately the question cannot be settled by experiment in a short period of time, nor is there strong guidance from theory. There is one theory of the origin of cancer (that it is due to somatic point mutation) which implies a proportional relationship. Where the effects of strontium-90 are concerned the authorities in the M.R.C. report appear to be inclined towards the proportional hypothesis, for they state: 'On the whole the experiments seem in favour of a proportionality between the frequency of tumours produced in a given length of time and the amount of radioactive material in the body even at low dose levels.'

"If the proportional relationship is accepted, it is then possible to make a rough estimate of the number of bone cancers which may result from a given H-bomb test. The calculations given in the appendix show that an H-bomb of the type tested at Bikini in 1954, if exploded high in the atmosphere, may eventually produce bone cancers in 1,000 people for every million tons of T.N.T. of equivalent explosive power. (It has been stated that bombs hitherto exploded were equivalent, in aggregate, to 50 million tons, in so far as their strontium-90 fall-out is concerned.) These thousand casualties would be spread all over the world and occur in the course of several decades. A somewhat larger number of people might suffer other bone changes, possibly without manifesting any clinical symptoms. There is also the probability of a number of cases of leukaemia resulting, but we have not enough data to estimate this number. At the same time it should be pointed out that these casualties, although large in absolute number, represent only a fraction of those due to the natural level of radioactivity; there would be no way of distinguishing one from the other.

"If other types of nuclear weapons were exploded, the number of casualties would vary in direct relation to the amount of fission products released into the upper atmosphere.

"In giving these estimates it must be emphasized again that, apart from the considerable margin of error due to lack of adequate data, they are based on the as yet unproved hypothesis of a proportional relationship applying to very

small doses. From this point of view they represent the most pessimistic approach. On the other hand, if this hypothesis is correct, then the figures may be an underestimate of the damage, since they do not allow for the radiation dose in children before or after birth. Children are known to take up much larger quantities of strontium than adults, and the likelihood of producing radiation damage in them is probably much greater for the same amount of radiation.

APPENDIX

"Estimate of Strontium-90 Hazard Based on an Assumed Linear Relationship between Bone Tumour Formation and Dose"

"1. The measurements of the ^{90}Sr content in human bone in this country, carried out by workers of the U.K.A.E.A.,¹ show that by the beginning of 1956 the average amount in all age groups from 10 years upwards was about 0.2 S.U.* (1 S.U. = 10^{-12} curies of ^{90}Sr per gramme of calcium).

"2. If this figure is applied to the data of the world survey of strontium-90 made by the Lamont group,² we conclude that the ^{90}Sr concentration resulting from all the tests carried out up to the autumn of 1956 will in 1970 amount to about 4 S.U. This value is in agreement with the estimate of 4-10 S.U. made by Libby³ for the U.S.A.

"3. The total fission yield from the tests carried out up to the autumn of 1956 is estimated² to be equivalent to 50 megatons. For one nominal high-yield weapon (as defined in the Indian Government's document⁴: 20 megatons with high fission yield) exploded high in the atmosphere, one may therefore expect a concentration in bone of 1.6 S.U.

"4. From Hasterlik's survey⁵ of bone sarcoma in people with a radium burden, we estimate that 0.1 microcurie of radium yields about 0.5% probability of bone sarcoma. (A factor of 2 has been allowed for the possible admixture of mesothorium with the radium.)

"5. Since 0.1 microcurie of radium is accepted⁶ to be equivalent to 1,000 S.U., applying this probability value to the population of the whole world (2.5×10^9 people) we obtain that the number of bone sarcomas from one nominal high-yield nuclear test may amount to 20,000 all over the world ($2.5 \times 10^9 \times 0.5 \times 10^{-2} \times 1.6 \times 10^{-3}$).

"6. The radium normally contained in the body and the external radiation from natural sources deliver to the bone a dose equivalent to 45 S.U., or 9 S.U. if one allows for the non-uniform concentration of strontium in bone (Spiers⁷). This means that the dose rate from strontium in bone will amount to 4/45 or 4/9 of that due to the natural background.

IMPERIAL CANCER RESEARCH FUND

The Imperial Cancer Research Fund held its annual meeting at the Royal College of Surgeons on April 15, under the chairmanship of Sir CECIL WAKELEY, chairman of the Fund's council. Besides presenting the Fund's 54th report, Sir Cecil Wakeley announced that it was hoped to begin demolition work in the autumn on Nos. 44 and 45, Lincoln's Inn Fields, on the opposite flank of the R.C.S. to the Nuffield College, in preparation for the Fund's new laboratories and offices. Mr. A. DICKSON WRIGHT, the honorary treasurer, said that the cost of the new laboratories was estimated at about £1m. They were planned to be up in about two years' time.

Progress in Research

The report for 1955-6 is introduced by a general outline of the chief problems in cancer research to-day and an

*S.U. is an abbreviation of "sunshine" or "strontium unit." "Sunshine unit" is more usual in the United States, "strontium unit" in Britain.

account of some of the ways in which they are being attacked. Then follow the directors' reports of research at the Central Laboratories at Mill Hill (Dr. JAMES CRAIGIE, F.R.S.) and at the Clinico-Pathological Research Unit at 48, Lincoln's Inn Fields (Professor GEOFFREY HADFIELD). Dr. Craigie's report records the retirement of Dr. A. M. BEGG, who discovered the first filterable fowl endothelioma, and of Mr. H. G. CRABTREE, who worked on tumour metabolism. Both joined the Fund in 1922.

Dr. CRAIGIE reviews nine years' experience of preserving tumours frozen. Over 60 experimental tumours are now stored at -79°C , and even after five or more years those tested have shown no significant progressive loss of viability. So far also there has been no observable change in the character of tumours so preserved. Freezing, among other advantages, is a far more economical way of maintaining a tumour than by serial transplantation. It costs rather less than £2 a year to keep a tumour in this way, and Dr. Craigie now meets most requests for experimental material from this frozen tumour bank. Other work being carried out at the Mill Hill laboratories includes *in vitro* studies of tumour cells in hanging-drop preparations. Here it appears that the carbon-dioxide concentration in the cell's atmosphere is a "critical factor" in deciding whether a cell rounds off or puts out cytoplasmic processes. Other related studies have concerned the "adhesiveness" of tumour cells which is thought to have a bearing on their ability to infiltrate and metastasize. Prolonged stilboestrol treatment of guinea-pigs has resulted in an apparent acceleration of the normal ageing process and also in changes in renal function similar to those seen in aldosteronism in man.

Clinico-pathological Research Unit

Professor HADFIELD, in his report, says that the obstacles in investigating human cancer on a strictly scientific basis are proving on the whole more easily surmountable than might be expected. Preparations are being made for a study of the heterologous transplantation of human tumours, and one of his staff has gone to New York to study the methods developed at the Sloan-Kettering Institute. On the biochemical side, hormone excretion in patients with cancers of the breast and prostate has been further investigated.

The question of possible differences between clinical (or active) and latent (or unsuspected) prostatic cancer has been investigated in various ways. In histologically proved prostatic cancer death without gross metastases (biological latency of the tumour) was common among the older patients, and the presence or absence of metastases bore no direct relation to the duration of the disease. A follow-up of 200 patients with clinically benign prostatic enlargement, now in its fourth year, has produced 19 with undoubted histological cancer, though none had died of the disease. Pointing out that presumably many of these patients have biologically latent cancers, Dr. L. M. FRANKS comments: "It is obvious that the morphology of a prostatic tumour is an unreliable guide to its biological behaviour. Other methods for assessing tumour activity are essential."

Work on the relationship between pituitary function and breast cancer has been continued. One of the reasons why some workers have been unable to confirm the reliability of the mouse-breast test for mammatrophic hormone in the urine is said to be the finding that the response to prolactin is a remarkably uncommon strain characteristic; only two out of 37 strains of laboratory mice exhibited it.

Dr. J. BAMFORTH reports on exfoliative cytology. "Judged by clinical standards," he says, it is "of immense service" in the early diagnosis of cancer of the cervix; in clinically recognizable prostatic cancer "the cytological characters of the smear are unmistakable," but in preclinical disease no firm claim for it can yet be made; in suspected lung cancer "cytological examination of the sputum by an experienced observer is an essential diagnostic measure."

Research on lung cancer by Dr. G. J. CUNNINGHAM is summarized as leading to the conclusion that pulmonary fibrosis, as in bronchiectasis, does not directly predispose to the development of primary bronchial carcinoma.

Correspondence

Because of heavy pressure on our space, correspondents are asked to keep their letters short.

Post-maturity

SIR,—In your annotation on the subject of post-maturity (*Journal*, April 13, p. 876), you end with Greenhill's dangerous assertion that "if the cervical canal is taken up and the external os is not closed, the patient is near, at, or after term." The implied corollary is that, if the cervix is *not* taken up, term has not been reached. While in the normal case the taking up of the cervix (which is a sign that labour is soon to begin) occurs more or less simultaneously with maturation of the foetus, it is wrong to assume that this happy coincidence is true in every case. A premature labour, say at 32 weeks, is preceded by the taking up of the cervix, and, on the other hand, in a prolonged pregnancy the foetus may die in utero because its growing demands exceed the diminishing ability of the dying placenta to supply it, while the cervix remains long and closed because the uterus is not yet ready for action. No, Sir, it is not enough to depend on the state of the cervix to decide whether term has been reached. The calculation of the duration of pregnancy requires careful assessment of a number of details—the menstrual history, comparison of the size of the uterus in early pregnancy with the estimated duration, the time when movements are first felt, the girth in late pregnancy, the clinical assessment of the size of the foetal head, the x-ray appearances of the foetus and its ossification centres, and last, and probably least, the state of the cervix. A *laissez faire* attitude is probably better than ill-considered, brash interference, but careful clinical assessment of every detail is surely better than either.—I am, etc.,

J. C. MCCLURE BROWNE.

Delayed Emptying of Gastric Stump

SIR,—I have followed with considerable interest the correspondence initiated by Mr. R. B. Welbourn (*Journal*, November 17, 1956, p. 1172) concerning delayed emptying of the gastric stump soon after gastrectomy. It has often been pointed out that operation usually reveals no apparent mechanical fault. Laparotomy therefore is better avoided, and in most cases gastric aspiration eventually results in resolution of the apparent obstruction. However, such obstruction may last, as Mr. Welbourn writes, for a matter of weeks, and, although gastric aspiration can be continued throughout this period, the problem soon arises as to the best way to maintain nutrition. The intravenous route has considerable limitations if an attempt is made to carry it on for a long period, and the sooner one can revert to alimentary feeding the better. The answer to this problem was given several years ago by Abbott and Rawson,¹ who described their double lumen tube, and by Einhorn,² who described a similar tube. Mr. Welbourn speculates as to the possibility of using such a tube, having not apparently heard of it before, and Mr. Maurice Lee (*Journal*, December 8, 1956, p. 1364) has devised such a tube, apparently not knowing of the work of Abbott, Rawson, and Einhorn. Although I have been using Abbott-Rawson intubation as a routine in all gastrectomies for many years, I was recently surprised to find that only a very small percentage of Australian surgeons use it.

Our routine in gastrectomy is as follows. The tube is introduced via the nares into the stomach shortly before operation, and at operation the end of the tube is placed into the efferent loop so that the gastric suction holes lie in the stomach. Printed instructions to nurses divide the post-operative treatment while the tube is in position into two phases. On return to the ward after operation, to

prevent the lumen of the tube from becoming blocked, the jejunal feeding portion of the tube is connected to a slow 5% dextrose drip. Hourly syringe suction is applied to the gastric suction portion. In the patient behaving normally, never more than a few centimetres are withdrawn at a time. Continuous suction never works satisfactorily. If it does it usually means that trouble is developing. With syringe suction any abnormal change in the behaviour of the aspirate very early becomes apparent. Suction is continued without oral intake until bile appears in the aspirate 12 to 48 hours after operation. This is taken to indicate that the usual temporary post-operative paralytic ileus is subsiding. Aspirations are continued for a few hours after bile appears to allow for the transition from the early irregular contractions of the small bowel to the stage of normal peristalsis. This is the end of the first phase, which is the time when it is decided that the bowel movements have recovered to such a degree that it becomes wise to introduce food into the small bowel. The gastric aspiration is continued, but the continuous jejunal drip is replaced by the hourly injection of 1 oz. of a suitable protein hydrolysate. This is followed by the injection of the gastric aspirate, which, if removed as it collects, consists of normal duodenal content, which should be conserved. This feeding is continued with increasing quantities for a couple of days until it becomes clear that the jejunum is tolerating the feedings. The tube is then removed and oral feeding commenced.

Two obstructive phenomena may occur in the early post-operative period—namely, obstruction to emptying of the stomach, and intestinal obstruction at a lower level. These are readily diagnosed at a very early stage. Normally the gastric aspirate by syringe every hour is only a matter of a few cubic centimetres. If it is found that the quantity gradually increases, though perhaps irregularly, and commences to come away very easily with syringe suction, then one of these obstructions is developing. The jejunal drip is stopped, and syringe suction is applied to the jejunal portion of the tube. If only a few cubic centimetres of fluid are withdrawn with difficulty, the fluid appearing to be only that which has been introduced to clear the lumen of the tube, then the obstruction is at the efferent stomach. If, however, there is an increase in the quantity of fluid that can be aspirated from the jejunal feeding tube, and this fluid comes away readily, and in volume, and appears to be similar to that withdrawn through the gastric suction, then the obstruction is in the small bowel.

With stomal obstruction, syringe suction is replaced by continuous suction. If the fluid is aspirated as secreted, it is normal duodenal content, and should be returned to the alimentary canal. With a double lumen tube this can readily be done by placing the gastric aspirate in a suitable container, and running it through a simple filter into the jejunal portion of the double lumen tube. To this can be added a continuous drip of high-protein fluid. It is sometimes found that sufficient fluid can be given by the jejunal feeding tube to allow of intravenous fluids being discontinued. I have had such a case enjoy perfect comfort for 14 days. At the end of this period the block resolved, this being shown by rapid fall in the amount of fluid that could be aspirated from the stomach. When this occurs the management of the Abbott-Rawson tube reverts to that of the second phase of normal management, and progress is uneventful. One does not have to worry with prolonged intravenous feeding, and does not have to discard the many pints of aspirated normal duodenal content which otherwise could only be given through a feeding jejunostomy. With small-bowel obstruction continuous suction is applied to whichever of the two lumens runs the easier, and this suction is continued until the obstruction resolves, which it usually does. This is again indicated by a rapid fall in the amount of aspirate coincident with relief of distension and pain and perhaps passage of flatus. The management again reverts to the normal management.

Concerning Mr. Welbourn's case report, I would like to state that oral intake is not allowed while suction is being carried out, except as a trial at the stage when one feels that the patient may tolerate a change from suction to oral feeding. As Mr. Lee advocates, some years ago we did start drip feeding into the jejunal feeding tube immediately after operation, but found that, if such were done into a small bowel in a state of the so-called "physiological ileus," it was often not tolerated, causing regurgitation and vomiting.

We therefore stopped this in favour of using the appearance of bile in the aspirate as an indication of the probability that the introduction of food was likely to be tolerated.—I am, etc.,

Geelong,
Victoria, Australia.

Strontium-90 in Man

SIR,—Your leading article (*Journal*, March 30, p. 752), relating to the dangers of strontium-90 absorption in man, apparently overlooks the special case of the marine habitat, which, since so many nuclear tests are carried out at sea, can hardly be regarded as insignificant.

It is, I believe, true that certain species of zoo-plankton concentrate strontium specifically. Since these organisms constitute the staple diet of larger marine forms used for human food, it is probable that sea-borne strontium would reach the human organism, and, in fish-eating communities washed by streams passing near to nuclear testing-grounds, could constitute a very real danger. Furthermore, while on land the spread of strontium-90 is uniform, the tendency for plankton organisms to concentrate in areas of suitable physical properties for maximum growth could produce, under suitable conditions, concentrations of strontium-90 considerably higher than the average level, with correspondingly higher levels in fish grazing in these areas.

While we are perhaps fortunate in England, in being a considerable distance from the nuclear testing-grounds, there are others who are less fortunate and whose shores are washed by ocean streams carried over immense distances.—I am, etc.,

London, N.8.

GORDON HYDE.

Benactyzine

SIR,—The paper by Professor G. R. Hargreaves and Drs. M. Hamilton and J. M. Roberts (*Journal*, February 9, p. 306) and the subsequent correspondence between Dr. E. H. Hare (*Journal*, March 9, p. 582) and Professor Hargreaves (*Journal*, April 6, p. 817) emphasize the importance of properly conducted "blind" investigations of the efficacy of therapeutic drugs "in order to circumvent the capacity for unwitting self-deception which both psychiatrists and their patients display"—as the authors of the original paper had put it. Alas, it seems that even the best intentions are not proof against the craft and ingenuity of unwitting self-deception. The investigation by Hargreaves and his colleagues shows an example of self-deception which is so marked as to be highly significant statistically.

It is debatable whether "blind" trials are possible at all in the case of a drug that does not remove symptoms and merely causes characteristic effects which reduce the distress occasioned by the patients' symptoms. Benactyzine produces (? in most cases) "a feeling of calmness, and sometimes a sense of detachment," as the original authors have reported. In more than half their cases (8 out of 14) there were complaints of dizziness and "muddled thinking." Obviously any psychiatrist worth his salt is likely to detect the characteristic effects of such a drug. He certainly may be expected to see through the transparent "blind" of such a trial, and to guess, with a success-rate far above chance, whether a patient received the drug or inert tablet.

Hargreaves and his colleagues removed six patients from their investigation because of changes in the patients' life situation. The patients were removed before the authors knew the coding employed for the dispensation of the tablets. Nevertheless this procedure violates the canons of statistical experimentation. Dr. Hare rightly pointed out that, had the patients not been removed, there would have been hardly any difference between the improvement scores in the control and the benactyzine patients. It is this removal of six patients from the investigation that betrays the working of unwitting self-deception. The exclusion of every one of these patients favoured a positive outcome of the trial. How often could

this have happened by chance? If we assume that in each case there had been an equal chance that the exclusion of a patient either increased or reduced the difference between the control and the benactyzine group, then the answer is: only once in 64 chance guesses could it have happened that the difference between the two groups was invariably increased. It is like the chance of throwing six heads in spinning a coin. P therefore is 0.016, which is of much higher significance than any of the P-values reported in the original paper. It supplies statistical evidence that the investigators had fallen victims to the wiles of unwitting self-deception which they had been trying so hard to circumvent.—I am etc.,

F. K. TAYLOR.

Defective Colour Vision

SIR,—People are often unaware of defective colour vision irrespective of their general intelligence and education. Occasionally the effects are damaging to their careers. Defective colour vision is common in men, the frequency being about 8%, and less common in women, being about 0.44%.

A case in point, a youth of 18 years, had worked satisfactorily in an industrial chemical laboratory on work which he could and did carry out satisfactorily for over a year. His further training, at a technical school, necessitated titrations using colorimetric methods. After a year he developed an anxiety neurosis due to difficulty in his school work owing to his colour defective vision, and after a further six months of effort he resigned his post.

A review of the effects of defective colour vision in industry was made in 1946 by the Colour Group of the Physical Society. They stated: "We have no doubt of the urgency of instituting tests of the colour vision of schoolchildren, especially boys. . . . They recommended that school tests should be carried out at 13 years by a confusion chart method—for example, Ishihara—and that pre-vocational tests should also be carried out. The use of a simple short method such as Ishihara charts can be made with little instruction by a nurse or other intelligent adult. By this means those with grossly defective colour vision will all be found and most of those with marked colour defects. Yet, 11 years after the Physical Society's report, only a minority of schoolchildren have colour vision tests.

The young man referred to above wasted about two years of his life in training for a task for which he was unsuitable through his colour defect. If he had completed the training period he could undoubtedly have taken some sort of post in a large laboratory, but promotion, which would be dependent on further training and the ability to move from task to task to gain general experience, would have been greatly hampered. The waste of time in training, bitter disappointment of cherished ambitions of would-be chemists, aircrew, seamen, railwaymen, etc., and the even more serious damage to people's careers later can be avoided by a school examination of colour vision.—I am, etc.,

Underfeeding of Babies

SIR,—In the second paragraph of Mr. Albert Davis's letter on this subject (*Journal*, April 6, p. 821) he refers to the "extensive paediatric practices" of some nurses. I would like to go one stage further in commenting on what I might call "risks the baby runs in being kept healthy."

No one would dispute the fact that infant welfare clinics and health visitors have done a lot towards education in baby-care and are a very big factor in the lowering infantile mortality. But now I feel there is a risk of going too far. Just as it is possible to overtreat peptic ulcers—as we read in the same copy of the *Journal* (p. 786)—so I am sure it is possible to overcare for babies. Let me give you three instances: (1) Weighing: Many mothers of newborn babies

are literally slaves to the scales. If baby does not put on his regulation 6 oz. (170 g.) per week, they rush round to the doctor to find out the cause. As I see it, weighing is largely unnecessary. If the baby is contented, taking his feeds, and there are no symptoms of trouble—e.g., vomiting or diarrhoea—and there is no apparent organic trouble, surely everything is fine. If he is breast-fed he is getting enough; and the amount of milk to be given to a bottle-fed baby should anyway be calculated on his expected weight, as opposed to his real weight (and even then one should not stick strictly to the 2½ oz. per lb. (156 ml. per kg.) body-weight per day). As far as I see it, the only point in weighing a healthy baby is to see if a breast-fed one is being underfed—and even then the only method is to test-feed for 24 hours. (2) Foreskins: How many cases of circumcision arise because someone in infancy has been bitten by the stretching bug, so that the foreskin develops into an inelastic scar? Let us recognize the physiologically tight foreskin of the neonate, and leave it well alone. It will then rarely need circumcision. (3) Umbilical herniae: In infancy we know these to be very common, and we also know that a very high percentage are "cured" spontaneously. Why not leave them alone? Strapping (especially with pennies) only becomes unhygienic, and if anything upsets the muscular balance of the abdominal wall it is the strapping that is usually carried out in clinics.

Let me hasten to repeat that in principle I have every admiration for the infant welfare service. But, if the members of it are not careful, their meddlesomeness may undo much of the good they are doing.—I am etc.,

Ramsgate.

W. G. BENSON.

SIR,—It is well that Mr. Albert Davis (*Journal*, April 6, p. 821) has moved us from the perennial, albeit important, topic of overfeeding into the realm of the role of the paediatrician; and how apposite that this should come from an obstetrician.

His concept of the consultant paediatrician as "much too senior to be bothered with trivia" approaches the core of the doctor-patient relationship. Paediatric practice has changed considerably in recent years and now includes not only diagnosis, treatment, and aftercare of the ill child but also the newer practice of preventive child health, starting with the neonates and seeing them through infancy and childhood to puberty. In so much of this work successful management of "trivia" may often prevent more serious and complicated events. The experienced paediatrician will see these in their right perspective and by his reinforcement of the mother's natural potentials will often enable her to feel able to deal with them herself or to know where to turn to for help.

We do not need a new brand of doctor to do this work but an improvement in those involved in child care. The paediatrician, through his contact with parents, health visitors, clinic doctors, and, above all, the general practitioners, can do so much by example and by helping in the better understanding of the everyday yet very real problems of motherhood and child management.—I am, etc.,

London, W.1.

DAVID MORRIS.

SIR,—"Carry oi out but don't bend oi," said the yokel at the feast when he had filled himself up with cider. The yokel was wise, because he knew that the capacity of the human stomach is limited. The truth of this must be remembered when discussing the question of overfeeding babies. While I agree entirely with Dr. Ian G. Wickes (*Journal*, March 23, p. 702) and Mr. A. Davis (*Journal*, April 6, p. 821) when they tell us that it is not possible to overfeed a baby, I am equally convinced that it is possible to overfill its stomach at any one time.

Overfilling produces stretching of the gastric muscle, which responds in the usual way with vigorous contraction. This will result either in regurgitation of the surplus, or, by stimulating intestinal peristalsis, the passage of loose stools. Either of these results, though quite harmless to the baby,

will, if the true explanation is not forthcoming, cause anxiety and lead to the giving of unwise advice, which in turn may produce untoward results.

In my view, much of the trouble caused by overfilling can be traced to the practice of insisting that babies' feeds be diluted with water—a practice based on the false notion that babies may be "upset" by the relatively thick curd of raw cow's milk. The dilute feed fills the baby's stomach but it does not satisfy its hunger; indeed, the attendant regurgitation may cause the loss of much-needed food. The baby cries for more food; the feed is increased and becomes even more bulky; so that a vicious circle is established of overfilling, regurgitation, hunger, overfilling. The remedy is to increase the calories without increasing the volume, first by giving undiluted milk, and secondly, if necessary, by adding an extra scoop of dried milk to the feed without the addition of any extra water. In breast-feeding, when babies can easily overfill themselves if allowed to feed too long (more than ten minutes a side), the remedy is to shorten the time of the feeds and increase their number in the day. It is water that is the curse of the hungry bottle-fed baby, and infancy therefore is perhaps the only time in our life when the right advice is, "Take less water with it."—I am, etc.,

London, S.E.26.

JOHN BURKINSHAW.

Mild Endogenous Depression

SIR,—If I may be permitted, Dr. R. J. T. Woodland's very interesting letter (*Journal*, April 6, p. 822) has prompted me to some further thought on this subject.

I accept Dr. Woodland's criticism of my "four or five E.C.T.s" (*Journal*, February 16, p. 401). I did not intend the latter to be taken quite too literally, but still I agree it could be misleading, and that in many cases it would be most unwise to stop at either of these figures. Ideally, I used to aim at giving two E.C.T.s after all symptoms of depression, sleeplessness, and tearfulness had vanished—that is, from the day the patient attended stating he felt "fully recovered." To stop while there is any suggestion of any one of the above symptoms remaining is usually, in my opinion, to court disappointment. On the other hand, in some cases mental confusion (going beyond the memory defects, which may be ignored) sets in early, and here I think one must hold off for a time and then again review the position. To continue with E.C.T. in the face of confusion only of course increases the confusion, and may lead to panic and a complete refusal to have further treatment.

But my main reason in wishing to re-enter this correspondence is to question the accuracy of the term "endogenous." The latter term suggests that this depression is largely innate or constitutional, which, in my experience, is quite rare. I think it is now fully appreciated that depression in the vast majority of cases simply means an exhaustion of "nature's bank" of nervous energy, due it may be to just the daily wear and tear of life, or in exceptional cases to exceptional causes—acute stress, shock, bereavement, etc. (in the latter cases I do not think there is anything to be gained by coining another term "reactive"; nor, in my opinion, does the diagnosis "reactive" alter in any way the treatment called for). Therefore I think the term "anxiety neurosis" is at once more elastic and all-embracing than "endogenous depression" and is to be preferred to it, provided we do not confuse it with hysterical states, which in my opinion, for the sake of clarity, we should call "anxiety hysteria" and not "anxiety state."—I am, etc.,

Northampton.

ROBERT THOMPSON.

Popular Delusion

SIR,—Rumours of the kind described by Dr. Clifford Allen (*Journal*, April 6, p. 822) are quite common, especially in times of war. Marie Bonaparte described some of them in her *Myths of War* (London: Imago Publishing Co., 1947). Her study is revealing and amusing.—I am etc.,

London, N.W.8.

W. HOFFER.

Road Accidents

SIR,—In your leading article (*Journal*, March 30, p. 753) on the above subject you refer to the American Medical Association symposium recently published, which advocates qualifying medical examinations and re-examinations for drivers; "safety cars," so built as to lessen the risk of damage from collision; and also various other devices to reduce the toll of the roads. But, as far as I can gather from your comments, no mention is made of intoxication as a major factor in accidents, both in the U.S.A. and in this country.

In my opinion, drinking drivers and pedestrians are responsible for 50% of those road fatalities occurring after 10 p.m. and for 10% of all road deaths in this country. I formed this conclusion after reviewing the police reports of all the fatal road accidents in Leicester, Leicestershire, and Rutland for the three years 1953 to 1955. These caused 254 deaths. In a letter in your *Journal* (March 17, 1956, p. 631) I concluded, "If we regard Leicestershire as a fair sample of the country as a whole, there would appear to be over 500 deaths annually in Great Britain due to drinking drivers or pedestrians." Dr. Maurice V. Stack (*Journal*, June 23, 1956, p. 1485) appealed to police surgeons or other interested persons to produce evidence refuting the above figures and conclusions, but none have appeared. Quite recently I have seen the reports of two more groups of fatal road accidents in different parts of the country, and both of these groups confirm my conclusions. In the hundreds of road deaths investigated, in not one instance was the driver involved charged with being "drunk" or "under the influence." I am told that these reports will be published later.

If my views are correct, over 500 deaths annually in Great Britain (and perhaps 25,000 injuries) result from intoxication. It is obvious that very few convictions can be obtained by our present methods of examination. It is surely time for this country to legalize some objective test, in the same way as a speed limit is legalized. Measurement of the alcohol in the urine or blood provides such an objective test, which has been used for many years both in Europe and America. As far as I am aware, no country or state has discarded this test when once adopted. Bad drivers or careless pedestrians are responsible for most accidents, and a very moderate degree of intoxication will convert a careful into a careless and therefore a dangerous driver.—I am, etc.,

Leicester.

N. I. SPRIGGS.

Lung Cancer

SIR,—Your correspondent, Dr. J. Millar Smith (*Journal*, April 13, p. 886), has answered his own question about a possible connexion between road tar and lung cancer. He says: "In fact, I wonder that any of us who live on and use the main roads escape." There is no evidence that road-users, such as traffic police, lorry drivers, and housewives, are particularly subject to lung cancer. There is ample evidence that smokers, especially town-dwelling ones, are. Even the urban factor may be largely accounted for by the fact that the change from pipe to cigarette smoking began in the towns.—I am, etc.,

Garboldisham, Norfolk.

ROBERT McCURDY.

Tetanus Prevention

SIR,—In view of the sometimes severe and occasionally fatal reactions to antitetanic serum (A.T.S.), it now seems quite unjustified to plan any long-term prevention of tetanus by A.T.S. rather than by active immunization with tetanus toxoid (T.T.). The latter has the double advantage of preventing or modifying the disease if infection is incurred and of allowing rapid mobilization of natural antitoxin (without the hazards of a serum reaction) by a booster dose of T.T. in circumstances of special risk.

The immune population will decrease when National Service ends. In the long run the growing practice of triple inoculation (diphtheria, tetanus, pertussis) for infants will build it up: meanwhile the gap could be bridged by active immunization offered by the school medical services, by casualty departments, and perhaps by industrial medical officers, who may meet a population at special risk. For such a policy to bear full fruit, as Dr. Derek Bunting (*Journal*, April 6, p. 819) points out, some accessible record of immunization state will be important.—I am, etc.,

Oxford.

C. W. M. WHITTY.

Budgerigars in Wards

SIR,—In recent years the keeping of budgerigars has become increasingly prevalent. Recently I have noticed their appearance in several general wards of one of the hospitals which I attend, and also in the infirmary ward of a mental hospital. While my personal view is that these birds, which may be carriers of psittacosis, are undesirable in acute wards of general hospitals, I should value the opinion of any of your readers concerning the advisability or otherwise of banning such pets from wards.—I am, etc.,

London, W.1.

N. A. THORNE.

Hungarian Refugees

SIR,—In the report of the proceedings of Council published in your issue of April 6 a statement by Dr. H. D. Chalke (*Supplement*, p. 155) is quoted which implies that many Hungarian refugees, among whom the prevalence of tuberculosis is unduly high, are working in mines all over the country in close contact with other workers, without having been submitted to any x-ray examination. This implication is incorrect. All Hungarian refugees brought into this country for work in the coal mines have been x-rayed—the majority by the National Coal Board's x-ray units and the remainder by mass x-ray units of the regional hospital boards. All cases of active and potentially active tuberculosis revealed by these examinations have been referred to chest physicians for treatment or observation.—I am, etc.,

London, S.W.1.

JOHN ROGAN,
Chief Medical Officer,
National Coal Board.

Sir Victor Horsley

SIR,—In your leading article in honour of Sir Victor Horsley (*Journal*, April 20, p. 937) you refer to the first successful operation for removal of a spinal tumour and mention that Mr. Steadman and Mr. (afterwards Sir Charles) Ballance assisted Horsley at the operation. I still have a letter, however, which Sir Charles wrote to me on July 6, 1934, not long before he died, in which he states, "I alone helped at the operation. Neither Horsley nor I were in favour of many hands in the operation field." He goes on to say, "The spinal cord was exposed too low down. The physicians, bar Ferrier, opposed any further exposure. I was teaching anatomy at that time and urged Horsley to expose the cord higher up. I was probably the only one present who was familiar with the relations of the vertebrae to the spinal roots. Well, Horsley agreed, exposed the cord higher up—the tumour was exposed and shelled out like a sweet [sic] pea."

The tumour, as you correctly remark, was called a fibromyoma. It became specimen 5063-1 in the museum of the Royal College of Surgeons, but cannot be re-examined, as it was, unfortunately, destroyed by the high explosive bomb which fell on the College on May 10, 1941. We shall therefore never know its precise nature, but from the fact that it was adherent to the fourth thoracic nerve root on the left side, where it had been a cause of intense pain of root type below the patient's scapula, and because it was partly cystic and partly solid, there must be a strong presumption that it was in reality a neurinoma and to-day would have been so classified.—I am, etc.,

Cardiff.

LAMBERT ROGERS.

Obituary

H. F. HOLLIS, M.B.

Dr. H. F. Hollis, a well-known general practitioner in Leeds and a former member of the General Medical Services Committee, died at his home at Headingley on April 13 after an illness borne with great patience and fortitude. He was 68 years of age.

Henry Fielden Hollis was born on May 27, 1888, and studied medicine at Glasgow University, where he graduated M.B., Ch.B. in 1917. He then served with the R.A.M.C. in the Middle East and East Africa for the remainder of the first world war. Returning to Leeds, he went into partnership with the late Dr. J. J. Anning in the Beeston district, where he built up a large and busy practice. He soon devoted himself to the duties of the local medical and panel committee and became its honorary secretary in 1933, continuing after 1948 as honorary secretary to the Leeds Local Medical Committee—an office he carried out with energy and zeal. Always ready and willing to assist his colleagues in their problems, he had their good will, friendship, and implicit confidence. There are few who did not benefit from his sound and helpful advice, gained from his many years of experience and close attention to the intricate details of the work. He retired from the secretaryship at the end of 1956 because of illness. His colleagues on the Leeds Local Medical Committee gave him an illuminated scroll inscribed with their names and a message of thanks for his unfailing courtesy and signal help during the 24 years he had served them, and presented him with a personal gift. A dinner was arranged, but unfortunately he was not well enough to attend the function. Dr. Hollis was also a member of the Leeds Executive Council from its inception in 1948.

A stalwart supporter of the British Medical Association, he served on the old Insurance Acts Committee and on its successor, the General Medical Services Committee, for many strenuous years, from 1943 to 1956, and he represented his Division at the Annual Representative Meeting from 1942 to 1956. He was also chairman of the Leeds Division in 1949–50.

Dr. Hollis was very interested in the St. John Ambulance Association and was corps surgeon for Leeds, and did very good work for the brigade. For his services he was appointed an officer of the Venerable Order of St. John of Jerusalem. He was medical officer to the Leeds United football club for 30 years. He held many other appointments, including the chairmanship of a local recruitment board, and he was a medical referee to the Leeds corporation. He leaves a widow, one son, and two daughters.

J. E. R. writes: Harry Hollis was a delightful man to work with, and his quiet efficiency and sustained interest in everything he undertook made him an ideal confidant. He had a charm of manner and a tactful approach which did much to help in solving the many problems which were put to him. His hobbies, when he had time to indulge them, were fishing and golf. He will be greatly missed by his many friends and numerous patients, who have lost a very capable, considerate, and conscientious doctor.

P. B. ROBINSON, M.B., D.P.H., D.T.M.

Dr. P. B. Robinson, formerly director of medical services in Northern Rhodesia, died at Lusaka, Northern Rhodesia, on March 20. He was 56 years of age.

Philip Bernard Robinson was born in Dublin in 1901 and was educated at Trinity College there, graduating M.B., B.Ch. from the University of Dublin in 1925. He obtained the Liverpool D.T.M. in 1929 and the Dublin D.P.H. seven years later. Soon after graduation he joined the Colonial Medical Service as a medical officer and went out to Northern Rhodesia. He served in that territory throughout his colonial career, with the exception of eighteen months during which he was deputy director of medical services in

Uganda. He served first at Solwezi, now no longer a station with a medical officer, and later in many other parts of Northern Rhodesia in various medical capacities. Finally he returned from Uganda in March, 1947, to replace his old chief, Dr. J. F. C. Haslam, as director of medical services. This position he held until he went on leave pending retirement on December 31, 1955. For some years he was an ex-officio member of the legislative council of Northern Rhodesia until the director of medical services ceased to be appointed to that body. He leaves a widow, one son, now a medical student at Dublin University, and two daughters. The sympathies of many people in Northern Rhodesia go to them in their loss.

W. C. B. H. writes: During his long service in Northern Rhodesia, "Barney" Robinson became well known to many people of all races and will be affectionately remembered by numerous members of the public as well as by the officers who served with him. Possessed of an unusually acute brain, he gained a very high reputation as a clinician and as a surgeon during his earlier days in the Colonial Medical Service. Later he devoted himself to administration and was equally successful in this sphere, guiding the Northern Rhodesia health services skilfully through an era of great expansion. In the two years preceding his retirement he played an important part in the difficult task of fusing three separate health services into one after the federation of the three territories of Southern and Northern Rhodesia and Nyasaland. In his dealings with his staff he was always kindly and scrupulously fair, although it was typical of him that he often did his best to conceal this under a gruff outer manner. Similarly his many acts of generosity were always, if possible, concealed.

S. G. JAMES, M.D., M.R.C.P., D.P.M.

Dr. S. G. James, medical superintendent of Broadmoor Institution, died on April 11 after a long illness. He was 53 years of age.

Stanley George James was born at Sydney, Australia, on October 4, 1903. After graduating M.B., Ch.M. from the University of Sydney in 1926, he held the appointments of house-physician, house-surgeon, and medical registrar at his teaching hospital, and in 1929 came to England. His first appointment in London was that of senior house-physician at the West End Hospital for Nervous Diseases, and he then became assistant medical officer at Friern Hospital. He was elected a Member of the Royal College of Physicians of London in 1931, obtained the D.P.M. of the English Royal Colleges in 1934, and proceeded to the M.D. in 1939. From 1935 to 1939 he was deputy medical superintendent at Rampton Hospital and from 1939 to 1952 medical superintendent at Moss Side Hospital, Maghull.

A colleague writes: Dr. James was appointed medical superintendent at Broadmoor in 1952. With his long service in State institutions, he brought the benefits of this experience to Broadmoor. His first interest, naturally, was the care of his patients, but in addition he was indefatigable in his efforts to improve conditions for members of the staff. He had a brilliant mind, and his contributions to clinical discussions and demonstrations in the post-mortem room were most inspiring. He was able to talk authoritatively and comprehensively about many subjects, particularly gardening, electronics, and carpentry, and his workshop was the envy of every visitor. He gave invaluable directions when the new handicraft centre at Broadmoor was equipped. He read widely, and especially was a great lover of the works of Charles Dickens and Gilbert and Sullivan. His early days at Broadmoor were so full of promise, and during the short time he was there he achieved so much, that it seems grievous he should have died so soon, but very many of us, both patients and staff, are comforted by gratitude for what he has done for us. Our heartfelt sympathy goes out to his widow, formerly Miss Winifred Boshier, who had been the matron at Broadmoor and who tended him unsparingly in his illness.

GEORGE MITCHELL, M.D., D.P.H.

Dr. George Mitchell died suddenly on April 6 at the age of 81, and his passing leaves a distinct gap in the medical life of Wolverhampton, where for so many years he had occupied a niche all his own.

Born on October 18, 1875, George Mitchell was a graduate of Aberdeen University, where he qualified in 1903, and proceeded to the M.D., with highest honours, in 1905, attaining the D.P.H. in the interim. After a period in general practice he entered the public health service, and after working for two years as chief school medical officer in Aberdeenshire, he became, in 1912, assistant medical officer of health and tuberculosis officer to the County Borough of Rochdale. From 1914 to 1919 he saw service in the first world war with the R.A.M.C.

In 1919 he went to Wolverhampton to take charge of the venereal diseases services for the district, with headquarters at what is now the Royal Hospital, Wolverhampton, and he held this post for 32 years until his retirement in 1951. During this period he developed such an interest in diseases of the skin that in recognition of his clinical abilities in this field a special department of dermatology was created and he became the first dermatologist to the hospital. He was chairman of the South Staffordshire Division of the British Medical Association in 1932-3. A mere catalogue of the details of his career would entirely fail to explain the peculiar regard in which he was held by all his colleagues in hospital and by the practitioners of the district. To an extent quite peculiar to himself, his personality evoked a mixture of the deepest affection and respect—respect for his intellectual abilities and intellectual honesty, two qualities by no means always synonymous, and respect for his clinical judgment and integrity of life, qualities which to many of us seemed to typify the granite of his native country but which by themselves could nevertheless suggest a personality essentially cold. By contrast it was his warmth and sense of humour which seemed to enlarge and almost transfigure his mental equipment, so that in the course of time he became a central figure beloved by all. He had anticipated his ending, which he met with the cheerful stoicism so characteristic of him. The passing of George Mitchell leaves those privileged to know him well with a great sense of loss. He will not be soon forgotten.—J. H. S.

THORVALD MADSEN, C.B.E., M.D.

Dr. Thorvald Madsen, the distinguished Danish microbiologist, died suddenly at St. Heddinge, East Zealand, on April 15 in his 88th year.

Thorvald Johannes Marius Madsen was born at Frederiksberg on February 18, 1870, and studied medicine at Copenhagen University, where he graduated in 1893. During the next few years he held a teaching post in the bacteriological laboratory of the university and studied abroad, working for a time at the Pasteur Institute in Paris and with Ehrlich at Frankfurt. In 1902 he was appointed director of the State Serum Laboratory at Copenhagen, a post he retained until his retirement in 1940. He was one of the most prominent medical scientists who worked for the League of Nations, and was president of its Health Committee from 1921 to 1940. He presided over the first meeting of the Commission on Biological Standardization in London in 1921 and remained president of the commission until 1940. As part of his work for the League he organized measures to control the many epidemics in east and south-east Europe which were an aftermath of the first world war.

Madsen published many works on immunology and immunochemistry and edited the *Communications de l'Institut Sérothérapique de l'Etat Danois* from 1906 to 1940. His scientific work gained him an international reputation and many awards, including the Buchanan Medal of the Royal Society in 1932 "for his theoretical and practical work in immunity, especially in relation to diphtheria antitoxin,"

the Swedish Pasteur Medal, the Grand Cross of the Order of the Dannebrog, and the Légion d'Honneur. He was created an honorary C.B.E. in 1921. An honorary fellow of the Pathological Society of Great Britain and Ireland, he held honorary doctorates of Glasgow, Frankfurt, Upsala, Riga, and Oslo. Even after retirement Madsen maintained his interest in humanitarian and scientific work. He headed the Unicef mission to Italy from 1947 to 1950, and was president of the Fourth International Congress on Microbiology held at Copenhagen in 1947.

Medical Notes in Parliament

INTERIM ADVANCE

The PRIME MINISTER announced on April 16 a 5% increase in the basic remuneration of senior hospital medical and dental staff, including consultants and specialists, and for all dentists engaged in the general dental service, and a corresponding addition of 5% to the aggregate net remuneration of general practitioners (that is, remuneration after deduction of practice expenses). It will operate from May 1. The increase will cost £4,900,000, divided as follows: senior medical staffs, about £1,200,000; general medical practitioners, £2,500,000; general dental practitioners, £1,200,000. To this should be added the 10% interim increase for junior hospital staff, amounting to £900,000.

The text of Mr. Macmillan's statement was as follows:

Before the Royal Commission was appointed I explained that its appointment did not preclude an interim adjustment in advance of and without prejudice to its recommendations. An adjustment was made in the remuneration of junior hospital staff, both medical and dental, at the beginning of this month, when their remuneration was increased by 10%. In announcing this increase I said that we were considering what should be done by way of an interim adjustment for the other doctors and dentists covered by the Commission's terms of reference.

The Government have now decided to increase the basic remuneration of senior hospital medical and dental staff including consultants and specialists and all dentists engaged in general dental services by 5% from May 1 next, and from the same date to add 5% to the aggregate net remuneration of general practitioners—that is, remuneration after the deduction of practice expenses. We propose to consult representatives of the profession as to the best method of distributing this sum between individual practitioners.

In the meantime, the Royal Commission have been asked to regard their work as a matter of urgency and have in fact already, I understand, held six meetings. I hope that the letters I have exchanged with the then President of the Royal College of Physicians, together with the statement issued by the chairman of the Royal Commission, will reassure those who have expressed their concern about the terms of reference.

I hope now that all concerned will turn their thoughts to the task of working out a satisfactory basis for future remuneration, and for keeping it under review.

Dr. EDITH SUMMERSKILL (Warrington, Lab.) asked these questions: What was the basis used to arrive at this award? Why has this decision been made in an arbitrary fashion, without negotiation with the doctors? Why has the decision been made without any consideration of the findings of the Royal Commission? Will the distribution from the central pool be similar to that made in 1952? Mr. MACMILLAN: It was always stated by the Government that they intended to make an interim award while the Commission was sitting. The 10% was given to the junior staff, and now 5% is given to the general body. The reason this procedure is adopted is that the present dispute is on a matter of the interpretation of the Spens Reports. Therefore there could not be any agreed basis for negotiation in the ordinary way. The object of the Commission, which is really an independent body, is to find and recommend what should be the basis of remuneration both now and in the future. As to the method of calculation, I do not know whether it is similar to that in 1952. In the case of the 10%, it is as I have already stated. In the case of the 5%, it is by adding to the aggregate net remuneration. Then we propose to

consult the doctors' organization on the best method of distributing this money.

Mrs. LENA JEGER (Holborn and St. Pancras, South, Lab.) asked the Prime Minister to give a better explanation. Was he saying that he thought up 10% in his sleep one night, and that on another night he thought up 5%? What was the arithmetic behind a suggestion that provides the same increase for highly paid consultants as for the humbler and overworked general practitioner? Mr. MACMILLAN: As I have explained, we appointed a Royal Commission because there is a disagreement on what should be the whole basis for calculating remuneration both now and in the future. I hope that this independent body, with terms of reference which I have explained to be very wide, will reach that basis. Meanwhile, since the Commission must take a considerable time—a substantial time—to make its report, it was thought right to make this advance. I hope and believe that it will be regarded on the whole as equitable and reasonable.

Mr. A. WOODBURN (Clackmannan and East Stirling, Lab.) asked what steps were to be taken to see that fairness was done to the assistants. In some parts of the country a lot of empire-building was going on among doctors and assistants. The public would like to know that the assistants were to get proper treatment under these arrangements. Mr. MACMILLAN: No doubt the Minister of Health will take the point into account in consultation with the doctors' representatives on the methods of distribution. We shall certainly take account of the point.

Collective Bargaining Machinery

Mr. M. LIPTON (Brixton, Lab.) asked how the Prime Minister expected employers and workers to accept the principle of collective bargaining if he ignored it in dealing with the doctors' increment. Was he aware that this contempt for established machinery was regarded as a grave injustice by the medical profession? Mr. MACMILLAN: I do not think that is really quite fair. It is a prerequisite of any arbitration that there should be common agreement on what the arbitration has to be about. The difficulty here is disagreement about the interpretation of the Spens Reports. The most practical way—I think there is general opinion in the country supporting this—is to get the most independent body we can, and I think we have in the Royal Commission a very good independent body, to try to reach an agreed basis from which in future these adjustments can be made without difficulty.

Dr. D. JOHNSON (Carlisle, Con.) asked the Prime Minister, or the Minister of Health, to press on the medical organization the necessity of bearing in mind in distributing the 5% that there was serious concern at the differences in remuneration among various practitioners within the same service, and that this should be given serious attention in the distribution of the extra sum. Mr. MACMILLAN suggested that no doubt Dr. Johnson would, if necessary, communicate with the Minister of Health.

Mr. A. BLENKINSOP (Newcastle upon Tyne, East, Lab.) asked whether the Prime Minister could assure him that at last the Minister of Health would have real power to carry out negotiations, and that he would not only take account of the position of assistants but also of doctors with smaller lists, and would try to get a constructive settlement that would help to reduce the large lists of the richer practitioners. Mr. MACMILLAN: It is not a question of negotiation but of consultation, and of how this interim award had better be distributed and applied. When we get the Royal Commission's report I hope we shall have a permanent solution of how the whole Service will work in the future.

Speed of Commission

Dr. BARNET STROSS (Stoke-on-Trent, Central, Lab.): As an important factor will be the speed at which the Royal Commission reports, can we have an assurance that its deliberations will not take more than eight or nine months from now? Mr. MACMILLAN: I have asked the Royal

Commission to do its work speedily. I have every confidence in the chairman and the members. The Commission has already had six meetings, and I hope that every possible assistance will be given to the Commission to conclude its task speedily.

Mr. J. RAMSDEN (Harrogate, Con.): In view of the business-like way in which the Commission is proceeding, as shown by the fact that it has already met six times, has the Prime Minister some hope that the doctors will, in these changed circumstances, modify their attitude towards the Commission? Will he make it clear, once and for all, that it will be within the competence of the Commission to have regard to the general relevance of the Spens Reports in its consideration of the matter? Mr. MACMILLAN: All these points about the competence of the Commission were cleared in the exchange of letters which took place, and which I think has been generally regarded as wise and satisfactory. I very much hope that everyone concerned will now turn his labours to the work of creating a satisfactory basis for the future remuneration and management of the Service.

Mr. F. LEE (Newton, Lab.) said now that the Prime Minister had pointed out that before they could have a successful arbitration it was necessary to have some sort of offer about which to arbitrate, would he make sure that a copy of his statement went to the shipbuilding and engineering employers? Mr. MACMILLAN: I did not say that we had to have some kind of offer, but some kind of basis. In this case, there was one interpretation which the doctors made and which the Government felt they could not accept. Therefore it was far better to have an independent body to deal with the matter.

Royal Commission's Inquiries

Mrs. LENA JEGER asked the Prime Minister on the same day when the Royal Commission on the remuneration of doctors and dentists started work, and from whom evidence had so far been taken.

Mr. MACMILLAN told her that he was informed that the Royal Commission held its first meeting on March 13, the day after he announced its appointment, and that it had already held six meetings. He understood that it had not yet received any formal evidence, but had held preliminary and informal discussions with representatives of the consultants, the dental profession, the Bar, architects, chartered surveyors, accountants, and different branches of the engineering profession. Representatives of the consultants and the dentists made it clear at that stage that their presence did not commit their organizations to giving evidence.

COMPENSATION FOR LOSS OF GOODWILL

The subject of compensation for loss of the right to sell goodwill of medical practices was discussed in the House of Commons on April 18. Mr. RONALD BELL (South Buckinghamshire, Con.) complained of a decision that had been given on an application for compensation by a doctor constituent of his. Normally, he said, a doctor received compensation when he retired for the right to sell his practice, which was lost under the National Health Service Act. There were, however, provisions providing for earlier payment of compensation. Paragraph 262 in the *Handbook for General Medical Practitioners* stated: "... where doctors have onerous loans outstanding which were raised for the purchase of their practices, or where an elderly doctor or one whose health is failing finds it necessary to take a partner in order to prevent the complete disintegration of his practice," early payment might be made.

His constituent suffered two attacks of virus pneumonia in June and October last year. He obtained the services of a locum tenens. As a result of the second attack the doctor became permanently unable to carry on his medical practice alone, giving the whole of his time to it, and an arrangement was made that the locum should remain with him in partnership. As a consequence certain expenses for residential and surgery accommodation were incurred, and the doctor made

an application to the Ministry of Health last December in respect of these. The application was unsuccessful because, it was stated, (1) from 1950 to 1956 his list had increased progressively from 1,400 to 2,450 patients (approximately), and (2) he had described himself as being actively engaged in the practice.

The first reason, Mr. Bell argued, was not relevant to the damage caused to the practice by the doctor's two illnesses last year. As for the second, it could easily happen that a medical practitioner became unable to carry an unlimited liability. He had asked the Ministry in what sort of circumstances an early payment of compensation under para. 262 might be made. The reply he had received was this:

"Para. 262 . . . owes its origin to discussions held in 1953 with the B.M.A., who were subsequently informed that the Department was willing to consider sympathetically advance payments of compensation to 'individual cases of hardship where an elderly doctor or one whose health is failing finds it necessary to take a partner in order to prevent the complete disintegration of his practice' . . ."; and: "As was expected, however, extremely few applications on these grounds had been received, and none has been sufficiently strong to justify an advance payment." The letter also stated: "Before regarding a payment as justified, we expect factual evidence that the practice was rapidly declining due to the ill-health . . . of the doctor."

That meant, said Mr. Bell, that in order to save the ship one must sink it first. Money would not be paid in advance of retirement until a doctor could prove that his practice had already undergone a rapid decline due to his ill-health. Therefore, if he had available a suitable locum who would prevent any disastrous consequences to the practice through his illness, and used the locum, he disintegrated himself to claim under para. 262. The Ministry's letter continued: "We would not consider a payment to be justified, however, if it appeared that the doctor could reasonably carry on the practice alone, albeit a reduced practice with a correspondingly reduced income."

To interpret para. 262 in this way, Mr. Bell argued, was not a fulfilment of the undertaking given in writing to the B.M.A. in 1953 that "the Minister will sympathetically consider any individual case of a doctor who through ill-health has to take in a partner to prevent the complete disintegration of his practice." It was misleading if practitioners were to be subsequently told that what it really meant was that only if their practice had got well on the way to disintegration they might have a case. It was also wrong on its merits. If a practitioner was fortunate enough to be able to take immediate action to prevent disintegration of his practice, he should not thereby in any way prejudice his right to apply under para. 262.

Government Reply

Mr. J. K. VAUGHAN-MORGAN, Parliamentary Secretary, Ministry of Health, said that in Section 36 (3) of the National Health Service Act, 1946, which stated that compensation should not be paid until the retirement or earlier death of the doctor concerned, a proviso was inserted "except in such circumstances as may be prescribed" to meet the circumstances of those doctors who had outstanding onerous loans for the purchase of the goodwill of the practice. The total number of claims for England and Wales was about 15,000, of which over 11,000 were outstanding. The total amount so far paid out was £21m., including £8m. in advance payments made on grounds of hardship. The Department had been generous in its interpretation of the provision. As a result of representations made by the profession in 1953 it was agreed to extend the proviso to make advances of compensation where a doctor found it necessary to take a partner in order to prevent the complete disintegration of his practice. There was some knowledge on the side of the Department that there would not be many such cases; the agreement was made so that machinery should be ready to alleviate cases of hardship that might arise. No claims had in fact been paid out under this proviso. No case had so

far been found to justify payment under this heading. There had been only three applications in the course of four years. No complaints had been received from the profession of any dissatisfaction with these decisions. It was obvious that individuals might feel it, but there had been no widespread feeling that there had been a failure to do justice.

It should be remembered that, as compensation was made for the loss of the right to sell the goodwill, the real test for any advance payments under the proviso was whether, in the days before the Health Service, a doctor would have sold his goodwill to meet expenditure that was now alleged to involve hardship. He would obviously have done so only in very exceptional circumstances, as he would be parting with his means of livelihood. It followed that the Department could not use this proviso to make advances to enable doctors to buy houses or cars or to equip their surgeries. To meet those needs other means were available, which did not concern the Ministry of Health. No fewer than nearly 1,400 doctors had borrowed money on the security of the compensation ultimately payable to them, and the amount involved was £4,500,000.

In the particular case cited by Mr. Bell the doctor gave in December five different reasons for immediate compensation. The first was that age and ill-health had compelled him to take a partner to prevent the complete disintegration of his practice. The four others were the need to buy a house for his partner, at a cost of £3,750; the need to adapt and equip surgery premises costing between £600 and £1,000; the inability to meet these costs because he had only 2,400 Health Service patients, and his share had been halved by the introduction of a partner; and lack of capital. The Department could not accept any of those reasons except the first: a doctor could not obviously have sold his goodwill to buy a house or equip a surgery. As for the disintegration of the practice, this was not the first claim made on grounds of ill-health. The doctor made a claim in 1951, when the number of his patients was 1,583. By July, 1956, just before he again made a claim, they had risen to 2,381; and on January 1, 1957, just after he made the new claim, the number had risen to 2,424. During the past quarter there had been a further increase to 2,489. This was on the doctor's own list and not his partner's. Whatever these figures showed they could not be interpreted as complete disintegration; nor did they support the contention that his illness would result in a permanent decrease in his capacity for work. The doctor's application to receive extra payment on the notional-list basis had been rejected by the executive council on the ground that the arrangement he had made with another doctor was not a bona-fide partnership, and that the other doctor might be considered to be engaged more in the capacity of assistant than partner; he had his own list.

He added that he would consider the criticisms of the wording used in the *Handbook*, and see whether any better wording could be found, though he doubted it. Before any changes were made the Department would in any case have to consult representatives of the profession.

Poliomyelitis Vaccine

Mr. WEDGWOOD BENN (Bristol, South-East, Lab.) asked the Minister of Health whether supplies of the anti-polio vaccine would be available in sufficient quantities to immunize all those children in the recommended age groups, and what percentage of this maximum potential demand could be met this year; and what plans he had for providing 100% coverage. Mr. VAUGHAN-MORGAN stated on April 18 that good progress was now being made with vaccination against poliomyelitis, and it was the Minister's aim to increase the coverage as rapidly as possible. There would, however, be no relaxation of the safety precautions applied to the vaccine, and he therefore did not think he would be justified in trying to make precise estimates of future progress.

INFECTIOUS DISEASES AND VITAL STATISTICS

Summary for British Isles for week ending April 6 (No. 14) and corresponding week 1956.

Figures of cases are for the countries shown and London administrative county. Figures of deaths and births are for the 160 great towns in England and Wales (London included), London administrative county, the 17 principal towns in Scotland, the 10 principal towns in Northern Ireland, and the 14 principal towns in Eire.

A blank space denotes disease not notifiable or no return available.

The table is based on information supplied by the Registrars-General of England and Wales, Scotland, N. Ireland, and Eire, the Ministry of Health and Local Government of N. Ireland, and the Department of Health of Eire.

* Measles not notifiable in Scotland, whence returns are approximate.
† Includes primary and influenza pneumonia.
§ Includes puerperal pyrexia.

Vital Statistics

GLASGOW X-RAY CAMPAIGN

During March 11 to April 12 nearly three-quarters of a million people in Glasgow had chest radiographs taken. Preliminary figures show that 1,600 active cases of tuberculosis were found, or 0.22% of the 710,838 people x-rayed. These figures were given on April 18 by Dr. A. K. BOWMAN, senior administrative medical officer of the Western Regional Hospital Board. A further 5,069 cases (0.7%) were still doubtful, and in 1,405 cases (0.19%) the disease appeared to be healed, but further observation was considered necessary. A total of 8,074 cases of pulmonary tuberculosis have thus so far been found which require further observation or treatment. We are indebted to Dr. W. A. HORNE, Medical Officer of Health of Glasgow, for the following account of the measures which made this campaign such a striking success.

When the Glasgow campaign ended more than 700,000 persons over 14 years of age had been radiographed. Several world records were broken, and on the last day, Friday, April 12, 46,077 persons were examined. The campaign has been most successful and will be the turning-point in the control of tuberculosis in Glasgow. During the five weeks 30 mass miniature x-ray units were open to the public, mainly in the afternoon and evening, but on the last day all the units opened at 10 a.m. and continued in action until the queues were exhausted. Seven additional units were set aside for the examination of members of the public recalled for a large film. Of the 37 units, 10 were Scottish, 21 English, four from the Army, one from the R.A.F., and one from the National Coal Board.

Initial planning started some eighteen months ago, when consideration was given to exact timing, the number of x-ray units required, the dispersal of the units in sites most suitable and attractive to the public, and important technical and other factors to be taken into account in the organization of the campaign, which was mounted jointly by the Corporation of Glasgow, the Department of Health for Scotland, and the Western Regional Hospital Board.

Publicity was regarded as vital and had to be inspired, sustained, and thorough, with nothing left to chance. Expert advice was essential, and this was found in a publicity committee on which were represented the press, the cinema, and the B.B.C. Valuable assistance was given by the Scottish Information Office, which supplied an expert press officer whose help was continuously available. Excellent support was obtained from the press in the initial stages, both before and during the campaign. Three short films were prepared, two by N.A.P.T., and with the co-operation of the owners and managers these were shown in all the Glasgow cinemas.

Adding spice and forming important publicity material was the scheme of prizes, which were of two types—six large and numerous small prizes. One of the large prizes was presented each week, and the most valuable, an A.35 motor-car donated by the Glasgow Austin agents, at the end of the campaign. The small prizes were distributed by "x-ray men" to members of the public, who wore the distinctive badge showing that they had been radiographed. Various other novel publicity methods were developed and used. Ideas bubbled up and when approved by the publicity committee were immediately developed. Two campaign songs were written and have proved intriguing and popular. The services of the writers, composers, and musicians were given free.

The defects of publicity were revealed by short public surveys carried out by a department of the university, and the material was adjusted to remedy the defects shown. Special attention was paid to the doubts and anxieties that were expressed, and particularly to the need to encourage parents of young children and older people to be radiographed.

The second major factor was community participation. Above all, the campaign was non-denominational and non-

political. Assistance was invited and willingly given by all denominations, and members of the Churches played a very important part. Some 12,000 voluntary workers were enrolled, divided into 49 ward groups, each with ward headquarters, chairman and secretary, and executive committee. These ward groups not only spread information about the campaign but also carried out house-to-house visiting and ascertained the attitude of the householders, and followed up that information by subsequent visits. The ward groups provided hostesses for the x-ray units, and these hostesses have proved to be an important factor in the successful working of the centres.

Every member of the Corporation and every group or association in the city, religious, political, social, industrial, and commercial, were behind the campaign and gave wholehearted support. Community participation was in fact universal. The campaign, of course, could not have been successful without the enthusiasm of the staffs of the x-ray units coming to Glasgow and their departmental, administrative, and organizing staffs.

The campaign began and ended with a religious service in the Cathedral and in St. Andrew's Church. To the citizens of Glasgow it was in the nature of a crusade, and their response has been a reward and a tribute to the organizers.

Graphs of Infectious Diseases

The graphs below show the uncorrected numbers of cases of certain diseases notified weekly in England and Wales. Highest and lowest figures reported in each week during the nine years 1948-56 are shown thus -----, the figures for 1957 ————. Except for the curves showing notifications in 1957, the graphs were prepared at the Department of Medical Statistics and Epidemiology, London School of Hygiene and Tropical Medicine.

Infectious Diseases

The largest variations in the notifications of infectious diseases in England and Wales during the week ending April 6 were increases of 95 for measles, from 25,185 to 25,280, 66 for scarlet fever, from 812 to 878, and decreases of 171 for dysentery, from 1,222 to 1,051, 81 for whooping-cough, from 2,849 to 2,768, and 79 for acute pneumonia, from 545 to 466.

37 cases of acute poliomyelitis were notified during the week, and these cases were 1 fewer for paralytic and 10 more for non-paralytic cases than in the preceding week. The largest returns were Essex 12 (Brightlingsea U.D. 10), Sussex 6 (Brighton C.B. 5), London 4.

Generally the incidence of measles continued to decline in the north and rise in the south of the country. In the north-west and northern regions the number of notifications fell by 999, from 6,947 to 5,948, and in London and the south-east region they rose by 483, from 4,787 to 5,270. The London boroughs with the largest increases in the number of notifications of measles were Greenwich 64, from 59 to 123, Hammersmith 45, from 26 to 71, Wandsworth 50, from 159 to 209. Other towns with large increases were Birmingham C.B. 200, from 640 to 840; Cardiff C.B. 169, from 226 to 395; Havant and Waterloo U.D. 102, from 72 to 174, and Chatham M.B. 78, from 147 to 225.

Only small variations were recorded in the returns of scarlet fever. The largest fluctuations in the trends of whooping-cough were decreases of 43 in Shropshire, from 73 to 30; 38 in Norfolk, from 110 to 72; 34 in Kent, from 228 to 194; and increases of 44 in Essex, from 146 to 190; and 37 in Cheshire, from 48 to 85. 9 cases of diphtheria were notified, being 3 more than in the preceding week; 2 of these cases were notified in Birmingham C.B.

The largest centres of dysentery were Yorkshire West Riding 245 (Bradford C.B. 54, Leeds C.B. 46, Rotherham R.D. 38, Sheffield C.B. 18, Rotherham C.B. 17, Huddersfield C.B. 15), Lancashire 123 (Blackburn C.B. 26, Stretford M.B. 18, Liverpool C.B. 14), Cheshire 58 (Hyde M.B. 25,

Stalybridge M.B. 22), Durham 56 (Whickham U.D. 23, Gateshead C.B. 12, Blaydon U.D. 10), Warwickshire 49 (Birmingham C.B. 34, Coventry C.B. 11), Nottinghamshire 43 (Nottingham C.B. 14, Carlton U.D. 11), Middlesex 41 (Hayes and Harlington U.D. 11, Ealing M.B. 10), Northumberland 38 (Longbenton U.D. 22), London 36 (scattered through 14 boroughs), Southampton County 35 (Southampton C.B. 13, Basingstoke M.B. 10), Essex 34 (East Ham C.B. 18), Bedfordshire 30 (Luton M.B. 22), Norfolk 22, Surrey 21, and Oxfordshire 21 (Bullington R.D. 14).

Medical News

Benefactions by the Wellcome Trust.—The Wellcome Trustees announce the following benefactions: (1) £95,000 to Birmingham University as a contribution to the cost of building an extension to the clinical research block at the Queen Elizabeth Hospital. The extension will substantially increase the research accommodation for the university departments of medicine and surgery. (2) Up to £11,000 to the Middlesex Hospital Medical School for the cost of providing an extension to the Institute of Clinical Research in Hanson Street. (3) £10,000 to the Christian Medical College Hospital, Vellore, South India, for the cost of setting up a metabolic research unit and maintaining it for five years. The unit is to be used in the first instance for a study of fat metabolism in relation to tropical sprue. The Trustees have also agreed to purchase the following items of special equipment for indefinite loan to research centres: a nuclear magnetic resonance spectrometer (costing approximately £17,000), for the department of chemistry, University College, London; and a photo-electric spectropolarimeter (costing approximately £3,600), for the department of biochemistry, Postgraduate Medical School of London.

Association of British Pharmaceutical Industry.—The scheme for regulating prices of proprietary drugs was referred to by speakers at the annual dinner of the Association of the British Pharmaceutical Industry, held last week at the Savoy Hotel. Mr. C. M. HILL, president of the association, said that the industry would do its best to ensure that the scheme worked satisfactorily, and he hoped that the agreement reached between the Ministry and the association would put an end to the exaggerated stories about the excessive cost of proprietary drugs. The industry had been built up on the good will of the medical and pharmaceutical profession. "Reputable firms," Mr. Hill continued, "do not overstate claims for their products." Finally Mr. Hill paid tribute to the work of Mr. W. K. FITCH, who would shortly be retiring from the editorship of the *Pharmaceutical Journal*. Mr. DENNIS VOSPER, Minister of Health, speaking in reply, congratulated the industry on voluntarily putting forward a scheme for price control and for the co-operation which had been shown during the discussions with the Ministry. Referring to criticisms of some of the publicity methods of which he had heard rumours, Mr. Vosper said that the consumers' point of view should be borne in mind, and he hoped that the industry would keep this sort of practices within reasonable control.

U.N. Committee on Atomic Radiation.—Starting on April 8, the General Assembly's committee on atomic radiation began a private 10-day session in Geneva. One of the items on the committee's agenda was the measurement of radioactive fall-out, especially strontium-90. Among the delegates to the 15-member committee were Dr. E. A. WATKINSON (Canada), who was elected vice-chairman; Dr. E. E. POCHIN, director of the M.R.C. department of clinical research at U.C.H. Medical School, London (United Kingdom); Mr. D. J. STEVENS (Australia); Mr. V. R. KHANOLKAR (India); and Dr. SHIELDS WARREN (United States). The committee also includes delegates from the U.S.S.R. and Japan.

Scope of Mass Radiography.—The Joint Tuberculosis Council has issued the following statement on the use of mass radiography in industry and general practice:

"The council, at its meeting on March 1, considered a report by its radiological committee and strongly supported the views expressed in this report—namely, that much more extensive use should be made of mass radiography; and that in industry both employers and employees should—in their own interest—arrange for pre-employment x-rays; and that, for the protection of the public, annual x-rays should be required of staff employed on public transport and in the catering trades. It also recommends that the present mass x-ray service should be improved by providing miniature x-ray units in all chest clinics for the examination of persons referred by general practitioners, and by others who wish to have a chest x-ray. The extension of the miniature x-ray service in this way would make chest x-ray easily available to everyone, and pre-employment x-rays could be provided either by the chest clinic service or by private arrangement with industry."

The Joint Tuberculosis Council comprises representatives of the British Tuberculosis Association, the Society of Medical Officers of Health, the B.M.A., N.A.P.T., the Society of Thoracic Surgeons, the Faculty of Radiologists, and other bodies and individuals interested in the prevention and treatment of tuberculosis.

Royal College of Surgeons.—Two benefactors of the College were honoured at the council meeting on April 11. Sir ARTHUR SIMS, the New Zealand industrialist, was admitted to the honorary fellowship, and, with Mr. EDWARD LUMLEY, to the Court of Patrons. Jacksonian prizes for 1956 were awarded to Mr. A. H. HUNT (St. Bartholomew's Hospital, London) and Mr. J. A. MACCREIDIE (Belfast) for their essays on portal hypertension; Mr. R. E. HORTON (Bristol) received a certificate of honourable mention. The subject for the 1958 Jacksonian prize will be an essay on "Factors Which Influence the Genesis and Progression of the Disease." The Hallet prize was presented to Dr. S. K. NAIR (Agra University). The title of Bland-Sutton lecturer in anatomy at the College. The following were elected fellows without examination, being practitioners of at least 20 years' standing: Mr. G. F. Burnell (Truro), Professor P. K. Chamugam (Colombo), Mr. R. F. Guymer (London School of Hygiene and Tropical Medicine), Mr. G. G. Lyttle (Belfast), Surgeon Vice-Admiral R. C. May (medical director-general, Royal Navy), and Colonel J. M. Shah (Karachi).

Alan Newton Prize.—The council of the Royal Australasian College of Surgeons has awarded the 1956 Alan Newton prize to Mr. L. I. PARTON, F.R.C.S., a urologist at Auckland, New Zealand. Mr. G. R. DAVIDSON, F.R.C.S.Ed., of Ballarat, Victoria, *proxime accessit*. The subject for the next prize will be an essay, not exceeding 75,000 words, on "The Surgery of Malformations of the Heart and Great Vessels." Candidates must hold one of the following qualifications: F.R.A.C.S., F.R.C.S.(Eng.), F.R.C.S.I., F.R.C.S.Ed., or F.R.F.P.S. (in surgery). The prize is biennial, and entries must be in the hands of the secretary of the Royal Australasian College of Surgeons (Spring Street, Melbourne, C.1) by December 1, 1958. Further details about the prize may be obtained from the College.

Russia and W.H.O.—The Russian government has informed the World Health Organization that it will resume active membership as from the current year. The U.S.S.R. became a member State in March, 1948, but discontinued active participation in February, 1949.

Glasgow University.—Among those on whom the Senatus Academicus has decided to bestow honorary degrees on Commemoration Day (June 19) are: Brigadier J. S. K. BOYD, F.R.S., formerly director of the Wellcome Laboratories of Tropical Medicine, and Sir JAMES PATERSON ROSS, professor of surgery in the University of London. Both are to receive the honorary degree of Doctor of Laws.

University College of the West Indies.—Dr. ROBERT MITCHELL, an assistant pathologist in Glasgow, has been

appointed lecturer in anatomy. Before turning to medicine Dr. Mitchell practised for a number of years as a veterinary surgeon. In 1944 he graduated M.B., Ch.B. at Glasgow University, later holding university appointments there as demonstrator in anatomy and lecturer in histology and embryology. He is expected to take up his appointment in Jamaica in June.

Psychiatrist Appointed Vice-chairman of L.C.C.—Dr. L. F. BROWNE was appointed vice-chairman of the London County Council at the annual meeting on April 16. Dr. Browne is a consulting psychiatrist and deputy chairman of the Tavistock Institute of Human Relations. He is also a J.P. for the County of London, and has been an alderman of the L.C.C. since 1949.

Sir Philip Manson-Bahr has been awarded the 1955 Emile Brumpt prize by the Faculty of Medicine and the Institute of Tropical Medicine of Paris. He will lecture on May 22 before the Société de Pathologie Exotique at the Institut Pasteur on the "History of the School of Tropical Medicine in London."

Dr. W. Lane-Petter, director of the Laboratory Animals' Bureau of the Medical Research Council, has been appointed by the Privy Council to the council of the Pharmaceutical Society. He succeeds Dr. J. A. GILES, who has retired.

Dr. Hilda Roberts, honorary research assistant at the Institute of Obstetrics and Gynaecology, London, is leaving England shortly to become director of obstetric anaesthesia at Women's College Hospital, Toronto. She was the guest of honour at a party at the House of Commons on April 11, when Mr. J. BIGGS-DAVISON, M.P., and Mr. E. L. MALLALIEU, Q.C., M.P., entertained members of the committee of the National Birthday Trust Fund. For the past two years Dr. Roberts has been the Trust's research fellow in obstetric analgesia.

COMING EVENTS

Medical Art Society.—Fifteenth annual exhibition at Walker's Galleries, 118, New Bond Street, London, W.1, April 26 to May 11.

Glasgow Medical Exhibition.—April 29 to May 3 (daily 11 a.m. to 6.30 p.m.), at McLellan Galleries, Sauchiehall Street, Glasgow. Professor S. ALSTEAD will open the exhibition at 11.30 a.m. on April 29.

Institute of Hospital Administrators.—Annual conference at Torre Abbey Mansion House, Torquay, May 2-4. Details from the Institute, 75, Portland Place, London, W.1.

Radio.—"The Falling Sickness": A documentary programme about epilepsy, produced with the co-operation of the British Epilepsy Association, at 7.45 p.m., May 3, in the Home Service.

N.A.P.T. Dedication Services.—Annual services of dedication for doctors and nurses, Sunday, May 5, at 3.30 p.m. at St. Martin-in-the-Fields, Trafalgar Square; and Corpus Christi, Maiden Lane, Strand. Similar services in Scotland on May 5, at Wellington Church, Glasgow; St. Aloysius, Glasgow; and Beechgrove Church, Aberdeen.

Institute of Dermatology.—May 7-28, semi-permanent exhibition on "Diseases of the Nails."

British Society for Immunology.—Spring meeting May 10 and 11, Westminster Medical School, Horseferry Road, London, S.W.1. Further details from Dr. R. G. WHITE, Department of Bacteriology, London Hospital, London, E.1.

London Medical Orchestral Society.—May 18, at 8 p.m. at Royal College of Surgeons, in aid of the Imperial Cancer Research Fund. Works by Beethoven, Schubert, and Schumann, soloist Liza Fuchsova. Tickets (5s., 7s. 6d., 10s.) from the hon. secretary, 6, Oxford Court, Queen's Drive, London, W.3, or at the door.

Symposium on Anaesthesia.—Arranged by the societies for anaesthesia of Germany, Switzerland, and Austria, July 13-15, at Palais Auersperg, 1, Auerspergstrasse, Vienna, 8.

SOCIETIES AND LECTURES

A fee is charged or a ticket is required for attending lectures marked ●. Application should be made first to the institution concerned.

Monday, April 29

● HUNTERIAN SOCIETY.—At Talbot Restaurant, E.C., 7 for 7.30 p.m., annual general (dinner) meeting. Mr. C. R. Rudolf: Hunteriana Part IV.
● INSTITUTE OF OBSTETRICS AND GYNAECOLOGY.—3 p.m., Dr. Sheila G. Ransom: Preparation for Childbirth.
POSTGRADUATE MEDICAL SCHOOL OF LONDON.—4 p.m., Dr. W. Somerville: Diagnosis and Treatment of Atrial Septal Defect.

Tuesday, April 30

FOUNTAIN HOSPITAL.—5.30 p.m., Dr. D. A. Pond and Dr. B. H. Kirman: Mental Retardation and Epilepsy.
ROYAL COLLEGE OF SURGEONS OF ENGLAND.—3.45 p.m., Erasmus Wilson Demonstration by Dr. J. B. Walter: Some Histological Aspects of Early Cancer.
ROYAL STATISTICAL SOCIETY: MEDICAL SECTION.—At Keene Lecture Theatre, 2nd Floor, Westminster Medical School, 5.30 p.m., Mr. R. G. Carpenter: Studying the Ravages of Time.
WEST END HOSPITAL FOR NEUROLOGY AND NEUROSURGERY.—5.30 p.m., Dr. B. G. Parsons-Smith: neurological demonstration.

Wednesday, May 1

ASSURANCE MEDICAL SOCIETY.—At 11, Chandos Street, W., 5 p.m., Dr. A. H. Douthwaite: Some Danagers of Therapeutics.
INSTITUTE OF DERMATOLOGY.—5.30 p.m., Dr. R. W. Riddell: Pathogenesis of Ringworm Infections.
INSTITUTE OF DISEASES OF THE CHEST.—5 p.m., Sir Russell Brock: Present Position of the Surgery of Pulmonary Stenosis.
● INSTITUTE OF OBSTETRICS AND GYNAECOLOGY.—4.30 p.m., Mr. Aleck Bourne: Vaginal Discharge.
LONDON UNIVERSITY.—At Senate House, 5.30 p.m., special university lecture in psychology by Dr. Else Frenkel-Brunswick (California): Logical Analysis of Psychoanalytic Concepts.
SOCIETY FOR ANALYTICAL CHEMISTRY: BIOLOGICAL METHODS GROUP.—At Chemical Society, Burlington House, W., 7 p.m., Dr. J. M. Ross: Antibiotics and the Public Health; Dr. N. J. Berridge, Ph.D.: Determination of Antibiotics in Milk with Special Reference to Penicillin; Dr. J. H. Taylor, Ph.D.: Determination of Antibiotic Research in the Tissues and Body Fluids of Animals.

Thursday, May 2

FACULTY OF HOMOEOPATHY.—8 p.m., Dr. James Connor: Homoeopathy and Obstetrics.
HONYMAN GILLESPIE LECTURE.—At Anatomy Theatre, University New Buildings, Edinburgh, 5 p.m., Dr. W. Sircus: Recurrent Aphthous Ulceration of the Mouth.
NUFFIELD ORTHOPAEDIC CENTRE.—At Wingfield-Morris Orthopaedic Hospital, 8.30 p.m., Professor J. Trueta: Bone Growth and Endochondral Ossification: An Experimental Study.
ROYAL COLLEGE OF SURGEONS OF ENGLAND.—3.45 p.m., Erasmus Wilson Demonstration by Dr. F. C. Chesterman: Transplantation of Human Tumours and Normal Tissues to Laboratory Animals. 5.30 p.m., Otolaryngology Lecture by Professor G. Dohleman: Physiology of the Cupula of the Ampulla in Relation to Vertigo.
ROYAL MEDICO-PSYCHOLOGICAL ASSOCIATION: CHILD PSYCHIATRY SECTION.—At Bristol Royal Hospital for Sick Children, 5.30 p.m., Dr. Gaynor Lacey: Young Children with Recurrent Abdominal Pains.
ST. JOHN'S HOSPITAL DERMATOLOGICAL SOCIETY.—5 p.m., Dr. A. G. McD. Weddell: Some Recent Investigations into Leprosy.

Friday, May 3

● INSTITUTE OF DERMATOLOGY.—5.30 p.m., Dr. B. F. Russell: clinical demonstration.
INSTITUTE OF DISEASES OF THE CHEST.—5 p.m., Dr. F. H. Young: clinical demonstration.
POSTGRADUATE MEDICAL SCHOOL OF LONDON.—10 a.m., Professor W. A. Mackay: Post-operative Complications.
ST. MARY'S HOSPITAL MEDICAL SCHOOL.—At Wright-Fleming Institute Theatre, 5 p.m., Professor W. C. W. Nixon: Prolonged Labour.

Sunday, May 5

LONDON JEWISH HOSPITAL MEDICAL SOCIETY.—10.30 a.m., clinical meeting.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Bickford.—On April 7, 1957, to Elizabeth, wife of Dr. C. A. Bickford, a son.

DEATHS

Copping.—On April 9, 1957, at Highlands, Midham Green, Woolhampton, Berks, Walter Valentine Copping, C.I.E., D.S.O., M.D., F.R.C.S.I., Major-General, I.M.S., retired.
Griffiths.—On March 31, 1957, at Rondebosch, South Africa, Henry Meredith Griffiths, F.R.C.S.Ed.
Groarke.—On April 9, 1957, Patrick Groarke, L.R.C.P.&S.Ed., L.R.F.P.S., at Dagenham, Essex.
Heanley.—On April 10, 1957, at Chy-Henley, Bigsby's Corner, Saxmundham, Suffolk, Katharine Heanley, L.M.S.S.A., late of East Ham, London, E., aged 87.
James.—On April 11, 1957, at his home, Stanley George James, M.D., Ch.M., M.R.C.P., of Broadmoor, Crowthorne, Berks, late of Sydney, Australia.
Lampough.—On April 7, 1957, Charles Lampough, M.D., of Alverstoke, Hants, aged 84.
Mitchell.—On April 6, 1957, at Royal Hospital, Wolverhampton, George Mitchell, M.D., D.P.H.
Singer.—On April 9, 1957, Ernest Oscar Adolph Singer, M.B., M.R.C.P., Colonel, R.A.M.C., retired.
Thompson.—On April 5, 1957, John Douglas Thompson, M.B., B.Ch., D.Phys.Med., of 355, Stag Lane, Edgware.
Walker.—On April 3, 1957, Cuthbert Ferguson Walker, M.D., D.P.H., of Grange-over-Sands, Lancs, aged 81.
Wilson.—On April 4, 1957, at Arngask, 71, Abbotswood Gardens, Ilford, Essex, James Leitch Wilson, M.B., Ch.B., D.P.M., aged 75.

Any Questions ?

We publish below a selection of those questions and answers which seem of general interest. It is regretted that it is not possible to supply answers to all questions submitted.

Arterial Changes in Hypertension

Q.—Have there been any recent advances in our knowledge of the causes of arterial degeneration in hypertension or of the factors immediately responsible for the rupture of a vessel in this condition ?

A.—There has been no notable advance in knowledge of this subject. The degenerations concerned are of two kinds: (a) atheroma, which affects mainly the large- and medium-sized arteries, and (b) hyaline arteriolar sclerosis, which affects the smaller vessels of various organs—e.g., spleen, kidneys, pancreas, adrenals, etc.

Atheroma, although not essentially dependent on hypertension, tends to be accentuated in that condition, and consequently its common sequelae such as thrombosis (coronary arteries) and rupture (intracerebral arteries) are more frequent in hypertensives than in others. The high pulse pressure which obtains in hypertension is doubtless the factor immediately responsible for the rupture of arteries which are already atheromatous.

Hyaline arteriolar sclerosis, on the other hand, is a specific feature of hypertension,¹ but its nature is obscure. The orthodox view is that it represents a physico-chemical alteration of the smooth muscle of the arterioles,² but the suggestion has also been made that the hyaline substance is a deposit of haematogenous origin in the blood vessels.³

Breast-feeding Difficulties and Complementary Feeds

Q.—If, owing to a mechanical difficulty such as retracted nipples, a baby fails to gain weight satisfactorily, is it better to take him off the breast completely or to use complementary feeds? How should complementary feeds be managed, and what decides how much should be given on each occasion?

A.—If the mechanical difficulty is severe, breast-feeding is usually unsuccessful. However, initially it is almost always worth giving breast-feeding a trial, as it is often surprising how, despite severely retracted nipples, satisfactory breast-feeding can be established; it is only by trial that the doubt can be settled. At the outset it is wise to ascertain the mother's own views, as the success of breast-feeding in these cases will often depend on her enthusiasm.

A plan is to offer the baby an artificial feed after the breast feeds (complementary) rather than substituting an artificial feed for a whole breast feed (supplementary). When the infant has taken what he can from each breast (do not allow him more than five to seven minutes on each side), he should be offered a full bottle of half-cream milk, made up with equal measures of powder and ounces of water, and added sugar if the manufacturers have not included it. The amount offered should be as much as the baby wants, which means he should be fed until he is satisfied. The best evidence that he is having sufficient is a gain of an ounce (28 g.) a day—or at least 5 oz. (140 g.) a week—and a contented infant.

If after trial it is evident that about less than half the total feed is being contributed by the breasts at each feed, it is usually not worth while continuing with breast-feeding. To establish this point, test feeds can be done, but should be delayed until complementary feeds have been given for several days, as test feeds often worry the mother.

Incidence of Allergy to Milk

Q.—Are there any statistics showing the incidence of allergy to milk among children?

A.—Vaughan and Black¹ review the literature on the frequency of allergy to milk, and report that, from replies to a query from the Bureau of Health and Public Instruction of the American Medical Association, Cooke estimated the incidence of sensitization to milk in all children as about 0.3% to 0.4%; Rachemann as less than 0.01%. Loveless,² from a poll of 191 specialists in paediatrics or allergy, found that 1.5% of 245,000 patients were considered allergic to milk by clinical standards. Collins-Williams³ found an incidence of allergy to milk of 0.3% in 3,000 infants and children seen by him as a general paediatrician, cases referred on account of suspected or definite allergic illnesses being purposely excluded.

Enuresis in Children

Q.—A healthy girl of 9 often wets her bed at night. She is second in a family of five children, of whom four are boys. Her disposition is happy and her parents understanding and encouraging. Sedatives, fluid restriction, ignoring the wet nights and praising her for the occasional dry night have all been tried over a long period, but without any improvement. What does your expert suggest now?

A.—It is questionable whether anyone can call himself an expert on this problem. From the wording of the query it seems that this 9-year-old girl is periodically dry at night, which tends to make any organic cause of the bed-wetting less likely. Spina bifida is occasionally responsible for enuresis and therefore needs exclusion as a cause. Spina bifida occulta is, of course, common, and therefore its mere radiological demonstration in an enuretic does not mean that there is any causal connexion. A renal abnormality is unlikely in a healthy girl who is dry during the day and even, at times, at night.

It is thought that a physiological aberration of the control and excretion of the body fluid may account for some cases of nocturnal enuresis, leading to increased output of urine at night. In such cases pituitrin, administered as snuff ("disipidin," 100 mg. on going to bed), has been claimed to be of value and is perhaps worth trying in persistent enuresis.

Some degree of emotional disturbance is likely to occur as a result of enuresis in most children after the age of infancy, and there is little doubt that the condition has a psychological basis in a large number of cases, if not the majority. It is sometimes possible, however, especially if the parents are understanding, to obtain improvement or even a cure by physical means. If this girl sleeps very deeply it may be possible to lighten sleep by giving amphetamine, 5-20 mg., in the evening; this may help the child to become sufficiently wakeful to respond to a full bladder and to get out of bed to empty it. Nocturnal enuresis is sometimes accompanied by some degree of frequency during the day, so that the bladder becomes accustomed to frequent emptying. A small dose of phenobarbitone ($\frac{1}{4}$ to $\frac{1}{2}$ gr.—16 to 32 mg.) in the morning may be helpful if this is the case. At the same time the child should be encouraged to hold her urine during the day for increasingly long periods with the idea of conditioning the bladder to retain larger quantities without discomfort. The ability to do this adds

to the child's confidence, and this, together with the increase in capacity of the bladder, may lead to cessation of the nocturnal enuresis.

An electric bell, which rings when the circuit is closed as a result of urine wetting a pad in the child's bed, is recommended by some as an effective way of producing a conditioned reflex which inhibits micturition.¹ It seems rather a crude type of therapy, but it may be worth trying, especially in children over the age of about 9.

It is very possible that even a happy child such as this, and with understanding parents, has an underlying emotional disturbance which may be responsible for the enuresis. It is, for instance, sometimes as difficult for a girl to be the only one in a family of boys as it is to be the only boy in a family of girls. Advice from a skilled child psychiatrist might certainly help the parents to gain enough insight into their daughter's difficulties to bring about a cure, or perhaps active psychological treatment might be required. It is worth noting that a recent survey of a large number of families showed that enuresis had cleared up soonest among the children of those parents who said that they had made no effort to treat or control the habit.

Toxicity of Detergents

Q.—What toxic effects may be expected from the ingestion of cetrimide or any similar cationic detergent?

A.—There is a single report of a woman who swallowed a mouthful of whisky and an undiluted cationic detergent mixed in error. She collapsed and died in a few hours, but nothing striking was seen at necropsy.

Several types of detergent have been incorporated in the diet of laboratory animals and fed to them for periods up to two years. In concentrations greatly in excess of anything that could be found in human food and drink from utensils washed in dilute detergent solutions, these substances did not upset the animals receiving them. These detergents react with and precipitate proteins in solution, so small quantities taken by mouth will not be absorbed unchanged from the alimentary tract.

Indications for Antirabic Vaccine

Q.—Should antirabic vaccine be given at once to persons bitten by a possibly rabid animal? If it has been possible to keep the animal under observation, is it safe to defer vaccination until a definite diagnosis of the animal's condition can be established?

A.—Not everyone who has been bitten by a rabid animal should be given a course of rabies vaccine, for the course itself is not free from the risk of dangerous complications, including demyelinating lesions of the central nervous system.

It is generally considered that persons, even though they have been bitten, should not be given a course of vaccination if the skin of the body, including the face and mouth, is unbroken; if tooth wounds have been made through clothing which has remained unbroken; or if the wounds were inflicted more than seven days prior to the development of signs of the disease in the animal. If the animal remains normal for seven or more days after inflicting wounds, treatment which may have been begun can be discontinued. There is only a very small possibility of being infected from an animal which survives this period, although it is desirable to confine it for a full 10 days. On the other hand, nervous complications may develop if a person receives 10 antirabic vaccinations; they are less likely to do so after only seven.

Vaccination is also unnecessary if exposure has been limited to handling an animal or objects contaminated with its saliva, or if wounds known to have been more than 24 hours old or to have been covered by an unbroken crust have been licked by a rabid animal. Mosquito bites, no matter how recently inflicted, may be ignored.

The decision whether to start treatment or not after a person has been bitten and the animal caught and confined will depend upon the foregoing considerations, in addition to the behaviour and clinical condition of the animal. If it appears probable that the bite has been received from a rabid animal, it is recommended that vaccinations be commenced but that they should be discontinued if the animal survives seven days.

Oesophageal Changes in Raynaud's Disease

Q.—What is the significance and pathology of the oesophageal changes sometimes encountered in cases of Raynaud's disease and revealed by a barium swallow? Do they cause any symptoms requiring treatment?

A.—Oesophageal changes occur only in those patients with Raynaud's phenomenon due to scleroderma. In these cases the pathological changes are due to swelling of the collagen in muscle bundles in either digital arteries or the oesophagus. The muscle may ultimately atrophy so that a mere immobile tube remains.

Oesophageal symptoms occur in cases where the changes are advanced. The lower reaches of the oesophagus are more commonly affected, and the symptoms may resemble those of achalasia where the cardia is affected, of hiatus hernia and short oesophagus where longitudinal contraction has occurred, or of benign fibrous stricture where there has been a circumferential contraction. In other cases there is a mere postural dysphagia, the patient being able to swallow in the erect but not in the horizontal position. The changes seen in the barium swallow in general may also resemble the conditions mimicked by the symptoms.

The symptoms require treatment according to their severity. Benign stricture needs to be treated by dilatation or in advanced cases by surgery. Further details about the condition may be found in a paper by Bourne.¹

Cerebral Cortex Biopsy

Q.—Is cerebral cortex biopsy a recognized diagnostic procedure, and, if so, what are the indications for it?

A.—I know of no study of biopsy of the cerebral cortex. This may be due to the fact that little useful information could usually be obtained from the examination of small fragments of cortex, while on the other hand the removal of large strips of grey matter, even from silent areas, would be followed by a real risk of post-traumatic epilepsy. Theoretically the procedure could be of value in the confirmation of the clinical diagnosis of such conditions as are associated with loss of cortical neurones or glial overgrowths.

Countless thousands...every day

It is a sobering revelation that over 50 per cent of the average practitioner's patients can be said to suffer from some degree of anxiety neurosis. This means that hundreds of thousands of such cases present themselves every day in Great Britain alone. A massive problem—yet one which has been vastly simplified by the advent of MILTOWN meprobamate. Uniform in action, and remarkably free from side reactions, MILTOWN acts safely and selectively to calm restlessness and irritability of anxiety states. It eases emotional and muscular tension without autonomic effects, and shows marked advantages over conventional sedatives. By day, MILTOWN secures true sedation; by night, it brings natural sleep without narcosis.

Tablets of 400 mg.; bottles of 50 and 500

Countless thousands can benefit from

An assessment of Roter therapy in PEPTIC ULCER

"The treatment is ideal for general practice, where its simplicity appeals to both patient and doctor . . ."

Roter tablets contain a balanced content of recognised buffers with supportive carminative and mildly laxative agents.

FORMULA PER TABLET

Magnesium Carbonate (400 mg.), Bismuth Subnitrate (350 mg.), Sodium Bicarbonate (200 mg.), Rhizoma Calami (25 mg.), and Cortex Rhamni Frangulae (25 mg.).

F. A. I. R. LABORATORIES LTD., TWICKENHAM, MIDDLESEX.

Results

"The immediate clinical results were assessed after the first month's treatment in four main groups: (A) pronounced relief (symptom free); (B) definite relief (minor symptoms with no pain); (C) doubtful relief (symptoms persisting but improved); (D) no relief. Table II shows that 81% of cases became symptom-free—70% of them during the first week and 30% during the second week; a further 9% were relieved of the majority of their symptoms. Thus there was a satisfactory response in 90% of cases."

TABLE II

Group	Active Ulcers	Presumptive Ulcers	Totals
A	63 (79.6%)	17 (89.0%)	80 (81.7%)
B	8 (10.2%)	1 (5.5%)	9 (9.2%)
C	6 (7.6%)	1 (5.5%)	7 (7.1%)
D	2 (2.5%)	0 (—)	2 (2.0%)
TOTALS	79 (100%)	19 (100%)	98 (100%)

"Four of the nine cases in groups C and D have elected to go to surgery, and one of the remaining cases has a hiatus hernia as well as a duodenal ulcer. Experience of treating these 'Failures' over the past six years leads one to believe that no form of medical treatment will be effective and that surgery is the only hope of relieving their symptoms. In 75% of cases the patients were of the opinion that the tablets were superior to alkaline powders, and they found that they were able to take foods which they had avoided for years."

Extracts from the
BRITISH MEDICAL JOURNAL
1955, 2, 827

"SUMMARY: Seventy-nine cases of peptic ulcer and 19 of presumptive peptic ulcer have been treated with Roter tablets. Immediate clinical response was satisfactory in 90% of patients, with a relapse rate of 57% in the first year; a reduction in the average number of relapses was recorded in 15 cases kept on a maintenance dose for one year."

PACKINGS: Tins of 40, 120, 640, and dispensing size 720 (P.T. exempt). Basic N.H.S. price: 1/- for 10 tablets.

Roter Tablets are not advertised to the public, and may be prescribed on E.C.10 forms. Literature and samples on request.

The graph above is of an experiment to measure the effect of Transvasin on skin temperature on a subject. The red line plots the skin temperature before and at intervals after a single application of one inch of cream (0.924 grams) from a tube of Transvasin. The black line gives similar information with regard to the application of a plain vanishing cream used as a control. Skin temperatures were measured with an electro-thermo couple every five minutes for two hours. Photographs show the affected area before application; three minutes and thirty minutes later.

COMPOSITION OF TRANSVASIN

Salicylic acid tetrahydrofurfuryl-ester	..	..	14%
Nicotinic acid ethyl-ester	..	..	2%
Nicotinic acid n-hexyl-ester	..	..	2%
p-Aminobenzoic acid ethyl-ester	..	..	2%
Water-miscible base ad	..	..	100%

Transvasin

"Transvasin" is a registered trade mark of Lloyd-Hamol Ltd

It is generally agreed that cases of soft-tissue rheumatism and of many types of arthritis benefit by hyperaemia of the affected tissues. Transvasin, which contains two quick-acting esters of nicotinic acid, induces such a deep and prolonged hyperaemia at the same time as it produces superficial erythema.

In addition to the esters of nicotinic acid, Transvasin contains the fat- and water-soluble esters of salicylic and p-aminobenzoic acids. Both these well-tried analgesic drugs are readily conveyed through the skin in therapeutic quantities and enable an effective concentration to be built up where they are needed.

Transvasin is now being widely prescribed, with successful clinical results. Since a very small quantity is sufficient for each application, the cost of treatment is extremely low.

Transvasin is available in 1 oz. tubes, basic N.H.S. price 2/6 plus P.T., and is not advertised to the public. Samples and literature will be gladly sent on application.

SURGICAL TREATMENT OF AORTIC STENOSIS

BY

Sir RUSSELL BROCK, M.S., F.R.C.S.

Thoracic Surgeon to Guy's Hospital; Surgeon to the Brompton Hospital

The surgical treatment of aortic stenosis has received little attention in the literature of this country, in spite of numerous articles from the United States. Logan and Turner (1954) reported on seven patients treated by operation, and Marquis and Logan (1955) described six cases of congenital aortic stenosis treated by operation, but were unenthusiastic about their results. More recently Baker and Campbell (1956) have presented the results in 16 of their patients operated upon at Guy's Hospital.

This article gives my views and experiences in operating on 120 cases of aortic stenosis; it necessarily touches on the clinical features of this disease, but is intended primarily as a surgical essay.

Historical

The history of the surgical treatment of aortic stenosis is inevitably short. It is usually stated that the first operation was done in 1913 by Tuffier, who attempted to dilate the stenosis by invaginating the aortic wall with his finger. This can scarcely be accepted as a serious contribution.

My own interest in valvotomy focused upon the aortic valve soon after the war, when, in common with a number of surgeons throughout the world, I was engaged in seeking ways to develop direct operations upon the heart valves as the next obvious and long-overdue surgical development.

Souttar (1925) had pointed the way to a simple technique to deal with mitral stenosis, but it proved difficult in 1946 to persuade cardiologists that herein lay a promising (and as it turned out, brilliant) therapeutic future; there was too much inborn reluctance to touch the heart. However, it seemed that aortic stenosis offered to the surgeon a route which avoided direct interference with the heart and therefore was less likely to evoke the superstition. The important fact seemed to be that the aortic valve could be approached with relative simplicity from above. The anatomical basis of the arterial route to the aortic valve and to the pulmonary valve has been described elsewhere (Brock, 1950); it suffices to say that an instrument introduced into the innominate artery either via its subclavian or common carotid branch, or directly into its trunk, can be passed straight down to the aortic valve cusps.

During 1946 I designed an operating cardioscope, or combined valvoscope and valvotome, and was able to use it on a case of aortic stenosis on March 27, 1947. The right subclavian artery was exposed through a small

incision in the neck, and the cardioscope was passed without difficulty to the aortic valve; a good view was obtained of the irregular calcified masses which distorted the diseased valve. It was realized that an attempt to cut this calcified valve semi-blindly with the small knife attached to the instrument was unlikely to be successful enough to justify the risk involved. The instrument was withdrawn; the patient suffered no harm nor derived any benefit.

About this time also Smithy (Smithy and Parker, 1947) was grappling with the problem until his own untimely death from the disease itself. Bailey *et al.* (1952) next reported that the technique of passing a cutting valvotome through the ventricular wall and then using an expanding dilator to split the valve open, although so satisfactory in pulmonary valve stenosis, was liable to cause severe regurgitation if used on the aortic valve. They suggested that instead of preliminary use of a valvotome the stenosis should be relieved by means of a powerful expanding dilator, and to this end designed a three-bladed one, based on the two-bladed dilator already used with success on pulmonary stenosis (Brock and Campbell, 1950). There is no doubt that Bailey's recommendation of the basic use of an expanding dilator was sound. In ordinary calcified aortic valvar stenosis the architecture of the fused cusps is so distorted that the blind use of a cutting instrument is dangerous and ineffective; dangerous because it is easy to miss the valve lumen and perforate the aortic wall or the tissue of a cusp; ineffective because it may encounter only calcified tissue it cannot cut. A properly designed expanding dilator finds its way through the valve lumen with less danger and can disrupt the fused cusps. When the valve is not calcified, as in children or young adults, there can still be a place for the preliminary use of a cutting valvotome before the valve is cautiously split open with a dilator, unless of course open valvotomy is used.

Bailey was soon able to report a large experience with this type of transventricular valvotomy (Bailey *et al.*, 1954), but after operating on some 65 patients he rejected the transventricular route for a transaortic one (Uricchio *et al.*, 1955; Bailey *et al.*, 1956). Harken (1955) has also accepted the aortic route to the valve, and, indeed, has stated dogmatically that it is the only route that should even be considered. A number of other American writers have also made the same recommendation, among them Fell (1955) and Likoff *et al.* (1955). In Great Britain, Logan has used the transventricular route (Logan and Turner, 1954).

After my initial case of retrograde approach to the valve in 1947 I used this route in two more patients. Instead of a small neck incision the upper part of the sternum was split and the innominate artery itself used for the passage of instruments. My experience with it was so bad that I abandoned it in 1952, with reluctance, for the transventricular route. After some initial troubles this route has proved so satisfactory for general use that I have continued to use it for most cases up to date. I cannot agree with the arguments put forward for the superiority of the transaortic route over the transventricular; the matter is discussed more fully below.

The use of the blind method in valvotomy, whatever the route, has much against it. Although one can feel content that in relieving aortic stenosis by dilatation something is being achieved where nothing was being done before, it is not possible to be really satisfied with it. Especially is this so in children or young adults in whom the valve is not calcified. Here it would seem essential for good surgery to achieve as near a perfect result as possible with the least chance of causing regurgitation. There is only one way to achieve this in a high proportion of cases, and that is by open direct-vision valvotomy. This is, of course, in keeping with the present inexorable trend of cardiac surgical technique, towards open-vision operating.

Open aortic valvotomy has been inevitable, and it is interesting and significant that the step was undertaken by two or three surgeons about the same time. My own first open aortic valvotomy was done on January 26, 1956 (Brock, 1956), and I have since done six cases. Lewis *et al.* (1956) have reported three cases of open aortic valvotomy under hypothermia, the first being operated upon on December 2, 1955. Lillehei *et al.* (1956) report a single case of open aortic valvotomy for calcified aortic stenosis using a complete by-pass and retrograde coronary perfusion; this operation was done on January 31, 1956, and since then Lillehei has done several more. In the discussion following Lewis's communication Swan mentions having used open aortic valvotomy twice (presumably under hypothermia) and Bailey also twice, using a pump oxygenator. It is as yet rather early to assess the true value of open aortic valvotomy, but it is certainly the most promising and logical method of treatment so far available.

Assessment of the results of closed valvotomy is easier and will be presented later.

Therapeutic Problem of Aortic Stenosis

As with many other heart diseases, there has been much loose and immature thought about aortic stenosis. Typical is the attitude that it is a relatively benign condition based on the observation that patients are encountered in the 50's or 60's with a short history. From this it is argued that all patients can live to 50 or 60! The same attitude was seen a few years ago with mitral stenosis: one patient aged 60 or even 70 can be so prominent in a clinician's mind that he may fix his attentions on him and conclude that any sufferer from valve stenosis can live so long. The countless thousands suffering grave or total disability or dying

Age Groups of 78 Patients With Aortic Stenosis

1-9	10-19	20-29	30-39	40-49	50-59	60-69
4	7	5	15	25	20	2

before 45 are ignored. The accompanying Table gives the age groups of the patients in my series; it should be realized that each and every one was referred for treatment because of severe symptoms. It is seen that 56 patients were below the age of 50 years and 31 below 40.

Aortic stenosis is a surgical disease and each case should be considered as possibly needing surgery; not, as is now usual, being accorded regular observation until some sinister or subterminal symptoms appear. This statement is bound to provoke protest and so must be justified. For this it is imperative to realize that one of the basic functions of the surgeon is to relieve obstruction to a hollow viscus or duct—a function which has become elaborated chiefly since the advent of modern surgery. The relief of obstruction to the oesophagus, the pylorus, the intestine, the urinary or biliary apparatus is accepted, without question, as a surgical matter. Happily, in recent years this acceptance is extending to the mitral valve and the pulmonary outflow tract, but its significance in relation to the aortic outflow is less appreciated. Neglect of, or a *laissez faire* attitude towards, chronic or subacute obstruction of the bladder or colon would be considered professional incompetence or neglect, and yet chronic or subacute obstruction of the left ventricle is still viewed with complacency.

The left ventricle is the most important muscular structure in the body; it is possible to live, and live well, without a bladder or a colon, but not without a left ventricle. To some it may seem wrong to think of the colon, the bladder, and the heart in the same terms. The heart still carries with it the atmosphere of nobility and an exalted place in the human economy which is exemplified in its being credited with the seat of the emotions. Noble it is in the same way as that other friend of man, the horse. The left ventricle in particular is the willing horse; it will go on, week after week, month after month, year after year, doing its job manfully under the severest burden and will make but little complaint. When it does at last begin to complain, when symptoms are insistent and can no longer be ignored, it is dangerously near its end. It will live but a few months or a year or two once the features of failure have appeared; it is liable to stop suddenly, just as the horse may go on until it drops down dead. Even at the late stage of impending failure it may be restored to many years of useful work if its burden is relieved, if the aortic stenosis is corrected. It behoves us to recognize and respect left ventricular obstruction and to relieve it much earlier than is now done.

It is, of course, realized that until very recently there was no safe or satisfactory surgical treatment for aortic stenosis, and thus nothing was to be gained by reference to a surgeon. The object of this article is to try to show that surgery now offers a great deal to the sufferer from aortic stenosis, but that to do his best the surgeon should be consulted before signs of chronic invalidism and impending death have appeared; that only in this way can good results be obtained and confidence be engendered.

Clinical Assessment

This brings us to another fact that has to be discussed—the need for a more scientific assessment of the clinical state of the patient than is generally used. The physician may defend his policy and practice of not referring his patients for surgical intervention because he has concluded that their disability or disease does not warrant it; that the aortic stenosis is not severe enough. Without doubt there are many cases in which this is the correct and proper decision. The point to be made is that in most cases this decision is empiric; it is in the nature of a "hunch"; a clinical hunch that may be right, and may be totally wrong. In such a responsible matter more than clinical sense is needed, for to-day methods are available to help towards a more precise assessment.

The simplest, and unfortunately the most ingenuous, assessment used is the patient's symptoms. There is, for instance, the astonishing statement in an important textbook (Lewis, 1933), "there are no symptoms of aortic stenosis." The most that can be said of this is that it is presumably meant to be subtle and it merely succeeds in being sinister. If the patient says he is not troubled or is conscious of only slight restriction on exertion, this is usually accepted as ruling out the need for operation. Clearly this may be so,

but we do not receive long training to become doctors, and longer still to become specialists, to apply a simple rule of thumb that could be applied by a layman. It is our duty to assess the situation in each patient so that he can be given sound and sober advice. This may well be reassurance and observation, but we must be able to recognize when the circumstances are not satisfactory even though they may appear to be so superficially. The left ventricle, in this matter, is its own worst enemy; it will go on doing its job with but little outward protest until it can continue no longer without grave complaint. What we need is to be able to assess the burden the left ventricle is carrying even though it carries this burden without noticeable complaint.

The first step in this is clinical assessment. Others have written of this—for example, Matthews *et al.* (1955) and Baker and Campbell (1956)—and so only a few comments are needed here, and it is best to start at the end. When the heart has grossly failed the patient may be too late for surgery and certainly too late for more than moderate amelioration. Yet how often is this the very time that the patient is first directed to the surgeon even though he may have been regularly observed for years. It is like guarding closely the sufferer from chronic prostatic obstruction until his bladder is up to his umbilicus, his urinary tract infected, and his kidneys barely functioning, and only then referring him for operation. Features of right-sided heart failure are usually features of inoperability, not indications for operation; established right-sided failure indicates a virtually totally inoperable state. Much the same applies to left-sided failure. The condition unrelieved or unrelievable by routine medical treatment indicates that the time for useful surgery has passed. It is useless to appeal that only an operation gives the patient a chance of survival; this is not surgery, it is the prostitution of surgery. Surgery is a valuable tool which should be used properly and with respect; it becomes damaged and blunted if misused. The bad results of surgery repeatedly invoked in such cases promote lack of confidence, impair morale, and hold up progress.

If left-sided failure has occurred but has responded satisfactorily to treatment, especially if it was precipitated by an acute infection or some such episode, then successful operation may still be possible. The same applies to the early features of left ventricular failure, such as a tendency to nocturnal dyspnoea; it is still not too late to save these patients. It must, however, be realized that these are not so much indications for operation as indications that if operation is not undertaken as an urgency it will be too late.

Angina pectoris is often considered as a contraindication to operation; this is not so. It should be regarded as a *cri du cœur* for relief. Anginal symptoms are usually completely relieved by a successful valvotomy.

Dyspnoea at night is a grave feature; dyspnoea on exertion is often brushed aside. This should not be so; it should always, however slight, be accepted as a significant symptom until full assessment has shown it not to be. Although it is a very difficult feature to assess, and though it may prove unimportant, nevertheless, if genuine, it indicates that under the conditions in which it occurs the heart is unable to do its work properly, its ability is limited, it is failing in its task. In other words, dyspnoea can be an important feature, an important warning of the need for help.

Except in emotion or on physical effort we are unconscious of the heart's action. In a patient with aortic stenosis simple awareness of the heart's action may be a feature that should lead to complete and critical assessment of the burden the left ventricle is carrying. Especially is this so in the child or young adult, in whom the left ventricle has a remarkable power of compensation for the demands placed upon it; a power that we should recognize, respect, and seek to relieve from burden rather than take advantage of to the extent of abuse.

How can this assessment be made in the absence of the obvious clinical stigmata of failure? Simple enlargement

of the ventricle may be only reasonable compensation. If considerable it indicates a considerable burden; in the absence of regurgitation much enlargement suggests a degree of actual failure. The electrocardiogram is indispensable in assessment, especially if over a period of observation it shows deterioration. The clinical examination of the pulse is also invaluable, particularly when extended by the more critical analysis of an arterial pulse tracing.

In many cases it is quite easy from the above findings to decide that operation is desirable or essential. In others more critical assessment is needed.

More Critical Assessment

Right-heart catheterization by itself can give little direct help; it may demonstrate a low cardiac output and poor response to exercise. The "pulmonary capillary venous pressure" may also indicate or confirm evidence of left ventricular limitation or failure. The information obtained is likely to be more useful if combined with a knowledge of the pressure in the left ventricle and aorta. This may be obtained by direct left atrial puncture according to the technique of Björk *et al.* (1953), but we have found that, although a left atrial pressure record can be secured, it is, disappointingly, frequently impossible to manipulate a catheter into the left ventricle in cases of aortic stenosis; it is much easier when the left atrium is dilated as in mitral valve disease. Moreover, left atrial puncture may be very distressing to the patient, and, if he is ill with aortic stenosis, may be frankly dangerous. However, we have been able to obtain valuable information in this way by simultaneous recording of the left ventricular pressure and the brachial or femoral artery pressure, thus obtaining the gradient across the valve.

In view of the uncertainty and drawbacks to left atrial puncture we have been using direct left ventricular puncture with greater satisfaction. This method is quick and simple, and so far has proved safe (Brock, Milstein, and Ross, 1956). It has been invaluable in deciding for or against operation in difficult cases. Thus, although clinical and other features may indicate the probable need for operation, direct left ventricular puncture has shown unequivocally a trivial gradient across the aortic valve; conversely, it has demonstrated in not dissimilar cases a very high left ventricular pressure and a very high gradient, indicating the urgent need for operation. In the 90 cases in which we have used this method it has been incomparably less disturbing than left atrial puncture; there has been no morbidity and no mortality. A more detailed report on the analysis of the information obtained from left ventricular puncture is given by Fleming and Gibson (1957), and I need not anticipate their observations.

Figs. 1 and 2 show the type of pressure record and information obtainable from the direct left ventricular puncture combined with a brachial artery pressure tracing. Fig. 2 illustrates that a direct left ventricular pressure record may exclude significant aortic stenosis.

The only time the gradient may be deceptively high is if significant regurgitation coexists; it should be possible to recognize such substantial regurgitation by other methods.

FIG. 1.—Left ventricular and brachial artery pressure records showing an aortic systolic gradient of 120 mm. Hg, thus demonstrating severe aortic stenosis. Left ventricular pressure recorded by direct percutaneous puncture of ventricle.

FIG. 2.—Brachial artery and left ventricular pressure records showing an aortic systolic gradient varying from 5 to 15 mm. Hg, thus excluding significant aortic stenosis. Left ventricular pressure recorded by direct percutaneous puncture of ventricle.

Usually the pulse pressure is too wide for dominant aortic stenosis and the actual gradient is rarely as high as 100 mm. Hg and more usually nearer 50 mm. Hg. Incidentally there is a tendency to be too ready to reject a patient for aortic valvotomy because of the presence of some regurgitation; a small amount may be quite unimportant and should not turn one away from relieving the dominant stenosis; in these cases study of the aortic gradient may be especially helpful. Valvotomy may even relieve the regurgitation as well as the stenosis if it restores greater mobility to the cusps.

In a short communication to the British Cardiac Society in 1954 I indicated the difficulty of diagnosing significant aortic stenosis from the physical signs alone in all cases; in particular the mere presence of a systolic thrill and murmur may be misleading. This was illustrated by pressure records taken at operation for aortic coarctation in a boy who had been diagnosed as also having dangerous aortic stenosis. It can be seen (Fig. 3) that there was no gradient across the valve. In another patient, observed for several years by a skilled cardiologist who requested operation as a result of his clinical observations and his knowledge of the patient's progress, pressures taken across the aortic valve at thoracotomy also showed no gradient. (Today this information would have been obtained by direct

FIG. 3.—Pressure records of aorta and left ventricle taken at thoracotomy; there is no gradient and no significant aortic stenosis.

left ventricular puncture.) These two cases emphasized that it is not enough to accept even a skilled clinical assessment in all cases and indicate that the surgeon must check the pressures across the valve at operation, if these have not been done before. Operation results and experiences in patients in whom this has not been routinely done may be, in my submission, valueless; they are certainly incomplete.

The ability to do percutaneous left ventricular puncture and simultaneous brachial artery or aortic records of pressure allows us to obtain this precise and valuable information as a part of routine pre-operative assessment.

So far we have found a reasonably close correlation between the pressures recorded before operation and those taken at operation. This is in direct disagreement with the statements made by others that observations at operation are unreliable (Matthews *et al.*, 1955; Bailey *et al.*, 1956).

Matthews *et al.* (1955) also state that it should not be necessary to know the gradient across the valve to assess the severity of the stenosis, and that, apart from the figures being unreliable, the requisite information can be obtained by other means. They give no figures to support this, nor disclose any experience obtained from cases studied before and at operation. In my experience it is not possible to obtain sufficient precise information on these cases without left as well as right-heart catheterization. It is difficult to imagine any pre-operative clinical assessment of cases much superior to that which I am privileged to enjoy from my very able cardiological colleagues, and yet we have found that the final essential information has on several occasions come only from left ventricular puncture with or without right-heart catheterization. This has enabled us to assess the severity of the lesion and thus has greatly helped the difficult task of advising operation in an anxious case, even though there was already a strong clinical indication for operation. Also it has enabled us, unequivocally, to rule out or postpone operation in others in whom operation had seemed indicated.

At present large numbers of patients with aortic stenosis are being observed at cardiac clinics throughout the world by virtually rule-of-thumb methods. Especially is this so with children. Their aortic stenosis may be mild and unimportant; it may be severe. With present practice there is little chance of the more severe cases being selected for operative relief until they begin to show signs of grave failure, by which time it may be too late.

If these patients are to be selected for operation at the proper time, when their left ventricle needs relief from its burden and before advanced secondary changes have occurred, this cannot be done by clinical "guessing," however shrewd this may be and however hard it is to accept that it often is guessing. If proper progress is to be made in the surgery of aortic stenosis then the approach to and management of these cases have got to be reorganized. Especially must this be so in children and young adults, for it is in them that the best results will be achieved before the valve has become so severely calcified that it cannot be made even remotely normal. Nadas and Ongley (1956), of Boston, reported a careful and complete study, including left- and right-heart catheterization, they had undertaken in a series of children with aortic stenosis. They realized the need for this after observing five sudden deaths in five years. Their findings revealed the need for urgent surgery in almost all their patients.

Clearly it would be unreasonable to expect patients with aortic stenosis to have been put forward for operation, or even necessarily critically examined with a view to operation, until quite recently. The surgery of aortic stenosis had not justified itself; the mortality was high and the results were poor. Clinicians have, quite properly, been hesitant and unconvinced. One of the objects of this article is to try to show that there is now every justification for confidence in advising patients to consider surgery and to undergo it if found to be suitable for operation.

Morbid Anatomy of Aortic Stenosis

The outstanding feature in aortic stenosis is the frequency with which the valve cusps are deformed by calcified deposits. On this rock-like substance the surgeon's efforts may founder, for he is often at the mercy of the anatomical accident of the disposition of these masses; what he can do to help may be decided largely by them. In extreme cases the whole valve and ring may be so calcified that little or nothing can be achieved; in others the commissures, or at any rate part of them, may be sufficiently free from calcium to allow a satisfactory result. The least favourable type is the bicuspid valve in which it may be impossible materially to increase the valve lumen without rupturing part of the cusps and thus causing severe regurgitation. In such a valve the cusp margins are straight lines, rigid and fixed; they are not curved like bucket-handles and so possessed of the power of swinging wide open as is the case when a stenosed but prominent valve cone is cut transversely by valvotomy.

Clearly it is desirable, whenever possible, to operate before calcification has developed. Unfortunately, only too often extensive calcification is already present when the patient first comes for advice. In my series in only one patient over the age of 30 was the valve not calcified; she was 32. Once calcification is present it has to be accepted and the efficacy of surgery is inevitably limited; cure, as such, is impossible. This is, however, no reason why operation should be rejected. Theory may be against it; practice proves it can give satisfactory results, as will be shown. At the very least the clock can be turned back several years, even though considerable stenosis remains; the patient may gain a larger valve orifice than, in fact, he has had for the greater part of his life.

The non-calcified valve has been studied at open operation in six cases; in five there were three fused cusps, in one the valve was bicuspid. The cusps were much more thickened and swollen than is seen in the stenosed pulmonary valve, the commissures in particular being swollen and difficult to define on their ventricular aspect. This may well be due to the higher pressures involved.

The patient who had a bicuspid valvar stenosis also had a severe subvalvar stenosis. This condition was also found as an isolated lesion in four other patients, and the five cases have been fully reported elsewhere (Brock and Fleming, 1956). It must suffice to state here that the pre-operative differentiation between valvar and subvalvar stenosis is difficult; the various clinical and semi-clinical differential features put forward are valueless. In four cases the diagnosis was made at operation by a withdrawal pressure record taken with a catheter passed into the aorta through the left ventricle. In the fifth case a withdrawal pressure record failed to show the subvalvar stenosis which was disclosed by open operation on a supposed valvar stenosis. It is our policy to make a withdrawal pressure record whenever there is any doubt about the lesion being valvar, especially in the absence of calcification. The possibility of the stenosis being subvalvar must be borne in mind and every effort made at a precise differentiation.

When the aortic stenosis is associated with mitral stenosis severe calcification is less frequent and consequently valvotomy offers more in isolated aortic stenosis. In 34 cases of combined aortic and mitral stenosis calcification was absent in 20 and was not severe in most of the others.

Surgical Technique

As already stated, the transventricular approach is preferred, except for open valvotomy. The heart is exposed by the standard left antero-lateral thoracotomy through the bed of the fifth rib, which is used for mitral valvotomy also. Although the skin incision extends backwards only some 2 inches (5 cm.) beyond the inferior angle of the scapula, the rib bed is opened for its whole length. This gives an excellent exposure and spares the big shoulder muscles. Occasionally, when the left ventricle is very large, it is

better to divide the sixth costal cartilage as well, and occasionally it may be more convenient to use the sixth rib bed.

Once the chest is opened the next step is dissection of the aortic branches to the head and neck and the passage of snares for their later control; it is essential to do this to help guard against calcified emboli. It is best to secure the vessels early in case emergency valvotomy is needed should the heart show distress.

The aorta is next palpated and the character of this thrill and pulsation is noted. The state of the valve and the valve ring is examined, especially for calcification. Pressures are then taken in the aorta and left ventricle by simultaneous needle puncture; in this way the gradient is assessed or confirmed. A catheter withdrawal tracing is not now used as a routine, because the manipulations of introducing it may be disturbing and may even produce ventricular fibrillation; it is used when there is a possibility of a subvalvar stenosis.

A favourable site on the left ventricle is selected for entry; this should be towards the apex and in a region as free as possible from coronary branches. A local anaesthetic solution is not injected into the myocardium; it does no good and may do harm. Formerly a heavy linen thread purse-string stitch was used and held in a Rumel tourniquet, but it was found that the strong pull that an assistant can exert may cause partial ischaemic atrophy within the constricted area. A light 00 silk stitch is now preferred, held by a short piece of soft rubber tubing; this is effective and not harmful. Sometimes no stitch at all is used.

Through a small incision a probe is inserted to feel the way into the ventricle; this is followed by a 0.4-cm. bougie. Neither of these instruments goes high enough to engage the valve lest calcium emboli are detached. The snares are now tightened on the aortic branches and the valve dilatation is done without loss of time. The 0.4-cm. bougie is advanced to the valve, and palpation will quickly give some idea of the size, shape, and disposition of the stoma. This is quickly followed by the 0.7-cm. bougie, and then the expanding dilator is introduced and opened in two or three directions. All these movements must be fully controlled. If there is any doubt at all of the true position of an instrument it should be withdrawn and a fresh start made. To push or to use force may be disastrous. Only rarely is the orifice so small that a bougie is really gripped tight, and then the advancing force must be steady and controlled; all movements of the instrument should be checked and guided by fingers placed outside the aorta. As the instruments are changed the assistant applies light pressure, if needed, to the purse-string tourniquet.

An observer calls out the duration of the time of occlusion of the head and neck vessels; first at 45 seconds, then at 60 seconds, and thereafter every 10 seconds. It is usually possible to complete the valve dilatation in 50-70 seconds (Fig. 4). A pause of some 5-10 heart beats is allowed to disperse any free calcium, and the snares are then loosened. Haemorrhage is usually slight and is controlled by finger pressure in addition to light tightening of the tourniquet.

FIG. 4.—A continuous brachial artery pressure record taken before, during, and after aortic valvotomy. Three features are demonstrated. (1) The fall in blood pressure to almost zero marks the duration of occlusion of the aortic branches to the head and neck to prevent calcium emboli; it lasts some 65 seconds, and during this time the valvotomy was completed. (2) The blood pressure rapidly returns to the pre-valvotomy level. (3) On the left and the right are slow tracings to show the form of the pulse wave. Before valvotomy the slow upstroke shows a classical anacrotic notch; after valvotomy the upstroke is steep and has no notch.

If bleeding is heavy a swab can be held over the wound. At this stage it is better to wait quietly a few minutes to let the heart settle down; this will always lessen the bleeding and may allow it to stop altogether. Palpation of the aorta will usually reveal changes in the thrill, pulsation, and pressure to indicate the degree of improvement. When the heart's action is steady the improvement can be checked by taking pressures across the valve once more by needle puncture. If these are satisfactory it only remains to close the small wound in the ventricle with two or three stitches. If the gradient is still high further instrumentation is needed.

It is necessary to take great care in tying the stitches. If the muscle is at all friable and they are tied too tightly they will cut out, and control may then be difficult; the sutures should be bedded down just so much and no more. Much has been written about uncontrollable haemorrhage and unsuturable wounds, but these have never been so in any of the cases in this series. It may be that the use of a large, heavy type of expanding dilator is responsible for severe damage to the myocardium. The simple two-bladed dilator of the type used for pulmonary stenosis and opening to 3.5 cm. is less than 1 cm. in diameter. It has given no

FIG. 5.—Two-bladed expanding dilator.

trouble and is very powerful and effective (Fig. 5). The suggestion that a three-bladed expanding dilator can open the three commissures is unconvincing.

The heart may show distress during the early manipulations, and ventricular fibrillation may even begin. In these circumstances it is best to proceed at once to complete the valvotomy and then begin resuscitation.

If fibrillation begins during the valve dilatation this can be completed and then massage and defibrillation carried out. Several patients have made a perfectly normal recovery even after going through a period of many minutes of ventricular fibrillation (Milstein and Brock, 1954).

When aortic and mitral stenosis coexist the heart is exposed in the same way. In most cases the mitral stenosis is the more important lesion and is dealt with first; pressures are always taken across both valves to try to elucidate this. If the aortic stenosis should be the more important it is naturally treated first. After the mitral valvotomy the aortic gradient is again checked before the aortic valve is dealt with according to the technique already described, except that the aortic branches would not be snared in the absence of calcification. Aortic valvotomy is usually well tolerated in these cases because the left ventricle has, as it were, been protected by the mitral stenosis.

The technique for open aortic valvotomy is, of course, quite different. The chest is opened by the standard transverse, transsternal incision through the bed of the right third and left fourth or fifth rib. Pressure estimations are done as usual and then venovenous cooling is instituted accord-

ing to the technique described elsewhere (Brock and Ross, 1955; Brock, 1956), the temperature being lowered to about 29° C.

After interruption of the circulation by clamping the superior and inferior venae cavae the aorta is opened to expose the valve for visual valvotomy; little more than five minutes is needed to complete this. The incision in the aorta is closed with a clamp and can then be sutured at leisure after the circulation has been re-established.

Pressure Records

A certain amount has been said about pressure records across the aortic valve, but this is a convenient moment at which to elaborate certain features.

The criticism has already been mentioned that pressure records taken at operation are unreliable, although these statements are rarely supported by actual figures.

Pressure recordings have been made at operation on all the cases of aortic stenosis in this series and on at least another 50 cases in which it has been necessary to assess the gradient critically (usually when mitral stenosis coexists). Over a period of years, and from this not inconsiderable

FIG. 6.—Pressure records from left ventricle and aorta taken at operation before and after aortic valvotomy. The pre-operative gradient of 90 mm. Hg has been reduced to 10 mm. Hg; the systemic pressure has actually risen 10 mm. Hg. The form of the aortic pulse tracing has improved.

number of cases, the impression has been formed that these observations cannot be dismissed as unreliable or misleading. It is obvious that the conditions at operation may be different from those existing at other times, and proper allowance can be made for this. Thus the heart's action may be poor, the systemic pressure low, and the gradient correspondingly reduced. Clearly this must be taken into account after the manipulations of aortic valvotomy, when the ventricular pressure might be lower from the insult the heart has received. It is not difficult to recognize this state and either wait until the condition has improved or just note that the observations are not fully reliable under the conditions pertaining.

It has already been stated that our experience with direct left ventricular puncture has shown that pressure records made before operation can be exactly confirmed at operation. Furthermore, far from the heart being embarrassed by valvotomy, its action is often immediately and strikingly improved so that an even higher systemic pressure is recorded (Fig. 6). If this is so, or the systemic pressure is at any rate not lowered, it can be inferred that the drop in left ventricular pressure is the expression of relief of stenosis and not ventricular failure. Thus typical records are:

	Before valvotomy	After valvotomy
Aorta	100/56 mm. Hg	100/50 mm. Hg
Left ventricle	260/40 mm. Hg	140/40 mm. Hg

The aortic and brachial artery tracings will also usually confirm the efficacy of the procedure (Figs. 4 and 7).

If pressure records made at operation are to be rejected as unreliable it would be good to know what other method

of assessment is to take their place. Even with open aortic valvotomy there is the problem of secondary subvalvar stenosis.

The pressure gradient in isolated aortic stenosis coming to operation is usually much higher than in aortic stenosis combined with mitral stenosis. Thus the usual gradient is

FIG. 7.—Brachial artery tracings taken before and after aortic valvotomy to show conversion from a grossly anacrotic to an almost normal tracing.

about 100 mm. Hg—for example, aorta 100 mm. Hg, left ventricle 200 mm. Hg. In severe cases the left ventricular pressure may be nearly 300 mm. Hg. In one patient it was found to be 325 mm. Hg when measured by direct left ventricular puncture; the brachial artery pressure was 115 mm. Hg.

It is difficult to lay down any firm rule for a figure below which one would probably not advise operation in pure aortic stenosis; 50 mm. Hg suggests itself, especially if this were a figure arrived at by left ventricular puncture before operation. If found at operation full weight would have to be given to the evidence of any general circulatory depression, particularly an unduly low aortic pressure. Normally, also, all the other clinical features would have to be taken into account, including cardiac output.

It is expecting too much to be able to obliterate the gradient completely in a case of severe calcified aortic stenosis. Occasionally this can be nearly achieved, as is shown by Fig. 6, in which there has been a reduction from 90 mm. Hg to 10 mm. Hg. Fig. 8 also shows almost complete obliteration of the gradient.

Often one must be content with a residual gradient of 30–50 mm. Hg. Occasionally it is not possible to achieve any satisfactory reduction of the gradient. In such cases, however, it would be wrong to assume always that there has been no specific relief of the actual valve stenosis. For instance, in a recent case the pressures before aortic valvotomy were: aorta, 100 mm. Hg; left ventricle, 200 mm. Hg; gradient, 100 mm. Hg.

The valve orifice was felt to split well and the dilator could be opened freely. In spite of this the pressures were: aorta, 80 mm. Hg; left ventricle, 150 mm. Hg; gradient, 70 mm. Hg. The dilator was again passed, and it was confirmed that the valve opened easily and widely; it seems certain that residual valve stenosis was slight.

The probable explanation lies in the appearance of a secondary subvalvar muscular obstruction due to gross left ventricular hypertrophy analogous to what has been fully described as occurring in the right ventricle in certain cases of pulmonary valvar stenosis (Brock, 1956). A catheter withdrawal record seemed to give support to this. It can be reasonably expected, if this is the explanation, that improvement may accompany diminution in the gross muscular hypertrophy.

The value of pressure records made before, during, and after operation may be judged from the following notes of a case.

A youth aged 16 had congenital aortic stenosis; the electrocardiogram showed severe left ventricular strain pattern. Right heart catheterization and direct left ventricular puncture gave the following data. Cardiac output: At rest, 5 litres; during exercise, 7.1 litres; during L.V. puncture, 6.3 litres. Pressures: Brachial artery—at rest, 110/60 mm. Hg; during L.V. puncture, 95/60 mm. Hg; left ventricle, 177/17 mm. Hg; systolic pressure gradient, 82 mm. Hg. Estimated aortic valve area, 0.8 square cm.

When the heart was exposed at operation the pressure records were: aorta, 69/52 mm. Hg; left ventricle, 136/15 mm. Hg—systolic gradient, 67 mm. Hg.

After venovenous cooling to 29.5° C. the aorta was opened to expose a stenosed valve cone with a central aperture about 0.4–0.5 cm. in diameter; the three fused commissures were cut accurately and a finger was passed into the left ventricle.

Pressure records were again taken when the temperature was 32° C. These showed: aorta, 60/42 mm. Hg; left ventricle, 73/11 mm. Hg; systolic gradient, 13 mm. Hg.

Investigations were repeated six months after operation with the following findings; figures at the pre-operative catheterization are given in parentheses. Cardiac output: At rest, 16.7 litres (5 litres); during L.V. puncture, 10.6 litres (6.3 litres). Pressures: Brachial artery—during L.V. puncture, 115/67 mm. Hg (95/60 mm. Hg); left ventricle, 135/12 mm. Hg (177/17 mm. Hg); systolic gradient, 20 mm. Hg (82 mm. Hg). Estimated aortic valve area, 2.32 square cm. (0.8 square cm.).

The brachial artery pressure pulse was now normal instead of being grossly anacrotic.

It should be noted that in addition to proof of the effectiveness of the open aortic valvotomy in improving the cardiac output and converting the pressure gradient across the valve, there is very close agreement between the pre-operation records and the pre-valvotomy records at operation; also between the post-valvotomy records at operation and those made six months after operation.

When mitral stenosis exists with aortic stenosis the gradient is usually much less than in pure aortic stenosis. My first combined aortic and mitral valvotomy was done in January, 1953, but for at least three years before this the practice was made of taking pressure records across the aortic valve in cases of mitral stenosis with features of aortic stenosis and trying to obtain some information by a post-operative follow-up. As a result of this experience it is felt that a gradient of only 25–30 mm. Hg is an indication for aortic valvotomy when there is a coexistent mitral stenosis, and of course associated with clinical features of aortic stenosis. This is based on a follow-up of patients in whom the gradient was as small as this and who seemed to have a degree of disability due to unrelieved aortic stenosis. There have, of course, been patients in whom a gradient of 25 mm. Hg was found who have shown no signs of disability. Two patients in whom the gradient was 50 mm. Hg and 70 mm. Hg were left with their aortic stenosis untouched, and both had to have secondary aortic valvotomy; both then obtained complete relief. There can be no doubt that a gradient of 50 mm. Hg in a patient with combined stenosis must not be left unrelieved.

In the presence of significant mitral stenosis the gradient must inevitably be smaller because of the diminished filling of the left ventricle and hence the restricted output. As a corollary, relief of the mitral stenosis will improve the filling and the output, and hence the gradient across the aortic valve stenosis will increase.

In these combined cases it is much easier to obliterate the pressure gradient completely (Fig. 9).

The aortic valve manipulations are so well tolerated in these patients that in any doubtful case it is now thought preferable to introduce a bougie and try to gauge the size

FIG. 9.—Pressure records from left ventricle and aorta in a case of combined aortic and mitral stenosis before and after combined aortic and mitral valvotomy. The small pre-valvotomy gradient of 18 mm. Hg has been reduced to 3 mm. Hg.

of the valve orifice, or even to insert an expanding dilator to try to assess this more closely, and, if need be, open it widely and split the valve.

There were three deaths among the 34 cases of combined aortic and mitral valvotomy, but in all three death was due to the mitral stenosis and not to the aortic valvotomy.

Results

The greater tolerance of aortic valvotomy when combined with mitral valvotomy makes it desirable to separate this group from pure aortic stenosis.

As stated above, combined aortic and mitral valvotomy was done in 34 patients with three deaths. In 12 patients the clinical result was excellent or good; it is in this group of combined aortic and mitral valvotomy that some of the very best results can be obtained. In only seven patients was the result classed as fair and in only one as poor.

Four patients have since died; in these the initial result had been judged as good in one, fair in one, poor in two.

In two cases aortic stenosis was associated with coarctation of the aorta, both lesions being severe.

There remain 84 cases of isolated aortic stenosis; from these should be deducted the first, 1947, case in which no valvotomy was done; 83 remain. Among these are five cases of subvalvar stenosis, and it would appear better not to consider them with the pure valvar stenosis group; 78 cases remain for consideration.

Among these 78, there occurred 14 deaths due to the operation—an overall mortality of 18%. It must, however, be pointed out that five of these deaths occurred in the first eight patients, all of whom were very bad risks; four were over the age of 50, one over 60; some were in advanced right- or left-sided failure.

This early experience was so disturbing that operations on aortic stenosis were nearly abandoned, but after consideration it was decided that it was wrong to select such desperate cases; thereafter the results improved vastly. It must not be supposed that only mild cases were chosen; it was simply that moribund patients were rejected.

If, for the moment, these first eight cases are excluded we find the mortality is 9 in 70 (12.8%). Actually there have been only three deaths in the last 48 cases of pure aortic stenosis; and in one of these the patient had been in left-sided failure and had grossly impaired lung function; one was a case of open aortic valvotomy under hypo-

thermia; the third patient died 10 days after operation from a heavy wound infection resistant to antibiotics. Included in these 48 are four cases of open aortic valvotomy.

In the last 63 cases of aortic valvotomy, including those with mitral stenosis, there have been only four deaths; all except one were very bad risks.

In an average-risk patient with isolated aortic stenosis the mortality from operation should be low; it is only when features of advanced secondary changes are present that the mortality rises. This means that in certain types of case the risk of operation may lie between 25 and 50%; for average cases the risk is probably no more than 5%.

Baker and Campbell (1956) made a detailed clinical survey of the results of the first 16 patients operated on at Guy's Hospital. How gravely ill were the patients in this series is seen by the fact that six died and in only five was the result good; even among these five one died after 18 months. Baker and Campbell, indicating how these patients were chosen for operation at a late stage of their disease, reveal that 9 of the 16 had left ventricular failure and three had progressed to right-sided failure as well; all had electrocardiographic signs of severe left ventricular strain. In this larger series of 78 cases 21 had left ventricular failure and a further 11 had progressed to right-sided failure as well; 68 had electrocardiographic features of severe left ventricular strain.

The clinical result in the 64 survivors in this series of 78 can be presented simply as follows:

Died since	..	..	..	..	..	9
Still alive	..	..	..	..	..	55
Excellent result	..	..	..	..	12	42
Good result	..	..	..	..	30	
Fair result	..	..	..	..	13	

The nine patients who have died since require more detailed analysis. In these the result had been classed as

Excellent	1	(died 13 months later of lung cancer)
Good	1	(died 6 months)
Fair	4	(died 2 years, 20 months, 15 months, 3 months)
Poor	3	(died 1 year, 9 months, 4 months)

Post-operative Aortic Regurgitation

A criticism of blind aortic valve dilatation has been that it is followed by a high incidence of severe regurgitation. In this series some degree of regurgitation was produced in 14 patients and was largely responsible for the death of four of these. In the others it varied from mild to moderate in degree, the result being classed as good in five and fair in five. To balance this, pre-operative regurgitation has been lessened or completely relieved in several patients. Regurgitation is a hazard, but only a small one, and certainly not large enough to weigh against operation.

Transventricular or Transaortic Approach?

The transaortic route for valvotomy is the one now most generally advocated, chiefly as a result of the strong recommendation of American surgeons. Unquestionably this must be the correct route for open aortic valvotomy, but we are concerned now with the "blind" procedure. For this I have been unable to accept that the transventricular route is inferior. These claims must now be examined.

As mentioned earlier, I first used a supravalar approach nearly 10 years ago; in two later cases the aorta was exposed by splitting the upper part of the sternum and instruments were inserted through the innominate artery. The results were so poor that this route was abandoned for the transventricular; this has since been used exclusively without reverting to the transaortic approach (except for open surgery).

The unfavourable features claimed for the transventricular route have not been manifest. These have been stated to be: undesirable interference with the left ventricle, liability to ventricular fibrillation, excessive or uncontrollable haemorrhage, inability to suture the ventricle, inability to do a satisfactory valvotomy, and higher mortality.

No one will question that it is better to avoid direct interference with the left ventricle if this can be avoided. However, one of the chief reasons why I abandoned the supravalar approach was that it did not seem to protect the ventricle, seeing that ventricular fibrillation occurred in two cases, proving immediately fatal in one; the second patient died a few hours later. It is true that these were bad risks and just the type in which incision in the left ventricle would have been badly tolerated; the point is that collapse was not avoided by sparing the ventricle. From reports and records this is also the experience of others. Among the 109 cases in which the ventricle has been transversed (75 cases of pure aortic stenosis; 34 cases with combined mitral stenosis) ventricular fibrillation due to this occurred in nine. Four of these patients died at operation or soon afterwards; the remaining five were successfully converted to normal rhythm. Of the nine deaths apart from these, in none can the incision in the ventricle be directly blamed.

Ventricular fibrillation occurred in two out of three supravalar cases in this series and in 9 out of 109 transventricular cases. In four of these, ventricular fibrillation began before the ventricle was incised, and was, in fact, a token of the serious heart condition. One great advantage of the transventricular route then becomes apparent in that the heart can be quickly massaged, immediate valvotomy can be done, and electric defibrillation achieved without delay. The transaortic operation can be a long and much more complicated procedure, a fact against using it in a very poor risk case in which a rapid, effective valvotomy is needed. There is no evidence that ventricular fibrillation is a more serious menace in the transventricular operation. Whether ventricular fibrillation occurs or not can be determined by the way the ventricle is handled: the utmost gentleness must be used; the slightest extra stimulation may precipitate distress or disaster. In addition to the surgeon, the assistants also carry a great responsibility, especially in regard to care in use of a sucker within the pericardium. This can easily cause ventricular tachycardia and fibrillation.

Although haemorrhage is claimed to be a danger in the transventricular procedure it would appear unlikely that the transaortic approach is itself free from the dangers of uncontrolled or severe bleeding, and, indeed, this is borne out from reports. Inability to control haemorrhage from the left ventricle has never occurred in this series. In a few cases with a huge left ventricle haemorrhage has been excessive, but no more. Perhaps this difference in experience lies in the use of a smaller, kinder instrument which inflicts little or no damage on the muscle; a large instrument can be very traumatic. In this also may lie the cause of the greater incidence of ventricular fibrillation complained of, and perhaps also the other objection of inability to close the wound.

Inability to suture safely has not been met with in any of our cases. When the disease is not grossly advanced there is no difficulty at all in muscle suture. When the ventricle is big and unhealthy the muscle may hold stitches badly and great care must be taken in tying sutures.

Deaths have certainly been reported from trouble with closure of the aortic incision in the supravalar approach; these include delayed rupture and haemorrhage and also aneurysm formation. On balance there seems little to favour the aorta over the ventricle as safer tissue for suture.

It is maintained that operation from above allows better relief of the stenosis from ability to use the finger as well as instruments. Blind transventricular dilatation is a rather crude and surgically unsatisfactory technique, but I am unconvinced that any better result can be achieved with the finger from above. Certainly the finger can feel the lesion, but the severe and vicarious calcification of the valve tissue prevents effective digital splitting; the pathological anatomy is in no way comparable to that of mitral stenosis, in which the finger can be so effective. It may well be that in occasional cases rather more can be done than from below, but

too rarely to form a significant argument in favour of a blind approach from above. A severely calcified valve is hopelessly unfavourable by any method.

The proponents of the supravalar approach state that the mortality is lower in their cases.

Thus Likoff *et al.* (1955) mention a mortality of 28% in 79 patients with the transventricular route and, following this, a mortality of 10% in 50 cases of the transaortic operation.

Bailey *et al.* (1956) state that since March, 1950, they have operated on 287 patients, and their mortality figures are: transventricular, 68 cases, 19 deaths (28%); combined mitral and aortic, 87 cases, 16 deaths (18.4%); transaortic, 47 cases, 7 deaths (14.7%). In my own small series the comparable figures are: transventricular, 76 cases, 12 deaths (16%); combined mitral and aortic, 34 cases, 3 deaths (9%); Transaortic, 3 cases, 2 deaths (66%).

It should, however, be noted that the cases in the three groups of Bailey *et al.* total 202, leaving 85 cases unaccounted for in their total series. It is difficult from their report to know which cases have been excluded, although by inference it is a convenient number of the earlier ones who were operated on in an earlier technical phase. If this is so it is difficult to know how exactly to appraise the results. In my own series, if the first seven cases in which technique and selection of cases was less mature are omitted the results are: transventricular 69 cases, 9 deaths (13%).

Direct comparison of mortality figures between different and relatively small series of cases is patently weak and unsatisfactory. The above comparison does, however, show that the mortality of the transventricular operation is not essentially greater than that of the transaortic.

My experience and practice is not presented as a plea for the transventricular operation; it is merely intended to show that there are no overwhelming advantages in favour of the transaortic approach such as have been claimed.

In actual fact neither blind method can carry any strong claim, because the basic morbid anatomical changes in the valve favour neither.

The answer to obtaining better technical results in aortic valvotomy must lie in the development of open direct-vision surgery. This has already been begun, and it will soon be possible to report on a large enough number of cases to enable a fair assessment of its value to be made. At present this must be awaited, and many surgeons may still prefer to continue to use the palliative procedure of transventricular dilatation of calcified aortic stenosis rather than to submit such patients routinely to the unassessed hazards of open valvotomy under hypothermia or with total heart-lung by-pass.

Summary

The historical development of the surgery of aortic stenosis is presented and also the principles governing the need for operation. It is pointed out that aortic stenosis is fundamentally a state of obstruction of the left ventricle and the same principles should be followed in its management as are already well established in obstruction of other hollow muscular viscera, such as the colon, stomach, or bladder.

Surgery can now offer sufficient relief with a relatively low mortality (10-15%) to make it thoroughly justifiable to refer patients for operation.

The importance of critical clinical assessment is emphasized, aided by the more objective methods of right and left heart catheterization. Percutaneous puncture of the left ventricle is a simple, safe, and quick way of determining the pressure gradient across the valve.

The various operative approaches are discussed. For calcified aortic stenosis the transventricular route is preferred. For non-calcified cases, open aortic valvotomy under direct vision and with hypothermia is used.

Operation was done in 130 cases, 34 being examples of combined mitral and aortic stenosis.

The mortality of operation need be no more than 10-15%. A good result was obtained in about 70% of survivors. The mortality will always be high if operation is deferred until features of heart failure have appeared.

The patients included in this study were almost all operated on in collaboration with Drs. Maurice Campbell, Paul Wood, Charles Baker, and Ronald Gibson; I am indebted to them all. I am also grateful for the invaluable help of various colleagues in the investigations before, during, and after operation. Fig. 8 is from records made by Dr. P. Fleming, and Figs. 1, 2, 3, 4, 6, and 9 are from records made by Dr. R. Gibson. I am grateful to Dr. Lawson McDonald for the arterial pulse tracing in Fig. 7.

MENTAL PERFORMANCE IN CHRONIC ANOXIA*

BY

RAYMOND GREENE, M.A., D.M., F.R.C.P.
 Formerly Vice-President of the Alpine Club

No one has ever had the opportunity to observe the unalloyed effects of prolonged severe oxygen deficiency in man. In physical illness there are always impurities present: in anaemia, the cause of the anaemia; in pulmonary disease, the toxic effects of the causative organism or of the secondary invaders; even in cardiac disease, such confusing factors as the presence of cerebral arteriosclerosis. At great altitudes the complicating factors are numerous. The most important is probably the psychological make-up of the climber. A full discussion of the problem would lead the inquirer into such private fields as his subject's reason for going to the mountains at all. The Walter Mitty complex, so well described by that excellent psychologist James Thurber, is probably the common thread which runs through all our tangled motives for being mountaineers, but in many of us some of the motives are less worthy of

*Read at a Symposium at the Royal Society, Burlington House, London, on January 28, 1954.

respect, and in consequence psychological breakdowns may occur and may have effects upon the other members of a party which may wrongly be ascribed to what on Everest in 1933 was vulgarly described as "alt."

Such considerations urge caution in attacking the question of the mental effects of chronic anoxia along the usual anecdotal lines. A description of the manic behaviour of A on Everest or the depressive interlude experienced by B on Kangchenjunga must be sceptically examined for possible psychological, as opposed to physiological, causes. Unfortunately the very proper loyalty which censors the reports of every returning mountaineer makes it impossible to obtain a sufficiently detailed description of the mental atmosphere of the party as a whole or the pattern of behaviour of individual members.

Confused though the problem is by psychological considerations and by such additional complications as wind and weather, nutrition, and technical mountaineering difficulties, we are not entirely without guidance in our search for essentials. We can look for the common factors in the conditions of chronic anoxia due to physical disease and chronic anoxia due to altitude. Bearing in mind that the clinical picture is modified by different impurities, we may justifiably assume as a working hypothesis that common factors are the result of chronic anoxia pure and simple. We can administer a further test by studying acute anoxia, whether it be anoxic, anaemic, stagnant, or histotoxic. Broadly speaking, a chronic condition produces signs and symptoms similar to those of an acute condition, modified by their being milder, more prolonged, and in consequence admixed with the syndrome produced by the adaptive reactions of the body, which, in the acute condition, have not had the necessary time to develop.

Chronic Anoxia

It is convenient first briefly to consider the effects upon the mind of chronic anoxia studied at moderate altitudes in health and at sea-level in other forms of anoxic anoxia (as in pulmonary disease); in anaemic anoxia (as in pernicious or Addisonian anaemia); and in stagnant anoxia (as in cardiac failure).

Perhaps the most reliable information bearing on our present purpose is that which has been obtained by the observation of man during prolonged residence at moderate altitudes. When I was in Darjeeling, which lies at about 7,000 feet (2,130 metres), I found a fairly general impression that those who stayed there for a year or more without a break at lower levels, often became somewhat irritable, and I have heard the same story from doctors practising in Johannesburg, which lies at a similar level. If we go twice as high, to 14,000 feet (4,270 metres), we have the observations of Barcroft (1925) at Cerro de Pasco. Mental tests disclosed nothing; and Barcroft wrote:

"Yet I am not prepared to admit that our mental capacity was the same at Cerro as it is here. All the party will agree, I believe, that the reason why the mental tests failed to reveal the difference was because our mental disability was of too subtle a character to be revealed by somewhat simple tests than because the fitness of our minds was unimpaired. It is possible to force oneself to do good work even though the test measures the quality of work done; but were it ideal it would also measure the degree of concentration brought to bear upon the task." [One is reminded of the interesting experiment conducted many years ago by some young gentlemen of a famous medical school, who by constant practice trained themselves to perform perfectly, even in a state of severe alcoholic intoxication, all the tests employed by the police for drunkenness.] "Apart from the actual processes of addition, subtraction, etc., there seemed to be an unwonted difficulty in stating a sum at Cerro if it were not of a quite simple character. The Van Slyke method of gas analysis

demands the application of some rather complicated tables of correction to the gas volumes as actually measured. These corrections loomed large at Cerro altogether out of proportion to their real difficulty. . . ."

Barcroft's observations on the inability of mental tests to show mental deterioration at 14,000 feet (4,270 metres) were confirmed by Hingston (1924) at 21,000 feet (6,400 metres). No deterioration in actual performance was demonstrable. Yet such a deterioration exists. I well remember the difference in effort needed to take samples of alveolar air at Base Camp on Everest (17,000 feet—5,180 metres) and at Camp V (25,600 feet—7,800 metres). At Base Camp it was an almost automatic process performed in a few seconds. At Camp V it needed a conscious effort of concentration.

Turning to other causes of chronic anoxic anoxia, one finds a dearth of recorded observations and there is equal silence on the subject of mental performance in chronic anaemic anoxia, though Thomas Addison himself noted personality changes in some of his patients.

In stagnant anoxia, such as that due to chronic congestive cardiac failure, observations on the mental processes have been numerous and have been correlated with the arterio-venous oxygen difference. The subject has been reviewed by Himwich (1951). Neuroses are common in cardiac failure, especially confusion, delusions of persecution, and exacerbation of previous anxiety states. It is difficult for the hospital doctor (by whom the majority of such observations are recorded) to assess such changes. He cannot compare the present mental state of his patient with the past. In general practice such observations are easy but have never been recorded. My own impression is that in the chronic anoxia of cardiac failure and advanced pulmonary disease one sees an accentuation of a previous mental abnormality rather than the creation of a new one. The man one has known for years as a well-balanced, placid, good-tempered, co-operative patient retains these characteristics in a state of chronic anoxia due to illness. One feels that one of the effects of the illness is to strip the veneer off a man and expose the quality of his mind naked to the world. I think that the same thing happens in alcoholic intoxication and in the chronic anoxia of great altitudes. The effects on the mind of a decrease in the A-V oxygen ratio are superimposed on individual characteristic patterns of behaviour.

Acute Anoxia

In acute anoxia we can study a relatively pure process, unaffected by the protective reactions of the body. This may be done at great altitudes in balloon ascents or in low-pressure chambers, and during carbon monoxide poisoning. Moreover, as there is good reason to believe that what we observe in acute anoxia is in fact the result of diminished cerebral metabolism, we may study its effects by analogy and in good experimental conditions, during myxoedema or hypoglycaemia, whether spontaneous, accidental (as in diabetics after an overdose of insulin), or purposeful (during the treatment by means of insulin of various mental abnormalities).

Haldane's description of acute anoxic anoxia is well known (Haldane and Priestley, 1935). It is worthy of fuller quotation than space will allow. He draws attention to several effects which are observable during chronic anoxia—the dulling of the senses and intellect, the loss of memory and of sane judgment, and the tendency to uncontrolled emotional outbursts. He comments on the likeness which exists between the effects of anoxaemia and of alcohol, a similarity stressed also by Barcroft and by Hingston. Yet these effects are demonstrated very unevenly. An extreme example of mental and physical control was that of Coxwell, who with Glaisher ascended in 1862 in a balloon to 29,000 feet (8,840 metres). Glaisher was by this time unconscious, but Coxwell was still able to clamber into the rigging to free a tangled rope and thus to save his own and Glaisher's life—an interesting fact in view of recent arguments about the necessity of oxygen apparatus on Everest.

More recently McFarland (1938) has described the results of acute exposure of human beings to low oxygen pressures. No change is observed below about 12,000 feet (3,660 metres), when the memory for recent events becomes slightly impaired. At about 14,000 feet (4,270 metres) changes in mood may be observed, differing from one individual to another, and there may be lassitude or euphoria. At 18,000 feet (5,490 metres) sensory perception is decreased, the field of attention is narrowed, irrational behaviour may be manifest, and judgment is impaired. Above 20,000 feet (6,100 metres) reaction times are slowed, awareness of the passage of time becomes inaccurate, and explosive emotional outbursts may occur.

The study of carbon monoxide poisoning and, more especially, of hypoglycaemia has given us much information about the processes involved. As the schizophrenic patient sinks into coma under the influence of insulin, his physical signs denote a steady deterioration of cerebral control from the cortex downwards and it is possible to watch the patient's bodily control dropping in phylogenetic stages from the cortex, via the diencephalon and the upper medulla to the lower medullary region. During recovery the development of the brain is recapitulated. Each area of the brain during the process called by Hughlings Jackson "dissolution" uses, as hypoglycaemia advances, a steadily decreasing amount of oxygen, and when the oxygen needs of each part of the brain are separately examined it is found that the higher the part of the brain examined the higher are its demands. It follows that the more voracious parts are the first to succumb. A relatively mild deficiency affects only the newer parts of the brain, and at the other end of the scale a very severe deficiency is needed to bring to a final end the function of the medulla.

In mild acute anoxia and the chronic anoxia of great altitudes this process stops at the first stage, the abolition in part of cortical control. Rarely indeed does the mountaineer evince the sham rage of the decorticated cat, but he may often come very near to doing so. There is reason to believe that the stratifications of the brain as a whole are reflected in the laminations of the highest centres. An analogy with the effects of alcohol in excess is not strictly sound, because although alcohol reduces brain metabolism very much as do anoxia and hypoglycaemia, it has probably another and separate activity. Nevertheless Barcroft's evidence, which I can support from my personal observations, strongly suggests that the analogy is a useful one. Within the cortex, it is the higher control which is first lost, the inhibitions imposed by recent training preceding in their exit those more deeply embedded in childhood. A similar though cruder sequence is seen during the slow induction of anaesthesia by barbituric acid derivatives. One sees first euphoria, then loss of inhibitions, ineptitude in obeying commands, loss of mental concentration, and finally loss of consciousness.

Great Altitudes

We must now turn to a consideration of the more complex phenomena of mental processes in man in the special circumstances of high mountains, and attempt to recognize changes in performance which reflect the changes of acute anoxia and of the milder and less complicated circumstances of chronic anoxia in human illness. The common factors may, *ex hypothesi*, be accepted as due to severe chronic anoxia and not to meteorological or strictly psychological causes. The earliest observations are those of Hingston (1924).

"High altitudes affect the operations of the mind. One member was confident of a dulling of the will power, a diminution in the strength of purpose, with less and less desire to reach the summit the farther he made the ascent. Somervell describes a lack of observance at and above 25,000 ft. (7,620 metres). Bruce records an enfeeblement of memory. He found an effort in recalling previous events. Above 23,000 ft. (7,010 metres) his ideas became increasingly inaccurate. It was necessary for him to record them immediately, as otherwise they would become forgotten or distorted. I think everyone experienced some mental

lassitude. Though the mind was clear, yet there was a disinclination for effort. It was far more pleasant to sit about than to do a job of work that required thought. . . . Though mental work is a burden at high altitudes, yet with an effort it can be done. One physiologist has said that sustained mental work is out of the question at anything over 10,000 ft. (3,050 metres). We certainly could not agree with this. Those who have read Norton's despatches to *The Times*, especially one dictated at Camp III, when he was burdened with anxiety and partially blind, will admit that this effort from 21,000 ft. (6,400 metres) was not a bad intellectual performance. The main effect of altitude is a mental laziness which determination can overcome."

Personal Observations

May I turn now to a few sketchy observations of my own? It is well that I recorded them at the time. It may in itself be significant that when I read my diary again after an interval of 20 years I found that I had completely forgotten a lot of what had happened under my eyes on the upper part of Everest, though the incidents below about 20,000 feet (6,100 metres) still seemed fresh in my mind.

Only one member of the expedition was seriously affected at Base Camp (17,000 feet—5,180 metres). Mental lassitude assailed him so severely that he gradually withdrew himself from the day-to-day work of the camp. He ceased to take any interest in the job which had been assigned to him, and his work was gradually taken over by other people without any protest or resistance. He ultimately improved and succeeded in reaching the North Col, but he never pulled his weight in the Expedition again. No one else showed any change in mental performance below the North Col (23,000 feet—7,010 metres), when several people began to complain of nightmares. Two members became argumentative, over-critical, and, if opposed, surly. One of these made a gradual recovery, but the other, after an ascent to 25,000 feet (7,620 metres), became extremely ill-tempered and suffered from the delusion that he was severely frost-bitten. In fact, he was not frost-bitten at all, but he spent several days at Base Camp refusing to leave his tent.

A curious case which I am inclined to ascribe to other causes than pure chronic anoxia was that of a member who acquitted himself well up to the North Col, the highest point planned for him. On his return to lower levels he developed a severe paranoid psychosis from which he did not recover until a few days before his return to Darjeeling. I think that here anoxia was only a contributory factor. He was a man whose physical and mental fitness were below the level demanded but who from a sense of duty had driven himself to breaking-point.

Apart from these examples, no mental changes were observed except in those who climbed above 27,000 feet (8,230 metres). All of these had "waking dreams" which took the form of terrifying nightmares except in the case of Frank Smythe, who recorded his impressions in his book *Camp 6*. He was convinced, when climbing alone, and of course without oxygen equipment, at about 28,000 feet (8,530 metres), that he had with him a friendly companion, to whom at one point he offered a sandwich. He also had visual hallucinations, seeing above the ridge of the mountains some curious dark bodies which came to be known as "Frank's pulsating teapots." Yet his judgment otherwise was quite unimpaired. At 28,100 feet (8,565 metres), with the summit less than 1,000 feet (305 metres) above him, he was able soberly to consider the pros and cons of continuing, weighing his feeling of physical fitness and the early hour against the bad condition of the snow, and coming to the unwelcome conclusion that he must return. Smythe never suffered from the irritability which occasionally appeared in all the rest of us who went high. It seemed that chronic anoxia increased his placidity. At low altitudes a little inclined to take offence, at great ones he emanated serenity and an infectious happiness.

Indeed, those who reached the highest points were, it seemed, less affected by ill-temper, perhaps because even ill-temper requires a certain level of oxygen tension to develop. They may by this time have reached a condition

of fatuous good-temper. This was certainly true of one of us, who after his return from the higher reaches was confused, somewhat aphasic, and disinclined to talk, preferring to sit in silence, benignly contemplating his surroundings. The failure of memory which has so often been described affected us very unequally. One man was very conscious of this at the time. He said his mental capacity was 25% of normal. He forgot that his job was the exploration of the Second Step, though this had been his much-discussed assignment for weeks. Happily his companion remembered.

Another effect of high altitudes which can be recognized as an effect of oxygen deficiency rather than of psychological and mental stress is a dulling of the special senses, for this occurs very noticeably in acute oxygen deficiency. This was first observed by Paul Bert (1943) and confirmed by Haldane and others (1919). The dulling is not as a rule observed: it is the return of brightness to light and colour, and of loudness to sound, which strikes one when the oxygen supply is increased. I wrote of this when returning from the summit of Kamet (25,447 feet—7,756 metres), in 1931 (Greene, 1932).

"In the neighbourhood of our old Camp One the snow began to fall less thickly, and far ahead we could see the end of the East Kamet Valley, and the dark and snow-streaked rock peaks lying above Base Camp. It was at this point—at about, I suppose, 16,500 feet (5,030 metres)—that a change came over my feelings. Haldane has written how, in his experiments on the effects of low air-pressure, he sat in his steel chamber with the pressure gradually rising towards the normal: and how, at a certain level, the electric light glowed suddenly more brightly. At first he thought that the current had been increased, but later he came to realize that the change was in himself and not in the current. For me, shut in no steel chamber, but walking slowly down the East Kamet Glacier, depressed by wind and weather and painful feet, the whole aspect of life as suddenly changed. I began once more to appreciate the pleasures of the senses. The snow was whiter and more scintillating. When, little by little, patches of sky began to show between the banks of cloud, they seemed a brighter blue than the skies of Kamet. One began to hear and to smell more acutely. It is clear that not only are one's senses dulled by lack of oxygen, so that the light in the steel chamber becomes dull and the Himalayan sky less blue, but that all one's mental processes suffer a like fate. Especially, at great heights one does not gloat over one's pleasures. One loses, as Goethe has put it, 'the capacity to submit to impressions; to be delighted, touched, and exalted.' But now this capacity was suddenly restored."

Conclusions

It is now possible to sift the observations of Everest doctors on the mental performances of their parties and to trace their similarity with those observed during anoxia in other circumstances. The following facts emerge.

1. Chronic anoxia affects different people very differently, both quantitatively and qualitatively. Some men are remarkably resistant, showing within the limits of the "experiment" little change at all. Those who show definite changes are affected very much as they are by alcoholic intoxication, the protective skins of their essential mental make-up being stripped off onion-fashion, the more recently acquired inhibitions being the first to go.

2. Memory is seriously affected, though to different degrees in different individuals.

3. The capacity accurately to perform mental tasks is affected. Tests hitherto performed have been too simple to show this, but more concentration has been needed in their performance at great altitudes, and harder tests might be employed in future.

4. Emotional instability may be severe. This usually takes the form of irritability. The tearfulness described by Barcroft does not occur in other descriptions than his and is probably the result of mental fatigue rather than of anoxia. Conversely, many travellers' tales of strange behaviour at great altitudes should be discounted because of a lack of similarity to mental changes occurring in acute anoxia and in chronic anoxia due to other causes.

May I end by quoting with sympathy the words of Mosso (1898)? "It is my wish to find some man with a hole in

his skull who would have been willing to come with me on the Monte Rosa Expedition, but I was not successful in my search. Some other physiologist will, I hope, be luckier."

PRODUCTION OF FIBRILLATION IN ISOLATED ATRIA OF RABBIT HEART

BY

W. C. HOLLAND, M.D.

AND

J. H. BURN, M.D., F.R.S.

From the Department of Pharmacology, University of Oxford

The atria of the hearts of small animals can be dissected from other tissue and suspended in a bath containing some modification of Ringer's solution, and in this bath they maintain their rhythmic contractions. A few observations have been made of the production of arrhythmias in such preparations. Dawes and Vane (1951) studied the guinea-pig atria at 37° C., stimulating them electrically at a rate slightly greater than the spontaneous rate. They observed that if a test-pulse was thrown in just outside the absolute refractory period, the atria often responded by repetitive discharges at a frequency much greater than the normal rate of beat. These discharges continued for periods up to one hour. DiPalma and Masciatello (1951) made similar observations in cat atria at 29° C., though the repetitive discharge was of shorter duration. West, Turner, and Loomis (1954), in the course of studies on excitability and conduction time, noted the occurrence of arrhythmias when the interval between two stimuli was near the absolute refractory period; these lasted from a few seconds to several minutes, and they said that the arrhythmias occurred regularly in the presence of acetylcholine.

Burn, Vaughan Williams, and Walker (1955) observed that during the infusion of acetylcholine into the heart-lung preparation of the dog stimulation of the right atrium resulted in fibrillation, which persisted when stimulation ceased. The fibrillation continued so long as acetylcholine was infused, and could be terminated at will by stopping the infusion or by injecting atropine. In a later paper

FIG. 1.—Broken lines show a glass tube, through which a pair of shielded and insulated wires run, terminating in platinum electrodes. The two limbs of the U are joined by a solid piece of glass, sloping as shown, to which the lower ends of the atria are attached. The electrodes pierce the atria.

Burn, Gunning, and Walker (1956) showed that the fibrillation was also stopped by a slow infusion of KCl.

We now describe the production of fibrillation in the isolated atria of the rabbit by stimulation in the presence of acetylcholine.

Method

Rabbits weighing 2–3 kg. were used. They were stunned by a blow on the head, and the hearts were removed and placed in Ringer's solution of the following composition: NaCl, 9 g.; KCl, 0.4 g.; CaCl₂, 0.24 g.; NaHCO₃, 0.5 g.; dextrose, 2 g.; distilled water, 1 litre. The atria were dissected free from fat and other tissue, attached to an electrode (see Fig. 1) designed by Mr. O. B. Saxby, of this department, and suspended in a bath of the solution described which was aerated with oxygen and maintained at 30–31° C. A mechanical record was taken on a kymograph. The atria were stimulated by square wave pulses of 0.75 msec. duration and of 6–10 volts strength. Surface electrograms were recorded from the stimulating electrodes on a Cossor machine (model 1314).

Production of Arrhythmia

In the initial experiments, atria, suspended in the bath, were stimulated at frequencies varying from 200 to 1,200 a minute for different periods. In all preparations the normal rhythm returned immediately on cessation of stimulation. Low concentrations of acetylcholine had very little effect on the sequence of events. With concentrations greater than 3×10^{-4} g. per ml. repetitive charges of brief duration, from 2 to 5 seconds, were occasionally observed after stopping the stimulation, but persistent arrhythmia was not seen.

In further experiments the concentration of KCl in the solution was reduced to one-quarter (100 mg. per litre). Stimulation still failed to produce arrhythmia in the presence of low concentrations of acetylcholine, but, when the concentration was greater than 3×10^{-4} g. per ml. and the frequency of stimulation was greater than 600 a minute, arrhythmia then persisted, as demonstrated in Fig. 2, which shows the electrogram record.

The electrogram in $\frac{1}{4}$ K solution is shown after stimulation in (c) and on addition of acetylcholine in (d). Stimulation in the presence of acetylcholine then caused fibrillation as in (e), continuing six minutes later as in (f). When the acetylcholine was removed by changing the bath fluid a normal rhythm returned as in (g).

Once the procedure which has been described was followed, flutter or

FIG. 2.—(c) E.C.G. in $\frac{1}{4}$ K solution after stimulation; (d) beats arrested by addition of acetylcholine; (e) fibrillation one minute after stimulation in presence of acetylcholine; (f) six minutes later; (g) after washing out acetylcholine.

fibrillation was observed in all atria tested. Flutter was observed in 43%, fibrillation in 40%, and a mixture of flutter and fibrillation in the rest. In one preparation fibrillation was observed for 45 minutes and was then terminated by removing the acetylcholine from the bath (see Fig. 3). Flutter or fibrillation was produced with regularity in either the right or the left atrium.

FIG. 3.—(a) E.C.G. in normal solution; (b) after changing to $\frac{1}{2}$ K solution; (c) one minute after stimulating in presence of acetylcholine 6×10^{-4} g. per ml.; (d) four minutes later; (e) 20 minutes later; (f) 35 minutes later; (g) 45 minutes later; (h) after removing acetylcholine.

Stimulus Frequency

The effect of stimulus frequency on the initiation of atrial fibrillation was carefully examined. The results are summarized in Fig. 4. Acetylcholine was added in a concentration of 3×10^{-4} g. per ml. in all trials, and atria were counted as fibrillating when the fibrillation persisted for three minutes after stimulation stopped. A low frequency was used first, and at the end of one minute's stimulation the stimulus was turned off for 10 seconds to see if an arrhythmia was persisting; if not, the frequency was increased and the stimulation continued. Fig. 4 shows that the commonest threshold frequency was between 500 and 600 a minute.

FIG. 4.—Effect of stimulus frequency on the initiation of fibrillation in isolated atria. Solution containing $\frac{1}{2}$ K, acetylcholine 3×10^{-4} g. per ml. On the abscissa is shown the rate of stimulation per minute. On the ordinate is the percentage of preparations in which fibrillation was produced. From 10 to 45 atria were used for each point.

Action of Atropine and Quinidine

Observations were made to test the effect of atropine and quinidine. By stimulation at 1,200 a minute in the presence of acetylcholine (3×10^{-4} g. per ml.) fibrillation was produced, and was observed for five minutes. It was then terminated by washing out the acetylcholine. Fifteen minutes later the fibrillation was induced again, and one minute after stimulation ceased atropine or quinidine was added to the bath. When atropine was added, fibrillation stopped within 30 seconds (see Fig. 5). When quinidine was added, fibrillation stopped after one to two minutes.

Discussion

The production of fibrillation in the isolated atria of the rabbit depends on three factors: the presence of a low concentration of potassium in the bath fluid, the presence of a high concentration of acetylcholine, and electrical stimulation at a high rate for a short period.

When the atria contract sodium enters the cells, and then, in order that they may become excitable once more, potassium leaves the cells. This potassium must then be replaced within the atrial cells by metabolic processes which occur in the pores of the cell membrane. If the external concentration of potassium is low the replacement of potassium within the cells becomes very difficult, and it is probably for this reason that the low potassium concentration favours fibrillation.

The presence of a high concentration of acetylcholine makes the cell membrane much more permeable to potassium (Harris and Hutter, 1956) and it greatly shortens the refractory period. Under normal conditions, when a contraction occurs there is a long interval (0.15 second) before excitability is restored and the fibres become re-excitable. In the presence of acetylcholine this interval is shortened, perhaps to 0.01 second (Hoffman and Suckling, 1953). If now stimulation is applied at a high rate (700 a minute) some of the fibres are probably unable to keep in phase, and some contract later than others. If these others have recovered their excitability very quickly (in the presence of acetylcholine) they may be stimulated by the ones contracting a little later. Thus fibrillation begins, and is perhaps a condition in which each fibre in contracting stimulates its neighbours. This process may go on indefinitely, until indeed the acetylcholine is removed and the time required for each fibre to recover excitability again becomes much longer.

The fibrillation process may, however, be related to a high net loss of potassium, for when the external potassium concentration is raised fibrillation is arrested (Burn, Gunning, and Walker, 1956).

Summary

Fibrillation can be produced in the isolated atria of the rabbit heart, using rabbits from 2–3 kg., by stimulation at frequencies from 500 to 800 a minute in the presence of acetylcholine (3 to 8×10^{-4} g. per ml.). The bath fluid should contain not more than 100 mg. of KCl per litre. The fibrillation continues after the

FIG. 5.—(c) E.C.G. in $\frac{1}{2}$ K solution after stimulation; (d) effect of adding acetylcholine 8×10^{-4} g. per ml.; (e) 30 seconds after stimulation stopped; (f) arrest of fibrillation by atropine (1×10^{-4} g. per ml.); (g) normal rhythm two minutes later.

stimulation stops. It can be arrested by removing acetylcholine from the bath or by adding atropine or quinidine.

POLIOMYELITIS ANTIBODY STUDIES IN A GROUP OF LONDON CHILDREN

BY

ANN M. PEACH, M.B., D.C.H.

Research Fellow in Paediatrics, St. George's Hospital,
London

AND

J. A. DUDGEON, M.C., M.D.

Department of Bacteriology, Medical School,
St. George's Hospital, London; now at the Virus Research
Unit, Glaxo Laboratories, Ltd., Greenford

In any virus disease in which subclinical infection takes place the distinction between those who have acquired natural immunity, and therefore have less pressing need for immunization, and those who are still susceptible is difficult. In this respect poliomyelitis stands in marked contrast to measles. It is known that recovery from paralytic poliomyelitis is followed by a prolonged state of immunity in that second attacks of paralysis are rarely encountered, but immunity also develops after non-paralytic and subclinical infection. It has now been clearly established that active immunity in all forms of poliomyelitis infection is closely associated with the presence of circulating antibody; moreover, the incidence of antibody in relation to different age groups has proved to be a reliable guide to the overall immune status of a population.

In the past, serological tests to determine this information were based almost exclusively on the incidence of type 2 antibody, as only one strain (Lansing, type 2 strain) could be handled with any convenience in the laboratory. Since the introduction of tissue-culture methods it is possible to examine sera for antibodies to all three types of poliomyelitis virus and thus gain an overall picture of the pattern of immunity, not only throughout the world but in different sections of a population. From the evidence so accumulated it is now apparent that the incidence of infection with each of the three types is much higher than would be assumed from the incidence of clinical disease, and varies greatly from one part of the world to another (Gear, 1955). For instance, 80% of children in Cairo have by the age of 3 years acquired antibodies to all three virus types. At the same time the evidence of clinical disease is low. In contrast, in an urban population in the United States the same figure of 80% is not reached until the 30–40 age group (Paul, 1955).

The present investigation was undertaken as a preliminary to the introduction of immunization with

poliomyelitis vaccine in the United Kingdom. The purpose of the study was first to determine the incidence of poliomyelitis antibodies (and therefore the inapparent infection rate amongst healthy children); and, secondly, to form some idea of the age at which natural infection begins to take place in such a group. A further purpose was to determine whether the complement-fixation test could be used as a screening test for evidence of past infection.

Materials and Methods

The Study Group.—Ninety children were included in the study during the period March–October, 1955. They were children who had been admitted to the Victoria Hospital for Children with minor medical or surgical complaints. There were approximately equal numbers in each yearly age group from 12 months to 10 years. In no case was there a history of contact with a known clinical case of poliomyelitis, nor of a febrile illness with signs of meningeal involvement. The majority of the children came from the Boroughs of Battersea, Chelsea, and Fulham and, except for three who had been abroad for a short time, had lived nowhere else. The socio-economic background of these children was assessed from the occupation of the father, the intelligence of the parents, and the care given to the child before admission, and was graded as poor, average, or good. The distribution of children from poor, average, and good homes was uniform throughout the age groups.

Sera.—A single specimen of blood was collected from each child. After separation from the clot, sera were divided into two parts; one part for neutralization tests was stored at -65° C., the other for complement-fixation tests at 4° C.

Virus Strains.—The following strains were used both for complement-fixation and for neutralization tests: Mahoney (type 1), MEF-1 (type 2), Saukett (type 3).

Complement-fixation Test.—In order to economize in material the "drop method" on "perspex" sheets was employed as described for use with poliomyelitis viruses by Svedmyr, Enders, and Holloway (1953) and by Le Bouvier (1953).

Antigens.—These were prepared from monkey-kidney tissue culture and HeLa-cell cultures inoculated with each virus type. The fluids were harvested when cellular degeneration was complete. In the early stages of this investigation complement-fixing antigens were heated to destroy infectivity, but when it became clear that heating resulted in a loss of specificity, subsequent tests were carried out with untreated antigens, special precautions being taken to avoid risk of infection to those carrying out the tests. After inactivation serial twofold dilutions of serum were made in Ca-Mg saline; 4 units of antigen and 2, $2\frac{1}{2}$, and 3 units of complement were used in each test. Fixation was allowed to proceed overnight in the refrigerator. The end-point was taken as the highest dilution of serum producing 50% fixation of antigen with $2\frac{1}{2}$ units of complement.

Neutralization Test.—Preliminary tests were made with the HeLa-cell tissue culture method described by Syverton, Scherer, and Elwood (1954), but, as the results in our hands were at times variable, it was decided to carry out all subsequent tests in monolayer cultures of monkey-kidney epithelium grown in synthetic medium 199 containing 2% horse serum (Youngner, 1954). Monkey-kidney culture tubes prepared seven to eight days previously were examined before use to ensure that sheets of monolayer cells were present. The growth medium was replaced by fresh synthetic medium 199 without horse serum.

Virus.—Types 1, 2, and 3 poliomyelitis viruses from monkey-kidney tissue cultures were diluted so as to contain 100 tissue-culture infective doses previously determined by titration.

Serum Dilutions.—After inactivation serial dilutions of serum were made in medium 199. Screening tests were carried out at $1/4$, $1/64$, and $1/256$; and final tests, if

permanent teeth; deciduous teeth do not present such a great difficulty, there being less trauma involved in the extractions. It is our belief that, unless there be special circumstances, deciduous teeth should be left to shed themselves in the normal manner.

Antibiotic Therapy.—As a result of the teeth being neglected, sepsis at the site of extraction was frequently present. To combat the additional risk of bleeding which might result from socket infection all the patients were given oral antibiotic therapy for five days, starting on the day of operation. Initially, parenteral penicillin was administered, but this resulted in troublesome haematoma at the site of intramuscular injection and was discontinued.

Anaesthesia.—In a small number of the earlier operations of the series anaesthesia was regional by inferior dental injections; the great majority of the operations were undertaken with local or infiltration anaesthesia, and this was eventually adopted as the method of choice. Regional anaesthesia by inferior dental injection carries the risk of haematoma in the neck and of permanent damage to the nerve by haemorrhage. Haemophiliacs not infrequently suffer peripheral nerve damage as a consequence of haemorrhage. Endotracheal intubation during general anaesthesia is potentially dangerous by virtue of the possible development of laryngeal haemorrhage or haematoma.

Acrylic Resin Protective Splint

For each patient a protective dental splint was prepared before the operation and inserted immediately after removal of the teeth. The splint was constructed in the following manner: an impression of the upper and lower teeth was taken with one of the alginate impression materials such as "zelex," and models from this were poured in stone-hard plaster. From the models the tooth or teeth to be extracted were removed and over this area a layer of dental wax was fitted. Another alginate impression was taken from the first model and a second model cast in stone. The models were then set up on an articulator with the aid of a wax bite. Upon the second model a layer of wax was placed, trimmed to the exact requirements of the splint, and then processed in clear acrylic resin.

The reason for the first layer of wax over the tooth socket was to allow sufficient space between the acrylic splint and the socket for insertion of black gutta-percha. From experience it was found that this gutta-percha was tolerated by the soft tissues in the region of the wound much better than the hard acrylic. At the same time there was a close seal. Fig. 1 illustrates a splint with the gutta-percha in position. When significant bleeding occurred there was no hesitation in removing the splint for reapplication of local haemostatic measures; the splint was then reinserted. Where insignificant bleeding occurred the splint was left in position for 10-14 days before removal; at the end of that time there was generally a healed socket when the splint was removed. In a few of the earlier operations, as indicated in Table I, no splint was used.

The purpose of the splint was to protect the soft friable clot in the socket from trauma by food or from disturbance

FIG. 1.—An acrylic resin dental splint with black gutta-percha inserted in the splint opposite the extraction site.

by the tongue; a less important role of the dental splint was to hold haemostatic dressings in position. The splint was not used for the purpose of exerting pressure on the socket. Such pressure may be dangerous in consequence of haemorrhage occurring into tissue; such a haematoma in the neck can be large enough to block the airway. Qvist, Endicott, and Mitchell (1942) report a case of fatal asphyxia following dental extraction in a haemophiliac where the obstruction to the airway was due to massive haemorrhagic infiltration of the floor of the mouth. Pressure on a socket also causes its enlargement and increases the area for potential haemorrhage. It is essential that the splint be made skilfully; a badly fitting splint is worse than no splint at all. The splint must fit accurately on the remaining teeth and remain firmly *in situ*; a loose splint causes disturbance of the poorly formed clot in the socket. It must not cause pressure on the gingival margin at any part, as such trauma will certainly result in an additional site for haemorrhage. The application of the black gutta-percha to the splint at the area of the wound was found to be of great value in preventing injury of the gum by the splint. The splint enables the patient to take a soft pulped diet and he can be ambulatory in the ward. The use of protective splints has also been favourably reported by White and Mallett (1949) and Matheson (1949).

Local Haemostatic Treatment

This consisted of an adsorbable dressing such as "calgitex" or gelatin sponge with bovine thrombin or Russell viper venom.

The application of local haemostatic agents to the tooth sockets was of very limited value. No surface application of haemostatic agents can be considered highly successful in haemophilic bleeding. To be of value a haemostatic requires to be carried to the site of bleeding by the patient's own circulation. Thrombin, for example, when applied to a socket will produce a surface layer of fibrin from the blood filling a socket, but this does not prevent bleeding occurring from the freely flowing vessels in the base of the wound.

Suturing of the gum is used in the control of haemorrhage following tooth extraction in normal persons. It is, however, contraindicated in haemophilia, as it provides an additional site for bleeding and may encourage haemorrhage into the adjacent tissue spaces rather than externally.

Replacement Therapy

Therapy with blood or blood products was used in an attempt to supply the coagulation components missing in these patients. In the earlier extractions of the series, bank blood was tried, but, later, fresh frozen plasma was used. Fresh frozen plasma was eventually adopted as the routine form of replacement therapy for deficiency of antihemophilic globulin. In one patient a large amount of the dried plasma fraction (Cohn I) containing antihemophilic globulin was given. In a few of the later extractions further plasma was administered 48 hours after the initial infusion, the third day being the time of highest incidence of haemorrhage.

In four patients the administration of plasma subsequent to the first occasion caused urticarial reactions. These were treated with a single dose of 100 mg. of oral cortisone and 50 mg. of promethazine hydrochloride. Any further administration of plasma was preceded by cortisone and promethazine hydrochloride one hour before giving the plasma. This appeared to prevent recurrence of the urticaria.

As already stated patients with haemophilia lack antihemophilic globulin and those with Christmas disease the Christmas factor. The only available therapeutic agents are contained in human plasma or derived therefrom by fractionation.

The life of antihemophilic globulin in blood stored at 4° C.—that is, in bank blood—is very short; after three to

four days only trace amounts are usually present. If plasma is collected fresh and immediately frozen to -20° C., at which temperature it is stored, there is very good preservation of the antihemophilic globulin. This fresh frozen plasma was used in many of the patients included in this investigation (Table I). Apart from the difficulties of preservation of the antihemophilic globulin there is the problem of the large amounts required in the management of the patients to maintain haemostatic levels over prolonged periods. The intravenous administration of 2 pints (1,140 ml.) of fresh plasma to a haemophiliac causes a rise in antihemophilic globulin content from nil to 5-10% of that present in normal plasma. More than half of this has disappeared by 12 hours and only trace amounts are present at 24 hours. The difficulties of the problem can readily be appreciated. Cohn's plasma fraction I, containing antihemophilic globulin, is available as a lyophil dried preparation in ampoules. In the transfusion services of this

region each ampoule is derived from 75 ml. of plasma. Even with full recovery of antihemophilic globulin in the ampoules, 10 or more would be needed to give the equivalent of 2 pints (1,140 ml.) of plasma.

In one patient the dried antihemophilic fraction from 15 pints (8.5 litres) of blood was given as a pre-operative measure, with satisfactory response. It is believed that at the present time the best available therapeutic agent is fresh frozen plasma and that this must be used in large quantities, such as 2 pints (1,140 ml.) at a time (A. S. Douglas, 1956, unpublished observations). Moss (1955) also reports on the value of fresh frozen plasma in the management of bleeding tooth sockets in haemophilia.

There should be no reliance on bank blood as a source of antihemophilic globulin unless it has been collected within a few hours of administration. The Christmas factor, on the other hand, is well preserved not only in fresh frozen plasma but also in bank blood.

FFP = Fresh frozen plasma
After = At times from first to eleventh day after extraction
AHG = Antihemophilic globulin fraction from 15 pints (8.5 litres) of blood

Time in days before bleeding ceased
No Bl. = No bleeding.

Haemorrhage

In Fig. 2 is shown the incidence of haemorrhage, subsequent to the 32 dental operations. Even when the bleeding was minimal in extent, possibly only the staining of saliva over a short period, haemorrhage was recorded as

FIG. 2—Histogram showing the incidence of haemorrhage during the days subsequent to the extraction. Abscissa—time in days after extraction of the teeth. Ordinate—number of dental operations.

having occurred on that particular day. Comparison with the fall in haemoglobin level as recorded in Table I will show that bleeding was often minimal in its extent. Bleeding was rare on the first day but very common on the third day—that is, 48 hours after extraction. There was some bleeding at this time in 23 out of the 32 operations. Haemorrhage was common up to the eighth day after extraction, but unusual after that time. In one patient bleeding stopped only at the seventeenth day. The relative immunity from haemorrhage during the first 36-48 hours following extraction may be explained by the replacement therapy given just before the operation or as a result of the thromboplastic activity of the damaged tissue at the extraction site.

Blood Loss.—In an attempt to estimate the blood loss, haemoglobin levels were assayed daily, and the lowest value recorded in the post-operative period was used as an approximate indication of the extent of the haemorrhage. The mean fall in haemoglobin over all the extractions was 7% per tooth removed. As would be expected, the loss of haemoglobin was proportional to the number of teeth removed at each operation (Table II). The numbers

TABLE II

Operation	Mean Fall of Haemoglobin per Operation
One tooth extracted	10%
Two teeth	13%
Three	25%
Four	37%

involved in each group are small, but the figures probably give some indication of the anticipated loss of blood from these extractions.

Blood Transfusion

Matched blood was held for each patient for a period of 10-14 days from the time of extraction. Haemophiliacs are often the recipients of multiple transfusions, and there is the danger of haemolytic transfusion reactions unless sensitive compatibility tests are employed. In case there should be a bleeding emergency, therefore, cross-matched blood was reserved for each patient. Two of the patients were

rhesus-negative and had anti-D antibodies in consequence of previous transfusion.

As haemophilic patients often require transfusion throughout their lives there is the consequent risk of development of immune antibodies. With the adoption of the measures described, transfusion after dental extraction was very rarely required. This benefits the patient in so far as the opportunity for development of immune antibodies is reduced.

Duration of In-patient Management

In-patient treatment varied from 9 to 23 days, with an average of 13 days per dental operation. It will be appreciated that where a complete clearance of teeth was required this involved a protracted stay in hospital. It was our policy to carry out a small number of operations, possibly two, on one hospital admission and discharge the patient for subsequent readmission. The morale of these patients is remarkably good, considering the life of chronic invalidism which they have to suffer. Nevertheless it is of benefit to them not to make their stay in hospital too protracted on any one admission.

Discussion

These experiences in dental extraction of haemophilic patients failed to provide a complete answer to the problems of management. We are satisfied, however, that the adoption of the measures described is successful in limiting haemorrhage. Such haemorrhage as occurs will not be severe enough to endanger life.

The first eight observations in the series may be regarded as pilot studies. As a consequence of these the measures finally adopted may be summarized as follows: (a) extraction of not more than two teeth at one time; (b) construction of an acrylic resin protective splint, with gutta-percha lining at the site of extraction; (c) administration of 2 pints (1,140 ml.) of fresh frozen plasma just before the extractions; and (d) oral antibiotic therapy.

During the eight pilot observations a total of 22 pints (12.5 litres) of blood was required for replacement of blood loss due to the extractions. In the subsequent 24 dental operations only 1 pint (570 ml.) of blood was used. It is tempting to assume that this striking difference was due to the measures adopted.

The observations in the last case form an interesting comparison. The first operation was performed without any of the above measures; in particular there was no splint and no previous administration of plasma. Bleeding continued for nine days and the haemoglobin fell by 24%. Two weeks later further extractions were done with the preparation of upper and lower jaw splints and the previous administration of plasma. The only bleeding consisted of some staining of saliva on the third day and there was no fall in the haemoglobin level.

The ideal answer to the problems of management of tooth extraction in these patients is the administration of adequate amounts of antihemophilic globulin or the Christmas factor over a sufficient period of time. The maintenance of haemostatic levels of these factors over the period of 10-14 days required for the complete healing of the socket is not a practical possibility at the present time.

Summary

The results of 32 dental operations for tooth extraction in patients with haemophilia or Christmas disease are reported. The commonest time for haemorrhage was the third day after extraction, but in one case this was still occurring as late as 17 days after the extractions. It was inadvisable to extract more than two teeth at a time; where possible, two adjacent teeth were removed. An acrylic resin protective dental splint was used to protect the operation site subsequent to extraction. Black gutta-percha was inserted in the splint opposite the extraction site. Replacement therapy consisted of 2 pints

(1,140 ml.) of fresh frozen plasma immediately before extraction and on the occurrence of bleeding, provided this was severe enough. Oral antibiotic therapy was used for five days from the time of extraction.

We thank Professor L. J. Davis and Professor J. Aitchison for advice and interest in this work. We acknowledge also the helpful co-operation of Dr. J. Wallace, director of the Glasgow and West of Scotland Blood Transfusion Service, and Dr. D. Ellis, of the Edinburgh and South-east Scotland Blood Transfusion Service. The work in the University Department of Medicine, Royal Infirmary, Glasgow, was in part financed by grants from the Advisory Committee on Medical Research for Scotland and from the Medical Research Council.

CHRISTMAS DISEASE IN A WOMAN

BY

R. M. HARDISTY, M.D., M.R.C.P.

Senior Lecturer in Clinical Pathology, Welsh National School of Medicine, Cardiff
Formerly of the Louis Jenner Laboratory, St. Thomas's Hospital and Medical School, London

In the majority of affected families the inheritance of Christmas disease is of the same sex-linked recessive pattern as true haemophilia, resulting in the transmission of the disease to males by apparently healthy females. In a small number of instances, however, heterozygous females have been found to be mildly affected, suggesting that the Christmas disease gene may be less completely recessive than that responsible for haemophilia. The case is presented here of a young woman with Christmas disease of the same order of severity as her affected male relatives.

Case History

A single woman aged 22 was investigated because of a history of prolonged bleeding following tooth extractions. She had had teeth extracted on several occasions since the age of 6, and each time had bled from the tooth socket intermittently for 7 to 14 days. It had always proved possible to control the bleeding eventually by plugging, and she had never had a blood transfusion. No abnormal bleeding occurred at the spontaneous shedding of the primary dentitions. Two teeth have been extracted since the diagnosis of Christmas disease was made, and on this occasion bleeding was successfully controlled by packing the tooth sockets with an absorbable dressing soaked in thrombin. With this treatment bleeding stopped within 24 hours, but started again three days after the extraction, necessitating repacking, which resulted in permanent haemostasis.

The patient has had no other haemorrhagic symptoms. She has never had any other operations or serious injuries, and does not bruise excessively from minor traumata. Superficial cuts soon stop bleeding, and menstruation is normal. She has never had haemarthroses, epistaxes, purpura, or haematuria. At the age of 17 she swallowed a small open safety-pin without ill-effect.

Family History.—The patient's family tree is shown in the diagram. Her paternal great-grandparents, I 1 and I 2, are said to have been first cousins. Her father, III 3, suffered from prolonged and excessive bleeding after tooth extraction

on several occasions, but had no other haemorrhagic symptoms. He had never had any other operations or serious injuries. He was accepted for military service and was killed at Anzio in 1944. One of his mother's five brothers (II 10), now deceased, is known to have bled excessively after tooth extraction, but another (II 11) has never had any haemorrhagic symptoms. It has unfortunately proved impossible to trace the remaining members of the patient's paternal grandmother's family. There is no history of abnormal bleeding in any other known relatives of either sex on the patient's father's side, nor in any member of her mother's family.

Laboratory Investigations.—The results of tests of the patient's haemostatic mechanism are shown in Table I. It will be seen that these were all within normal limits.

A thromboplastin generation test was performed by the method of Biggs and Douglas (1953), using a suspension of normal platelets with various combinations of serum and Al(OH)₃-adsorbed plasma. All sera were obtained from blood shaken with glass beads until coagulation occurred, and then incubated at 37° C. for two hours. The sera were

TABLE I.—Results of Routine Laboratory Tests on Patient's Blood

Test	Patient	Normal Control Range
Whole-blood clotting-time (Lee and White) (minutes)	7½-10	5-10
One-stage prothrombin time (Quick) (seconds)	17.3	17.2-18.6
Proconvertin (Owren) (%)	80	70-120
Prothrombin consumption index (Merskey) (%)	18	Less than 40
Bleeding-time (Ivy) (minutes)	3	3-7
Platelet count (per c.mm.)	353,000	200,000-500,000

Normal	10% Patient	21	24
Normal	90% Christmas disease		

diluted 1 in 10 (vol./vol.) in 0.85% saline, and stored at -20°C . until required. The results in Table II show that the patient has a serum deficiency, and that her serum is incapable of correcting that of a patient with Christmas disease. Her $\text{Al}(\text{OH})_3$ -adsorbed plasma corrected that of a haemophilic subject better than did that of the normal control, and her own serum was corrected by an equal volume of normal serum, showing that the defect was not due to the presence of an inhibitor of thromboplastin generation. It was concluded that she had a true deficiency of Christmas factor. No PTA-deficient blood (Rosenthal *et al.*, 1953) was available for matching experiments, but the failure of mutual correction of Christmas disease and patient's serum is taken to exclude the diagnosis of PTA deficiency in this case.

On another occasion the Christmas factor content of the patient's serum was determined by measuring its ability to correct the defect of Christmas disease serum in the thromboplastin generation test. Serial dilutions of normal serum in Christmas disease serum were tested, all the other reagents being kept constant, and the concentrations of normal serum were plotted against the corresponding shortest second-stage clotting-times, to obtain a Christmas factor dilution curve. A 10% dilution of the patient's serum in Christmas disease serum was then tested in the same way. By interpolation on the dilution curve, it was found that the patient's serum contained approximately 8% of Christmas factor relative to the control. This method of assay has given results between 0 and 20% of normal in males with Christmas disease investigated in this laboratory. Serum from the most severely affected of these was used as the diluent in the present case.

Christmas factor and proconvertin (factor VII) assays have also been carried out on the serum of the patient's mother, sister, and two first cousins. None of these have any haemorrhagic tendency, and all have had teeth extracted without excessive bleeding. It was found that none had significant deficiency of either factor (Table III), though the amount of each factor in the sister's blood was slightly less than in the other members of the family.

TABLE III.—Christmas Factor and Proconvertin (Factor VII) in the Patient's Relatives

Relationship to Patient	Christmas Factor (%)	Proconvertin (%)
Mother (III 4)	80	100
Sister (IV 4)	65	70
Cousin (IV 1)	90	96
" (IV 2)	90	96

Discussion

The laboratory investigations show that the patient suffers from a Christmas factor deficiency, and her history suggests that it is a congenital one. It is unfortunate that no affected relatives were available for testing, but the family history strongly suggests that her father and great-uncle suffered from the same condition. A unifying though somewhat unusual feature was the limitation of symptoms in each affected member of the family to bleeding after tooth extraction. It may be that this merely indicates the occurrence of a mild degree of the disorder in three people who all escaped serious injury.

There are two genetically possible explanations for the occurrence of Christmas disease in the daughter of an affected male. Unless the patient is homozygous for the Christmas disease gene, it is necessary to postulate that the gene is not completely recessive.

There is no evidence in the present case for the first of these alternatives. Although the silent transmission of the gene to the patient's mother through several generations of carriers cannot be excluded with certainty, the fact that none of her eight known male relatives were affected makes such an explanation extremely unlikely. Still more so is the possibility that the patient has received a second Christmas disease gene as the result of a mutation occurring in the ovum which gave rise to her.

It is therefore reasonable to assume that the occurrence of Christmas disease in this patient represents the effect of an incompletely recessive gene. Some degree of expression of the Christmas disease gene in heterozygotes has already been reported by Biggs *et al.* (1952), Biggs and Macfarlane (1954), Brinkhous *et al.* (1954), Rosenthal and Sanders (1954), and Ramot *et al.* (1955). Graham *et al.* (1953) have observed a similar phenomenon in a large family with a mild form of haemophilia. In most of these cases the heterozygotes have been symptomless, the abnormality being detectable only by laboratory tests; in the remainder the heterozygous females appear to have had milder symptoms than their affected male relatives. The present case differs from these in that the patient's disability is apparently very similar in degree to that experienced by her father and great-uncle. While it must be admitted that such an assessment, based on second-hand evidence, is necessarily inexact, the observation that the patient's serum contains less than 10% of the normal amount of Christmas factor also suggests that the degree of deficiency is of the same order as in her male relatives, whose disability was slight.

It is of interest that the patient's sister, who must also be assumed to be a heterozygote but who has no history of abnormal bleeding, has a slightly reduced amount of Christmas factor in her serum. This finding is consistent with the view that the Christmas disease gene is incompletely recessive in this family; the difference in degree of the defect between the patient and her sister may be taken as evidence of the variable expressivity of the gene, the expression apparently being almost complete in the patient's case.

Summary

The case of a young woman with Christmas disease is reported, in which the presenting symptom was prolonged haemorrhage following tooth extraction.

Her serum was found to contain approximately 8% of the normal amount of Christmas factor.

The family history suggested that the patient's father and his uncle suffered from Christmas disease of a similar degree of severity.

The genetic implication of these observations is that the gene for Christmas disease may be intermediate rather than completely recessive.

I am indebted to the patient and her family for their co-operation, and to Dr. Rosemary Biggs and Dr. C. O. Carter for helpful discussion.

ADDENDUM.—Since this paper was written, the patient has undergone bilateral intranasal anastomies with diathermy to the inferior turbinates. Following this operation, she bled intermittently from the nose for a fortnight. At the end of this time, when her haemoglobin had fallen to 7.7 g. per 100 ml., she was transfused with three pints (1.7 l.) of fresh blood, which successfully controlled the bleeding. This is of some interest as the only recorded instance of bleeding in this family other than after tooth extraction, and supports the view that the patient's disability is comparable in degree with that of her affected male relatives.

IMPROVED L.E. CELL TEST USING FINGER-PRICK BLOOD

BY

H. LEMPert, M.D., M.Sc., A.R.I.C.

Assistant Director

AND

G. M. BERLYNE, M.B., M.R.C.P.

Resident Clinical Pathologist

Department of Clinical Pathology, Manchester Royal Infirmary

The L.E. cell is recognized as a neutrophil polymorphonuclear leucocyte whose nuclear lobes are compressed to the periphery of the cell by the inclusion of homogeneous material which stains a reddish purple with the usual blood stains. There is much evidence in favour of the inclusion material being nuclear in origin. Occasionally cells are found in which an ingested cell can still be recognized; these cells are "tart" cells and must not be confused with L.E. cells, in which the ingested material has lost all its nuclear structure.

The production of L.E. cells from bone marrow or blood of patients suffering from systemic lupus erythematosus (S.L.E.) would appear to be essential for a complete diagnosis. Many methods have been devised for producing L.E. cells from venous blood, amongst which the one devised by Marten and Blackburn (1953) and used by us for some time has been found reliable. It often happens that L.E. cells are detected only after several specimens of blood have been examined, and these repeated venepunctures become very tiresome for patient and physician. The processing of venous blood specimens and the microscopical examination of the final blood smears are also time-consuming.

A method in which capillary blood could be used would solve some of these problems, and in fact L.E. cells have been found in finger-prick blood preparations by several workers (Eppes and Ludovic, 1951; Rohn and Bond, 1952; Chomet *et al.*, 1953; Rosenfeld *et al.*, 1954; Sickley *et al.*, 1955); but these have been chance findings or have involved techniques which could not be adapted for routine use.

Snapper and Nathan (1955a, 1955b) have devised a more practical method which requires only one drop of blood from an S.L.E. patient, and it is based on the recognition that three essential factors are involved in L.E. cell formation: (1) plasma or serum from an S.L.E. patient; (2) nucleoprotein from nuclei of damaged cells, which form the "substrate"; and (3) active phagocytic polymorphonuclears. They recommend that the substrate be prepared from a drop of normal blood incubated for an hour in a moist-chamber at 37°C . The blood clot which forms is removed, and it is then found that large numbers of leucocytes, particularly polymorphonuclears, are left on the air-dried slide. The test proper is then carried out by making a hanging-drop preparation of the patient's blood so that the drop of blood just touches the substrate on the slide. This hanging-drop preparation is then incubated in a moist-chamber at 37°C . for one hour. During this period the L.E. factor in the patient's serum acts on the nucleoprotein of the dead leucocytes in the substrate to form an

intermediate product. The latter undergoes phagocytosis by the live polymorphonuclears migrating from the small drop of blood which clots. After incubation the clot is removed and the material on the slide stained with the usual blood stains. The small area on the slide is quickly identified and easily examined microscopically in a very short time.

In our hands the use of leucocytes from normal blood, which is strongly recommended by these workers, has not proved as reliable as a substrate which we describe below prepared from chronic lymphatic leukaemia blood. Details of this method are given and the results, with illustrations, discussed.

Methods

Preparation of Substrate Suspension.—Fifteen millilitres of venous blood from a chronic lymphatic leukaemia patient (white-cell count over 75,000 per c.mm.) is placed in a sterile 1-oz. (28-ml.) screw-capped bottle containing two partially opened steel-wire paper-clips. The bottle is slowly inverted intermittently until the formation of fibrin occurs, and then shaken rapidly for another five minutes. Complete defibrination occurs within 15 minutes of taking the blood, the fibrin becoming attached to the paper-clips. The blood is decanted into a sterile 6 by $\frac{1}{2}$ in. (15 by 1.3 cm.) test-tube, plugged or covered and then inclined at an angle of 60° degrees in a 37°C . water-bath until the red blood cells have sedimented about one-third of the way down. This usually takes one hour, but may take up to three hours. The opalescent supernatant and a buffy layer containing the bulk of the lymphocytes and a small proportion of red blood cells (about 5%) are pipetted off into a 3 by $\frac{1}{2}$ in. (7.5 by 1.3 cm.) test-tube. The cell suspension is mixed gently and a white-cell count carried out. If the white-cell count is below 200,000 per c.mm. the suspension is centrifuged for five minutes at 2,500 r.p.m. and then some of the supernatant removed to give the correct cell count of 200,000 per c.mm. If the count is much above 200,000 per c.mm. dilution can be made with the patient's serum, obtained by centrifuging the blood remaining in the 6 by $\frac{1}{2}$ in. (15 by 1.3 cm.) test-tube.

Preparation of Substrate Slide.—New 3 by 1 in. (7.5 by 2.5 cm.) microscope slides are used, rinsed in hot water and wiped dry. A small drop of the substrate suspension, about 1 to 2 mm. in diameter, is placed at the centre of the slide. With a narrow smooth-ended glass rod the drop is spread out to cover a circular area 12 to 15 mm. in diameter, which takes only a short time to dry at room temperature.

Storage of Substrate Slides.—A large stock of many hundreds of dried substrate slides prepared in the above manner are stored in closely packed cardboard boxes in a laboratory bench drawer at room temperature. The temperature varies between 17° and 20°C . Storage in the refrigerator or at temperatures much above the usual room temperatures causes deterioration.

Finger-prick Blood Technique.—A $\frac{1}{4}$ in. (2.2 cm.) square cover-glass (No. 2 thickness) is divided in half. The two pieces are positioned on opposite sides of the dried substrate area of a substrate slide placed in a Petri dish, the bottom of which contains a well-moistened perfectly flat filter-paper. A drop of blood from a finger-prick is allowed to touch the centre of a $\frac{1}{4}$ by $\frac{1}{4}$ in. (3.2 by 2.2 cm.) cover-glass (No. 1 thickness) so that a drop of blood 4 mm. in diameter is obtained. This cover-glass is now lowered on to the slide and the drop of blood positioned on the periphery of the substrate area. The drop of blood on the No. 1 cover-glass just touches the substrate because of the pieces of No. 2 cover-glass, which are thick enough to prevent obliteration of the drop by capillary action. The Petri dish is now covered with its lid and transferred to a 37°C . incubator for one hour only. The slide with its cover-glass preparation is then gently removed from the Petri dish and any moisture on the under side of the slide wiped off. The large cover-

glass is now slid off. If the clot sticks to the slide it can easily be released with the corner of the cover-glass and then slid to the edge of the slide and removed. The slide is rapidly dried by waving it in the air. Our preparations are stained as for blood with Jenner-Giemsa stains.

Test for L.E. Factor in Serum.—A drop of the serum is placed in a small watch-glass. Two drops of blood from a healthy group O subject are added and quickly mixed. A

FIG. 1.—Low-power appearance of a positive stained preparation. ($\times 300$.)

FIG. 2.—High-power appearance. ($\times 500$.)

FIG. 3.—Appearance with oil-immersion objective. ($\times 950$.)

The substrates were tested with finger-prick blood from patients who were suffering from S.L.E. and who showed L.E. cells in venous blood preparations made by the Marten and Blackburn (1953) method, henceforth referred to as the venous blood method. The results were as follows:

Normal Blood Leucocytes Substrate.—Variable results were obtained even with substrate preparations less than 10 days old. In several cases no L.E. cells could be found with the finger-prick blood method although moderate numbers were being found by the venous blood method.

Chronic Myeloid and Acute Leukaemia Substrate.—False-negative results were obtained as with normal blood leuco-

cytes substrate. There was also difficulty in assessing which was the reaction area and which the substrate area.

Chronic Lymphatic Leukaemia Substrate.—L.E. cells were found with the finger-prick blood method in every case where they had been found by the venous blood method. In some cases a more conclusive picture was obtained with this substrate and finger-prick blood than by the venous blood method. Substrates up to three months old still gave reliable results.

Results of the Finger-prick L.E. Test

Normal Subjects.—Of 50 normal subjects, 75% showed an occasional "tart" cell. In two normal subjects an occasional cell morphologically indistinguishable from the L.E. cell was found. The cells were not always found on repeating the tests with a substrate slide made either from the same or from different lymphatic leukaemia blood. This was quite different from the cases of S.L.E., where L.E. cells in moderate or large numbers were consistently found on repeated examinations. In the Table we have denoted this as "positive."

Results of L.E. Cell Tests in 10 Patients who were Clinically Cases of Systemic Lupus Erythematosus

Patient	Age	Sex	L.E. Cell Test	
			Venous Blood	Finger-prick Blood
1	51	M	Positive	Positive
2	64	M	Negative*	"
3	46	M	Positive	"
4	42	F	Positive	"
5	30	F	Not done†	"
6	41	F	Positive	"
7	11	M	"	"
8	21	M	"	"
9	24	F	"	"
10	41	F	"	"

* Only tart cells found. † Patient refused venepuncture.

Systemic Lupus Erythematosus.—A total of 10 "positive" cases have been seen in the past year. Eight of these showed numerous L.E. cells by the finger-prick and venous blood methods. The other two showed moderate numbers of L.E. cells only by the finger-prick method (see Table). One of these latter patients had refused a venepuncture. Following treatment with cortisone the patients have all improved clinically and the number of L.E. cells in finger-prick and venous blood preparations has diminished.

Patients Suffering from Other Diseases.—Scanty L.E. cells have been found in only one or two cases of rheumatoid arthritis, but were not found consistently on repeat examinations.

Discussion

Harvey *et al.* (1954) have noted that in systemic lupus erythematosus L.E. cells are not found constantly, and repeated testing is necessary. L.E. cells were originally found in bone-marrow preparations (Hargraves *et al.*, 1948), but venous blood preparations were later shown to give reliable results (Hargraves, 1949; Sundberg and Lick, 1949).

Eppes and Ludovic (1951) found only one L.E. cell in peripheral blood smears taken from numerous patients, and Chomet *et al.* (1953) found L.E. cells in the peripheral blood smears of a patient three days before death. They put forward the theory that the L.E. factor was then at its peak concentration, but were uncertain that the L.E. cell was an *in vivo* phenomenon, since a peripheral blood smear could be regarded as a post-vital artefact. Rohn and Bond (1952) actually observed L.E. cell formation in a cover-glass preparation of a drop of blood stained with supravital stains. This method, while of great interest from the point of view of L.E. cell formation, would appear to be unsuitable for routine use. From their observations they concluded that the polymorphonuclears and not lymphocytes underwent autolysis, and the product was then ingested by active polymorphonuclears to produce L.E. cells. This is an opposite

view to the one put forward by Moyer and Fisher (1950), who gave experimental evidence that the lymphocyte was the autolysed cell involved and that the best results were obtained with lymphocytes whose cell walls were first damaged. Moyer and Fisher concluded that three factors were necessary for L.E. cell formation: (1) L.E. plasma or serum factor; (2) nucleoprotein from damaged lymphocytes (substrate); and (3) active neutrophils.

Zimmer and Hargraves (1952) compared various methods for producing L.E. cells and decided that methods in which clotted blood was used gave the best results. The method of Marten and Blackburn (1953) is such a method; we have used it for the past two years and found it satisfactory.

Thus it became feasible that the peripheral or finger-prick clotted-blood methods might be developed if factors 2 and 3 previously mentioned could be obtained in an adequate concentration. Snapper and Nathan (1955a, 1955b) have devised an ingenious method for doing this. The nucleoprotein factor, or substrate, is obtained by incubating a drop of blood for an hour at 37° C. in a moist-chamber. An outpouring of neutrophils occurs, and these cells remain on the slide after the blood clot is removed. The air-dried neutrophils act as substrate. A drop of the patient's blood is now incubated in the same area as the substrate. If the patient is suffering from S.L.E., then the L.E. factor in the serum causes an autolysis of the dead neutrophils and the product is phagocytosed by the fresh neutrophils which migrate from the patient's blood clot. Snapper and Nathan mention that cells other than neutrophils can be used as substrate—for example, leukaemic blood cells or tissue cells from Hodgkin's disease or carcinoma.

We have confirmed these authors' observations but find their method for producing substrate slides rather difficult. The preparations were stable for only 10 days, and we have not been able to find L.E. cells by their method when undoubtedly positive results were found by the venous blood method. However, with the use of lymphocytes from chronic lymphatic leukaemia, which are regularly available in a large teaching hospital, much more reliable substrate slides, which were stable for several months, were obtained. The results compared well with the venous blood method. The fact that lymphocytes give such good results would seem to confirm the conclusions of Moyer and Fisher (1950) concerning the mechanism of L.E. cell formation.

The high proportion of false-negative results obtained when leucocytes from normal blood are used as substrate may be due to the small proportion of lymphocytes that are to be found in the substrate area. Polymorphonuclears will always be found there, and one is not certain whether they were derived from the patient's drop of blood. When lymphocytes from blood of patients with chronic lymphatic leukaemia are used as substrate there is little doubt about the source of the polymorphonuclears seen. There appears to be an optimum concentration of lymphocytes required for the test, and to achieve this we recommend placing the patient's drop of blood on to the periphery of the lymphocyte substrate area. The test should always be done in duplicate or triplicate.

Substrates prepared from the buffy coats of normal blood and leukaemias other than chronic lymphatic leukaemia have often given poor results. Kurnick *et al.* (1953) have discussed the probability of an L.E. cell phenomenon inhibitor, and it is possible we are dealing with such an inhibitor when failures occur. It is worth noting that the polymorphonuclear is the cell which can produce this inhibition.

Recently a method has been reported for producing L.E. cells from finger blood in which the digit is first constricted for 20 minutes and tight enough to produce cyanosis (Sickley *et al.*, 1955). This procedure appeared to be rather upsetting to the patient and not reliable, as a high proportion of false negatives were obtained by these workers. Since in S.L.E. Raynaud's phenomenon can occur, the procedure might lead to gangrene.

Fifteen millilitres of blood from one patient with chronic lymphatic leukaemia provides many hundreds of substrate slides, which can be stored for future use by a group of hospitals. The slides are stable at room temperature for three months and in some cases even six months after preparation. It is possible that the temperature of storage is a deciding factor on the stability, and this is being investigated further. With a reliable and stable substrate slide the L.E. cell test is now very simple to perform, and the finger-prick method should soon find its place in many laboratories.

In 10 S.L.E. patients tested repeatedly by us, moderate numbers or numerous L.E. cells were always found by the finger-prick blood method, using various substrates from lymphatic leukaemia blood. This occurred prior to and during treatment. Following the initiation of treatment with cortisone, symptoms were soon relieved, but in most cases a much longer time elapsed before the L.E. cells in the test diminished.

The finding of an occasional cell resembling the L.E. cell in some normal subjects and in few cases of rheumatoid arthritis requires explanation. Fortunately the finding differs from that in S.L.E., where L.E. cells are found in large numbers by the finger-prick blood method. The dried lymphatic leukaemia serum which remains on the lymphocytes of the substrate may have L.E.-cell-forming properties in minimal amount. Another hypothesis is that minimal amounts of L.E. cell factor are occasionally found in human plasma.

Summary

A method for producing L.E. cells from finger-prick blood is described in which the substrate recommended is obtained from lymphocytes of cases of chronic lymphatic leukaemia.

The method compares favourably with a reliable venous blood method, and has the added advantage of simplicity and ease of microscopical examination.

The substrate slides prepared from lymphocytes appear to be stable for at least three months.

In patients suffering from systemic lupus erythematosus numerous L.E. cells are found consistently by the finger-prick method prior to and during treatment.

In some normal subjects, and in a few cases of rheumatoid arthritis, an occasional cell resembling the L.E. cell may be found, but the finding is not consistent.

We wish to thank the patients who willingly donated blood both for substrate preparation and the tests; the physicians of the Manchester Royal Infirmary for their co-operation; Dr. J. F. Wilkinson and Dr. M. C. G. Israels, of the department of haematology, for their advice; Miss Margaret Kenwright, of the department of clinical pathology, for technical assistance; and Mr. Brian Figg, of the department of obstetrics and gynaecology, who took the microphotographs.

Clinical Pathologist

ROSEMARY C. POPE, B.Sc.
Bacteriologist

AND

K. SIMPSON, M.D., M.R.C.P.
Senior Paediatric Registrar
United Bristol Hospitals

Recent work has shown that most of the staphylococci isolated from the lesions of impetigo contagiosa are of a type uncommon in other situations, and are defined by their susceptibility to the typing phage 71 (Spittlehouse, 1955; Parker *et al.*, 1955; Barrow, 1955).

In this paper we describe a small epidemic of pemphigus neonatorum caused by staphylococci of the same phage-pattern. The outbreak took place during the course of a general investigation of staphylococcal cross-infection in the nursery wards of a maternity hospital. During the outbreak, and for four months before it, cultures for staphylococci were made from all cases of neonatal skin sepsis and from various other sources described below. As a result it was possible to trace the staphylococcus subsequently responsible for the pemphigus from its introduction by a nasal carrier and during its dissemination in the hospital.

All the staphylococci referred to in this paper were coagulase-positive.

Bacteriological Methods.—Swabs were moistened with saline before use. Settle-plates were exposed for two hours. Cultures from blankets and garments were made by the sweep-plate technique (Williams, quoted by Blowers and Wallace, 1955). Coagulase-positive staphylococci were isolated and investigated as described elsewhere (Alder *et al.*, 1955), except that the phages 71 and 80 were added to the set of typing phages (Williams and Rippon, 1952), making 21 in all.

General Investigation of Staphylococcal Cross-infection

There was one nursery on each of the three floors of the hospital, that on the first floor being occupied by premature infants. The investigation was carried out on the second and third floors, which on the average contained 25 and 18 cots respectively.

The study began on September 18, 1955—that is, 18 weeks before the first case of pemphigus. This study is still being carried on, but only the results obtained in the period up to February 3, 1956, are given in detail, because the outbreak came to an end then. During the 20 weeks, 385 babies were accommodated in the two nurseries. The noses of 227 of the babies were swabbed repeatedly until they yielded *Staph. aureus*. By the fourth day 67.1% were positive. Swabs taken from normal skin on the back of the neck, the umbilical region, and the groin often yielded *Staph. aureus*; 75% of those from the umbilical region were positive on the second day of life.

Nasal and hand swabs were taken once a week from the nurses on day duty in the nurseries, except for those who happened to be off duty at the time of swabbing. Also,

staphylococci isolated from the noses and hands of nurses before joining the hospital were kindly sent to us from the Department of Preventive Medicine, University of Bristol. Nasal swabs were taken from 85 mothers on admission to the hospital. Two settle-plates were exposed three times a week in each nursery. From November 15 cultures were taken from the babies' garments and bedclothes. The practice of the hospital was to send all articles to the laundry as soon as they were used. Babies' garments and bedclothes from both floors were washed together (the woollens at a lower temperature than the non-woollen goods), but were kept separate from other laundry. Cultures were made from 144 cot blankets, 62 woollen vests and jackets, and several cotton articles. All of these had been freshly laundered except for a few of the blankets. Many of the woollens yielded heavy growths of bacteria, which often included staphylococci. The non-woollen articles, which had been more strongly heated, yielded very scanty growths and no staphylococci.

From all these sources 874 coagulase-positive staphylococci were isolated, 551 of them being penicillin-resistant. In addition, 13 pustular lesions of babies' skins and 17 cases of neonatal conjunctivitis yielded coagulase-positive staphylococci. The staphylococcal cross-infection on the two floors was about equal in amount, as judged by bacteriological and clinical observations. The clinical infections were mild, and were very few in comparison with the numbers of staphylococci which were isolated. Except for the cases of pemphigus described below, they consisted entirely of conjunctivitis and of skin pustules, which were usually small and trivial.

We hope to report in a later paper our observations on the staphylococcal cross-infection as a whole.

Cases of Pemphigus

There were nine cases, none of which was seriously affected (Table I). The first was a baby on floor 3 who developed the disease on January 23, 1956. There were

* See text for possible explanation of failure to isolate *Staph. aureus* type 71 from these cases.

seven more cases on floor 3, and one on floor 2. The latter (Case 6) had been delivered by caesarean section in the operating theatre on floor 3, and his first garments had been provided by the nursery on that floor.

Swabs from the bullae of seven of the cases were cultured, and all gave profuse growths of *Staph. aureus*. Four of them, including the first two cases, yielded penicillin-resistant staphylococci lysed by phage 71 but by no other dilute phage. They were lysed by other group II phages at 1,000 × R.T.D., and thus were the same as the "normal 71" strains of Parker *et al.* (1955). From three others, type 71 staphylococci were not isolated. These negative results may have been due to failure to examine the cultures thoroughly enough. By mistake, the plates were discarded after one colony from each plate had been picked for typing. All three cultures from which we failed to isolate type 71 staphylococci were from already ruptured bullae near the umbilicus. Staphylococci of various phage patterns were

often present in large numbers on normal skin in this area, and cultures of ruptured bullae would no doubt often contain more than one strain.

Staphylococci of type 71 had not been identified previously in the hospital. However, a number of the cultures which had been isolated from various sources since late November, 1955, had not then been typed. Completion of this work revealed that one nurse, Nurse C, who joined the staff on November 30, 1955, was a persistent heavy nasal carrier of type 71 penicillin-resistant staphylococci, and that similar staphylococci had been isolated subsequently from a variety of sources, chiefly on floor 3 (Table II). All these strains

TABLE II.—Sources and Dates of Isolation of Penicillin-resistant *Staph. aureus*, Phage-type 71

Date	Floor	Site
30/11/55	3	Nurse C's nose

were resistant to penicillin but sensitive to streptomycin, chloramphenicol, and oxytetracycline. They inhibited the growth of corynebacteria (Parker *et al.*, 1955) and were egg-yolk negative (Gillespie and Alder, 1952).

Subsequent inquiry revealed that Nurse C had had impetigo three years previously. She had worked only in the nursery of floor 3 since her arrival, and had been in close contact with the first case. This baby had been separated from his mother for some days on account of her past history of tuberculosis, and Nurse C had been given special duties with him. Nurse C left the hospital, for personal reasons, on January 30, 1956, seven days after the outbreak of pemphigus began.

The steps taken to stop the outbreak consisted in isolation and barrier nursing of the cases and treating them with intramuscular streptomycin and local antiseptics, isolating the contacts, and autoclaving all garments and bedding of the cases and contacts and of their mothers. Most of the blankets and garments on floor 3 and many on floor 2 were thus sterilized. Admissions to floor 3 were stopped until all cases and contacts had been discharged. As an emergency measure, nose swabs were taken from all members of the nursing, domestic, physiotherapy, and resident medical staff, and from all mothers and babies in the hospital. Hand swabs were taken from some nurses, and umbilical swabs from some babies. Of the 165 swabs thus taken, 62 yielded *Staph. aureus*, but the epidemic strain was not isolated.

There were no more cases of pemphigus until March 15, 1956, when a baby on floor 3 developed a small bulla on the scalp which yielded a penicillin-sensitive type 71 staphylococcus. This may have been a variant of the epidemic strain. There have been no cases during the subsequent five months, but the epidemic strain has been isolated occasionally from other sources—a nurse's nose, a nurse's hand, a baby's nose, a baby's eye, a settle plate, and two blankets.

Since the beginning of April, all babies' garments and blankets have been disinfected by means of cetyl trimethylamine bromide ("cirrasol OD") (Blowers and Wallace, 1955).

Discussion

In several outbreaks of pemphigus neonatorum typing by sera or phages has shown the causative organisms to be particular epidemic strains of *Staph. aureus* (Elliott *et al.*, 1941; Hobbs, 1944; Allison and Hobbs, 1947; Williams *et al.*, 1947; Parker and Kennedy, 1949; Rowntree *et al.*, 1956). Our findings again illustrate the specific nature of the infection and show that it is sometimes caused by type 71 staphylococci, which in older people causes staphylococcal impetigo. The nurse who brought the organism into the hospital may have been carrying it in her nose since her own attack of impetigo three years before. A persistent nasal carrier may harbour the same strain for several years (Gould and McKillop, 1954).

The dissemination of the type 71 strain on floor 3, after Nurse C's arrival, illustrates the importance of nasal carriers in contributing staphylococci to the environment. Nevertheless, it is likely that the first case of pemphigus resulted from direct infection by Nurse C, possibly via her hands. The rapidity with which the subsequent cases followed showed that most of them were caused by cross-infection from the first case; the organisms were probably transferred by contact by members of the staff.

The transfer of organisms to floor 2, where they were found on a few occasions, may have taken place through the laundry. Case 6 may have been infected in this way.

Our experience before the outbreak of pemphigus illustrates the well-known fact that clinical staphylococcal infections are often few and mild even when there is a great deal of "bacteriological" cross-infection in a hospital (Rountree and Barbour, 1950; Barber *et al.*, 1953; Clarke *et al.*, 1954). But the introduction of more virulent strains, or the presence of patients with lowered resistance or with wounds which expose susceptible tissues, may at any time result in serious infections. Therefore it is important to reduce staphylococcal cross-infection so far as is possible, irrespective of its clinical results at any particular time.

When an outbreak of infection is caused by a particular epidemic strain, special precautions should be taken to limit its spread. Bedclothes should be disinfected after use if this is not already being done. The oiling of blankets, which merely suppresses dust, is not enough (Clarke *et al.*, 1954). A hand cream containing a disinfectant such as chlorhexidine ("hibitane") (Murray and Calman, 1955) may be used by nurses. Affected patients should if possible be isolated and nursed by a separate staff. Nasal carriers of the epidemic strain should be detected and treated if possible. We have recently had encouraging results in a preliminary trial of "graneodin" ointment in the treatment of nasal carriers. This ointment contains gramicidin and neomycin. Its application to the nostrils four times a day for a week or two has usually cured the carrier state. E. S. Duthie (personal communication) has also had encouraging results in a more extensive trial of this method. Rountree *et al.* (1956) have reported success in controlling neonatal staphylococcal infection by treating the noses of the staff with an ointment containing bacitracin and neomycin.

Summary

An outbreak of pemphigus neonatorum in a maternity hospital followed the introduction by a nasal carrier of *Staph. aureus* phage type 71.

For four months before the outbreak started an investigation of staphylococcal cross-infection had been conducted in the hospital, and this investigation was continued during the outbreak. It was therefore possible to detect the epidemic strain during the period which elapsed between its introduction into the hospital and the outbreak of pemphigus.

We thank the consultant clinical staff of the Bristol Maternity Hospital for permission to carry out this investigation, and the matron and nursing staff for their co-operation.

Medical Memoranda

Fatal Thrombocytopenic Purpura Due to Quinidine

Moodie (1950) reported the first case of thrombocytopenic purpura due to quinidine in this country and reviewed five others. Since then 22 further cases have been described, all of which recovered completely. We wish to report a fatal case.

CASE REPORT

A foundry manager aged 40 had no serious illnesses until the onset of angina pectoris in September, 1955. He was away from work for four weeks following myocardial infarction in April, 1956, and was admitted to hospital on July 17 with a fresh antero-septal infarct. He was treated with heparin for 24 hours after admission and phenindione ("dindevan") for six weeks, until September 1, when he left hospital. The prothrombin index was maintained around 40, without bleeding episodes or purpura.

On his fifth day in hospital he developed paroxysmal ventricular tachycardia, for which he was given procaine amide ("pronestyl"). Because of recurrent paroxysms a total of 68 g. of procaine amide was given over the next 20 days. His leucocyte count fell from 9,700 to 3,700 per c.mm., as frequently occurs with this drug, and later returned to the normal level. When the paroxysms started he was given a test dose of quinidine followed by 5 gr. (0.32 g.) six-hourly for six days, and 10 gr. (0.65 g.) six-hourly for 37 days until he left hospital.

He was sent home on a maintenance dose of quinidine, 5 gr. (0.32 g.) three times a day. After 16 days—when he had taken a total of 1,840 gr. (119 g.)—he noticed spots on his legs, and haematuria developed two days later. We saw him on the twentieth day, stopped the drug, and readmitted him to hospital (September 21). He then had severe purpura on the face and limbs, some spots on the trunk, and macroscopic haematuria. There were no retinal haemorrhages and the spleen was not palpable. The blood pressure was 130/80.

Blood examination showed: haemoglobin, 95% (14 g./100 ml.); W.B.C., 7,500 per c.mm., with a normal differential count; platelets 56,000 per c.mm.

At 3.20 a.m. the next day he woke with dysarthria and weakness of the right arm and the right side of the face. At 5 a.m. he lost consciousness, had a severe epistaxis at 6 a.m., and died one and a half hours later.

Necropsy.—Small submucous haemorrhages were found in many viscera and in the muscles and connective tissue throughout the body, and large haemorrhages occurred in both renal pelves and in the left cerebral hemisphere. The spleen was enlarged (370 g.) and very soft. There was severe coronary atheroma with old and recent myocardial

infarction. The bone marrow appeared normal on microscopy, and megakaryocytes were numerous, but details of their morphology could not be studied in the material available.

COMMENT

The subject of quinidine purpura has been reviewed by Bolton and Dameshek (1956).

Sex and Age.—Of the 29 recorded cases only 5, including this one, were in men. This is parallel with the incidence of idiopathic thrombocytopenic purpura, which is said to be "almost wholly confined to women when the first symptoms appear in adults" (Castle, 1955). There have been no reported cases of quinidine purpura in children; most patients have been over 55 years and a few were over 70 (Collins, 1950; Lipson, 1952; Aakesson, 1952). Since quinidine is more often employed in young patients it seems that elderly women are most liable to the hazard.

Sensitizing Dose.—Purpura may occur at any stage in quinidine therapy, and in this case it appeared after eight weeks' treatment and a total dosage of 1,840 gr. (119 g.). Some patients have become sensitive after only a few days and a total dose of less than 50 gr. (3.2 g.) (Larimer, 1949; Moodie, 1950). Others have taken several hundred grains over one or two months before developing purpura for the first time. Bigelow and Desforges (1952) had a patient who had taken quinidine daily for two years before purpura appeared. In patients who have previously had quinidine purpura a test dose of 3–6 gr. (0.2–0.4 g.) has rapidly produced severe thrombocytopenia in almost all recorded cases. One exception developed fever and a rash. A patient (Norcross, 1950) who had three purpuric episodes in seven years nearly died in coma with convulsions after 9 gr. (0.6 g.); and a later test dose of 3 mg. reduced the platelets to 33,500 per c.mm. Moodie (1950) describes an unsuccessful attempt at desensitization. It thus appears that quinidine is absolutely contraindicated in patients who have had quinidine purpura.

Pathogenesis.—Platelet antibodies, defective maturation of the megakaryocytes, and capillary damage have all been implicated in the production of quinidine purpura. The extreme thrombocytopenia occurring within a few hours of a test dose of quinidine (Nussbaum and Shulman, 1952; Larson, 1953) implies destruction or removal of circulating platelets, apart from any action on the bone marrow, the usual platelet life being two to seven days. As in purpura due to "sedormid" (Ackroyd, 1949), the patient probably forms antibodies to a drug-platelet complex. The serum of these patients agglutinates normal platelets in the presence of quinidine (Bigelow and Desforges, 1952), and agglutination is followed by lysis if complement is also present (Ackroyd, 1949; Bolton and Dameshek, 1956). In essential thrombocytopenia the marrow usually contains a normal proportion of megakaryocytes, though there may be a preponderance of abnormal or immature forms, of which the appearances suggest depressed platelet formation. This latter picture is described by Hirsch and Dameshek (1950) and Phelps (1951) in cases of quinidine purpura. Marrow obtained at necropsy in the present case contained a normal proportion of megakaryocytes, but their morphological details could not be discerned. Bleeding is not simply related to the severity of thrombocytopenia, and capillary dysfunction is equally important. Ackroyd (1949) demonstrated that in susceptible patients patch tests with sedormid produce local haemorrhage and capillary fragility without thrombocytopenia. However, a patch test with quinidine was negative in Larson's (1953) case, and Bolton and Dameshek (1956) were unable to detect capillary antibodies in their cases.

Prognosis.—In 28 published cases purpura subsided within a few days of stopping the quinidine, and the platelets were normal in one or two weeks. The platelets may continue to fall for two days (Phelps, 1951). The fatal outcome in this case cannot be attributed solely to his taking quinidine for four days after the appearance of petechiae, since many other patients did this without serious consequences. One

other fatal case of purpura was mentioned at a discussion on quinidine therapy (Gold, 1954), but details are not available. Although spontaneous recovery is the rule, it is by no means certain or predictable. In view of the action of cortisone and corticotrophin in suppressing antigen-antibody reactions, there are good grounds for the early use of these drugs in all cases of drug purpura.

CONCLUSIONS

A test dose of quinidine, however small, is contraindicated in patients who have had purpura due to quinidine. Drug purpura should be treated with cortisone or corticotrophin, since the condition is potentially fatal and antigen-antibody reactions appear to be involved.

We are grateful to Dr. R. L. Mackay for permission to report this case and to Dr. A. G. Marshall for the necropsy findings.

Rheumatoid Arthritis of the Larynx

A male clerk aged 61 had developed rheumatoid arthritis 30 years previously and had received various treatments during this period, leaving him with marked deformity of hands, wrists, and elbows, and rheumatoid nodules over the latter. For some years he had had a productive cough, and chest x-ray changes were known to be compatible with some bilateral basal bronchiectasis. For three months he had noticed increasing dyspnoea on exertion and huskiness of his voice; severe dyspnoea and wheezing had supervened for two days before I was asked to see him at his home as a case of "asthma." He had marked inspiratory and moderate expiratory stridor; laryngeal obstruction was diagnosed and he was admitted to hospital at once.

Laryngoscopy and bronchoscopy were performed under local analgesia by Mr. Mearns Milne. The vocal cords showed some whitish nodules on both vocal processes and a very narrow glottic aperture. The bronchial tree contained a large quantity of infected sputum but was otherwise normal. Tracheostomy was performed with great relief to the patient's condition. Biopsy of one of the vocal nodules showed a vascular fibrous core covered by somewhat hyperplastic squamous epithelium; no significant inflammatory reaction was present. Indirect laryngoscopy was later performed by Mr. Douglas Fairman, who reported that the vocal cords showed slight abduction on inspiration so as to produce a very small glottic chink, and they adducted on phonation. He confirmed the presence of nodules on the vocal processes of the arytenoids and the upper surface of the left vocal cord, and he suggested that the laryngeal condition was produced by an ankylosing arthritis of the crico-arytenoid joints.

The patient was thereafter treated by physiotherapy for his bronchial infection, together with catheter suction through his tracheostomy tube, which was later changed to a permanent type. Constant difficulty in expectoration persisted,

however, and four months after admission he developed an acute respiratory infection with extensive consolidation in both lower lobes. This failed to respond to treatment, including antibiotics, and he died.

Necropsy by Dr. R. J. Sandry confirmed the cause of death as bilateral basal bronchopneumonia; some bronchiectasis was present in both lower lobes, but no "rheumatoid" changes were found in the lungs. The laryngeal appearances previously seen were confirmed, and histological section showed, as suspected, changes in the crico-arytenoid joints characteristic of rheumatoid arthritis (see illustration).

COMMENT

This same condition seemed very probable in a patient who recently died at home, with no necropsy. When seen at the age of 83 she gave a 35-year history of rheumatoid arthritis, with which she was completely crippled. Some degree of laryngeal stridor and dyspnoea at rest had been

Longitudinal section of larynx (x4). V.C.=vocal cord. C.A.=crico-arytenoid joint showing villous synovial proliferation.

noted progressively for over three years, and her voice had become more husky and deep in tone, rather similar to that in myxoedema, of which in her case there was no evidence. Her general condition and neck posture made even indirect laryngoscopy impossible, so that the laryngeal diagnosis remained unproved.

While crico-arytenoid arthritis has been recorded by laryngologists (Ellis, 1951; de Vido and Ancetti, 1952) it is a rare and scarcely recognized condition in general medical practice. Hart and Mackenzie (1955) encountered laryngeal stridor requiring tracheostomy in a man with chronic rheumatoid arthritis. They considered that abductor palsy was the cause but could not account for this except possibly on a basis of previous deep x-ray therapy for thyrotoxicosis. Histologically they reported diffuse fibrosis in the region of the vocal cords, but did not specifically refer to the crico-arytenoid joints. It seems likely that, in their case also, arthritis of these joints was present as an explanation of the findings.

If laryngeal stridor occurs in a case of rheumatoid arthritis, it is suggested that the most likely cause is involvement of the crico-arytenoid joints by the disease process.

Reviews

CELL FUNCTION

New Pathways in Cellular Pathology. By Gordon Roy Cameron, M.B., D.Sc.(Melb.), F.R.C.P., F.R.S. (Pp. 90+ vii; illustrated. 16s.) London: Edward Arnold (Publishers) Ltd. 1956.

This slim volume of 88 pages and eight short chapters is an expansion into a monograph of two lectures given by the author, one in Leeds in 1954, the other in Dublin in the following year. The book serves as an excellent and remarkably stimulating introduction to the author's authoritative treatise on the pathology of the cell. He is the leader of a group of scientific optimists who found themselves "dissatisfied and often discouraged by the morphological outlook on cellular pathology" and "turned to recent biochemical and biophysical techniques" which they hoped "might illuminate" some of their difficulties. They have been "encouraged to go on with increasing hope." The following are some of the modern techniques they have used: (1) The study of cell respiration in organ and tissue homogenates and in organ slices; (2) differential centrifugation of the disrupted cell at speeds reaching several hundred thousand times gravity; (3) investigation of the enzymatic potencies of each cell constituent—for example, the mitochondria, in which more than 20 enzyme systems have already been identified; (4) electron photomicrography of excessively thin slices of cells at a magnification exceeding 90,000 diameters; (5) autoradiography.

These new techniques ruthlessly reduce conventional morphology to the molecular level and produce valid evidence about cell function. For example, each of the millions of leaf-like laminae which can be seen crossing the long axis of the suitably magnified mitochondria have the same size as a molecule of succinoxidase, an enzyme which occurs exclusively in these organelles.

The author warns us that the application of these new disciplines to pathology is fraught with disappointments "which will daunt the courage of the most intrepid voyager," but "it would be wrong to despair even though discovery often means one step forward and two steps backward." In spite of this he is able to describe with uncanny accuracy and precision the intracellular biochemical lesions which many injuries produce, to account for functional cellular failure, and to locate this at the cell membrane or in a particular cell organelle. The effect on cell function of poisons such as thioacetamide, carbon tetrachloride, fluoracetic acid, *o*-dinitroresol, *Clostridium welchii* toxin, and lewisite are pin-pointed at the molecular level, and infinitely more satisfying reasons than simple morphological change are adduced for the manifestation of copper deficiency in cattle, vitamin-B₁₂ deficiency, cloudy swelling, hydropic degeneration, fatty degeneration, calcification, and proteinuria.

Professor Cameron's book is a challenge to the complacent attitude of the conventional pathologist. He appeals for recruits to this new scientific discipline in these words: "My one purpose is to talk to you about the way we are working and thinking in the hope that you, too, may share the excitement of exploring new pathways in cellular pathology," and "if I can entice the reader to set his imagination to work in designing this new world, then I shall have succeeded in my task."

GEOFFREY HADFIELD.

BACTERIOLOGY AND IMMUNITY

An Outline of Bacteriology and Immunity. By Ronald Hare, M.D. (Pp. 418+ix; illustrated. 35s.) London, New York, Toronto: Longmans, Green and Co. 1956.

It is refreshing to find a textbook of bacteriology written on really original lines. Professor Hare has reduced the descriptive part of his book to a minimum—all the cocci and bacilli are herded together in only four chapters occupying 73 pages—in order to concentrate on the general aspects

of his subject. Six chapters are given to immunity, and they include fuller and clearer explanations of many phenomena than are to be found in most other books; there are numerous graphs of antibody responses and illustrations of various antigen-antibody reactions. Another favoured subject is what may be called hygiene, with a very full discussion of how micro-organisms are disseminated by cases or carriers, including original observations by the author. This section includes an exceptionally full list of animal sources of infection, and an interesting original compilation of data in graphic form showing variations in the duration of infectivity after attacks of six diseases. The usual chapters on morphology and cultivation treat viruses equally with bacteria in the text and much more generously in illustration. There are also chapters on bacterial metabolism, on disinfection (is it not rather sweeping to condemn alcohol as "too weak to be of practical value"?), and on chemotherapy. The nomenclature is ultra-modern, including the adoption of *Bordetella*; we are not told how to pronounce this name; nor in denying the entitlement of the organism of whooping-cough to be called *Haemophilus* is it mentioned that the medium best suited to its growth contains much more blood than any other in regular use. There are many very beautiful illustrations, and (as seems to happen even in the best books) a few unrecognizable ones, such as those on pages 317 and 347. The footnote references to important papers are a useful feature.

The book will be deservedly popular among students who are learning the subject as they need to know it for the intelligent practice of medicine. For those so fortunate as to do rather more bench work, or for anyone using it as a practical guide in diagnostic proceedings, the scanty references to technique and rather meagre descriptions of individual species may be a drawback. If the descriptive section were expanded and included some of the material from Chapter XI on methods of immunization, it could also give a clearer picture of the kinds of disease for which each organism is responsible, and reflect a little of the drama of early work on such subjects as anthrax, rabies, and plague.

L. P. GARROD.

CEREBRAL ORGANIZATION

The Organization of the Cerebral Cortex. By D. A. Sholl. (Pp. 125+xvi; illustrated. 18s.) London: Methuen and Co. Ltd. 1956.

All whose studies are concerned with the organization of the cerebral cortex should make a point of reading this book, for it contains compelling evidence that they should think in terms of a model based on the concept of probability and discuss their observations in statistical terms. Readers not conversant with the technical language of neurology, or those without any scientific training, may find the early chapters a little heavy going, but they should not allow this to deter them from finishing the book, for the meaning is never obscured by the technical terms employed. The use of such terms in a book of this scope and length is necessary if only to persuade specialists that they cannot afford to ignore its message.

The author has attempted to present a unified view of some of the recent work on the organization of the cerebral cortex which has been carried out by anatomists, clinicians, physiologists, and psychologists in order to correlate the results of these various disciplines. His own work has led him to adopt a statistical approach to the problems, and the book is written from this point of view. The account which he gives is necessarily incomplete, and he admits that future research may show that some of the interpretations which he has made are unjustified. Even if this proves to be the case, it is unlikely to affect the conclusions at which he arrives.

Dr. Sholl is to be congratulated on having written this book. He has approached a most difficult subject with commendable caution and modesty. The account which he gives is judicious and entirely free from special pleading. It offers no easy solution; on the contrary, he shows that none is

TEXTBOOK OF MEDICINE

Internal Medicine: A Physiologic and Clinical Approach to Disease. By Robert P. McCombs, B.S., M.D., F.A.C.P. (Pp. 706+xxi; illustrated. 75s.) Chicago: The Year Book Publishers Inc. London: Interscience Publishers Ltd. 1956.

This short textbook by the professor of medicine at Tufts University, Boston, is divided into 12 chapters dealing respectively with the heart, hypertension and vascular disorders, the kidney, body fluids and electrolytes, endocrinology, infectious diseases, the lung, allergy, gastro-enterology, the blood, rheumatic disorders, and metabolic disorders. Thus neurology, psychiatry, electrocardiology, and dermatology have been deliberately omitted. Each chapter gives an excellent summary of the relevant applied physiology, followed by brief but accurate and well-balanced accounts of the commoner diseases. At the end of each section there is a short list of useful references (all save one or two, it need hardly be added, to American work). Salt and water metabolism and endocrinology are particularly well done; by contrast, the gastro-enterology section is perhaps a little disappointing. The approach is essentially practical throughout, so that discussion of controversial or purely theoretical matters has been avoided and laboratory diagnostic procedures have not been over-stressed at the expense of clinical methods.

The emphasis being, commendably, on the common and important things, there is an absence of detail which, together with a rather sketchy index, limits the value of the book as a work of reference. It is clearly intended to be read as an introduction to medicine, or for revision, and for these purposes it is admirable. It can be strongly recommended to anyone seeking a concise account of the fundamentals of internal medicine to-day.

J. C. HOUSTON.

ESSENTIALS OF SURGERY

A Short Practice of Surgery. By Hamilton Bailey, F.R.C.S., F.A.C.S., F.I.C.S., F.R.S.E., and R. J. McNeill Love, M.S., F.R.C.S., F.A.C.S., F.I.C.S., with chapters by John Charnley, F.R.C.S., William P. Cleland, M.R.C.P., F.R.C.S., and Geoffrey Knight, F.R.C.S., and pathological illustrations by L. C. D. Hermitte, M.B., Ch.B. Tenth edition. (Pp. 1,126+ viii; illustrated. 84s.) London: H. K. Lewis and Co. Ltd. 1956.

The facts that this well-known textbook has reached a tenth edition and that 80,000 copies have been sold within the last 25 years are sufficient testimony that it presents an adequate account of the essentials of modern surgery. Surgery is now so vast a subject that even a "short practice" needs over 1,000 pages to contain it; and reading through several sections of this book convinces one that the authors have needed considerable skill to condense necessary knowledge into small compass.

The surgery of three specialties has in this edition been described by specialists. Mr. William Cleland, Mr. John Charnley, and Mr. Geoffrey Knight deal respectively with thoracic surgery, orthopaedic surgery, and neurosurgery, and in each instance the rewritten section is excellent. The style of writing is clear and there are even traces of humour and mild satire. On page 764 we are told of the only known pathological evidence of the existence of a weaker sex, while on page 930 the advice is given to administer the latest fashionable drug for vasospasm. The description of intra- and extra-capsular fractures of the neck of the femur on page 958 shows how radiological is displacing clinical diagnosis. The parts written by Mr. Hamilton Bailey and Mr. McNeill Love maintain their high standard of excellence.

No review of this book would be complete without a tribute to the publishers and printers for the excellent production. Paper and typography are good, and both plain and coloured illustrations are well placed and excellently reproduced. This edition certainly gives as succinct and up-to-date an account of modern surgery as is possible in these days of rapid progress.

ZACHARY COPE.

IMMUNOLOGY

Fundamentals of Immunology. By William C. Boyd. Third edition. (Pp. 776+xiv; illustrated. \$10.) London and New York: Interscience Publishers Inc. 1956.

This is a well-produced and readable work. As the title implies, it deals with the fundamentals of immunology and gives an excellent account and appraisal of the facts and theories relating to immunology, antibodies, antigens, blood groups, antigen-antibody reactions, and hypersensitivity as well as autoimmunization. There is also a most helpful chapter on the practical use of immunity and hypersensitivity, but the final chapter on laboratory and clinical technique leaves much to be desired and deserves much more than the space (118 pages) allotted to it. At the end of each chapter a well-selected list of references is given which should be useful to those readers who wish to consult original papers. The main difficulty of the reviewer is to decide for whom the book is written. It is certainly not suitable for the majority of undergraduate medical students in this country. For example, few have the time to contemplate the mathematical arguments concerning antigen-antibody reactions (pp. 336-45), and most of them would be intimidated by the equation at the top of page 344. This volume could be used as a book of reference, but would probably have a greater appeal to those students taking a science degree in bacteriology or those qualified practitioners who are in the early stages of a clinical bacteriological career.

I. N. ORPWOOD PRICE.

METABOLIC REGULATION

La Régulation des Processus Métaboliques dans l'Organisme. By Théophile Cohn. (Pp. 681. No price.) Paris: Presses Universitaires de France. 1956.

This is a colossal work, probably representing the labour of many years, in some 700 large pages, all of which I do not pretend to have read. The author is a director of research in Paris and has set out to co-ordinate our knowledge of the total regulation of the metabolic processes of the body, and fulfils this task as well as possible in such a widespread field. He divides his book into three sections. The first deals in detail with the metabolism of carbohydrate, proteins, and fats; the second with the transformation of metabolites and their combustion; the third with total metabolic co-ordination. Detailed biochemistry is avoided throughout and most emphasis laid on the endocrine system and the fundamental animal experiments from which knowledge grew. The relation of these to human disease is briefly but adequately mentioned, and in all sections historical aspects are interestingly included. The bibliography is enormous, including some 1,700 references, and the spelling of non-French names is unusually accurate. The only error noted is that Banting and Best discovered insulin in 1921, not 1923, and it seems strange that Banting's name does not appear in the references.

This book is a fine intellectual study on which the author is to be congratulated. But inevitably there is this tragedy with such books in that they are always out of date, at least for specialists, before they are published. The latest references are 1952, since when new knowledge and ideas make the work already behind the times.

R. D. LAWRENCE.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY MAY 4 1957

FOURTH SYMPOSIUM ON ANTIBIOTICS

A symposium on antibiotics in Washington seems now to be a regular annual event, and the report¹ of the fourth of these meetings, held in October last, is again larger than its forerunners. It consists of 1,134 pages and contains 154 papers and apparently verbatim reports of three panel discussions. The grain in these contributions is mixed with a high proportion of chaff, and not only are no major discoveries reported but the number of papers containing really significant and hitherto unreported material is small. Nevertheless this unwieldy volume has much value in reflecting trends of thought, particularly in the United States. The problem which evidently most exercised the minds of participants was that of antibiotic-resistant infections and measures for their prevention. So far as this concerns cross-infection in hospitals, it is refreshing to read a spirited contribution to a panel discussion by Pulaski, demanding as rigid an application of aseptic principles in wards as in operating theatres and specifying features of a safer wound-dressing technique. It is mentioned here that 70% of the antibiotics used in surgical services are given prophylactically, and that proof of the efficacy of many such procedures is lacking. Unfortunately there appears to have been little discussion of the more questionable of these uses: the only specific example in the programme was entitled "Antibiotics in Intestinal Antisepsis." In this connexion speakers seem to have been agreed that antibiotic preparation before colonic surgery is valuable, and that the sulphonamides are outmoded for this purpose. Although methods in great variety were advocated, neomycin was the favourite stand-by, usually given, after mechanical cleansing of the bowel, for only one day before operation and usually combined with another antibiotic such as erythromycin or bacitracin, which has an action particularly on the Gram-positive flora.

Many of the communications were concerned, explicitly or implicitly, with another aspect of the

problem of bacterial resistance—that is, the advisability of using pairs of antibiotics in the hope of delaying the emergence of resistance. Studies of several new combinations of this kind were reported, notably the mixture of tetracycline and oleandomycin known as "sigmamycin," and the chairman, Dr. Henry Welch, went so far in his introductory remarks as to divide the history of antibiotic therapy into three eras—"narrow spectrum," "broad spectrum," and "combinations." This elevation of a selling point to the status of a major advance in therapeutics has provoked a vigorous rejoinder from Maxwell Finland and eighteen other internationally known physicians² in the U.S.A., who conclude by saying that they conceive it the duty of clinical investigators and authors "to protect the medical profession and the public against the abuse of preliminary scientific information and against the improper and premature exploitation of conclusions based on inadequate data." A full-scale debate on this important question of principle would have been interesting, and never took place, but it is quite evident that leading medical authorities in the United States dislike fixed commercial combinations, and would prefer to prescribe mixtures in the proportions they deem desirable for such individual patients as they think require them. It was repeatedly emphasized that combinations do not have the advantage claimed unless the organism is sensitive to both components. The only study reported of which the object was to determine whether combinations delay the clinical acquisition of resistance was made by M. H. Lepper and his colleagues at the Municipal Contagious Disease Hospital, Chicago: novobiocin and spiramycin were the drugs used, and the conclusion was that combined treatment delayed the appearance of resistant strains by about two months only.

Another panel discussion and many other papers were concerned with the use of antibiotics as food preservatives. Statistics of food production and wastage in the United States show how huge the possible savings might be if food could be effectively and safely preserved by this means. It seems that only the tetracyclines are suitable for the preservation of flesh foods. So far only the treatment of poultry is permitted, and assays of chicken meat so treated show that the residue of antibiotic is destroyed by cooking. This does not appear to be true of fish when baked or fried, and should the preservation of fish be permitted it will have to be asked whether the human consumption of food containing small but detectable amounts of tetracycline antibiotics has any serious disadvantages. Does exposure to such low concentrations evoke bacterial resistance to higher

ones? It is surprising that apparently none of the numerous workers who have devoted so much energy to this subject should have tried to settle this fundamental question. Vegetables and fruit are also in this picture, and there is even the tentative suggestion that an antibiotic might be added to milk, but this only in areas affected by kwashiorkor and innocent of refrigerators. One speaker declared that it "will be necessary to engineer and integrate the use of the antibiotic compounds into production lines" and envisaged the successive treatment of foods by antibiotics, vacuum packing with an antioxidant, microwave heating to inactivate enzymes, radiation to produce surface sterilization—possibly with the addition of chemicals to reduce consequent flavour changes—and finally low-temperature storage. It seems superfluous to add: "Such a procedure would produce foods and food products certainly different from those that we are accustomed to to-day. . . ."

Other papers read at the symposium dealt with new antibiotics, new forms of old antibiotics and some less familiar uses for them, and methods of sensitivity-testing with their results. Comparatively new antibiotics about which there is further but largely repetitive information are vancomycin, oleandomycin, and novobiocin. One paper reports favourably on the treatment of urinary-tract infections with novobiocin, although the concentrations attained in the urine were in some cases lower than those in the blood: so little of this antibiotic is excreted by the kidney that its choice for this purpose seems strange. A series of six papers on synnematin B, now known to be a form of penicillin, deals exclusively with laboratory studies: it is not clear whether further clinical application of this antibiotic is contemplated. Workers in the American antibiotic industry are continuing to unearth far more new antibiotics than all the rest of the world put together, and two among the actually new antibiotics described at the symposium appear more interesting than the rest: amphotericin has some action in the systemic mycoses, and ristocetin has a wide range of antibacterial action, embracing among other species the tubercle bacillus. The origins of ristocetin are agreeably colourful: the species forming it is named *Nocardia lurida*, and the soil sample from which this was isolated came from the Garden of the Gods, Colorado. Although ristocetin can be given only intravenously, it has been used by M. J. Romansky and his colleagues for the treatment of 16 patients, including cases of pneumonia and one of bacterial endocarditis, with satisfactory results. Among miscellaneous items of information, it is interesting to read that the delicious perfume of the balsam poplar has a powerful action on tubercle bacilli.

AUTHORITY AND TREATMENT

Juvenile courts were legally established in Great Britain just under fifty years ago. It is generally agreed that in most respects they have worked well, but the development of child psychiatry on the one hand and, on the other, the growth of special social services for children under the Children Act (after the Curtis Report) have led to many suggestions for reform. The departmental committee recently set up by the Home Secretary, with Viscount Ingleby as chairman, will doubtless be considering such new ideas. Its terms of reference fall into two parts, the one concerned with the legal side—powers, procedure, available methods of disposal and so forth in the juvenile courts—the other with preventive action by the child-care authorities for children neglected in their own homes. The report^{1 2} by the joint committee of the British Medical Association and the Magistrates' Association made valuable recommendations in this second topic. It is of interest also to note that the Ingleby Committee is asked to look at the working of the law in relation to "the prevention of cruelty to, and exposure to moral and physical danger of, juveniles."

In all the evidence that the new committee will receive, as Dr. Eileen Younghusband points out in a special number of the *British Journal of Delinquency*,³ there will unfortunately be none by the children themselves. In their anxiety to see that what they do is in the interests of the welfare of the child before them, many magistrates are facing the dilemma that the children and adolescents fail to appreciate (or even listen to) their words of helpful advice, while at the same time this sort of approach may weaken the value of the awe and prestige which the majesty of the law is held to confer. The comments of some intelligent teenagers would be helpful but do not seem to have been recorded. The confusion is especially apparent for children brought to the court as in need of care or protection or even as "beyond control." The need for the family and child-welfare services advocated by Dr. Younghusband is then paramount, yet the whole setting of the court system is not far removed from that used in the trial of adult criminals. It is perhaps a preoccupation with this aspect of the work of the juvenile courts that has led certain reformers to question the attribution of guilt, leading to such an antithesis as "sickness or sin," which was the title of a provocative article⁴ last year by Professor Barbara Wootton, herself an experienced juvenile-

² *Antibiot. Med.*, 1957, 4, 17.

court magistrate. The same theme is seen in the phrase "clinic or court?" And it must be admitted that with certain behaviour problems it is often a matter of chance whether or not a child is sent to a child-guidance centre or brought before the courts. Dr. Younghusband describes the difficulties by posing the two aspects: the law assumes that the law-breaker could have refrained from breaking it "and is therefore guilty of an offence; while medical treatment . . . is based upon an attempt to understand causation and to prescribe appropriate treatment." Her comment is that this is "the new wine which is proving so heady in the juvenile courts." One weakness is that, whereas in London the panel of magistrates for juvenile courts is specially chosen and is thus essentially composed of people with an interest in children, outside this area the method of appointment to the Bench restricts it to those already on the Bench for adult courts. In consequence magistrates may be deplorably ignorant of modern work on the emotional development of children and their personal difficulties in a faulty family setting.

Perhaps an even more dangerous feature of the new doctrine is that whereas something in the nature of child welfare committees, as in Sweden, may be admirable for sorting out a child's problems, when it comes to removing the child from his parents there must be some legal sanction. Mrs. W. E. Cavenagh,⁵ also a contributor to the *British Journal of Delinquency* symposium, quotes the Lord Chief Justice as saying last year: "No persons of any age are to be confined in institutions merely because doctors and officials think it would be good for them." Even, then, if the welfare of the child after careful investigation on judicial lines points strongly to the need for institutional care, public (and legal) opinion would probably always insist that this can be achieved only by the processes of the law. The difficulty here is that a relatively minor offence may reveal a deplorable family situation crying out for at any rate temporary removal of the child offender to different surroundings to give him a chance in life, while a more serious lapse, when the child has reliable parents prepared to take responsibility for the future, may well be dealt with by a period of probation. Superficially, and certainly to the parents in the former instance, there is here something which looks grossly unjust.

This is one of the problems which the Ingleby Committee will have to consider, and indeed throughout its deliberations the twin functions of the present-day juvenile court—authority and treatment—will be ever before them. As Dr. Younghusband remarks, it is the probation officers who now reconcile these two functions and seek by good case-work to "help the offender and his parents to come to terms with each

other and with society." Public opinion, with medical approval, has been moving away from physical punishment for the juvenile offender, whether by birch or restraint on freedom. There is just a danger that sentimentality may be creeping in heavily disguised as ill-digested psychological knowledge. To correct this there is room for more medical practitioners, interested and experienced in children's troubles, to sit on the Bench in the juvenile courts to-day.

SURGERY OF AORTIC STENOSIS

Several hundred operations for aortic stenosis have now been performed, nearly all during the past five years. C. P. Bailey of Philadelphia in 1956 with several colleagues¹ published a report on 287 operations, and in the opening pages of this issue Sir Russell Brock describes his experiences, based on 108 operations, and gives an encompassing review of what is known of this lesion. Surgery, the only treatment which can alter a stenotic aortic valve, should now at least be considered in all cases, certainly if there is evidence of deterioration. Sir Russell Brock makes a strong plea for operation before the left ventricle is damaged, and his arguments demand attention. He rightly stresses that obstruction to the outlet of the left ventricle, the most important muscular organ in the body, should be relieved as urgently as obstruction to the exit from any other hollow viscus, such as the bladder, the colon, or the biliary system. As in these fields of surgery, good results cannot be expected if obstruction has been long-standing and its effects profound and perhaps nearly fatal.

Aortic stenosis is usually a sequel to rheumatic fever. Rarely it is a congenital lesion, when hypoplasia of the base of the aorta, an associated sub-valvar stenosis, and post-stenotic dilatation of the ascending aorta are often present. Arteriosclerosis may sometimes cause aortic stenosis, usually with associated regurgitation. As in disease of the mitral valve, rheumatic aortic stenosis may also be accompanied by regurgitation. The abnormality of the valve is due to the organization of vegetations and fibrin deposits on cusps; scar tissue thickens the lunules and obliterates the commissures, asymmetrically and centripetally; and late contraction further narrows the lumen or, by preventing approximation of the cusps, allows reflux. I. K. R. McMillan² has clearly shown the inefficient action of the diseased

¹ Bailey, C. P., Bolton, H. E., Nichols, H. T., Jamison, W. L., and Litwak, R. S., *J. thorac. Surg.*, 1956, 31, 375.

valve by post-mortem cinephotography. Calcification eventually occurs in nearly all cases, especially at the commissures near the ring; it hampers the surgeon's efforts and adds to the dangers by providing a source of emboli, but does not inevitably preclude a good result. Aortic stenosis is about five times less common than mitral stenosis, but both valves are often diseased. Some reduction of the valve lumen can be tolerated without ill effects, probably to one-quarter or less of the normal, but beyond this the left ventricle hypertrophies and eventually fails. If there is aortic regurgitation the ventricle also dilates. The systolic blood pressure is low and the pulse pressure small, and the flow in the coronary arteries is impaired.

The clinical course of aortic stenosis typically begins with a latent period without serious symptoms or disability, which may last for many years; then symptoms appear and are fairly soon followed by heart failure and death. Relief by medical treatment is seldom long lasting. In contrast to mitral stenosis, in which the course is usually a gradual decline with periods of satisfactory but gradually lessening response to medical treatment, the patient's decline in aortic stenosis is relatively abrupt and inexorable, seldom lasting more than two years from the first evidence of heart failure. It follows that surgical treatment should seldom be delayed if it is to be effective. The earliest symptoms are often tiredness and dyspnoea on exertion: palpitations, or simply awareness of the heart's action, may be significant. Fainting or dizziness usually points to inadequate aortic flow, as does angina, which may be felt as a tightness of the throat or as chest pain. Such patients may die suddenly, presumably from ventricular fibrillation following myocardial anoxia. Angina, especially in older patients, may be due to independent disease of the coronary arteries, and its significance should be cautiously assessed. Nocturnal dyspnoea and orthopnoea are serious symptoms of left ventricular failure. A short harsh basal systolic murmur, best heard in the right second interspace, is the most constant physical sign. It sometimes radiates towards the apex, is usually transmitted to the carotid arteries, and, if intense, is palpable as a thrill. A long, blowing, early diastolic murmur, replacing the second sound, is a sign of aortic regurgitation. The classical plateau pulse and small pulse-pressure are not always present, and blood-pressure readings may be within normal limits. The electrocardiogram may show left ventricular strain or preponderance. The pulse is usually regular; atrial fibrillation suggests an associated mitral lesion. There may be evidence of left ventricular enlargement—the most important radiological sign. A boot-shaped heart suggests aortic

incompetence. Calcifications is best seen by fluoroscopy. An associated mitral stenosis, present in about one-third of patients coming to operation, means a less serious prognosis. The left ventricle is less likely to enlarge, though the left atrium and the right ventricle do so. Operative correction of stenosis of one valve may unmask a relatively silent lesion of the other, so if necessary both should be dealt with at the same time. Occasionally a third lesion, tricuspid stenosis, is also present.

Pressure measurements can give useful information, particularly in cases complicated by other valve lesions, or with regurgitation or misleading symptoms. The most useful finding is a pressure gradient across the aortic valve: this can be shown by catheterization of the left side of the heart. The catheter can be introduced into the left atrium either by direct puncture through the chest wall or through the wall of a bronchus via a bronchoscope. But the procedure carries a definite risk, and it is not always possible to manipulate the catheter into the ventricle and aorta. Direct puncture of the left ventricle through the anterior chest wall is feasible and not dangerous³; simultaneous puncture of the brachial artery gives an accurate approximation to the aortic pressure and so will show the gradient. The measurements may also be made at operation. Sir Russell Brock advises that in general a gradient of 50 mm. Hg or over is an indication for operation.

The surgical approach to the aortic valve may be from below through the wall of the left ventricle, or from above through the aorta. Sir Russell Brock prefers the former route. The heart is approached by left lateral thoracotomy. Temporary occlusion of the innominate and carotid arteries reduces the risk of cerebral embolism. Through a tiny incision in the ventricle, controlled by a purse-string stitch, probes and an expanding dilator can be introduced and guided to the valve. The dilator is expanded in various directions. The effectiveness of the dilatation can be checked by pressure measurements. The ventricular wound is usually sutured without great difficulty, though care is necessary to avoid stitches cutting through, and serious haemorrhage is seldom a problem. The risk of ventricular fibrillation is a greater one, but it can often be treated successfully by carrying out the valvotomy if this has not been done, and by cardiac massage and electric shock. Bailey now prefers the approach from above, though in many hands this route is probably more dangerous. It has not been established that it carries any less risk of ventricular fibrillation.⁴ A right or mid-line anterior thoracotomy is used. An artificial pouch of pericardium or of plastic material is sutured to the side of the aorta: this allows the introduction of the surgeon's

finger and of instruments, in the same way as the natural auricular appendage does to the mitral valve. Palpation of the valve carries a slight advantage, and sometimes digital pressure alone causes sufficient rupture, but this is seldom as effective as it is for the mitral valve.

These techniques are both blind. More recently, through the aortic approach, open operations with direct inspection of the valve and accurate division of the three commissures have been performed, with the help of hypothermia⁵ or a pump-oxygenator. These methods are very promising, but the techniques carry their own additional hazards. The grossly distorted, heavily calcified valve so often the end result of aortic stenosis cannot be restored to normal by any manoeuvre; but the incomplete enlargement that can be obtained by transventricular dilatation often greatly improves the prognosis. Perhaps eventually it may prove possible to incorporate an efficient artificial or grafted valve into the patient's heart. Further experience will enable indications for operation to be more clearly defined, and as in congenital heart disease assessment by elaborate investigation may prove less often necessary. Operation now appears to be indicated in cases of predominant aortic stenosis when there is inadequate left ventricular outflow. Contraindications include heart failure not responding to treatment, active rheumatism, and bacterial endocarditis. Good results are less likely in older patients and when there is extensive calcification or great cardiac enlargement. In favourable cases the present operative mortality appears to be about 5%.

RESISTANCE TO CORTICOTROPHIN

Though cortisone and corticotrophin seem to act in the same manner, both raising the level of hydrocortisone in the body fluids, many clinicians consider that corticotrophin is the more potent therapeutic agent of the two. Possibly, therefore, the adrenal cortex produces some additional unknown steroid of therapeutic importance. This may be mainly why corticotrophin maintains its considerable popularity as a drug in spite of the inconveniences of its administration; but many physicians have encountered wide variations in the clinical effects it produces. There are several reasons for this. First, the therapeutic effects of corticotrophin are mediated entirely through the adrenal cortex, and the responsiveness of this organ varies considerably even in healthy individuals. Secondly, its rate of absorption into the blood stream is known to modify its effect. Thirdly, there is a possibility that the corticotrophin may decompose in the muscle at the injection site. That this could occur was shown by A. E. Renold and colleagues,¹ who found that eight of 100 patients developed frank resistance to corticotrophin given intramuscularly, though all continued to give an entirely normal response

to the same preparation given intravenously. Fourthly, corticotrophin is a protein obtainable only by extraction of mammalian pituitary glands, and because of the difficulties of manufacture and of assay the resultant product is apt to vary considerably in potency. All these variables make the task of obtaining a repeatable therapeutic effect a matter largely of trial and error.

P. H. Forsham² noted the development of sensitivity to impure preparations, though he found none when using purer products. A careful study of the development of such resistance to injected corticotrophin has been recently made by H. F. West.³ In a series of 51 patients treated with corticotrophin for periods of up to three years, 42 (80%) acquired resistance to one or more preparations. This resistance was revealed by a failure to maintain a sufficiently high output of ketogenic steroids or of 17-hydroxycorticoids as well as by the failure to maintain clinical improvement. The development of resistance to one preparation was often associated with continued sensitivity to another, though resistance to the second preparation might develop if its administration was continued. Thirteen patients became insensitive to two preparations and seven to three different preparations of corticotrophin. Local allergic reactions developed in 17 patients of the series, consisting in an area of induration at the injection site 3-4 cm. across, but the development of this local sensitivity seemed to be independent of the development of resistance to corticotrophin. Patients showing local allergy might remain sensitive, and those who had developed resistance did not necessarily show local allergy. In the subjects who developed resistance to corticotrophin there was no suggestion of adrenal exhaustion, and the possibility of deterioration of the preparation during storage was effectively excluded. The resistance developed was usually a species resistance, for sensitivity to corticotrophin from another animal source usually persisted. In no case was there evidence of a non-specific resistance to all corticotrophins, and sensitivity to endogenous corticotrophin remained unimpaired. In most of the cases in this series no distinction was made between local and general inactivation, but in the two cases tested resistance was not overcome by using the intravenous route. Two patients who had become resistant to both pork and beef corticotrophin showed a satisfactory response to a highly purified sample of corticotrophin A.⁴ West considers that there is less risk of developing resistance from highly purified corticotrophins.

There is clearly great need for an extended trial of a preparation of greater and more constant purity than many of the commercial products at present available. Corticotrophin is a drug of such potency and value that it deserves stricter pharmaceutical control than it has had in the past. On May 1 preparations of corticotrophin were brought under the control of the Therapeutic Substances Act, 1956.

REPLACEMENT THERAPY FOR THE HAEMOPHILIAC

The aim of treatment in the management of the haemophiliac is to correct the haemostatic defect by supplying antihæmophilic globulin in an effective amount. The missing component is present in normal human plasma, and thus the therapeutic problem might seem to be a simple one. But in practice the supply of adequate amounts of antihæmophilic globulin to the haemophiliac is extremely difficult. The survival *in vivo* of antihæmophilic globulin once administered is very short, probably about 6 to 12 hours. To raise the level of antihæmophilic globulin in a haemophiliac to about a tenth of the level in the normal person requires the rapid administration of approximately a litre of fresh plasma; and to maintain even this limited objective would mean that a litre of plasma, or its content of antihæmophilic globulin, would have to be given every six to twelve hours. It is not even certain what concentration of antihæmophilic globulin in the recipient's blood represents a haemostatic level; this probably varies with the task demanded of it. For example, for the control of hæmaturia in these patients 10% of antihæmophilic globulin might be sufficient, though quite inadequate for the control of hæmorrhage from a surgical wound.

The difficulty in providing antihæmophilic globulin for the haemophiliac patient lies not only in the large amounts required to stop bleeding but also in the lability of this component of normal plasma when stored. In bank blood the survival of antihæmophilic globulin is very variable: it may lessen in quantity by as much as 50% in a matter of twenty-four hours under the standard conditions of storage in a refrigerator at 4° C. If the plasma is separated from the red cells and maintained frozen at -20° C—the so-called fresh-frozen plasma—survival of antihæmophilic globulin is much improved. At present such fresh-frozen plasma supplied by many transfusion services is the best readily available preparation for the treatment of the haemophiliac in an emergency. It has to be used in large quantities, such as a litre of plasma every 6 to 12 hours. Elsewhere in this issue (p. 1035) Mr. J. A. Orr and Dr. A. S. Douglas, reporting on the management of dental extractions in patients with hæmophilia and Christmas disease, describe their method of using fresh-frozen plasma. The large volumes which are necessary, though in general well tolerated, carry some risk of circulatory overloading. Concentrated preparations of antihæmophilic globulin would therefore prove a great advance in the management of these patients. R. G. Macfarlane and his colleagues^{1,2} in Oxford have prepared concentrated preparations of antihæmophilic globulin from bovine and pig blood. In animal blood the concentration of the factor is often very much higher than in human blood. R. A. Kekwick and P. Wolf³ have recently reported the preparation of very concentrated antihæmophilic globulin from human blood. Though obviously the human preparations of antihæmophilic globulin have

advantages over those obtained from animal sources, particularly in relation to antigenicity, it seems unlikely that enough of the material can be obtained from human plasma to treat the hæmophilic population of the whole country. Another potentially rich source of antihæmophilic globulin is tissue, and F. Nour-Eldin and J. F. Wilkinson⁴ have prepared it from brain. It is to be hoped that in the foreseeable future the long-term management of hæmophilic patients will be made simpler by the readier availability of suitable preparations of antihæmophilic globulin.

HARVEY TERCENTENARY CONGRESS

Like many another stroke of genius, William Harvey's discovery of the circulation of the blood was not at first generally accepted. The new idea was difficult to relate to the anatomy and physiology then current, and its use in clinical medicine seemed slight, even negligible.¹ The beam of light shone so far out that it left on either side great areas of darkness, which only succeeding centuries were to see gradually illuminated. But to *De Motu Cordis* may be traced the beginnings of modern cardiology, until recently the province of physicians, though it is symptomatic of the times that half the papers reviewing "the present knowledge of the circulation" at the Harveian Tercentenary Congress in June are by surgeons. The programme includes a discussion on cardiac surgery to be held jointly, by transatlantic telephone, with participants in the American Medical Association's annual meeting in New York. These will include Drs. A. Blalock, M. De Bakey, and G. Burch.

The main theme of the congress, which is timed to commemorate Harvey's death on June 3, 1657, is to review the store of knowledge which has accumulated since Harvey's momentous observations and deductions. It is therefore appropriate that the opening session should be devoted to a historical review of studies of the circulation from the seventeenth to the twentieth century. Other symposia are concerned with pulmonary, coronary, cerebral, splanchnic, peripheral, and foetal circulations. One session, devoted to the results of cardiac surgery, will define the experience of Great Britain, France, Sweden, and the U.S.A. in the tremendous advances achieved in the last two decades. At the close of the scientific meetings in London the congress will be transferred to Harvey's birthplace, Folkestone, where more personal and biographical aspects of his life will be discussed under the chairmanship of Sir Geoffrey Keynes. The organizing committee is composed of representatives of the Royal Society, Medical Research Council, Royal College of Physicians, British Cardiac Society, Physiological Society, Society of Thoracic Surgeons, Thoracic Society, and the Harveian Society of London, while the main meetings are to be held at the Royal College of Surgeons in London. The variety of interests thus brought together gives some indication of the influence that Harvey's work has had on medicine. Full details of the congress may be obtained from the organizing secretary, Mrs. E. M. Fraser, 11, Chandos Street, London, W.1.

ALKYLATING AGENTS IN CANCER

CLINICAL USEFULNESS AND MODE OF ACTION

[FROM A SPECIAL CORRESPONDENT]

The Section of Biology of the New York Academy of Sciences sponsored an international conference on the comparative clinical and biological effects of alkylating agents in New York recently. It ran from March 28 to March 30. The organizing committee, under the chairmanship of Dr. LEON H. SCHMIDT, included among its members Professor F. BERGEL and Professor ALEXANDER HADDOW from Britain. Some fifty papers were read, including twenty by invited delegates from Canada, Britain, Western Germany, Hungary, and Japan, and a paper had been received from the U.S.S.R.

Mode of Action

Dr. C. C. PRICE (University of Pennsylvania) and Dr. W. C. J. ROSS (Chester Beatty Research Institute, the Royal Cancer Hospital, London) opened the proceedings with descriptions of the fundamental mechanisms of alkylation and the *in vitro* reactions of alkylating agents. An alkylating agent could be defined as one which under certain conditions possesses one (monofunctional) or more (polyfunctional) centres capable of reacting with electron-rich groups in biological systems. At the Chester Beatty Research Institute it had been found that agents which readily alkylated ionized acid groups, particularly phosphate, were more powerful inhibitors of tumour growth than those especially reactive towards amino-groups and sulphhydryl groups. Materials rich in nucleic acids were highly susceptible to alkylating agents. Dr. K. A. STACEY (Chester Beatty Research Institute) had shown that nitrogen mustards, epoxides, and esters of methanesulphonic acid would esterify the primary phosphate groups of deoxyribosenucleic acid *in vitro*, and of deoxyribosenucleic acid in the form of nucleoprotein obtained from herring sperm heads. Chlorambucil reacted only with the deoxyribosenucleic acid of intact nucleoprotein. By contrast Dr. J. J. ROBERTS (Chester Beatty Research Institute), who had studied ¹⁴C-labelled chloroethylmethanesulphonate (C.B. 1506) *in vivo*, said that a high proportion of the drug had alkylated thiol groups, and suggested that this might be an integral part of the growth-inhibiting mechanism of these agents. If so, nucleic acids would play little part in the reaction, since they are entirely devoid of thiol groups.

Dr. CHARLOTTE AUERBACH, F.R.S. (Institute of Animal Genetics, Edinburgh), on the other hand, thought it hazardous to try to relate the mutagenicity of alkylating agents to their chemical properties. She did not think they had any specific qualities distinguishing them from other mutagens. Spermatids were more sensitive to alkylating agents than spermatogonia, but only the latter synthesized deoxyribosenucleic acid. Nor could mutagenic ability be related to alkylation of thiol groups.

Professor P. C. KOLLER (Chester Beatty Research Institute) described the various types of cytological damage observed after the administration of drugs, and thought the alkylating agents produced certain characteristic types of injury.

Pharmacology and Toxicology

Dr. C. C. STOCK (Sloan-Kettering Institute for Cancer Research, New York) said that many alkylating agents had been shown to have tumour-inhibitory activity in both experimental animals and man. Some investigators felt that most of what could be expected had already been achieved with this type of agent; others thought further exploration was still worth while. This would repeatedly raise the question of whether the new compounds were sufficiently superior to those already available to warrant clinical trial.

Dr. S. S. STERNBERG (Sloan-Kettering Institute for Cancer Research) described the pharmacological and toxic effects of the different classes of alkylating agent. When median

lethal or supra-lethal doses were used the same basic effects were observed with all types of agent—namely, convulsions, paralysis, and a variety of cholinergic effects. Anorexia, vomiting, diarrhoea, and leucopenia occurred, and there was gross destruction of lymphoid tissue, bone marrow, and intestinal mucosa. In man, the similarities of the effects of alkylating agents to those produced by ionizing radiations were less than in animals, but intra-arterial nitrogen mustard had caused epilation and erythema similar to that resulting from irradiation. Dr. L. A. ELSON (Chester Beatty Research Institute), using relatively small single doses of alkylating agents in rats, had found them to be only partially radiomimetic in their effects on the blood picture. All nitrogen-mustard analogues tested produced one pattern of response, whereas busulphan analogues brought about a different but equally characteristic pattern. Simultaneous administration of a nitrogen mustard and busulphan closely simulated the complete haematological effects of radiation.

Dr. P. K. SMITH (George Washington University, Washington, D.C.) described his studies on the distribution and metabolism of isotope-labelled sulphur mustard, nitrogen mustard, triethylenephosphoramide, tretamine (T.E.M.; triethylene melamine), and busulphan in mice, rats, and man. These compounds disappeared rapidly from the blood, they did not localize selectively in tumours, and only in the case of busulphan was any unaltered substance detected in the urine.

Nitrogen Mustard and Tretamine

Dr. D. A. KARNOFSKY (Sloan-Kettering Institute for Cancer Research) summarized the clinical results obtained with nitrogen mustard, which had been in use now for 15 years. It was the most widely used alkylating agent, and related drugs should be compared with it in terms of route of administration, immediate and delayed toxicity, spectrum of therapeutic action in neoplastic diseases, and activity in patients who had failed to respond to nitrogen mustard. Its chief application was in the later stages of Hodgkin's disease. Improvement lasting from one week to one year or more (average six to eight weeks) could be expected in 80 to 90% of patients and repeated responses could sometimes be obtained. Occasionally it was necessary to push treatment until severe leucopenia occurred before the patient remitted, and in one case repeated treatment for seven months was necessary to achieve remission. Nitrogen mustard did not prolong life in most cases but conferred real clinical benefit. Its role in the treatment of other lymphomas and in other forms of malignancy was less easy to evaluate. In bronchial carcinoma absorption of pleural effusions, relief of superior vena caval obstruction, and other objective effects had occurred in some 40% of cases, but benefit rarely exceeded eight weeks.

Dr. H. D. DIAMOND (Memorial Center for Cancer and Allied Diseases, New York), discussing the indications for using nitrogen mustard or tretamine (T.E.M.; triethylene melamine) in malignant lymphomas emphasized their value in relieving the symptoms of superior vena caval obstruction and of compression paraplegia. Full doses of nitrogen mustard should be followed immediately by x-ray therapy. Nitrogen mustard should also be used in the acute, toxic, highly febrile syndrome and in cases with recurrent pulmonary lesions (where it was necessary to differentiate between radiation fibrosis and active disease). Nitrogen mustard was also of value in treating the "homme rouge" type of mycosis fungoides.

Dr. A. S. WEISBERGER (Western Reserve University, Cleveland, Ohio) described the results of direct instillation of nitrogen mustard into serous cavities in 88 patients with malignant effusions. The results were as good as or better than those obtained with radioactive colloidal gold, and he preferred nitrogen mustard on the grounds of its availability, ease of administration, inexpensiveness, and lack of radiation hazard. Dr. W. H. COLE (University of Illinois College of Medicine, Chicago) described the intraperitoneal use of nitrogen mustard in man at the time of resection of

the colon and rectum for carcinoma.* The rationale for this procedure was the finding that the number of "takes" of the Walker rat carcinoma injected into the portal vein was reduced if nitrogen mustard was injected simultaneously. There was a slight increase in bleeding tendency during and after the operation and paralytic ileus was more common, but with proper precautions the method was considered safe.

Dr. R. W. RUNDLES (Duke University School of Medicine, Durham, N. Carolina) summarized his results with tetramine (T.E.M.; triethylene melamine) in 54 cases of chronic lymphocytic leukaemia. Tetramine was a most effective agent in controlling the disease, but the range of sensitivity to the drug was very great and he thought it would be replaced by chlorambucil. Tretamine had also proved useful in about half of the patients with widespread ovarian carcinomas and in a few with undifferentiated metastatic carcinoma.

Chlorambucil

Dr. L. G. ISRAELS (University of Manitoba, Winnipeg) described the results obtained with chlorambucil (C.B. 1348) in the treatment of 107 patients with malignant lymphoma during the past four years. Excellent remissions were obtained in 3 of 35 patients with Hodgkin's disease, 9 of 12 with follicular lymphoma, 12 of 27 with chronic lymphocytic leukaemia, and 7 of 20 with lymphocytic lymphoma. Some benefit (less than six months) was obtained in a further 21 cases of Hodgkin's disease, 3 of follicular lymphoma, 9 of chronic lymphocytic leukaemia, and 5 of lymphocytic lymphoma. Transient benefit occurred in 8 of 13 cases of reticulosarcoma. Chlorambucil was well tolerated and was less toxic to haemopoietic tissue than other cytotoxic agents in common use. It was probably the treatment of choice in follicular lymphoma, chronic lymphocytic leukaemia, and lymphocytic lymphoma, but nitrogen mustard was to be preferred in the treatment of Hodgkin's disease.

Dr. C. A. DOAN (Ohio State University College of Medicine) had treated 100 patients with chlorambucil in the past two and a half years. Twenty-two of 47 patients with Hodgkin's disease had obtained remissions lasting four months or more, one had a second remission, and one a third. Twelve of 18 patients with chronic lymphocytic leukaemia benefited, 5 having previously failed to respond to radioactive phosphorus or x-ray therapy. Six of eight patients with lymphosarcoma responded well. Dr. J. E. ULTMANN (Columbia University College of Physicians and Surgeons, New York) had found chlorambucil of particular value in cases of chronic lymphocytic leukaemia with moderate thrombocytopenia but without clinical haemorrhagic manifestations. In Hodgkin's disease the results were less encouraging, only two of eight patients having responded. Dr. B. E. HALL (Stanford University School of Medicine, California) had treated 120 patients with chlorambucil. Significant benefit was conferred on 7 of 21 patients with Hodgkin's disease, 2 of 6 with lymphosarcoma, 6 of 8 with chronic lymphocytic leukaemia, and on the only patient with follicular lymphoma. Occasional patients with undifferentiated carcinoma metastases responded. Drs. Doan, Ultmann, and Hall had not found chlorambucil to be of value in myelomatosis, and the bone marrow in this condition was easily depressed by the drug. Dr. K. B. OLSON (Albany Medical College, New York), however, described one patient, in remission after eight months, who had experienced marked relief of pain and some improvement in bone-marrow findings. Dr. S. L. GUMPERT (New York University Bellevue Medical Center) described benefit in one case of ovarian carcinoma.

Busulphan

Dr. D. A. G. GALTON (Chester Beatty Research Institute) described the clinical effects of busulphan ("myleran"). Its chief role was in the treatment of chronic granulocytic leukaemia. When the leucocyte count had risen quickly after a course of treatment continuous therapy had been

*See also *British Medical Journal*, April 13, p. 899.

of value and had been given for periods of 8 to 45 months in 25 cases. Dimethylmyleran at half the dosage of busulphan had been equally effective.

Dr. F. H. BETHELL (Simpson Memorial Institute for Medical Research, Ann Arbor, Michigan) had used busulphan or tretamine in 54 cases of chronic granulocytic leukaemia and preferred continuous therapy to intermittent courses of treatment. Both drugs were equally useful and were superior to intermittent courses of irradiation. There was cross-resistance to these drugs.

Dr. W. DAMESHEK (New England Medical Center, Boston) said he had been particularly impressed with the regularity and reproducibility of response to busulphan in chronic granulocytic leukaemia. The best remissions were in patients whose leucocyte counts were brought to slightly leucopenic levels (between 5,000 and 6,000 per cubic mm.). He had also found the drug useful in four of eight patients with myeloid metaplasia who obtained symptomatic relief, reduction in splenomegaly, and a rise in haemoglobin.

Dr. M. P. SYKES (Sloan-Kettering Institute for Cancer Research) had used busulphan in 21 cases of malignant lymphoma and had given short courses with large doses. Six patients responded in some degree, but in only two were the remissions lasting; one was a case of very chronic lymphocytic leukaemia, the other of lymphoma. A comparative study, under similar conditions, with busulphan as well as other alkylating agents would be necessary to establish any quantitative differences in their therapeutic activity and response at various levels of haematological depression. Dr. R. D. SULLIVAN (Veterans Administration Hospital, Manhattan) had treated 18 patients with bronchial carcinoma, using dosage schedules comparable in bone-marrow depressing activity to those employed with nitrogen mustard. Six showed objective evidence of tumour regression lasting 2 to 12 weeks, and the results were considered to parallel those obtained with nitrogen mustard. Dr. H. R. BIERMAN (City of Hope Medical Center, Duarte, California) had injected dimethylmyleran in warm alcohol intravenously in the human subject. Depression of the neutrophil count began three hours later. The bone marrow showed abnormal myeloid and erythroid precursors. Single intravenous doses of dimethylmyleran had led to improvement in one of three cases of acute leukaemia refractory to other forms of therapy.

Thio-TEPA and R.48

Dr. J. C. WRIGHT (New York University Bellevue Medical Center) reviewed 93 cases of carcinoma, sarcoma, and miscellaneous tumours in which triethylenethiophosphoramide (thio-TEPA) had been given. Some 30% of patients had derived benefit; the only side-effect was bone-marrow depression. Dr. J. E. ULTMANN (Columbia University College of Physicians and Surgeons, New York) had treated 100 patients with various malignant neoplasms. In malignant lymphomas remissions were usually short-lived, but in 27 cases of disseminated ovarian carcinoma significant objective improvement was observed and the mean survival was 13 months compared with 3 months in untreated patients. Severe haemopoietic depression occurred in 43 instances with clinical manifestations in 17 patients. This limited the usefulness of thio-TEPA. Dr. K. B. OLSON (Albany Medical College, New York) had used thio-TEPA in 42 cases of advanced malignant disease. In general the results were inferior to those obtained with nitrogen mustard and the effects on the bone marrow were often serious. Dr. H. SHAY (Fels Research Institute, Temple University Medical Center, Philadelphia) felt that the doses employed by the previous speakers were too large and that thio-TEPA had proved very effective in the management of chronic granulocytic leukaemia and in advanced mammary and ovarian carcinoma. Improvement and unquestionable prolongation of life had been secured in occasional cases of advanced gastro-intestinal carcinoma.

Dr. JEANNE BATEMAN (Garfield Memorial Hospital, Washington, D.C.) had used thio-TEPA in 486 patients. Main-

tenance therapy from 2 weeks to 3 years (average 5½ months) had been given. Oral, intravenous, intrapleural, intrapericardial, intraperitoneal routes, and direct injections into tumours had been employed. Palliation had been achieved in a high percentage of cases of advanced mammary, ovarian, uterine, and other tumours, and in some tumours of the central nervous system. Dr. L. K. ALPERT (George Washington University Cancer Clinic, Washington, D.C.) had obtained significant though limited improvement in metastatic mammary and ovarian carcinoma. Eleven of 16 patients with bone involvement from mammary carcinoma experienced temporary relief of pain and 3 of 5 patients with serous effusions obtained prolonged relief. Five of 13 patients with ovarian carcinoma had a prolonged objective regression of abdominal disease. Dr. L. A. LEONE (Medical College of Virginia, Richmond) felt that systemic administration of thio-TEPA was of extremely limited value, but intracavitary injections might be helpful in the management of malignant serous effusions.

Dr. O. H. WARWICK (Toronto General Hospital) had treated 88 patients with malignant lymphoma, leukaemia, and myeloma with 2-naphthylamine mustard (C.B. 1048; R. 48). The drug had proved useful in about half of the 36 cases of lymphosarcoma and chronic lymphocytic leukaemia, but was of little value in other conditions. Dr. A. ROTTINO (St. Vincent's Hospital, New York) had obtained remissions in 5 of 22 cases of Hodgkin's disease treated with R. 48, and partial remissions occurred in another 12. Five patients refractory to chlorambucil responded well to R. 48.

Summing Up and Verdict

The final session of the conference was devoted to summing up. Dr. P. ALEXANDER (Chester Beatty Research Institute) felt that most of the available evidence supported the view that the main biological consequences of exposure to alkylating agents resulted from damage to deoxyribonucleic acid (D.N.A.) through alkylation of its exposed phosphate groups. The fact that D.N.A. was apparently so resistant to ionizing radiations could now be explained. Dr. STACEY had found that post-treatment with urea revealed considerable damage to single chains of D.N.A. As long as the twin helices of D.N.A. were bound together, multiple single breaks of either chain induced by radiation would remain hidden. Urea split the twin helix lengthwise by disrupting the hydrogen bonding, and the damaged single chains then fell into fragments.

Professor F. BERGEL (Chester Beatty Research Institute) surveyed the whole field of chemical synthesis of alkylating agents, and pointed out that there was still considerable scope for attempting to achieve selectivity of action by modifying the carrier group of the alkylating agent. This might offer the possibility of designing agents to be transported selectively to different tissues or tumours. Professor A. HADDOW (Chester Beatty Research Institute) felt that no compelling evidence had been presented to suggest that alkylating agents had any special chemotherapeutic properties that distinguished them from other classes of compounds. He doubted whether they would have any ultimate or permanent place in the chemotherapy of malignant disease.

Dr. GELLHORN, summing up, said the several compounds discussed had all been claimed to produce some degree of benefit in a variety of malignant conditions but that it was not easy to say what factors made one drug more desirable than another. Such differences as had been demonstrated were probably not qualitative but were similar to those which would lead to the choice of one of a number of preparations of, say, digitalis. The alkylating agents had a definite place in the treatment of Hodgkin's disease, lymphomas, and leukaemias; their efficacy in mammary carcinoma required further classification but might be important. In carcinoma of the bronchus the effects were always transient and there was no good reason to advocate their use as a routine.

MEDICAL ART SOCIETY'S EXHIBITION

The fifteenth annual exhibition of the Medical Art Society is now showing at Walker's Galleries, New Bond Street, London, where it will remain until May 11. We are indebted to Mr. MERVYN LEVY, A.R.C.A., M.R.S.L., for the following notes on the outstanding exhibits.

Critical Appreciation

The two most notable exhibitors this year are J. S. Tomkinson and Audrey Hanson. The one for his compelling vitality, the other for her haunting loveliness. One excites and stirs, the other enchants and lulls. Yet both artists are concerned with springs of elemental energy; Mr. Tomkinson with a young child—Miss Hanson with the sea. In both one feels the urgency of the idea, the triumphant moment of conception from which the paintings have burst in due time as naturally as at birth. There is rather more evidence of the birth pang in Mr. Tomkinson's studies of "Claudia Asleep" and "Claudia," but there may well be some purely physiological reason why women painters so often, it seems to me, manipulate the medium of expression with such a direct and unimpeded fluency. The Claudia pictures, quite small—as indeed is Miss Hanson's "March Sea"—are painted with the knife-edge of nervous gusto. The painter has used a considerable distortion of both form and colour, particularly in "Claudia Asleep," in order to present a sort of "lemon-juice essence" of this subject. It is as though at any moment Claudia might awaken with a crotchety squawk. So great is the dramatic tension in this little picture that one finds oneself on tiptoe for fear the peace of the gallery should be shattered like glass by the brick of an infant's screech. But that of course is the precise nature of the dramatic tension which any haggard father might feel looking down in awe and fear at some capricious infant tyrant taking a momentary refresher.

Miss Hanson's "March Sea" moves one in quite a different way. It is painted in an exquisite filigree style. A silver breaker rolls in with a muffled roar across two overlapping sheets of ghost-grey water that have raced ahead to kiss the cold sands. It is not any particular sea, but all the oceans of the world mingling in the mind and heart of the spectator; all the seas of poetry and imagination curiously blended in this one little picture so miraculously gentle, yet so strong. It is the sea of dreams that we carry with us everywhere—it is not the sea at Blackpool or Bournemouth—but the sea of Shelley and Byron, of Poe and Flecker. It is the true aesthetic ocean, half real, half dream, washing and sounding, in every cove of the heart.

Some Notable Pictures

Nowhere is the presence of "significant form" more genuinely evident than in P. Tuttnauer's "The Pond, Regent's Park." Here the orchestration of colour, shape, and line has been contrived with a superb duality; the subject and its abstract potential have been cunningly blended by a painter of outstanding quality and vision. I also commend with enthusiasm the brilliantly executed sky in A. M. Rackow's "Château Gaillard, Seine"; the devotion, tenderness, and subtle aerial perspective of A. B. Hewlett's crumbling "Italian Stronghold"; Josephine Roth's fine characterization in her portraits "Mrs. Knight" and "The Twisted Smile"; the pure light which suffuses both Bruno Lux's "Orchard" and Humphrey Neame's "Old Farm House"; John Crosley's really damp "Thaw—Berkshire Downs"; Edith Whetnall's watercolour, "Pepe's House," executed with superb clarity and a minimum of the standard tricks of the water-colour trade; and, lastly, G. Konstom's plaster head of Alfred Wolmark, glinting with good humour.

All in all, this is a tremendously interesting and many-faceted exhibition by one of the most progressive and mature art societies in the country.

AUTOMATION AND INDUSTRIAL HEALTH

[FROM A SPECIAL CORRESPONDENT]

There is now some experience of automatic processes in industry. The Ergonomics Research Society therefore chose as the theme for its recent symposium at Bristol a consideration of the "Changing Demands of Modern Work and Control." The question of automation's effects on the industrial worker was one of the major topics discussed, and some of the papers on the likely medical and social consequences are here summarized. The symposium was held at Bristol University from April 8 to 11, and Sir PHILIP MORRIS, Vice-Chancellor of the University, presided at the opening session.

Revolution in Working Conditions

Appropriately enough, the first paper looked forward to the age of automation. Mr. J. CHRIS JONES (Metropolitan-Vickers Electrical Co.) attempted in general terms to foresee the effects of such future industrial changes on the structure of working life. He predicted a change in the role of the worker as radical as that when the crafts became mechanized. The individual worker would evolve, he thought, into a sort of mental craftsman, with almost a free-lance status. The home and the factory would tend to come together again as in the heyday of the crafts. Periods of "on call" work might become typical of automation, and the brain worker might spend much of his time at home, being mainly needed only in the event of an emergency such as a stoppage. Pollution of the environment could be avoided and zoning of industrial and residential districts would no longer be necessary. Canteens for workers, health and welfare departments, rest rooms, etc., might prove to have been only a temporary expedient, characteristic of the "past age" of mechanization.

If Mr. Chris Jones's paper gave promise of the fruits of automation, Dr. G. C. BURGER (medical director, N. V. Philips Gloeilampenfabrieken, Eindhoven, Holland) made it abundantly clear that automation also brought new problems and responsibilities. Ergonomics and industrial health work should go hand in hand, he said, if the goal of using human beings to the best of their powers was to be achieved. Medical men must be included in the ergonomics research team.

While the introduction of automation would lead, he believed, to an increase in wealth and to generally better health, there would also be an inevitable, if paradoxical, rise in sickness and absenteeism in industry, due to the anxiety and uncertainty engendered by the changing demands. Meeting so much rationalization in the factory would make the worker hanker for irrationalism and foster an unpreparedness to accept the inevitable. These were probably the most important effects automation would have on the worker. However, the physical consequences of automation might prove equally serious. Long periods of muscular inactivity, with greater responsibility and mental stress, might lead to an increase in degenerative vascular disease. Coupled with this was the fact that increases in wealth were often accompanied by over-consumption of food and a preference for sedentary "canned recreation" such as watching television. Dr. Burger's picture was of a costly human machine, only moderately extended. It would be necessary to compensate this lack of physical activity at work by greater leisure activity.

That this might become a serious problem was instanced by Mr. K. F. H. MURRELL (University of Bristol), who said that the high incidence of coronary disease in the U.S.A. was causing grave concern there, especially as it was higher in the groups with greater responsibility.

Easing the Transition

Continuing, Dr. BURGER urged the need to study the worker-job relationship. The job must be tailored to the

worker and vice versa, and here a combined physiological and medical approach was important. There were also special problems to be considered, such as that of the worker with well-developed muscles but limited brain-power who might be asked to do light work at high speeds. Social, mental, and political tensions might result from too little physical and too much mental stress. Machines would dictate the speed of work, and the resulting mental stresses called for intensive study by ergonomists. The demands on the worker were not so much in terms of muscle power but in ability to deal intelligently with "information." Thus the ergonomists should direct their attention not to calories and beats per minute, but to "bits" per second, cybernetics, and information theory.

An automatic factory, said Dr. Burger, must also be safe. To this end the industrial physician and the designer should co-operate with the ergonomist in order to make it so. All too often industrial medicine was the forgotten factor here. Finally, he warned against the results of transferring labour without regard to the fact that many groups of workers have their own characteristic traditions, skills, and social standards. Experience in industry had already shown that special problems of adaptation arose in such cases. The progress of industrial automation should be regulated so as to achieve benefit for the largest possible groups without at the same time producing fear and uncertainty. Education could help make the transition to automation smoother by removing misunderstandings, one of the main causes of fear; so also would a sense of social responsibility.

Discussing Dr. Burger's paper, some speakers suggested that automatic factories could be designed so as to demand the expenditure of a certain amount of muscular effort by the workers; it might even be necessary to reverse the search for "easy" controls in order to accomplish this.

Boredom and Density of Machinery

Mr. A. T. WELFORD (University of Cambridge) said the general effect of automation was to reduce the load of fine adjustments while increasing that for sensory vigilance. There was more listening and watching for subtle information. Equipment should therefore be designed so as not to impose too great a strain on the operator or produce too great a demand on him during an emergency.

Boredom was a special problem, as it could not be overcome by using dullards, since in an emergency considerable skill and intelligence might be required. One answer might be to add some operation to the worker's task which was not strictly necessary; another perhaps to employ two people, one for routine operation and the other intelligent enough to deal with emergencies.

Dr. A. LUCAS (Régie Nationale des Usines Renault, Billancourt, France), an industrial psychologist in a factory with a considerable amount of automation, spoke of the need to differentiate muscular from nervous strain. In general, automation lightened the muscular load in all departments of industrial plant, he said. But whether it also led to an increase in nervous strain was difficult to say with certainty, as so far this question had not been investigated rigorously enough. However, since with automation the effect of errors was more serious and the responsibility of the maintenance worker higher, these coming on the top of the added intricacy of the machines might be expected to increase the nervous strain. The increased density of electrical motors and equipment in the factory, and the consequent increase in noise, were bound to impose an extra nervous strain also, if not countered by correspondingly better noise- and vibration-proofing.

Mr. J. A. SAROGROVE (Automation Consultants and Associates Ltd., London) provided a useful corrective to the more starry-eyed thoughts on automation by pointing out that the general rule was for its cost to rise progressively

*"Bit" is short for binary digit and is a measure of information.

with the amount achieved. For complete automation the cost would be infinitely high. There was therefore only a limited useful range for automation. The human operator would always be needed.

THE CONTEMPORARY EMBRYOLOGIST INTERNATIONAL CONFERENCE AT CAMBRIDGE

[FROM A SPECIAL CORRESPONDENT]

Since the time of Aristotle the study of unborn animals has been of great interest to biologists and medical men, for it seeks to provide an explanation of the way in which the complex organs of the normal adult are formed and of how malformations can arise. Until the nineteenth century the majority of embryologists were physicians concerned primarily with the treatment of disease. In recent times, however, embryologists have been drawn from many fields of science, and zoologists, biochemists, and anatomists, as well as practising doctors, have all added their quota to the subject.

Five years ago, to contend with the increasing volume of embryological research, the *Journal of Embryology and Experimental Morphology* was founded, and from time to time its editorial board sponsors international congresses for the discussion of current problems. The third of these congresses was held at the invitation of Professor J. D. Boyd in the anatomy department at Cambridge from April 10 to 13.

Causal Embryology

Modern embryological research is concerned with the underlying causes of development. This contrasts sharply with the detailed descriptive studies that characterized research in the last century and still form the major fare of the present-day medical student. It is now known that certain tissues cannot develop in isolation; the presence of some other specific tissue is necessary for their differentiation. For example, the neural plate will not arise and complete its development unless mesoderm and notochord lie beneath it. It is therefore accepted that these tissues influence the neural plate, and this phenomenon is known as neural induction. Such causal relationships can be demonstrated by taking tissues from their normal positions and grafting them into other parts of the embryo. Embryologists are also concerned with the possible chemical nature of embryonic inductions, although perhaps less so than they were 20 years ago. At that time they were searching for a single chemical substance which they believed might be responsible for neural induction and which was thought to be produced by a part of the embryo termed "the organizer." The search for this elixir-like substance appears to have been largely abandoned.

Biochemical changes in embryos are also widely studied nowadays. For example, protein metabolism can be investigated by administering amino-acids which include radioactive atoms. Another important aspect of embryology is the study of regeneration; such work is clearly related to processes of great medical interest such as the healing of wounds and nerve regeneration. Unfortunately the mammalian embryo, secluded as it is within the uterus, is a very difficult subject for the experimenter, and much of our knowledge of causal embryology is derived from the study of the chick embryo and from that of the aquatic eggs and tadpoles of amphibians. However, the basic processes of development in mammals are unlikely to differ greatly from those in other vertebrates.

Embryonic Induction and Differentiation

These research trends were fully reflected in the topics discussed at the conference. Several papers were directly concerned with the problems of embryonic induction. Dr. P. TSCHUMI (Cambridge) dealt with the interaction between

ectoderm and mesoderm during the growth of the limb-buds in the tadpole of the South African clawed toad, *Xenopus laevis*. First, he had separated the epidermis from the underlying mesoderm. The tissues could then be grown separately, or could be recombined with each other or with different tissues. He found that provided the epidermis was present the limb-bud would form a limb, but if the epidermis was absent a complete limb never developed. Dr. P. SENGEL (Paris) described his experiments on the growth of the feather rudiments in the chick embryo. It was found that at one stage the epidermis needed a stimulus from the dermis in order to develop properly; in the following stage the mesoderm became dependent on the influences from the overlying ectoderm. Professor T. YAMADA (Nagoya, Japan) gave an account of experiments in which the chemical nature of neural induction was studied. After establishing that lipids were not the substances involved he presented evidence to suggest that the protein component of ribonucleoproteins played a major role.

The factors controlling the differentiation of the embryonic eye were considered in a paper sent by Dr. G. V. LOPASHOV (Moscow), who was unfortunately unable to be present. His report drew attention to the importance of spatial relationships between developing cells of the retinal and pigment layers. His observations were made on tissues growing *in vitro* and in transplants, and he found that if the cells were overcrowded the pigment layer failed to develop, whereas if the cells were too widely separated the retina did not form.

Sites of Protein Synthesis

Protein metabolism was considered by Professor C. H. WADDINGTON, F.R.S. (Edinburgh). After immersing embryos in solutions of radioactive amino-acids he found that these compounds were incorporated more rapidly into some regions of the embryo than into others. For instance, they were taken up first into the cells around the blastopore lip and only later were they found elsewhere. The radioactive amino-acids had become concentrated mainly in the nucleoli and around the nuclear membrane. Professor Waddington suggested that these regions were the main sites of protein synthesis.

Studies of Regeneration

Some remarkable experiments were reported by Dr. D. R. NEWTH (London), who dealt with the regeneration of abnormal structures. The tissues with which he was mainly concerned were supernumerary limbs in newt larvae. These had been previously induced by implanting a nasal placode* into the flank region. These limbs tended to possess abnormal numbers of digits. Dr. Newth amputated them through the humerus, and in many cases they regenerated; if the amputation were repeated they usually regenerated again. Each new limb which formed was not, however, a replica of the one it replaced; the numbers of digits became more nearly normal with each regeneration, and after the second amputation a normal limb with the correct number of digits usually developed. Dr. Newth suggested that the influence of the surrounding flank ectoderm might perhaps play a part in this extraordinary process.

It was pleasing to be reminded of evolutionary problems during the paper by Professor E. C. WOLFF (Paris). It is well known that a complete fibula is seldom found in modern birds, and Professor Wolff was able to show that this may be because not enough cells are present in the normal limb bud before the various parts of the limb begin to form. He found that the limb bud was able to develop a complete fibula if extra prospective limb-tissue was grafted into it.

The papers mentioned above were, of course, only a few of those read at the Conference. Moreover, one afternoon was devoted entirely to research demonstrations. The conference provided an ideal opportunity for the exchange of ideas between embryologists from many different countries.

Correspondence

Because of heavy pressure on our space, correspondents are asked to keep their letters short.

Foetal Post-maturity

SIR,—I hesitate to cross swords with such a senior and respected obstetrician as Professor F. J. Browne, but I feel that his paper on foetal post-maturity and prolongation of pregnancy (*Journal*, April 13, p. 851) has confused rather than clarified the problem.

It is well known that even where pregnancy and labour are clinically normal the foetus may die before, during, or soon after labour—"unexplained" deaths.¹ In primigravidae such deaths are least common in the very young and become steadily more frequent with increasing age of the mother. They are most common when pregnancy lasts longer than 42 weeks. The incidence of dystocia also increases with increasing age and length of gestation. These facts suggest that the uterus becomes steadily more inefficient as the mother gets older, both as regards placental function and labour. The studies of Walker and Turnbull,² referred to by Professor Browne, have shown that the passage of oxygen from the mother to the foetus decreases steadily from the 41st week onwards, and Turnbull³ has shown that, in apparently healthy primigravidae over the age of 30, the oxygen content of the umbilical vein often reaches dangerously low levels by the end of the 42nd week.

In the University of Aberdeen midwifery department clinic, between the years 1938-47, there were 46 "unexplained" deaths in booked primigravidae and half of them occurred after the end of the 41st week. In 40% of the cases death occurred before the onset of labour. Of 73 other deaths attributed to the effects of difficult labour, 46% occurred after the end of the 41st week.

Some advocate expectant treatment and caesarean section if foetal distress develops, but, as I have already shown, many of the deaths occur before the onset of labour, often before the patient reaches hospital. Even if she is under observation in hospital the foetal heart may stop suddenly and with little, if any, warning. It is clearly difficult to anticipate the death if it occurs at or about the expected date of delivery, but induction of labour to avoid undue prolongation of pregnancy seemed to us worth while. Our method initially was to rupture the membranes in the 42nd week routinely in primigravidae of 25 years or more, but the treatment spread to some extent to the younger age groups (doubtless, in time, tests for placental function may render treatment more selective). In some cases the liquor amnii was found to be heavily stained with meconium, indicating that the oxygen supply to the foetus was probably dangerously low. Sometimes this led to immediate caesarean section and in others to a shorter trial of labour. The results of this regime have already been described,⁴ and the following figures give the latest results:

Age groups:	Perinatal Mortality per 1,000 Births					
	15-19	20-24	25-29	30-34	35+	All Ages
1938-47	36	35	57	76	101	45
1953-6	40	26	28	17	25	28

They show that the trend of perinatal mortality with age has been changed to such an extent that the rate in primigravidae over 30 is now lower than in those under 20. The rate in very young primigravidae is unaffected by this regime, since in this group prematurity, accidental haemorrhage, and malformations account for most of the deaths, and unexplained intrauterine death and birth trauma are relatively unimportant. Undoubtedly artificial rupture of the membranes will increase the risk of intrapartum infection of the foetus, but, as our results show, this danger is small compared to the benefits of the method.

The present policy—namely, routine surgical induction of labour in the 42nd week and the greater use of caesarean section, instituted in 1952—has improved our results so much that we are convinced that the avoidance of prolonged pregnancy helps to decrease the number of foetal deaths due to placental insufficiency.—I am, etc.,

Aberdeen.

SIR,—Many of the younger obstetricians will be sorry to find that Professor F. J. Browne (*Journal*, April 13, p. 851) has reopened the old controversy on post-maturity, suggesting that any danger to the foetus would come from an increase in size with potential disproportion. He somehow discounts the classical studies of Walker, who would appear to have shown conclusively that danger arises from diminishing oxygen tension in foetal arterial blood. He quotes foetal mortality statistics from various hospitals without reference to whether they serve a closed community or admit solely abnormal cases. He gives evidence to show that in certain countries prolongation of pregnancy is extremely uncommon. He also mentions various complications that may ensue when cases are unwisely selected for surgical induction of labour, suggesting that the disorders of uterine action so commonly found with post-maturity are due to this unwarrantable interference. In short, he tries to convince us that post-maturity is merely a process of slow maturation, and that anyway it is remarkably rare.

It is perhaps a pity that he does not discuss the reason for the onset of labour; although it remains largely obscure, it seems certain that it is not caused by the perfection of foetal maturity, although its usual association with this has been fortunate for the continuation of the human race. He does not mention the fact that graphs for foetal weights show a levelling off followed by a decline after the forty-second week, which is in line with the clinical observation that post-maturity is often most dangerous in cases which do not show any increased foetal growth. These are cases which frequently show the morbid changes of post-maturity, the dry foetal skin, the scraggy lean physique, and the absorption of the liquor amnii. The association of poor uterine action with these cases is surely due to the fact that the post-maturity is caused by poor uterine action of pregnancy with imperfect formation of the lower uterine segment, so that prolongation of the first stage of labour is almost inevitable.

It is well known that pregnancies may appear to be prolonged owing to delay in fertilization or embedding of the fertilized ovum. It would be bad obstetric practice to attempt an induction on every woman who believed that forty-two weeks had passed since her last period. But in pregnancies that have been followed carefully from the early weeks it would be foolish and retrograde to adopt a complacent attitude to the steadily falling foetal oxygen tension that accompanies post-maturity.—I am, etc.,

Birmingham, 15.

Hospital Confinement

SIR,—Dr. J. P. O'Dwyer (*Journal*, April 20, p. 947) is right up to a point. The safety of the mother is paramount. All other human and psychological considerations take second place. However, I suggest that it need not be safer for any woman to be confined in hospital, only more convenient. No general practitioner should do domiciliary midwifery unless he has at his command the same expert help as has the resident house-surgeon in hospital. With modern communications a woman can be as safely moved from her home to the operating theatre of a hospital as from the labour ward to the theatre in hospital. If she is unfit to be moved, expert help goes to her in bed whether at home or in hospital.

Obviously, if you anticipate trouble, you will book a bed for the patient in hospital for everyone's convenience; but the rules need not be hard and fast. A primigravida anxious to have her child at home will be told that she may make arrangements for a home confinement, but that if the labour gives any cause for anxiety it may be more convenient for her to be delivered in hospital. This in turn means that there must be real co-operation between general practitioner and hospital. In other words, every domiciliary confinement concerns the hospital as well as the general practitioner. The shame is that domiciliary confinements are being actively encouraged before this co-operation is secured.—I am, etc.,

Cambridge.

CLEMENT W. WALKER.

SIR,—Dr. J. P. O'Dwyer asserts (*Journal*, April 20, p. 947) that it is so much safer to have a baby in hospital than at home, and incidentally wonders how many doctors' wives are confined at home. I know he has had experience of working in maternity hospitals, but wonder what experience he has of general practice. As to his first point—is it so much safer? The same issue has a paper on the umbilicus as a reservoir of infection in a maternity hospital (p. 925). Surely it is recognized that cross-infection is a problem that constantly has to be tackled in hospital, and yet it hardly exists in even the poorest home.

We are lucky in having an excellent maternity hospital locally, and as our third child, born in the 27th week of pregnancy, has been successfully matured there we have every reason to be grateful for the hospital's special care. But he was booked for home delivery with our G.P. until he considered hospital necessary, and the other two children were born happily at home through choice. I am a G.P. My wife was a laboratory technician concerned with bacteriology in a laboratory attached to a general and maternity hospital. I have noticed experienced nurses decide not to have their second baby in hospital. As to what most doctors' wives do, there is no guarantee that their choice is the best one. By training, a doctor is still largely concerned with the treatment of abnormality, rather than the study of normality. It would be illogical to send one's child to a reformatory just in case it turned out to be a delinquent (even though the cost per boy is higher than Eton, I understand).

I suggest that, instead of this home v. hospital becoming an undignified battle of vested interests, we all keep our sense of proportion. I feel the G.P. should discuss the various points for and against the two places and let the mother decide. I have not seen much attention given to the mother's wishes in all that has been written on this "battle." In case you think I have a vested interest also, I do not now do obstetrics, although I believe that home is the normal place for a normal confinement.

Incidentally, my wife would have written to disagree with Dr. O'Dwyer, but she is feeding the baby, and anyhow she thought other doctors would be able to reply more adequately. And she is probably right.—I am, etc.,

York.

PAUL ROWNTREE.

Cardiac Arrest During Trichlorethylene Anaesthesia

SIR,—As one who has always found trichlorethylene a most useful and safe anaesthetic agent, I was interested to read the article by Drs. Walter Norris and Peter Stuart (*Journal*, April 13, p. 860). I have always thought that this drug should not be used for anaesthesia without full premedication and a thiopentone induction, and was therefore particularly interested to read that in the four personal cases of cardiac arrest occurring during induction no thiopentone had been given. In three of these premedication was with atropine alone. This suggests that trichlorethylene was being used to induce anaesthesia. In the cases surveyed from the literature the use of thiopentone is mentioned in only one. While I am aware that this is not common to all reports, I would be glad to know the opinion of the authors and other anaesthetists on the protective role of thiopentone, at least during induction. Finally, with

reference to air embolism, in my experience this does occur suddenly, and, if small, I believe is consistent with equally rapid and complete recovery.—I am, etc.,

London, E.C.1

ROBERT I. W. BALLANTINE.

REFERENCE

¹ Committee upon Deaths Associated with Anaesthesia. *Anaesthesia*, 1956, 11, 194.

SIR,—I have been using trichlorethylene for some years as a non-inflammable supplement to nitrous oxide and oxygen anaesthesia, and would regard it as suitable for almost all types of anaesthesia.

I have not seen a case of cardiac arrest during trichlorethylene anaesthesia, but on two occasions, however, using a Walton machine with a Rowbotham's "trilene" bottle, the patient has suddenly lost colour with diminished respiratory effort. The trichlorethylene was discontinued and the patient quickly returned to near normal—i.e., her colour was fair, but she felt dizzy and sick. In these cases I feel that no arrest had taken place, but certainly a diminished cardiac output. On each occasion the trichlorethylene had been in the Rowbotham's bottle for a week.

Now, Sir, this I maintain is the cause of cardiac arrest during trichlorethylene anaesthesia—i.e., that the trichlorethylene is not fresh and some deterioration has taken place. I feel certain that some, if not all, cases reported by Drs. W. Norris and P. Stuart (*Journal*, April 13, p. 860) were due to this cause. I never use trichlorethylene that has stood for any length of time other than in its tin container.—I am, etc.,

Ecclestone, Staffs.

E. R. SINTON.

SIR,—I was interested to read the paper on cardiac arrest during trichlorethylene anaesthesia by Drs. Walter Norris and Peter Stuart (*Journal*, April 13, p. 860). From my experience of this anaesthetic agent used in small children undergoing cardiac catheterization, I have good reason to dislike and fear what appears to be its effect on myocardial excitability. In 1955 I described a case of ventricular fibrillation in Fallot's tetralogy during cardiac catheterization under trichlorethylene. This case fortunately resumed sinus rhythm after treatment with procaine amide. At Sully Hospital we had a number of lesser, but very disturbing, episodes of ventricular arrhythmia during catheterization when trichlorethylene was used, so that we eventually refused to accept this anaesthetic for this purpose. Our definite impression of the higher incidence of troublesome ventricular arrhythmia during the use of this agent was confirmed by the cases in which the occurrence of myocardial excitability in a previously tolerant heart closely followed the administration of the drug and, again, by the fall in the incidence when trichlorethylene was abandoned.

Apart from the anxiety we felt for these patients, the frequency of the runs of ventricular tachycardia greatly impeded the efficiency of the catheterization. It appeared that small amounts of trichlorethylene were sufficient to have this effect, for these cases had rectal bromethol as a basal anaesthetic and trichlorethylene was only added when necessary to ensure a quiet child. As already mentioned, the increase in myocardial irritability was frequently noticed to be closely related to the first administration of the drug. All our cases had continuous E.C.G. monitoring, and it is likely that the tendency to ventricular arrhythmia which we observed passes unnoticed in many cases. The matter may need further investigation, but in the type of case we were dealing with our only desire was to avoid the effects described.—I am, etc.,

London, S.W.3

Premedication in Children

SIR,—The article by Dr. R. Goulding and his colleagues (*Journal*, April 13, p. 855) is a most provocative one, as doubtless was intended. As one of the workers charged with drawing unfair conclusions from their results, there are some points which I would like to take up with them.

As they themselves admit, the assessment of anxiety in a child is most difficult, and certainly behaviour is no measurement. I am sure that the psychologist in their team would be the first to admit that the apparently controlled child is probably suffering more emotional upset than the child who openly resists. In my original work¹ a trained psychiatric worker visited all the cases in their own homes after discharge from hospital and made an independent report. This showed that methylpentynol was at least as effective as the barbiturates in allaying fear of operation. To state, as they do, that neither a barbiturate nor chlorpromazine is more effective than a placebo can only mean that the dosage used by them was inadequate. And this is just where methylpentynol is so useful—it can be given in large enough dosage without danger of respiratory depression or uncontrolled behaviour. I would suggest that they use just twice the dose mentioned in their article.

I would also suggest a good way of assessing its value. Many of their cases will have to return for a further session in the "gas room." I am sure that a careful follow-up of these children will show a difference between those properly sedated and those without anything. And may I criticize their technique of removing all children, especially the younger ones, from their mothers to wait in a common waiting-room till their turn comes? A similar incident is indelibly fixed in my memory, which is perhaps why I am so keen to prevent other children suffering it. The mother should surely stay with the child until it has lost consciousness, which is one advantage of out-patient anaesthesia. If the mother is "too nervous" I would suggest that she receives a good dose of methylpentynol.

Another method of assessment I would recommend is the opinion of a good ward sister, which admittedly could not come within the scope of their trial. But I must record the insistence with which my ward sisters maintain that methylpentynol gives just the right amount of sedation without troublesome after-effects. Only this last week I had to anaesthetize a boy who had already received many anaesthetics at another hospital. His comment, unasked for, in the anaesthetic room was, "I have never felt like this before; I don't mind it to-day." In any case I should be very unhappy if 20% of my children, even the young ones, were "turbulent" at even an out-patient gas session. If this figure can be reduced slightly I am sure it is worth while, provided that safety is maintained.—I am, etc.,

Worthing.

F. R. GUSTERSON.

REFERENCE

¹ Gusterson, F. R., *Lancet*, 1955, 1, 940.

SIR,—Dr. R. Goulding and his colleagues (*Journal*, April 13, p. 855) have made a significant and much-needed contribution to the study of premedication in children. I was particularly impressed with the results of their analysis of behaviour in relation to age (figure 7), and take the liberty of offering some further factual data on this point.

Several years ago I set out to investigate the effects of ethyl chloride, when given by the open method, with the object of obtaining information bearing on the safety of this "old-fashioned" procedure. This investigation was not designed to test the efficacy of the premedication used. However, the behaviour of the children was noted as a matter of subsidiary interest. These behaviour patterns now seem worthy of recording, since they can be considered in conjunction with those of the carefully controlled experiment to which reference has been made.

I will refer to figures from a single homogeneous group—those for children about to undergo operation for tonsillitis and adenoidectomy. These children all came from the same ward, where they had all been given quinalbarbitone, $\frac{1}{4}$ gr. (50 mg.), by mouth pre-operatively (the reasons for, and the merits and demerits of, this oversimplified premedication regime do not concern us now). The children all came to the same anaesthetic room, where they received the attentions of the same nurse and the same anaesthetist (myself). Their behaviour was classified as follows: A: arrived asleep, and continued so; B: arrived awake and calm, and showed

no disapproval in any way of the experiences to which they were subjected; C: arrived awake and calm, but became a little upset during the induction of anaesthesia; D: arrived awake and calm, but became violently antagonistic to induction; E: arrived awake and already showing disapproval of their new environment. The numbers of children falling into these categories are tabulated below.

Age	Category				
	A	B	C	D	E
3	7	38	13	3	2
4	12	58	9	3	2
5	22	158	14	3	5
6	13	154	12	1	3
7	15	123	13	2	—
8	2	97	4	2	—
9	2	75	6	1	—
10	2	46	4	2	—

Making the same age division as that used by Dr. Goulding *et al.* for their dental cases, we note that in the 3–6 age group 54 (10.2%) out of 532 arrived asleep. In the 7–10 age group only 21 (5.3%) out of 397 were in a similar state. This difference is significant ($\chi^2 = 6.6$, $p = 0.01$). On a body-weight basis the younger children undoubtedly received a larger dose of sedative than the older ones, and the hypothesis could be put forward that the difference in results was due to this. However, in the absence of controls, giving comparable figures for unpremedicated children, no more can be said. Bearing in mind both the relatively greater dose of sedative used for the younger children in my own series, and the findings of Dr. Goulding *et al.* in theirs, it is of greater interest to consider the behaviour of the 854 children who came to the anaesthetic room awake. In the 3–6 age group 70 (14.6%) out of 478 children expressed disapproval of their experience in one way or another. The corresponding figures for the 7–10 age group are 35 (9.3%) out of 376. This difference is also significant ($\chi^2 = 5.1$, $p = 0.02$). And the discrepancy with respect to disapproval is even greater if we compare the 3–4 and 9–10 age groups (25% : 9.7%, $\chi^2 = 9.7$, $p = 0.002$).

It seems to me that the work of Dr. Goulding *et al.* has not only re-emphasized the futility of uncontrolled experiments in this field but also raised a big issue, at least where the value of premedication judged by objective methods is concerned. An experiment of a similarly excellent design, to evaluate the efficacy of premedication for in-patient children, might merely serve to remind us of the importance of the correct timing of administration. But it might also reveal that some of the drugs in general use for small children, when given in dosage insufficient to cause sleep, are not nearly so effective as is commonly supposed.—I am, etc.,

Hillingdon, Middlesex.

H. J. V. MORTON.

Prevention of Tetanus

SIR,—We are grateful for the comments on our notes and recommendations (*Journal*, March 16, p. 639). Dr. W. A. Reynard (*Journal*, April 6, p. 818) mentions our acceptance of 1,500 international units as the routine protective dose of antitoxin in a non-immune individual, and draws attention to Dr. L. S. Kind's article (*Journal*, March 2, p. 498) where an increase to 10,000 was suggested. Dr. M. R. Madigan (*Journal*, March 23, p. 706) also favours a larger dosage than we advised—i.e., a minimum initial dose of 3,000 units for adults and 1,500 units for children. This correspondent's recommendation may partly be based on articles published before 1950 to which he makes reference: no mention is made in his letter of the change in the value of the international unit on July 1 of that year. The present unit is equivalent to the U.S.A. unit and is twice the potency of the former (1928) international unit.

A prophylactic dose of 1,500 units is sufficient for routine use, and is still the initial dosage advised for non-immune

Service personnel and their families. This routine is based on the advice of a committee of Service and civilian experts. Two more similar doses may be given at weekly intervals if the surgeon in charge of the case considers this necessary; while this procedure may afford better protection than one large dose, it carries a slight risk of accelerated serum reaction after the third dose. A prophylactic dose of antitoxin is also advised before any fresh surgical interference with the wound.

There is a long tradition of injecting as a routine 1,500 units or less, including Army experience in two world wars. Nevertheless, some doctors, particularly in the U.S.A., prefer a dose of 5,000 or even 10,000 units. One reason for this preference is fear of the accelerated elimination of serum. As stated in our paper, certain patients may have become sensitized to horse serum, with the result that if they are given it again at some future date they may eliminate it so rapidly that protection is inadequate. This is now recognized as one of the main troubles in connexion with the repeated administration of serum. Unfortunately, the fall in blood antitoxin levels may be so rapid in sensitized individuals that there is little, if any, advantage to be expected from the higher dosage. There is, however, the possibility that in rare instances 10,000 units might offer some advantage in heavily contaminated wounds by neutralizing tetanus toxin, which may form very rapidly: the action of the serum would then be therapeutic rather than prophylactic.

With regard to the dosage of antitoxin for children, we favour uniformity in dosage for persons of all ages, as is recommended officially for British Service personnel and their families. The volume of refined serum injected for the 1,500 unit dose is quite small, and reactions would not be appreciably lessened by reducing the volume of the dose. There is thus no point in reducing the dose for children and some advantage in having the same dose for everybody.

Dr. E. D. B. Wolfe (*Journal*, April 13, p. 885) inquires about the best procedure to adopt when immunizing with diphtheria-tetanus-pertussis and T.A.B.T. vaccines. We shall first compare the recommendations for triple prophylactic with those for tetanus toxoid alone. The usual primary course for triple prophylactic is three injections at intervals of one month to six weeks in the first six months of life, say, between the second and fifth months; this should be followed by a boosting dose six to twelve months later. It will be recalled that we state in our article: "For primary immunization three 1-ml. doses of tetanus toxoid are injected subcutaneously or intramuscularly at intervals of 6 to 12 weeks between the first and second injections and 6 to 12 months between the second and third injections." Thus, in approximately the same period of time, four injections of triple prophylactic or three injections of tetanus toxoid are advised in the respective schemes for these two preparations. The recommendations in respect of tetanus in connexion with the schemes fall into line if the second dose of triple vaccine is disregarded from the tetanus standpoint. We would suggest that, in recommending a three-dose course of triple prophylactic for the early months of life, the makers have been more concerned about obtaining useful protection against pertussis: a two-dose rather than a three-dose course would have sufficed against tetanus. The first and third doses of triple prophylactic (omitting the second) could be expected to give similar titres of tetanus antitoxin to those which result from two doses of tetanus toxoid by itself in later life. In neither instance must the further injection six to twelve months later be disregarded, as it ensures much higher titres of circulating antitoxin. T.A.B.T. does not give rise to any difficulty, as the intervals between the three doses now recommended in the Forces are similar to those usually advised in this country for tetanus toxoid. The recommendations for T.A.B.T. and tetanus toxoid fall into line.

It is of course impossible to give exact instructions to cover every possible contingency, but the definitions already given in our article, supplemented by this letter, should serve as a useful guide to procedure. In conclusion, we would again urge active immunization, which is the ideal method

for the prevention of tetanus. This should preferably be begun in infancy, when a combined preparation is virtually essential to keep the number of needle-pricks within reasonable bounds.—We are, etc.,

H. J. PARISH.
L. J. M. LAURENT.

Beckenham, Kent.

SIR,—I have read the recent correspondence about tetanus prophylaxis with interest, and should like to put forward a suggestion for the comment of other readers. In my view all patients treated for a minor injury should be given an injection of 1 ml. of tetanus toxoid. The only exceptions should be patients with deep puncture wounds or other injuries known to carry a special risk of tetanus. These cases would be treated in the usual way with anti-tetanus serum.

By this system a fairly large proportion of the community would quite soon become actively immune to tetanus. Those whose occupations carry a high risk of minor injury would tend to receive frequent injections of the toxoid, and would therefore achieve a high antibody level. No special clinics or other arrangements would be needed, and the main population at risk would be protected.—I am, etc.,

London, N.6.

JOHN W. MYLES.

Athlete's Foot

SIR,—The extent of communal disability produced by athlete's foot well merits the space devoted in your issue of March 30 to two excellent articles and an annotation on the subject. Mr. J. C. Gentles in his article (p. 746) concludes that any measures for the control of infection must be taken by the individual. The formidable list of personal precautions given in your annotation (p. 755) would surely dampen the ardour of any but the most fastidious and over-zealous sufferer. Personal measures, if they are to be generally effective, must be simple. Something in the nature of a fungicidal soak, used routinely in sock washing, and of such a nature as to remain effective during the wearing period of the socks, might prove more effective and more popular than the application of sticky ointments and chalky powders.—I am, etc.,

Chester.

T. D. S. HOLLIDAY.

SIR,—Thirty years ago half my practice was with the boys of one of our great public schools, and I saw a good deal of ringworm of the groin and ringworm between the toes. At one time there were a number of cases of ringworm of the toes in a particular house, and the housemaster rather reluctantly gave me permission to examine the feet of all the 40 boys in his house. None of the little boys were affected, but among those from puberty onwards the majority had some degree, mostly extremely slight, of fissuring or scaling in the cleft between the 4th and 5th toes, and in all of these spores were found on microscopic examination. A little trouble was found in the matron's toes and a considerable amount in the housemaster's—much to his indignation. In most of these cases there were practically no symptoms, and, apart from the possibility of infecting others or developing a phase of more active inflammation oneself, the condition was of no importance.

It may well be that some individuals are more susceptible to this infection than others, and that there are many symptomless carriers. And of those that do get symptoms some will go to a doctor, but probably many more will keep the trouble to themselves and say nothing. I feel sure from my school experience that this infection can be passed round the members of a household. But quality of skin is also important. Boys before puberty were hardly ever affected, and I suppose their skin has a different quality from that of adults. I am told that the same trouble does occur in girls' schools, but much less frequently. This again may be because girls' skin is more like that of small boys and not so coarse as men's. Or is it because girls are cleaner in their habits?—I am, etc.,

Jersey.

N. A. SPROTT.

Sir Victor Horsley

SIR,—May I congratulate you and their authors on the most excellent centenary essays (*Journal*, April 20) on Sir Victor Horsley, which bring back vividly the memory of that eager and masterful personality? I was his house-surgeon in 1902, the year he was knighted, and he was a frequent visitor in my house in Harley Street when Wilfred Trotter, then his private assistant, was living with me. The deftness and accuracy of his operating on the brain were something one could never forget, and he would coax a tumour from the thyroid as if by a gentle magic. His ambidexterity naturally helped him in this, and he seemed to expect the same gift in others. I remember when I fumbled over tying an artery with my left hand, my right hand being occupied with a Spencer Wells, he advised me to have my eyes tested for astigmatism. With abdominal operations, however, he was more slapdash, having none of the meticulous patience of a Barker. He was always glad to leave other operations to his juniors, and I imagine few house-surgeons would have had the opportunity that fell to me of amputating a thigh single-handed.

He got through more work in a day than anyone else I have known, making use of every moment. Guests he entertained at breakfast, dashing out in the middle to develop photographs. Yet, with all his swiftness he was never hurried. Ward visits were accomplished in half the usual time, but the concentrated attention he devoted to each patient gave him the impression that he was his sole care in life, and he would arrange their pillows with a tender deftness that was the envy of the nurses. A hospital story illustrates this remarkable combination. When an assistant surgeon he had to see out-patients at half-past one, an occupation that normally took two or three hours. His senior, Christopher Heath, who used to chide him on not giving enough time to his hospital work, arrived for his ward visit one day at two o'clock to find Horsley leaning against the mantelpiece in the staff room. A tirade followed, culminating in the words: "And here I find you loitering when you should be seeing your out-patients." Horsley quietly replied: "I've seen them all already," and left for his laboratory.—I am, etc.,

Elsted, Sussex.

ERNEST JONES.

SIR,—The elephant's brain mentioned by Mr. Ernest Sachs in his interesting reminiscences of Sir Victor Horsley (*Journal*, April 20, p. 903) was certainly not the only one he received.

Colonel Martin-Leake, who won a bar to his Victoria Cross in the first world war, was after the South African war appointed as medical officer to the Bengal-Nagpur railway. In addition to being a very skilful surgeon and administrator, he was a notable shikari. On one occasion, in 1907 he was pursuing a wounded rogue elephant which had killed a man. After some six hours' tracking he found himself suddenly confronted by the infuriated animal, some 10 ft. 6 in. (3 m.) tall. He administered the *coup de grâce* and spent nine hours the following day in removing the brain, which he sent to Sir Victor in a stew-pan. He tells how he had to attach a rope to the trunk and have some twenty lusty coolies pulling before the vertebral ligaments went with a snap and the head was freed. One of the feet of this famous animal was mounted and is now in the officers' mess of 5 Field Ambulance, the unit to which Leake was posted in 1914 and with which he was serving when he obtained the bar to his Victoria Cross.—I am, etc.,

Crookham, Hants.

R. E. BARNESLEY.

SIR,—Sir Victor Horsley lived in our field ambulance in the forward area for a few days before he returned to Amara, where he died. One day when I came into lunch I mentioned that the last "mahela" (*anglicised* barge) which came up the river was loaded with "poshteens for the Piffer Brigade" (sheepskin coats for the Punjab Frontier Force). He said he would go at once to verify that statement, which

meant walking up or down the river to cross over. We tried to dissuade him in the heat of the day, but he said he had nothing to fear from the sun, as he was not a "drunkard" as we were. In those days we were very short of drinks except Tigris water. I do not doubt this example of the muddles in Mesopotamia was added to the notes which he did not live to pass on, but am pretty sure it was recorded.—I am, etc.,

Camberley, Surrey.

C. H. REINHOLD.

Safety Factor in Car Design

SIR,—Dr. Gareth R. Davies (*Journal*, April 20, p. 949) should not condemn three-wheeled cars because he has seen one turn over. Four-wheelers often turn somersaults, according to press reports, though I have never seen one do so. It is only a question of driving.

Strangely enough, since quite early days the most important safety factor in design for independently driven cars on public roads has been the one most completely neglected—namely, the driver's view. For many years, though the mode has lately changed somewhat, it has been the fashion to build up a long, high bonnet in front of the driver, who is seated as low as possible. To these disabilities are added obstructions and blind spots caused by low roof, thick pillars, mirrors, mascots, etc., on eye level, which may well account for many of the apparently inexplicable collisions and runnings-down. An extreme example occurred a few years ago, when, in the account of an inquest on a little girl killed in the street, the driver of the car concerned was reported as saying that if she had only been a foot or so taller it would not have happened, as he had not seen her. In this respect the latest three-wheelers seem admirable, and, since their drivers are not protected by several feet of steel in front of them, they are perhaps less likely to take risks which endanger others as well as themselves.—I am, etc.,

London, N.W.8.

R. J. CLAUSEN.

Speed Warning Device

SIR,—I was pleased to read the letter of Dr. G. E. Pinkerton (*Journal*, April 6, p. 820). My letter (*Journal* March 23, p. 705) was a letter of introduction to the idea of a device. Between 1932 and 1938 several patents were taken out. The one he mentions must have escaped the oblivion of the rest. A description of a device recently patented will, I trust, answer some of the questions he raises. First let me say the modern car has many contrivances which are concerned with its safety and that of its occupants. Since the casualties among pedestrians, and near pedestrians—the cyclists—are more than 50% of the total (car drivers and occupants only 22%—see leading article, "Road Accidents," *Journal*, March 30, p. 753), I would suggest that it may become necessary to get accustomed to the idea of a speed warning device. I agree with his suggestion that in many areas 40 m.p.h. is reasonable, and I keenly appreciate his further statement "whereas half that speed is *deadly dangerous* . . . in many other built-up areas" (my italics). With that pregnant phrase he destroys much of his argument and justifies the imposition of a warning device in these areas. The description and purpose of this device is to warn the driver of his speed, by means of two changing lights opposite to him on the dashboard, and, by a duplication of these lights on the roof of his car, to warn the external observer that he is aware of his speed. As with all other safety units on his car, it should be compulsory, and will require to be switched on in a protected area. A white light indicates that this has been done. At about 32 m.p.h. a red light also appears, and at about 37 m.p.h. the white light goes out, leaving only the red light. Changing lights are as necessary on this unit as are the intermittent trafficator lights and zebra crossing beacons. I am concerned with the humanity side, not the legality, though I would like to say more than space permits on this aspect.—I am, etc.,

Bradford, Yorks.

ALLEN GLENN.

Obituary

J. P. LOCKHART-MUMMERY, M.B., F.R.C.S.
F.A.C.S.

Mr. J. P. Lockhart-Mummery, consulting surgeon to St Mark's Hospital for Diseases of the Rectum, died at Hove, in his sleep, on April 24. He was 82 years of age.

John Percy Lockhart-Mummery was born on February 14, 1875, the son of J. Howard Mummery, a distinguished dental surgeon and research worker and former president of the Odontological Society. From the Leys School, Cambridge, he went on to Caius College, Cambridge, where he took second-class honours in the Natural Sciences Tripos and where for a time he was assistant demonstrator of anatomy in the medical school. Like so many Cambridge students at that time he went to St. George's Hospital for his clinical training, where he won the Thompson gold medal and qualified in 1899. After qualification he held the posts of assistant house-surgeon, house-physician, house-surgeon, and assistant in throat department at St. George's, took the F.R.C.S. in 1900, and graduated M.B., B.Ch. at Cambridge in 1901. For a time he worked as demonstrator of operative surgery at St. George's, but his first honorary appointments were at the King Edward VII Hospital, St. Mark's Hospital, and the North-East Hospital for Children (now Queen Elizabeth Hospital for Children, Hackney). Lockhart-Mummery soon made a name for himself as an able surgeon, and it was not long before he began to specialize in rectal surgery, though for many years he maintained an interest in the surgery of children's diseases. In 1904 he was Hunterian professor at the Royal College of Surgeons, his Hunterian lecture being on "The Physiology and Treatment of Surgical Shock and Collapse." He was also Jacksonian prizewinner at the College in 1909.

Lockhart-Mummery wrote easily and well and was in demand as a contributor to textbooks. In 1903 he published a paper on the diagnosis of tumours in the upper rectum and sigmoid flexure by means of the electric sigmoidoscope and four years later he described in this *Journal* an operation for removal of the entire rectum and neighbouring lymphatic area for carcinoma. Contributions from his pen appeared in *Allbutt's System of Medicine* and in the *Index of Treatment*. The first book he wrote himself, *Diseases of the Rectum and Anus*, was published in 1914. He also wrote *Diseases of the Rectum and Colon*, first published in 1923, and *The Origin of Cancer* (1932). His writings were not confined to technical subjects, for he was the author of two collections of essays, *After Us* (1936) and *Nothing New Under the Sun* (1947): the former of these contained some highly controversial suggestions on improving the human race by eugenic methods, but it was a book by one, as we said in our review, "who has obviously devoted much thought to the problem of the betterment of the human race."

Lockhart-Mummery was appointed assistant surgeon at St. Mark's in 1903. He became senior surgeon there in 1913. On retirement at the age of 60 in 1935 he was appointed emeritus surgeon there with charge of six beds. In 1940 he became consulting surgeon and was elected vice-president of the hospital. During the first world war he worked as special surgeon for diseases of the bowel at a number of military hospitals in London. At

the Annual Meeting of the B.M.A. in Newcastle in 1921 he was president of the Section of Proctology and he was also president of the same Section at the Royal Society of Medicine. An active supporter of the British Empire Cancer Campaign, he was for some time honorary secretary and chairman of the executive committee and he was also honorary editor of the Annual Reports of the Campaign. In 1937 he was elected a Fellow of the American College of Surgeons.

Mr. Lockhart-Mummery was twice married, first to Cynthia, daughter of R. A. Gibbons, and secondly to Georgette, daughter of H. Polak, of Paris. There were two sons of the first marriage.

We are indebted to Mr. W. B. GABRIEL for the following appreciation: The death last week of J. P. Lockhart-Mummery represents the loss of a great figure in proctology and the last member of that grand trio—Ernest Miles, Lockhart-Mummery, and Sir Charles Gordon-Watson. They were very active in the late nineteen-twenties and early 'thirties, and in their genial picturesque way contributed so much to the discussions held in that period, especially on cancer of the rectum. No one who was there will forget the impressive International Conference on Cancer held in London in July, 1928. Lockhart-Mummery contributed an important paper to this conference (*Report of the International Conference on Cancer*, 1928, p. 117) and described his clinical classification of cancer of the rectum into A, B, and C cases, which was the forerunner of Duke's more accurate pathological classification presented some years later.

J. P. Lockhart-Mummery was appointed to the honorary staff of St. Mark's Hospital in 1903, and he proceeded steadily to build up the reputation of the hospital. He raised the specialty of proctology until it was recognized as an important subject worthy of special study and training. He was the secretary of the British Proctological Society when it was founded in 1913, with F. Swinford Edwards as its first president, and later that year or early in 1914 it became the Subsection of Proctology (Section of Surgery) of the Royal Society of Medicine. It was through Lockhart-Mummery's efforts that proctology at last became an independent section in 1939. Lockhart-Mummery's work at St. Mark's Hospital and his writings attracted visitors from all over the world. His method of perineal dissection of the rectum by blunt-ended straight scissors was quick and accurate; it was greatly admired and is current practice to this day. His mortality for perineal excision of the rectum as a two-stage procedure was remarkably low—3.4% in 117 private cases is recorded. He did original work in teaching the importance of antiseptic technique in anorectal operations, and his method of scrupulous local cleansing with ether soap and "lysol" solution was certainly a great advance; it led to improved results and has been used ever since.

Lockhart-Mummery was a wise and far-seeing man in committee, and early saw the importance of pathology and x-ray diagnosis. He was largely instrumental in interesting the British Empire Cancer Campaign in the work done at St. Mark's on polyposis and cancer of the rectum. His impressive list of publications is recorded in the *Collected Papers of St. Mark's Hospital*, Centenary Volume (1935). It would be fitting here to record the terms of a resolution passed by the committee of management at a meeting held at St. Mark's Hospital on February 20, 1940:

"The Committee of Management wish to place on record their sense of the inestimable services Mr. J. P. Lockhart-Mummery has rendered to the Hospital during his terms of office as Honorary Surgeon and Emeritus Surgeon, and as a member of the Committee of Management."

"Over a period of 37 years his brilliant surgery, judgment, and skill have enhanced the reputation and usefulness of the Hospital. His wise counsels in the administration of its affairs have been of great value,

and his work an inspiration to all who have come into contact with him.

"The Committee of Management unanimously elected him an Honorary Consulting Surgeon."

In the following year Mr. Lockhart-Mummery was elected a vice-president of the hospital and continued to serve until the inauguration of the National Health Service in 1948. Lockhart-Mummery must have been the most senior Honorary Fellow of the American Proctologic Society, having been elected as far back as 1910.

We, his colleagues who survive him, would like to record our appreciation of his great services to St. Mark's Hospital and to proctology in general, and our pride at having served under him.

C. E. D. writes: J. P. Lockhart-Mummery was appointed to the staff of St. Mark's Hospital in 1903. He became senior surgeon on the retirement of Mr. Swinford Edwards in 1913 and held this position for the following 27 years, during which time he became well known as a surgeon of exceptional skill and experience in diseases of the rectum and colon, both in this country and abroad. In the smaller world encompassed by the walls of the hospital in which he worked he was equally esteemed and respected for other qualities also, such as his administrative ability and far-sighted plans for the development of the hospital. He made his influence felt in every department of the hospital life, and his colleagues who worked with him in the years between the first and second world wars will always retain a vivid impression of his inspiring leadership.

Looking back through the vistas of nearly twenty years, perhaps one's first recollection would be of the eager way he hopped up the steps of the hospital punctually at 2 p.m. (or even before this) each Monday afternoon to begin his operating session. He literally "hopped," because, as is well known, one of his legs was amputated when he was still a student in his early 20's: but perhaps it is not so well known that the surgeon who performed the operation was none other than Lord Lister and that it was carried out with full antiseptic ritual in a nursing-home in Cavendish Square. Lockhart-Mummery very seldom referred to his disability and did not let it debar him from sports in which he was interested. Thus for many years he played golf regularly with a handicap of 9. He was a keen fisherman, and became a devoted follower of dog racing, and was immensely proud when one of his dogs won the Dog Derby. After retirement from hospital work he took to bowls and quickly became proficient in this pastime. If he met any of his former hospital friends he would tell them with boyish enthusiasm of this latest achievement.

Another memory which those who worked with him at St. Mark's will always retain is of the way in which he relaxed after his operating list on Monday afternoon or after his regular round of the hospital on a Thursday morning. He never hurried away from hospital: in fact, he would not allow his secretary to make appointments for private patients which might in any way curtail his operating sessions or his weekly morning round. At the end of these he would sit down for a spell, and, if he had an audience, he greatly enjoyed expounding his views on the world in general, in picturesque language seldom free from exaggeration. He was an eager talker but also a willing listener, and if any colleague wanted his advice or help this was the time to approach P. L.-M. He interested himself in every department of the hospital life, particularly perhaps in the pathology laboratory, which he visited regularly at least once a week. He liked to know all that was going on, and, if there was any way in which he thought he could help, out came his notebook and he jotted it down at once. One could be quite sure the matter would be attended to and reasonably sure also that he would get what he wanted, even if this exceeded estimates, because P. L.-M. had a most persuasive way with hospital management committees. He attended to his committee obligations regularly, and if he took anything up one could rely on him to see it through to the end.

Finally his colleagues at St. Mark's will always remember Lockhart-Mummery's absorbing interest in anything related to the diagnosis and treatment of cancer. This found expression eventually in the plan he made for the founding of the British Empire Cancer Campaign. His main motive in this was to bring cancer research back to the human patient. He felt that existing cancer research organizations were divorced from the realities of human cancer and that what was necessary was the encouragement of research work in hospitals where cancer patients were being treated. He might be described as the real founder of the B.E.C.C., and in due course he became the first chairman of its executive committee and the editor of its annual reports.

If as a young man he had taken up cancer research as a career he might well have made some notable discovery, because he had originality, plenty of imagination, and indefatigable energy. Even in the odd moments of a very busy professional life as a consulting surgeon he found time to initiate at least two important advances in knowledge which will always be associated with his name. The first was his operation of perineal excision for cancer of the rectum, which was published in 1920 and became widely adopted for some years. The second was his paper on the inheritance of familial polyposis, which was published in the *Lancet* in 1925 under the heading "Cancer and Heredity." In this he gave details of three families he had personally investigated, and drew attention to their high incidence of intestinal cancer. The publication of this paper initiated a research into the inheritance of familial polyposis which has since been continued with the aid of a grant from the B.E.C.C. As a result more than 60 polyposis families have been investigated and family pedigrees prepared. These families now include approximately 1,200 members, amongst whom no fewer than 241 are known to have suffered from polyposis and 169 have developed intestinal cancer. This is one example out of many which might be mentioned to illustrate Lockhart-Mummery's influence at St. Mark's Hospital. His colleagues and successors have reason to be grateful to him and to cherish the memory of a versatile and colourful personality, a stimulating companion, and loyal friend.

W. L. HARNETT, C.I.E., M.D., F.R.C.S.

Lieutenant-Colonel W. L. Harnett died suddenly in London on April 24 at the age of 76. After a distinguished career as a surgeon in the Indian Medical Service, he became well known for his work as medical secretary of the Clinical Cancer Research Committee of the British Cancer Campaign.

Walter Lidwell Harnett was born on June 7, 1879, the son of Dr. W. J. Harnett, F.R.C.P.Ed., of Barnet, Hertfordshire. From the City of London School, he entered St. John's College, Cambridge, where he was a scholar and an exhibitor. He obtained a first-class in the Natural Sciences Tripos in 1899, and in the following year went on to St. Thomas's Hospital with a university scholarship. He graduated M.B., B.Chir. in 1903, was admitted to the Fellowship of the Royal College of Surgeons of England in 1904, and proceeded to the M.D. in 1929. After graduation he held the appointments of house-surgeon, demonstrator of morbid anatomy, and assistant pathologist at St. Thomas's Hospital. Harnett entered the Indian Medical Service in 1907, taking first place at the entrance examination and being awarded the first Montefiore Prize for Military Surgery at the Royal Army Medical College. While in India he held the appointment of surgeon to the Governor of Bengal, and was superintendent of the Campbell Medical School, Calcutta, from 1925 to 1930. For the last four years of his service in the I.M.S.—he retired in 1934—he was professor of surgery at the Medical College, Calcutta. His earlier appointments included those of civil surgeon, Gauhati (1911), and resident surgeon at Calcutta Medical College (1914). During the first world war he served in India and Salonika

and with the Army of the Black Sea, being mentioned in dispatches. He was appointed C.I.E. in 1933.

After his retirement from the I.M.S., Harnett returned to London and began to take an active part in the work of several medical organizations, including the B.M.A. He served on the Council of the Association from 1938 to 1942 and on the old Naval and Military Committee from 1935 to 1940, and his work as a member of the Committee on the Organization of the Medical Profession in India (1935-9) and the Committee on the Relationship of the Association to the Profession in India (1947-9) was particularly valuable. Earlier, in 1934, he was president of the Calcutta Branch, and from 1950 until his death chairman of the Chelsea and Fulham Division. During the second world war he served as an additional member of the India Office Medical Board, and for a good many years he was chairman of the Hammer-smith branch of the Invalid Children's Aid Association.

From 1938 to 1951 he was medical secretary to the Clinical Cancer Research Committee of the British Empire Cancer Campaign. His work for the Campaign culminated in the publication in 1952 of his *Survey of Cancer in London*.

Colonel Harnett married Miss Nellie Bartingale in 1909. There were no children.

We are indebted to Sir HENEAGE OGILVIE for the following appreciation :

Others will speak of Harnett's position in surgery, of his work in the Indian Medical Service and at the Postgraduate Hospital, and of his long and honourable service to Masonry. I came to know him in connexion with the compilation, analysis, and publication of the results of the investigation into cancer in Greater London conducted by the British Empire Cancer Campaign. After two years spent in preliminary planning, the registration of cases was begun in April, 1938, and, in view of the amount of work entailed, Colonel Harnett was appointed to take charge of the investigation. He visited several centres in the United States to study their recording systems and methods of analysis, and finally drew up a code for each of the 31 types of sheet intended for recording cancer of different regions.

Harnett was uniquely fitted for the exacting and onerous task of analysing the enormous mass of information that had been collected, a task to which he brought the experience of a life-time devoted to clinical surgery and surgical teaching, and to which he applied himself with unselfish devotion. Though not a statistician by training, he was at pains to subject the figures in each group to an actuarial estimation of the normal life expectation of that group. It is an index of his zeal that of the 15,201 cases entered on the records all but 2.63% were traced.

Between 1942 and 1950 Harnett published in the Annual Reports of the British Empire Cancer Campaign analyses of cases of cancer in 15 different regions of the body. In 1952 the Campaign decided to publish a report on the whole survey. All the previously published analyses were revised and brought up to date, and statistical analyses of cancer in regions of the body not previously dealt with were included. The whole of this work was done by Harnett, and the volume that he produced is something unique in scientific literature. Never before has so large a series, entirely unselected, been got together. Never before had an analysis so detailed, so carefully checked, and so impartial been presented.

Harnett was a man of great personal charm, and uncommon modesty. His industry in the statistical analysis of the immense mass of material over so many years, and his advice at all stages, were greatly appreciated by all those members of the British Empire Cancer Campaign who had the privilege of working with him. *A Survey of Cancer in London* will remain an enduring tribute to his memory in the profession he did so much to adorn.

V. B. G.-A. writes: After holding several house appointments at St. Thomas's Walter Harnett was lured to the East at a time when India beckoned only the very best men from every medical school. After a short spell in Assam as a civil surgeon he went to Bengal, where he quickly made a

niche for himself as a very skilled genito-urinary surgeon, but it was his administrative ability and quick grasp of financial problems that most endeared him to the Government of Bengal and earned him a C.I.E. Walter quietly pursued the things that attracted him, such as Freemasonry, fishing, and his own special branch of surgery, together with the study of statistics, which held for him a peculiar attraction. During the 20 years we lived so close to each other in Calcutta I do not think he ever played any form of game in club or private house, but nevertheless he was always happy and made great friends. After retirement he closely followed the rapid progress of surgery, and particularly the prognostic side thereof. He took a special part and interest in B.M.A. affairs, though fishing, Freemasonry, and high reading absorbed him. To me it was always a joy to meet him on a Saturday and talk of cabbages and kings, for he could be great fun with those he knew well.

MAUD CHADBURN, C.B.E., M.D.

Miss Maud Chadburn, consulting surgeon to the South London Hospital for Women and to the Marie Curie Hospital, died at the Elizabeth Garrett Anderson Hospital on April 24. She was 89 years of age.

Maud Mary Chadburn was born at Middlesbrough, the daughter of the Rev. James Chadburn, and was educated at Milton Mount College, Crawley, and at University College, London. She studied medicine at the London (Royal Free Hospital) School of Medicine for Women, qualifying L.S.A. in 1893. Obtaining the London degree of M.B. in 1894, she proceeded to the M.D. four years later, and took the B.S. in 1899. At the Royal Free Hospital she held for a time the post of curator of the museum, and after qualification she was resident anaesthetist there.

She then held senior and junior resident appointments at the Clapham Maternity Hospital, from which she went on to the New Hospital for Women (now the Elizabeth Garrett Anderson Hospital) as senior house-surgeon. After this impressive series of house appointments she became an assistant physician at the New Hospital for Women and surgical registrar at the Royal Free. In later years she worked as assistant obstetrician, surgeon to out-patients, and, ultimately, senior surgeon and obstetrician at the Elizabeth Garrett Anderson Hospital, where her devoted work and interest helped to build up the obstetric department. From 1902 to 1916 she was surgeon to the Women's Settlement Hospital at Canning Town.

Miss Chadburn also had a long association with the South London Hospital for Women, which she founded. She became senior surgeon there in 1912, just before the first part of the hospital, the out-patients department, was officially opened in April, 1913. She was largely instrumental in the founding of another hospital in 1928, the Marie Curie Hospital, at Hampstead, being its chairman from that year until 1934, and chairman of its cancer research committee until 1951. She was president of the London Association of the Medical Women's Federation in 1926-7, and for 63 years she was a member of the B.M.A. She was appointed C.B.E. in 1934.

We are indebted to Dr. MARY GILMOUR for the following appreciation: Miss Maud Mary Chadburn was a pioneer and one of the most prominent women who have worked for the advancement of women in medicine. As a medical woman holding senior posts while in her early years, she appreciated that many of the younger women at that time were not having opportunities of holding responsible posts, and it was for this reason that she resolved that there should be another general hospital created in London and began working in 1911 for the establishment of a women's hospital in the south of London, staffed entirely by women. At the commencement of this venture, a very disparaging letter about it in *The Times* evoked from Miss Chadburn a reply which was published in the same newspaper. As a result of her letter Miss Chadburn was invited to meet and discuss her project with the representatives of certain anonymous individuals. These latter became the anonymous donors to the South London Hospital of £35,000, which not only

defrayed the cost of the hospital but also established a trust, the income from which was to be used towards the working expenses of the institution. It was in Miss Chadburn's house at 16, Harley Street, that the first meeting of subscribers was held. She was the first surgeon appointed to the hospital, and she remained vice-chairman until the implementation of the National Health Service Act in 1948. Miss Chadburn liked to recall how notable a part her lifelong friend, Miss Merrilees, in the capacity of honorary organizer of the Patients' League, played in the smooth running of the hospital throughout the earlier years. In 1947 the College of Arms granted the hospital armorial bearings. The cross in the crest is the emblem of Chad, a man who died in the seventh century, noted for his merciful outlook. Chad, along with a sun, which also appears in the crest, suggests Chadburn. The motto *Et dato gaudetis*—"and in giving you rejoice"—is a worthy tribute to the honoured founder of the hospital.

Since her early days as an obstetrician and gynaecologist, Miss Chadburn had maintained a lively interest in the treatment of cancer in women, and this interest later crystallized in the founding of the Marie Curie Hospital in 1928. When the need arose of finding money to secure a site and a building to centralize the research work, the money was again found by Miss Chadburn. During a conversation with Dr. Elizabeth Courtauld Miss Chadburn described the work and the needs of research on cancer of the uterus—work which she had so much at heart—and Dr. Courtauld promised to give £10,000 towards the cost. In this way the establishment of the Marie Curie Hospital in Hampstead was secured. (Miss Chadburn often remarked to me that people had frequently said to her that she was a "good beggar," but that this was not so. She would meet and talk with people describing the work in which she was interested, but she did not ask for money. It was always offered spontaneously.) She became the first chairman of the Marie Curie Hospital, relinquishing this post in 1934, when it was put on record that "it was mainly due to her unflinching personal care and wise judgment that the hospital had steadily grown and prospered." She continued to be vice-chairman, retaining also the chairmanship of the cancer research committee and of the medical committee until her retirement in 1951. Throughout the last war, and indeed until her retirement, she continued, as always, to be a pillar of strength to the Marie Curie Hospital. Her energies and devotion were given wholeheartedly to safeguarding the research nature of the work done there. When the National Health Service Act came into force Miss Chadburn was the sole surviving member of the foundation committee of the hospital still on the active medical staff.

As a chairman, whether of boards of management, or cancer research or medical committees, she possessed in a most extraordinary degree the qualities of impartiality and sincerity, sound judgment, and wise guidance.

Vital Statistics

Acute Poliomyelitis

A feature of the outbreaks of acute poliomyelitis in recent years has been the rise in the number of cases towards the end of the second quarter of the year. The week of the peak incidence has varied between the 29th week (1951) and the 41st week (1949). The curve of the peak has varied in shape, but generally the incidence has fallen rapidly by the middle of the fourth quarter. With the exception of the seasonal rise in incidence there has been no well-marked periodic characteristic in the distribution of the cases. As the figures in the table show, it is not possible to estimate the approximate size of the summer epidemic from the returns of the first quarter.

Apart from 1957 the largest number of notifications in a first quarter was in 1950, and the total of cases recorded that year was almost as high as in the initial outbreak of 1947. The number of notifications in the first quarter of 1948 was the next largest to 1950, but the number of cases notified

Uncorrected Notifications of Acute Poliomyelitis in England and Wales

Year	1st Quarter	2nd Quarter	3rd Quarter	4th Quarter	Total
1947	125	273	6,263	2,593	9,254
1948	417	263	768	728	2,176
1949	245	306	3,085	3,224	6,860
1950	512	723	5,119	2,345	8,699
1951	339	468	1,398	888	3,093
1952	288	518	2,514	1,184	4,504
1953	345	672	3,063	1,171	5,251
1954	332	340	1,055	661	2,388
1955	208	367	4,060	1,321	7,305
1956	366	465	1,701		3,853
1957	516				

during the year was the lowest for the 10 years. On the other hand, the number of notifications in the first quarter of 1955 was, except for 1947, the lowest for any first quarter, but the total for the year was next highest to 1950. Consequently, though the number of notifications for the first quarter of 1957 slightly exceeds that of 1950, it is impossible to forecast from that what the incidence of poliomyelitis will be this summer. If a forecast is attempted, one feature of the recent returns may be relevant. It is that the loci of infection are few, one-third of the cases in the past fortnight having been notified from one county (Essex). Whether this presages a relatively restricted summer outbreak will be worth studying.

England and Wales in First Quarter 1957

The infant mortality rate of 25.0 per thousand related live births was the lowest recorded for a first quarter. The previous lowest for this quarter was 28.4 in 1956. Live births numbered 183,676, giving a rate of 16.7 per thousand population. Comparable rates in 1956 and 1955 were 16.2 and 15.4. Deaths numbered 134,621, giving a rate of 12.2 per thousand population, the lowest ever recorded in this country for the first quarter. The previous lowest was 12.3 in 1948. The rate in 1956 was 15.3. 4,246 stillbirths were registered, giving a rate of 22.6 per thousand live and stillbirths, which compares with 23.4 in 1956.

The deaths of infants under 4 weeks of age during the year 1956 numbered 11,780, giving a rate of 16.9 per 1,000 related live births. This is the lowest annual rate recorded in this country; the previous lowest was 17.3 in 1955.—*Registrar-General's Weekly Return*, No. 16, 1957, H.M.S.O.

Graphs of Infectious Diseases

The graphs below show the uncorrected numbers of cases of certain diseases notified weekly in England and Wales. Highest and lowest figures reported in each week during the nine years 1948-56 are shown thus -----, the figures for 1957 ————. Except for the curves showing notifications in 1957, the graphs were prepared at the Department of Medical Statistics and Epidemiology, London School of Hygiene and Tropical Medicine.

Infectious Diseases

The largest variation in the trends of infectious diseases in England and Wales during the week ending April 13 were increases of 1,995 for measles, from 25,280 to 27,275, 120 for dysentery, from 1,051 to 1,171, and decreases of 152 for whooping-cough, from 2,768 to 2,616, 138 for scarlet fever, from 878 to 740.

Acute poliomyelitis notifications numbered 37, and these were 5 more for paralytic and 5 fewer for non-paralytic cases than in the preceding week. The largest returns were Essex 12 (Brightlingsea U.D. 7, Wivenhoe U.D. 4), London 3 (Wandsworth 2), and Hertfordshire 3.

In contrast to the general rise in the incidence of measles large falls were recorded in two counties—268 in Lancashire, from 3,055 to 2,787, and 226 in Essex, from 1,563 to 1,337. The towns with the largest rises in the notifications of measles were 293 in Birmingham C.B., from 840 to 1,133, 227 in Leeds C.B., from 500 to 727, 171 in Sunderland C.B., from 170 to 341, and 101 in Plymouth C.B., from 137 to 238. Only small variations were reported in the local returns of scarlet fever. The largest fall in the incidence of whooping-cough was 54 in Essex, from 190 to 136. 3 cases of diphtheria were notified, 6 fewer than in the preceding week.

The largest rises in the number of notifications of dysentery were Yorkshire West Riding 101, Lancashire 50, and Nottinghamshire 44. In the remainder of the country the incidence contracted and only 11 counties reported 20 or more cases, compared with 15 counties in the preceding week. The largest returns during the week were Yorkshire West Riding 346 (Leeds C.B. 85, Bradford C.B. 77, Rotherham C.B. 42, Rotherham R.D. 37, York C.B. 26, Huddersfield C.B. 14, Worsborough U.D. 13, Shipley U.D. 11, Aireborough U.D. 10), Lancashire 173 (Blackburn C.B. 22, Ashton under Lyne M.B. 21, Irlam U.D. 21, Manchester C.B. 20, Fylde R.D. 18, Liverpool C.B. 12, Stretford M.B. 12), Nottinghamshire 87 (Mansfield M.B. 41, Nottingham C.B. 22, Carlton U.D. 10), Cheshire 85 (Hyde M.B. 39, Stalybridge M.B. 26), London 62 (Lewisham 16, Islington 10), Northumberland 62 (Newcastle upon Tyne C.B. 25, Seaton Valley U.D. 23), Bedfordshire 38 (Luton M.B. 24), Durham 33 (Gateshead C.B. 12).

Week Ending April 20

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 567, whooping-cough 1,890, diphtheria 7, measles 21,787, acute pneumonia 382, acute poliomyelitis 42, dysentery 874, paratyphoid fever 4, and typhoid fever 4.

INFECTIOUS DISEASES AND VITAL STATISTICS

Summary for British Isles for week ending April 13 (No. 15) and corresponding week 1956.

Figures of cases are for the countries shown and London administrative county. Figures of deaths and births are for the 160 great towns in England and Wales (London included), London administrative county, the 17 principal towns in Scotland, the 10 principal towns in Northern Ireland, and the 14 principal towns in Eire.

A blank space denotes disease not notifiable or no return available. The table is based on information supplied by the Registrars-General of England and Wales, Scotland, N. Ireland, and Eire, the Ministry of Health and Local Government of N. Ireland, and the Department of Health of Eire.

Medical News

Durham University to Honour B.M.A. Meeting.—Durham University is holding a special congregation on July 18 during the B.M.A. meeting in Newcastle in order to confer honorary degrees. Dr. A. H. HALL, the Association's outgoing president, and Dr. S. WAND, Chairman of Council, are to receive the honorary D.C.L.; Professor G. W. PICKERING, regius professor of medicine at Oxford, the honorary D.Sc.; and Dr. MONA MACNAUGHTON, a general practitioner in Newcastle, the honorary M.D. At an earlier congregation, on July 5, Sir JOHN STOPFORD, F.R.S., until recently Vice-Chancellor of Manchester University, is to receive the honorary D.C.L.

Virus Research at Glasgow.—The first news of the endowment of a new department of virology at Glasgow University was given to a press conference in Glasgow on April 26. A sum of £225,000 has been provided by the Scottish Hospital Endowments Research Trust for building and equipping an institute, and for its initial running expenses. The institute, which is to be at Gilmorehill within the University grounds, is expected to be ready by about 1960. According to reports of the news conference, Sir JOHN ERSKINE, chairman of the Trust, described the main purpose of the new department as fundamental research into virus diseases of man, animals, and plants. Sir HECTOR HETHERINGTON, principal of the University, said that a chair of virology—claimed to be the first in Britain—would be established, and its occupant, besides directing the institute, would engage in a certain amount of postgraduate teaching. He added that the Medical Research Council had agreed to attach a research unit to the institute once it was functioning. Professor J. W. HOWIE, professor of bacteriology at Glasgow, is quoted as stating that, apart from fundamental work at the National Institute for Medical Research, Mill Hill, there was no virus research being done in Britain comparable to that in America and Australia. It was hoped, he said, that the new institute at Glasgow would become a centre for research workers from all parts of the world. Discussing virus diseases, Professor Howie emphasized the better prospects for their prevention than cure. Research on measles and latent viral infections was specially needed.

Empire Rheumatism Council.—The council's annual meeting was held at the House of Lords on May 1, with Lord ALEXANDER OF HILLSBOROUGH presiding. Dr. W. S. C. COPEMAN, chairman of the council, proposing the adoption of the twentieth annual report (1955-6), stressed the importance of research in the battle against rheumatic diseases. These diseases were estimated to cost the country £80m. annually in lost production, he said, but the council's activities were limited by its income—about £30,000 a year. This had decided the council to launch a nation-wide appeal to industry for £250,000 this year; the council's twenty-first anniversary. Lord ASTOR OF HEVER, a vice-president of the council, had agreed to undertake the appeal, and support was already forthcoming from both sides of industry. Dr. Copeman then gave two examples of recent major research discoveries. Electron-microscopy had now shattered the old conception that muscle consisted of homogeneous fibres. It had been established, he said, that muscle consisted, not of one, but of many different varieties of fibre. "The implications of a fundamental discovery of this nature are enormous," he added. The other example was the isolation of a hitherto unknown chondroitin sulphate complex from connective tissue fluid by Miss H. M. MUIR, one of the council's research fellows. After the adoption of the annual and financial reports Dr. COPEMAN was re-elected chairman of the council for the fifth year in succession, and Sir CHARLES DODDS, F.R.S., vice-chairman. The annual report is a 45-page booklet, obtainable from the council's offices at Tavistock House (North), Tavistock Square, London, W.C.1. It gives membership lists of the council's various administrative and research committees, the chairman's address, reports of the research and educational work sponsored by the

council, and details of administration, finance, and developments in the Commonwealth. An appendix describes the council's twenty-first birthday appeal.

World Medical Association.—The Norwegian Medical Association is acting as host to the W.M.A. council now meeting in Oslo (April 29–May 5). This session is preparatory for the Eleventh General Assembly of the World Medical Association in Istanbul from September 29 to October 5. Among the subjects being discussed by the council are the recognition of the emblem for civilian doctors in war; medical secrecy under social security schemes; international medical law; and the programme for the Second World Conference on Medical Education (Chicago, 1959). The present officers of W.M.A. are:—*president*: Dr. J. A. BUSTAMANTE (Cuba); *president elect*: Dr. AHMET RASIM ONAT (Turkey); *treasurer*: Dr. ERNST FROMM (Germany). Council officials include: Dr. LORENZO GARCIA-TORNEL (Spain), *chairman*; Dr. LEON GERIN-LAJOIE (Canada), *assistant to chairman*; Dr. T. C. ROUTLEY (Canada), *consultant general*; Dr. AUSTIN SMITH (U.S.A.), *executive editor*; Dr. S. S. B. GILDER (Canada), *associate editor*; Dr. JEAN MAYSTRE (Switzerland), *liaison officer*; and Dr. LOUIS H. BAUER (U.S.A.), *secretary general*.

World Health Assembly.—The tenth World Health Assembly opens on May 7 in the Palais des Nations, Geneva. According to the director-general's annual report W.H.O. participated last year in nearly 700 health projects in 120 countries and territories. Malaria eradication was one of W.H.O.'s main concerns, policy having shifted from control to eradication in view of the increasing insecticide-resistance among mosquitoes. During the mass campaigns against endemic syphilis and yaws—by the end of 1956 55 million people had been examined and 16 million treated with penicillin—a number of fatal reactions to penicillin were reported. W.H.O. was therefore co-ordinating research on the comparative value of different penicillin preparations and other antibiotics for such campaigns. W.H.O. continued its co-operation with Unicef against tuberculosis, particularly in primitive areas. Among other measures, the possibility of large-scale chemotherapy was being studied. W.H.O. recommended isoniazid for its field studies as the only antituberculous drug cheap enough for a public health budget and also likely to be taken readily by contacts. Among other subjects discussed in the director-general's report are public health administration, the health aspects of atomic energy, and international quarantine. W.H.O.'s income last year was \$10.2m. from its active member states supplemented by an allocation of \$5.4m. under the United Nations technical assistance programme.

Royal College of Physicians.—A quarterly comitia was held on April 25, at which the new president, Professor ROBERT PLATT, took the chair for the first time. The following were elected to fellowship and membership, respectively, of the College:

Fellows.—M. M. Suzman (South Africa), J. L. H. Easton (Bedford), P. C. C. de Silva (Ceylon), C. McDowell (New Zealand), A. B. Stokes (Canada), M. Hynes (London), O. A. Savage (London), E. C. O. Jewesbury (London), F. J. W. Miller (Newcastle upon Tyne), G. W. Boden (London), A. Leese (Leeds), J. N. Morris (London), J. H. Bolton (Australia), W. R. S. Doll (London), G. M. Komrower (Manchester), I. M. Anderson (London), R. B. Evans (Cardiff), J. C. Gilson (Penarth, London), P. L. Mollison (London), W. Somerville (Long-Glamorganshire), C. D. Needham (Aberdeen), J. M. Malins (Birmingham), N. D. Compston (London), J. F. Goodwin (London), A. G. Leatham (London), W. D. Brinton (Winchester, Hampshire), D. A. P. Anderson (Reading, Berkshire), E. J. Moynahan (London), J. M. Ledingham (London), J. A. Scott (London), P. M. F. Bishop (London), J. H. Biggart (Belfast), R. F. Loeb (U.S.A.), J. R. Paul (U.S.A.).

Members.—L. J. H. Arthur, J. H. Baron, N. M. Bleehen, D. R. Coles, J. M. Duggan, H. Duncan, D. A. W. Edwards, J. S. Garfield, J. M. Greenaway, L. Henry, T. H. Hughes-Davies, M. Kingsbourne, J. J. P. Lomas, P. J. Maloney, I. D. Melville, P. Mestitz, M. B. Morton, I. B. Munro, A. K. M. Nawab Ali, J. R. Officer, A. M. Parfitt, J. Platnauer, S. Shaldon, D. H. Trapnell, M. P. Wilkinson, R. T. Williams, B. W. Windeyer.

Therapeutic Substances Amendment Regulations, 1957.—These regulations, which came into force on May 1, bring under the control of the Therapeutic Substances Act, 1956, absorbent haemostatic materials used in surgery; parenteral preparations of tetracycline, polymyxin B, viomycin, hyaluronidase, streptokinase, streptodornase, and streptokinase-streptodornase; and heparin and corticotrophin and preparations of them. These are all added to the First Schedule of the Act as being therapeutic substances "the potency of which cannot be adequately tested by chemical means." Details are given of the requirements for their manufacture and testing. In addition the new regulations include a revised procedure for testing for pyrogens, and amendments to existing regulations concerning B.C.G. and smallpox vaccines, the labelling of antibiotics, and the manufacture of poliomyelitis vaccine. An earlier provision that the total volume of a poliomyelitis virus suspension should not exceed 50 litres has now been amended to read "such volume as may for the time being be approved by the licensing authority." This amendment is stated by the Ministry of Health to have been agreed to by the Medical Research Council's advisory committee. Copies of the regulations (S.I. 1957, No. 550) are obtainable from Her Majesty's Stationery Office, price 9d. net.

National Society for Clean Air.—At a special general meeting of the National Smoke Abatement Society on April 11 it was unanimously agreed that the society should seek incorporation as a company limited by guarantee and without share capital, and with the new name "National Society for Clean Air."

Professor R. J. Kellar, professor of obstetrics and gynaecology at Edinburgh University, is visiting New Zealand and Australia during June, July, and August as a guest lecturer. He has accepted invitations from the Australian Postgraduate Federation in Medicine and Auckland University College.

Mr. Hermon Taylor, surgeon to the London Hospital, is to be the guest of the American Gastroenterological Association at its annual meeting in Denver this month. While there he will also receive the Schindler award of the American Gastroscopic Society.

COMING EVENTS

Radio.—In "Science Survey" on May 9, 16, and 23, at 7 p.m. in the Home Service, Dr. D. R. NEWTH, Ph.D., will speak on the biology of development. Repeat broadcasts on May 11, 18, and 25, at 9 a.m.

Gideon de Laune Lecture.—Sir HENRY DALE, O.M., F.R.S., will lecture at the Society of Apothecaries of London on May 14 at 5.30 p.m. His subject will be "Medicinal Treatment; its Aims and Results."

Croonian Lectures.—Professor G. W. PICKERING will deliver the Croonian Lectures on May 14 and 16 at 5 p.m. at the Royal College of Physicians. His subject will be "The Regulation of Body Temperature in Health and Disease."

Association of Police Surgeons of Great Britain.—Sixth annual conference at Lytham St. Annes, Lancs, May 23–25. Details from the hon. secretary, Dr. R. D. SUMMERS, 69, Bow Road, London, E.3.

Symposium on Trichomonas.—Organized by the French Society of Gynaecology, May 28 to 30, at Rheims. Details from Dr. R. SENECHAL, 31, rue Raynouard, Paris, 16.

SOCIETIES AND LECTURES

A fee is charged or a ticket is required for attending lectures marked ●. Application should be made first to the institution concerned.

Sunday, May 5

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL.—10.15 a.m., clinical demonstration for general practitioners. Dr. D. A. Pond: Acute Psychiatric Emergencies in General Practice.

Monday, May 6

MARLBOROUGH DAY HOSPITAL.—8.15 p.m., Dr. G. D. Fraser Steele: Psychotherapy in Mental Hospital Practice. Its Instruments and Aims. UNIVERSITY COLLEGE, LONDON: DEPARTMENT OF BIOCHEMISTRY.—At Physiology Theatre, Gower Street, W.C.2, 5 p.m., public lecture by Professor R. A. Alberty (Wisconsin): Kinetic Studies of Fumarase.

Tuesday, May 7

BIRMINGHAM UNIVERSITY: FACULTY OF MEDICINE.—At Large Anatomy Theatre, Medical School, 4 p.m., Leonard Parsons Memorial Lecture by Professor Rustin McIntosh (New York): Growth and Development—Somatic Growth.

INSTITUTE OF DERMATOLOGY.—5.30 p.m., Dr. R. H. Meara: Xanthomatosis. LONDON UNIVERSITY.—At London Hospital Medical College, 5.30 p.m., special university lecture in pharmacology by Dr. S. Udenfriend (Bethesda, U.S.A.): Pharmacological Studies Relating to Serotonin.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—3.45 p.m., Arnold Demonstration by Dr. R. McP. Livingston: The Placenta.

ROYAL VETERINARY COLLEGE.—4 p.m., special university lecture by Professor R. A. Gregory: Some Aspects of Mammalian Gastroenterology.

ST. MARY'S HOSPITAL MEDICAL SCHOOL.—At Wright-Fleming Institute, 5 p.m., Almoth Wright Lecture by Sir Cyril Hinshelwood: Some Quantitative Aspects of Bacteriology.

WEST END HOSPITAL FOR NEUROLOGY AND NEUROSURGERY.—5.30 p.m., Dr. N. G. Hulbert: neurological demonstration.

Wednesday, May 8

BIRMINGHAM UNIVERSITY: FACULTY OF MEDICINE.—At Large Anatomy Theatre, Medical School, 4 p.m., Leonard Parsons Memorial Lecture by Professor Rustin McIntosh (New York): Growth and Development—Physiological Growth.

INSTITUTE OF DERMATOLOGY.—5.30 p.m., Dr. H. Haber: Eosinophilic Granulomas of the Skin.

INSTITUTE OF DISEASES OF THE CHEST.—5 p.m., Dr. R. W. Riddell: Fungous Infections of the Lungs.

OXFORD UNIVERSITY.—At Radcliffe Infirmary, 5 p.m., Litchfield Lecture by Mr. I. S. Hall: Some Aspects of the Histopathology of the Temporal Bone.

POSTGRADUATE MEDICAL SCHOOL OF LONDON.—2 p.m., Dr. D. A. Long: Relationship of the Haemolytic Streptococcus to Rheumatic Fever.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m., Moynihan Lecture by Dr. J. Lyle (Cincinnati): Causes and Treatment of Exophthalmos.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—5 p.m., Dr. Henry Doubilet (New York): Pathology and Treatment of Pancreatitis.

SOCIETY FOR ENDOCRINOLOGY.—At Royal Society of Tropical Medicine and Hygiene, 5.30 p.m., Professor C. De Duve (Louvain University): Present Status of Glucagon.

Thursday, May 9

HONYMAN GILLESPIE LECTURE.—At Anatomy Theatre, University New Buildings, Edinburgh, 5 p.m., Professor W. I. C. Morris: Obstetrical Haemorrhage in Relation to Impaired Blood Clotting.

INSTITUTE OF DERMATOLOGY.—5.30 p.m., Dr. O. L. S. Scott: Inherited Abnormalities of the Skin.

POSTGRADUATE MEDICAL SCHOOL OF LONDON.—2 p.m., Professor T. Pomfret Kilner: Investigation of Defective Speech with Special Reference to Cleft Palate Conditions.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m., Hunterian Lecture by Professor A. C. McEachern: Evolution of Safety in Prostatectomy.

Friday, May 10

INSTITUTE OF CHILD HEALTH.—5 p.m., Professor Rustin McIntosh (New York): Meconium Ileus.

INSTITUTE OF DERMATOLOGY.—5.30 p.m., Dr. G. B. Dowling: clinical demonstration.

INSTITUTE OF DISEASES OF THE CHEST.—5 p.m., Dr. Brian Taylor: clinical demonstration.

INSTITUTE OF LARYNGOLOGY AND OTOLARYNGOLOGY.—3.30 p.m., Miss Edith A. M. Whetnall: Care and Training of Deaf Children.

POSTGRADUATE MEDICAL SCHOOL OF LONDON.—4 p.m., Dr. W. C. Cockburn: Provocation Poliomyelitis.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—3 p.m., Professor M. F. A. Woodruff: Surgery of Replacement.

ST. MARY'S HOSPITAL MEDICAL SCHOOL.—At Wright-Fleming Institute Theatre, 5 p.m., Mr. J. Suchet: Rupture of the Uterus in Pregnancy and Labour.

Saturday, May 11

KENT PAEDIATRIC AND CHILD HEALTH SOCIETY.—2.30 for 3 p.m., visit to "Rudolf Steiner" Schools, Larkfield Hall and the Gate House, Larkfield Hall, near Maidstone.

YORKSHIRE SOCIETY OF ANAESTHETISTS.—At Royal Bath Hospital, Harrogate, 11 a.m., Dr. E. J. L. Pearce: Demonstration of Patients Illustrating the Use of Therapeutic Nerve Block; Dr. Olive M. G. Jones: Recent Trends in Anaesthesia for Neurosurgery.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Edwards.—On April 21, 1957, to Phyllis, wife of Dr. David G. Edwards, of "Lynton," 1, Eaton Road, Cressington Park, Liverpool, a daughter—Jacqueline Mary.

Ellthorn.—On April 28, 1957, at University College Hospital, London, W.C.2, to Dr. Helen ("Wendy") Grant, wife of Dr. Alick Ellthorn, twins—Justin Richard and Sandra Clare.

Levy.—On April 20, 1957, at Cambridge, to Ruth, wife of Dr. J. I. Levy, D.M.R.D., a son.

Shribman.—On March 29, 1957, at Royal Bucks Hospital, Aylesbury, to Hazel and Irving Shribman, a sister for Jonathan Andrew—Amanda Helene.

Stone.—On April 18, 1957, at Wanganui, New Zealand, to Barbara Mary (formerly Dana), M.B., B.S., and Arthur Richard Stone, M.B., Ch.B., M.R.C.P., M.R.A.C.P., a son.

DEATHS

Hannigan.—On April 13, 1957, in hospital, London, Joseph Hannigan, M.B., B.Ch., of Epsom, Surrey, late of Ashgrove, Highfield Road, Dublin, aged 52.

Jeffcoat.—On April 15, 1957, at Aldershot, Hants, Leslie Fraser Elliott Jeffcoat, M.B., Ch.B., Major, R.A.M.C.

Minshull.—On April 17, 1957, at Warwick Hospital, Michael John Wilmott Minshull, B.M., B.Ch., of The Firs, Theatre Street, Warwick, aged 57.

Robertson.—On April 12, 1957, Arthur Robertson, M.B., Ch.B., D.P.H., of 8, Bracken Road, Seaford, Sussex, late of Beckenham, Kent.

Shattock.—On April 12, 1957, at 1, Burlington Gardens, Chiswick, London, W. Charles Robert Shattock, M.R.C.S., L.R.C.P., L.D.S.

Williams.—On April 17, 1957, in a nursing home, Poole, Dorset, Harold Austin Williams, M.D.

Any Questions?

We publish below a selection of those questions and answers which seem of general interest. It is regretted that it is not possible to supply answers to all questions submitted.

Long-term Anticoagulant Therapy

Q.—After a third attack of coronary thrombosis, a patient has been advised permanent phenylindanedione therapy. How should this treatment be managed? What are the indications for vitamin K₁ administration, and how effective is it?

A.—Long-term anticoagulant treatment using phenylindanedione needs the same careful laboratory control as the short-term treatment now widely used in the treatment of an attack of cardiac infarction. The aim is to reduce the prothrombin level of the blood to about 25% of normal and maintain it at this level throughout the period of treatment. The initial dose is 150 mg., with 100 mg. on the second day and subsequent doses adjusted according to the prothrombin level. In most patients a maintenance dose of 75–100 mg. daily, given in divided doses morning and evening, will be adequate, but the actual level of the dose must be adjusted according to the patient's response.

The chief danger of anticoagulant therapy is haemorrhage caused by undue depression of the prothrombin level, and this form of treatment should not be embarked on unless full laboratory control is available. Using phenylindanedione, the prothrombin levels remain reasonably stable, and blood estimations at weekly or fortnightly intervals are adequate after the initial period of stabilization during which more frequent estimations are essential.

Anticoagulants should not be given to patients with a history of peptic ulceration, or with liver disease. If surgical operation is needed the drug should be withheld for three days prior to operation, as its effects are usually over in 48 hours. With intercurrent illness, particularly infections, it is unwise to continue with anticoagulant therapy without more frequent prothrombin estimations. If undue depression of the prothrombin level occurs, withholding the drug for one to two days will usually result in the level rising to safe limits.

The chief indication for vitamin K₁ administration is haemorrhage or the need for emergency surgery, and the prothrombin level can be returned to normal quickly by giving 5 mg. intravenously or 15 mg. orally.

Drug Treatment of Vitiligo and Hyperpigmentation

Q.—Recent reports from the U.S.A. state that pigment-controlling drugs are being commercially produced now and are available on prescription. 8-Methoxypsoralen, under the trade name of "oxsoralen," is being used in the treatment of vitiligo. "Benoquin" is said to be effective against hyperpigmentation such as occurs on freckled skin. How are these drugs used, what are their hazards, and what results may be expected from them?

A.—There are considerable dangers in using local psoralens, combined with exposure to sunlight, for repigmenting areas of vitiligo. They are potent light-sensitizers, and consequently acute erythematous blistering reactions often result following incautious exposure to sunlight after painting mercury-vapour source is valueless after the painting; natural sunlight should be employed, and this of course limits the application of local therapy in this country.

For practical purposes psoralen treatment is limited to the "relative" types of vitiligo.¹ In these cases affected areas are not entirely devoid of pigment. These types usually occur in dark-skinned races and are diagnosed

clinically by the fact that the patches are not completely depigmented but are of a lighter colour than the surrounding skin. During treatment care must be taken to avoid hyperpigmentation of the normal surrounding skin. "Absolute" vitiligo—that is, lesions in which there are no dopa-positive melanocytes—does not repigment. Also these areas tend to react violently with erythema and blistering following the local application of psoralens and exposure to sunlight.

The treatment of "relative cases" should begin with painting the affected areas with a dilute solution of psoralens. We used 25% of the original strength as supplied by the Memphis Chemical Co.; the diluent was acetone. Paintings are carried out twice weekly and are combined with cautious exposure to sunlight. If no untoward reactions occur the strength should be gradually increased until a satisfactory repigmentation has been obtained. I have little experience of oral treatment with psoralens, but the cases I have treated have not responded satisfactorily.

"Benoquin" (monobenzyloether of hydroquinone) has been used for the treatment of hyperpigmentation. It may be used either as a lotion or as an ointment containing 5–33% of the hydroquinone.² It appears that the higher concentrations have been used with good results, but I have found these to be irritating to the skin. The results obtained are variable, and I have never had any satisfactory results myself. Some cases where success has been claimed may have been at the hyperpigmentary stage of vitiligo (this occurs most commonly in the darker races), the ensuing vitiligo being mistaken for a response to the treatment with hydroquinone.

Death and E.E.G. Activity

Q.—For how long after death can electroencephalographic activity be detected? What is its significance?

A.—There have been isolated observations on electroencephalographic activity at death, but since the forms of death were very varied no general statement can be made in answer to the question. It is probable that where the onset of death is slow electroencephalographic activity ceases before respiration ceases. In fact in one case studied by Schwab¹ very little electrical activity could be recorded from either hemisphere 14 minutes before death, although five minutes before death a single burst of normal alpha activity appeared on the left side. After respiration ceased no electrical activity could be detected from the head, but 26 minutes after death moving the chest induced three abnormal beats on the electrocardiogram. In this case the electrocardiogram was a better indicator of the point of death than study of the electroencephalogram.

Nodular Vasculitis

Q.—A woman of about 48 has had her year-old skin lesions diagnosed after biopsy as nodular vasculitis. What relationship has this condition to periarthritis nodosa, and could it account for a coincident menorrhagia?

A.—Nodular vasculitis was described by Montgomery, O'Leary, and Barker¹ as a non-tuberculous form of erythema induratum in which painful persistent or recurrent nodular lesions which seldom ulcerate occur chiefly on the calves, usually in women over 30. Histologically there is a vasculitis with obliterative changes affecting both arteries and veins, together with fibrosis of, and collections of giant cells in, the subcutaneous fat. The absence of distinct tubercles helps to distinguish this condition from erythema induratum, but prolonged observation of the case is advisable before making a firm diagnosis. Treatment is rest in bed with elevation of the legs.

The condition is distinct from periarteritis nodosa, in which systemic manifestations are usually also present. I know of no association between nodular vasculitis and menorrhagia.

Refusal of Post-mortem Examination

Q.—Relatives of patients who die in hospital may refuse permission for a post-mortem examination for a variety of reasons. What can be done to obtain such an examination in a hospital patient where necropsy may be important from a scientific or research point of view? Can the doctor decline to sign the death certificate on the grounds that the cause of death is insufficiently known or understood? What is the legal position?

A.—Except when the death has to be, or has been, reported to the coroner or procurator fiscal, it appears to be the right of the relatives to grant or refuse permission for a post-mortem examination. Refusal, for which reasons need not be given, is then a bar to examinations which are conducted solely for clinical or scientific purposes.

It is the statutory duty of a doctor in attendance upon the deceased during his last illness to issue a medical certificate of cause of death. To bring pressure on relatives to permit a post-mortem examination by declining to sign the death certificate merely on the grounds that the cause of death is not exactly known would thus be illegal as well as utterly reprehensible. It is not a course of action to be recommended in any circumstances.

Whenever it is desired to make a post-mortem examination solely for clinical and scientific purposes, the executor, next of kin, or nearest available relative should be asked to give consent in writing. Experience has shown that, where the duty of obtaining consent is allocated to a carefully chosen official, refusals are rare. On the contrary, the relatives, properly approached, are usually most co-operative; most of them readily appreciate the potential scientific value of the examination.

Food Allergy in a Child

Q.—Since being weaned a 2-year-old boy has suffered severe allergic oedema of the face and limbs and asthmatic attacks whenever given any food other than soya meal. The slightest dietary indiscretion brings on an attack. What can be done to help establish a more normal diet?

A.—The information submitted is insufficient to enable specific advice to be given in this difficult case. Other factors besides foods could be causing some of the symptoms, and it is hard to believe that every food except soya meal provokes an allergic reaction. Presumably the child is allergic to cow's milk, and that is why soya meal was introduced into the diet. Egg, fish, and orange juice are other common sensitivities at this age.

If a child is allergic to a food, then the eating of even a trace of that food may cause allergic reactions. It is therefore important to be especially careful of all "made-up" foods which might contain traces of the food or foods to which the child is allergic. By careful attention to the diet on these lines the number of basic foods to which a child is apparently sensitive may be reduced and the problem narrowed. Foods rarely causing allergic symptoms in children are sugar, synthetic vitamins, meats (especially lamb), rice, tapioca, and olive oil. Occasionally children allergic to cow's milk will tolerate evaporated or well-boiled cow's milk and quite a proportion will tolerate goat's milk. Soya-bean milk is of course an accepted substitute for milk, as also are "meat-base milks," in which meats are used as the protein base. For a full and comprehensive account of the detailed management of food allergies in children *Allergy in Childhood*, by Jerome Glaser (Charles C. Thomas, 1956), is recommended.

NOTES AND COMMENTS

Drugs for Tension and Anxiety.—Dr. G. R. FRYERS (Medical Director, John Wyeth and Brother Ltd., London, N.W.1) writes: The expert's answer on drugs for tension and anxiety ("Any Questions?" March 30, p. 777) needs comment. The only published comparison of amylobarbitone and meprobamate¹ resulted in about the same proportion of patients improving on each drug. However, this simple statement conceals the fact that it was not the same patients that were improved; the differences in action were commented on. The statement that meprobamate is certainly more dangerous than barbiturate is not, so far as I can trace, based on published observations. The reference quoted by your expert² only lists 17 troublesome but non-fatal side-effects collected from the literature. This is in marked contrast to the numerous reports of fatalities with barbiturates (for example, 184 accidental deaths from barbiturates in 1954³). Additionally, the very large number of successful suicides with barbiturates (391 suicides with barbiturates in 1954³) is in marked contrast to the total lack of reports of suicides with meprobamate, despite many attempts. The observation that barbiturates in sedative doses impair judgment and make it inadvisable for a patient to undertake responsible tasks results in them being less suitable than meprobamate for use in patients leading active lives. Very large quantities of meprobamate have been safely used in the U.S.A. and elsewhere. In this country many patients have been treated with meprobamate; the number is now well into six figures. The occurrence of minor reactions and the absence of fatal complications must be set in perspective against the very great usage of the drug.

OUR EXPERT replies: I would not agree that suicide should be included among the complications of any drug. By a complication we normally mean an unexpected injury to health following the administration of the drug in normal doses. Dr. Fryers's observations become even less relevant when it is noted that he speaks of barbiturates whereas I was writing simply about amylobarbitone. The figures he takes from Miss Brooke's well-known article also refer to barbiturates in general, and there was nothing in Miss Brooke's paper to indicate what type of barbiturate had been used to cause death. A fairly extensive experience in a general hospital leads me to believe that most accidental deaths and must suicidal attempts from barbiturate involve dangerous members of the groups such as phenobarbitone or barbitone sodium. Amylobarbitone is used wherever possible because very large quantities of it can be tolerated, and it is difficult to commit suicide with it. I do not know who has observed that amylobarbitone in sedative doses impairs judgment, for I am sure this is not so. I hope Dr. Fryers will feel able to agree with my very moderate claim for amylobarbitone. If we were talking about barbiturates in general, I would agree with everything he says.

Books of "Any Questions?" and Refresher Course Articles.

The following books are available through booksellers or from the Publishing Manager, B.M.A. House. Prices include postage. *Any Questions?*, Volumes 2 and 3 (8s. each); *Refresher Course for General Practitioners*, Volumes 2 and 3 (26s. 6d. each inland, 26s. overseas); *Clinical Pathology in General Practice* (22s. 3d. inland, 21s. 9d. overseas).

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 4499. TELEGRAMS: *Aithology, Westcent, London*. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors overseas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

THE RENAISSANCE OF GENERAL PRACTICE*

BY

JOHN H. HUNT, D.M., M.R.C.P.
(General Practitioner, London)

In Great Britain, at present, our impression of general practice is coloured by the National Health Service, which was launched in rather a hurry for financial and political as well as for medical reasons. I am not concerned here with the pros and cons of this service at its present stage of development. Some are satisfied with it, others are not. If we look to the future we must realize that to be successful and permanent, with a contented profession doing its work well, it must give doctors a satisfactory wage, favourable settings for their work with enough time and the right instruments to do it properly, and encouragement to keep up to date. If, ten or twenty years from now, the National Health Service in this country satisfies these three conditions it will be successful and survive. If it does not, it will be replaced by something better—by some other type of service first developed, perhaps, in another land whose politicians will have been proved in the long run wiser than ours. Let us all be clear in our minds that the present service is in the nature of a long-term experiment, and that it is on trial in the eyes of the world. With good medicine, based on good general practice, as our primary aim, we should constantly compare progress with that of similar experiments in other countries and learn all we can from them; in that way we shall develop a medical organization in the British Isles second to none.

The renaissance of general practice, to which I refer in the title of my paper, stretches out beyond local health services and party politics. It is a world-wide movement concerned with the academic welfare and the scientific encouragement of family doctors in every continent. It is a movement which recognizes that *modern medicine, to do its greatest good, must reach patients promptly in and near their homes*. We have heard and read so much lately to the detriment of general practice in the British Isles that I would like to put on record something to its credit.

Definition of a General Practitioner

General practice is usually, but not always, synonymous with family doctoring; some families have different doctors for the father, the mother and for the children. A great deal of thought has been given in recent years to the definition of a general practitioner. I would like to suggest the following: *A doctor in direct touch with patients, who accepts continuing responsibility for providing or arranging their general medical*

care, which includes the prevention and treatment of any illness or injury affecting the mind or any part of the body. This definition covers the essentials of the general practice of medicine in the depths of the country or in the heart of a great modern city like Manchester; in a family, school, or university; in the merchant navy or the armed forces of the Crown; in a factory, prison, or other institution, at home or overseas. As the name so clearly implies, it is the general nature of the work which is characteristic, and part of it may be connected with neither illness nor injury—for example, infant feeding, marriage guidance, normal obstetrics, and the management of old age. Direct access of patient to doctor is even more important than that of doctor to patient. Continuing care may be from day to day, from month to month, from year to year or from generation to generation. Some specialists, it is true, such as ophthalmologists, dentists, and psychiatrists, have both direct access to patients and their continuing care, but the extent of this care is limited to one part of the body.

Early Development and Continuity of General Practice

To see general practice in its proper perspective it is helpful to consider how the first family doctors may have developed, some hundreds of thousands of years ago, when prehistoric men, women and their families lived in small groups, getting what food they could from plants and from hunting. One can visualize some of them having to treat an ill child or a wounded adult, or perhaps one poisoned by unsuitable food, or with a boil, a splinter in the hand, a foreign body in the eye, a broken bone, frost-bite, or a burn. These medical ancestors of ours were the most *general* practitioners of all time; they did everything, with whatever instruments, dressings, splints, or drugs that were handy or they could make themselves.

The specialists must have started hard on their heels. It is wrong to think of specialism as a product of the last hundred years. Some of these prehistoric men and women must have become adept, beyond the average, at extracting teeth, splinting bones, or delivering babies; we know for certain that some were trephining skulls many thousand years ago. Herodotus tells us that in ancient Egypt, with its full-time medical service, specialism was rife⁸; and you will remember that Hippocrates in his oath said, "I will not use the knife, not even on sufferers from the stone, but will withdraw in favour of such men as are engaged in this work."¹⁰ One can imagine these early specialists even developing small

Even for your problem patient

For patients who are sensitive to aspirin, for asthmatics and for those with a history of allergy, Panadol is a valuable alternative to routine mild analgesics.

Panadol does not exacerbate the symptoms of peptic ulcer (where aspirin may even cause bleeding) and, unlike preparations which contain codeine, it does not cause constipation.

Trade Mark

Contains no aspirin in any form

Tablets, 0.5 g. N-acetyl-p-aminophenol, in cartons of 20, bottles of 100 and 500, and tins of 2,500.

BAYER PRODUCTS LIMITED

Neville House, Kingston-on-Thames, Surrey

clinics of their own: but nature has never dispensed illness or injury in a tidy manner entirely suitable for clinics; people have been ill or injured at any time or place, and many of them have had to be cared for in their homes, especially the children, pregnant women and older folk. So general practice gradually developed. Family doctors and specialists have worked together, on the whole happily, for tens of thousands of years, and I believe that they will continue to do so.

Scope of General Practice To-day

To-day we still have at one end of our medical scale truly general doctors, like those working single-handed on the islands off our coast, in the bush of Australia, or as missionaries in Central Africa, who cannot limit their doctoring at all and who have to turn their hands to any surgical, medical, gynaecological, or psychological problems that crop up. At the other end of the scale we have highly trained specialists studying small fields in microscopic detail: for example, Professor C. I. Thomas, of Cleveland, Ohio, has just written a book of 1,318 pages, with 400 illustrations, on the cornea—a part of the body 1 mm. thick and 12 mm. in diameter.⁵⁰ In between these two extremes there is every type of doctor.

However good the microscopes, the naked human eye with its breadth of vision will always be essential for everyday life. No matter how clever the consultants or how excellent the hospitals, it is the efficiency of the family doctors, and the work they do in and near the homes of their patients, which will determine the calibre of the medical services in any country. One sometimes hears the suggestion that general practice may be slowly disappearing, especially in the United States; but a recent survey there⁵¹ shows that 82% of the population claim to have a personal or family doctor—one whom they usually call first—which is probably as high a figure as ever before. In Great Britain in 1955 Mr. Iain Macleod, then Minister of Health, said: "I think we ought to make—and for it to be seen that we are making—the general practitioner the king-pin of the whole of the National Health Services in this country."⁵²

As medical science has become more complex, the tendency throughout the world has been for general practitioners, like their specialist colleagues, to limit their technique and share their work with others, so that they themselves may be more efficient in that which they elect to do. This trend is not new; it has been there from the beginning, but the rapid growth of medicine during the last one hundred years has made it more evident. In large communities, now, no family doctor can possibly be truly "general," giving his patients that excellence of care and attention in every branch of medicine which modern science leads them, rightly, to expect as their due. In this respect general practice to-day does differ from that of our ancestors long ago. A considerable part of what was once done in a simple way by a family doctor must now be carried out by teams of experts, under his direction. This has tended to reduce one severe handicap of the past—the isolation of the general practitioner.

Medicine, which was once as simple as a dugout canoe, is now as complicated as a modern battleship. Both need to be guided. The family doctor of to-day has to work, on his patients' behalf, in close and friendly co-operation with many different people, who include his general-practitioner colleagues (perhaps in partnership or in a group practice), all the specialists and consultants in his area (several of whom may be concerned in the diagnosis of even one difficult case), and all those ancillary services which are essential for his own task—secretarial, receptionist, nursing, the laboratory service, medical officers of health, and the personal health services of local authorities (maternity, child welfare, and school health with their personnel—health visitors, midwives, district nurses, home helps), and the special services for patients in particular categories (the tuberculous, the blind, the mentally ill, the aged and chronic

sick). To these must be added all other parts of the hospital service (including almoners, dietitians, chemists, dentists, oculists, physiotherapists, chiropodists, etc.) and also the instrument makers, pharmaceutical manufacturers, school-teachers, parsons, lawyers, and so on. This is a long list, and it could easily be made longer still; its length underlines the point I wish to make, which is that the activities of all these different people must be co-ordinated and correlated by the general practitioner to ensure that all of his patients' particular needs are met. In the general practice of the future this guidance of patients by their family doctors, and this team-work, will be needed still more; and all our plans must be based upon them.

Dr. Richard Scott, of Edinburgh, in his concept of the family doctor team and the personal relationships between doctors, their helpers, and the patients they serve, lays special emphasis on the need for reinforcing medical skill with that of the trained medico-social worker or almoner, and he points out how much is achieved and how much time is saved by regular personal discussions between members of this team.⁵³ It is a pity, and a mistake, when the personal and human nature of these relationships is forgotten. On July 21 last year, a doctor in the South of England wrote to the President of the College of General Practitioners saying that he had just received a letter from a certain executive council addressing him on the envelope as "Dr. 2126."

The Art of General Practice

You will have observed that in my definition of a general practitioner I have put care of the patient's mind before that of his body. This was done deliberately, because I know we all agree that the family doctor's awareness of what his patients think and feel is vitally important for the whole of his or her work. I should now like to discuss the future of the doctor-patient relationship and what is popularly called the "bedside manner," and also the parts to be played by more formal psychology and psychiatry in the general practice of to-morrow.

The Bedside Manner

In treating almost every illness there is need to strike a proper balance between science on the one hand and the art of medicine on the other; and much of the latter is to be found in the manner of the doctor by the bedside of his patients or in his surgery. It is true that, occasionally, either the art or the science of medicine may be paramount. When one is treating a mother who has lost an only child, or helping someone else in the last stages of cancer, compassion and sympathy may be all that really matter and science may hardly enter into the problem. On other occasions science and technique are all-important, as when a surgeon is doing a difficult operation, or a physician is treating an unconscious patient. By and large, we must agree with Dr. Geoffrey Barber when he says, "I would rather be in the hands of a man with an accurate knowledge of medicine, and with but little of the milk of human kindness, than in the care of the kindest man imaginable who didn't really know his job";⁵⁴ but luckily it is often possible to have the two together, because both the science and the art of medicine play essential parts in the care of nearly every patient. Not long ago a patient of mine had a baby girl who was born with a hare-lip and cleft-palate. We asked a famous plastic surgeon to talk to the mother a few hours after the child arrived, and I wish those who believe that modern science and a good bedside manner are incompatible could have heard what he said; the mother will remember it with gratitude all her life. No matter how much science develops during the next few hundred years, the need for the art of medicine will still be there. As Sir Arthur Hall wrote in 1941: "The need for it is as great to-day as it ever was, or ever will be, so long as human sickness continues."⁵⁵

The courtesy of a good doctor is not something he puts on like a white coat when approaching a patient's bed, or in the surgery, or when speaking to him on the phone; when that is so, it will inevitably be artificial and insincere.

Doctors with the best bedside manners—and it is largely a question of manners—are those who are their own natural, decent selves with their families, their friends, servants, nurses, secretaries, and with their patients. It is a paradox that the doctor with the best bedside manner is the one who puts on no special manner by the bedside of his patients.

Let us try to analyse what we mean by this term "bedside manner," which is now out of date and a target for the wit of the music-hall artist and the caricaturist; and let us see what others have thought about it in the past. Although there are very few papers on it, several references are to be found tucked away in the journals. It is something that gives confidence to patient and doctor alike, and helps them both. Like charm, it is almost impossible to define. Its components, I think most people will agree, are personal interest, kindness, sympathy, friendliness, understanding, cheerfulness, and humour; beyond this the list may easily deteriorate into a dull one of all the virtues, missing the important points. Oliver Wendell Holmes, nearly a hundred years ago, added: "Good dressing, quiet ways, low tones of voice, lips that can wait, and eyes that do not wander . . . to belong to the company you are in."⁵⁶ Sir Archibald Garrod in 1926 supplemented this with "tact, resourcefulness, courage and prudence . . . patience with fads."⁵⁷ This last, I think, is important. Good doctors are often those with "high boiling points."

Sir Francis Walshe, a scientist of renown and a Fellow of the Royal Society, added, "vigilant and humane insight . . . and at times . . . firmness." I agree with him there. It is no use trying to please everyone. One cannot help feeling that if Hippocrates himself was now a doctor in Manchester or London there might be several who would not want him as their personal physician. Sir Francis deplored the fact that the term "bedside manner" was so vulnerable to the simple-minded jester. "Long experience," he said, "has taught me that those who most readily make wisecracks about the bedside manner are themselves, when sick, commonly most exigent of what they conceive this manner to be. They like to eat their cake and have it."⁵⁸

There are other attributes which are helpful. One is a good memory for names. Dr. William Pickles, the first President of our College, whose practice is in a Yorkshire dale at Aysgarth, has told us recently that he used to know the Christian names of every man, woman, and child in all the villages in his dale.⁵⁹ To be able to do this one must be fond of one's patients; and Francis Peabody epitomized the whole matter when he said, "The secret of the care of the patient is in caring for the patient."⁶⁰

The point I wish to make is that scientific medicine and a good manner by the bedside are not incompatible; indeed, they are really complementary to each other. The best clinicians of the future, as in the past, will be those who can combine them to the fullest extent; they are both essential to all good doctoring. This idea is not at all new, but it is sometimes forgotten. There is an urgent need for some of the scientific and organized medicine of to-day to be infused with more of the wisdom, courtesy, and charity of our predecessors, to bring up to date the psychological insight of the family doctors of fifty or a hundred years ago.

Psychology and Psychiatry in General Practice

This brings us to the part that more formal psychology and psychiatry play in general practice. Psychology has been defined as "the science which deals with the mind and mental processes,"⁶¹ and psychiatry as "the recognition and treatment of diseases of the mind."⁶² The attitude of general practitioners towards patients with nervous symptoms should, I believe, be based primarily on normal psychology and on study of variations in normal behaviour, rather than on psychiatry and mental disease. The limits of normal behaviour are far wider than was at one time thought. The Kinsey Reports,⁶³ based on the sexual behaviour of normal men and women, illustrate this; and honest reports on other aspects of human activity and emotions show the same wide range of normality. It can be argued that the

great majority of behaviour problems in children and in adults which confront family doctors, and many cases of emotional disorders with anxiety and depression arising from the disappointments, frustrations, anxieties, and sorrows of everyday life, fall within this wide range of normality, and should be regarded fundamentally as physiological rather than as pathological or psychiatric. In so many of these cases the patient, his relatives, his friends, and his family doctor know that he is not really mentally "diseased"; and it is natural that they should all dislike the idea of the patient being under the care of one who specializes in mental illness, which is, by definition, what treatment by a psychiatrist implies.⁶⁴ I believe that this fact is at the root of much of the distrust and resentment which have for so long surrounded the management of these particular cases by psychiatrists. A much wider popular interpretation of the word "psychiatry" is required. A definition said recently to be "fairly acceptable" in America is "the study of interpersonal relationships."⁶⁵

Wise family doctors of the past have nearly always been depicted as elderly men who, by long experience in a life of general practice, came to recognize the wide range of normal behaviour—to "understand human nature." The same has applied to specialists. W. E. Fothergill has told us that David Lloyd Roberts was "A born healer, it did people good merely to see him; he could not only help those who were ill, but he could also cure those who were well—a much more difficult matter."⁶⁶ This wisdom can be learned, as Dr. Lindsey Batten has charmingly put it, "from the professors or from the poets, the novelists, the Bible, and your own experience, or you can mix them all; but you must not suppose that Psyche is an illusion, an invention of the psychologists, or that you can afford to neglect her. She has a finger—sometimes a fist—in every medical pie."⁶⁷

Given the opportunity, many older doctors still learn this lesson in time; but all medical students, especially those who are to enter general practice, should be given more instruction than they get at present concerning the surprisingly wide range and variation of normal human behaviour and emotional reaction. Some medical schools are already doing this—especially Leeds, Cardiff, Guy's, and the Middlesex—teaching psychology from the dynamic point of view, imparting an understanding of the principles underlying good mental health. Students must also be taught the art of listening, which can be acquired. It is not unknown for doctors to talk so much, and to ask so many questions when taking a history, that the patient learns far more about the doctor than the doctor does about the patient. With adequate training and a charitable disposition, a family doctor, even if he is rushed and has little time to spare, can manage fairly well many of these behaviour and emotional problems. When he can do this himself the result is often better than when such patients are referred to a psychiatric clinic, there to mingle with some who are really mentally sick with more severe personality or behaviour upsets, neuroses, depression, hysteria, psychoses, organic cerebral disease, etc. One would like to see the general practitioner of the future an expert at recognizing and dealing with more of these normal variations—a wonderful field for further observational research.

The treatment of these emotional upsets by general practitioners raises the problem of how much time they can spare for it. The "time versus service" difficulty is one that confronts every practising doctor nearly every day; each must solve it for himself. There is little doubt that every new patient should be allowed, one time or other, at least half an hour's conversation with his doctor. In some circumstances the history can be taken on one occasion and the examination done on another. Four sessions of a quarter of an hour each may sometimes be nearly as good (though not quite so good) as one hour at a stretch; and by adding together even shorter periods a full history and examination can in the end be made, if there is order behind the investigation and if suitable notes are taken. In certain

circumstances, when personal problems are being unravelled, an hour or more of uninterrupted conversation may be required; but these longer sessions are not so often needed as is sometimes supposed and, when they are, time can usually be found for them by planning ahead. It is impossible to state categorically the number of patients whom any general practitioner may look after well. Doctors and patients vary so much—in different age groups and in different communities—that each doctor must decide for himself, at each stage of his career, how many patients he should rightly have under his care.

General Practitioners with Special Interests

In cities and large towns, family doctors, whether they work on their own, in partnership, in group practice or in a health centre, can get their specialist assistance from hospitals or consultants working near by. The advantages and disadvantages of these different types of practice have been discussed elsewhere.²²⁻²⁶ Over much of this country, however, and indeed over a great part of the world, consultants are further away, and groups of practitioners are working together more in teams, developing special interests among themselves so that they can help one another by pooling a variety of experiences, skills, and techniques.

Let us take obstetrics as an example of one of these special interests. Not all the members of a partnership may have the inclination, time, or training to do midwifery. If one of them has taken the trouble to train himself carefully in this subject he may be of inestimable value to his group. In its memorandum to Lord Cranbrook's Committee, presented this year, the Royal College of Obstetricians and Gynaecologists said about the maternity services in the Oxford area: "... Every encouragement is given to those general practitioners who have fitted themselves by postgraduate study to practise obstetrics, and general-practitioner maternity units are encouraged and are regarded as integral parts of the area department. ... These general-practitioner obstetricians can become highly skilled and exert a powerful influence over the work of their colleagues both in the maternity unit and in domiciliary practice."²⁷

From their memoranda to the Cranbrook Committee, the Royal College of Obstetricians and Gynaecologists and the College of General Practitioners¹⁷ seem to be in complete agreement regarding the role of the general-practitioner obstetrician, whose future seems likely to be assured. The problem and its solution is much the same for family doctors with one or more special interests in other branches of our profession—medicine, surgery, anaesthetics, paediatrics, geriatrics, dermatology, rheumatology, psychiatry, allergy, public health, tropical medicine and so on. Every group practice of the future must borrow from the specialties as much of their knowledge and technique as is applicable to family doctoring. To call these general practitioners with special interests "general-practitioner consultants" as has been done recently¹² is, I believe, wrong. They are primarily general practitioners who have studied, in a limited way, one or more particular fields of medicine. The more complex the specialties become, the more will these general practitioners with special interests be needed; but it is extremely important that they should remain first and foremost general practitioners, and that they should limit themselves strictly to the general-practice aspects of their special subjects as these apply to family doctoring in and near their patients' homes. Their success depends on the proper limitation and supervision of this special work.

One of the main advantages of this type of group practice is that its members can teach each other as they go along; each of them leavens the whole group. A specialist appreciates a general practitioner who uses him efficiently; and often there are no greater friends or more loyal colleagues than a general practitioner with a special interest and a consultant in that subject, be they neighbours or many miles apart. They speak the same technical language, and learn from each other every time they meet. Such close and

friendly co-operation between general practitioners and consultants is possible in all branches of medicine, and is much to be desired.

The encouragement of general practitioners with special interests, so that a group may fulfil all the functions of the family doctor as we have known him in the past, is the way that general practice in many places, especially those far from hospitals and consultants, can keep in step with the rapid expansion of modern medicine. It is a logical development, and one that is already working well in a great many parts of the world. It helps patients by saving them much travelling and time, and many visits to hospitals; it helps groups of family doctors by making general practice more interesting, by easing their burden of responsibility and in many other ways which have been described elsewhere²⁸; it helps hospitals by relieving crowded out-patient departments and in-patient waiting-lists, giving consultants more time to do their own work properly.

Many excellent new types of group practice are being tried out at present in this country—in Bristol,²⁹ at Corby,³⁰ and at Harlow,³¹ among others. At Harlow the family doctors are doing nearly all the work of the maternity and infant welfare clinics, and running the industrial health service. In future, emphasis must be more and more on prevention, early consultation, and early treatment; and it is a pity that the statutory term "health centre" applies, now, only to one form of group practice.²⁹

Diagnostic and Therapeutic Aids for General Practitioners

One of the most essential needs of every family doctor is direct and easy contact with diagnostic and therapeutic procedures—pathological, radiological, nursing, minor surgical, etc. This is his right, for with them he can diagnose and treat many of his patients more quickly, more fully, and more cheaply than has hitherto been possible.³² One of the medical lessons we have learned in this country during the last ten years is that when family doctors are given these diagnostic and therapeutic aids they do not squander them. The recent reports of Dr. F. N. Marshall, of the Manchester Regional Hospital Board,³³ and of Dr. H. W. Ashworth and others, of the Darbshire House Health Centre,³⁴ have shown this again. Patients and their doctors, consultants and their hospital departments, all benefit. Considerable progress has already been made, but there is still a great deal to be done to help general practitioners in this way, especially in places far from a general hospital.

General Practitioners in Hospitals

General practitioners visit hospitals, or work there, for five main reasons, which may overlap: (1) to diagnose and treat their own patients or those of their partners; (2) to visit or consult over their patients; (3) to foster their own general postgraduate education; (4) to acquire and maintain experience in a special subject in which they are interested; and (5) to teach undergraduate medical students. Here I would like to comment briefly on the first three of these; the fourth has already been discussed and the fifth is mentioned later.

(1) In small hospitals in country districts, family doctors for many years have done excellent work on their own patients who, for purely social or economic reasons and not because they need specialist care, have had to be moved from their homes into hospital beds. In larger towns and cities, family doctors do the same work as their country colleagues, their patients have the same straightforward complaints, some of which may be difficult to treat at home; and yet, in towns, for a reason never properly explained, it is considered that family doctors should have few, if any, hospital beds. Throughout England and Wales each general practitioner has, on an average, one-third of a share of one hospital bed.³⁵ This means that many consultants, specialists and their assistants are doing general-practitioner jobs, spending their valuable time being responsible for the

treatment of patients in hospital who do not really need their expert knowledge and attention and who, in many instances, would prefer to be cared for by their family doctors. Overseas this anachronism does not exist to such an extent, and in time it will, perhaps, be corrected in the British Isles.

(2) Every opportunity should be taken by general practitioners to visit their own patients who have been admitted into hospital under the care of specialists; to talk to the house officers and nurses in charge; to be present at a consultation in an out-patient department, a ward, pathological laboratory or elsewhere; and to attend an operation or perhaps the post-mortem room. This entrée of family doctors to hospitals, and the contacts thus made with hospital staff and consultants, may sometimes be difficult to arrange and be time-consuming for all concerned, but they are well worth while.

(3) For their continuing education general practitioners may learn much from attendance in hospitals—at lectures, ward rounds, clinical demonstrations or other meetings which have been enumerated elsewhere.¹⁶ They can also work with specialists in hospital out-patient or in-patient departments as senior or junior hospital medical officers, or as clinical assistants, for one or two sessions a week.¹⁶ If these appointments in hospital departments are held in rotation, several subjects may be covered in a few years. This may not help the hospital as much as when a general practitioner works in one department permanently, as he may do if he has a special interest, but it is almost certainly better for the doctor's general postgraduate education. It should be remembered that the primary object of this particular hospital work by a family doctor is to help him to keep up to date, and not to use him as a convenient source of extra help when there is a shortage of staff, or when the specialist is busy or away; that is a job for a trainee consultant. The temptation must be resisted to make use of family doctors, as has recently been suggested, "to keep the hospital services going" or as "pairs of hands for ... relieving the junior staff of much routine work."³⁶ In an emergency, or at specially busy times, general practitioners will nearly always be most willing to help a hospital; but with all their responsibilities in the homes of their patients—their first concern—they have more than enough of their own work to do.

The College of General Practitioners

In many countries general practitioners are developing academic headquarters of their own. The Americans were first with their Academy of General Practice in 1947; we were second with the foundation of the College of General Practitioners in 1952; and the Canadians third with the College of General Practice of Canada, founded in 1954. The Netherlands, Germany, India, the South American states, Australia, and other countries are following these examples. There is talk of an International Committee of General Practice to co-ordinate the activities of them all.

If our College had, in fact, been formed a hundred years ago, as it nearly was, the development of general practice in this country and the part which family doctors play in the National Health Service would have been, I am sure, different from what they are to-day. The response to its foundation on November 19, 1952—over 1,200 members and associates joining within the first three weeks, the steadily growing membership since then (it is now 4,152), and the co-operation of the Ministry of Health, the General Medical Council, the British Medical Association, the Medical Research Council, the Society of Apothecaries, and many other institutions—has made it abundantly clear that this College was needed, and that it has an important part to play in the future of medicine in this country and in the Commonwealth. When we began it seemed to us, as Dr. G. F. Abercrombie said at our last annual general meeting, that "the home of our College would have to be in the hearts and minds of men"; but the generosity of an anonymous donor, and the foresight and co-operation of the President

and Council of the Royal College of Surgeons, have made it likely that we shall, before long, have a fine building of our own.

During its first four years the College has developed 35 regional faculties, 13 of them overseas—in Eire, Australia, New Zealand and Africa. It has published fourteen issues of a *Research Newsletter*, of more than 1,000 pages, with Dr. R. M. S. McConaghey as editor; it has a research register of more than 500 general practitioners interested in doing original work. A College Records Unit is being developed; a General-Practitioner Teaching Register is being drawn up of those family doctors who are willing to take students and to lecture; and a list of those diseases and injuries which are met significantly often by general practitioners in this country has been prepared. A ten-page questionnaire on the continuing education of family doctors has received more than 2,000 replies. Each month a list of postgraduate lectures, demonstrations, and courses in London and the Home Counties is circulated as a Postgraduate Information Diary. A College Research Fund has been opened.

The College is represented on many academic bodies, and has worked in the closest possible liaison with the Ministry of Health in England (and the corresponding departments in Scotland, Northern Ireland, Eire, and Australia), with the British, Irish, and Australian Medical Associations, and with the British Postgraduate Medical Federation of the University of London. It has been invited to submit reports to the General Medical Council on the "Medical Curriculum," and to the Ministry of Health on "Medical Manpower," "General-Practitioner Obstetrics," and "Psychiatry and the General Practitioner." It has been presented with the annual James Mackenzie Lecture, the Butterworth Gold Medal, the Pfizer Postgraduate Grant, and the Public Welfare Foundation Grant, and it has been invited to adjudicate for the Benger Prizes for original observations by general practitioners. The College hopes to help young doctors with their equipment and premises. Twenty thousand copies of an obstetric record card designed by members have already been distributed, and other cards, charts and diet sheets are being prepared.

Dr. F. M. Rose said at our first annual general meeting that doctors have joined the College "not because we think we are good practitioners but because we want to be better ones." On June 17, 1954, on the occasion of the foundation of the College of General Practice of Canada, our first President, Dr. W. N. Pickles, sent a recorded message across the Atlantic: "It is my firm hope and belief," he said, "that the inauguration of our Colleges will be a turning point in the history of general practice, and that the patient endeavour of each will inevitably raise its standard and perpetuate the high ideals which we associate with this great branch of our profession."¹³

It is not only the foundation and other members and associates of our College who believe sincerely in its future, and in the good work that it will do; thousands of others, both within the medical profession and outside it, think so too. It is right and fair that everyone should now co-operate with us and help us to carry out our difficult task. I would ask all individuals and institutions to search their hearts and their records for what they themselves have done during the past half century to encourage, academically, family doctors in active general practice; and I would invite them to compare their lists with what our College has achieved during its first four years.¹¹⁻¹⁵

Teaching of General Practice

In spite of attempts to prove otherwise, by juggling with figures and definitions, there is no reasonable doubt that the majority of students still enter general medical practice of some sort or another—at home or overseas, in towns or in the country, in schools, factories, or other institutions, or in the armed forces. While this remains so—and it is unlikely to change—it seems illogical that students should not be taught something by those with personal knowledge of this important branch of medicine. Our College is

encouraging general practitioners to teach, and the majority of the medical schools have already accepted this idea. The report of the British Medical Students' Association last year showed how well the schemes of student-attachment to family doctors, and lectures by general practitioners, were developing—supplementing and not replacing in any way specialist teaching. In some teaching hospitals in this country (St. Bartholomew's and others), and also in Canada⁷ and in the U.S.A.,⁸ general-practice resident appointments are being developed for those who wish to become family doctors. In Australia the attachment of students to general-practitioner hospitals is becoming popular.

Dr. John Ellis, who has had so much to do with the recent reports of the Royal College of Physicians on Medical Education, said in his Goulstonian Lectures last year: "The standard of medical care in this country depends upon the standard of general practice, and medical schools must regard it as their first duty to ensure the best possible undergraduate education and postgraduate training for their students who will take up general practice. . . . This branch has for centuries attracted many of the finest men in medicine, and it will continue to do so."⁹

Teaching hospitals have departments allotted to many different subjects, and it is probable that before long a department of general practice will be considered an essential part of each medical school in this country, as it already is in many medical schools in the United States¹ and Canada.¹⁰ Last year the House of Delegates of the American Medical Association unanimously approved a resolution directing "that all possible means be taken to stimulate the formation of a Department of General Practice in each medical school."¹¹ All that it may be possible to have, to start with, in some of the teaching hospitals in our country may be a small room, perhaps shared with another department, where a general practitioner of experience, preferably one who works near by, can give advice on any problem connected with general practice to anyone in the hospital—from the most junior student to a full-time professor or other member of the staff. These problems may be concerned with family doctoring in the neighbourhood of the hospital or further afield, with the selection of students, with the teaching of general practice through student-attachment to family doctors or through lectures by them, with the problems of the pre-registration year, with the difficulties met with by young doctors entering practice in this country or overseas, and with the continuing education of old students of the hospital.

From these small beginnings—with a part-time practitioner in a single room—this service will be given a chance to prove its value. Its future development will depend on the needs of that particular school, the response from the students, and the enterprise of the general practitioner concerned. Departments in different medical schools will develop along different lines; and it is likely that in time they will all prove as valuable as the general-practice teaching units have already done in Edinburgh^{12,13} and at Darbshire House in Manchester¹ for conveying to students a proper appreciation of general practice. Before long, perhaps, one of our enlightened universities will found a Chair of General Practice as an example for others to follow.

The less a medical school has taught its students about general practice, the more will they need to learn about it after they have left their teaching hospital. Paucity of training in this subject may be one of the reasons why such a small proportion of general practitioners return to their own medical schools for help and advice once they have left. A department of general practice in each school, keeping in touch with its old students year by year, would supply a permanent centre of information and assistance which, if properly organized, would do the school and its sons and daughters a great deal of good. Until such departments are formed the Regional Faculties of our College, which are nearly all based on a medical school, may do much to help students and young doctors in this way.

The Continuing Education of General Practitioners

A new attitude of mind towards the continuing education of family doctors is developing, and our College is particularly interested in it. The academic status of the general practitioner of the future will depend very largely upon his keeping up to date. As Dr. E. G. Housden has said: "If we wish to be thought of and treated as a learned profession we must live to justify it."¹⁴ Medicine is changing so much, and so quickly, that if the family doctor is to contribute his proper share to the well-being of his patients he must know about recent developments as they occur, not only in diagnostic and therapeutic techniques but also in public health, preventive medicine, social and industrial medicine, and so on. The need for this postgraduate training was stressed recently by the Canadians,¹⁵ who have shown that about 90% of prescriptions written now by family doctors could not possibly have been written twenty years ago, because the drugs did not then exist. Nowadays, in a maze of specialties and new forms of specialist treatment—many of them frightening and some of them dangerous—the general practitioner has got to be his patients' trusted guide. This he cannot be unless he keeps in touch with each major diagnostic and therapeutic advance, unless he knows his patients and his judgment is sound. A broad education, wide experience, and a deep understanding of medicine and personalities, and the knowledge that he has kept himself up to date, will establish him as a competent and responsible leader of his patients' medical team.

Apart from keeping in touch with these recent advances, he needs also much revision. His time is limited, and one must remember that he has the whole of medicine to cover. If he can do one hour of formal postgraduate training a week he has done well, though this is a total of only fifty-two hours a year. This is too little time for an enormous job, so that the subjects for his postgraduate classes must be chosen carefully and be limited to those of interest to him. Postgraduate courses must be organized thoughtfully and integrated one with another; anyone who has tried to do this will realize what a stupendous task it is. A country-wide general-practitioner postgraduate curriculum is really what is needed.

Less than half of the varieties of postgraduate education for general practitioners are measurable¹⁶ or formal enough to allow the Ministry of Health to pay for them. One doctor may keep much more up to date by reading his journals carefully, seeing his patients with consultants, and attending meetings of his local medical society, than does another who goes to formal intensive or extended courses once or twice a year. The second programme may be paid for by the State, while the first is not. Official postgraduate courses are by no means necessarily the most important part of the continuing education of a general practitioner; we must remember that all the rest is important too—carrying on his practice efficiently, attending consultations and meeting consultants elsewhere, reading, going to medical society meetings or lectures, demonstrations, or ward rounds, working in hospitals, taking students, entering for prizes or travelling scholarships, doing research, and so on.¹⁶ Family doctors must learn to teach themselves and each other more, and not look to specialists for all their instruction.

The part played by general practitioners in the work of medical societies is steadily increasing; the recent development and success of the General Practice Section of the Royal Society of Medicine is an outstanding example of this.

Travelling fellowships may be of greater importance to family doctors in future: and so will correspondence courses for those in outlying areas, especially abroad.

Publications for General Practitioners

For the last half-century many of the articles and books published for general practitioners have been written by specialists. At first they were generally acceptable, because the writers had themselves been in general practice and

known its problems; but in recent years many of these authors have spent little or no time as family doctors, and some of their writings have become less and less applicable to the work of those for whom they are intended. For example, in a recent textbook on the practice of medicine published in this country, and in by no means its first edition, there are scores of pages on diseases which the average general practitioner in the British Isles may not meet even once in his professional lifetime, while such important things as insomnia and breathing exercises are omitted from the index and from detailed discussion.

There is an increasing need for books on general practice to be written by general practitioners and specialists working in co-operation. This will ensure that the content and the emphasis of the articles will be correct from the family doctor's point of view. Many general practitioners are taking an interest in one or other of the different specialties—about one-quarter of the members and associates of our College have obtained a higher diploma in a special subject that interests them, others have studied special branches of medicine that have no diploma—so that it should not be difficult, in time, to find a general practitioner to cover every article. Several excellent books have been written recently by general practitioners and by those closely connected with them,^{18,19,20,21,22} and there has been a marked increase in the number of articles by family doctors appearing in the medical journals.

This leads to another matter of concern. From the mass of medical literature now published each year, how may good material best be picked out and kept for future use? Our recent questionnaire has shown that no fewer than seventy-five medical journals, published in different parts of the world, are taken regularly and read by members and associates of the College of General Practitioners. No doctor in practice has time to read more than a few of these, though he may perhaps glance through several others. He cannot attempt to remember all he reads. Few bind their journals or have room in their houses to store them; fewer still are in close touch with a medical library. What, then, should the average general practitioner do with the articles he wishes to keep? The easiest solution is for him to tear them out of the journals and file them, as many already do. The tearing up of journals has now become almost essential for those who wish to keep articles for easy reference. Many journals are bound in such a way that tearing out pages is easy; in others it is well-nigh impossible to do so without leaving an untidy, jagged edge which frequently tears into the script. The *Proceedings of the Royal Society of Medicine* and the *Canadian Medical Association Journal* are among the most difficult in this respect. It may be cheaper to bind these journals as they are, but it must reduce their value to many a busy doctor, who may not always have a pair of scissors or a penknife at hand while he reads them. It is surprising, too, that some journals still fail to give an adequate reference (to the journal, year, and volume) on the first page of each article, yet this is most important if articles are to be filed.

It is hoped to develop soon a general-practitioner library service, in connexion with the College, perhaps with a full-time director and secretary. This service will give general practitioners much literary help in collecting references and extracts from journals and monographs, and photostatic copies of papers. It should be of great value, too, in the continuing education of family doctors.

I cannot leave the subject of publications without mentioning a form of literature for general practitioners which is steadily increasing in size—that which reaches us at our breakfast tables six mornings a week, as leaflets, pamphlets, booklets and blotters from pharmaceutical firms. It has been described somewhat cynically as our "blotting-paper reference library." That from the reputable firms contains much useful information about new drugs and preparations which is sometimes difficult to find elsewhere. Much of it is as scientific, well set out, and documented as one could wish, and I am now thinking particularly of some of the recent

booklets on the new hypotensive drugs. General practitioners can help themselves greatly, when filing information about the proprietary medicines they prescribe, by being highly selective and by using as few preparations as possible of any one drug. Selective replacement in one's files is much more helpful than frequent addition.

I would make a plea to the pharmaceutical industry not to flood us general practitioners with too much paper, smothering useful information with advertising technique, to avoid mixtures as much as they can, and not to duplicate preparations more than is absolutely necessary. Doctors and patients are easily bewildered and confused by too many different names for the same substance. I have weighed the literature from the pharmaceutical firms which has reached me by post during the past year; it comes to about half a hundredweight. Those doctors who have worked out some plan of campaign for making good use of this mass of postal information can gain a great deal from it; but if the volume increases much more it will defeat its own object, because we shall all be forced to consign it at once to our "round files," as an American once described to me his wastepaper baskets.

Research by General Practitioners

The idea that family doctors can do research, and good research, is not new. That they can be successfully encouraged to take part in large-scale investigations over a period of time has been shown recently to be possible. One of the most valuable and stimulating contributions which the College of General Practitioners is making to medicine at present is concerned with such organized general-practitioner research. As Dr. R. J. F. H. Pinsent has written: "Never before have general practitioners in this country had an opportunity to develop a sense of corporate endeavour in their work, nor have they had the inducement to apply themselves to research into the problems which they encounter every day."²³

The recent Measles Survey, the work of the Epidemic Observation Unit under the direction of Dr. G. I. Watson, the Obstetric Survey of the South-west England Faculty, and the National Morbidity Survey carried out with the help of Dr. W. P. D. Logan of the Registrar-General's Department, are good examples of this. Hitherto it has not been practicable to arrange a study for a whole year of morbidity in a hundred general practices scattered over England and Wales; all previous studies have been limited to a handful of doctors over a short period of time. This latest investigation has been on a scale so much greater than anything ever attempted previously, anywhere in the world, that it may well prove to be a landmark in the history of collective investigations and an example for other countries to follow. The College Records Unit, mentioned already, will seek to carry on the work of this National Morbidity Survey, attempting a continuing study of the morbidity met by family doctors; and it is hoped that this will reveal changes in the patterns of disease in the community as soon as they occur.

Joint investigations by small groups of practitioners interested in a particular subject, working perhaps even in different continents, open up vistas of research on unusual matters never before attempted. A report from one study group on acute chest infections has already been published; others are still at work. Many faculty-sponsored investigations are also under way. By means of the Register of Research Interests compiled by our College, its members and others can now be put in touch with general practitioners who are prepared to help in the study of particular problems.

Investigations by single individuals, too, have been encouraged. The Benger Award of annual prizes worth £500, for original observations by general practitioners, may lead to some fascinating and unexpected discoveries.

There are proposals for developing, through the College, a central organization to help with the planning and analysis

of individual and collective research in general practice, especially in epidemiological problems. There is also a need to increase the number of "research practices" (some of them subsidized perhaps by the Clinical Research Board) in which the doctor is given a grant to enable him to employ trained assistance to carry out observational research into epidemiology, therapeutics or other subjects according to his bent or capacity.

Conclusion

We are living in exciting times for the medical profession, academically and politically. Everyone in our country now has a family doctor and can receive attention without financial embarrassment. There are, it is true, certain disquieting signs—excessive resort to hospitals and to specialists, the partial avoidance of responsibility by some general practitioners and their subsequent loss of efficiency, the incursions of clinics, the deadening effect of a uniform and universal capitation fee, and now money-squabbles with the State—all of which threaten the future welfare of medicine in Great Britain. We must see to it that these setbacks are only temporary. Unless conditions become such as to stimulate initiative and enthusiasm, to open out the possibilities of advancement, and to create the maximum sense of responsibility, there is a danger that many general practitioners will soon find themselves doing mainly routine sorting work.

Fortunately there are signs of a new birth too, of which I have tried to tell something in this lecture. Modern science has equipped us as we have never been before; whether we reach our patients by car, on foot in the jungle, by breeches buoy between two ships at sea, or by air as a flying doctor, we now have drugs for treating them in their own beds, or while they remain at work, that were undreamed of thirty years ago. We have many more helpers, both within the profession and outside it, co-operation with whom should bring lasting benefits to our patients in and near their homes; and several new types of group practice are being successfully tried out. The academic renaissance of general practice that is taking place throughout the world, just now, is a very real thing; and among its most convincing manifestations has been the foundation, growth, and vitality of our new College and of its sisters overseas. They have all made tremendous progress in a short time; their future is bright, and in many other places there is enthusiasm to follow their example.

We inherit from our predecessors a better concept of the art of family doctoring than any other country in the world; and a great responsibility rests on us all—doctors, laymen, and politicians alike—to ensure that here and throughout the Commonwealth the present opportunity is seized to regain for general practice its rightful place as one of the finest branches of our profession and one of the most interesting and satisfactory in which to serve.

MANAGEMENT OF THE TUBERCULOUS DIABETIC

FOLLOW-UP OF 84 CASES FOR ONE YEAR

BY

G. R. W. N. LUNTZ, M.R.C.P.

Consultant Physician-in-Charge, Diabetic Unit, Romsley Hill Hospital, Birmingham; Consultant Chest Physician, Birmingham Chest Clinic

Pulmonary tuberculosis is a common and important complication of diabetes mellitus, but only in the last few years has there been an increasing appreciation of the necessity to ensure special treatment for patients with the combined diseases. Oakley (1947), Luntz (1947), and Lawrence (1948) advocated the establishment of special units for the treatment of tuberculous diabetics. The Central Health Services Council (1952) suggested that tuberculous diabetics should be concentrated in sanatoria where expert advice and full facilities for laboratory investigation and supervision would be available. The Ministry of Health (1953) recommended regional planning for diabetic services with special provision for tuberculous diabetics.

In September, 1951, a scheme for the management of tuberculous diabetics was introduced in Birmingham. It comprises a hospital unit of 25 beds, an out-patient clinic, and a domiciliary service, and provides continuity of treatment and supervision (Luntz, 1952, 1954).

Present Study

This report gives a one-year follow-up of 84 tuberculous diabetics who have been under my care at the Regional Diabetic Unit at Romsley Hill Hospital in Birmingham. These cases were all the patients admitted consecutively over the four years between September, 1951, and September, 1955, and have been under observation for periods ranging from five years to one year. Of the 84 patients, 66 were known diabetics in whom pulmonary tuberculosis had recently been diagnosed; in 18 patients both diseases were diagnosed

Age distribution of the series of 84 tuberculous diabetics.

simultaneously. There were 49 males and 35 females, and their age distribution is shown in the Chart. The majority of the cases fall into two main groups—40 patients aged 20-39, and 35 aged 45-64. These are the age groups at which both diabetes and tuberculosis are commonly diagnosed. The youngest patient was 13 and the oldest 71. The mean age was 41 years.

Condition on Admission.—Clinical assessment of the patient's condition was made by studying symptoms, physical findings, general condition, temperature, weight, and sedimentation rate (E.S.R., Westergren, 200 mm. reading at one hour). Table I shows the condition of the patients on

TABLE I.—Clinical Condition on Admission

admission and before treatment for tuberculosis was started. The general condition was poor in 22 (26%), 56 (67%) were pyrexial, the E.S.R. was raised in 69 (82%), and 74 (88%) had a positive sputum. The data indicate that clinically most of the patients were rather ill.

Radiographic Appearances at Start of Treatment.—The radiographic appearances at the start of treatment are set out in Table II. Over half the patients had bilateral disease, 68% had three or more zones involved, and cavitation was present in 87% of the cases. An assessment of the extent of cavitation was made in each case by adding the maximum diameters of the individual cavities; 34 patients had cavi-

tion of an extent greater than 5 cm. Twenty-seven (32%) had acute disease and one had miliary tuberculosis. The principal type of shadowing was confluent in 45% of the cases.

Results During the Year

Clinical, radiographic, and bacteriological assessments were made regularly, and those at three months, six months, and one year are presented.

Mortality.—During the year there was one death, and this was non-tuberculous. The patient, a 58-year-old man, died in the fifth month of treatment. Necropsy revealed an aneurysm of the bifurcation of the aorta with a massive thrombosis of the aorta, the common iliac arteries, and the inferior vena cava.

Disease Status at One Year.—The disease status in the 83 survivors at 12 months was classified as quiescent or active (Table III). One year is a short period when assessing the progress of tuberculous patients, but quiescence was

* The figures in parentheses indicate the total number of patients upon which the percentages are based.

attained in 70 (83%). Of these, 31 had neither collapse therapy nor resection. Thirteen patients still had active disease, but in only two was the disease worse.

Clinical Assessments.—The changes in clinical condition and in weight, and the resolution of pyrexia and the lowering of the E.S.R., are set out in Table IV. Seventy-nine (94%) of the patients had improved clinically at three and six months, and 80 (95%) by a year, considerable improvement being recorded in 17%, 35%, and 49% of patients at these three intervals respectively. The average gain in weight was 11.5 lb. (5.2 kg.) at three months, 18.3 lb. (8.3 kg.) at six months, and 25.6 lb. (11.6 kg.) at one year. Only two patients had lost weight at one year. Of a total of 56 febrile patients in the week before the start of treatment, 47 (84%) were afebrile at three months, 48 (87%) at six months, and 50 (91%) at one year. Of 69 patients with an initial E.S.R. of 11 or more, a fall occurred in 67 (97%) at three months, in 100% of 67 at six months, and in 97% of 66 at one year, the sedimentation rate being normal in 15 at three months, in 25 at six months, and in 34 at one year.

Radiographic Changes.—Radiographic assessments (Table V) were made by a physician who was unaware that the radiographs were those of tuberculous diabetics. Moderate,

TABLE V.—Radiographic Assessments at Three Months, Six Months, and One Year

Radiographic Changes	At 3 Months		At 6 Months		At 1 Year	
	No.	%	No.	%	No.	%
Exceptional improvement ..	1	1	11	13	27	32
Considerable ..	28	33	42	50	38	45

Slight deterioration ..	2	2	1	1	1	1
Moderate ..	1	1	2	2	1	1
Considerable ..	0	0	0	0	0	0
Death ..	0	0	1	1	1	1
Total ..	84	98	84	99	84	99

considerable, or exceptional improvement had occurred in 75% of the patients at three months, in 87% at six months, and in 93% at a year, considerable or exceptional improvement having been recorded in 35%, 63%, and 77% of patients at these three intervals respectively. There were three deteriorations at three months, three deteriorations and one death at six months, and two deteriorations and one death at a year. An analysis of the timing of the radiographic changes showed that the greatest radiographic improvement occurred in the first three months in 56 (67%) patients and in the second three months in 17 (20%). In 7 (8%) patients improvement was evenly divided between the first and second three-month periods. In only two cases did the greatest improvement occur in the second six months. One patient improved steadily throughout the 12 months.

Changes in Cavitation.—The changes in the extent of cavitation were assessed from postero-anterior and lateral radiographs (Table VI). Considering the patients with

TABLE VI.—Changes in Cavitation

initial cavitation, cavitation was no longer visible in 34% of 73 patients at three months, in 58% of 72 patients at six months, and in 83% of 72 patients at one year. Only one patient had more cavitation at a year than at the start of treatment.

Bacteriology

If available, sputum was examined monthly by direct smear and by culture; when there was no sputum, laryngeal swab cultures were sometimes performed. The results in Table VII are biased in favour of positivity, since regular

TABLE VII.—Examination of Sputum for Tubercle Bacilli

Total ..	84	100	84	100	83	100	83	100

examinations were performed only in patients considered at all likely to be positive bacteriologically. Examinations were often omitted in patients considered very likely to be negative bacteriologically. It is noteworthy that whereas 83% of 83 patients were initially positive on direct examination only 6% of 79 patients still had a sputum positive on direct examination at a year; 78% of the 79 patients were known to be negative even on culture.

Treatment of the Tuberculosis

Rest in bed together with chemotherapy was the basis of treatment for nearly all the patients. Chemotherapy with an effective combination in full dosage was begun as soon as possible after diagnosis. The combinations used were streptomycin plus para-aminosalicylic acid (P.A.S.), streptomycin plus isoniazid, P.A.S. plus isoniazid, and all three drugs. Two patients had no chemotherapy. The average duration of chemotherapy was 28 weeks, the shortest course being six weeks and the longest 52 weeks.

Collapse therapy or resection was undertaken in 47 patients. The procedures are set out in Table VIII. Minor collapse therapy was undertaken in 29 patients, major sur-

gery in 18 patients (thoracoplasty in 7 and resection in 11). No difficulty was encountered with major surgery, and all the operative procedures were well tolerated. Physician and surgeon collaborated closely in the management of the patients undergoing thoracic surgery. The physician was present in the theatre during the operation, and the following procedure was adopted.

Resections were carried out first thing in the morning at the beginning of a list. Long-acting insulins, such as protamine-zinc insulin and insulin zinc suspension, were discontinued and soluble insulin was substituted. A dose of 20–30 units of soluble insulin was given at 7 a.m. together with 50–60 g. of glucose and the resection carried out under general anaesthesia some two hours later. Blood-sugar levels were estimated at intervals throughout the day, and small doses (10–20 units) of soluble insulin were begun in the evening together with 25-g. carbohydrate feeds at four-hourly intervals. Four or five doses of soluble insulin were given the day after operation and continued for the next three to four days. The carbohydrate requirements were supplied in the form of glucose until the patient was able to take light solids. The patients were generally back on their usual regime of a mixture of soluble insulin and

protamine-zinc insulin in the morning with or without a further dose of soluble insulin in the evening within a week and often by the fifth day.

Thoracoplasty, on the other hand, was carried out under local analgesia in the afternoon, the patient having had his usual dose of insulin in the morning and his ordinary breakfast and an early lunch. In this way no meals were missed. In the evening a small dose of soluble insulin (10–20 units) was given together with a carbohydrate feed. On the day after thoracoplasty control of the diabetes was maintained with four or five doses of soluble insulin together with two-hourly 25-g. carbohydrate feeds. The patients were back on their usual routine by the third or fourth day.

Treatment of the Diabetes

From the beginning of treatment the patients were placed on a diet whose caloric value and food components were considered suitable for their needs. The diet depended on their age, bodily habitus, weight, and state of nutrition. Three main diets were used as set out in Table IX. As the

TABLE IX.—Three Types of Diet Used

Diet	Calorie Value	Proportions of Three Main Component Foodstuffs	At Start of Treatment		At 3 Months		At 6 Months		At 1 Year	
			No.	%	No.	%	No.	%	No.	%
Basic	2,500	275 g. carbohydrate 100 „ protein 110 „ fat	63	75	63	75	60	72	57	69

Total			84	100	84	100	83	100	83	101

body weight increased the patients were sometimes given a lower calorie diet. The majority of patients (never less than 69%) received the 2,500-calorie diet. Few (5–10%) received the 1,750 calorie diet.

When the patients first came under the care of the unit at the start of treatment they were receiving a variety of insulin combinations. These are set out in Table X. The

TABLE X.—Combinations of Insulin when Patients First Came Into the Scheme and Subsequently at Three Months, Six Months, and One Year

three main combinations were soluble insulin (S.I.) morning and evening, S.I. and protamine-zinc insulin (P.Z.I.) in the mornings, and S.I. plus P.Z.I. in the mornings with a further dose of S.I. in the evenings. Four patients were receiving no insulin.

Insulin requirements were then determined with the help of regular urine examinations for sugar and acetone and estimations of blood-sugar levels. The main treatments used were S.I. plus P.Z.I. in the mornings in approximately a fifth of the cases, and S.I. plus P.Z.I. in the mornings together with a further dose of S.I. in the evenings in half the cases. Insulin zinc suspension was used in seven patients

at the start of treatment and 19 patients at one year. The insulin requirements were steadily increased during rest in bed and also as most patients were having too little to begin with. It is difficult to express the average insulin requirements for a group of patients receiving several insulins in a number of combinations. A rough assessment of insulin requirements expressed in terms of soluble insulin showed that the average was 68 units at the start of treatment and 96 units at one year. For insulin zinc suspension the corresponding figures were 37 units and 66 units.

The insulin dosage was altered when indicated by urine tests and blood sugar pattern throughout the day, and by the occurrence of hypoglycaemia. Even when good control of the diabetes was established, blood-sugar estimations were carried out at weekly or two-weekly intervals. Studies of the diurnal variations were performed so that the overall control could be more accurately assessed.

There was usually a fall in insulin requirements when the patient was allowed up, and in anticipation the dosage of insulin was reduced beforehand.

Discussion

A one-year follow-up is given of 84 tuberculous diabetics treated in the special unit for patients with the combined diseases. The patients, the majority with poorly controlled diabetes, had recently diagnosed pulmonary tuberculosis. On average they were ill and many had acute and extensive lesions. They were admitted to the unit without delay. The immediate response to treatment and the progress one year after the start of treatment have been very satisfactory. The success achieved may be ascribed to the fact that prompt and adequate treatment for both diseases was given in a hospital unit with adequate laboratory facilities, where the detailed attention required for the careful and precise management of both diseases was possible.

Results published during the past 25 years report a poor prognosis for the combined diseases, with a high death rate. The great majority of patients died within three years of diagnosis of the pulmonary lesion. In 18 published reports, set out in Table XI, there were 1,051 (52.8%) deaths in a total of 2,010 patients. Some of these reports include deaths up to five years, but, even so, the immediate mortality when presented was very severe. All but two of these reports concern the pre-chemotherapy era.

This very bad prognosis in tuberculous diabetics has improved with the use of modern chemotherapy according to the two reports so far published. Thosteson and Tibbits (1953) reported on the results in 294 tuberculous diabetics (1953) reported on the results in 294 tuberculous diabetics discharged between 1940 and 1952 in Detroit and had an overall mortality of 58%. They divided their cases into the pre-chemotherapy (1940–6) and chemotherapy (1947–52) eras. Of 167 discharged in the former period, 50 (30%) are living. Of 127 cases discharged in the era of anti-tuberculous antibiotics, 73 (57%) are living. Reaud (1953), describing the results of treatment of 38 patients in Cuba

during 1950-2, showed that 19 (50%) were improved, 15 (40%) were unimproved, and 4 (11%) died during their stay in the sanatorium. Little can be drawn in the way of conclusions from these reports. The bad prognosis given in the literature is no longer justified and should be regarded as largely of historical interest only.

In view of the high mortality previously reported the single death in the present series of 84 patients is particularly noteworthy. Mortality figures alone, however, give an incomplete picture of the effects of treatment, and it is important to know the clinical condition of those who survived and the activity of their tuberculosis. At the end of a year 70 of the patients have quiescent disease, and of the 13 with active disease improvement has occurred in 11. A total of 47 (56%) of the patients had collapse therapy or resection as part of their treatment, and these played an important part in helping to control the disease. Major thoracic surgery has proved perfectly safe in the well-controlled tuberculous diabetic.

Results at one year can only be regarded as a short-term evaluation, but the attainment of quiescent disease was closely linked to the immediate clinical and radiographic response to treatment. Even patients with features usually indicative of acute or extensive disease made striking progress. Quiescent disease was attained in the presence of such individual factors as an initial pyrexia of over 100° F. (37.8° C.) (in 77% of 13 patients), a high E.S.R. (in 78% of 27 patients), involvement of five or six zones of the lungs on a standard radiograph (in 75% of 20 patients), and even in the presence of all of these features in five patients. In these cases most of the radiological improvement occurred in the first six months with chemotherapy. It can be said that the prognosis depends on the early response to treatment, and where the clinical and radiological response in the first six months with chemotherapy is good the outlook may be regarded as favourable. Acute bilateral pulmonary tuberculosis in a diabetic is a serious complication to be regarded as a medical emergency. It calls for immediate treatment in a special hospital unit with an effective dosage of combined chemotherapy for the tuberculosis and stabilization of the diabetes as a matter of great urgency. The start of chemotherapy should not be delayed until the patient is admitted to hospital.

In conclusion, the immediate response to treatment in this group of cases as judged by the results at one year has been very satisfactory. The progress of the pulmonary tuberculosis—despite the diabetes—compares very favourably with the progress in the non-diabetic. As with the non-diabetic, however, it is necessary to follow these cases for several years before the final picture will be clear.

Summary

A one-year follow-up of 84 tuberculous diabetics is presented. Clinically most of the patients were ill. The pulmonary tuberculosis was bilateral in 48 patients, and 57 had involvement of three or more zones; 27 had acute disease, and cavitation was present in 73.

By one year there was only one death and this was non-tuberculous. Quiescence of the tuberculosis was attained in 70 patients. The average gain in weight per patient was 25.6 lb. (11.6 kg.) at a year. At least moderate clinical and radiological improvement occurred in over 90% of patients. Cavitation had either disappeared in 83% or become less evident in a further 15%. Only 5 of 83 patients still had a positive sputum on direct examination.

Rest in bed and chemotherapy, with an effective combination of anti-tuberculosis antibiotics in full dosage, was the basis of treatment for the tuberculosis in nearly all cases, and 47 had collapse therapy or resection, major surgery being carried out in 18 patients. In addition the diabetes was carefully controlled. Three diets were used, but the majority of patients had a 2,500-

calorie diet. The commonest combination of insulin used was a mixture of S.I. plus P.Z.I. in the mornings and a further dose of S.I. in the evenings.

I am grateful to numerous colleagues for kindly referring patients to me; Dr. Wallace Fox for valuable advice and criticism in the preparation of this paper; Dr. M. H. Zirk for help with the care of the patients; Dr. Jack Aspin for the radiographic assessments; Mr. S. J. MacHale for operating on these patients personally; Dr. Hector Ross for help with the pre- and post-operative care of the patients; Sister B. Crocombe and the nursing staff for their invaluable and devoted attention to the patients in the diabetic wards; Miss Joanna Tilley, the therapeutic dietitian; and Mrs. B. I. Roe for secretarial assistance.

PERIODIC DISEASE: PERIODIC FEVER REPORT OF A CASE

BY

KRIS SOMERS, M.B., M.R.C.P.

From the Department of Medicine, Postgraduate Medical School of London, Ducane Road, London, W.12

Disease conditions manifesting rhythmic recurrence of symptomatology of diagnosable organic origin are well known in medicine—notably epilepsy, Hodgkin's disease, malaria, and brucellosis, to mention a few. The natural history of such illnesses is known and some of them are curable.

However, a distinct group of conditions with periodic symptoms and signs which elude exact diagnosis has been reviewed by Reimann (1951) and called periodic disease. These conditions may occur in childhood or adult life and recur regularly over several years, sometimes for a decade. Various systems may be involved, and symptoms are so regularly cyclic as often to be predictable. The general health is unaffected and patients have been fully investigated without a correct diagnosis or cure being made. They have sought advice from numbers of physicians and have been known at times to seek the help of unorthodox practitioners.

Reimann has included such conditions as periodic fever, periodic abdominal pain, periodic arthralgia, and perhaps periodic (cyclic) vomiting and Behcet's syndrome (recurrent ulceration of oral and genital mucosa with hypopyon) in his description of periodic disease. Several cases of periodically occurring fever closely resembling Reimann's description of periodic fever are to be found in the literature (Wolf and Wolff, 1942; Albahary and de Villero, 1951; Hitzig and Fanconi,

1953). Reimann (1947, 1948, 1951, 1953) has followed up a number of cases himself.

The following is presented as a case of periodic fever because of regularly occurring pyrexia for over five years with no convincing evidence of aetiology and, so far, no palliation.

Case Report

A housewife, aged 51, has had undiagnosed pyrexia for five years. Her symptoms date from 1951, about a year after her menopause, at the age of 45. About this time she developed diarrhoea and vomiting lasting several days. She improved, but was left with persistent fever and headache. She was treated without success by her own doctor, who then referred her to a local hospital, where she was admitted for observation three weeks after the onset of her illness.

She had migraine-like headaches at the age of 17. The headache used to be right-sided, lasted most of the day, and was accompanied by nausea and occasionally sickness. At the age of 21 tuberculous lymph nodes were excised on the right side of her neck. She was reported to have had "dry pleurisy" for a few days at the age of 26. At 38 she had shingles on the right side of her chest. She has never been outside England, has never kept pets—bird or animal—and has never been a drinker of raw milk.

The patient has always presented a picture of good nutrition and fitness, and, in particular, has not lost weight. There is an operation scar on the right side of her neck. The ears, throat, and teeth have always been healthy and no abnormal physical signs have been noted in the systems at any of the several careful examinations documented on admission to various hospitals. The spleen has never been palpable, and examinations of the central nervous system have revealed no abnormal signs. Her blood pressure has been in the region of 135/70 mm. Hg.

Her temperature chart has been characteristically periodic, rising over a day or two to 102-103° F. (38.9-39.4° C.), accompanied by a concomitant rise of pulse rate, every third or fourth day, falling again over a day or two to normal levels (see Chart). Associated with the pyrexial bouts she has headaches, anorexia, and malaise. Rectal temperatures taken in hospital have always confirmed simultaneous oral readings.

Investigations

A multitude of investigations have been done and many have been repeated on several occasions.

Haematological.—Routine blood counts made when the temperature was normal and during pyrexial periods showed: Hb, 80-100%; W.B.C., 5,000-8,000 per c.mm. (neutrophils 50-60%, eosinophils 4-5%, lymphocytes 32-43%, monocytes 0.2%). Films—normochromia, normocytosis. E.S.R. 5-12 mm. in one hour (Westergren): normal throughout illness. Platelet count, 262,000 per c.mm. Bleeding time 2½ minutes. Thick and thin smears negative for malarial parasites. Sternal marrow: no evidence of any specific infection, no reticulosis.

Bacteriological.—Blood cultures sterile (specimens taken at height of pyrexia). No agglutinations for *Salm. typhi* H and O; *Salm. paratyphi* A H, A O, B H, B O, L O; composite salmonellae; *Brucella abortus*; or *Brucella melitensis*. Paul-Bunnell test negative. Leptospiral agglutinations negative with *L. icterohaemorrhagiae*, *L. canicola*, *L. sejevae*, *L. grippityphosa*, *L. bataviae*, and *L. pomona*.

Complement-fixation Tests.—Lymphocytic choriomeningitis virus, negative 1/2; mumps virus, negative (Virus Reference Laboratory, Colindale); influenza virus tests negative;

influenza sol. A<1/8, sol. B<1/8; Q fever, <1/4; psittacosis L.G.V., <1/8; agglutination streptococcus M.G., ±1/10. All negative results (Virus Reference Laboratory, Colindale).

Tests for Toxoplasmosis.—Dye test negative; C.F.T. negative (Hospital for Sick Children, Great Ormond Street).

Miscellaneous.—Mantoux, positive 1/100. Intradermal brucellin test negative. Plasma proteins: total 7.1 g. per 100 ml. (albumin 4.3 g., globulin 2.8 g.). Normal electrophoretic pattern.

Urine Examination.—No albuminuria, sugar, or acetone. No abnormalities on direct examination of deposit on numerous occasions. Culture sterile. Tubercle bacilli not seen on direct examination of deposit or culture on four occasions: 24-hour collections.

Cerebrospinal Fluid.—Lumbar puncture was first done in 1951 after the onset of the pyrexial illness. Pleocytosis was the only abnormal finding that has been inconstantly noted at subsequent examinations (see Table). C.S.F.

Cerebrospinal Fluid Findings

Date	Cells	Protein	Chloride	Sugar	Miscellaneous
		mg. per 100 ml.			
2/2/52	44 red, 2 white	10			Wassermann negative
27/2/52	36 white (70% lymphs, 30% polys.)	20			
5/3/52	50 lymphs	10	770	63	No organisms on direct exam. Negative agglutinations for <i>Br. abortus</i> . Culture sterile. <i>Myc. tuberculosis</i> not grown
18/4/52	27 lymphs	30		57	Lange—no change. No yeasts found. <i>Myc. tuberculosis</i> not isolated on direct exam. or culture
30/5/52	29 white (90% lymphs, 8% polys.)	20	740	53	No organism seen. Torula not isolated on culture
21/5/54	5 red, 11 lymphs	30	720		No organisms on direct exam. No <i>Myc. tuberculosis</i> . Culture sterile. Lange negative

pressure has always been within normal limits and no block has been demonstrated; fluid clear and colourless. A suggestion that lymphocytes in the C.S.F. might, in fact, be yeast cells was unconfirmed. Torulosis was also excluded.

Radiological.—Chest: calcification in both hilar glands; lung fields clear; heart shadow normal. Skeletal: films

Temperature and pulse chart. Rectal temperature indicated by interrupted lines.

of sacro-iliac joints, lumbar spine, and hips showed mild osteoarthritic changes; no other abnormality. Skull: no abnormality shown; pineal body calcified but not displaced. Sinuses: clear. Electroencephalogram: no significant asymmetry or focal abnormality suggestive of a localized lesion.

Treatment

Courses of various antibiotics were tried empirically—sulphonamide, penicillin, chloramphenicol, and chlortetracycline (aureomycin). All were without effect. A course of streptomycin and isoniazid was given, as it was thought that a deep-seated tuberculoma might account for her symptoms and also her persistently abnormal C.S.F. It had no beneficial effect.

On a second occasion she was given a course of cortisone, together with streptomycin, isoniazid, and P.A.S., for about nine weeks. Again her symptoms did not improve at all.

Quinine was tried for a week without any change in the periodicity of her pyrexia. Arsenicals, antihistamines, including chlorpromazine, thyroid, and codeine phosphate were all ineffective.

She did mention that she had been having severe hot flushes, and herself suggested that her symptoms might be related to the menopause. Oestrogens and also testosterone was tried, but no benefit accrued.

Finally, she had a course of mild hypnotherapy in the hope that it might enable her to accept her symptoms rationally, but her state remained unchanged.

Discussion

The whole condition of the patient is puzzling. The outstanding feature is a regularly occurring pyrexia at intervals of three to four days for as long a duration as five years. Careful checks on the temperature ensure that it is not an artifact.

Physical examination has been quite negative apart from the scar of an operation for a tuberculous lymph node twenty years ago. There are no abnormalities in the central nervous system. All relevant investigations have drawn a blank. Interestingly enough, the first lumbar puncture was negative, and it may be just possible that the slight pleocytosis could be a consequence of repeated lumbar puncture.

The patient has been under observation at regular intervals and no change has been noted. The condition is apparently benign. Her general health and nutrition remain unaltered, except that over the years she has become nervous and introspective, which seems a reasonable reaction to such a prolonged and tedious organic disease.

Various specialists—medical, surgical, and gynaecological—have seen this patient and are unable to arrive at an aetiological diagnosis.

An infective cause appears unlikely. The pattern has been one of regular, uniform, recurrent pyrexia over many years, not suggestive of a known condition. It seems reasonable to assume that there is no good evidence of tuberculous activity. Empirical treatment with sulphonamide, penicillin, broad-spectrum antibiotics, and anti-tuberculosis drugs (with the possibility that she might have a tuberculoma) have been of no avail.

Atypical epilepsy has been suggested as a diagnosis in patients with periodic abdominal pain in whom abnormal electroencephalographic patterns are demonstrated, relief being obtained with anticonvulsants (Moore, 1944, 1948). Our patient, however, shows no suggestion of epilepsy on electroencephalography.

An obvious reticulosis has been excluded on clinical and haematological grounds.

Periodic fever may be a hypothalamic sign of craniopharyngioma (Müller and Wohlfart, 1950). In the absence of pituitary involvement, radiological calcification of the

tumour, and signs of raised intracranial tension with such a prolonged history, that diagnosis seems untenable.

Reimann's Case 9 (1949) developed periodic fever, similarly after the menopause, which may or may not have served as a trigger mechanism to set it off. It is difficult to postulate a definite endocrine basis. In some patients episodes lessen in intensity or cease after the menopause. Menstruation does not seem to influence periodic disease (Reiman, 1956, personal communication).

Allergy might be suggested as a cause of periodic disease; but in the absence of associated allergic phenomena, such as asthma, urticaria, and hay-fever, family history and lack of response to antihistamines and corticotrophin and to cortisone given empirically in adequate doses, it seems hardly tenable here.

In Wolf and Wolff's case (1942) fever was related to emotional disturbances. No one, however, has been able to entertain a psychogenic cause for this patient's illness. If anything, her nervous symptoms are secondary to her prolonged periodic fever. She herself suggested that her condition might be related to the menopause, and, indeed, as one physician remarked, "who are we to say that it is not?" She has reached the stage where she most adamantly resists the suggestion of any further investigation, such as lumbar puncture, cerebral angiography, or ventriculography unless it can be guaranteed to produce the answer to her illness.

It is difficult to know what management is advisable. Amidopyrine slightly reduced the temperature in one of Reimann's (1951) cases, but the cycles of periodic fever were unaltered. Another case appeared to respond temporarily on cortisone (Reimann, 1953). We have not been able to demonstrate any change with antipyretics or cortisone.

Dr. Reimann has been consulted about this case and has made these comments: "I feel quite sure that this patient has periodic disease, or, more specifically, periodic fever. From all the evidence, positive and negative, I don't know what else it could be. You have excluded most other possibilities, but, from the old history, the spectre of tuberculosis remains despite the absence of evidence. Even if tuberculosis were present, the periodicity of fever still would be of interest. She is lucky that (as yet) none of the more distressing symptoms of severe abdominal and thoracic pain or of arthralgia occur. This should be of some consolation to her. Unless you find some cure the best she can hope for is that the intervals may lengthen and/or the episodes may lessen in severity as time passes."

With all the therapeutic failures it seems necessary to regard her illness as periodic fever, if only to save her from further medical and surgical measures.

Summary

A case of periodically recurring pyrexia for five years is detailed. No satisfactory explanation is possible. It would seem a sufficiently clear-cut case to merit inclusion in Reimann's well-described condition—periodic disease.

Thanks are due to Professor J. McMichael for his constant encouragement, to Dr. H. A. Reimann, of New York, for his kind help and advice, and to Dr. Horace Joules, Central Middlesex Hospital, London, for access to notes made whilst the patient was under his care.

PLASMA FIBRINOGEN IN RHEUMATIC FEVER

BY

JAMES REID, M.D., M.R.C.P.

AND

D. H. SPROULL, M.B., B.Sc.

Clinical Chemotherapeutic Research Unit of the Medical Research Council, Western Infirmary, Glasgow

In a study of indices of rheumatic activity, Ernstene (1930) investigated the fall in plasma fibrinogen concentration in 22 patients with rheumatic fever. He found that the mean fibrinogen concentration did not reach the normal value of 0.3 g. per 100 ml. until after about 12 weeks of intermittent salicylate therapy, and that there was pronounced individual variation in the rate of fall of plasma fibrinogen, so that the distribution of fibrinogen concentrations apparently became increasingly dispersed with the passage of time.

We have been studying the plasma fibrinogen concentration in rheumatic fever for some time, and since our experience, in 33 consecutive cases of acute rheumatic fever during the first 21 days of full salicylate therapy, differs from that of Ernstene (1930), our results are presented in this paper and their implications discussed.

Clinical Particulars and Methods

All the patients were febrile, and had a migrating polyarthritis with involvement of at least two joints when admitted to hospital. Patients with temperatures below

Plasma Fibrinogen Concentrations in Acute Rheumatic Fever Treated with Full Doses of Aspirin

Time	No. of Obs.	Range (g. per 100 ml.)	Mean Plasma Fibrinogen (g. per 100 ml.)	S.D.
On admission	33	0.49-1.15	0.78	0.14
4th day of aspirin therapy	32	0.40-1.02	0.64	0.14
7th " " " "	33	0.30-0.82	0.51	0.12
14th " " " "	32	0.24-0.63	0.39	0.10
21st " " " "	31	0.20-0.59	0.35	0.09
On discharge	33	0.20-0.41	0.30	0.05

100° F. (37.8° C.) or who complained of arthralgia unaccompanied by objective signs of arthritis were excluded, so that there was no doubt about the clinical diagnosis of acute rheumatic fever. Twenty-two were males and 11 females. Their ages ranged from 10 to 46 years; 26 were between 10 and 20 years.

Each patient was given full doses of aspirin to maintain the serum salicylate concentration between 30 and 45 mg. per 100 ml. Serum salicylate was estimated by Trinder's (1954) method, which we have found the simplest and most reliable for clinical use. The drug was given four-hourly, omitting one dose in the middle of the night, and actual doses ranged from 1 to 1.6 g. five times daily. In this way maximal doses were given without inducing serious side-effects.

Fibrinogen was estimated gravimetrically as fibrin, by the method of Foster and Whipple (1922), modified as follows: the fibrin was whipped on to a 30 s.w.g. stainless-steel wire held in a pin vice; the wire was trimmed and bent into a hook for drying and weighing on a 10-mg. capacity torsion balance.

Results

The plasma fibrinogen concentration before treatment was, in every patient, above the upper limit of normal,

taken as 0.4 g. per 100 ml. (see Table). It ranged from 0.49 to 1.15 g. per 100 ml. and the mean was 0.78 g. per 100 ml. During aspirin therapy the fibrinogen concentrations returned steadily to normal. By the 4th day, when polyarthritis had been relieved and fever had subsided, the mean value had fallen to 0.64 g.; on the 7th day it was 0.51 g.; on the 14th day 0.39 g.; and on the 21st day of intensive aspirin therapy 0.35 g. per 100 ml. At the time of discharge it was 0.3 g. per 100 ml., but this figure is not strictly comparable with the others because of the great variation of the duration of stay in hospital.

The frequency distribution of plasma fibrinogen concentrations (Fig. 1) during the first three weeks of aspirin treatment shows a remarkable uniformity in the return of the fibrinogen concentrations to normal. There is no evidence of progressively increasing variance. In terms of plasma fibrinogen concentration these cases form a homogeneous group during the first 21 days of full salicylate therapy. This is an unexpected result in a disease which, even with salicylate treatment, runs a notoriously variable course. It is particularly striking when compared with the great variation in rate of fall of plasma fibrinogen concentration found by Ernstene (1930),

FIG. 1.—Frequency distributions of plasma fibrinogen concentrations in acute rheumatic fever treated with aspirin, (a) on admission, (b) to (e) 4, 7, 14, and 21 days respectively after the start of treatment.

FIG. 2.—Plasma fibrinogen and serum salicylate concentrations in a case of rheumatic fever with relapses. —●—●— plasma fibrinogen, - - - - - serum salicylate.

who used short intermittent courses of salicylate, in contrast to our continuous intensive and controlled therapy. In all other respects the two series are comparable, and, like Ernstene (1930), we had a small number of "polycyclic" cases which promptly relapsed after salicylate was discontinued. This happened in six of our patients, and each relapse was accompanied by elevation of the plasma fibrinogen, which reverted to normal after a second course of aspirin.

One of the patients developed a second similar relapse, and the findings are shown in Fig. 2, where it will be observed that discontinuation of salicylate was followed by clinical relapse and simultaneous elevation of plasma fibrinogen; these changes were immediately reversed when aspirin was started again. It is also noteworthy that in this case two parenteral courses of penicillin, in which 0.6 million units and 1.2 million units daily were started 12 and 7 days respectively before the first and second relapses, were not effective in preventing relapses.

Discussion

The plasma fibrinogen concentration in acute rheumatic fever treated with full doses of aspirin has been found to fall rapidly and uniformly in a series of 33 cases. Comparison of the present results with those of Ernstene (1930) emphasizes these features of our results: the mean plasma fibrinogen of his best, "monocyclic," subgroup did not reach 0.4 g. per 100 ml. till the fourth week of treatment; the corresponding time for all the present cases was two weeks. Even more striking in the present series is the lack of increasing scatter in the plasma fibrinogen concentration with the passage of time. This finding is difficult to reconcile with the view that salicylate only relieves the symptoms of rheumatic fever, and is impossible to interpret in relation to the careful study of Ernstene (1930) without inferring that an intensive and continuous course of salicylate does indeed, within three weeks, consistently lead to a rapid reduction in the plasma fibrinogen concentration in acute rheumatic fever.

Certain practical implications arise from the present study. Since hyperfibrinogenaemia is an essential feature of rheumatic fever (Fig. 1(a)), (1) the plasma fibrinogen concentration may be a reliable index of the course of the disease, and (2) sufficient salicylate, given for an adequate time, can restore the plasma fibrinogen to normal, and presumably arrest the rheumatic process, without necessarily influencing the chain of events leading to the elevation of the plasma fibrinogen concentration.

Above all, the present results provide definite evidence that salicylate does more than relieve symptoms. Even after 21 days' treatment seven of our cases showed fibrinogen levels which, although reduced, were still slightly abnormal; this confirms that there is no set optimum dosage schedule of the drug, and that in each case dosage and duration of therapy must be controlled not only by frequent serum salicylate estimations but also with reference to the fibrinogen concentration or some comparable index of rheumatic activity.

The connexion between plasma fibrinogen and the characteristic clinical and pathological features of rheumatic fever is being investigated further.

Summary

The abnormally high plasma fibrinogen concentrations found on admission to hospital in 33 patients with acute rheumatic fever fell rapidly and uniformly during a continuous intensive course of aspirin, controlled by serum salicylate estimations. This clearly demonstrates the advantage of proper aspirin therapy.

SUPERFICIAL MALIGNANT LESIONS OF BLADDER TREATED BY RADIOACTIVE COLLOIDAL GOLD (^{198}Au)

BY

P. L. TUOVINEN, M.D.

AND

KALEVI KETTUNEN, M.D.

From the Department of Surgery of the Maria Hospital, Helsinki, Finland

In the treatment of multiple superficial lesions of the bladder intracavitary irradiation has a distinct advantage over external deep x-ray therapy because it protects adjacent healthy organs. Several techniques have been developed for the use of gamma-radiation-emitting radioactive substances as an intravesical source of irradiation (Friedman and Lewis, 1949; Becker and Scheer, 1952; Schulte, Hinman, and Low-Beer, 1952; Walton and Sinclair, 1952). The disadvantage of penetrating gamma-radiation, however, is the development of secondary cystitis and a risk of fibrosis with impaired function of the bladder.

For very superficial lesions it seemed possible to use beta-radiation. Because the dose of beta-emission falls rapidly at depth the best method is the instillation of a radioactive solution direct into the bladder in order to get the emitting substance into close contact with the bladder mucosa and to surround the papillomatous villi by the radioactive material. Ellis and Oliver (1955) used radioactive gold (^{198}Au) in this way. Einhorn, Larsson, and Ragnhult (1955) suggest the use of radioactive yttrium (^{90}Y), and Walinder (1955) colloidal $^{76}\text{As}_2\text{S}_3$ for the purpose.

Radioactive colloidal gold is suitable for this method because of its half-life, its type of emission, and its colloidal nature. Since the half-life is short (2.7 days), there will be no danger of contamination after a few days. It emits about 95% of beta-radiation with 0.96 MeV energy, and 5% of gamma-radiation with 0.41 MeV energy. The maximal penetration of its beta-particles in soft tissue is about 3.8 mm., and of the half-value layer about 0.3 mm. Thus its maximum effect is confined to the bladder epithelium, leaving the sub-epithelial tissue almost unirradiated. Its colloidal nature protects against its resorption.

This preliminary report is based on our experience with radioactive colloidal gold (^{198}Au) in the treatment of superficial malignant lesions of the bladder since May, 1955. Our material included papillary cancer and also recurring extensive papillomata without histological cancer. Three cases are here briefly reported.

Methods

The radioactive material was obtained from Harwell. After the decision to use the colloidal gold method, fluid intake was restricted on the day prior to treatment and forbidden on the day of treatment. When the activity in millicuries per millilitre had been determined, the desired dose in millicuries was drawn into the lead-shielded syringe and introduced into the bladder through an ordinary bladder catheter. Injection was readily accomplished after removal of urine by catheter. Sterile isotonic saline solution was used for rinses. At an appropriate time the contents of the bladder were run off, and the bladder was washed out with a warm solution. The volume of the removed fluid was measured for dose calculation. With suitable precautions the personnel received no hazardous amounts of radiation.

Most patients received approximately 300 mc. of gold. The range was 100 to 375 mc., the former amount being used in one instance because no more was available at the time. The injected gold was retained in the bladder for four to six hours. With the dose-rate formula of Walinder (1955) it was calculated that some 300 mc. should be given in about 70 ml. of saline; so that, taking into account the increase of volume of the bladder due to the flow of urine from the ureters, the total dose of beta- and gamma-radiation received by the bladder epithelium in six hours would be 4,000 to 5,000 r.

Case Reports

Case 1.—A 56-year-old man was seen for the first time in March, 1952, complaining of haematuria of one month's duration. Cystographic and cystoscopic examinations revealed a tumour about 4 cm. in diameter situated in the left of the bladder. The growth was removed by suprapubic electroresection and histologically reported as transitional-cell papilloma. During the following three years papillary tumours reappeared in the bladder serially, requiring six transurethral fulgurations and two suprapubic coagulations. The histological diagnosis was benign papilloma. As the repeated call for fulguration was thought to indicate a malignant change, it was decided to try radioactive colloidal gold radiation for multiple villous papillomata. On May 5, 1955, 300 mc. of gold was instilled into the bladder for six hours. Thus the bladder epithelium was estimated to have received a total dose of 4,640 r of beta- and gamma-radiation. Three weeks after instillation cystoscopic studies revealed a slight redness of the bladder mucosa. The tumour seemed to be eradicated. However, six months later cystoscopy revealed recurrent papillomata in the base of the bladder. Another treatment with radiogold was suggested, and on November 11, 1955, 215 mc. of radioactive colloidal gold was instilled into the bladder for six hours and twenty minutes. The estimated dose at the bladder epithelium was 3,860 r. When examined three weeks after instillation no tumour was seen in the base of the bladder. Four months after the second instillation, in March, 1956, cystoscopy revealed a small recurrent papilloma in the fundus of the bladder.

Case 2.—A 50-year-old man was referred in August, 1955, from another hospital with a diagnosis of tumour of the urinary bladder. Cystoscopic examination revealed a band-form area of low papilliferous tumour extending from the right ureteric orifice to the mid-portion of the right bladder wall. The biopsy specimen was reported as malignant papilloma. On August 11 100 mc. of radioactive colloidal gold was instilled into the bladder for six hours. The estimated dose at the bladder mucosa was 1,700 r. Ten days later an attempt at cystoscopy resulted in a marked haemorrhage presumably due to irradiation epithelitis. One month after treatment cystoscopic examination revealed a normal bladder except for an epithelial defect at the site where the tumour had been. Cystoscopy on September 26 showed the site of the tumour to be indistinguishable from the remainder of the bladder mucosa, but near the prostatic orifice there was a small polypoid tumour; this was removed by diathermy. The histological diagnosis of the tumour was polyp. On October 29, two and a half months after the radioactive gold treatment, there was no sign cystoscopically of any neoplastic lesion. The patient had no clinical evidence of tumour at the time of writing.

Case 3.—A 58-year-old man was admitted in May, 1955, with a history of haematuria of one month's duration. Cystoscopy revealed a papillomatous growth about 3 cm. in diameter lateral to the right ureteral orifice. The bladder was opened suprapubically, and the tumour was electroresected. The histological diagnosis was transitional-cell papilloma. In February, 1956, cystoscopy revealed multiple papillomata of various sizes at the operation scar. Furthermore, there were small villous dots throughout the bladder epithelium. The bladder was opened suprapubically and the scar was widely excised. Because of the multiplicity of growth it was decided to treat the patient with radioactive gold instillation. One month post-operatively, on March 14, 200 mc. of

radioactive gold solution was instilled into the urinary bladder for six hours. The estimated surface dose was 3,400 r. One month after instillation, cystoscopy revealed that the small multiple papillomata had entirely disappeared. In the fundus of the bladder there was a solitary persistent papilloma which was fulgurated transurethrally.

Discussion

It is our opinion that radioactive gold therapy yields good results in certain selected cases of bladder tumours. Each case, however, should be considered individually before deciding whether or not radiogold instillation is advisable. Primarily we divided our material into two groups, one including all papillary tumours and the other including non-papillary infiltrating solid carcinomas.

The essential character of the papillary type of cancer is that the lesion is superficial, involving only the mucosa of the bladder. The papillary type includes those formerly benign papillomata which have undergone malignant changes. However, it is difficult to say when the malignant change has developed. Small biopsy specimens can completely miss malignant portions of a papillary tumour and show only the innocent appearance of benign villous epithelium. Multiplicity is regarded by most urologists as an indication of malignancy. Our material included papillary cancer and recurring extensive papillomata without histological cancer.

Papillary tumours are well known to have a tendency to serial reappearances. Most of the patients received surgical treatment before the radioactive gold therapy, consisting of multiple transurethral or suprapubic fulgurations and segmental resection of the bladder. In some of the cases radioactive cobalt needles had been implanted. None of these patients received external x-ray treatment to the bladder.

Before instituting radiogold therapy we considered the histopathology, size, number, and location of the tumours of each case, as well as other complicating factors such as severe infection, with or without the formation of incrustations or stones, and severe haemorrhage. It is clear that infiltrating lesions cannot be treated by intracavitary instillation of radioactive gold because the dose received at depth will be too small to be effective. This method is designed to treat non-infiltrating lesions in which the tumorous lining is not beyond the range of the maximum penetration of the beta-rays emitted by radioactive gold.

We avoided instillation when thick papillomata were present in cases of multiple or extensive lesions. Nevertheless, when the small tumour seedlings and the thin frosting of tumour of the bladder epithelium have disappeared, small residual tumours might be easily eradicated by fulguration. In some cases bulky tumours were removed prior to instillation, leaving small villous tumours to be exposed to subsequent radioactive gold radiation.

The radiation dose in most cases ranged between 4,000 and 5,000 r, estimated at the mucosal surface. The doses were given as single exposures for four to six hours. In reference to dosage, Case 2 deserves special mention. Prior to the use of radioactive gold the patient had had no other treatment. Following intravesical instillation of 100 mc. of radioactive gold for six hours, the tumour had completely disappeared on cystoscopic examination. The estimated surface dose was 1,700 r. One patient (Case 3) had a persistent lesion following a dose of 3,400 r. It was borne out, in these cases, that villous tumours responded satisfactorily to adequate doses of intracavitary radioactive gold irradiation. Thick papillomata do not respond to the treatment.

In Case 1 new lesions developed in the bladder after radioactive gold therapy. This patient received two treatments of 4,600 r and 3,800 r, respectively. We do not expect, however, that even with higher doses all lesions will be permanently eradicated. Papillomatosis is a disease of the entire bladder epithelium, and radiation treatment will not, of course, prevent the development of new lesions.

In patients of this group, no significant bladder symptoms developed following treatment by radiation. Cystoscopically, the immediate reaction after radiogold instillation was

transient epithelitis, which subsided within the next weeks. No evidence of more severe tissue reaction was observed. None of the patients treated experienced radiation sickness characterized by the symptoms of lassitude, anorexia, nausea, or vomiting.

We know that the number of patients studied is not large enough or the time of observation long enough for conclusive evaluation of this method of treatment. However, we feel that the results to date are encouraging. Complete regression of the tumour was accomplished in cases of really superficial lesions. It is realized that any anatomical classification based on cystoscopic findings is subject to error. None the less, we believe that when the clinical findings are favourable this therapy should be considered as a primary measure.

Summary

Intracavitary instillation of colloidal radioactive gold (^{198}Au) was used for treatment of patients with multiple papillomata of the bladder. Approximately 300 mc. of gold was instilled into the bladder for four to six hours to deliver a dose of about 4,000 to 5,000 r to the bladder epithelium. The treatment had no harmful side-effects locally or on the general condition of the patient.

Three selected cases suitable for radioactive gold therapy are briefly reported.

It is our impression that this method is an excellent type of irradiation for really superficial malignant lesions. The method was used for treatment of multiple papillomatosis of the bladder alone or in conjunction with surgery.

DIPIPANONE HYDROCHLORIDE AS AN ADJUNCT TO ANAESTHESIA IN OBSTETRICS AND SURGERY

BY

DAVID J. COLEMAN, M.B., F.F.A.R.C.S., D.A.
 Senior Registrar, Department of Anaesthetics, St. George's
 Hospital, London

JACK LEVIN, M.B., B.Sc., F.F.A.R.C.S., D.A.

 Hospital, London

AND

PERCY O. JONES, M.B., B.Sc., A.R.I.C.
 Department of Medical Research, the Wellcome
 Foundation Ltd.

Balanced anaesthesia developed over recent years has been made possible by the introduction of a large range of drugs with specific actions. In 1947 Neff, of San Francisco, introduced pethidine into anaesthetic practice as an adjunct to nitrous oxide anaesthesia. Since then pethidine has proved itself as useful in the operating theatre as in the general and obstetric wards. Over the past 18 months we have investigated the use of another analgesic, dipipanone hydrochloride, in obstetrics and as an adjunct to general anaesthesia. This paper describes our results.

Pharmacology

Dipipanone hydrochloride (DL-6-piperidino-4,4-diphenylheptan-3-one), which is the piperidino analogue of meth-

adone ("physeptone"), was first described by Ofner, Thorp, and Walton in 1949. Its analgesic properties in animals were investigated by Ofner, Walton, Green, and White (1950) and by Green and Young (1951). Its use as an analgesic for the control of post-operative pain and that arising from a variety of acute and chronic medical conditions has been

reported on by Gillhespy, Cope, and Jones (1956). In man 25 mg. of dipipanone administered intramuscularly or subcutaneously is equi-analgesic with 10 mg. of morphine, 100 mg. of pethidine, or 10 mg. of methadone. The analgesic effect develops within 15 minutes and lasts from five to six hours. Nausea and vomiting are rare and there is no significant change in the blood pressure or pulse rate. As with morphine, the respiratory minute-volume is reduced mainly by a reduction in the respiratory rate; this effect, however, is less than that of an equi-analgesic dose of morphine. There is no appreciable hypnotic effect, and prolonged administration produces no significant change in the blood picture.

Dipipanone hydrochloride, like methadone, is metabolized in the liver and excreted in the faeces and urine. Therefore it should be used with caution in patients with severe liver or kidney disease.

Methods

Clinical Material.—The cases investigated were (1) a series of 53 consecutive obstetric cases which received dipipanone to relieve pain in labour (as a control pethidine was used in a further series of 53 consecutive cases); (2) a series of 200 general surgical cases which received dipipanone as an adjunct to general anaesthesia, and (3) a series of 100 thoracic surgical cases in which dipipanone was the main supplement to nitrous oxide anaesthesia and was used in place of a muscle relaxant.

Obstetric Cases.—During a period of one month, 53 consecutive patients were given dipipanone hydrochloride for the relief of pain in labour. As a control, a similar number of cases were treated with pethidine. For ease of statistical analysis, the midwife present at each delivery recorded the particulars of the case, the dose of analgesic given, the relief obtained, and the progress of labour on a specially designed form. The similarity of the two series of cases with respect to age and body weight will be seen from Table I.

General Surgical Cases.—Anaesthesia for the general surgical cases followed a standard technique. The patients were premedicated with papaveretum ("omnupon"), $\frac{1}{2}$ gr. (20 mg.), and hyoscine, 1/150 gr. (0.43 mg.), or with

TABLE I.—Age and Weight of Obstetric Patients

morphine, $\frac{1}{2}$ gr. (10 mg.), and atropine, 1/100 gr. (0.65 mg.), subcutaneously. After induction with thiopentone, anaesthesia was maintained with nitrous oxide and oxygen. The initial dose of dipipanone was given intravenously, the dose being graded according to the patient's age, weight, and physical condition, and varied from 2.5 to 5 mg. The concentration of dipipanone found most convenient was 2.5 mg. per ml. When an endotracheal tube was passed, 50 mg. of suxamethonium was given and gallamine triethiodide was injected later in divided doses if full muscular relaxation was required. The adequacy of the initial dose of dipipanone was judged from the respiratory rate. A rate of 10 to 12 respirations a minute was aimed at, and when this returned to 16 to 18 a minute a further dose of dipipanone was given. It must be stressed here that patients may easily receive an overdose if subsequent doses are given at fixed intervals without reference to the respiratory rate. The nature of the operations performed is shown in Table II.

TABLE II.—Operations Performed in 200 General Surgical Cases

Hernia	27	Thyroidectomy (toxic)	4
Cystoscopy	18	D + C	4
Partial gastrectomy	16	Fothergill repair	4

Laparotomy	5	Sympathectomy	1

Thoracic Surgical Cases.—Guedel and Treweek (1934) and Nosworthy (1941) established controlled respiration to provide greater safety for thoracotomy. They induced apnoea by deep anaesthesia aided by hyperventilation of the lungs. Present-day methods employ light nitrous oxide anaesthesia with a muscle relaxant to produce apnoea, thereby avoiding deep anaesthesia. However, some muscle relaxants, for instance, D-tubocurarine, are reported to produce excessive bleeding, and in cases where haemorrhage should be carefully avoided it is preferable that they should not be used. In the series of thoracic surgical cases reported, dipipanone in sufficient dosage, combined with hyperventilation, was used to produce apnoea. Following intubation under thiopentone and suxamethonium, and, if necessary, the insertion of an endobronchial blocker or tube, apnoea was induced with an intravenous injection of dipipanone aided by hyperventilation. Anaesthesia was then maintained with nitrous oxide and oxygen, with the occasional addition of 2.5 to 5 mg. of dipipanone intravenously.

Results in Obstetric Cases

In the series of obstetric cases dipipanone was found to be a perfectly satisfactory analgesic for use in labour (see Table III). Only in the occasional case was supplementation with nitrous oxide and air required in the second stage. The doses used, the times of administration, and the results obtained are given in detail in Table IV.

In many cases 25 mg. of dipipanone appeared to produce better analgesia than 100 mg. of pethidine. This was particularly so in the early stages of labour in those cases in which there was a large baby or where the foetal head had presented in the occipito-posterior position. Where adequate

analgesia could not be produced with dipipanone, morphine and pethidine also failed. The midwives formed the impression that dipipanone speeded up labour relative to pethidine and that relaxation between the contractions was better.

Buthalitone sodium, a short-acting thiobarbiturate, was first described by Miller *et al.* (1936). Following reports by Weese and Koss (1954) on its pharmacology and clinical use, it has been marketed as "transithal," "ulbreval," "baytenal," and thialbutone. Weese and Koss report on its use in 350 cases, both alone and combined with other anaesthetic agents. Similarly, Davidson and Love (1956) describe a series of 200 cases, the majority of which had buthalitone alone as a single dose. In both series an unspecified proportion of cases were out-patients, although in Davidson and Love's they constituted the largest group. Previously Nobes (1955b) had reported that if buthalitone is used for induction only and nitrous oxide and oxygen used for maintenance "a smooth and rapid recovery can be predicted far more confidently than with other intravenous agents used in the same way." No data were given in support of this statement, and the present paper describes an investigation into this technique of using buthalitone in 150 out-patients. Two other small series of cases are also included, illustrating the use of this drug in younger children and in out-patients where intubation was required.

Operations were performed for the following conditions : septic hands, 77 cases ; other septic lesions, 25 ; removal of toenails, 13 ; manipulation of fractures, 21 ; miscellaneous, 14.

As can be seen from Table I, the majority of anaesthetics lasted between 5½ and 10 minutes; the average duration was 7.2 minutes, and the longest lasted 40 minutes.

TABLE I.—Duration of Anaesthesia

Time in Minutes	No. of Cases	Percentage of Total No. of Cases
Up to 5	55	36.66
5½ to 10	76	50.66
Over 10	19	12.66

All cases were premedicated with atropine, 1/100 gr. (0.65 mg.), half an hour before operation, as was the routine in this out-patient department. The reason for this was that there was always a possibility that the operation might prove to be a prolonged one and thus require the addition of trichlorethylene to the nitrous oxide-oxygen mixture. This is in accord with the recommendation of Ostlere (1953) that when trichlorethylene is used "atropine or hyoscine premedication should always be given." The use of atropine was continued in this series, so that in comparing it with previous methods a possible variable factor could be eliminated. Nothing was allowed by mouth for four hours before operation.

A 10% solution of buthalitone was used. After trial in a few cases with varying dosages, it was found that an induction dose of 70 mg. per stone (11 mg. per kg.) body weight was the most suitable for our purposes. With larger doses recovery was delayed in most patients, while smaller doses produced insufficient basal narcosis, often requiring undue restraint of the patients.

All patients were therefore given a single induction dose at the rate of 70 mg. (0.7 ml.) per stone (11 mg. (0.11 ml.) per kg.) body weight, and anaesthesia was continued with nitrous oxide 8 litres a minute and oxygen 2 litres a minute. The injection was given rapidly and the patients fell asleep during or a few seconds after injection. They were particularly sensitive to extraneous noise during the induction period, and sudden noises were found to disturb them and often led to a stormy anaesthesia. This confirms the findings of Ruddell (1955), who emphasizes the need for quietness during induction. There were no instances of respiratory depression with this rate of dosage.

The following times were observed: "waking-time," "sitting-time," and "standing-time." These were recorded to the nearest half-minute and were measured from the conclusion of the anaesthesia. The waking-time was that at which the patient was awake and able to answer questions. Sitting-time was that at which the patient could sit up unaided; it corresponded to the time at which he or she could be assisted into a wheel-chair for removal from the casualty theatre. The standing-time was when the patient could stand unaided and was fit enough to leave for home. Although the patients were quite fit and mentally alert at the time of leaving, they were all sent home accompanied, travelling by car or ambulance.

Results

The results are shown in Table II. Approximately 90% of patients were awake by three minutes, able to sit by four minutes, and able to stand, and therefore be ready to leave for home, within 20 minutes of the cessation of the anaesthesia.

The trial was free from any serious complications. Slight movements occurred in 17 cases (11.3%), but they did not affect the operation in any way. In another 10 cases (6.6%) the movements were more marked, but with a moderate amount of restraint there was no interference with the operation. Retching occurred in 5 cases (3.3%) and vomiting whilst recovering consciousness in 9 (6%). Cough during induction was troublesome in 6 cases (4%) and hiccup occurred in 2 (1.3%), but disappeared quickly and spontaneously without special treatment. There was no instance of laryngeal spasm or of respiratory depression.

Series B: Use of Buthalitone in Children

Buthalitone has also been given to a group of 25 children (out-patients) aged from 6 to 9 years, using the same technique as described above. For these cases a smaller level of dosage was found to be adequate, and each child was given 50 mg. (0.5 ml.) per stone (8 mg. (0.08 ml.) per kg.) body weight. Anaesthesia was continued in the same way as with the adults and the same times were observed. The duration of anaesthesia varied from 4 to 39½ minutes, the average being 9.76 minutes.

The results, shown in Table III, demonstrate that this technique can be used in children when it is possible to give an intravenous injection. The results are similar to those obtained with adults, as can be seen by a comparison of the average times of waking, sitting, and standing in Tables II and III.

Series C: Use of Buthalitone where Intubation is Required

Dietmann (1954) was the first worker to advocate the use of buthalitone with suxamethonium chloride for endotracheal intubation, and this combination has been tried on a group of 25 out-patients who, by nature of the surgical operation proposed, required intubation. Twenty-two cases required complicated dental extractions, and the other three the suturing of lacerations of the face and mouth. Their ages ranged from 10 to 57 years. The technique used was induction with buthalitone in similar dosage to that described in series A, immediately followed by suxamethonium chloride, 50 mg., and intubation. Maintenance was with nitrous oxide 6 litres a minute, oxygen 2 litres a minute, and trichlorethylene.

The recovery times (Table IV) are prolonged when compared with those in the other series. This is presumably due to the time required for the elimination of trichlorethylene by these patients.

TABLE IV.—Results in Series C

	Limits in Minutes	Average in Minutes
Duration of anaesthesia	5-35	14.54
Waking-time	1-12	2.94
Sitting-time	1-13	4.74
Standing-time	6½-56	21.32

Discussion

In most hospitals the routine method for out-patient anaesthesia is nitrous oxide and oxygen, either alone or with trichlorethylene. When nitrous oxide and oxygen are used alone it is not always easy to anaesthetize every patient, and often undesirable restraint has to be used to enable the operation to be performed, the patient remaining in the stage of analgesia throughout. Also, if the operation is prolonged for more than two or three minutes it may be difficult to avoid cyanosis and anoxia. These difficulties can be overcome if the nitrous oxide and oxygen are supplemented with trichlorethylene, but the recovery period is then often prolonged—a characteristic feature of trichlorethylene anaesthesia.

In the out-patient department where this work was carried out these problems were particularly acute because the surgical techniques employed often demanded a longer operating-time than is usual in most out-patient departments. This meant that the full recovery times were often prolonged, with consequent increased demands for post-operative supervision and space for recovery. Therefore, for these reasons and others given below, it was decided to try buthalitone for induction, followed by nitrous oxide and oxygen, in the hope that a more satisfactory anaesthesia could be obtained for the majority of patients.

Thiopentone was not chosen initially for the inducing agent, as, generally speaking, it has not found full acceptance as a suitable routine agent for out-patient anaesthesia, in spite of its use with other types of surgery for many years. Nobes (1955a) was the first in this country to suggest buthalitone as a suitable drug for out-patient anaesthesia because of its apparent shorter duration of action than thiopentone. It was this fact that led to buthalitone being adopted as an inducing agent when a new technique was being considered. The experience gained with buthalitone has led us to reconsider the position of thiopentone in out-patient anaesthesia. We have used the latter in equipotent dosage for a number of cases, but, as yet, our experience is not sufficient to justify a definite comparison between the two drugs. We hope to report on this in a subsequent paper.

On the basis of the results from our three series, totalling 200 cases, we consider that this method of out-patient anaesthesia is a satisfactory alternative to those involving inhalation anaesthesia alone, and, in fact, has some advantages over them.

For the anaesthetist, induction is smooth and rapid, and adequate oxygenation can be maintained throughout the anaesthetic. Satisfactory operating conditions are produced for the surgeon. The speedy recovery ensures that, in a busy out-patient department, the need to provide nursing supervision and space for recovery is lessened compared with that often required by more orthodox inhalation techniques when the operating-time is prolonged.

For the patient, induction is rapid and pleasant, and is usually preferred to methods involving the use of a mask. Recovery is also rapid, and the most striking feature is absence of post-anaesthetic drowsiness and confusion. This latter has been confirmed by spontaneous remarks from patients who have experienced other methods and from the casualty nursing staff, who report that there is less post-anaesthetic nausea and confusion after this method than when nitrous oxide and oxygen combined with trichlorethylene or thiopentone have been used.

Summary

A short review of buthalitone sodium and its use in out-patient anaesthesia is given.

Three series of cases totalling 200 are reviewed and a method of using it combined with nitrous oxide and oxygen is described. The view is put forward that this technique is a suitable method of anaesthesia for use in out-patient departments.

Reasons for suggesting that this technique has some advantages over inhalational methods of anaesthesia, especially when surgery is prolonged, are given.

We thank Professor W. W. Mushin, of the Department of Anaesthetics, Welsh National School of Medicine, Cardiff, for his help in the preparation of this paper.

MITRAL VALVOTOMY DURING PREGNANCY

BY

R. J. MARSHALL, M.D., M.R.C.P.

Principal Registrar

AND

J. F. PANTRIDGE, M.C., M.D., M.R.C.P.

Physician

Royal Victoria and Royal Maternity Hospitals, Belfast

Rheumatic valvular lesions constitute over 90% of all cases of organic heart disease complicating pregnancy (Hamilton, 1954). Predominant or pure mitral stenosis is by far the most common individual lesion. Pulmonary oedema resulting from mitral stenosis is the most important cardiac cause of death in pregnancy (Jones, 1951). It appeared to us that mitral valvotomy might diminish mortality from mitral stenosis complicated by pregnancy. Several reports of valvotomy performed during pregnancy have appeared (Brock, 1952; Cooley and Chapman, 1952; Logan and Turner, 1952; Mulcahy, 1954; Watt *et al.*, 1954; O'Connell and Mulcahy, 1955; Glover *et al.*, 1955; Bailey and Bolton, 1956). However, the published experience of each of these authors is limited.

Since 1950, 404 patients under the care of one of us (J. F. P.) have had mitral valvotomy; 274 were women of child-bearing age, and 18 of these had the operation performed during pregnancy. Our experience with these cases is summarized below.

Clinical Features

The clinical features are summarized in Table I. The majority of the patients had been supervised during their pregnancy at an antenatal clinic, but despite careful medical management had undergone rapid deterioration at various times between the 6th and 36th weeks of gestation.

The 12 multigravidae had suffered from dyspnoea requiring prolonged bed rest during one or more previous pregnancies. Only one of the primigravidae had significant disability before the onset of pregnancy, but dyspnoea was noted in each toward the end of the second month and increased rapidly in severity.

In each case the physical signs at the time of presentation indicated a diagnosis of pure mitral stenosis with severe pulmonary congestion or actual pulmonary oedema. The rhythm was regular; the first sound at the mitral area was slapping in quality and there was a rumbling mitral diastolic murmur with pre-systolic accentuation; an opening snap was usually heard; the pulmonary second sound was

moderately or greatly accentuated. In no instance was there clinical evidence of aortic valve disease or of mitral incompetence. Crepitations were audible over the lung bases, and in a few cases pleural transudates were detectable.

Electrocardiograms showed unequivocal evidence of mild to gross right ventricular hypertrophy in six cases; there was no evidence of left ventricular hypertrophy in any record. Chest radiograms showed moderate to gross increase in hilar vascularity and increased vascular markings throughout the lung fields, and in a few cases pericardial and pleural effusions were noted.

In several instances fluoroscopy was not performed, since these patients were operated on when still in pulmonary oedema a few hours or days after admission; in the remainder the appearances were characteristic of pure mitral stenosis with gross pulmonary congestion.

The occasional necessity for emergency operation is illustrated by Case 1 (previously reported—Pantridge *et al.*, 1953).

A woman aged 34 noted rapidly increasing dyspnoea on exertion since the onset of pregnancy. On admission on December 4, 1952, during the 34th week of pregnancy, she was in *extremis*, with acute dyspnoea, cyanosis, and tachycardia. She had the signs of pure mitral stenosis. Crepitations were audible over both lungs and there was an extensive left-sided pleural effusion. Despite rigorous medical measures, deterioration continued. Operation was undertaken in the upright position. The lungs were sodden, pleural and pericardial effusions were present, and the mitral valve orifice would not admit a finger-tip. Both commissures were easily split with the finger and there was immediately a striking improvement in the patient's condition. Her baby was born two days later and survived. Convalescence was uneventful and she is now well.

In patients whose condition on admission was less critical, operation was not immediately undertaken; they were treated with complete bed rest, rigid salt restriction, and mercurial diuretics.

Cardiac catheterization was performed in two cases after an initial period of rigorous medical treatment (Table II). In view of the persistent marked increase in "pulmonary capillary-venous pressure" despite medical treatment, operation was considered mandatory. In the remaining patients in this group, persistence or recurrence of pulmonary congestion after periods of one to four weeks indicated the necessity for operative treatment.

13	39	29

Results of Mitral Valvotomy

Standard techniques were employed. The findings at operation and the effectiveness of the procedure are shown in Table I.

Valvotomy was undertaken at various times between the 12th and 36th weeks of pregnancy. In Cases 1 and 3 premature infants were born two days after operation and one of these failed to survive. Two patients recently submitted to operation (Cases 17 and 18) were still pregnant at the time of writing; the remainder continued without incident to term, and with one exception (Case 16) were fit for normal household duties and free from dyspnoea on ordinary activity.

The women invariably noted symptomatic relief within 24 hours of operation. Significant post-operative complications were few and had no relationship to the pregnancy; one patient had a small pneumothorax, a second had localized surgical emphysema, and two others developed atrial fibrillation which proved refractory to quinidine therapy.

Following mitral valvotomy it became evident that one patient (Case 16) had an associated tricuspid valve lesion. Cardiac catheterization demonstrated an end diastolic gradient of 10 mm. Hg across the tricuspid valve. This patient was awaiting tricuspid valvotomy.

Three patients have undergone subsequent pregnancies. One of these (Case 7), the only patient in whom valvotomy was not technically satisfactory, required prolonged bed rest. The others (Cases 5 and 8) had uneventful pregnancies.

Discussion

During pregnancy increased demands are made on the cardiovascular system owing to salt and water retention, rise in blood volume, and increased cardiac output. In healthy women these changes are readily tolerated. Patients with severe mitral stenosis can, however, maintain the

altered circulatory state only at the expense of a considerable rise in left atrial and subsequently pulmonary capillary-venous pressure. Hence, pulmonary oedema during pregnancy is a not uncommon event. As previously noted, Morgan Jones (1951) found pulmonary oedema to be the most important cardiac cause of death in pregnancy.

In four of our cases (Nos. 13, 14, 16, and 18) the stenosis was only moderate, the valve orifice admitting the index finger to the proximal interphalangeal joint. Nevertheless, these women presented with pulmonary congestion or oedema which persisted or recurred despite treatment with salt-free diets, complete bed rest, and mercurial diuretics. In one of the patients in whom cardiac catheterization was performed the resting pulmonary "capillary" pressure was still 29 mm. Hg after two weeks' such treatment. It is clear that moderate stenosis in the presence of the raised cardiac output and hypervolaemia of pregnancy can produce the same effects as tight stenosis in the non-pregnant patients, and that pre-operative assessment of the size of the valve orifice in many cases is a matter of great difficulty.

Opinions are still divided concerning the indications for mitral valvotomy in pregnancy. Burwell and Metcalfe (1954) state that surgery of the mitral valve should be avoided if at all possible and that the operation should be carried out only when "the safer procedure of interruption is not practicable." It is their opinion that most women who undergo valvotomy during pregnancy "would probably do well without an operation if the medical supervision was adequate" and that the operation is more hazardous during pregnancy.

It is true that pulmonary congestion and mild pulmonary oedema occurring in pregnant women with mitral stenosis are often easily controlled by medical means. However, in the cases reported here several of the patients were admitted in *extremis* and remained so despite therapy. The others showed pulmonary congestion or oedema uncontrolled by a fair trial of medical measures. It is apparent that patients in this state demand valvotomy. This is particularly so since the experience recorded here indicates that the operative risk is no greater during pregnancy than in the non-pregnant state.

In two patients (Cases 1 and 3) the operation was apparently the cause of premature labour at the 34th and 32nd weeks; one of these infants failed to survive. The remaining pregnancies, however, continued without incident. Since valvotomy was undertaken at the 18th week or later in all but three cases, it might be held that the incidence of post-operative abortion would be higher for operations performed earlier in pregnancy. However, all seven cases reported by Watt *et al.* (1954) had their operations between the second and fifth months of pregnancy; in none of these was there "any hint of threatened abortion." Several authors (Glover *et al.*, 1955; Bailey and Bolton, 1956) recommend that when surgery is likely to be required it should be undertaken as early as possible in pregnancy.

Summary

Mitral stenosis is an important cause of morbidity and mortality during pregnancy. The principal hazard is pulmonary oedema, which may develop with dramatic suddenness. Moderate mitral stenosis during pregnancy may produce the same effects as tight stenosis in the non-pregnant patient.

In the past six years 18 patients have undergone mitral valvotomy during pregnancy. The indications for the operation and the results are reported. The operation was undertaken in some as an emergency and in the remainder after a fair trial of medical treatment. There was no maternal death or any important post-operative complication. One foetus, born prematurely, failed to survive.

In suitably selected cases mitral valvotomy is preferable to termination of pregnancy.

We are indebted for the co-operation of Mr. T. B. Smiley, who performed valvotomy in 14 of the cases, and that of Mr. J. A. W. Bingham, who performed the operation in four cases.

NYDRANE IN THE TREATMENT OF EPILEPSY

BY

L. R. ROBINSON, M.D., D.P.H., D.P.M.
 Senior Registrar in Psychiatry, Purdysburn Hospital,
 Belfast

Epilepsy is a disease which presents a continual challenge to the skill of the physician. He has waged war against this disease throughout the centuries, using whatever therapeutic weapons were at his disposal and influenced by the prejudice and state of knowledge of his era. Epileptics were subjected to treatment which embraced the whole gamut of empirical medicine. They were exorcised for devils, blistered, and bled according to the prevailing fashion.

Many remedies were tried and discarded, such as borax, amylene hydrate, zinc, chlorbutol, urethane, simulo, hydrotherapy, and serotherapy. The first measure of any importance was the introduction of bromides by Laycock just over a century ago. These drugs were applied with such enthusiasm during the ensuing years that Spratling (1904) mentions bromide acne as being the hall-mark of the epileptic.

Modern drug therapy was ushered in in 1912 by the synthesis of phenobarbitone, a drug which has established itself firmly in the treatment of epilepsy right up to the present day. Hydantoins were introduced in 1938 and proved effective in the control of grand-mal convulsions, while drugs of the oxazolidine: dione series have been in use since 1945 in the treatment of petit mal. Biochemists in different parts of the world have been intensifying their researches recently, and their efforts have brought to light several new compounds which have been shown to possess anticonvulsant activity. This modern empiricism reminds one of the biblical admonition that "many are called, but few are chosen"; nevertheless it is to the advantage of the patient that the physician should have at his disposal as many useful drugs as possible and each new drug must be studied carefully, so that its uses and limitations may be assessed.

It was with these considerations in mind that a trial was begun of a recently introduced anticonvulsant called "nydrane." It has the chemical composition of N-benzyl-β-chloropropionamide and was originally discovered in America, where it was marketed as "hibicon." Experimental studies on laboratory animals have shown that nydrane raises the electrical threshold and

will protect them against a lethal dose of pentylene-tetrazole and artificially produced convulsions. It is a benzylamide with the formula $\text{Cl-CH}_2\text{-CH}_2\text{-CO-NH-CH}_2\text{-C}_6\text{H}_5$, and as such differs considerably from the anticonvulsants in everyday use. It is supplied in the form of tablets, each tablet containing 0.5 g.

Clinical Material

The drug was administered to 11 male patients. All were in-patients of Purdysburn Hospital, a mental hospital, and, as well as having epileptic fits of varying frequency, they suffered from an associated psychosis with some confusion, retardation, and antisocial behaviour. All were subject to convulsions of grand-mal type (idiopathic epilepsy) in spite of long-continued anticonvulsant therapy. They may be regarded as a refractory group resistant to ordinary medication and a severe test for any drug. Their ages ranged from 28 to 53, and detailed reports of their past behaviour, convulsion frequency, etc., were available for several years previously. All were under continual observation. The average number of convulsions per month to which the patients were subject varied from thirty-six to one. They were receiving phenobarbitone, phenytoin sodium, and primidone in varying dosages and combinations—for example, phenobarbitone, 1½ gr. (0.1 g.) twice daily, and phenytoin sodium, 1½ gr. (0.1 g.) twice daily, or phenobarbitone, 1½ gr. (0.1 g.), and 3 primidone tablets a day.

Before the trial started each patient was given a thorough examination, which included testing the urine and a full blood and differential white-cell count. Electroencephalograph (E.E.G.) tracings were taken of five patients.

Administration.—Initially nydrane was given in a dosage of one tablet (0.5 g.) three times a day in addition to existing medication, which was continued throughout the course of the trial in all cases. After one week this was increased to five tablets a day, and thereafter the dosage was increased by one tablet weekly until all patients were receiving seven tablets (3.5 g.) daily in divided doses. This was continued for a period of five months, after which the nydrane was gradually withdrawn. During this time a close check was kept on the blood picture, which showed minor variations, but in all cases the leucocyte count and haemoglobin were approximately the same at the end of the trial as at the beginning. There was no agranulocytosis or anaemia at any time. There was no albuminuria or sign of liver damage. The only side-effect noted was a slight gastro-intestinal upset in four patients within two days of beginning treatment, but this was of short duration and did not return.

Results

In assessing results, attention was paid both to the anticonvulsant activity and to the other actions of the drug. The usual criterion on which an anticonvulsant drug is assessed is its ability to reduce or abolish convulsions, although this strictly arithmetical method does not tell the whole story. The average number of fits per month was estimated in each case for the five months preceding the trial and compared with the average number over the five months during which they received nydrane.

Average Number of Convulsions Per Month in 11 Epileptics During Five Months' Treatment with Nydrane, Compared with the Preceding Five Months

Case	Age	Average Fits per Month	
		Before Treatment	While Receiving Nydrane
1	33	36.6	19.2
2	46	4.8	5.8
3	32	11.0	9.0
4	46	8.8	5.8
5	53	1.8	3.0
6	40	6.6	5.0
7	28	6.0	2.4
8	44	2.6	3.6
9	37	2.8	0.8
10	31	10.6	7.4
11	33	4.8	3.0

The results are given in the Table. It will be seen that eight out of the eleven patients showed some improvement—that is, a reduction in fits—and this was quite considerable in one patient, who was the most severely affected in the series. Three patients had an increase in convulsions. There was no difference in the E.E.G. tracings. Four of the patients volunteered the information that they felt better during the time they were receiving the drug. Subjective assessments are justifiably suspect, but an increased alertness was also noted by nurses in charge of the patients.

Discussion

In considering the results it must be borne in mind that these patients were a highly selected group in that they were so severely disabled by epilepsy with psychosis that they required mental hospital treatment—that is, they were the most refractory type of epileptics. The number in the group was small, and for that reason it would not be profitable to apply statistical tests; nevertheless certain facts are evident, and the opinions expressed may be helpful to future users of the drug.

The most important fact which emerged from the trial was the lack of toxicity. Although the dosage was moderately high, especially when combined with other anticonvulsants, there was no evidence of depression of bone-marrow function and the white-cell count was always within normal limits. There was no evidence of liver or kidney damage. Nausea and diarrhoea were experienced by a few patients at first, but this was purely transitory and did not necessitate any adjustment in dosage.

The convulsion pattern showed, in general, a downward trend, which was considered satisfactory. One patient improved considerably and his convulsions were reduced from 36 to 19 a month. The others showed the usual fluctuation which one expects with anticonvulsants, and altogether eight were improved to some degree.

There have not been many trials carried out with nydrane, but the results given here appear to be very similar to those obtained by Hoenig *et al.* (1956) in a series of epileptics, including 19 who were in-patients of a mental hospital and apparently comparable to the patients treated here. Those workers also comment on the lack of toxicity and side-effects, although three cases developed status epilepticus during the withdrawal stage. They mention a subjective sense of well-being, which was also noted in a few patients in the present group. There appear to be two possible explanations of this—either that it is due to a direct stimulating effect of the drug on the cerebral cortex, or that it is a secondary effect following control of convulsions. The chemical formula of nydrane is certainly different from that of other anticonvulsants, but it seems unlikely that a drug which suppresses convulsions would also stimulate. It must be remembered, however, that the motor cortex is only a small part of the total brain substance, and a feeling of euphoria must be largely a summation effect. The E.E.G. did not indicate any great change in cerebral rhythms in those cases in which it was performed, but, in any case, it does not admit of sufficient refinement to be used as an index of mental activity.

Hoenig *et al.* comment on some loss of weight among their patients, with three cases of status epilepticus during the withdrawal stage, but such mishaps were entirely absent from the present series. It has been my experience that status epilepticus is provoked as often by a disturbance of homeostasis due to causes easily overlooked—for example, slight infection or constipation—as by cortical hyperexcitability due to drug imbalance.

The only minor disadvantage in the treatment was the number of tablets which the patient had to take in the day, especially when, as in this case, other drugs are given as well. The pharmaceutical chemist, however, may be able to find the answer to this.

In conclusion, then, I may state that we found nydrane a satisfactory drug to use. It was not the purpose of this trial to compare it with other anticonvulsants, but it does

appear to be synergistic or additive. We were particularly impressed by its safety and freedom from side-effects, and its action tends to counteract depression. Its judicious use should prove to be of benefit to large numbers of epileptics.

Summary

Eleven patients suffering from grand-mal epilepsy with psychosis were treated for five months with nydrane in addition to other anticonvulsants. The results were considered to be satisfactory by subjective and objective standards. Very few side-effects were observed, and in particular there was no evidence of any damage to liver or kidney or depression of haemopoietic function.

We thank the resident medical superintendent for permission to carry out the trial, and Rona Laboratories for their supply of the drug.

PARTIAL GASTRECTOMY IN VON WILLEBRAND'S DISEASE

BY

R. E. IRVINE, M.D., M.R.C.P.

AND

J. D. T. JONES, M.S., F.R.C.S.

From the Royal Victoria Infirmary, Newcastle upon Tyne

In the haemorrhagic diseases major operations are rightly held to be contraindicated except under the most desperate circumstances. To some extent von Willebrand's (1931) disease (pseudohaemophilia, constitutional thrombopathy) is an exception, and the following case is reported to show that the hazard of operation, though unpredictable, is not as great as is commonly supposed.

Case Report

The patient, a crane-driver aged 42, was one of a family of eight children. His father, one brother, and two sisters all suffered from a tendency to bleed. As a child he had been admitted to hospital on several occasions for severe nose bleeds, and at the age of 27 he had to have a blood transfusion for haemorrhage following a tooth extraction. On other occasions teeth had been extracted without incident. He had often noticed a tendency to easy bruising and had bled for as long as three to four hours after a cut while shaving. After a blood count he usually stopped bleeding at once, but had on one occasion continued to bleed for two hours.

This irregular bleeding tendency was investigated during 1954 and 1955. The bleeding-time (Duke) was generally prolonged. On eight occasions it was between 5 and 30 minutes and on five it was normal. The clotting-time and clot retraction were invariably normal. Hess's capillary fragility test was positive on 16 occasions, sometimes quite strongly, but on five others it was completely negative. The platelet count was always normal. Prothrombin estimations by the one- and two-stage methods and the thromboplastin generation test gave normal results. The family history and the evidence of a normal clotting mechanism associated with a prolonged bleeding-time and frequently positive capillary fragility tests confirmed the diagnosis of von Willebrand's disease, in which the cause of the haemorrhagic tendency is thought to lie in an abnormality of capillary function.

Since the age of 36 the patient had often been troubled by dyspepsia and gastro-intestinal haemorrhage. This was eventually shown radiologically and gastroscopically to be due to a lesser-curve gastric ulcer which healed once under medical treatment, only to recur later. In 1953 operation was thought to be indicated so far as the ulcer was concerned, but was not undertaken on account of the risk of haemorrhage. By 1955, however, the recurrent haemorrhages and increasing pain were causing severe disability, and it was evident that more drastic measures would be needed. It was decided to take advantage of the apparent variability of the haemorrhagic tendency and to operate when the bleeding-time was normal and the capillary fragility test negative.

Accordingly on August 5 laparotomy was performed by one of us: a chronic partly healed ulcer was found on the lesser curve of the stomach and a Billroth-I partial gastrectomy was carried out. No excessive bleeding occurred during the operation, but there was some continued oozing into the stomach for 48 hours afterwards, culminating in a brisk haematemesis, for which 5 pints (2,840 ml.) of blood was transfused. A five-day course of corticotrophin (100 mg. a day) was given, beginning 24 hours after the haematemesis. Recovery was uninterrupted, but there is no clear evidence that this drug affected the issue.

Three months after the operation the patient was very well, had no dyspeptic symptoms, and had put on half a stone (3.2 kg.) in weight.

Discussion

Von Willebrand's disease has recently been the subject of two able studies. Horler (1955) stresses the variability and unpredictability of the haemorrhagic tendency. He points out that the bleeding-time varies greatly from patient to patient, and in the same patient at different times. This agrees well with the experience of our patient, whose bleeding-time was normal on three occasions but prolonged, sometimes greatly, on others. Buchanan and Leavell (1956) have extended this observation by showing that the bleeding-times may vary when estimated simultaneously in different parts of the body. In a patient of theirs the bleeding-time was 17½ minutes in one ear and 180 minutes in the other.

This variability of the haemorrhagic tendency is reflected also in the patient's reaction to surgical operations. A patient may bleed heavily at one operation and no more than normal at another. In one of Horler's cases tonsillectomy led to severe haemorrhage, but a subsequent appendicectomy was uneventful. This author's series included nine major operations in five patients. In five operations the bleeding was excessive and in four it was not. In one case the operation had to be abandoned on account of the bleeding, but there were no deaths. Buchanan and Leavell's experience was similar. Thirteen of their patients were submitted to surgery. Several bled heavily, but the haemorrhage was ultimately controlled in all cases. There were no deaths, and no operation had to be abandoned. In their review of the literature these authors show that among 199 reported cases of von Willebrand's disease 39 have undergone surgical operation (excluding the extraction of teeth), with only one death, which followed a splenectomy (Little and Ayres, 1928). Even allowing for the natural tendency for successes to be reported and failures forgotten, this is a remarkable fact, and contrasts sharply with haemophilia, in which the mortality of major operations is at least 50% (Biggs and Macfarlane, 1953).

The cause of von Willebrand's disease is unknown and there is no specific treatment. Therefore nothing can be done at operation to prevent haemorrhage apart from the most scrupulous attention to the usual surgical techniques of haemostasis. Buchanan and Leavell state that the bleeding-time is not always a reliable guide to the behaviour of the patient at operation. Yet it is the only guide of any sort which we possess, and it would seem reasonable to avoid an elective operation when the bleeding-time is greatly

prolonged. The literature contains very little information about the bleeding-time on the day of operation, and there is room for more careful recording of data concerning this point.

Summary

The case is reported of a patient with von Willebrand's disease who had a successful partial gastrectomy for gastric ulcer. The operation was performed at a time when the bleeding-time was normal. There was no excessive haemorrhage at operation, but a haematemesis on the second post-operative day responded well to blood transfusion.

The case is discussed in relation to those previously reported, and it is emphasized that, although all authors stress the hazards of operation in von Willebrand's disease, the literature contains only one record of a fatal operation. The relatively favourable prospects for surgery in von Willebrand's disease are contrasted with the extremely bad results of operations in cases of haemophilia.

It is probably desirable to take advantage of the natural fluctuation of the bleeding tendency and to perform an elective operation when the bleeding-time is not greatly prolonged.

We are grateful to Dr. T. H. Boon for permission to report this case.

Medical Memoranda

A Case of Acute Inversion of the Uterus

As the incidence of acute puerperal inversion of the uterus is estimated at between 1 in 17,000 and 1 in 200,000 deliveries and the extreme gravity of this condition is equalled only by its rarity, it is worth while to record this case.

CASE REPORT

A 2-gravida aged 19 was admitted to hospital at midnight on March 19, 1955, with a history of having started in labour four hours before admission. Her pregnancy had been quite uneventful and the expected date of delivery was March 22.

On examination she was found to be a healthy young woman, well established in labour. The size of the uterus was consistent with a full-term pregnancy and the foetus was presenting by the vertex. The position was left occipito-anterior, with the foetal head in mid-cavity and the cervix uteri well applied to the head and dilated to one finger-breadth. Uterine contractions recurred every four minutes and the foetal heart was satisfactory.

Labour proceeded normally until spontaneous delivery of a live male child, weighing 8 lb. 9 oz. (3.9 kg.), at 3 a.m. after a first stage of seven hours and a second stage of 20 minutes. The placenta appeared to be in the vagina 30 minutes after delivery. There had been only very slight haemorrhage up to this point. An expulsive effort on the part of the mother delivered the placenta readily. There was slight delay with the membranes, but these eventually delivered following gentle traction. Immediately after the delivery of the placenta a severe post-partum haemorrhage occurred, a total of 3 pints (1.7 litres) being lost within a few minutes. On examining the abdomen no definite fundus could be palpated, nor could one be rubbed up. Ergometrine tartrate, 0.2 mg., was immediately given intraven-

ously, and within a minute what appeared to be a fundus developed low in the abdomen.

The blood loss ceased, but the patient's condition continued to deteriorate rapidly. She was in profound shock, was restless, and complained feebly of lower abdominal pain. The pulse rate was 120 a minute and the blood pressure could not be recorded.

On further examination what appeared to be the fundus had a definite cup-shaped depression on its upper surface. A vaginal examination revealed the uterus to be inverted and lying in the vagina. At this point, six minutes from delivery, the only pulses detectable were the carotids and the apex beat. The patient was unconscious. A dextran drip was set up while blood was being cross-matched. The transfusion was run in rapidly, 1 pint (570 ml.) being given in about 15 minutes. Cross-matched blood was then available and a rapid transfusion of this was begun.

The blood pressure was 70/50 mm. Hg and the wrist pulses were detectable. Slight improvement in the general condition having occurred, it was decided to reduce the inversion. With the transfusion continuing, and under nitrous oxide and oxygen anaesthesia, reduction by taxis was accomplished without undue difficulty. After the reduction, recovery could only be described as dramatic. The blood pressure rose to 110/80 mm. Hg and the pulse rate dropped to 80. Colour, respiration, and general appearance improved rapidly.

A further 2 pints (1,140 ml.) of blood was given to replace the initial loss. The patient recovered consciousness two hours after the reduction of the inversion, "feeling fine."

The puerperium was uneventful, involution proceeding normally. Breast-feeding was readily established and the patient was discharged from hospital on the tenth post-partum day, feeling fit and well, with a haemoglobin of 10 g. per 100 ml. Further progress at home was maintained.

COMMENT

Though the majority of inversions seem to be due to some error of management on the part of the attendants, cases of spontaneous inversion have been recorded. In this case the placenta was expelled by the mother's effort, and the only factor that may have contributed to the production of inversion was traction on the foetal membranes. This was very gentle and no resistance to the delivery could be discerned. It is felt that this was probably a case of spontaneous inversion, though traction on the membranes, however gentle, cannot be excluded as a probable cause.

The importance of making a vaginal examination in a case of shock following delivery must be stressed, as an incomplete inversion of the uterus may not be diagnosed unless it is done. We were grateful to have available a plasma substitute: its effect was life-saving while blood was being obtained and matched.

Agranulocytosis during Phenindione Therapy

Agranulocytosis is an apparently rare complication of anticoagulant treatment with phenindione (phenylindanedione, "dindevan," "indema"). MacMillan and Brown (1953) reported two Canadian cases, one being fatal; both, however, had also received other drugs. Kirkeby (1954) described a definite case from Norway. A suspected case (without blood counts) was contributed by Mayer (1954).

We estimate that some 900 patients have been treated with phenindione in this hospital: we have been unable to trace a previous case associated with agranulocytosis.

CASE REPORT

A man aged 59, editor of a periodical, was admitted on October 23, 1956, five days after a myocardial infarction and three years after a previous attack. Routine phenindione treatment was supported with heparin for the first

two days, and thereafter continued on 100-125 mg. daily in two doses, with prothrombin times (Quick) between 1.4 and 2.1 times the control readings—that is, in the range of moderate therapeutic effect.

After 27 days of treatment, during which the only additional drugs given were chloral hydrate and liquid paraffin, a fever of 102° F. (38.9° C.) was recorded. The following day the white-cell count was 3,700 per c.mm. (polymorphonuclears 3%, mononuclears 97%), compared with a count of 11,000 (polymorphonuclears 80%) on admission. The throat was injected but not sore, and there was no rash on the skin. Phenindione was withdrawn and 600,000 units of procaine penicillin injected daily. On the next day a marrow aspirate showed numerous myelocytes but no mature polymorphs; a few metamyelocytes and band polymorphs were seen in the peripheral blood.

After four days of fever the temperature dropped to around 100° F. (37.8° C.), finally settling after a further week. Mature polymorphs reappeared in the peripheral blood on the sixth febrile day.

COMMENT

It seems from the reported cases that, when agranulocytosis occurs, it is to be looked for after 20 to 30 days of phenindione treatment. In Kirkeby's case, that of a man aged 58, the complication presented with a rash during the fourth week of treatment, which was apparently continued, and agranulocytosis appeared in the fifth week. MacMillan and Brown observed fever in the fourth week, followed by agranulocytosis after some days, in one of their cases, that of a woman aged 57; and in the other case, that of a woman of 64, pyrexia, rash, and agranulocytosis appeared together in the fifth week of a course of treatment which had been interrupted during the fourth week. Mayer's patient developed a rash and fever also in the fourth week. This time interval was observed in our case.

It would probably be wise to withdraw phenindione if a rash or fever appears during treatment, particularly during the fourth week. In our case heparin was substituted.

Kirkeby's patient died in uraemia after marrow function had recovered. MacMillan and Brown's second patient died of agranulocytosis. The other, with our own, recovered.

Numerous myelocytes in the marrow aspirate, as in the present case, suggest a favourable prognosis, provided that infection can be controlled. This is in line with Plum's (1937) work on amidopyrine agranulocytosis and with Hutt's (1951) observations on the agranulocytosis of thiouracil. Plum demonstrated the sequence of events to be: a fall in granulocyte precursors in the marrow; a fall in circulating polymorphs; return of marrow precursors; and, lastly, return of circulating adult cells. Thus to find myelocytes in the marrow during the phase of granulopenia is to observe the beginning of recovery.

We are grateful to Dr. A. C. Dornhorst for permission to publish.

Twin Pregnancy: Well-formed Hydatidiform Mole Associated with Normal Viable Child

An African, Jalu, woman aged about 28 was admitted to the Nyanza General Hospital, Kisumu, on July 6, 1955. She was a multipara and had not been attending the hospital or other antenatal clinic. So far as could be judged, she had a menstrual period about mid-December, 1954, and was expecting her child in September. Her obstetric history was: a girl in 1945, a boy in 1947, a girl in 1951, and a boy

in 1952 (all these children are still alive and well, and there was no history of obstetrical complication either during pregnancy or on confinement); four-months abortion in March, 1954, apparently complete and uncomplicated.

The patient could only give mid-December as the nearest date of her last menstrual period. She stated that her pregnancy proceeded normally until during the first week in June, when she noticed a slight blood-stained vaginal discharge. This continued until her admission, and, although slight, was more or less continuous.

On examination the height of the fundus of the uterus corresponded to an eight-months pregnancy. The foetus was readily palpated in the R.O.A. position, but was high. The

feel of the lower segment indicated that there was an apparent soft mass in the lower left-hand quarter. The foetus seemed to be small, but the foetal heart was strong. The vaginal discharge was a bright red and appeared to be normal blood. On vaginal examination a soggy mass was felt between the examining finger and the foetal head. A tentative diagnosis was made of left-sided marginal placenta praevia, but as loss per vaginam was minimal it was decided to be conservative in treatment.

The patient was confined to bed and sedated with 10 gr. (0.65 g.) of potassium bromide thrice daily. She settled down under this treatment and the bleeding ceased. On July 26 she went into spontaneous labour, and within an hour delivered herself of a live male child weighing 4 lb. (1.8 kg.) and obviously premature. Its state of development was approximately that of a 30-weeks gestation. While waiting for pulsation to cease in the cord, a mass appeared at the perineum and a moderate-sized hydatidiform mole (see Fig.) slipped out, aided by slight pressure on the fundus. The cord was separated and a complete normal placenta and membranes were delivered five minutes later.

It is the intention to follow up the case by Aschheim-Zondek tests at regular intervals, subject to the patient's co-operation—a doubtful possibility in a peasant African. At the time of writing the mother was well and fit, and the puerperium was running a normal course. The baby, on the other hand, was very weakly, and it is doubtful if it will survive.

COMMENT

It is admitted that if the possibility of hydatidiform mole even crossed my mind it was almost immediately discarded because of the advanced stage of pregnancy. My previous experience is of one similar twin pregnancy, but the patient, an Asian, spontaneously emptied her uterus in the fifth month. Discussion with colleagues at the Nyanza General Hospital confirmed my opinion that such pregnancies were a rarity, and no one had heard of one proceeding so far. Investigation at the Medical Research Laboratory Library produced an article by Dr. Elizabeth M. Rose (1952), who had a similar case on June 13, 1949. She could trace only two such previous cases: one by Waters and Crunden (1943) and the other by Favreau and Bélanger (1939).

My thanks are due to the Honorary Director of Medical Services, Kenya, for permission to publish this case; to Mr. McVeigh, of Kisumu, for the photograph; and to Miss Allen, Librarian, M.R.L., Nairobi.

Reviews

MIGRAINE

Treatment of Migraine. By John R. Graham, M.D. (Pp. 149+vii; illustrated. 28s.) Toronto, Boston: Little, Brown and Company. London: J. and A. Churchill Ltd. 1956.

Dr. Graham is chief of medical service, Faulkner Hospital, Boston; clinical associate in medicine, Massachusetts General Hospital; attending physician, Veterans' Administration, Roxbury, Mass.; instructor in medicine, Harvard Medical School; and director of the headache clinic, Massachusetts General Hospital.

It isn't usual at the beginning of a review of a book to expend so much space on the qualifications of the author to write it. When the book deals with so important a subject as migraine it is worth the space, because of the extraordinary amount of nonsense that has been written about it by publicists with no such qualifications. You may or may not agree with Dr. Graham, but you may as well know from the beginning that you are agreeing or disagreeing with somebody worth the effort of either. The introduction, anyway, will put you in the right mood. Never has so bad a frontispiece or paltry a poem so perfectly expressed the present chaos in thought about migraine, a field in which at least six groups of specialists compete without understanding of each other. It may or may not be significant that, in his drawing, Dr. Graham puts the endocrinologist in the position of the mahout of the migraine elephant, but thereafter gives him scant notice. The introduction is superb, disposing altogether of the possibility of any such animal as the specialist in migraine. It will infuriate any who aspire to be mahouts, which is a good thing.

The theme of the book is that the treatment of the patient with migraine must be "tailor-made"—a point strongly made by our own Macdonald Critchley, to whom Dr. Graham pays tribute rarely given to British by American authors. He stresses the importance of general considerations, such as the psychological and social backgrounds of the patients, the necessity for taking the patient into one's confidence and discussing the problem in all its aspects with him, for avoiding the facile prescription of the "wonder drug" in every case. Enthusiasm in the doctor for a single line of approach, whether it be psychological, pharmacological, allergic, or endocrinological, will almost invariably produce temporary alleviation and will make more difficult the attempts of subsequent less specialized physicians, who will find themselves dealing with patients whose illusions have previously been shattered. "Complete freedom from migraine is rarely achieved by any [one] therapeutic program."

But perhaps Dr. Graham does to a certain extent fall into the trap he seeks to expose for others. His advice on the manifold ways in which ergot may be prescribed is worthy of the most careful study. No one who has read this book will prescribe ergotamine tartrate during an attack and, having failed to achieve the perfect result, will then consign ergot to the rubbish heap, as so many of us have done. But it may be thought that he pins his faith (for all his protests) a little too hopefully to this super-eminent drug. He forgets to mention carbachol. He pays almost no attention to fluid retention and the use of urea, to which Sir Walter Langdon-Brown directed our attention a generation ago. His discussion of the use of hormones is vague and superficial, and he has obviously not appreciated the frequency with which migraine in women occurs in the ovulatory and premenstrual phases of the menstrual cycle and the frequency with which such attacks can be allayed by progesterone. One gets the impression that progesterone, oestrogens, cortisone, and corticotrophin are useful in certain cases, but he apparently does not fully realize that such remedies should be used only after careful study and, if so used, can often produce the results expected of them more often than mere chance allows.

Despite these minor criticisms, this is a book which not only should be read with care by everyone from whom the sufferers from migraine habitually seek advice, but should be bought and often read again. It takes only an hour or two.

RAYMOND GREENE.

RECURRENT LARYNGEAL NERVES

The Recurrent Laryngeal Nerves in Thyroid Surgery. By William H. Rustad, M.D. Illustrations by Ralph Sweet. (Pp. 47+xiii, illustrated. 34s.) Springfield, Illinois: Charles C. Thomas. Oxford: Blackwell Scientific Publications. 1956.

This brief, well-illustrated, and beautifully printed monograph on the recurrent laryngeal nerves is a welcome addition to the subject, as it may help to reduce what was described at a recent meeting of the Section of Surgery at the Royal Society of Medicine as the "inherent risk of damage to the recurrent laryngeal nerve in thyroidectomy." The book starts off with a pleasant historical account of the recurrent nerves and their identification, and then describes how the nerves have been dissected out in 110 cadavers in the dissecting-room and the results grouped and subsequently drawn. There follows a series of partly schematic drawings, 77 in all, illustrating the eleven different groups of anatomical type that were found. These form a useful guide to those who want to know what the pattern of the nerves is likely to be if they are displayed at operation and the sort of risk to which they may be exposed. The idea of using a partly schematic type of drawing is excellent, as any additional detail would have provided no further information but only obscured the essential anatomy. There is a good bibliography, but no recent British contributions to this subject, such as those of Riddell (*Lancet*, 1956, 2, 638), Bowden (*Brit. J. Surg.*, 1955, 43, 153), or Barry (*Proc. roy. Soc. Med.*, 1955, 48, 437), are included. There will always be two schools of thought—those who wish to identify the nerves at operation, and those who feel that the nerves are only safe if not seen. Perhaps a happy middle way, such as that described by Riddell, provides the best answer for most surgeons, but it is always very comforting to see the nerve and see also that it is not damaged.

This little book will provide a useful work of reference for the thyroid surgeon, and its beautiful typography and illustrations make it a pleasure to handle.

SELWYN TAYLOR.

MENTAL HEALTH AND DISORDER

Mental Health and Mental Disorder: A Sociological Approach. Edited by Arnold M. Rose and eight others. (Pp. 626+xii; 40s.) London: Routledge and Kegan Paul Ltd. 1956.

The general physician glancing through the contents of this "sociological approach" to mental health and disorder might be forgiven if for a moment he thought he had purchased by mistake a textbook of psychiatry. The psychiatrist, however, accustomed to exploiting the services of psychiatric social workers, will have no difficulty in recognizing the book for what it is, a survey of social psychiatry overlapping on one side with clinical psychiatry and on the other with pure (non-clinical) sociology. Because of his own bias in favour of environmental factors in mental disease he may have more difficulty in recognizing that, although the social psychiatrist and his friend the statistician combine to form one of our more recent portents, the former is nevertheless faced with the same limitations that eternally confront the sociologist, in particular that the peripheral approach to mental function is likely to be peripheral in understanding. Nevertheless psychiatrists should make a point of reading this book if only as an exercise in mortifying the psychiatric flesh. The 36 papers of which it is comprised vary, it is true, in scope, quality, and comprehension, many of them being born of a sociological industry which,

in the view of most dynamic psychologists, leaves their problems precisely where the writers found them. But it contains some excellent surveys, not only of existing literature and of socio-psychiatric ideologies, but of such subjects as trends in mental disorders, schizophrenia among primitives, mental health among the Hutterites (an isolated Anabaptist religious sect), changing ideas on mental treatment, and the social psychology of mental health. Psychoanalysts will be intrigued by an essay on infant training and the personality of the child, the burden of which is that the personality adjustment and traits of children who have undergone varying training experiences do not differ significantly. On the whole and despite the varying orientation of the writers, the book can be recommended as representative of social psychiatry at its best and worst. It might well be made obligatory reading for the D.P.H., possibly also for the D.P.M.

EDWARD GLOVER.

CEREBRAL INJURIES

Das Hirntrauma. Beiträge zur Behandlung, Begutachtung und Betreuung Hirnverletzter. By Dr. Med. E. Rehwald. (Pp. 527+xii; illustrated. D.M.44.) Stuttgart: Georg Thieme Verlag. 1956.

This is a selection from papers given at the annual meetings of the Society (*Die Arbeitsgemeinschaft*) for Problems of Traumatic Brain Injury, which was founded in Germany in 1948. There is a clinical chapter on the acute and late stages of head injury, a chapter on neuropathology and on pneumo- and electro-encephalography, on forensic aspects and rehabilitation, and on the effect of traumatic brain injury in children. The majority of the contributions are short and consist of case reports; a few others give a more comprehensive picture of certain aspects of the problem. In particular, Frowein and Harrer describe the vegetative disorders and the biochemical methods of investigation. Zuelch demonstrates characteristic changes of the pneumo-encephalogram in diagrams and photographs. The E.E.G. finding and its significance is discussed by Duensing: the E.E.G. in pure concussion, when taken a week after the injury or later, was always negative; in the late stages of contusion, changes in the E.E.G. were present only in post-traumatic epilepsy or indicated complications such as abscess and encephalitis. A number of articles refer specially to the clinical symptomatology and the E.E.G. findings in lesions of the frontal and temporal lobes. Tönnis gives some case histories of traumatic brain damage in children. In his experience the defects are, contrary to the opinion widely held, essentially identical with those in adults; they are less distinct when they occur very early in childhood.

In a collection such as this a balanced presentation of the various problems of traumatic brain injury cannot be expected, nor is it surprising that the individual contributions should vary in usefulness. However, the articles are in general of good standard and of interest for psychiatrists and neurologists, although the literature referred to is almost exclusively German.

R. KLEIN.

CHILD PSYCHIATRY

Six Children. By Estelle J. Foote, M.D. (Pp. 317+ix. 42s.) Springfield, Illinois: Charles C. Thomas. Oxford: Blackwell Scientific Publications. 1956.

The title of this book leads the reader to expect a detailed study of six children. Instead one gets a review of the diagnosis and disposal of six kinds of child. These are: the quick-thinking child; the slow-thinking child; the child whose brain has been injured; the child maladjusted emotionally; the child of unusual cultural background; and the child of unusual training. The author has worked through her 3,600 personal cases with good common sense,

and in this book has tried to give a generalized statement. This statement, unfortunately, adds nothing to our knowledge, and is written in too discursive a manner for use by any significant group in this country. As an example of the author's style it might be fair to extract a couple of paragraphs:

"A symptom to be studied carefully was bedwetting. Characteristically, he had become tidy at not far from the usual age; then after some psychic trauma—some hurt to his feelings—as the threat of being displaced from first place in his parents' affection by the birth of a sibling, he started bedwetting again. I rather thought that this occurred only when the child was already more or less emotionally insecure."

"I had a theory, as far as I know held by no other psychiatrist, that a cheerful, friendly first grade teacher who likes children and shows understanding to all equally, has saved many a child from eventual psychosis, to which he would certainly have progressed had he spent his entire childhood in his own home where one or both parents covertly or openly rejected him. Who has not seen first grade children run to meet a popular first grade teacher?"

Of psychometrists she writes: "To be bossed around freely by a psychometrist is the mark of an inept and spineless psychiatrist. Why bother with the psychiatrist in the clinic at all if the psychometrist gives the diagnosis?" Nevertheless she uses intelligence tests in every case, and it would seem that the main work on each case is kept at the emotional level of the educational psychologist. One remark gave me fellow-feeling: "Occasionally she would smile normally, as when I let her listen, with my stethoscope, to her own heart beat." But this human detail does not indicate by itself a very profound understanding of psychology or case work.

D. W. WINNICOTT.

HUMAN THOUGHT

On Human Thinking. By K. W. Monsarrat. (Pp. 155. 15s.) London: Methuen and Co. Ltd. 1955.

Several members of the medical profession have been eminent philosophers—for example, John Locke, who practised medicine at Oxford; Thomas Brown (1778–1820), a Scottish metaphysician; and William James, who graduated M.D. at Harvard and became professor of philosophy there in 1872. Mr. K. W. Monsarrat has found or made time in his busy life as a surgeon to write a number of books on philosophy which have received attention, and the present book indicates that his study of the subject continues to be vivid and interesting. Space will not permit of a detailed analysis of a complex thesis. Broadly, the author first points out that there has been a general failure within and between the nations of the world to give the individual the kind of life that he desires. This probably lies deeply in our habits of thought, so full of inconsistencies and confusion. The earlier chapters of the book are devoted to a philosophical analysis of human thinking, with quotations from Locke, Berkeley, Hume, and Kant. This is still a vexed question, and many will still feel after reading these chapters that little advance has been made since Descartes wrote: "Cogito, ergo sum." Other chapters deal with beliefs and ideas concerning the self and the body, images of a world and images of the other man. Here evolution, physics, anatomy, physiology, and biochemistry are marshalled in support of a socialized philosophy. Finally, an appeal is made to experience and the histories to enable the human being to decide what organization of social relations will give him the life he desires. Many readers will disagree with Mr. Monsarrat's conclusions, especially with his references to revealed religion, but none will doubt his serious purpose in writing this book.

ARTHUR S. MACNALT.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY MAY 11 1957

THE CHANGED PICTURE

The General Medical Services Committee decided on April 30 by 24 votes to 22 to recommend to the Special Conference of Local Medical Committees that "in view of latest developments evidence should now be given to the Royal Commission and a decision on withdrawal from the Service should be deferred." On the same day the Central Consultants and Specialists Committee unanimously approved of co-operation with the Royal Commission. The Special Conference of Local Medical Committees, however, decided to defer a decision until the meeting of the Annual Conference in June. The Special Representative Meeting, a day later, on May 1, reached a similar decision in the form of the following resolution:

"(1) that in the opinion of this meeting circumstances have so changed that the position has altered since the Council issued its recommendation to the Representative Body not to give evidence to the Royal Commission; but, realizing that Divisions and the profession generally have not had an opportunity of considering the statements by the Chairman of the Royal Commission or the letter (April 26) from the Minister of Health to the Chairman of Council, this special representative meeting defers a decision on the question of giving evidence to the Royal Commission until the next meeting of the Representative Body; (2) that the decision on withdrawal of service be deferred."

What are the circumstances? After hearing of the exchange of letters between Sir Russell Brain and the Prime Minister, the Royal College of Physicians on April 12 decided to co-operate with the Royal Commission, and on the same day the Royal Commission issued a statement explaining how they intended to proceed. Dr. S. Wand, Chairman of the B.M.A. Council, had conversations with the Minister of Health, whose assurances on certain points were given in a letter dated April 26. All these facts have been recorded in recent issues of the *Supplement*, and it will not be until the Special Representative Meeting on June 12 that the policy of the B.M.A. will be finally decided. Decision will not be easy. The profession is unfortunately not united. The Royal College of Physicians was quick off the mark in advocating co-operation with the Royal Commission. In this confused situation the general practitioners, through the

G.M.S. Committee, by a narrow margin of two votes, followed suit. But the Special Conference and Representative Meeting delayed action by the resolutions referred to above. The three courses open seem to be: (1) to withdraw from service and to refuse to give evidence to the Commission; (2) to suspend plans for withdrawal but to continue to refuse to give evidence; (3) to give evidence but to hold in reserve plans for withdrawal.

There can be little doubt that many general practitioners dislike the idea of withdrawal from the N.H.S. to enforce a claim for more pay. Withdrawal has not been presented as a method of enforcing a claim for 24% increase in pay, but of securing the elementary rights of negotiation or arbitration. Many have regarded the threat to withdraw as distasteful and undignified and as equivalent to threatening to strike. To strike is to withhold certain services; but it is not proposed to do this. Our colleagues in Denmark before the war withdrew their services under an insurance scheme in order to remedy an injustice, and our colleagues in Sweden are doing the same to-day. There are also now severe conflicts between doctors in France and Belgium and those in charge of the social security schemes under which they give their services. Dental surgeons in Holland are at this moment engaged in a similar conflict. Hearing of these events last week the Council of the World Medical Association considered it was wrong to call such actions as withdrawal from service strikes, so long as doctors continued to look after their patients. Nevertheless, if a substantial number of doctors are to withdraw from a service so comprehensive as the N.H.S. the issue must in its impact be big enough to persuade them to take such an action. It will be for the R.B. in June to decide whether the present conflict demands such a method of settlement.

It is, of course, necessary to define just what the conflict is about. A claim was made for an increase of 24% for consultants and hospital staff and for general practitioners working in the Health Service. This claim was based on the recommendations of the reports of the two Spens Committees. It was not an arbitrary claim for new money. It was simply a rather belated request that a promise should be fulfilled, that a bargain should be kept. And Dr. Wand, as Chairman of the Council of the B.M.A., made it quite plain that the profession would accept a fair decision of an arbitrator in the event of disagreement. In his letter to *The Times* on April 8 he wrote: "May I say, on behalf of the Council of the British Medical Association, how warmly we concur in Lord Jowitt's plea in the House of Lords yesterday that there may be acceptance 'far more generally of the principle of

arbitration rather than resort to force, pressure, and the like to win desired ends' in the present dispute between the medical profession and the Government." The B.M.A. advertised its desire for arbitration in the national press. Now one thing is clear. The profession has not been offered arbitration. All its efforts to secure this have failed. It has been plainly stated to the profession's representatives that the Royal Commission is not an arbitrating or adjudicating body. The B.M.A.'s legal advisers state that it is "abundantly clear that the Royal Commission will not consider the essential basis of the present claim—namely, the binding promise of the Government to give effect to the Spens Reports." There can be no doubt that the Government firmly intends to nullify the Spens Reports and that it has set up a Royal Commission to do this. No one can feel happy about this, or about the exclusion of our colleagues in the public health service from consideration by the Commission.

Certainly the events set in train by the exchange of letters between Sir Russell Brain and the Prime Minister have altered circumstances, and it is possible that the Representative Meeting in June may think that the alteration justifies a reversal of decisions previously reached, especially if it accepts the view that non-cooperation with the Commission is linked with withdrawal from the Health Service. If eventually co-operation with the Commission is agreed upon it would be unwise to expect too much from this. After all, the medical profession really did believe that the promises made in the two Spens Reports of 1946 and 1948 were binding upon the Government. And it believed in these so sincerely that its doubts about the wisdom of entering the N.H.S. were considerably modified. The Spens Reports are now a dead letter so far as the Government is concerned, a Government, moreover, that has refused to negotiate or to arbitrate, and, by establishing a Royal Commission, has avoided all normal procedures of settling disputes. The Government is succeeding in imposing its will on the profession, and as the paymaster has the whip hand.

PHARMACEUTICAL RESEARCH

Few of the recently introduced drugs were discovered in Britain, and because of this there may be a suspicion that we are behindhand in pharmaceutical research. Of the more important tranquillizing drugs, reserpine, an active principle of *Rauwolfia*, was isolated in Switzerland and chlorpromazine was synthesized in France. From Germany we have received analgesic drugs like pethidine and methadone, drugs for use in schistosomiasis like miracil, and recently a

lead towards the oral treatment of diabetes. The United States must be thanked for the newer antibiotics, for cortisone and the purified forms of A.C.T.H., for the Salk vaccine for poliomyelitis, and recently for a ganglion-blocking drug that can be taken by mouth. This is not to say that there have been no British advances. Vitamin B₁₂ was isolated almost at the same time in Britain and the United States. Two important antimalarial drugs, proguanil and pyrimethamine, were introduced here, and also the trypanocide antrycide. Piperazine has been discovered as a cure for roundworms. And within the last few months "fluothane," a non-explosive anaesthetic, has been put on the market.

The money spent on research and the size of the research staffs must be greatest in the United States, where the rewards both to firms and to the individual members of their staffs are also greatest. This is in part the result of the activity of the American Medical Association, which has helped a great deal to make the public conscious of the value of the doctors' services to the nation. Because of this, and of the constant publicity given to medical discoveries in newspapers and magazines with enormous circulations, the American public takes an enthusiastic interest in clinical medicine, particularly in new methods of treatment. The channels for exploiting popular and fashionable new remedies in the U.S.A. are so extensive that the sales in a year run into millions of dollars.

Research is for many American firms the main business: their aims are to make the very large profits which the introduction of a new drug can bring. British firms rely for the greater part of their income on the sales of established remedies or well-known substances with proprietary names, and, while they hope to be successful in discovering something new, they do not in any way depend on this. It would be, perhaps, misleading to make a very sharp distinction of this sort, but it is clearly true that far more is at stake for many American firms if the research does not yield results. The certainty that successful research brings the highest profits leads American firms to offer their leaders of research much more than they would earn in a university. The salaries run from \$25,000 to \$60,000 a year. Even a young man who has recently taken his Ph.D. will earn \$6,000 to \$8,000 a year. This means that American firms attract some very able research workers: people of the same calibre in Britain would probably refuse to leave a university post because the difference in salary would not be attractive enough. In Britain the salaries paid by firms are usually not sufficient to compensate for the alleged loss in freedom

suffered on joining a commercial firm; and, when the salary is high, the Inland Revenue takes the bulk of it. Because of this biologists, who are few in number, mostly prefer to stay in university posts. The direction of pharmaceutical research is therefore placed more and more in the hands of chemists, and it may be doubted whether the chemist always knows where the opportunity lies. This being so, the question arises whether more in the way of useful as distinct from academic research could be done in the universities. This might be arranged as a collaborative effort between the department of organic chemistry and the biological departments—biochemistry, microbiology, and pharmacology. Such collaboration, however, is rare, because the head of a department has his own research plans made without reference to those of other departments. If the plans concern the fundamental aspects of his work he is right to pursue them to the exclusion of others, for they are likely to prove of greater value to the nation and to the world. But it might be worth considering whether, without interruption of their own work, the heads of the departments concerned could form a committee to organize pharmaceutical research to be carried out by workers free from other duties. Such a suggestion would no doubt arouse opposition, for many would take the view that the field was an industrial one into which university workers should not enter. Nevertheless, with the concentration of talent in the science departments of some of our universities, such a scheme might achieve great results.

MALARIA CONTROL

The name of Sir Ronald Ross, who was born on May 13, 1857, will live for ever as one of the great benefactors of mankind. Though he was himself disappointed that his discovery of the transmission of malaria by the mosquito did not have the immediate practical results he hoped for, his work, as we recorded at the time of his death in 1932, "laid the foundation on which a truly scientific prophylaxis might be built, and [he] himself did much to build it." Since his death, and particularly in recent years, few subjects have been studied more thoroughly and more fruitfully than malaria. New methods of control and better drugs for prophylaxis and treatment have been discovered, and by the application of these discoveries the disease has been wellnigh overcome in some parts of the world. Quoting data gathered by the World Health Organization, Dr. Paul Russell¹ reports that eradication is

practically complete in Barbados, Corsica, Chile, Cyprus, French Guiana, Italy, Mauritius, Puerto Rico, and the United States, while in another 15 countries the process is well under way. Yet the sober fact remains that malaria still ranks as one of the major diseases of the world, for in 1955 there were 200,000,000 cases of clinical malaria and over 2,000,000 deaths from it. The position may be summarized by saying that in well-populated and more advanced countries, if the necessary measures are adopted, the disease can be eradicated, but that in sparsely populated and underdeveloped regions only the fringe of the problem can be touched. There is much still to be done in working out the most efficient and economical way of applying these control measures, and many lessons to be learnt about the best way of maintaining control once eradication has been achieved. This is an expensive procedure and the need for it apt to be overlooked.

A recent issue of the *Bulletin of the World Health Organization*² brings together under one cover a series of papers on malaria control which were presented by international authorities at recent conferences. They give a comprehensive account of modern methods and modern trends of investigation, together with the results which have been achieved in certain countries. Emphasis throughout is on vector control, particularly by the use of the synthetic insecticides—D.D.T., gammexane, and dieldrin. The most important innovation of the last decade has been the development of residual spraying, a process which entails spraying the walls of huts and other dwellings with a suspension of one or other of these compounds so as to leave, after drying, a surface film of the insecticide. Under suitable conditions this remains active for some months (hence the term "residual"), and any susceptible mosquito which alights on the treated surface becomes contaminated and is killed by the poison. These compounds are equally effective as larvicides when scattered on the surface of or mixed with the water on which the mosquitoes lay their eggs, and thus can be used for killing the insects at every stage of their development.

Unfortunately the margin of effectiveness of residual spraying is not great, and mosquitoes, with the ebullient adaptability which characterizes most living

creatures of a lower order (and especially those which can be classified as pests), are beginning to develop resistance to these insecticides, a circumstance which arouses some anxiety for the future. It is true that they have not yet reached the carefree level of immunity acquired in certain localities by the housefly, and that resistance to one of the insecticides does not necessarily mean resistance to all, but the danger is nevertheless there. It is causing particular concern in Greece, and G. A. Livadas and K. Thymakis³ give an account of the position in that country, while C. Y. Chow and H. T. Soeparmo⁴ report a somewhat similar state of affairs in Java.

Resistance of this kind is not the only reason why residual spraying sometimes fails to do all that is expected. Certain species of mosquito have a tendency to rest outside rather than inside man-made shelters—a characteristic which has been called *exophily*—and thus may fly into a sprayed hut, bite their victim, and fly out again without alighting on the poisoned surface. Such behaviour may be a natural or instinctive habit, but this is not always the case. *Anopheles gambiae*, the most important vector in Central Africa, acts in this way for a different reason; it is irritated by the insecticide, and, if it alights on a treated surface, quickly flies off again before it has picked up a lethal dose. Clearly it is important to know the exact habits of each vector species, not only in general terms but in each particular area, for there is considerable local variation in their behaviour, and new ways of studying mosquito ecology are now being used. It is important to be able to estimate the age of the female mosquitoes, and information on this point can be gleaned from the stage of development of the ovaries. M. T. Gillies⁵ now describes a mating-plug found in the common oviduct which persists for 12 hours after mating, and is finally absorbed within 36 hours. This provides an objective feature for recognizing one section of the nulliparous population, and, taken in conjunction with other characteristics, is of value in assessing the age composition of different mosquito catches, say before and after spraying. Again, some mosquitoes feed on domestic animals as well as on human beings, and in certain circumstances it is necessary to know the source of the blood in an engorged insect. For this purpose a delicate precipitin test devised by B. Weitz has been used, by means of which the species of the animal "donor" can usually be recognized with certainty. L. J. Bruce-Chwatt⁶ discusses the use of radioisotopes for labelling insects to be used for experimental purposes, while G. Frizzi and M. Holstein⁷ describe variations in the chromosome structure of *A. gambiae* which they believe may be related to differences in the behaviour of that versatile insect in different localities. By these and other perhaps more commonplace methods a store of useful knowledge is rapidly being accumulated.

In general, it can be said that chemoprophylaxis plays a relatively minor part in modern control schemes, and there are only scanty references to it in this *Bulletin*. H. Munro Archibald and L. J. Bruce-Chwatt⁸ successfully suppressed malaria in Nigerian schoolchildren with pyrimethamine; and in Morocco, where vector eradication is well advanced, G. Houel⁹ has obtained satisfactory results by mass treatment with widely spaced doses of chloroquine, amodiaquine, and pyrimethamine. In Rumania¹⁰ and Yugoslavia¹¹ chemoprophylaxis has been used as an adjuvant to insect control, mainly with a view to eliminating gametocyte carriers, and this indeed is the policy generally recommended. Those who had experience of the striking successes achieved by chemoprophylaxis in the second world war in circumstances where vector control was impossible may wonder if this very effective method of attacking the problem is receiving as much attention as it deserves.

It would be unrealistic to imply that there is any likelihood that research now in progress will provide a short cut to the eradication of malaria throughout the world. It is mainly designed to allow existing methods to be used with more effect. Given the necessary funds and the necessary manpower, there is no reason to doubt that world-wide eradication could in time be achieved, but this is at present economically impracticable. The first and fundamental requirement in backward countries where the disease is now rife is steady progress in education and an accompanying increase in material prosperity. Only when these have undergone a substantial improvement can it be hoped to apply with the necessary intensity and determination the methods of malaria control which are proving successful in more developed countries.

MEDICAL SERVICES IN NORWAY

Norway seems to have solved the insoluble. It has provided a comprehensive medical service for the whole population in a way that meets with the approval of everyone concerned—public, profession, and Government. Our Norwegian colleagues explained the system to the Council of the World Medical Association when it met in Oslo last week. They laid great stress on the fact that their system of organized medical care had evolved slowly, and that in this way they had escaped the manifest disadvantages of sudden revolu-

tionary changes, as had happened in Britain. Compulsory health insurance was introduced in 1911 for a small proportion of the population. Last year the final step was taken by making health insurance compulsory for the whole population. The employee contributes about half the premium (amounting to about 2% of his weekly wage), his employer a third, and the municipality where he works and the State about 10% each. Premiums are graded according to income: a student, for example, pays less than a shilling a week, and a well-to-do person about five shillings.¹ The administration of this system is spread over some 750 local insurance offices.

Norway has for some years been under a Labour Government, but the authorities there believe in making the individual patient bear some direct responsibility for the cost of illness, in order, as the Director-General of Health Services, Dr. Karl Evang, puts it, to "prevent abuse of the privileges of the system and to help out with its total cost." Accident insurance for workers in factory and forest, and for seamen, provides completely free treatment. For all but a few services the patient has to pay part of the fee—between a third and a quarter. There is complete freedom of choice of doctor, and no "lists." Any doctor can start a practice anywhere he likes. The patient has to pay for ordinary medicines (except in hospital). For what the Australians call the "life-savers" the patient has to pay about a quarter of the cost, and drugs are prescribed free of direct charge only in certain prolonged illnesses, such as diabetes, pernicious anaemia, tuberculosis, epilepsy. Nearly all the hospitals are owned by the State and the municipality; there are few private hospitals. Under the compulsory health insurance scheme hospital treatment is free for all who need it. Admission is usually on the advice of the general practitioner, though patients have the right to go direct. If a practitioner sends a patient to hospital "for immediate treatment" the hospital has to admit him however overcrowded it is. The hospital staff is employed on a whole-time basis, and senior physicians and surgeons are allowed a certain amount of private practice. If a patient goes to a private hospital all he has to pay is the difference in the cost between it and the public hospital.

There appears to be a remarkably happy relationship between the medical profession and the administration of the insurance scheme. The Norwegian doctor is a highly respected person in Norwegian society, and enjoys on the whole a better income than other professional men. There is, if anything, a shortage of doctors, and the number of new students admitted each year to the university is limited.

Norway has managed to combine compulsory health insurance with maximum freedom for the doctor to pursue his own career in a system which brings out a maximum sense of responsibility in both physician and patient. There seems to be peculiarly little abuse of the method of paying the general practitioner by fee for

item of service, and an efficient machinery for dealing with the abuse when it occurs. We have much to learn from our northern forebears.

TREATMENT OF LIVER CANCER

Cancer of the liver, whether primary or secondary, is such a depressing therapeutic problem that any measure, even with possible toxic side-effects, must be carefully considered. Recently Theodore Gillman and his colleagues from Durban have reported preliminary results with alloxan in the treatment of primary liver cancer.¹ This substance was originally observed to cause degeneration in the cells of the islets of Langerhans of the pancreas in laboratory animals² and has proved useful for the experimental production of diabetes. The effect on liver cancer might be linked with the diabetogenic one, and D. A. Salzberg and A. C. Griffin have shown that alloxan diabetes in rats prevents the induction of hepatomas by feeding them with azo dyes.³ However, Gillman and his co-workers⁴ now believe that alloxan may perhaps have an anticarcinogenic action by exerting a widespread effect, intracellularly, on carbohydrate metabolism in all cells and especially on tumour cells, which are believed to be more dependent on glycolysis; hepatocellular carcinomas might be expected to be specially sensitive to interference with their carbohydrate metabolism. Eight patients with primary liver cancer have been treated. In two pain disappeared and in four the grossly enlarged liver diminished in size. Maintained hyperglycaemia was noted in only one. One patient developed anuria for four days, a complication that emphasizes the known nephrotoxic effects of alloxan. The drug should not be given to patients with renal damage. Histological study of two cases showed extensive necrosis of the tumour and in one sclerosis was also present. In one case the kidney and pancreas were not damaged. Results of further experience with this drug will be awaited with interest.

A recent paper by Irving M. Ariel, of New York, reviews the other methods available for the treatment of primary and metastatic cancer of the liver.⁵ Radiologists have been chary of administering radiation to patients with liver tumours, believing that the organ is particularly sensitive to its effects. This does not prove to be the case, provided the liver damage is not gross and the beam can be localized on a tumour. Ten patients with primary hepatoma were treated and five responded well, the liver decreasing in size and the mean duration of life after treatment being 3½ years. The five who did not respond lived only a mean of five months after treatment. The ten patients with metastatic carcinoma did not respond to radiation and were all dead within six months. Nitrogen mustard introduced via a polyethylene cannula into the aorta at the level of the coeliac axis might be expected to arrive in high concen-

tration in the tumour, which is supplied by the hepatic artery. However, fourteen patients with metastatic carcinoma treated thus showed little benefit, the mean duration of life after treatment being only five months. Surgical removal of malignant tumours is usually doomed to failure, though partial hepatectomy is a technically feasible procedure in skilled hands. But the growths are usually multiple and post-operative recurrence is usual.

INCIDENCE OF GLANDULAR FEVER

The true incidence of glandular fever is difficult to assess, for it is not notifiable and there must be many cases in which the diagnosis is never confirmed. Some idea of the prevalence of the disease in England and Wales in 1955 is given by K. W. Newell¹ in a recent analysis. The information was provided voluntarily by pathologists in hospital and public-health laboratories, but it is not claimed that all known cases were reported. Rather more than half the 1,861 cases were in people aged 15 to 24, while the remainder were almost equally divided between those under 15 or over 24 years. But the rates per 100,000 show that young people between 15 and 24 were much the most susceptible. Many of these were nurses or members of the defence services—occupations associated with communal living. It might be expected that most infections would arise in people who had recently joined these groups, but statistical analysis showed that this was probably not so. Male doctors provided only 7 cases, but their occupation carried an attack rate of 59.8 per 100,000, this figure being surpassed only by nurses and midwives. By contrast the risk to workers in wood, metal, or transport industries was only 2.6 per 100,000. These figures, as Newell points out, may reflect only the accessibility of diagnostic services. The reported incidence of the disease in the south of the country (6 per 100,000) was three times as great as in the north. Cases were spread fairly evenly through the year, but there was a slight increase in summer and autumn in persons over 15. None of the cases in this report occurred in outbreaks.

It is pleasing to find that the diagnosis was based on clinical and haematological evidence in 92 cases only; in all the others it was confirmed serologically. The original serological test for glandular fever described by Paul and Bunnell depends on the presence in the patient's serum of antibodies which agglutinate sheep red cells. This test has its limitations, for the antibodies are not specific. They are present in low titre in most normal persons; they rise in a variety of infections, and in serum sickness may be present in a titre as high as in glandular fever. Final confirmation of the diagnosis requires the differential test,² which shows that the antibodies associated with glandular fever remain after the serum has been absorbed with guinea-pig kidney, while they are almost completely removed by absorption with ox red cells. A simplification of this test has recently

been described by A. I. Messer.³ Before the development of the differential test there was confusion about what constituted glandular fever and whether the epidemic and sporadic cases were one and the same disease. Further use of it may help to solve this problem, but the final solution awaits the isolation of the causative agent.

SIGNALS FROM THE GUT

There is now little novel in the idea of a meteorologist setting free balloons which transmit back to him information about the temperature and pressure in the upper atmosphere. Thanks to the ingenuity of workers at the Rockefeller Institute it is now possible to set free into the alimentary tract a similar transmitter on a smaller scale which will signal the pressures it encounters to a wireless receiver close to the subject. The device, referred to as a "radio pill," is contained in a plastic capsule 2.8 cm. long and 1 cm. in diameter. Variations in pressure cause a change in the frequency of transmission of a small transistor oscillator, the signal from which is picked up, amplified, and recorded by the receiving set. The device can be traced by fluoroscopy and possibly held or manipulated by a magnet after the manner described by A. H. James.¹

Although a comparison is sometimes made between the value of measurements of arterial blood pressure and the potential value of measurements of pressure in the alimentary tract, there is a fundamental difference between the two. In large arteries the bore is relatively fixed in most circumstances, whereas in the alimentary tube the bore may change by a factor of ten—indeed, the transferring function of the gut depends upon such active changes. Equal pressures, therefore, do not signify equal tensions in the wall of the gut, since the tension in the circumference of a cylinder varies with the radius of the cylinder, a fact that can easily be appreciated by examining a balloon at its point of maximal circumference and at its neck. Since the sensation of pain arising from the gut and the initiation of peristalsis probably depends upon tension, the fact that tension in the wall and pressure within the gut cannot with certainty be equated renders difficult the interpretation of records of pressures within the alimentary tract. Nevertheless changes of pressure recorded by the "radio pill" will at least indicate activity at the site of the instrument. In the study of the physiology of the intact animal such a miniature transmitter which can be modified to signal other variables will certainly have its uses. In fact H. S. Wolff² has already described a similar telemetering device on a larger scale.

The next session of the General Medical Council will open on Tuesday, May 28, at 2.15 p.m., when the President, Sir David Campbell, will take the chair and will deliver an address.

THE RESEARCH REGISTER OF THE COLLEGE OF GENERAL PRACTITIONERS

BY

C. A. H. WATTS, M.D., D.R.C.O.G.

College of General Practitioners

AND

K. W. CROSS, Ph.D.

Department of Medical Statistics, University of Birmingham

The Research Committee of the Foundation Council of the College of General Practitioners was formed on January 21, 1953. The Steering Committee before then had been aware that some doctors in general practice realized the value of the clinical material in their hands, but the number of potential research workers and the range of their interests were unknown. One of the first decisions of the research committee, therefore, was to open a College Research Register to members and associates who were interested in the conduct of research in their practices. This was done by an invitation published in both the *British Medical Journal* (1953) and the *Lancet* (1953) inviting members and associates to join the register, specifying their particular research interests.

The first object of the register was therefore to locate and record those general practitioners who had an interest in research. A second was to bring about collaboration between doctors who might live miles apart, so that they could work together on some subject in which they had a common interest. This type of group research can be done by private arrangement, but it can be arranged more easily if a central organization exists. The Morbidity Survey (which was jointly organized by the College and General Register Office) and the Group Investigation of Acute Chest Infections were examples of this procedure. These studies were made possible by recruiting those who had expressed an interest in the subjects concerned.

A rough-and-ready form had been designed on which the applicants were asked to record basic details of their practices as well as their interests, and an analysis of the interests of the earliest members to join the register was published in the first Research Newsletter (*Practitioner*, 1953). Subsequent entrants to the register were asked to complete a practice classification sheet, which was enlarged and improved as time went on. On January 1, 1957, there were over 500 names on the research register, and classification sheets have been completed by the large majority. Analysis of these records is interesting and provides useful information showing the extent to which the register has developed, the range of interests, and the practice details of the doctors concerned.

Doctors' Interests

An examination was first made of the interests of the members on the register. These results, of course, do not remain static, and the Registrar is continually receiving additions to those originally recorded by doctors. These findings therefore refer to those interests recorded at a given time. A very wide variety exists, including those subsumed under broad groupings, such as obstetrics and paediatrics, and more specific conditions such as lead-poisoning and tetanus. Furthermore, interests are not confined to clinical

subjects; the administration of general practice has its adherents, while others are interested in subjects as diverse as clergy and doctors, medical photography, and the medical aspects of sailing. It is difficult to classify such an assortment of interests. This problem has been discussed by Bevan (1948), who adopted a twofold system of classification for the analysis of contributions to "Any Questions?" in the *British Medical Journal*. One group was made up of specific diseases, and the other of subjects belonging to the field of medical science generally.

It seemed that interests specified in the register fell more naturally into three groups: (1) disease groups, specialties and allied subjects; (2) clinical entities and symptoms; and (3) miscellaneous topics. Other methods of classification could be adopted, but this one was considered satisfactory for our purpose, which was to show their range and relative popularity.

The results of such an analysis are shown in Table I, which lists the interests in order of frequency within each group. Where a doctor entered more than one interest,

TABLE I.—Doctors' Interests

Group 1		Group 2	
Paediatrics	90	Measles	114
Obstetrics	74	Asthma	55
Respiratory diseases	74	Hypertension	11

		Clergy and doctors	1
		Equipment	1
		Research analysis	1
		Sailing, medical problems of	1
		Special schools	1
		Manipulation	1
		Somatotyping	1

each has been included. As was to be expected, the first group contains the bulk of the interests specified. Measles and asthma are both outstanding, although the figures are artificially inflated because the College had been conducting a survey on measles (Research Newsletter, 1956) and a long-term study of asthma is still in progress. The relatively large number of doctors who are interested in statistics, morbidity surveys, and therapeutic trials denotes a useful potential research weapon.

Distribution of Members According to Type of Practice

By recourse to the classification sheets, members on the register have also been grouped according to the type of area in which they are practising and to the organization of their practices. These results are given in Table II, and correspond with figures given in a report of the Ministry of

TABLE II.—Distribution by Type of Area and Number of Practitioners

No. of Practitioners	Urban	Rural	Mixed	Total
Single-handed, no assistant	79	17	23	119
2 partners with "	9	4	7	20
3 " " "	71	23	41	135
4 " " "	29	12	37	78
5 " " "	14	11	7	32
6 " " "	9	1	9	19
7 " " "	—	—	4	4
8 " " "	1	—	3	4
Total	212	69	131	412

Health (1955). The division into urban, rural, and mixed areas, however, is not strictly comparable, since the classification used by the Ministry was based on a "mileage" scheme, whereas our system is based on the interpretation of the doctor.

Knowledge of the type of practice has two uses. Firstly it makes it possible for one research worker to compare his findings with a colleague in a similar type of practice. Hopkins (1956), for example, was able to compare some of his findings with those given by Logan (1953) for similar urban types of practice. The value of being able to check and compare statistical data is obvious. Secondly, by careful selection of various practices—urban, rural, and mixed—it is possible to have under survey a sample of the population representative of the country as a whole.

One-third of the members on the register are in single-handed practice, with or without assistants, and a further third are in partnership with one other doctor. Almost one-fifth are in partnership with two other doctors. The proportion of members who are single-handed is much greater among those practising in urban areas than for those in the other two types of area. The distribution of members geographically and by type of area is given in Table III, taking a standard region as a unit of area in which they are practising.

TABLE III.—Distribution by Type of Area and Standard Regions

Standard Regions	Urban	Rural	Mixed	Total
Ireland	6	6	6	18
Scotland	6	6	7	21

for whom the member himself was responsible, were also recorded on the classification sheet. Members' own lists varied in size from fewer than 500 patients to over 3,500. These figures are valuable in the planning stages of research work, since it is essential to be able to draw upon an adequate sample representative of the population. If it is assumed, for example, that there are five epileptics to every 1,000 of the population, and one wishes to make an analysis of 1,000 epileptics, it is a matter of simple arithmetic to work out how many practices must be included in the survey.

The sizes of the lists of practices represented by members of the register have been used to calculate the average number of patients per doctor in different parts of the country and in each type of area. Details are given in Table IV. Where two or more partners in the same practice are members of the register, that practice is included once only; the number of doctors specified is the total number responsible for patients on combined lists. With the exception of patient-doctor ratios based on small numbers of doctors there is close agreement between regions. This is true of each type of area, and for each region in England there are rather more patients per doctor in urban than in rural areas.

Discussion

The Research Register of the College of General Practitioners has been analysed in some detail to demonstrate the function and the potential of the organization. It may help workers both inside and outside the College. Any member or associate of the College can obtain from the registrar a list of names and addresses of other doctors who are interested in a particular subject or who live in a particular region. It has been suggested that any general practitioner who undertakes research should inform the secretary or the chairman of the Research Committee of his project. This suggestion has been made for two reasons: (1) an investigator, if he so desires, can obtain advice on methods of collecting, handling, and analysing data; and (2) the risk of work overlapping and wasteful repetition is reduced. Although it is useful deliberately to check the work of others, it is disappointing for a doctor to discover that work that he thought was original has already been carried out by others. Workers outside the College, such as consultants who need the assistance of general practitioners, can ask the Research Committee for the names of those who are likely to be able to help them in their problems. A number of subjects lend themselves to a combined operation by both specialist and general practitioner, as was demonstrated in two recent surveys of alcohol addiction.

By the co-ordinated work of individuals and groups of practitioners, new methods of research in general practice are being evolved and improved; and for the first time it will be possible to make an accurate assessment of morbidity in relation to the background against which it arises. The discipline of research not only assists in the investigation of problems that confront doctors in their work, but it gives

to those who take part in such projects a stimulus to observe and record which inevitably improves the quality of their medical practice.

We acknowledge all the help and encouragement we have received from Drs. R. J. F. H. Pinsent, D. L. Crombie, and the Publications Committee of the College of General Practitioners.

ROYAL SOCIETY OF HEALTH

CONGRESS AT FOLKESTONE

The Royal Society of Health held its 64th annual congress at Folkestone from April 30 to May 3. There were 13 sectional meetings and five conferences. The Congress was inaugurated by Mr. J. K. VAUGHAN-MORGAN, Parliamentary Secretary to the Ministry of Health.

Here, besides Mr. Vaughan-Morgan's inaugural address, we give short accounts of the Conference of Medical Officers of Health and of some of the papers read in the Sections of Food and Nutrition, Occupational Health, and Hospitals. Other Sections, not here reported, were concerned with subjects such as preventive medicine, health education, the health and welfare of the family, mental health, tropical hygiene, "World Health," and housing and town planning. There were also special conferences for domiciliary nurses and midwives, engineers and surveyors, health visitors, and public health inspectors. Some 3,000 delegates and their friends attended the Congress, many from abroad.

Mr. Vaughan-Morgan's Address

The Congress opened in the Odeon Cinema, Folkestone, on April 30, under the chairmanship of Professor HAROLD BURROW, of the Royal Veterinary College, London, chairman of council of the Society. After a welcome to delegates by the Mayor of Folkestone, Professor Burrow installed Mr. Vaughan-Morgan as President of the Congress, and called upon him to deliver the inaugural address.

Mr. VAUGHAN-MORGAN began by referring to the food and catering trades. They had shown a gradual improvement in hygiene, he thought, since the Food Hygiene Regulations had come into force 15 months ago. People could see for themselves some of the improvements in shop layout which had taken place. But thanks to the work of medical officers of health and public health inspectors, and with the good will of the trades, he believed there had also been a similar improvement behind the scenes, where hygiene mattered just as much.

The President then raised the question of the health visitor. To-day the health visitor was faced by a dilemma, he said: whether to stick firmly to the job on which she had concentrated since the beginning of the century and in which she had seen such remarkable improvements—the care of mothers and young children—or whether to devote more and more of her time to special problems and to adopt what was now known as "selective visiting." But, said Mr. Vaughan-Morgan, the health visitor was the starting-point from which many of the more specialized services began to operate, and much would be lost if she was not, as a routine, watching for the early signs of physical or mental handicap among all the young children in her care. Although the total number of health visitors had been rising year by year since the Health Service started, there was an alarming drop in the numbers training. He hoped the publication of the Working Party Report would stimulate recruitment.

Turning to mental health, Mr. Vaughan-Morgan said it was essential for the child welfare services to pay increasing

attention to the mental and emotional development of the child. The recent reports of both the committees on mal-adjusted children and the Working Party on Health Visitors had emphasized this. A working party, appointed last year, was now inquiring into the field of work and training of all types of social workers employed by local authorities, but in view of the very wide range of this inquiry its report could not be expected for some time.

New Methods of Food Preservation

The use of antibiotics and ionizing radiations in food preservation was discussed by two of the staff of the D.S.I.R.'s low-temperature research station at Cambridge at the opening session of the Section of Food and Nutrition. The Section was meeting in conjunction with the Food Group of the Society of Chemical Industry. Miss ELLA M. BARNES, D.Phil., said that during the past year there had been a steady increase in the number of countries using one or more antibiotics as food preservatives, although at the moment this was not allowed in Britain. Almost all the antibiotics used therapeutically were active against the bacteria but they had little activity against yeasts and moulds. Some had a narrow range of antibacterial activity, others a broad spectrum, but the choice of a suitable antibiotic for food preservation depended not only on the type of spoilage to be controlled but also on other important considerations. Would the use of antibiotics ensure a better quality of food for the consumer, she asked, or would they be employed merely to disguise insanitary conditions in the food-processing plants or to prolong the marketing period?

In the case of fish it was the time necessarily spent at sea before bringing the haul to market which largely governed its condition on arrival. Although the flesh and body fluids of newly caught fish were sterile, their external surface (as well as the gut) might carry considerable bacterial loads. Ice was used to prevent the rapid growth of these organisms, but even at freezing-point most marine bacteria grew actively. Fish remained fresh for only about 14 days under the best conditions of handling. The use of chlortetracycline in the ice would enable fish to reach the market in a considerably better bacteriological condition. The position with meat and poultry was different. Other factors being equal, the rate of spoilage depended on both temperature of storage and the initial load of micro-organisms. Tetracycline compounds were of little value for meat or poultry of low initial bacteriological quality or if kept at temperatures higher than usual. The use of antibiotics in hospitals had led to a progressive build-up of resistant staphylococci, and it was difficult to believe, said Miss Barnes, that there would not be a similar development in the holds of trawlers, in slaughterhouses, or in poultry-processing plants unless suitable precautions were taken.

Dr. R. S. HANNAN, Ph.D., said that food preservation by irradiation was still some way from general application in Britain, but there were some aspects of it which were beginning to show promise for commercial use. Foodstuffs were irradiated until they had accumulated a given dose of radiation, for times ranging from minutes or hours with gamma-ray sources to seconds or less with cathode-ray generators. Several aspects of this work were of obvious interest to the public-health worker, the most obvious being the possibility of the food itself becoming radioactive. If radiation energies not exceeding 15 MeV were used there was not much danger, but above that energy common elements in food could become radioactive, although in many cases their half-life was short. The other possible harmful effect was the induction of changes in the chemical composition of the food. It would need considerable work before irradiated foods could be accepted as harmless after treatment at any but the lowest dose levels.

Conference of M.O.H.s

Dr. J. D. KERSHAW, President of the Society of Medical Officers of Health, opened the Conference of Medical Officers of Health with an address entitled "Physicians in

Public Health." The founder and succeeding generations of medical officers of health had had inspiring tasks before them, said Dr. Kershaw. To-day most of those tasks had been accomplished. Were they, the great grandchildren, left with nothing but the glory of the past for inspiration? He thought not. Certainly public health and the public health service had been dealt some crippling blows by the Education Act of 1944 and the National Health Service Act, and the enthusiasm of some of their most able and promising medical officers of health had been suddenly damped and the administrative machine so remodelled that it was inevitably less attractive to the eager mind. They could not, however, avoid some self-doubt, and he thought not the least among their faults was that they were forgetting that they were doctors. There might be an insidious fascination in bureaucracy, but he suspected they were also being persuaded into the acceptance of some inferior status.

Within the community's services it was vital that someone should see people as patients and be ready and willing to intervene on their behalf, especially with the vulnerable groups, the young, the old, and the handicapped. Every man, woman, or child who asked or received the services of the health department was as much a doctor's patient as the sick man whom the G.P. visited at home or the sick woman in a hospital. It was by no means illogical to extend that principle also to some other aspects of local authority work not officially recognized or described as health services. If the keeping of houses in repair was their concern, so also was the provision of new houses. New sewage schemes, refuse-disposal plans, and water supplies ought to be their business. It was not too difficult to get that recognized, but why should they stop there? Schools, swimming-baths, libraries, recreation grounds, and in fact all the services the authorities provided were the tools of living, whose absence or misuse played an important part in impairing health. Every state of illness had its social components, and social therapy played an essential part in its treatment. To return a patient to the social environment which had helped to make him ill was as stupid as to dress the burns of a child and throw it back into the fire which had burned it.

Medical officers of health had the means of social therapy in their hands and were the specialists in its use. They were the physicians to the community and society at large. Society could be sick, just as each of its members could be sick. A community in which delinquency and neurosis were increasing, in which the sense of responsibility was running down, in which the philosophy of "couldn't care less" was accepted as part of the way of life, was far from healthy. A society which accepted total war as inevitable or was content fatalistically to drift towards its own destruction was sick to the heart. Whether they liked it or not they had a duty of community leadership. Since it was they, the medical officers of health, who were most intimate with the community aspects of medicine the obligation was theirs in a special degree. They had before them more inspiring tasks than their predecessors had had—if only they were prepared to look for them.

Health of the Adolescent

The Conference of M.O.H.s then proceeded to a symposium on "The Health of the Adolescent." A student health service, geared to the needs of the adolescent at college, must recognize not only the health needs of the student community but also the fact that the sick student often presented problems of a socio-medical nature which could not be effectively solved by the usual health agencies, said Dr. GRAHAM GRANT, senior health officer of the University of Wales Student Health Service. Family doctors, he continued, had not access to the information needed for a complete evaluation of the medical and psychological problems of the student group. The possible effects of social, academic, and athletic stresses on the physically or emotionally handicapped student had to be assessed in every case. Indeed, a university health service

was best thought of as an integral part of the whole educational process through which the undergraduate was passing. Environmental factors, both at home and at college, had to be taken into account. Physical fitness and the promotion of healthy recreational interests were other matters in which a university health service was legitimately interested. It was, moreover, as much concerned with the undergraduates' academic performance as were the academic departments themselves. But perhaps most important of all was its growing understanding of the relationships between learning and living at college and the developing physical, social, emotional, and intellectual maturity of the student.

Dr. M. E. HERFORD dealt with the medical supervision of the adolescent in the factory. He thought the great task of education for health in the fullest sense was a partnership in which doctors and teachers shared. They had to help people not only to live well but to live well together. Doctors were helping to form the pattern of the future attitude towards health and towards doctors. One of their functions must be to give patients, so far as they could, a reasonable understanding of and attitude towards health. They had to help young people to come to terms with their inescapable ailments. Health, in no small measure, was dependent on an attitude of mind; the mental and physical aspects of health were indivisible.

Technically the power of the doctor was increasing steadily: could he develop mentally and spiritually to be worthy of that power? There was a great test in work with adolescents. In it they had to seek the integration of medicine, or else the steady fragmentation would continue, leaving the doctor as a mere technician. Every medical examination was an opportunity for constructive influence. Although the basic patterns were laid down in early years through parental influence, all through life, and especially in the impressionable years of adolescence, mental attitudes created an atmosphere as real as the air we breathed. It could be healthy or poisonous. The doctor and nurse could help to influence attitudes of people at work as they affected adolescents. For the adolescent, the early years in employment must be concerned with learning in the fullest sense, as well as earning. There had to be continuity of education as well as of medical supervision.

Occupational Health

Addressing the Occupational Health Section, Dr. R. S. F. SCHILLING, President of the Association of Industrial Medical Officers, said the most notable advance in industrial medicine had been the growth of medical services in factories, mines, transport, shops, and offices. The doctor first went into industry with a narrow concept of his work and concentrated on providing a treatment service and on preventing occupational disease, because that was the employer's idea of industrial medicine. Although the scope of industrial medicine had now broadened, the giving of treatment to sick and injured workers was still one of the main functions of the service. Where the treatment was good and readily available, time lost from accidents was reduced by preventing complications and aiding rehabilitation. But, above all, treatment provided data for preventive action.

Many diseases had been successfully prevented by changing the physical environment. Prevention was now more dependent on changing people in their ways of living. Similarly the promotion of occupational health depended very much on the attitude of working communities to occupational health services, on educating and encouraging them to use guards on dangerous machines, to wear protective clothing, and so on. Health education was now an accepted part of preventive medicine. But how useful was it? Was it not time, said Dr. Schilling, to try to evaluate more critically our methods of health education?

If an attempt to reduce sickness-absence was to succeed, it must have the good will of all parties, said Dr. W. E. CHIESMAN, speaking in the Occupational Health Section's symposium on "Absenteeism in Industry." He had been

arguing the case for the "sickness-record." A record containing such details as the extent of sickness-absence year by year, the diagnosis causing each absence and their number, and the worker's age enabled a preliminary assessment of the likely type of problem to be found, without even seeing the patient. A good sickness-record interrupted by a long illness suggested something serious, while a record showing a number of short absences for a great variety of indefinite diagnoses indicated that the patient had not been adequately investigated, that he had a high standard of health for his job, or that he was, perhaps, wrongly placed. It was surprising how many patients and their doctors did not realize the extent of the sickness-record until it was presented as a fact. There was a tendency to treat each illness separately, overlooking the possibility that previous episodes might have some bearing on the present state. A study of the records of bronchitis cases often suggested that, had energetic treatment been undertaken at a very early stage when the chest symptoms were considered unimportant, the inevitable deterioration of the condition winter by winter would have been avoided. Psychological upset due to poor management, or ill-health owing to a previously unrecognized toxic hazard, could be suspected and investigated when a high proportion of a group had frequent absences due to similar symptoms.

Most observers agreed that true malingering was very rare. Dr. Chiesman continued, and, although uncertified sick absence was often quoted as an important factor, in spite of an allowance of seven days' uncertified sick leave per annum in the Civil Service that accounted for only 8% of the total sickness-absence. Ideally a man should have a job neither below nor above his physical and mental capacity, both of which were very flexible. Dissatisfaction with working conditions could often be counteracted by escape to outside interests, which, unfortunately, included ill-health and absence from work. Lax certification was often suggested as an important factor in absenteeism, but when diagnoses were checked it was difficult to disagree with them, even though many were vague.

Dr. D. D. REID said that most of the lost working-time in industry was due to general diseases not specifically associated with occupational hazards. Any hope for its control must come from a better understanding of those features of our environment which favoured the onset of disease.

Hospitals and Local Authority Health Services

There was no room for complacency in the National Health Service, was the conclusion arrived at by Dr. H. M. C. MACAULAY, S.A.M.O. of the North-west Metropolitan Regional Hospital Board, in his review of "The Hospital Service and its Relationship to Other Branches of the National Health Service" before the Hospitals Section. It had, he continued, certain glaring faults, of which one was fragmentation. This led to gaps and overlaps. Much could be done to overcome this defect by co-operation at hospital level, for that was the point where the shoe pinched. Possibly a small committee representative of the senior medical staff of the hospital and of the local medical practitioners could do much to resolve local difficulties or provide explanations where no satisfactory redress seemed possible.

A second serious fault was rigidity of control. The Civil Service was a magnificent instrument composed of men and women of ability and of the highest integrity, but it was one never designed for the detailed administration of a personal service. It was fantastic that a regional hospital board entrusted with the spending of £20m. annually should have to go cap in hand to the Ministry of Health if it wanted to engage an additional junior clerk on its establishment; or that a hospital management committee entrusted with the spending of £1m. a year should have to seek the approval of the regional hospital board before it could have put on the telephone a radiographer, laboratory technician, or engineer whom it might want to summon in the middle of the night to deal with an emergency.

Such faults, however, were not fundamental and did not imply inherent defects in the Service. They were just instances of plain bad administration, perpetrated in the name of economy, but frequently producing just the reverse. The essential structure of the National Health Service was sound and did not call for any radical and iconoclastic reform. Since 1948 phenomenal progress had been made, and in most hospitals in Great Britain the standard of service to the public was immeasurably higher than it was at the time the Act came into operation.

Dr. J. F. GALLOWAY, M.O.H. of Wolverhampton, who spoke on "The Local Authority Health Services and their Relationship to Other Branches of the National Health Service," thought local authorities were making a contribution to the National Health Service which was undervalued.

Most people now realized that the time had come to consider conserving manpower and concentrating our resources, he said. As the third largest employer of labour in the country, the Health Service was spending £540m. annually—a figure which would soon be over £600m.—yet it did not give the greatest possible value for the manpower and money spent upon it, in spite of the verdict of the Guillebaud Committee. Few could be unaware of the unhealthy state of the National Health Service. The fundamental defect was the tripartite structure of the Service, but in 1948 there was no alternative. Although that was unavoidable, the results had been unsatisfactory and called for consideration. While patients had to wait considerable lengths of time to see the doctor, there were doctors unable to satisfy their desire to enter general practice; hospitals had difficulty in securing medical staff, while experienced men desiring a career in a specialty were dismissed from the hospital service because they were surplus to the requirements for consultants; while the public health service sought experienced doctors, they were discouraged by it being the only branch of medicine in which in-training was not provided.

One problem was simple and urgent: they needed administrative units that were not too large for the maintenance of local interest but were large enough to allow areas of health, welfare, and properly financed hospital management committees to be co-extensive. That was a requirement essential for introducing not only efficiency but sanity into the administration. The reorganization of the local administration of our health services was an urgent need if we were to reverse their growing paralysis, gradual enfeeblement, and mounting expenditure and the decline of local interest. Radical reconstruction of the National Health Service might even need considering.

NEW RESEARCH BUILDING AT THE LONDON HOSPITAL

On May 1 the London Hospital's new research building was opened. It is a three-story block in Ashfield Street, just behind the hospital itself. The cost of the building—£200,000—was met from the hospital's endowment funds. The new building brings conveniently together seven research units connected with the hospital, and the instrument workshop. At the same time it frees space at the hospital for clinical laboratories. The research units accommodated in the building are the hospital's physics, dental research, and experimental surgery units; the Medical Research Council's industrial medicine and social medicine research units; the V.D. reference laboratory (partly hospital and partly Public Health Laboratory Service); and the cancer research department, which is largely maintained by the British Empire Cancer Campaign. Among those present at the opening was the Minister of Health, Mr. DENNIS VOSPER.

Research Units

A large section of the ground floor is taken up by the hospital instrument workshop. The workshop makes instruments for both clinical and research departments of

the hospital, but mainly for the physics unit. The latter unit, which originated in 1943 as a branch of the radiotherapy department, achieved independent status in 1951, although most of its work has continued to be connected with radiotherapy. The chief physicist is Dr. L. A. W. Kemp, Ph.D. In addition to the usual facilities, the unit has a small laboratory which can be screened against electricity, and a small isotope dosimetry laboratory. Most of the research on isotopes, however, is carried out in the department of experimental surgery on the top floor, under the direction of Professor V. W. Dix. In the main laboratory of the physics unit is the apparatus with which Dr. Kemp recently revalued the roentgen. Also on the ground floor is the M.R.C. department for research in industrial medicine, under Dr. Donald Hunter. This department, as its name suggests, studies occupational diseases and methods for their prevention. Present research includes a study of chronic cadmium poisoning, a hazard of metal workers. For this, rats are subjected to cadmium dust in a tunnel for five hours a day. At intervals the amounts of cadmium in the tissues and the degree of histological damage are assessed. The P.H.L.S. venereal diseases reference laboratory was joined with the London Hospital Whitechapel Clinic last year and the present venereal diseases reference laboratory was formed, under the directorship of Dr. I. N. Orpwood Price. This unit, situated on the first floor, besides carrying out serological and bacteriological examinations for the Whitechapel Clinic and the hospital, examines "problem sera" from laboratories in Britain and elsewhere in the Commonwealth, and prepares and standardizes reagents used in the laboratory diagnosis of venereal disease. The M.R.C. social medicine unit, directed by Dr. J. N. Morris, is also on this floor. It was transferred to the London Hospital last year. Its work includes studies on the aetiology of coronary thrombosis, the aftercare implications of the advances in the treatment of mental diseases, and problems within the London Hospital itself. Professor A. E. W. Miles directs the dental research department, where experimental studies on the relationship of defective nutrition to dental caries are proceeding. The cancer research department is directed by Dr. M. H. Salaman. The two principal subjects of study here are chemical carcinogenesis and the action of tumours on the enzymes of the host. As stated above, most of the department's funds come from the British Empire Cancer Campaign. The new accommodation is expected to make possible a considerable extension in the cancer department's research.

B.M.A. OFFICIAL SEAL

We reproduce below a photograph of the Association's new seal. It was designed and engraved by Mr. WILLIAM M. GARDNER, A.R.C.A., F.R.S.A., one of the Royal Mint's panel of artists. The seal is included in this year's exhibition of the Royal Academy of Arts at Burlington House, where it may be seen in the Royal Mint's case of coins, medals, and seals (Exhibit No. 1439).

One aspect of Mr. Gardner's work is familiar to all of us—his engravings on our coinage. He designed the reverses for the English and Scottish shillings and for the threepenny piece. Less well known perhaps is the fact that he is the designer of the Royal Signet—the seal used by Her Majesty's Ministers of State—and the seal of the Privy Council. He is also a skilled craftsman in heraldry and lettering and in the illumination of manuscripts. We are indebted to Mr. Gardner for the following description of the Association's seal.

Artist's Description

One of the consequences of the granting of armorial bearings to the British Medical Association by Letters Patent dated May 25, 1955, has been the taking into use of a newly engraved Official Seal.

To impress parchment or paper with or without wax or wafer requires crisp shallow cutting of the kind which allows seal and document to part readily when released from pressure, and the Association is fortunate in its possession of a fine nineteenth century sealing press by Alan Wyon, now adapted by the Royal Mint to the new seal.

At a diameter of 2½ in. (6.3 cm.) the full armorial bearings are displayed within a circumscription "THE BRITISH MEDICAL ASSOCIATION" and outer border of pomegranate flower and fruit. The shield is charged with a Maunch, or sleeve, as borne by the ancient family of Hastings, to commemorate the foundation of the Association by Dr. (later Sir) Charles Hastings in 1832. A Lion passant in a Chief differences the Hastings arms.

On a tablet below is inscribed the Association's motto "WITH HEAD AND HEART AND HAND," while the shield is flanked by figures of Hippocrates and Harvey to left and right respectively. Only as recently as 1940 the excavation of a burial ground near Porta de Roma on the mouth of the Tiber yielded a contemporary marble bust of the philosopher, carved during a period of acknowledged skill in portraiture. The facial expression is one of benevolence. He wears the humbler dress of his compatriots and holds a pomegranate (*Punica granatum*), symbol of Life and Regeneration.

Of William Harvey there exists an embarrassment of portraiture in various media, but the researches of Sir Geoffrey Keynes, as set forth in his Thomas Vicary Lecture of 1948, were bound to influence and assist any endeavour towards a true likeness of the physician. Harvey appears in the gown of his profession and bears in the left hand an Annulet divided horizontally—red above, blue below—in token of the discovery by which he is so largely remembered.

The Shield is surmounted by a mantled helm, which in turn carries for a crest the Rod of Aesculapius combined with crossed torches aflame.

It is of interest to follow the Blazon, or herald's description in words, from the Letters Patent of 1955: "Per pale Or and Azure a Maunch counterchanged, on a Chief of the first a Lion passant also Azure." And for the Crest on a Wreath of the Colours: "In front of two Torches in saltire Azure enflamed proper a Rod of Aesculapius Or." Also the supporters: "On the dexter side a figure representing Hippocrates holding in the exterior hand a Pomegranate proper, and on the sinister side a figure representing William Harvey Physician also proper holding in the exterior hand an Annulet per fesse Gules and Azure."

Correspondence

Because of heavy pressure on our space, correspondents are asked to keep their letters short.

Retirement and Employment

SIR.—Your annotation (*Journal*, April 20, p. 937) on retirement and employment was of particular interest and value to us because of our study of the influences on the health of older men of work and retirement.¹ This was carried out on 323 men aged 65 and more at the Rutherglen Consultative Health Centre. It showed that most of the retired men were compelled against their desire to cease work. The commonest factors were the "heaviness" or strain of work, ill-health, and compulsory retirement. Few had the privilege to retire truly contented and mentally adjusted to meet their altered mode of life. When work was lost late in life it was difficult to obtain other employment. The men successful in their quest for work usually experienced a decline in social status from skilled to unskilled or semi-skilled jobs. Arterial degeneration was the most frequent cause of retirement due to ill-health. Of 80 men working at the time of their examination, 51% were not in good health. Older men may continue to work with significant degrees of ill-health. There was no evidence that children neglected their parents. Financial aid given when required is a measure of filial responsibility, and this was commonly provided by the relations if they could afford it.

We believe that, as men in their youth train to enter employment, so should older men be educated in the art of retirement. Painful adjustments by trial and error from an active regulated life to one of leisure would be reduced to a minimum with an enhancement in mental health. An educational and medico-social service is urgently needed to cover the older worker before, during, and after retirement. Work should, where necessary, be modified to meet the decline in physical or mental powers. Non-gainful pursuits should be learned, and the mind attuned to regard retirement as a happy period in life, thus avoiding the emptiness and the insecurity, financial and otherwise, associated by so many with cessation of work. A further essential is an employment office to co-ordinate available jobs for older men, advertise them adequately, and interview and test candidates.

Further study (as yet unpublished) on men aged 55 to 64 underlines the need for our suggested services. Of 64 men in this age group, 9 were already retired because of ill-health and the inability to find work within their capacity. One man stated that he was looking forward to the time when he retired. Thirty were definite in their minds that they were going to work on after 65. Twenty-four, however, had given no thought to the subject and were vague in their ideas as to how retirement would affect them. The nearer men were to 65 the greater was the number wishing to delay the time of their retirement.—We are, etc.,

W. FERGUSON ANDERSON.

Rh-Hr Nomenclature

SIR.—According to R. R. Race¹ the chief advantage of the C-D-E notations is that they are "self-explanatory." Race and Sanger² assert: "The C-D-E notation is invaluable; it alone indicates which antigens and genes are present. . . ." If this were true, the C-D-E notations would be unique, since in no other field of science are the symbols used expected to be self-explanatory, until certain basic definitions and conventions are first established. For example, in chemistry only after one learns that the symbol

Na stands for sodium and Cl for chlorine, and one adopts the convention that two symbols in juxtaposition represent a compound, does it become obvious that the symbol NaCl represents the compound sodium chloride. Similarly, in my own Rh-Hr nomenclature, after defining the symbol R¹ to represent a gene which gives rise to an agglutinin Rh₁, and gene r as representing a gene giving rise to an agglutinin rh, one can readily deduce that a person of genotype R¹r must have blood cells which react with anti-sera for the blood factors characteristic of both the agglutinogens Rh₁ and rh. On the other hand, if one attempts to make a nomenclature completely self-explanatory, paradoxes are inevitable unless the symbols are changed whenever something new is learned about the substances they represent. For example, to avoid paradoxes the symbols for chromosome cde would have to be changed to cdef, and the corresponding gene products from cde to cef, now that it is known that anti-d was never really found.

As an example I would like to cite a sentence from the *American Journal of Clinical Pathology*³: "The D-negative control of genotype dce/dce serves chiefly for the detection of anti-c, anti-e, and anti-f." To me this statement appears self-contradictory rather than self-explanatory. I wonder can Dr. Race demonstrate how the use of the C-D-E notations in this sentence is self-explanatory as he claims? Incidentally, this sentence again illustrates the incorrect use of the genotype symbols, because all that is determined by the blood tests is the individual's phenotype. I have already discussed⁴ some of the errors to which this practice had led.—I am, etc.,

Brooklyn, New York, U.S.A.

E.C.T. Fractures

SIR.—The recent law case (*Bolam v. Friern Hospital*, *Journal*, March 9, p. 591) of a patient who sued a mental hospital for having suffered a fracture of both acetabula when receiving E.C.T. would seem to show a regrettable lack of agreement regarding the best technique for this procedure.

As with other treatments in medicine, there is (1) the ideal technique, where expense and other factors allow, and (2) the best technique which is practicable under mental hospital conditions and which still avoids serious risks to the patient.

Nine years ago a film was made at the West London Hospital showing a technique for giving electroshock and electronarcosis. In these treatments the anaesthetist gives premedication which consists of atropine, thiopentone intravenously, and tubocurarine. The respiratory equipment includes a rubber reservoir bag, and to this is attached a respiratory valve and a face mask. During the period of muscular relaxation a rhythmic manipulation of the reservoir bag is kept up. An even simpler apparatus is the Oxford inflating bellows. This film has been shown regularly at different mental hospitals, the only essential modification being the substitution of a quick-acting relaxant like succinylcholine for tubocurarine. If this technique could have been used during the past ten years in every hospital, practically all the accidents and deaths described by Maclay¹ as occurring in England and Wales would have been avoided. It was said in court that the two dangers of treatment with succinylcholine were prolonged apnoea and regurgitation of stomach contents. The former, however, is extremely rare. There is no danger to life as long as respiration is maintained with the above apparatus. Blood transfusion has, however, been used to shorten the apnoea by providing the deficient cholinesterase.² The second hazard can be prevented by the patient fasting, but where he has managed to secure food unobserved a suction apparatus can be used. Intubating forceps and endotracheal tubes should also be available. Where a hospital

cannot provide an anaesthetist, doctors should be trained in this work by one of that specialty.

Many thousands of treatments, however, are carried out all over the world at the present time without anaesthetic or relaxant. Often a treatment has to be given as an emergency. Where an E.C.T. has to be given without a relaxant, it is essential that the psychiatrist should understand that the current can cause muscular contractions in two different ways.³

It was stated in court that the acetabula were fractured while the patient was having an epileptic convulsion, but from the evidence it is by no means certain that this was so. The sequence of events during E.C.T. is as follows: The current is passed between bitemporally placed electrodes for a period of between one-tenth of a second and several seconds, and the current spreads to some extent throughout the brain. This gives rise to two quite different sequences of events, both of which cause contractions of muscle, the first sequence being called indirect stimulation and the second direct stimulation. (1) *Indirect stimulation*.—With bitemporally placed electrodes an adequate current will cause an impulse to be transmitted physiologically to a trigger area in the mid-brain, and from there back to the motor area of the cortex, so that a tonic-clonic self-continuing convulsion is initiated. This process may take as long as fifteen seconds from the (often brief) initial stimulus until the onset of the convulsion. (2) *Again, with bitemporal placement of electrodes, in addition to the above process there is a direct stimulation of other intracranial structures, including the pyramidal tracts, mostly at the level of the internal capsule. There is also stimulation of the cranial nerves as they leave the skull. There is a sudden, powerful flexion of the thighs and arms, and generally of the vertebral column. The suddenness of onset makes the danger of a fracture particularly great. In the case of the thighs, the head of the femur may strike the socket like a hammer. The phenomenon has been called a "jack-knife contraction."*

In electrocerebral treatment the main therapeutic effect comes from the tonic-clonic convulsion. Fractures and other complications occur more commonly from the way in which the original stimulus is given to cause the convulsion than from the convulsion itself. The only safe way to prevent fractures and other complications is by employing an anaesthetist to give thiopentone and a quick-acting relaxant. Where that is impossible it is safer to give the original impulse by placing the electrodes rather far forward on the forehead, over the outer half of the eyebrows. The current should be turned on gradually, taking less than a second to reach the maximum, and allowing the current to pass only for the minimum period.—We are, etc.,

Tropical Pulmonary Eosinophilia

SIR.—The article by Dr. Rosemary Davies entitled "Tropical Pulmonary Eosinophilia" (*Journal*, December 22, 1956, p. 1470) demonstrates again how in Europe we are sometimes confronted with problems which are the rule in the tropics. Therefore it is very useful to publish our incidental experiences with tropical disease, so that attention does not slacken. That is why I should like to add the following to the above-mentioned article.

Besides the English literature, various contributions have been made in the Dutch literature on the differential diagnosis and the aetiology of tropical eosinophilia. Among others, filariasis was pointed out to be the causal factor.¹⁻⁴ Together with Winckel and Collier I⁵ described at Paramaribo (Surinam) three cases of relapsing asthmatic bronchitis with tropical eosinophilia (63-82%). Blood examination for syphilis, malaria, and filaria was negative. A remarkable

point was that all three patients were infected with histoplasma, which appeared after histopathological examination of removed lymph glands (Giemsa and Gram staining) and repeated animal tests (mice). The glands, when examined in sections, did not contain filariae.

The first patient, a Hindustani soldier, also suffered from *Strongyloides stercoralis* and ankylostomiasis. After a course of gentian violet and antimony ("fuadin") the worms disappeared, but leucocytosis and hypereosinophilia persisted. This patient failed to react to modern treatment against filariasis (diethylcarbamazine, "hetrazan"), but improved considerably after administration of oxophenarsine hydrochloride ("mapharsen"). The two other patients, a Creole boy of 15 and a Creole girl of 9 years old, did not suffer from worms. They showed the marked therapeutic effect of diethylcarbamazine.

Some authors consider hypereosinophilia as a first reaction to an early infection with filaria. However, this does not explain why hypereosinophilia is comparatively rarely discovered in the out-patient clinics of Paramaribo, where blood examinations are regularly made. For in this town, where microfilariae are found daily in the blood of clinically healthy people, it is to be expected that a considerable number of persons harbour microfilariae in the lymphatic system, though they cannot yet be demonstrated in the peripheral blood.

It was very remarkable that our three patients were all carriers of a type of histoplasma. But according to Collier and de la Fuente⁶ a high percentage (43%) of the population of Paramaribo is hypersensitive to histoplasmin. Wildervanck, Winckel, and Collier⁷ described a case of a 5-year-old healthy boy who died after an accident and had a positive histoplasmin test two months earlier. Mice tests showed that the liver, thymus, spleen, lung, and a lymph gland were infected with histoplasma. Histoplasmosis may probably be assumed as a markedly prevalent disease, even without clinical symptoms, in humans and animals in Paramaribo. Therefore the combination of tropical eosinophilia with histoplasmosis in our three patients might only be a coincidence.

Nevertheless, various authors hold the opinion that a combination of factors is necessary to cause the hypereosinophilia syndrome. The aim of our paper was to suggest such a possibility in future examinations of lymph glands and to look for histoplasma by means of Giemsa and Gram staining, and eventually by animal tests and cultures, too. Moreover, I believe it would be desirable to do a blood-examination for microfilariae in all cases with tropical eosinophilia, while treatment with diethylcarbamazine possibly might be considered.—I am, etc.,

Herpes Zoster and Chicken-pox

SIR.—In view of the current correspondence, I think the following two cases will be of interest.

Case 1.—A man, 41 years, presented with a severe facial herpes on September 10, 1956. There was conjunctival involvement. He was seen by the ophthalmologist and put on chloramphenicol eye ointment, and was also given chloramphenicol systemically, with liq. pic. carb. in calamine for the skin. On the fourth day of the illness he developed a generalized eruption typical of chicken-pox. He eventually made a complete recovery without any residual scarring or neuralgia. *Case 2.*—A housewife, 68 years, presented on April 15, 1957, with a rash on the adductor aspect of the left thigh, of six days' duration. The lesion was typical of

herpes zoster. On questioning she had no knowledge of contact with either chicken-pox or herpes. However, she stated that a fortnight before the rash started she had an airmail letter from her sister, aged 73 years, in California, U.S.A., who said she was in bed suffering from a severe attack of shingles. The coincidence with the approximate period of incubation is remarkable. It would be interesting to hear of any similar cases.—I am, etc.,

Camborne, Cornwall.

S. W. VIVIAN DAVIES.

Mental Deficiency

SIR,—The modern medical concept of mental deficiency is of social incapacity due to incompleteness of development of mind. Thus we find detained on order under the Mental Deficiency Acts not only the obviously idiot, imbecile, and feeble-minded, but patients who might equally well be regarded as aggressive psychopaths, habitual criminals, or merely members of the social problem group. Whatever our professional concept may be, there is no doubt that in the public's mind mental deficiency is identified with low I.Q. I feel it is the interpretation of this concept to include a wide range of I.Q.s which underlies the recurring allegations of wrongful certification. It was repeatedly put to the Royal Commission on the law relating to mental illness and mental deficiency that high-grade patients should not be cared for in the same hospital as lower-grade patients, and there is no doubt they resent being classified in the same way as patients in whom the defect is more obvious.

Those of us concerned with the care of mental defectives have been at some pains in the past to avoid the acceptance of the I.Q. as a basis for diagnosing mental defect. However, it seems to me that it would help clarify the present position and ultimately improve the therapeutic possibilities if we limited the term "mental defect" to a condition of social incapacity with low I.Q. (below 70) and treated as a separate problem social incapacity with higher I.Q.s. Patients falling into the latter group are often more in need of psychotherapy than the type of training given in most mental deficiency hospitals. To this extent they are more a mental treatment problem than a mental deficiency problem, and if they are considered to require institutional care I suggest this should be given outside the provisions of the Mental Deficiency Acts. At present there is no other legislation to cover this group, apart from their voluntary admission to a mental hospital. Most of these patients are not suitable for admission to the ordinary mental hospital, and there would seem to be a need for separate accommodation for them. Where their voluntary admission was not considered appropriate, their admission could be obtained on magistrates' order after the presentation of a petition as under Section 6 of the Mental Deficiency Act; such legislation should be incorporated in the Mental Treatment Acts.

I am aware that there will always be borderline cases which will give rise to difficulty, but the sooner we stop calling the socially inadequate group with "normal" I.Q. "mental defectives" the sooner we shall remove a powerful source of resentment among these patients, the greater will be our chance of obtaining their co-operation in psychotherapy, and the less frequently will we be accused of wrongful certification.—I am, etc.,

Bristol, 8.

W. ALAN HEATON-WARD.

Eleven-plus Examination

SIR,—Recent changes proposed in the secondary schools' selection procedure have once more brought the bogey of the so-called 11-plus examination into the limelight. It is interesting to speculate why the advice of the children's psychiatrists has never been sought in a matter that is alleged to concern the happiness and mental stability of children. In the last five years of child guidance work, with an annual average of 350 new cases, I have seen less than a handful of children whose problems could be directly related to the strain of this examination, and this experience seems shared by my colleagues. Temporary anxiety

symptoms induced by parental apprehension are only slightly more frequent, but I have yet to see the child who has suffered more permanent damage emotionally because of failure at the 11-plus. No child of that age does appreciate, on his own accord, the possible consequence of failure, and if given the right support he readily identifies himself with any secondary school community selected for him by his elders.

At the present system of selection girls would be at a slight disadvantage over boys because of the unsettling physical and emotional changes accompanying the pre-pubertal age, but their advanced social maturity amply compensates for this. In any selection procedure between the age of 13 and 15 years parents will find that boys are at a great disadvantage because even the promising high flyers are then passing through the temporary phase of a negative attitude toward their scholastic obligations, well known and accepted by all experienced teachers in grammar schools, while girls, having overcome the turmoil of earlier adolescence, are at ease at examinations. We will therefore find that an unfair proportion of girls will be accepted for higher studies, while the potential male scholars, who would have easily reassured themselves in the sixth form or at the university, will be discouraged from an academic career. This would result in a large number of disgruntled and emotionally dissatisfied clever men who could have filled the many vacant university places that girls, whose academic promise and interest was not sustained into more mature years, did not accept.—I am, etc.,

Leicester.

A. K. GRAF.

Hospital Confinement

SIR,—With reference to the letter by Dr. Aileen M. Dickens and her colleagues (*Journal*, March 16, p. 645) upon this matter, I would like to answer and give my observations.

It is my contention that, so far as possible, all mothers should be confined in hospital. The accent is upon the word "confined," and this does not necessarily mean the addition of lying-in in hospital. I believe that this policy would secure the following advantages: (1) the better use of hospital beds; (2) a saving of the doctor's time in travelling to and from a confinement while it is in progress when he has many other duties in his practice; (3) proximity of confinement to the doctor's surgeries in the event of the doctor being wanted for abnormalities; (4) to lessen two particular risks inherent in any confinement, but of particular danger to a home confinement, neither of which can be foreseen: (a) haemorrhage—obviously best treated in hospital, blood bank, and giving sets; and (b) anaesthetic risks, inhalation of vomit—anaesthetists these days are very fussy, and will soon refuse to give an anaesthetic in the home because of the impossibility or difficulty of fixing up a sucker: the tilting bed cannot be arranged in the home; (5) to lessen the risks to the foetus—resuscitation on modern lines with intubation cannot await transfer to hospital; (6) lessen risks of cross-infection, which increase with the longer the hospital stay. In addition to the foregoing, I personally dislike doing difficult forceps in the home and large-scale suturing if it is required.

There is no reason why the mother should not be returned home within a few hours of delivery if her condition permits, but certainly, I think, she should be discharged at least within two days—that is, before the milk comes in. When I first thought of this arrangement I had imagined that the mother would be looked after in hospital by a hospital midwife and discharged home to the district nurse, so that the latter could undertake all breast-feeding supervision before the milk came in. To discharge her a little later once some of the earliest difficulties have occurred would be unsuitable.

Since reading an article by Drs. Sluglett and Sarah Walker,¹ it would seem most desirable that the district midwife should herself bring the mother into hospital when she is in labour, and stay with her throughout, and see her home, conducting the delivery herself, or with the patient's doctor taking over as and when necessary. This would get over the difficulty

of doing district midwives out of their legitimate confinement experience. The latter would, presumably, have necessitated some rota system in which district midwives come into hospital for three months or so at a time to keep up their practice. This would be unnecessary if they could be allowed to come in to conduct their cases in the hospital. Since they have other duties in the district, they might not necessarily have to remain with the mother throughout the whole of the labour, but be allowed to go and do domiciliary visits during the first stage, as, of course, they do now when they are in charge of the mother at home.

Difficulties to be overcome: (1) Allowing district midwives to come into hospital to work presumably under the maternity sister: I think this is not insuperable, and mainly relies on the willingness to create precedent and team in one with the other. (2) The mother would not be allowed the £3 home confinement grant if she knew well beforehand that arrangements had been made for hospital confinement, even if the hospital stay was for as little as twelve hours: regulations would have to be made to amend this. When it is a last-minute decision due to abnormality, the money is payable. When applying, the mother has to state in writing when she first knew admission to hospital was going to be arranged. (3) At present, hospital bookings can only be made for ten days' stay by Ministry regulation. The county on behalf of the R.H.B. cannot therefore book a 48-hour stay or less without the Ministry revising its regulations. Of course it would be for the mother's own doctor to decide whether or not she should come in for confinement only. The mother might wish for home confinement and have to be persuaded to agree to hospital confinement. No regulation could be made; the doctor himself would decide. As I foresee it at present a number of ten-day stays would still have to be booked for domestic reasons, but not nearly so many as at present. It is usually the difficulties of domestic confinement itself, not the lying-in, that determine the hospital booking. The general move would be towards encouraging admission and early discharge whenever the home conditions permit.

Then to express a personal opinion on this matter of use of hospital beds. It is only a matter of time before something of this nature comes about. I think it is inevitable. Already discharge from hospital after operations can be considerably hastened by the more enlightened surgeon in team-work with the general practitioner, with advantage to all. We must not be hidebound by traditional ten-day lying-in periods and fortnight for appendicectomy, three weeks for repair, etc., unless we can be sure there is no better way. On the basis of cost alone, a vast amount of money is being wasted by keeping people in hospital unnecessarily long. They are being fed, heated and lit, and laundered at Government expense without any money being recouped from them. This they would have to have paid out if living at home.—I am, etc.,

Tiverton, Devon.

Premedication in Children

SIR,—I read with much interest the article on sedation for dental out-patient children by Dr. R. Goulding and his colleagues (*Journal*, April 13, p. 885). Since this study was primarily a pharmacological one, the emphasis, naturally enough, was laid on the findings that no drug tested helped to improve children's behaviour better than a placebo. What the authors have not stressed—and I feel this to be of at least equal importance—is that the behaviour of the children given a "medicine," whether an inert placebo or active drug, was less disturbed than the behaviour of the children observed in the preliminary assessment.

On the basis of the figures and charts available, in both pilot and main studies, it appears that in this preliminary assessment the proportion of children showing distress (adding the "disturbed" and "turbulent" groups) was 42% in the theatre and 56% when presented with the anaesthetic,

as compared with the group receiving the placebo, where the corresponding figures were 31% and 44% respectively. Whether such a change in behaviour is statistically significant can perhaps only be determined by the authors, who know the exact context of the experiment, but, at any rate, the matter might with profit be looked into further. It would certainly be of interest to know more of the manner in which the "medicine" was administered and the personality of the person who gave it out. Could it have been that the hand that held the medicine glass was more therapeutic than the drug that glass contained?

Might I, in conclusion, express the hope that further work of this kind be undertaken? I work next door to a dental hospital, where the screams of terrified children demonstrate daily how present techniques in dental anaesthesia lie still in some small way short of perfection.—I am, etc.,

Leeds, 2.

C. H. NEVILLE-SMITH.

Amphetamine Psychosis

SIR,—Dr. P. H. Connell's letter on amphetamine psychosis (*Journal*, March 9, p. 582) and the article on the inter-related subject of acute amphetamine poisoning by Drs. Raymond Greenwood and R. S. Peachey (*Journal*, March 30, p. 742) suggest that reports of amphetamine psychosis in this country are still relatively rare. It may therefore be worth while briefly to record one more such patient who was recently in my care.

A man, aged 20, was admitted to hospital because he appeared acutely agitated, tremulous, and apprehensive. He believed that he was being followed and watched, and that a door-handle had turned of its own accord. He had been terrified to observe a stain on a door growing larger and appearing to him to be smoke. Later he imagined that he saw and smelt smoke coming through a keyhole. He heard a noise "like someone squeezing a rubber bulb" and felt as though he was being burnt behind the right knee. He saw the faces of his sister and others outside the ward window. Thus he had hallucinations of all sensory modalities other than the kinaesthetic. He admitted that shortly before the onset of symptoms he had swallowed the best part of the contents of two "benzedrine" inhalers.

He recovered within a few days and was discharged from hospital. However, he was very soon readmitted because he had taken another and very similar quantity of benzedrine from inhalers. He thought that he might be a "research guinea-pig" and that "gases and fumes and sprays" were playing on him. Again he was the subject of illusions ("every shadow appeared as the figure of a person") and again smoke figured prominently in his hallucinations.

Ultimately he proved to be an early schizophrenic, and it transpired that he took benzedrine, as well as excesses of alcohol, in an effort to reduce his distress caused by ideas of reference and by the "gap" between himself and others. Very possibly this underlying psychosis coloured the acute toxic reactions to amphetamine.—I am, etc.,

Gosport, Hants.

G. G. WALLIS.

Safety Factor in Car Design

SIR,—The press has recently contained reports of statements made by prominent members of our profession, and others, regarding the dangers of the new miniature cars—especially those of "bubble" design.

I have recently acquired one of these for use as a runabout, and have found difficulty in obtaining fully comprehensive insurance cover. As it seems possible that note may have been taken of this publicly voiced criticism, I should like to make two points: (1) In view of the small number of these cars in use up to the present time I do feel that this criticism must be based on theoretical consideration rather than practical experience. (2) It is surely wrong to lump all the various makes together and condemn them out of hand. Mine, for instance, is a four-wheeler with a tubular

steel chassis, very positive steering, and an engine capable of useful acceleration. Because of the fourth wheel I have to pay a full road-fund tax, and it seems unfair that this fact is not reflected in the insurance rates.

If it can be shown that criticism is justified, and that all these vehicles, whether three- or four-wheelers, whether with or without a chassis, are a menace, then the profession is right in condemning them. We should be careful to see, however, that experience of any one particular model does not lead to an unjustified criticism of the whole group.—I am, etc.,

Ely, Cambs.

J. LEONARD HINE.

Operations for Varicose Veins

SIR,—In connexion with your very interesting leading article on operations for varicose veins (*Journal*, March 23, p. 692) I would like to draw the attention of your readers to two papers on this subject: that of M. G. Wilson¹ and my own written in collaboration with Dr. F. B. MacDonald.² These two papers describe the method of subcutaneous ligation using two different techniques developed independently by the respective writers. In our experience, this method has achieved very satisfactory results and has now been used in quite a large series of cases which will later be published.

A perfect cosmetic result is obtained because the operation leaves no scars. But it is quite apart from this advantage that we value the method. Much more important is the fact that by employing so-called "tandem ligation" on several levels we are able to control not only all incompetent perforating and communication veins but also the anastomoses of normal collaterals. Since this "tandem ligation" can be extended to include a large part or even the entire circumference of the limb on several levels, the column of blood is interrupted at these points and thus venous pressure is reduced. Owing to this, the cause of recurrence (high venous pressure) is removed: the more so, in that the collaterals themselves, which might be the site of recurrence, are also controlled. To accomplish this would be very difficult by the most radical operations proposed by those who consider the stripping operation unsatisfactory because of recurrences—for example, the method devised by W. H. Prioleau and J. M. Stallworth.³

Because of the success with our method we abandoned first the stripping operation, and then the conventional high ligation—used in conjunction with subcutaneous ligation for a period of time—in favour of subcutaneous ligation alone regardless of the extent of the varices. It seems to me that this method is the best answer at present to the difficulty of "locating incompetent communications" which you point out in your leading article.—I am, etc.,

Sydney, N.S., Canada.

The Hurt Brain

SIR,—Dr. E. E. Prebble states (*Journal*, April 13, p. 885) that "the trivalent arsenicals, being incapable of reaching the cerebrospinal fluid, have long been known to be useless in neurosyphilis." In 1919, as I could not understand why my clinical results were often so satisfactory if the trivalent arsenicals were indeed incapable of reaching the cerebrospinal fluid, I gave a long series of injections of nearsphenamine (N.A.B.) to a paretic policeman and then withdrew his cerebrospinal fluid one hour after the last injection. The fluid was analysed for me by Professor Hugh Maclean in the chemical pathological laboratory at St. Thomas's Hospital. Under stringent analytical precautions with arsenic-free reagents and apparatus, he showed me the metallic deposit of arsenic obtained from this cerebrospinal fluid. Thus, it was proved in 1919 at St. Thomas's Hospital that the trivalent arsenicals do penetrate into the cerebrospinal fluid, and this is confirmed by authorities such as Brahme¹ and Fordyce, Rosen, and Myers.² Arsenic is absorbed so

rapidly, mostly within the first two hours, into the cerebrospinal fluid, and eliminated so quickly, that this may be the reason why others have failed to detect it.

My experience forces me even more emphatically to agree with both Dr. Prebble and Dr. J. Purdon Martin (*Journal*, April 13, p. 885) that to rely on a meagre ten injections of penicillin to cure neurosyphilis is to invite failure. This comparatively small dosage may destroy any natural immunity that exists while replacing it with a modicum of therapy, which, as Dr. Martin writes, can hardly satisfy one's obligations to the patient.—I am, etc.,

Immediate Treatment of Apoplexy

SIR,—Following your annotation, "Immediate Treatment of Apoplexy" (*Journal*, January 7, 1956, p. 35), we decided to undertake a controlled investigation of the value of cortisone in this condition. As you pointed out, in the original report¹ no controls were studied, so that no definite conclusions could be drawn from the results. We adopted a "double blind" programme with independent clinical and physiotherapeutic assessment of progress, and a series of 12 patients with cerebral thrombosis has been studied. Six received prednisolone tablets in the dosage recommended, while six received placebo tablets which were similarly scored to the prednisolone tablets.

The following were the results in brief:

	Placebo	Prednisolone
Number of patients	6	6
Mean age	71	64
Unconscious on admission	2	1
Hypertension	2	3
Death	3	2
Improved	2	4
Not improved	1	1

At this stage we read the report of Dyken and White² in which a similar trial was reported with 17 patients in the control and 15 patients in the cortisone-treated group. These observers also found no benefit from cortisone treatment compared with placebo—in fact, the cortisone may even have been deleterious.

Under these circumstances, Sir, we have decided to discontinue our own therapeutic trial, as we believe further use of large doses of cortisone to be of no value and even contraindicated in these patients.—We are, etc.,

Lymphadenoid Goitre

SIR,—The title, "Lymphadenoid Goitre (Hashimoto's Disease)," of the paper by Dr. Deborah Doniach and Mr. R. Vaughan Hudson (*Journal*, March 23, p. 672) is, I fear, misleading. Lymphadenoid goitre is free of the atrophy and disappearance of follicles with replacement fibrosis as described by Hashimoto.¹ Lymphadenoid goitre, on the other hand, has a relatively natural follicular structure with the added feature of numerous lymphoid follicles.² It is perhaps unfortunate that Hashimoto used the term "struma lymphomatosa" in his title, which has led many unfamiliar with his paper in the original German to apply his name to thyroid conditions with prominent lymphoid tissues but lacking the fibrosis he described.—I am, etc.,

Los Angeles, U.S.A.

Budgerigars in Wards

SIR,—Your correspondent Dr. N. A. Thorne (*Journal*, April 27, p. 1008) writes regarding the "advisability or otherwise of banning the presence of budgerigars from hospital wards." My experience is confined solely to the keeping of these pets in tuberculosis wards in sanatoria, but perhaps some of my observations may be applicable to certain wards of other types of hospitals.

I feel that, while there is very little danger of infection from psittacosis from a budgerigar obtained from a breeder of repute in this country (or, in fact, of any infection from a bird that is kept clean and healthy), such a pet is not to be recommended in any acute ward, as it could prove distracting for a very ill patient. As regards having budgerigars in other types of wards, I have found that the average "long-term" bed cases—as well as ambulant patients—derive much pleasure and interest from these pets, which certainly aid in relieving tedium, and that they can provide an excellent kind of diversional therapy, especially for women who spend interminable hours at high-speed knitting (a potent source of nervous tension). Incidentally, more than one bird in a cage can be distracting, with their constant chatter. In short, a healthy budgerigar can give valuable relaxation (with a minimum risk of infection) for non-acute patients, particularly for those undergoing prolonged hospitalization.—I am, etc.,

High Wycombe, Bucks.

MURIEL G. E. CLARK.

Smoking and Lung Cancer

SIR,—It may be of interest to record that the Council of the British Tuberculosis Association decided recently that a letter should be written to the lay press on its behalf, affirming the relationship between carcinoma of the lung and cigarette-smoking. The Council was not optimistic enough to suppose that such a letter would have any great effect in diminishing the smoking habit, but at least no member of the public would be able to say, either now or in the future, that the British Tuberculosis Association had not attempted to give guidance in the matter. I was accordingly instructed to write a letter, briefly drawing attention to the evidence relating carcinoma of the lung to heavy smoking, and also to the recent work which indicated that this might also be a factor in the development of pulmonary tuberculosis in the middle-aged male. A final plea was made to those in charge of children to prevent them starting the smoking habit.

This letter was sent to the two leading British daily papers. One replied that they found the letter of interest but lacked space for publication, and the other referred only to lack of space. The letter was then sent to a popular daily newspaper and a daily picture paper. One replied that it had recently published a leading article on the subject and would keep the letter for reference, and the other ignored it. The letter was finally sent to the best-known provincial newspaper, which published it in an abbreviated form, so that it drew attention only to the possible relationship between tuberculosis and smoking.—I am, etc.,

W. E. SNELL,

President,
The British Tuberculosis Association.

London, N.W.9.

Cardiac Arrest During Trichlorethylene Anaesthesia

SIR,—In their interesting article (*Journal*, April 13, p. 860) Drs. Walter Norris and Peter Stuart describe several cases of cardiac arrest occurring during trichlorethylene anaesthesia. There is no doubt at all that, in common with most if not all inhalation and intravenous anaesthetics, trichlorethylene can cause this condition, but it seems to me that the important question is the approximate risk compared with other drugs. The mere reporting of individual cases is of limited value, as it has been estimated that in Great Britain about 2,250,000 anaesthetics are admin-

istered annually and, as a large proportion of these include trichlorethylene, a minute incidence of cardiac arrest would soon account for an impressive total.

This question was discussed at a recent meeting of the Society of Anaesthetists of the North-east Metropolitan Region, and Mr. T. B. Boulton, then senior anaesthetic registrar to St. Bartholomew's Hospital, kindly spent a great deal of time and trouble looking up the figures for in-patients at this hospital for the ten years beginning January 1, 1946. In just over 29,000 administrations in which trichlorethylene had been used, there were two deaths which were considered due to primary cardiac arrest. One of these followed the infiltration of the neck with 1 in 250,000 adrenaline solution for a cervical sympathectomy (it might be mentioned that our usual practice is not to exceed 1 in 500,000). The figures for Hill End Hospital (St. Bartholomew's) are unfortunately incomplete owing to the lack of clerical assistance, but I kept a record of the first 15,000 administrations after the introduction of the drug in 1940. There was one death suggestive of primary cardiac arrest, which incidentally is included in the article. On a basis of 44,000 cases the approximate incidence is therefore 1 in 14,600.

Some comparison with chloroform can be made on the figures obtained in the classical work of R. M. Waters and his colleagues at Madison, Wisconsin.¹ One thousand one hundred and eleven administrations were made under ideal and controlled conditions, and sudden cardiac arrest occurred in four patients, an incidence of 1 in 278. I am aware of the statistical perils of comparing a large series with a small one, but the difference is, to say the least, striking. The possible occurrence of cardiac arrest is a constant nightmare to the introducers of new anaesthetic agents, especially as animal experiments are not of great value in this respect. It may be that "fluothane" will prove to be a safer non-flammable inhalation anaesthetic and analgesic than trichlorethylene, but time alone will tell. Meanwhile it is desirable to keep a sense of proportion.—I am, etc.,

London, E.C.1.

Bolus Obstruction

SIR,—Recent interest in bolus obstruction prompts me to record a recent case.

A man of 67 gave a history of mild pain in the left umbilical and lumbar regions for 48 hours, which had for the past 24 hours been more severe, colicky in nature, and had moved across the centre of the abdomen. The patient did not vomit, nor, however, did he pass flatus. On examination he was found to be tender to the left of the umbilicus; there was no distension, but the bowel sounds were high-pitched and excessively frequent. An x-ray confirmed the existence of a low small-gut obstruction. Five and a half years previously the patient had a lesser curve gastric ulcer treated in another hospital by Billroth I gastrectomy. The operation note remarked, "Good stoma." Laparotomy was performed and a considerable amount of free fluid was present. The small intestine was obstructed by a sausage-shaped food bolus 7.5 × 2.5 cm. situated about 1 metre proximal to the ileocaecal valve. This bolus was gently "milked" into the caecum, where it was broken up. A normal Meckel's diverticulum was noted just proximal to the obstruction. The post-operative recovery was uneventful. After careful questioning post-operatively the patient remembered eating an orange somewhat voraciously on the day of onset of symptoms. The obstructing bolus could well have been orange pith.

This case emphasizes the importance of surgeons ascertaining that patients subjected to gastrectomy are equipped with adequate teeth or dentures which they use. Miss Irene S. Cade and Mr. G. Qvist (*Journal*, April 20, p. 948) and Dr. J. T. Corbett (*Journal*, March 2, p. 524) in earlier correspondence have already stressed the importance of adequate mastication, especially following gastric surgery.—I am, etc.,

Leicester.

WILLIAM J. GALL.

B.C.G. Vaccination on Christmas Island

SIR.—The total population of Christmas Island is employed in the phosphate industry, except for a limited few who are employed as servants. A complete medical service is provided by the employer. B.C.G. vaccination was performed for the first time in August, 1955, and applied to the age groups ranging from 6 months to 20 years. It is intended that further vaccinations shall be carried out this year on those who did not undergo Mantoux conversion, or have lost their induced allergy to tuberculin, or have not been vaccinated previously. This year the population is greater by 900 persons, and I am fortunate in having the help of another medical officer. Supplies of tuberculin and B.C.G. vaccine were obtained from the Ministry of Health in Singapore.

The vaccinations were carried out on almost all members of the group selected. Figures for total child population are quoted and these approximate to the total number of persons in the group vaccinated. The population statistics for the month of August, 1955, were as follows:

Europeans		Chinese		Malay		Total
Male	Female	Male	Female	Male	Female	
19	19	328	315	114	94	889

Results of Mantoux Tests and Vaccinations			
Number Tested	Positive	Negative	Vaccinated
776	79	697	558

All results were recorded on the individual medical record cards. Tuberculosis is a problem of no great magnitude here and does not need more than the medical facilities which already exist, which include help from Tan Tock Seng Hospital in Singapore at stages needing more than chemotherapy and sanatorium regime.

The main interest, to my mind, is the fact that such a programme as this could be carried out within any general-practitioner unit. By the latter term I mean that unit comprised by the doctor and that doctor's patients. The unity becomes more real with each succeeding year, as all co-operate in maintaining the health of the unit.—I am, etc.,

Christmas Island.

E. R. BLAY.

Post-maturity

SIR.—With reference to Professor F. J. Browne's article (*Journal*, April 13, p. 851) and Mr. J. McClure Browne's letter (*Journal*, April 27, p. 1005), when considering induction for post-maturity, one factor that never is listed in hospital statistics, but greatly concerns the general practitioner, is maternal fatigue. The last weeks of any pregnancy are very tiring for the housewife, especially if she has an energetic toddler. When this "heavy" period is prolonged for two or three weeks the strain becomes almost intolerable. The slightly larger child and possibly longer labour add to the strain. I think of one patient whose second baby was allowed to go three weeks over term. Labour was very long, although obstetrically normal. The baby weighed 11 lb. (5 kg.). It was eight or nine months before the mother felt really fit. Her next two pregnancies miscarried. When she did achieve a full-term pregnancy the baby was induced at term. Labour was short and easy. The baby weighed 7 lb. (3 kg.). The mother regained her vigour in five or six weeks, although her life was much harder, in other ways, than it had been after the birth of number two. Possibly it is a coincidence that the first and third children born at term have always been exceedingly fit, while the second child has never been a really robust person.—I am, etc.,

London, W.8.

ROSAMOND BISCHOFF.

Obituary

W. V. COPPINGER, C.I.E., D.S.O., M.D., F.R.C.S.I.

Major-General W. V. Coppinger, formerly Surgeon-General under the Government of Bengal, died at his home at Midgham Green, near Woolhampton, Berkshire, on April 9. He was 82 years of age.

Walter Valentine Coppinger was born in Dublin on March 1, 1875, the son of a barrister, and studied medicine at Trinity College, Dublin, where he was a gold medallist and senior moderator in natural science. Graduating M.B., B.Ch. in 1897, he proceeded to the M.D. two years later. After graduation he held the appointment of house-surgeon at the Mater Misericordiae Hospital, Dublin. From 1900, when he entered the Indian Medical Service, until the outbreak of the first world war in 1914 he served as a district civil surgeon in various parts of Bengal and Assam and as a member of the staffs of the Calcutta and Rangoon general hospitals. He took the F.R.C.S. of Ireland in 1909. During the first world war he was employed on the Indian frontier and in Mesopotamia, being mentioned in dispatches. He was awarded the D.S.O. in 1918.

From 1918 to 1928 Coppinger was professor of ophthalmic surgery at the Medical College Hospital, Calcutta, and superintendent of the Mayo Hospital, and he then became inspector-general of civil hospitals in the Central Provinces. In 1930 he was appointed C.I.E., and in the same year became Surgeon-General under the Government of Bengal, a post he held until he retired from the I.M.S. in 1933. He was president of the Calcutta Branch of the British Medical Association in 1932-3. He is survived by his wife, formerly Miss Margaret M. O'Kelly, whom he married in 1910 and by whom he had one son and one daughter. He was the elder brother of Colonel F. R. Coppinger, late R.A.M.C., and Rear-Admiral R. H. Coppinger.

JOHN ARMSTRONG, M.D., F.R.C.S.I.

By the death of Dr. John Armstrong on April 1, Northern Ireland has lost one of its best-known and most respected figures and Ballymena one of its most loyal citizens. He was in his 80th year.

John Armstrong was born on December 11, 1877, and received his early education at the Belfast Royal Academy, going on to Queen's College, as it then was, in 1895. After a year in the faculty of arts, as was the custom with all matriculated students, he entered the medical school, obtaining his clinical training in the old Royal Hospital in Frederick Street. In 1902 he graduated M.B., B.Ch., with honours, from the former Royal University of Ireland. After graduation Professor Johnson Symington invited him to become demonstrator in anatomy, and he soon obtained his Primary Fellowship of the Royal College of Surgeons in Ireland, taking the final in 1907. He had proceeded to the M.D. in the previous year.

S. T. I. writes: When the young John Armstrong entered general practice at Ballymena in 1903 he can hardly have foreseen what fate held in store for him. The beginning of the century was the time when medicine was only just emerging from an age of empiricism and the study of living pathology in the operating theatre was replacing the pathology of the mortuary. The surgeon was for the first time demonstrating to the naked eye the early and curable stages of disease, especially those within the abdomen. No doubt Armstrong held the view which was then prevalent that so far as the foreseeable future in medicine was concerned surgery held the key. He took his first steps in surgery by using the beds in the cottage hospital. Within its limited capacity it was a very pleasant place in which to work. But a wider vista was opening, for plans were in existence for

the building of the new Waveney Hospital in the town, and it seems certain that he saw clearly the opportunities which this would offer. When it was opened in 1914 with its 185 beds, the sole medical appointment was that of the man who had held the post in the old infirmary. He made no pretence of being a surgeon, and surgery was going to be an essential feature of the hospital from its very beginning. The committee of management thus found itself in a quandary, but Armstrong stepped into the breach and became the unofficial, and almost unpaid, surgeon to the Waveney. He was in fact the first honorary surgeon, in the best meaning of the term, to a hospital in Northern Ireland outside the city of Belfast.

It was at this time, too, that the first world war broke out, and the recently opened Waveney Hospital became a military hospital and almost its first admissions were war casualties from France. Armstrong became its civil surgeon and was responsible throughout the war for dealing with the varied and often difficult problems which these cases presented. This greatly widened his experience of surgery and entitled him henceforth to be considered a general surgeon—at a time when this term bore no reproach. The post of surgeon which he then attained he held for the remainder of his professional life, giving generously of his operative skill and knowledge to all the people of the district without thought or prospect of reward. I use this phrase advisedly, and the truth of it will be apparent when it is told that upon retirement it was only after a legal battle that he was given a miserably inadequate pension.

But Armstrong was more to the profession in Ballymena than merely the surgeon to the hospital. He set a high standard of scientific medicine in all departments of medical practice, and his precept and example were of inestimable benefit to the town in general. John Armstrong's main attributes were ability, industry, and modesty. He served the Waveney Hospital with unswerving devotion for more than half a century. But in his early days great difficulties surrounded the surgeon working in isolation in Ballymena. The Waveney was not then the well-equipped institution which it is to-day. It is true there was an x-ray plant—but no technician to use it. Anaesthesia was still at the "rag-and-bottle" stage and there were none of the ancillaries now considered essential and which to-day make surgery straightforward and comparatively easy. And so we find that in order to practise his specialty our young surgeon had also to keep himself competent in radiology, anaesthesia, and bacteriology. His hospital duties were carried out for years by day and by night without fully skilled assistants and for such a scanty remuneration that he had at first to combine surgery with general practice. His time was so fully occupied with his work that he had little left for hobbies, but he was a competent photographer, first in black and white and later in colour. When he retired in 1949 he took up painting with very considerable success, but his absorbing interest in later years was that of the new geriatric unit at the Braid Valley Hospital, which was a pioneer venture in Northern Ireland. He was chairman of the committee of management from its foundation, and it was while showing a deputation over the hospital that he was struck down by his final illness—an extensive haemorrhage from an oesophageal varix.

Dr. Armstrong's wife was Dr. Maria Rowan, whose father and grandfather had been doctors in general practice in County Down. The Armstrongs had a family of five sons and one daughter, all but one of whom were graduates in medicine in Queen's University: James Rowan is an orthopaedic surgeon in London; Arthur is anaesthetist to the Mid-Ulster Hospital; Jack and Sydney are in general practice; and his daughter, Moira, who was in general practice in Ballymena, died some years ago. His fifth son, Edward Brian Armstrong, is a physicist holding a lectureship at Queen's and working at the research establishment at Armagh Observatory.

Armstrong served on many professional committees. From 1927 to 1939 he was a member of the Council of the British Medical Association, and from 1927 to 1936 a mem-

ber of the Irish Committee. In 1926-7 he was chairman of the Belfast Division and in 1933-4 president of the Northern Ireland Branch. From its foundation in 1939 he was a member of the Northern Ireland Council for Orthopaedic Development.

CHARLES LAMPLOUGH, M.D.

Dr. Charles Lamplough, who was in general practice at Gosport, Hampshire, for over forty years, died in Gosport War Memorial Hospital on April 7, a few days after a fall in which he sustained a fractured hip and humerus. He was 84 years of age.

Charles Lamplough was born at Wetwang, Yorkshire, on November 13, 1872, and was educated at Leamington College and at Mason College, Birmingham, from which he went on to St. Bartholomew's Hospital. Qualifying M.R.C.S., L.R.C.P. in 1895, he took the Brussels M.D. three years later. After qualification he held the appointment of resident medical officer at Marylebone Infirmary, and then became senior house-physician and, later, resident medical officer at the City of London Hospital for Diseases of the Chest. He first went into practice at Chatteris, in the Isle of Ely, where he was also medical officer of health to the urban district council, but in 1904 he settled at Gosport as a young married man, taking over a practice which he greatly increased in the course of time. In 1908 he was joined by his brother, the late Dr. Wharram H. Lamplough, and, some years after the first world war, by Dr. N. L. Russell. After the war, in which he served as a captain in the R.A.M.C. at the 5th Southern General Hospital at Portsmouth, Dr. Lamplough was one of the most active supporters of the project to build a hospital at Gosport, and when the War Memorial Hospital was completed he became an honorary consulting physician and a vice-president. At the hospital he instituted a medical committee which has helped to maintain a very friendly atmosphere among Gosport doctors. Kindly and charming in manner, he was an excellent diagnostician, and was especially interested in diseases of the chest. He published a paper on the treatment of tuberculosis in this *Journal* sixty years ago. He retired from practice in 1947. For recreation, Dr. Lamplough had a shoot in the Meon valley, but his great hobby was rose-growing. He was amateur champion rose-grower in 1919, 1920, and 1921, and later acted as a judge for the National Rose Society. The Mrs. Charles Lamplough rose is called after his wife, who survives him, together with two sons and a daughter.—D. C. M.

J. L. HAMILTON, M.C., T.D., M.D.

Dr. J. L. Hamilton, who had had a distinguished career as a Territorial officer, and who had also rendered many years of valuable service to the St. John Ambulance Brigade, died on April 24. He was 68 years of age.

John Livingston Hamilton was born at Great Missenden, Buckinghamshire, on January 29, 1889, the eldest son of Lieutenant-Colonel D. L. Hamilton, R.A.M.C., and was educated at Epsom College and at Downing College, Cambridge. Receiving his clinical training at the London Hospital, he qualified L.M.S.S.A. in 1915, and then held the appointment of senior house-surgeon at the Albert Dock Seamen's Hospital. Soon afterwards he entered the R.A.M.C. as a lieutenant, and saw service during the first world war in Egypt, Palestine, and Syria, and was wounded. In 1917 he was awarded the Military Cross. After the war Hamilton returned to London, and held the appointments of resident anaesthetist, senior clinical assistant, and receiving-room officer at the London Hospital. For a time he was in partnership with his father in North London, but in 1921 he set up in practice on his own account in the Kingsland Road. While there he also acted as public vaccinator for the south-west district of Shoreditch and as honorary medical officer to the Mission of the Good Shepherd, in Harman Street. In 1928 he moved to Chingford, where he stayed

for a few years until he finally settled at Colchester in 1933. He obtained the Durham M.D. in the previous year.

Hamilton had been associated with the Territorial movement for close on forty years. Returning from the first world war with the rank of captain, he was promoted major in the early 'twenties, lieutenant-colonel in 1932, and brevet colonel four years later, retiring from the Territorial Army in 1949. He was awarded the Territorial Decoration in 1927, and four clasps to the decoration in 1950. During the second world war he was at different times A.D.M.S. of the 54th and 38th divisions and officer commanding the 37th and 55th general hospitals. Last year the Queen approved his appointment as honorary colonel of the 21st General Hospital. Since 1922, when he became an examiner, he had given similar devoted service to the St. John Ambulance Brigade. Appointed divisional surgeon in 1926, he became county surgeon for Essex in 1932. From 1937 to 1950, when he relinquished the appointment, he was county commissioner. In recognition of his services he was appointed a Knight of the Venerable Order of St. John of Jerusalem, and he received the service medal with two bars. He had been a deputy lieutenant for the county of Essex since 1950, a past president of the Colchester Medical Society, and chairman of the North-east Essex Division of the British Medical Association in 1948-9. He is survived by his widow, formerly Miss Winifred M. Gunningham, whom he married in 1922, and two sons.

STEWART HUNTER, M.B., F.R.C.S.Ed.
M.R.C.P., D.C.H.

Dr. Stewart Hunter, who practised in Christchurch, New Zealand, died on March 19, aged 54.

Stewart Hunter was the son of a doctor, and studied medicine at the University of Otago, graduating M.B., Ch.B. in 1925. After graduation he held the appointment of house-surgeon at Ashburton Hospital before coming to Britain for postgraduate study. He spent two years in Scotland, taking the Fellowship of the Royal College of Surgeons of Edinburgh in 1928. Later he worked at the Rotunda Hospital, Dublin, and the Chelsea Hospital for Women. During the second world war he served with the New Zealand Medical Corps, and after demobilization returned to London to take the M.R.C.P. and the D.C.H. of the English Royal Colleges, both in 1947. On return to New Zealand he became assistant obstetrician at St. Helen's Hospital, Christchurch, and assistant physician in paediatrics at Christchurch Hospital. Dr. Hunter was honorary secretary of the Canterbury Division of the B.M.A. from 1937 to 1942 and president of the New Zealand Branch in 1948-9.

A. C. NORMAN, C.B.E., M.D.

Dr. A. C. Norman, formerly professor of radiology in the Royal College of Medicine, Bagdad, died at his home at Tillingham, Essex, on April 23. He was 75 years of age.

Alfred Clarence Norman was born at Shepton Mallet, Somerset, on August 20, 1881, the son of a well-known farmer, and was educated at Tewksbury, Bromsgrove, and Edinburgh University, where he graduated M.B., Ch.B., in 1908. After holding a number of resident appointments, including one at the Sunderland Eye Infirmary, he decided to specialize in ophthalmology, and proceeded to the M.D. in 1911 with a thesis on miners' nystagmus. Later he turned to radiology, in which he had always taken a keen interest. As a student he spent much of his spare time in the x-ray department of Edinburgh Royal Infirmary. In August, 1914, he published a handbook entitled *Practical Medical Electricity*, which was very well reviewed by the medical press. Commissioned into the R.A.M.C. in 1914, he served as a radiologist in India and Mesopotamia, and in the following year was appointed consulting radiologist to the Mesopotamian

Expeditionary Force. At the end of the war he joined the then infant medical service of Iraq, which later became the Iraq Health Service. He founded the x-ray Institute of Iraq in Bagdad and was its director until his retirement in 1948. Responsible for its development from the lowest minimum into a well-organized and up-to-date institution, he trained staff and arranged for the provision of equipment for the many off-shoots of the institute in the provincial hospitals. On the formation of the Royal College of Medicine at Bagdad he became professor of radiology. For his services Norman was appointed O.B.E. in 1931 and C.B.E. in 1942. He was also awarded the Order of Al-Rafidain (class III, civil division). After his retirement he settled at Tillingham, where he died after a prolonged illness. He was a keen golfer and in his time a first-class shot. He is survived by his widow and two sons.—W.D.

M. J. McCORMACK, M.R.C.S., L.R.C.P.

Dr. M. J. McCormack, who had been in general practice at West Ham for many years, died on April 28, after a long illness, at the age of 51.

Michael Joseph McCormack was born on September 21, 1905, at West Ham, where his father, the late Dr. James McCormack, had been in practice for over fifty years. He was educated at Beulah Hill College, Norwood, and at St. George's, Weybridge. He studied medicine at the London Hospital, qualifying M.R.C.S., L.R.C.P. in 1933. After holding hospital appointments for two years, he went into partnership with his father at West Ham, where he remained until his death. He took a full share in the organization work of the profession, serving on the old local medical panel committees, and presiding over the local medical committee in more recent years. Up to his death he was a member of the local executive council. An active supporter of the B.M.A., he was chairman of the Stratford Division in 1952. For some years he had been a member of the board of governors of St. Bonaventure's and St. Anthony's schools, Forest Gate, and he was also a syndic of the Franciscan Friary there. He leaves a widow, one son, and one daughter.

Dr. J. W. DIGNAN writes: Dr. M. J. McCormack, during his long association with West Ham, gave over twenty years of devoted public service in an unobtrusive manner. He was a man who liked the simple way of life, and although he served on many important medical committees he never sought the limelight or high office: but he was a very shrewd observer, and a delightful man to work with. He loved his patients, particularly children, and his sincerity, quiet efficiency, and sustained interest in everything he undertook made him an ideal confidant. He delighted to watch motor-racing and cricket, and to play a little golf, but most of all he loved to talk with his colleagues about everyday affairs. He was a devout Roman Catholic and a staunch supporter of the Guild of St. Luke, SS. Cosmas and Damian, being master of the Brentwood branch in 1951 and again in 1955. It may be truly stated that he commanded the respect and affection of all who knew him.

E. C. EROKWU, M.R.C.S., L.R.C.P.

Dr. E. C. Erokwu, senior medical officer of the Eastern Nigeria Ministry of Health, died at Park Lane Hospital, Enugu, on March 10, nine days before his 43rd birthday.

Dr. C. NWOKOLO writes: Edward Chukwunwike Erokwu was born on March 19, 1914, the son of a court clerk. He showed great promise early in his life and won a scholarship to Government College, Umuahia. After a brilliant secondary school career he was again awarded a scholarship to study medicine in the old School of Medicine of Nigeria at Yaba. In 1939 he qualified as an assistant medical officer, with honourable mention in surgery. Those were the days when the local graduate occupied an inferior place

to his colleague trained overseas, and Erokwu at once set to work to rectify this anomaly. He knew that recognition would come to the "Yaba Doctor" only by honest hard work and dignified behaviour: in this respect he and his colleagues were not found wanting. Indeed, it was largely as a result of the high standard set by Erokwu and his colleagues that the efficiency of the local graduate came to be accepted by all, and when the agitation came for better recognition the general public were unequivocal in their support. Erokwu led several delegations in this fight for recognition, but the most fruitful was the one before the Elliot Commission for Higher Education in the Colonies in 1944. He outlined his case with characteristic lucidity, and there can be no doubt that the commission was favourably impressed, for soon afterwards the General Medical Council announced its concession to enable the graduates of the School of Medicine of Nigeria to obtain qualifications registrable in the United Kingdom and so opened the door to higher qualifications. With the battle won, Erokwu was given a Government scholarship, and, with a view to specializing later in surgery, he took the London Conjoint Diploma in 1951.

Erokwu was a well-built man of dignified appearance. Kind and reliable, he was a most consistent and dogged fighter when convinced about the rightness of a cause. Though often engaged in battles for the betterment of his profession, he was a very clean fighter and despised recklessness and irresponsibility. He was always prepared to consider both sides of a case, and this level-headedness earned him the respect of his friends and opponents alike. It is not surprising that he was elected chairman of most organizations to which he belonged. He believed that the African should be second to none in integrity, dignity, and discipline, and he believed that local conditions should encourage nothing but the highest ethical behaviour. His shining personal example was an eloquent expression of these beliefs.

Professionally, he was interested in surgery, and it was a pleasure to watch his well-proportioned fingers moving swiftly and skilfully at the operating table. When a few years ago he was called on to accept an administrative post it was with regret that he gave up surgery, but he accepted it in good part because it was a national call.

"Eddie," as he was popularly called by his friends, was a very sociable figure, but he was happiest when with his colleagues discussing old school days and entertaining everyone with his inexhaustible stock of timely jokes. His health began to fail about five years ago, and he knew then that he was suffering from a disease for which medical science has found no lasting answer. It is remarkable that in spite of this knowledge of his fate he continued to give his best for the service of his country and his people. Many would have retired broken-hearted, but he stood up to his misfortunes like a man, and two days before his death he still discussed freely the welfare of his department and his colleagues. This was characteristic of the man. He was always selfless and courteous, and always put others before himself.

By his death the eastern region of the Nigeria Branch of the British Medical Association, of which he was an active member, has lost its most dynamic exponent of professional dignity, and Nigeria is infinitely poorer for his untimely loss. He is survived by his widow and six children, to whom goes the heartfelt and profound sympathy of his many colleagues and friends.

RAYMOND GAUTIER, M.D.

Dr. Raymond Gautier, Research Director for the International Children's Centre in Paris, and a former Assistant Director-General of the World Health Organization, died recently in Geneva at the age of 72.

Raymond Gautier was born in Geneva on January 7, 1885, and after graduating in medicine at Basle in 1915 he was appointed an assistant in the institute of pathological anatomy there. Two years later he left to become first assistant in

the physiological laboratory at the University of Geneva. Here he gained the Bizot award for his research on the cerebrospinal fluid and his enunciation of the concept of the "blood-brain barrier." As director of the university institute of hygiene and bacteriology at Geneva he carried out research on bovine fluorosis. In 1924 Gautier joined the League of Nations Health Organization, where he was at first concerned with biological standardization. From 1926 to 1930 he was director of its Eastern Office at Singapore, where he established a radio service of epidemiological information. Returning to Geneva in 1930, he devoted his full time to biological standardization and published some important studies. In 1939 he became Acting Director of the Health Section of the League, and from 1942 until the end of the war he was entrusted with missions to London and Washington for the purpose of organizing public health in the liberated territories of Europe. On the establishment of the World Health Organization Interim Commission in 1946, Gautier became Counsellor and, later that year, Director of the Geneva Office; in 1948 he was appointed Assistant Director-General of the permanent Organization. His retirement in February, 1950, did not mean the end of his career, for he became research director for the International Children's Centre, then recently formed in Paris by the French Government for the promotion of infant and child welfare at international level.

Raymond Gautier was a member of the Senate of the Swiss Academy of Medical Sciences and an honorary member of the Epidemiological Section of the Royal Society of Medicine. Besides his studies on biological standards, he published numerous works on epidemiology and immunology, but his greatest contribution to medicine was as an international health administrator, who, on the occasion of his retirement, was described as "truly the soul of the World Health Organization."

JEKABS ALKSNIS, M.D.

Dr. Jekabs Alksnis, formerly professor of surgery in the University of Riga, died at the German Hospital, London, on March 7. He was 86 years of age.

Jekabs Alksnis was born in Latvia on August 22, 1870, the son of a carpenter. He studied medicine at Dorpat University in Estonia, then a Russian province, where he qualified in 1895 and later obtained his degree of M.D. From 1897 until 1910 he served as a surgeon in the Russian army, being attached to the Academy of War Medicine in St. Petersburg from 1903 to 1907, and taking part in the Russo-Japanese war of 1905-6. In 1910 he left the army to take up private practice at Liepaja, Latvia. He was a general surgeon who subsequently specialized in urology and later interested himself largely in surgery of the thorax. Whereas in the first world war he was surgeon-in-chief of several Russian military hospitals he became leading surgeon and medical inspector of the Latvian forces when Latvia became an independent state in 1918. In 1920 he was appointed professor of surgery and director of the surgical clinic of the Latvian University of Riga, a post which he held until 1940. During his tenure of office he was also dean of the faculty of medicine, founder and editor of the *Latvian Medical Journal*. During the second world war, when Latvia was overrun in succession by the Germans and the Russians, his properties were confiscated and he was forced to return to private practice to earn a living. In September, 1944, he escaped from communist Latvia and worked, at the request of the French and American authorities, first at the displaced persons camp at Mulhouse and later at a similar camp at Blomberg, in Germany. In both places he earned the highest praise from the respective governments. Finally, in August, 1948, he sought refuge in England, where he stayed with his daughters until his death.

Dr. Alksnis was the author of a large number of scientific papers in the Latvian, Russian, and German languages. He

travelled extensively and visited the universities of most European countries. The Lithuanian University of Kaunas conferred on him an honorary degree, and the Finnish and Estonian medical societies elected him an honorary member. Over forty of his former pupils, including his son, are practising in exile or in occupied Latvia. A Professor J. Alksnis Scholarship for medical students has been created by the Latvian Medical Association in exile to perpetuate the memory of their eminent master. His unselfish devotion to his suffering Baltic compatriots gained him the admiration and affection of everybody. His greatness was matched by a rare nobility of character and unusual modesty.—H. R.

G. MONTUS, M.D.

Dr. G. Montus, deputy director of the World Health Organization's regional office for Europe, died in Geneva on April 1. Gérard Montus was born in 1902 at Carry-le-Rouet, near Marseilles, and graduated in medicine at Montpellier University. After postgraduate study in Paris at the Pasteur Institute and at the university, he took a degree in public health. For some time thereafter he was in charge of the children's clinic at the University of Marseilles, and later became departmental director and then regional director of health at Marseilles, and director of child health at the Ministry of Health in Paris. Dr. Montus was a member of several French delegations to the World Health Organization and its Interim Commission. He joined W.H.O. in 1949 as European regional adviser on maternal and child health, and later became chief of the headquarters social and occupational health section. In 1952 he was appointed deputy director of the regional office for Europe, and after the death of the Director, Dr. Begg, in 1956, he took over the direction of the office until ill-health forced him to relinquish his duties.

W. L. HARNETT, C.I.E., M.D., F.R.C.S.

J. B. H. writes: The death of Lieutenant-Colonel W. L. Harnett, whose obituary was printed in last week's *Journal* (p. 1067), removes one of the most distinguished officers of the late Indian Medical Service, remarkable alike for his work in the Service and after retirement. A surgeon of great judgment and dexterity, he was one of a group of outstanding teachers of surgery in the years between the wars. His influence was felt throughout North-East India and beyond, where he did more than any other man to instil the principles and practice of asepsis. He was a man of great charm and simplicity, always accessible, never hurried or discourteous, and, as the writer of these notes has good reason to remember, always helpful to juniors whom he considered to be keen. His pride and affection for his service were deep; and of late years nothing gave him more pleasure than to meet its members and talk over old days. It was characteristic of him on these occasions that he seldom mentioned his own great contributions to its reputation.

SIR JOHN MEGAW, K.C.I.E., writes: The news of the sudden death of Lieutenant-Colonel Harnett will cause deep sorrow to his many friends—he had no enemies. Few men have been so richly endowed with a natural gift for enlisting the esteem and friendship of everyone with whom he came in contact. There is an element of tragedy in the circumstances that only five days before the funeral at which he died he had been attending another one, that of his very old friend Major-General W. V. Coppinger, I.M.S., though for himself the sudden end was not a tragedy but a blessing. Harnett served with great distinction, especially in the last years of his career in India, and he would certainly have been selected for a high administrative appointment if it had been possible for him to delay his retirement. The award of the distinction of C.I.E. was universally regarded as a fitting recognition of his outstanding work as professor of surgery at the Medical College of Calcutta, where he was equally successful as a teacher and a highly

skilled surgeon. He was one of the most distinguished of the many able alumni of the great London hospitals who occupied this post and did so much to maintain high standards of surgery in Calcutta and eastern India.

FREDERIC DURAN-JORDA, M.D.

The obituary of Dr. Frederic Duran-Jorda was printed in the *Journal* of April 20 (p. 953).

B. H. writes: I was among the first to meet "Frederico" in his laboratory technician days at Ancoats Hospital. I shall never forget the charm of his personality, the cheerfulness that radiated from him, the dynamic energy, the smile, originating from Hispanic sunshine, that even Manchester fog could not subdue. He had fought for what he thought was right, had lost everything, and then had had to start all over again, from a lab-boy position (or bottle-washer, as he would describe it with a smile), and then he would tell me without any bitterness of the degradation and humiliation of the refugee before he is accepted. His smile was for all, even for the most junior of his staff, who all worshipped him. Here was a man whose personality was completely emancipated from the virus of prejudice of any kind. I shall miss his "Amigo mio." He was finally doomed to die from a blood disease whose remorseless advance he knew, as it came within his own specialty, and yet in spite of this knowledge he carried on with his work till a couple of days before his death. Verily, *Sunt lacrimae rerum et mentem mortalita tangunt*. My deepest sympathy goes out to his wife and children.

R. H. DALE, M.B., F.R.C.S.Ed.

The obituary of Dr. R. H. Dale was printed in the *Journal* of April 13 (p. 887). The following appreciation was given by Professor ERIC M. NANSON, professor of surgery in the University of Saskatchewan, at the opening of surgical "grand rounds" on April 6.

"This morning I wish to speak to you about Dr. Robin Dale, who died suddenly last Tuesday and whose funeral will take place this afternoon. I purposely did not cancel these 'grand rounds' because I wanted to take this opportunity to speak to you about Dr. Dale, and because I felt that he would have preferred us to continue with our rounds as usual and for you to feel that he was with us in spirit as we carried on with our discussions. As you know, he was a regular attendee of these surgical rounds and contributed much to our discussions from his broad knowledge. I feel that I can speak on three counts about Dr. Robin Dale. First as a friend and colleague: I was very fond of him, and he often used to visit our house and have a meal with us. I got to know him reasonably well and admired him tremendously. Secondly, as a surgeon I can speak of him, as he and I operated on several cases together. He was a most pleasant colleague to work with, and he was a most able surgeon. I had a great admiration for his judgment and his ability, and we in this university and in this department of surgery are going to miss his ability in the field of plastic surgery a great deal. Thirdly, I can speak of him as a teacher. I often used to call upon him to give lectures and clinics to the students, and he was always willing to do so and never turned me down. He prepared his lectures with great care. He was not a fluent speaker; if anything, he tended to be somewhat hesitant, but the material which he presented and the order in which he presented it, and the clarity with which he presented it, were indeed excellent, and the students who have listened to him, I am sure, will remember him always and be grateful to him. On these three counts, therefore, I feel confident to express the deep regrets of the department of surgery on the untimely death of our colleague Dr. Dale, and I would therefore ask you to rise for a minute's silence to express our sorrow at his passing."

Medical Notes in Parliament

Strontium Contamination

Mr. HECTOR HUGHES (Aberdeen, North, Lab.) called attention on May 3 to the necessity of preserving world food supplies from contamination by strontium-90 released in nuclear bomb tests. He asked what was being done by the British Government, alone or in conjunction with others, to protect people from the dangers of this infection, and urged that it was the duty of any Government undertaking these tests to provide protective measures.

Mr. J. GODBER, Parliamentary Secretary, Ministry of Agriculture, Fisheries and Food, said the danger of contamination of fish from the gradual fall-out from the upper atmosphere was negligible. In 1956 the Agricultural Research Council embarked on a field trial at Compton Research Station of the uptake of strontium from the soil by barley, grass, and sugar beet, using strontium-89. This experiment provided fundamental knowledge in the event of agricultural land becoming contaminated by nuclear attack or by an accident at an atomic power station. The results had not been published, but he could say that the uptake of strontium by the plants grown was less than 1% of the amount put down. The trial was being extended this year to various experimental husbandry farms of the Ministry, and five different types of soil had been chosen. Crop and soil samples would be taken during the growing season, and it was hoped that a report on the results would be available before the end of the year.

The Atomic Research Establishment at Harwell, in co-operation with the Ministry of Agriculture, had been for some years carrying out investigations to show the uptake of strontium-90 from the soil and in its movement through plants, animal tissues, and milk. Nine sites had been chosen, and samples of soil, grass, animal bones, and milk were taken. The results were being compared with the results of similar work in the United States, and the work was also extended to Commonwealth countries. The seriousness of the possible results of radioactivity must be realized, but it would be wrong to leave the impression that all this work was being done because of any immediate or foreseeable danger to human beings or farm animals.

Strontium Contamination in Wales

Dr. BARNET STROSS (Stoke-on-Trent, Central, Lab.) asked the Minister of Agriculture, Fisheries, and Food if he had considered the report of the Medical Research Council regarding the heavy contamination of the soil and of green vegetables by radio-strontium in some areas of Wales; and what warning or advice he had issued. Mr. J. GODBER, the Parliamentary Secretary, replying on May 6, said that in a few mountain areas precipitation had been found to be higher than average. The report of the Medical Research Council did not, however, suggest that this was a cause for alarm, and the Minister was advised that the safety margin before there could be any fear of risk to human beings or to animals was a very wide one. The position was being closely watched.

Mr. CLEDWYN HUGHES (Anglesey, Lab.) asked what was the reason for this greater contamination in Wales, and what specifically was being done to watch the situation. Mr. GODBER said he was unable to give any reason. The Government had arranged for tests to be made at regular intervals. It was necessary to find out more about this subject before any more could be said.

Compensation Sought for Dr. Adams

Mr. HECTOR HUGHES (Aberdeen, North, Lab.) asked the Home Secretary on May 2 whether he proposed to award out of public moneys a payment to Dr. Adams, who was wrongly detained in custody for a considerable period on a charge of murder, tried and found not guilty, and discharged;

and whether he would set up a tribunal to hear and determine publicly in a judicial manner on evidence and argument the correct amount to be so assessed and awarded to Dr. Adams. Mr. R. A. BUTLER replied that it was not the practice to make an *ex-gratia* payment from public funds to a person who had been acquitted of a criminal charge unless there had been misconduct or negligence on the part of the police or other public officials. If a defendant was acquitted after trial on indictment the court had power under the Costs in Criminal Cases Act, 1952, to order the payment of such sums as appeared to the court to be reasonably sufficient to compensate the accused for the expenses incurred in carrying on the defence. He understood that the court did not make any order in this case, and he could find no grounds on which he would be justified in making a payment out of public funds.

Mr. ENOCH POWELL, Secretary to the Treasury, told Mr. Hughes that the accounts and claims for fees had not yet all been received. Mr. HUGHES then asked him whether the Treasury intended to pay any part of the expenses for Dr. Adams's defence. Mr. POWELL said he would like to see that question before answering. Mr. SYDNEY SILVERMAN (Nelson and Colne, Lab.) said that, in spite of the expenditure of what must have been a very large sum of money, at the trial the prosecution seemed to be totally unaware of a number of basic and elementary facts which the defence was able to produce. Would the Financial Secretary consider whether the money, whatever sum it was, was wisely and efficiently spent? Mr. POWELL said that the initiation and conduct of the case was a matter not for him but for the Attorney-General.

Freedom to Prescribe Drugs

The EARL OF CRAVEN asked the Government on May 1 if they would consider, in the light of conditions arising out of the case of Dr. Adams, whether the time was appropriate for a review of the laws relating to the use of drugs for medical purposes. Lord STRATHCLYDE, Minister of State at the Scottish Office, said the Government did not consider it appropriate to circumscribe the clinical freedom of doctors to treat their patients in accordance with their individual judgment, except in so far as a doctor's authority to possess or prescribe dangerous drugs might be withdrawn after conviction for an offence under the Dangerous Drugs Act, as might happen at present. The EARL OF CRAVEN then asked if the Government were prepared to sanction euthanasia in any form. Lord STRATHCLYDE said that was a completely different question, of which he would require notice before answering.

Vacancies in the Colonies

Mr. DAVID JONES (The Hartlepoons, Lab.) asked the Secretary of State for the Colonies to what extent there were still vacancies for doctors in the Colonial territories, after the 300 applications which he received each year from qualified doctors already in the Health Service in this country had been appointed to the Colonial medical service and allocated their posts. Mr. A. LENNOX-BOYD stated on May 1 that there were generally some 120 to 150 vacancies at any given time, recruitment being roughly balanced by normal wastage, and, in some cases, by expansion in territorial establishments. By no means all the 300 applicants took up appointments.

He stated in another reply that approximately 45 of the 300 applicants were, on the average, rejected. Of the remainder, about half withdrew their applications or declined offers of appointment. Not all of these applicants were employed in the Health Service.

General Practitioners in Health Service

In reply to Mr. SOMERVILLE HASTINGS (Barking, Lab.), Mr. D. VOSPER stated on May 3 that the number of doctors providing unrestricted general medical services under the Health Service in England and Wales on July 1, 1956, was 20,996. Of these, 19,082 were principals, 1,546 were assistants, and 368 were trainees.

Mental Hospital Superintendents

Mr. KENNETH ROBINSON (St. Pancras North, Lab.) asked the Minister of Health if he was aware of the increasing difficulty in obtaining suitable candidates for the post of physician superintendent in mental and mental deficiency hospitals, owing to the lack of any financial inducement to compensate for the extra responsibilities involved; whether he had considered the views of the Bradbeer and Guillebaud Committees which had a bearing on this subject; and what he proposed to do to remedy the situation. Mr. D. VOSPER replied that he was aware of the difficulty. The level of remuneration of these officers was within the terms of reference of the Royal Commission on the pay of doctors and dentists.

Weekly National Health Contribution

The introduction of separate weekly contributions by all nationally insured people to the National Health Service is the main provision of a Bill published last week. At present about £40m. a year is transferred from the National Insurance Fund to the Health Service. This corresponds to 10d. a week for insured men, 8d. for insured women, and 6d. for insured boys and girls. The Bill provides for these contributions to be doubled, for them to be paid into a separate fund for the Health Service, and in consequence for the contribution of about £40m. from the National Insurance Fund to cease.

Medico-Legal

FAMILY LIMITATION AND DESERTION

[FROM OUR MEDICO-LEGAL CORRESPONDENT]

Mr. and Mrs. Whitehead were married in 1945, when both were in their twenties. They had two children. The elder, a boy born in 1948, subsequently died. Mr. Whitehead wanted further children, but his wife expressed a marked unwillingness, amounting in effect to a refusal, to have any more. Her husband then left, and after leaving her said everything he could to make it clear that his intention to leave her was absolute and permanent. Mrs. Whitehead took out a summons for maintenance against him before the Burnley justices on the grounds of desertion and wilful neglect to maintain, but the justices decided that her refusal to have a third child was a good defence for the husband. Mrs. Whitehead then appealed to the Divorce Divisional Court.

In giving the judgment of the court allowing the appeal¹ the President, Lord Merriman, said that the real question in the case was whether the husband had proved that he had "just cause" for leaving his wife. What the magistrates had found was that the wife's refusal to have a third child, though he would prefer to call it marked unwillingness, was governed by the same principle as refusal to have any children at all. A refusal to have sexual intercourse at all or without contraceptives could, if calculated to injure the husband's health, amount to cruelty and therefore be an answer to any complaint of desertion or wilful neglect to maintain. But to apply that principle where there were children already was a step for which there was no authority. Where was it to stop? At the Scriptural quiverful of three, or at four or at five? It would make havoc of the conception of marriage if after what many people might think a large enough family had been raised the husband could then say: "Thank you very much. You refuse to have any more children. I am now justified in leaving you." That was reducing marriage to an absurdity.

The court held that Mr. Whitehead had both deserted his wife and wilfully neglected to provide reasonable maintenance for her, and ordered that the amount of maintenance should be referred for determination to a different bench of justices.

¹ Daily Telegraph, May 3, 1957.

INFECTIOUS DISEASES AND VITAL STATISTICS

Summary for British Isles for week ending April 20 (No. 16) and corresponding week 1956.

Figures of cases are for the countries shown and London administrative county. Figures of deaths and births are for the 160 great towns in England and Wales (London included), London administrative county, the 17 principal towns in Scotland, the 10 principal towns in Northern Ireland, and the 14 principal towns in Eire.

A blank space denotes disease not notifiable or no return available. The table is based on information supplied by the Registrars-General of England and Wales, Scotland, N. Ireland, and Eire, the Ministry of Health and Local Government of N. Ireland, and the Department of Health of Eire.

† Includes primary and influenza pneumonia.

‡ Includes puerperal pyrexia.

Vital Statistics

Scotland in 1956

The preliminary return for the year shows that the birth rate for 1956 was 18.5 per 1,000 population. This was 0.5 above the rate for 1955 and was the highest since 1949. The infant mortality rate, at 29 per 1,000 live births, was 1 below the rate for 1955 and the lowest ever recorded. The death rate was 12.0 per 1,000 population, the same as for 1955 and 1954. The 318 deaths attributed to the principal infectious diseases included 262 from influenza, 26 from meningococcal infections, 14 from whooping-cough, 10 from measles, and 2 each from diphtheria, scarlet fever, and typhoid. Deaths from tuberculosis numbered 714 from respiratory and 85 from other forms, and these were 146 and 37, respectively, fewer than in 1955. Deaths attributed to violent causes included 397 to suicide, and 586 to road transport accidents.

In the December quarter of 1956 the birth rate was 17.9 per 1,000 population, and was 0.9 above the average of the five preceding fourth quarters. The infant mortality rate was 30 per 1,000 registered live births and was the lowest for any fourth quarter, being 1 below the preceding lowest level. The death rate was 11.6 per 1,000 population and was 0.1 below the five years' average.

Graphs of Infectious Diseases

The graphs below show the uncorrected numbers of cases of certain diseases notified weekly in England and Wales. Highest and lowest figures reported in each week during the nine years 1948-56 are shown thus -----, the figures for 1957 are shown as a solid line. Except for the curves showing notifications in 1957, the graphs were prepared at the Department of Medical Statistics and Epidemiology, London School of Hygiene and Tropical Medicine.

Infectious Diseases

Infectious diseases were less prevalent in England and Wales during the week ending April 20. The falls in the notifications included 5,488 for measles, from 27,275 to 21,787, 726 for whooping-cough, from 2,616 to 1,890, 297 for dysentery, from 1,171 to 874, and 173 for scarlet fever, from 740 to 567.

42 cases of acute poliomyelitis were notified, being 4 more for paralytic and 1 more for non-paralytic cases than in the preceding week. The largest returns were Essex 14 (Brightlingsea U.D. 11, Colchester M.B. 2), London 4 (Lambeth 2), Kent 3 (Beckenham M.B. 2), and Surrey 3 (Malden and Coombe M.B. 2).

The chief exception to the falling trend in the incidence of measles was a rise of 212 in Leicestershire, from 195 to 407, and the main contributors to this rise were 71 in Barrow upon Soar R.D., from 28 to 99, 55 in Castle Donington R.D., from 0 to 55, and 42 in Market Harborough U.D., from 102 to 144. Decreases of 100 or more in the notifications of measles were reported from 13 counties. Within these counties some areas recorded large increases, the principal being 82 in Essex, Romford M.B., from 52 to 134, 73 in Lancashire, St. Helens C.B., from 143 to 216, 67 in London, Lewisham, from 120 to 187, and 59 in Yorkshire West Riding, Dewsbury C.B., from 121 to 180. The largest declines in the notifications of whooping-cough were 65 in Hertfordshire, from 109 to 44, 59 in Yorkshire West Riding, from 145 to 86, 58 in Kent, from 201 to 143, 51 in Glamorganshire, from 94 to 43. 7 cases of diphtheria were notified, being 4 more than in the preceding week; the largest returns were Birmingham C.B. 3, and Hull C.B. 2. A small fall in the incidence of scarlet fever occurred throughout the country; the largest fall was 33 in Middlesex, from 53 to 20.

The chief feature of the returns for dysentery was an increase of 95 in the number of notifications from Surrey. The largest falls were 133 in Yorkshire West Riding, 71 in Lancashire, 51 in Cheshire, and 50 in Nottinghamshire. The

chief centres of infection during the week were Yorkshire West Riding 213 (Bradford C.B. 64, Leeds C.B. 40, Rotherham R.D. 26, Rotherham C.B. 23, Sheffield C.B. 18), Surrey 114 (Chertsey U.D. 108), Lancashire 102 (Liverpool C.B. 17, Manchester C.B. 17, Ashton under Lyne M.B. 14, Blackpool C.B. 13), Northumberland 66 (Longbenton U.D. 31, Seaton Valley U.D. 24), Nottinghamshire 37 (Nottingham C.B. 13, Mansfield C.B. 12), London 36 (scattered through 13 boroughs), Essex 34 (West Ham C.B. 19), Cheshire 34 (Hyde M.B. 19), Kent 33 (Dartford M.B. 16, Chislehurst and Sidcup U.D. 12), Durham 31 (South Shields C.B. 14), Southampton County 26 (Southampton C.B. 13), and Warwickshire 22 (Birmingham C.B. 19).

The largest outbreak of food-poisoning was 67 notifications in Glamorganshire, Cowbridge R.D., and this was the largest outbreak in recent weeks.

Week Ending April 27

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 542, whooping-cough 2,237, diphtheria 7, measles 26,960, acute pneumonia 425, acute poliomyelitis 63, dysentery 570, paratyphoid fever 2, and typhoid fever 5.

Industrial Accidents and Diseases

The number of workpeople (other than seamen) in the United Kingdom whose deaths from accidents in the course of their employment were reported in March was 123, compared with 101 (revised figure) in the previous month and 117 (revised figure) in March, 1956.

The numbers of cases of industrial diseases in the United Kingdom reported during March, 1957, were as follows: lead poisoning 1, phosphorus poisoning 1, epitheliomatous ulceration 10, chrome ulceration 18, total 30. There were no deaths.—*Ministry of Labour Gazette*, April, 1957.

Northern Ireland in 1956

The Registrar-General for Northern Ireland reports that in 1956 the general death rate, infant mortality rate, and tuberculosis death rate were the lowest ever recorded. As elsewhere, the cancer death rate for males increased.

The birth rate was 21.1 per 1,000 population, an increase of 0.3 over that for 1955. The general death rate was 10.6 per 1,000 live births. The death rate from cancer for males rose from 155 per 100,000 male population in 1955 to 162 in 1956. The corresponding rates for females were 157 and 154. The increase in the rate for males was mainly due to deaths from lung cancer and to a less extent to deaths from cancer of the stomach. Since 1946 male mortality from lung cancer has increased by 210%. The death rate from tuberculosis was 12 per 100,000 population. No deaths from diphtheria were registered.

Universities and Colleges

UNIVERSITY OF OXFORD

Dr. E. D. Acheson has been elected to a Radcliffe Travelling Fellowship.

UNIVERSITY OF CAMBRIDGE

In Congregation on March 23 the following degrees were conferred:

M.Chir.—C. H. Talbot (by proxy).
M.B.—S. J. Steele, D. E. R. Bateman, W. M. A. Wright.

UNIVERSITY OF LONDON

Professor B. S. Platt has been nominated as representative of the University on the governing body of the National Society's Training College of Domestic Subjects, and Dr. Aubrey Kagan as representative on the governing body of the Holland Park Secondary School.

The Paul Philip Reitlinger Prize for 1956 has been awarded to Lionel Edgar Thomas (King's College Hospital Medical School).

Medical News

World Red Cross Day.—May 8, the 129th anniversary of the birth of Jean Henry Dunant, the Swiss philanthropist and founder of the Red Cross movement, was celebrated as "World Red Cross Day." When it began the Red Cross was almost entirely confined to the treatment of those wounded in war, but to-day, states LORD WOOLTON, chairman of the British Red Cross Society, the peacetime demands on it are almost as great as those in times of war. Lord Woolton appeals for both money and more members. "Helping in inter-nation disasters, providing nursing and education, work in the Colonies—where we have 47 branches—is costing the British Red Cross £70,000 a year more than its income," he states, "and for my part I do not know where we could withdraw or withhold the help we give." Describing the Society's work, Lord Woolton tells of the setting up of a new organization, the Radio Amateur Emergency Network, to deal with breakdowns in communications as occurred during the East Coast floods in January, 1953. It is a co-operative venture between the G.P.O., the Red Cross, and the Radio Society of Great Britain.

Clinical Genetics Research Unit.—The Medical Research Council announces the establishment of a Clinical Genetics Research Unit under the directorship of Dr. J. A. FRASER ROBERTS, lecturer in medical genetics at the London School of Hygiene and Tropical Medicine. Accommodation for the unit has been provided at the Institute of Child Health, The Hospital for Sick Children, Great Ormond Street, London, W.C.1. The unit's research programme includes the investigation of congenital malformations and hereditary abnormalities and diseases and studies of the role of inheritance in common diseases.

Clinical Research in the N.H.S.—The Ministry of Health has issued a memorandum on clinical research, stressing the importance of its continuance and development for the efficiency of the Health Service. The memorandum describes the powers and duties of regional hospital boards, boards of governors, and management committees for promoting clinical research; the opportunities for co-operation in this field; and the means of financing it. Attention is drawn specifically to the four-year-old White Paper, *Clinical Research in Relation to the National Health Service* (H.M.S.O., 1953), whose recommendations were accepted in principle by the Government at the time (see *British Medical Journal*, 1953, 2, 140), and to the powers to conduct research conferred on hospital boards and committees by Section 16 (2) of the National Health Service Act, 1946. The Minister, states the memorandum, hopes that boards and committees will do "all that lies in their power to foster clinical research in their hospitals." The memorandum goes on to recall the functions of the Medical Research Council's Clinical Research Board—the organization of major clinical research schemes financed from Exchequer funds and the suggestion of new clinical research units for which the M.R.C. might assume responsibility—and explains how hospital boards and committees may avail themselves of the Clinical Research Board's assistance. Besides this "centrally organized" research, the memorandum also deals with "decentralized" research carried out with Exchequer funds by hospital boards and committees themselves. There is also a short note on locally organized research from non-Exchequer funds. An appendix gives the composition of the Clinical Research Board. Its chairman is Sir GEOFFREY JEFFERSON, F.R.S., and the secretary, Dr. F. J. C. HERRALD, of the M.R.C. Headquarters Staff, at 38, Old Queen Street, London, S.W.1.

Children in Hospital.—The Paediatric Committee of the Royal College of Physicians has issued a five-page report on the care of children in hospital. The committee was

appointed in October, 1952, under the chairmanship of Professor N. B. CAPON. After affirming that special children's hospitals offer the best service for children, the report recommends that the children's block in large general hospitals should be self-contained. Close association with the obstetric department is desirable. If there is no separate children's block, then all children should be in special wards in a single unit supervised by a paediatrician. Units of less than 20 beds are uneconomic; and the report goes on, "It is unnecessary and undesirable to attempt to provide a children's unit in every general hospital or even every area hospital... the emphasis should be on the best treatment for children and on the best training for those who are responsible for the medical and nursing care of children, and this implies some concentration of children's beds." The establishment of branch out-patient departments lessens the need for small residential units. In teaching centres there should be at least one paediatric bed for "each annual student entry." As to the nursing of sick children, the report states that the most suitable curriculum and training has yet to be evolved. Experiments now being carried out at some centres may help to solve this problem. In the larger paediatric units a child psychiatric unit of 8 to 12 beds would be an advantage. Accommodation for the isolation of infectious cases must be available in all paediatric units, and hospitals for infectious disease should work in close association with paediatric departments. When a vacancy occurs on the staff of an existing infectious disease hospital, the committee recommends that a paediatrician should be appointed. The committee's final recommendation is that in each region there should be a paediatric committee to advise the regional board.

W.M.A. Delegation to World Health Assembly.—The World Medical Association has sent a delegation to the tenth World Health Assembly which opened in Geneva on May 7. The delegation's object, in accordance with one of the aims of the W.M.A., is "to present the views of the medical profession to the World Health Organization." The W.M.A. council is specially concerned to give evidence in the Assembly's technical discussion on "The Role of the Hospital in the Public Health Programme," and it has forwarded a document to W.H.O. setting forth the "practising doctor's evaluation" of what this role should be. Among others, the W.M.A. document makes this point: "The general practitioner is the doctor best qualified to offer continuity of health care. He should have free access to the hospital to continue the patient's health care and to provide him with the opportunities of continuing medical education provided through hospital meetings and research."

Rockefeller Foundation Grants.—In the Rockefeller Foundation's list for the first quarter of 1957, grants totalling \$2.7m. are reported. Medical education and public health received \$571,000, biological and medical research \$806,600. Grants to the British Commonwealth included: \$36,000 for research equipment for the School of Biochemistry, Cambridge; \$25,000 for research equipment for the Calcutta School of Tropical Medicine; £10,000 (over two years) to London University to support work directed by Professor J. Z. YOUNG, F.R.S., at University College, on the structure and functioning of the brain; \$27,500 (over three years) to support research on the physical chemistry of nucleic acids, directed by Professor D. O. JORDAN at Adelaide University; and \$25,000 (over three years) to support research on the biochemical factors affecting fertility by Dr. T. R. R. MANN, F.R.S., at the School of Veterinary Medicine, Cambridge. In the Republic of Ireland Professor E. J. CONWAY, F.R.S., of University College, Dublin, receives \$12,000 (over three years) towards his research on the biochemistry of cell membranes. Harvard University receives a grant of \$8,500 for the preparation of an edition of Newton's *Principia*.

Medical Portraits at Royal Academy.—The 189th exhibition of the Royal Academy of Arts, which opened at Burling-

ton House last week, includes a number of portraits of doctors. Among the oil paintings are portraits of Sir GORDON HOLMES, F.R.S. (No. 37), the late Dr. JOAN MALLESON (No. 55), Sir HUGH GRIFFITHS (No. 114), Sir HAROLD BOLDERO (No. 306), Professor JOHN FULTON, of Yale (No. 585), and Dr. ARTHUR BOUSFIELD (No. 664). There are also a pencil drawing of Sir GEOFFREY KEYNES (No. 1141), a bronze medallion of Sir HENRY DALE, O.M., F.R.S. (No. 1382), and a bronze bust of Mr. DOUGLAS ROBB, F.R.C.S., Vice-president of Auckland University College, New Zealand (No. 1422). Among other exhibits of medical interest are the B.M.A.'s new seal (No. 1439), described by its designer, Mr. W. M. Gardner, on p. 1117 of this *Journal*, an oil painting, "Anti-polio Vaccination Begins" (No. 294), and a pen drawing called "Minor Operation" (No. 1012).

Sir Hugh Cairns Memorial Fund.—At a meeting of Congregation at Oxford on April 30 approval was given to the establishment of a Fund in memory of the late Sir HUGH CAIRNS. Viscount NUFFIELD is associated with the University in the memorial, which is to take the form of a fund for neurological research. The fund will be administered by the Nuffield Committee for the Advancement of Medicine and will receive a sum of £2,000 annually from the Nuffield Medical Benefaction to assist research in neurology and neurosurgery in the Oxford Medical School. Sir Hugh Cairns was Nuffield professor of surgery at Oxford at the time of his death in 1952. He was then 56.

Gift to Wright-Fleming Institute.—The Pfizer Corporation has presented an automatic sample-changer Geiger counter to the Wright-Fleming Institute of Microbiology at St. Mary's Hospital, Paddington. The counter, which was built in the United States and is valued at about £1,500, brings up automatically 35 different sample-pans containing isotopically labelled samples for counting. It is currently being used by Dr. D. ROWLEY, head of the department of bacterial physiology at St. Mary's, for research on non-specific immunity. It is stated that the only other similar machine in Britain is the one in the department of radiotherapy at Cambridge.

Treatment Centres for Venereal Diseases.—The Ministry of Health has published a revised list of treatment centres in the United Kingdom and the Republic of Ireland. This list has been issued to treatment centres, regional hospital boards, hospital management committees, medical officers of health, and port health authorities. The leaflet for seamen, naming treatment centres in ports of Great Britain and Northern Ireland, has also been revised. It has been issued to port health authorities and through the Ministry of Transport to ships.

Dr. H. L. Glyn Hughes has retired as S.A.M.O. of the South-east Metropolitan Regional Hospital Board. He is to survey the needs of homes for the dying in Britain on behalf of the Calouste Gulbenkian Foundation. Most of these homes are religious foundations. Dr. Glyn Hughes's successor is Dr. J. S. S. FAIRLEY, the Board's deputy S.A.M.O.

Middle East Medical Assembly.—Sir RUSSELL BROCK (Guy's Hospital), Dr. PAUL WOOD (Institute of Cardiology), and Mr. RODNEY MAINGOT (Royal Free Hospital) are attending the Middle East Medical Assembly in Beirut, Lebanon, from May 10 to 12. Afterwards Sir Russell Brock will lecture in Turkey, and Dr. Wood in Italy. These visits are under British Council auspices.

Dr. A. S. Parkes, F.R.S., head of the division of experimental biology at the National Institute for Medical Research, left for a three-week visit to Yugoslavia on May 5. He is lecturing in Belgrade, Zagreb, and Ljubljana on low-temperature research and the grafting of ovarian tissue. His visit is at the invitation of the Yugoslav National Commission for Unesco and the British Council.

COMING EVENTS

National Conference on Medical Records.—Arranged by the Association of Medical Records Officers. Brighton, May 16–19. Details from Mr. B. B. BONNER, 11, Queensway, Horsham, Sussex.

German Postgraduate Medical Congress.—Sixth congress, West Berlin, June 12–16. Details from the secretariat, Klingsorstrasse 21, Berlin-Steglitz.

British Council Courses for Overseas Specialists.—"Plastic Surgery," East Grinstead and Oxford, June 16–29 (£46); "Radioisotopes in Medicine," Sheffield and London, September 15–28 (£44); "Psychological Treatment of the Problem Child," London, November 17–30 (£42). Apply to local representative of the British Council.

Problems of Child and Juvenile Health.—International Conference in Berlin, June 25 to 27. Papers in English, German, and Russian. The conference aims at an exchange of experience between specialists from Eastern and Western countries. Details from Professor WINTER, Institut für Sozial-hygiene, Neue Wilhelm Strasse 15, Berlin W. 8.

NEW ISSUES

British Journal of Preventive and Social Medicine.—The new issue (Vol. 11, No. 1) is now available. The contents include:

CONTROL OF TUBERCULOSIS. IMPORTANCE OF HEREDITY AND ENVIRONMENT. A. W. Anderson, B. Benjamin, R. Grenville-Mathers, and H. J. Trenchard.
HOUSING AND TUBERCULOSIS IN A MASS RADIOGRAPHY SURVEY. G. Z. Breit and B. Benjamin.
CONTRIBUTION OF CIGARETTE SMOKING TO RESPIRATORY DISEASE. J. H. Edwards.
A SURVEY OF HANDICAPPED PERSONS. A. Leslie Banks, R. G. Carpenter, James A. Hislop, and George Nisbet.
RETINOBLASTOMA. OCCURRENCE OF THE CONDITION IN NORTHERN IRELAND, 1938–1956. A. C. Stevenson and V. A. F. Martin.
OBSERVATIONS ON THE INCIDENCE OF UPPER RESPIRATORY INFECTIONS IN A ROYAL AIR FORCE FORMATION IN SOUTHERN RHODESIA. W. B. Thorburn.
THE CONTRIBUTION OF THE NURSE IN GENERAL PRACTICE. D. L. Crombie and K. W. Cross.
VARIATIONS OF LOCAL MORTALITY RATES UNDER THE 1953–54 RULES FOR TRANSFER OF DEATHS. David Hewitt.

Issued quarterly; annual subscription £2 2s.; single copy 12s. 6d.; obtainable from the Publishing Manager, B.M.A. House, Tavistock Square, London, W.C.1.

Medical and Biological Illustration.—The new issue (Vol. 7, No. 2) is now available. The contents include:

FRONTISPIECE.
CASTING FINGERS IN PLASTER. W. Looker.
PHOTOSENSITIVE ANODISED ALUMINIUM PLATES. R. A. Kempe.
LINE PHOTOGRAPHY. Percy W. Bullock.
THE IDEAL LECTURE THEATRE—I. PROJECT IN SIGHT AND SOUND. Peter Hudson and Allan Low.
RETINAL CAMERA REVIEW. Peter Hansell.
A TECHNIQUE FOR DISPLAYING DEMONSTRATION SPECIMENS. Fred L. Miltenberger and Carroll R. Ball.
EQUIPMENT AND METHODS.
CLOSE RANGE STEREOSCOPY.
PHILIPS MICRORADIOGRAPH.
ADDITIONS TO ILFORD COLOUR FILM AND PRINT SERVICE.
ABSTRACTS.
BOOK REVIEWS.
MOTION PICTURES.
REPORTS FROM SOCIETIES.

Issued quarterly; annual subscription £2 2s.; single copy 12s. 6d.; obtainable from the Publishing Manager, B.M.A. House, Tavistock Square, London, W.C.1.

SOCIETIES AND LECTURES

A fee is charged or a ticket is required for attending lectures marked ●. Application should be made first to the institution concerned.

Sunday, May 12

KING'S COLLEGE HOSPITAL.—10.30 a.m. to 12 noon, clinical meeting for general practitioners.

Monday, May 13

LONDON UNIVERSITY.—At London School of Hygiene and Tropical Medicine, 5.30 p.m., special university lecture in medicine by Professor Charles Huggins (Chicago): On the Treatment of Mammary Cancer.

ROYAL INSTITUTE OF PUBLIC HEALTH AND HYGIENE.—5 p.m., Harben Lecture by Professor P. Drinker, D.Sc.: Air Pollution and the Public Health—Problem of Great Cities (illustrated).

UNIVERSITY COLLEGE LONDON.—At Chemistry Theatre, Gower Street, W.C., 5.30 p.m. Karl Pearson Centenary Lecture by Professor J. B. S. Haldane, F.R.S.

Tuesday, May 14

CHELSEA CLINICAL SOCIETY.—At Rembrandt Hotel, Thurloe Place, S.W., 7.30 p.m., annual dinner.

INSTITUTE OF DERMATOLOGY.—5.30 p.m., Dr. F. A. Whitlock: Neuro-physiology of Itching.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—5 p.m., Croonian Lecture by Professor G. W. Pickering: Regulation of Body Temperature in Health and Disease.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—3.45 p.m., Imperial Cancer Research Fund Lecture by Professor G. Hadfield: Application of Physiological Principles to Hormone-dependent Human Breast Cancer.

ROYAL INSTITUTE OF PUBLIC HEALTH AND HYGIENE.—5 p.m., Harben Lecture by Professor P. Drinker, D.Sc.: Air Pollution and the Public Health—Problem of Industry (illustrated).

ROYAL VETERINARY COLLEGE.—4 p.m., special university lecture by Professor R. A. Gregory: Some Aspects of Mammalian Gastroenterology.

ST. MARY'S HOSPITAL MEDICAL SCHOOL.—At Wright-Fleming Institute, 5 p.m., Almroth Wright Lecture by Dr. B. A. D. Stocker: Heritable Transformations of Bacteria.

SOCIETY OF APOTHECARIES OF LONDON.—5.30 p.m., 2nd Gideon de Laune Lecture by Sir Henry Dale, O.M., F.R.S.: Medicinal Treatment: Its Aims and Results.

WEST END HOSPITAL FOR NEUROLOGY AND NEUROSURGERY.—5.30 p.m., Dr. D. F. Bosanquet: Neuropathology.

Wednesday, May 15

INSTITUTE OF DERMATOLOGY.—5.30 p.m., Dr. H. Haber: The Dyskeratoses.

INSTITUTE OF DISEASES OF THE CHEST.—5 p.m., Mr. C. E. Drew: Experimental studies of the Extracorporeal Circulation.

LIVERPOOL UNIVERSITY: FACULTY OF MEDICINE.—At Physiology Lecture Theatre, Old Medical School, 5.15 p.m., Professor G. Wald (Harvard): Molecular Basis of Vision.

POSTGRADUATE MEDICAL SCHOOL OF LONDON.—2 p.m., Sir Howard Florey, F.R.S.: Endothelium.

ROYAL INSTITUTE OF PUBLIC HEALTH AND HYGIENE.—5 p.m., Harben Lecture by Professor P. Drinker, D.Sc.: Air Pollution and the Public Health—Prevention and Control (illustrated).

ROYAL MICROSCOPICAL SOCIETY.—5.30 p.m., Dr. E. H. Huxley and Dr. Jean Hanson: Studies on the Mechanism of Muscular Contraction.

WILKESDEN GENERAL HOSPITAL MEDICAL SOCIETY.—At Department of Physical Medicine, 8.45 p.m., Dr. P. R. Evans: Recent Changes in Paediatrics.

Thursday, May 16

ALFRED ADLER MEDICAL SOCIETY.—At 11, Chandos Street, W., 8 p.m., Dr. A. Spencer Paterson: Psychopathology of Schizophrenia.

BRITISH INSTITUTE OF RADIOLOGY.—8.30 p.m., Presidential Address by Mr. I. G. Williams: Role of Surgery and Radiotherapy in the Treatment of Breast Cancer.

INSTITUTE OF NEUROLOGY.—5.30 p.m., Dr. R. D. Hahn (U.S.A.): Tabes Dorsalis, with especial reference to Primary Optic Atrophy.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—5 p.m., Croonian Lecture by Professor G. W. Pickering: Regulation of Body Temperature in Health and Disease.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—3.45 p.m., Arnott Demonstration by Miss J. Dobson: Curiosities of Natural History.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE.—7.30 p.m., symposium to be opened by Dr. C. A. Hoare, followed by Group Captain W. P. Stamm, Dr. R. A. Neal, and Dr. G. Woolfe: Laboratory Aspects of Amoebiasis. A discussion will follow.

Friday, May 17

DUBLIN UNIVERSITY. TRINITY COLLEGE.—At Anatomy Theatre, 5 p.m., Montgometry Lecture on Ophthalmology by Dr. F. B. Walsh (Baltimore): Ocular Movements Associated with Regeneration of the Third Nerve.

INSTITUTE OF DERMATOLOGY.—5.30 p.m., Dr. P. J. Hare: clinical demonstration.

INSTITUTE OF DISEASES OF THE CHEST.—5 p.m., Dr. F. H. Young: open clinical demonstration.

POSTGRADUATE MEDICAL SCHOOL OF LONDON.—10 a.m., Professor A. M. Boyd: Management of Obliterative Arteriosclerosis of the Lower Extremity.

ST. MARY'S HOSPITAL MEDICAL SCHOOL.—At Wright-Fleming Institute Theatre, 5 p.m., Mr. J. D. S. Flew: Genital Prolapse.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Laidlaw.—On May 1, 1957, at Ronswood Hospital, Worcester, to Greta (formerly Mair), wife of Dr. A. J. Laidlaw, a brother for Fiona and Alastair—Kelvin Alexander Mair.

Nathanson.—On March 15, 1957, to Margaret (formerly Milman), wife of Dr. N. E. Nathanson, of 61, Mill Road, Higher Bebington, Cheshire, a daughter.

O'Kelly.—On April 18, 1957, at British Military Hospital, Tripoli, to Dorothy, wife of Captain Frank O'Kelly, R.A.M.C., a sister for Margaret.

DEATHS

Balleney.—On April 22, 1957, George Christopher Balleney, M.B., Ch.B., of 61, Higher Drive, Banstead, Surrey, aged 28.

Brown.—On April 18, 1957, at the London Hospital, Gerald Rowland Hamilton Brown, M.R.C.S., L.R.C.P., of 40, Lancaster Road, London, N.

Causton.—On April 18, 1957, at St. John of God Nursing Home, Torquay, Devon, Edward Postle Gwyn Causton, O.B.E., aged 80.

Cheyne.—On April 19, 1957, William Hunter Watson Cheyne, M.B., B.Ch., D.T.M., of Crewkerne, Somerset, aged 67.

Fison.—On April 20, 1957, James Fison, M.D., of Flat 2, 28, York Place, Harrogate, Yorks.

Isaac.—On April 21, 1957, at his home, 1, Harwood Court, Upper Richmond Road, Putney, London, S.W., Hyman (George) Isaac, M.B., B.S., D.P.H., aged 77.

Norman.—On April 23, 1957, at the Old House, Tillingham, Essex, Alfred Clarence Norman, C.B.E., M.D., late of Bagdad, Iraq.

Porritt.—On April 23, 1957, at 71, Wavertree Court, Streatham Hill, London, S.W., Austin Thomas Porritt, M.R.C.S., L.R.C.P., Warwick.

Whitehouse.—On April 18, 1957, at 14, The Crescent, Solihull, Warwickshire, Edwin St. John Whitehouse, M.B.E., M.R.C.S., L.R.C.P., aged 89.

Any Questions?

We publish below a selection of those questions and answers which seem of general interest. It is regretted that it is not possible to supply answers to all questions submitted.

Indications for Exchange Transfusion

Q.—What are the clinical indications for carrying out an exchange transfusion in a newborn infant suspected of having haemolytic disease? Is it safe to defer decision for a day or two in a doubtful case, or should the transfusion be carried out at once?

A.—Infants with very severe haemolytic disease of the newborn are pale and oedematous at birth and may display signs of cardiac failure; exchange transfusion should be carried out immediately. Less severely affected infants appear healthy at birth but may develop jaundice within a few hours. The onset of jaundice within the first 24 hours is an indication for exchange transfusion.

It is much better not to wait for the onset of jaundice but to carry out laboratory tests immediately after birth to discover whether the infant is affected, and, if so, how severely. Exchange transfusion can then sometimes be carried out before jaundice develops and the results are likely to be better.

Respiratory Failure after General Anaesthesia

Q.—What are the likely causes of respiratory failure after apparent recovery from a long anaesthetic? The patient in question gradually stopped breathing soon after the operation, and, although oxygen and artificial respiration were administered, circulatory failure and death ensued. At post-mortem examination no cause was found to account for death.

A.—Hypoventilation is commonly permitted to occur in patients under general anaesthesia: it may be caused by central respiratory depression by opiates and anaesthetics, or by peripheral respiratory paralysis induced by curare or similar agents, or by both acting together. However, the usual signs of underventilation may easily be masked if an oxygen-rich mixture is being used. In addition, the anaesthetic apparatus itself, by imposing additional dead space and often by permitting carbon-dioxide accumulation (for example, from faulty design, incomplete carbon-dioxide absorption, or inadequate gas flows), may accentuate this hypercapnia. At the end of the operation, when the patient is disconnected from the anaesthetic apparatus a sharp fall in carbon-dioxide levels results, and this may be followed by a state of collapse with circulatory and respiratory depression—the condition named "cyclopropane shock." Some patients may succumb to this type of depression.

Respiratory depression in the post-operative period may result from partial respiratory paralysis due to the persisting effects of relaxants administered during anaesthesia; in addition there may be central respiratory depression from persisting anaesthetics (for example, intravenous barbiturates). Respiratory depression in the post-operative period due to opiates may be caused in various ways. Premedication given late may exert its maximal effect after anaesthesia; similarly, in shock the absorption of drugs may be retarded. Overdosage is especially likely to occur in elderly and debilitated patients, and the effect of drugs such as pethidine given during maintenance of anaesthesia may persist afterwards. The too early administration of post-operative analgesics or their inadvertent intravenous injection may also produce serious respiratory depression. Respiratory obstruction arising from inadequate post-operative supervision may also impair ventilation, and the signs of this may be minimal if respiratory depression coexists. In all these circumstances a climb in carbon-dioxide levels is certain and

oxygen lack may also develop (but this is often prevented by the use of oxygen during the recovery period).

It is believed that central depression can result from carbon-dioxide retention beyond a certain level, a vicious circle then being established. The progressive rise in carbon-dioxide tension will ultimately lead to cardiac failure, and, as in the case cited in the question, no characteristic changes are likely to be found at necropsy.

The results of the various factors discussed will be accentuated in the presence of surgical or haemorrhagic shock and also in the poor-risk patient—for example, with fluid and electrolyte depletion or emphysema.

Respiratory inadequacy is usually therefore the result of errors in technique. A greater awareness of the dangers of respiratory depression and paralysis should help to prevent deaths of this type.

Flea Repellent

Q.—What is the best flea repellent?

A.—Fleas cannot jump very far—probably less than 9 in. (23 cm.) upwards—and a common method by which they may gain access to a new host is by crawling up the lower limbs. It is therefore advisable to apply repellent to socks and the lower part of trouser legs. The best available repellent is dimethyl phthalate (DMP), which should be used undiluted. A few drops are poured into one hand, and the hands are rubbed together and then dried by wiping them on the garments mentioned. This should be repeated two or three times. Women can safely use the same repellent on nylon or cotton stockings, but its effect on cellulose fibres (e.g., artificial silk) is deleterious. A single treatment would last for several days, but would be removed by washing. This cannot guarantee protection from fleas which jump on to the person from infested furniture, or from infested individuals in a crowd. The only protection from these pests would be to dust the underwear with a rapidly acting insecticide such as pyrethrum, a powder containing 1% of pyrethrins.

Antilipæmic Therapy in Atherosclerosis

Q.—What place have thyroid extract and laminarin sulphate in the treatment of atherosclerosis?

A.—The use of thyroid extract or laminarin sulphate in the treatment of atherosclerosis is based on the assumption that it may be desirable to lower the levels of the circulating lipids, which are often elevated in patients who have developed clinical features of coronary or cerebral atherosclerosis. Thyroid extract lowers the plasma cholesterol and beta-lipoproteins, and laminarin sulphate decreases the prolonged lipaemia, but both are unsuitable for the treatment of atherosclerosis.

The administration of thyroid extract will increase the oxygen consumption and metabolic requirements of most tissues, and relative anoxaemia can result if the blood supply is impaired by atherosclerosis. For example, the function of atherosclerotic coronary arteries may be just adequate for the ordinary demands of the myocardium, but as soon as metabolism is increased by the administration of a thyroid derivative the atherosclerotic coronary arteries become relatively inadequate and angina develops or is aggravated; indeed, myocardial infarction can be precipitated by disturbing the balance between the supply and demand of the myocardium. Equally, thyroid extract should not be used for the treatment of cerebral atherosclerosis, since anoxaemia can lead to disorientation. Recently it has been shown that triiodothyronine and triiodothyroacetic acid can depress the plasma cholesterol without elevating the basal metabolic rate. However, this dissociation may be more apparent than real, since the oxygen uptake of certain tissues, particularly the myocardium, is increased even although there is no reflection of this in the overall measurement of the basal metabolic rate.

Laminarin is a polysaccharide obtained from seaweed, and when sulphated it possesses properties analogous to heparin. If it is only weakly sulphated, it retains its antilipæmic

property but no longer has any anticoagulant activity. Intravenous injection of laminarin sulphate results in temporary clearing of lipaemia and a temporary increase in the mobility of the beta-lipoproteins. Laminarin sulphate must be administered at least once daily to maintain either of these actions, and is apparently ineffective except when given intravenously. Even if some other parenteral route is found to be effective, it is unjustifiable to submit patients to an indefinite course of injections until more evidence is produced to show that the clearing of lipaemia is desirable.

This question is important because it raises a fundamental issue which is sometimes overlooked. It is not on the correction of the abnormal circulating lipids or of lipaemia that the efficiency and suitability of any particular treatment must be judged, but on its effect on prognosis. It has not yet been shown that the prolonged correction of the abnormal circulating lipids by any treatment has been associated with improvement in morbidity and mortality, and there is no conclusive evidence that the atherosclerotic process can be inhibited in the human. When an efficient and acceptable treatment can be proved to influence prognosis and inhibit the atherosclerotic process in the human, it should probably be offered primarily to the younger and apparently healthy members of the community. Any such prophylactic regime will depend on the perfection of diagnostic tests, so that those individuals who are likely to develop the clinical features of atherosclerosis can be selected with certainty from the healthy population.

Psychological Effects of Castration in Prostatic Cancer

Q.—What intellectual and temperamental changes result from therapeutic castration in the male (biochemical or surgical), as, for instance, in the treatment of cancer of the prostate?

A.—The type of case selected for this treatment is usually of an age where little or no temperamental or other changes occur. For the most part they are people who are more worried about the advance of their malignant disease than about the effects of castration, and if the situation is discussed with both them and their wives pre-operatively little or no trouble should ensue.

Royal Jelly

Q.—Startling claims are made for the rejuvenating effects of royal jelly, the food given to bee larvae to convert them into queens. What is the composition of the jelly, what is known of its mode of action on the bee larva, and what grounds are there for expecting a therapeutic effect in man?

A.—Royal jelly is the term reserved for bee milk in or from queen cells. This secretion is very rich in protein and contains some sugar and small quantities of thiamine, pyridoxine, nicotinic acid, pantothenic acid, biotin, inositol, and folic acid. It has a moisture content of about 67%.¹ Queen larvae and young worker larvae are entirely fed on bee milk, and subtle differences between the quality of the bee milk provided for queens and workers have been postulated. A very full presentation of the findings of a number of investigators on the composition of the food of queen and worker larvae and of the vitamin-B analysis of larvae and their foods, as well as a careful exposition of the whole position, is given by Ribbands.² He writes, "All investigators consider that the basis of the differentiation is nutritional, but the food supply of worker larvae differs from that of the queen larvae in both quantity and quality and the relative importance of these two attributes has not been agreed."

It is largely on the basis of the pantothenic acid and biotin content of royal jelly that the idea of a qualitative significance in food supply has arisen. Ribbands points out that considerable difficulties appertain to these vitamin analyses. Bee milk undergoes chemical changes when exposed in the open air and the sampling is of minute quantities. He also writes, "The idea of a vitamin-controlled differentiation based on biotin, pantothenic acid, or some combination of

vitamins is not fantastic. But there is no proof that these substances control the differentiation of queens and workers."

The theoretical basis for the use of royal jelly in man thus rests on a hypothesis which even in bees is as yet unproved. It will be extremely surprising, therefore, if the startling claims made for royal jelly as a human rejuvenator are eventually substantiated.

Improving the Nose

Q.—What are the essential principles of the various plastic operations to improve the shape of the nose?

A.—Plastic operations to improve the shape of the nose usually follow a set plan, of which the following are the main features: (1) The approach is by intranasal incisions between the lateral and alar cartilages and continued medially so as to detach the columella from the septum. An elevator is introduced and the skin over the nose completely freed from its osteocartilaginous framework. (2) Bone and cartilage from the bridge are then removed to give the desired profile. (3) Shortening of the nose is achieved by removing a wedge from the lower end of the septum, narrowing by infracturing the bony arch. (4) If there is a deformity of the tip of the nose needing correction, it is usually necessary to excise portions of the alar and lateral cartilages to reduce the bulk and the breadth of the tip. (5) Finally a splint is applied to immobilize the nasal bones and help mould the nose to its new shape.

Mercurial Diuretics and Falling Hair

Q.—Two women in their seventies have been taking a mercurial diuretic for the last eighteen months. Both now complain that their hair is rapidly falling out. Is this a recognized toxic effect of mercurial diuretics?

A.—Falling hair, unassociated with dermatitis, is not a recognized toxic effect of mercurial diuretics; nor is it typical of chronic inorganic mercury poisoning, all the symptoms of which may occur with organic mercury diuretics, although it has occasionally been recorded as occurring with mercury as with other heavy metals. It is extremely unlikely that these two patients are suffering from mercury poisoning, especially if there has been a good response to the diuretic. Poor growth of hair has been described in chronic heart failure.

Correction.—We regret that in the *Journal* of April 27 (p. 999) the late Mr. Stephen Paget, founder of the Research Defence Society, was inadvertently described as Sir Stephen Paget.

Books of "Any Questions?" and Refresher Course Articles.—The following books are available through booksellers or from the Publishing Manager, B.M.A. House. Prices include postage. *Any Questions?*, Volumes 2 and 3 (8s. each); *Refresher Course for General Practitioners*, Volumes 2 and 3 (26s. 6d. each inland, 26s. overseas); *Clinical Pathology in General Practice* (22s. 3d. inland, 21s. 9d. overseas).

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 4499. TELEGRAMS: MEDICIS. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proof. Authors overseas should indicate on MSS. if reprints are required, as proofs are not sent abroad. ADVERTISEMENTS should be addressed to the Advertisement Director, B.M.A. House, Tavistock Square, London, W.C.1 (hours 9 a.m. to 5 p.m.). TELEPHONE: EUSTON 4499. TELEGRAMS: BRIMEDADS. AETIOLOGICAL FACTORS IN MOUTH CANCER AN APPROACH TO ITS PREVENTION

BY

ERNEST L. WYNDER, M.D.

AND

IRWIN J. BROSS, Ph.D.

From the Section of Epidemiology, Division of Preventive Medicine, and the Research, Design and Analysis Service, Sloan-Kettering Institute, New York City

History has always been one of man's best teachers, a truism which applies also to man's quest to comprehend the nature of disease. We call to mind Snow's classical study on cholera through the use of epidemiological techniques. Through his observations a disease was curtailed and the mechanism of an illness more closely understood at a time when its exact pathogenesis was unestablished. To be learned from this historical study, too, is that one does not need to understand the mechanism of a disease completely in order to accomplish a reduction of its incidence.

This point is stressed because it represents the basis of current epidemiological studies in the field of cancer. While many factors may induce cancer and the basic mechanism of cancer is still beyond our reach, we know factors which do play a part in the development of cancer whose removal or reduction will lead to a decrease in incidence of this disease. This is the primary goal of the epidemiologist in his fight against any disease. If a given factor is found to contribute to a disease it is of little importance to the patient whether this factor was of causative or of catalytic nature. What matters to the population is whether the removal of a given factor will reduce the incidence of a given disease. The present investigation on aetiological factors of cancer of the oral cavity was designed to serve towards this end. This report, to be presented in greater detail elsewhere, will outline some of the factors which influence the development of cancer of the mouth and whose control can lead to a drastic reduction in this type of cancer (Wynder, Bross, and Feldman, 1957).

Incidence Pattern

One reason why environmental factors are thought to play a part in certain types of cancers is that these cancers have a varying incidence distribution. Environmental factors found to be statistically significant in an epidemiological study must, at least in part, account for variations in incidence patterns in any given cancer. Some interesting features of the incidence pattern of cancer of the oral cavity are as follows: (1) Cancer of the oral cavity in males has not increased during the last two or three decades, and even may have slightly decreased (Public Health Service, 1950-2). (2) A small increase has been noted in cancer of the oral cavity among women (Public Health Service, 1950-2). (3) Can-

cer of the oral cavity is predominantly a male disease, with sex ratios for different sites ranging from 2:1 to 10:1. (4) Cancer of the oral cavity is relatively common in Swedish women. In Sweden cancer of the tongue, gum, and buccal mucosa is about as frequent in women as in men (Wynder, Hultberg, Jacobsson, and Bross, 1957). (5) Cancer of the oral cavity is common in India, where it accounts for 40% of all male cancer admissions to the Tata Memorial Hospital (Khanolkar, 1950). (6) Cancer of the lip is more common in southern than in northern areas. Cancer of the lip is very uncommon among negro patients (Public Health Service, 1950-2). (7) At the Memorial Center for Cancer and Allied Diseases, New York, mouth cancer occurs relatively more often among Catholic than among Jewish men.

Methodology

The method was similar to that used in our previous studies (Wynder, Bross, and Day, 1956). We obtained information from a series of study-group and control patients through trained interviewers. The questions related to environmental, medical, and social background. This study sought to investigate all of those factors that at one time or another had been suspected to be associated with cancer of the oral cavity (Table I).

TABLE I.—Factors Suspected to be Related to Cancer of the Oral Cavity

1. Tobacco smoking	7. Dentures
2. Tobacco chewing	8. Dentures irritation and sharp teeth
3. Betel-nut chewing	9. Nutritional deficiencies (iron, riboflavin)
4. Sunlight	10. Hot beverages and foods
5. Alcohol consumption	
6. Syphilis	

With the exception of data on tobacco and syphilis, however, none of the factors had hitherto been based upon statistical analysis of data (Martin *et al.*, 1940; Moore, Bissinger, and Proehl, 1953; Sadowsky, Gilliam, and Cornfield, 1953; Sanghvi, Rao, and Khanolkar, 1955).

Upon completion of the interviews, the information was coded on International Business Machine (IBM) cards and the controls and the cancer cases were matched for age, religion, hospital status, and socio-economic background. The study cases were analysed separately for each specific site as well as for the whole group.

All cases had microscopical diagnosis and represented epidermoid cancer. The statistical analyses were carried out by one of us (I. B.), with the assistance of R. Feldman.

If a given factor was found to differ significantly, it was tested against other variables to determine possible interdependence.

The study is based upon 543 male cases of cancer of the oral cavity compared with 207 male control patients who had benign diseases of the head and neck, lymphomas, benign diseases of the thoracic region, or cancer

TABLE II.—Number of Cases by Site and Sex (Whites)

Site	Male	Female	Total
Lip	74	2	76
Floor of mouth	86	8	94
Gum	41	18	59
Buccal mucosa	40	12	52
Tongue	180	57	237
Palate	41	7	48
Tonsil	57	7	64
Pharynx	24	5	29
Total	543	116	659
Controls	207	246	453

of the lower gastro-intestinal tract as well as of the skin. The female group includes 116 female patients with cancer of the oral cavity who have been matched against 246 female control patients* (Table II). All cases studied—male and female, study and control—have been matched for the same background factors.

Results in Males

Tobacco

Smoking was found to be an important factor in the development of cancer of the mouth. Three per cent. of the study group were non-smokers, in contrast to 10% of the controls. Twenty-nine per cent. of the study cases had smoked 35 cigarettes or the equivalent of cigars or pipes per day for at least 20 years, in contrast to 17% among the controls (Fig. 1). No significant variations were found within the study group. The two sites which contained no non-smokers were the floor of the mouth and the buccal mucosa. The former site had been of particular interest to us because we have rarely seen a lesion of the floor of the mouth in a non-smoking male.

FIG. 1.—Incidence of mouth cancer according to number of cigarettes smoked daily.

The type of tobacco consumed by patients with cancer of the oral cavity is of considerable importance. The percentage of cigar and pipe smokers among patients with cancer of the mouth is higher for all sites than for the controls. Twenty per cent. among the study cases smoked predominantly cigars, 12% predominantly pipes, and 3% cigars and pipes equally. The respective percentages for controls were 13, 5, and 2 (Fig. 2). This again was uniform for the total study group. The group with the fewest predominant cigarette smokers was the buccal mucosa cancer group containing 43% predominant cigarette smokers. The highest group of predominant cigarette smokers were patients with cancer of the floor of the mouth, 67% (Table III).

TABLE III.—Diagnosis by Type of Smoking (Percentages Males)

Site	None	Cigarette	Cigar	Pipe	Mixed, With Cigarettes	Mixed, Without Cigarettes
Lip (74)	4	51	18	15	8	4
Floor of mouth (86)	2	67	16	12	2	2
Gum (41)	2	54	20	15	7	2
Buccal mucosa (40)	4	43	30	18	10	4
Tongue (180)	4	63	18	7	4	4
Palate (41)	2	54	22	12	7	2
Tonsil (57)	4	56	21	14	2	4
Pharynx (24)	4	50	25	13	4	4
Total (543)	3	59	20	12	5	3
Controls (207)	10	63	13	5	6	2

TABLE IV.—Percentage Distribution of Male Patients with Different Cancer by Predominant Type of Tobacco Smoked

Predominant Type of Tobacco	Lung (132)	Intrinsic Larynx (107)	Extrinsic Larynx (93)	Oral (543)	Control (207)
None	1	1	0	3	10
Cigarette	93	90	82	63	69
Pipe	1	2	9	20	13
Cigar	5	7	9	12	5

ance. The percentage of cigar and pipe smokers among patients with cancer of the mouth is higher for all sites than for the controls. Twenty per cent. among the study cases smoked predominantly cigars, 12% predominantly pipes, and 3% cigars and pipes equally. The respective percentages for controls were 13, 5, and 2 (Fig. 2). This again was uniform for the total study group. The group with the fewest predominant cigarette smokers was the buccal mucosa cancer group containing 43% predominant cigarette smokers. The highest group of predominant cigarette smokers were patients with cancer of the floor of the mouth, 67% (Table III).

It was of interest to compare the type of smoking against the data previously determined for cancer of the lung and larynx (Table IV). These data show the percentage of pipe and cigar smokers to increase as one moves upward in the respiratory tract. A comparison between the group with lung cancer and the group with oral cavity cancer is particularly remarkable, with the former including only 5.4% pipe and cigar smokers.

Seventeen per cent. of the study group chewed tobacco, compared with 8% of the controls. With one exception, however, a patient with cancer of the gum, all the tobacco chewers were also tobacco smokers. In cases of lip and gum cancer the lesion was usually found at the site where the tobacco was held. No relationship of tobacco chewing

FIG. 3.—Risk of oral cancer in males in relation to amount of tobacco smoked.

FIG. 4.—Risks of smoking 35+ cigarettes a day relative to pipe and cigar smokers, by cancer site.

was found to cancer of the pharynx, floor of the mouth, and tonsil. The highest percentage of tobacco chewers was among patients with cancer of the palate, 22%, and buccal mucosa, 20%. Among the 17% tobacco chewers in the total study group, 11% had chewed for more than 10 years, the remainder having chewed less than 10 years. Though tobacco chewing appears to have some influence on the development of some cancer sites of the mouth, it is less important than tobacco smoking.

The relative risk of smokers developing cancer of the mouth rises with the amount of tobacco consumed (Fig. 3). This risk among cigarette smokers, however, does not appear to the same degree as that found for cancer of the lung, while the relative risk among cigar and pipe smokers of developing mouth cancer is greater than that of cigarette smokers (Fig. 4).

TABLE V.—Diagnosis by Quantity of Alcohol (Percentages) (Males)

Site	Rare and Occasional	Units			Sporadic Binges
		1-2	3-6	7 or More	
Lip (74)	36	26	23	15	1
Floor of mouth (86)	26	6	24	42	2
Gum (41)	34	24	17	24	—
Buccal (40)	48	18	18	18	—
Tongue (180)	21	19	22	34	3
Palate (41)	14	20	32	35	—
Tonsil (57)	18	11	30	37	5
Pharynx (24)	12	17	25	42	4
Total (543)	26	17	24	31	2
Controls (207)	46	27	15	12	—

Heavy alcohol consumption, particularly that of whisky, was found to be a significant factor among patients with cancer of the oral cavity. Forty-six per cent. of the controls were occasional drinkers or non-drinkers compared with 26% among the study group (Fig. 5, Table V). In contrast,

FIG. 5.—Incidence of mouth cancer relative to amount of alcohol consumed per day (males).

The types of alcohol consumed among the study cases include 31% whisky, 7% wine, and 36% beer, while 26% varied in type of alcohol consumed, roughly the same distribution as found for the controls. Among the study cases the percentage of people who drank whisky straight was 44%, which is greater than found among the controls, 26%, a difference which is probably associated with the fact that

the patients in the study group were heavy drinkers. Analysis for relative risk shows heavy alcohol consumption to significantly influence the development of cancer of the oral cavity. Whereas this relative risk increases in the moderate drinker, it rises very sharply among the heavy drinkers. The increased risk of developing oral-cavity cancer is significantly greater among people who drink whisky predominantly than among those who drink wine and beer predominantly (Fig. 6).

It was again of interest to compare the alcohol intake among patients with cancer of the oral cavity with patients with cancer of the lung and larynx (Table VI). Alcohol intake is significantly greater among patients with cancer of the mouth than among patients with cancer of the lung.

TABLE VI.—Percentage Distribution of Male Patients with Different Cancer Types by Amount of Average Daily Alcohol Consumption

Alcohol Consumption (Units)	Lung (132)	Intrinsic Larynx (107)	Extrinsic Larynx (93)	Oral (543)	Control (207)
Less than 1 a day	36	35	22	26	46
1-2 a day	26	18	15	17	27
3-6 ..	25	21	20	24	15
7 plus or sporadic	14	24	42	33	12

and also, though to a less extent, among patients with cancer of the vocal cords. The alcohol intake for patients with cancer of the extrinsic larynx is slightly (but not significantly) higher than for the oral-cavity series. This effect may be in part due to the lip-cancer cases in the oral-cavity series, where there is little, if any, influence of alcohol.

Syphilis

A history of syphilis or positive serology was found more common among patients with cancer of the mouth, 11%, than among the controls, 5%. The only sites, however, which showed statistically significant differences were lip, 17% (at the 1% level) and tongue, 12% (at the 5% level). Dividing the results for the tongue into anterior two-thirds and posterior one-third showed that among 86 cases of cancer of the anterior two-thirds of the tongue 22% had a history of syphilis, whereas among 89 cases of posterior one-third only 3% gave such a history. A relationship of syphilis to cancer is therefore particularly significant among those with the anterior two-thirds of the tongue affected. We attempted to determine what effect, if any, therapy might have on this association. Forty-three per cent. of those patients who could recall the type of therapy employed stated that they had received arsenical treatment. This, however, is roughly the same percentage as that found in the controls, since a majority of these patients were treated at a time when arsenical therapy was in vogue. We are thus unable to determine what influence, if any, arsenical therapy has on cancer of the tongue in man.

Dental Conditions

Edentia was more prevalent among male patients with cancer of the oral cavity, 44%, than among the controls, 28%. Edentia did not appear to be related to the tobacco and alcohol consumption of the two groups. Sixty per cent. of the study group wore dentures, compared with 63% among the controls. Eleven per cent. among the denture-wearers in the study group gave a history of irritation from the denture compared with 7% of the controls, a difference which was not significant. Six per cent. among the study group complained of sharp teeth compared with 4.7% among the controls. There were a few instances (especially in two cases involving cancer of the buccal mucosa and one case of cancer of the tongue) where a sharp tooth present for many years was in direct line with the lesion; however, no definitive conclusions can be drawn from such isolated cases. Dental hygiene was somewhat poorer among the study group, a finding not related to alcohol and tobacco consumption.

Miscellaneous

Analysis of previous disease showed no significant differences between study and control groups with the exception of a high level of leucoplakia, 19%, present in the study group. The two sites with the least history of leucoplakia among the study group were tonsil and pharynx, 4% each, and the highest buccal mucosa, where 45% of the patients gave a history of leucoplakia. We cannot make a comparison here with the control group because an individual with leucoplakia could not enter the control series. Fifty-nine patients with cancer of the mouth gave a history of multiple primary cancers. In 60% of these cases the second or third cancer occurred in the upper alimentary or respiratory tract. The alcohol consumption and the history of syphilis were similar among patients with multiple primary cancers, but the percentage of excessive smokers among the cases with double primaries was twice as high as in the remaining study cases.

Evaluation of nutritional intake of the patients showed no significant differences. This does not necessarily mean, however, that no differences exist. It would be surprising if there were no nutritional differences among people who drink more heavily than those who drink moderately. However, it is difficult to obtain accurate nutritional histories by interview technique, particularly in a country with such variations in dietary patterns as in the United States.

Outside exposure was suggestively, but not significantly, higher in the lip series than in the controls. However, the proportion of outdoor labourers was significantly higher in the group with lip cancer. The 3 non-smokers among 74 patients with cancer of the lip were all outdoor workers.

A certain group of occupations, though not more prevalent for the entire study group, were more commonly affected at specific sites. These included plumbers among patients with cancer of the tonsil, 12%, and pharynx, 16%, compared with 6% for the controls; cold-metal workers among those with the gum lesion, 17%, in contrast to 4% among the controls; painters among those with cancer of the pharynx, 13%, in contrast to 2% among the controls; and labourers among those with cancer of the lip, 15%, compared with 4% among the controls.

Among the factors studied which did not give significant findings were food temperatures, a history of general trauma to the oral cavity, and family history of cancer.

Results in Females

The study included 116 cases of cancer of the oral cavity and 246 controls. In general, the female data confirm the previous findings for the male cases. Forty-seven per cent. of the female study cases were non-smokers compared with 70% of the controls. Thirty-four per cent. of the females smoked more than 16 cigarettes per day for at least 20 years compared with 11% of the controls, a significant difference.

Fig. 7.—Incidence of oral cancer relative to number of cigarettes smoked by females.

No differences were found for the individual study sites, some of which of course contained too few cases to permit statistical analysis. All of the smokers were cigarette smokers (Fig. 7).

There was also a slightly greater amount of heavy alcohol consumption among the female study cases than among the controls. Ten per cent. among the

former drank more than two "shots" of whisky a day compared with 3.4% among the controls. Obviously, a much smaller group admitted alcohol consumption than was demonstrated for the males.

A history of syphilis was found in five patients in the study group (including two with tongue cancer), compared with three of the controls (3.8% and 0.8% respectively).

Forty-nine per cent. of the study cases gave a history of edentia compared with 29% among the controls, and 14% among the study cases had lost their teeth prior to the age of 40 compared with 8% among the controls. The variable of edentia was analysed against the variable of pregnancy.

TABLE VII.—Per Cent Edentulous by Number of Pregnancies—Study and Control Groups

No. of Pregnancies	Study Group (116)	Control Group (246)
None	29	22
1-2	44	30
3-4	70	24
5+	71	62
Total	49	29

A significant association exists between the number of pregnancies and edentia (Table VII). In the study group, among the women who had never been pregnant 29% were edentulous, those with three or four children 70%, and those with five or more children 71%. A similar phenomenon, though to a less marked extent, was noted among the controls. These data therefore indicate that pregnancies have a marked influence on the loss of teeth, particularly among patients with cancer of the mouth.

Study of the history of dental irritation or trauma due to sharp teeth showed that, in general, women tend to recall such histories more often than men. But again, with the exception of a few isolated cases, the histories of site and duration of irritation were not particularly impressive.

As to previous disease, no differences were found, with the exception of a slightly higher proportion of women with glossitis, 8%, as compared with the controls, 3%, and with oral fissures, 5%, against the control, 2%. The study includes only one case of Plummer-Vinson disease that could be verified by x-ray studies of the hypopharynx; the patient was a 64-year-old woman with cancer of the gum who was born and raised in Scotland. Leucoplakia was again found to be more common among women in the study group, 30%, and the largest proportion was again found for the buccal mucosa, 58%. Nutrition-wise, there was again no remarkable difference with the exception of tongue cancer cases, whose intake of citrus fruit was deficient among 38% of the study group compared with 25% among the controls.

Discussion

It is pertinent to determine how different variables found to be significant in the development of cancer of the oral cavity act and interact, and to ascertain to what extent their reduction or modification can lead to a decrease in the incidence of cancer of the oral cavity.

Tobacco

Smoking, as in previous studies of lung and larynx cancer, was found to be an important factor in the development of cancer of the mouth. This applies to all sites of mouth cancer and to women as well as men. Of particular interest is the fact that the relative risk of a cigar and pipe smoker developing cancer of the mouth appears greater than for a cigarette smoker, which is in contrast to the pattern encountered in lung cancer, where the risk of developing this type of cancer is far greater for the cigarette smoker than for the pipe and cigar smokers.

One can only speculate on why cigar and pipe smoking carries a greater risk for mouth cancer than cigarette smoking. One must consider the fact that inhalation is practised more commonly among cigarette than among cigar and pipe smokers. We found 90% of the former and only

15% of the latter to claim that they inhale intentionally. The smoker who does not consciously inhale perhaps keeps the smoke condensate in his mouth longer than those who inhale it into their lungs. It is also possible that the cigar and pipe smoker who tends to keep the cigar and pipe in his mouth longer than a cigarette smoker is exposed more extensively to the tobacco juices.

The fact that the relative risk of a cigarette smoker to develop lung cancer is greater than the corresponding relative risk for mouth cancer might be due to a greater susceptibility of bronchial epithelium compared with oral mucosa. It is also likely that in the smaller confines of the bronchial tree tobacco condensate tends to accumulate more extensively than on the wider and smoother surfaces of the oral mucosa. Furthermore, the constant washing of the oral mucosa through salivation and mastication may prevent the settling of tobacco condensate on its surfaces.

Experimental work has demonstrated that cigarette tar extracted with hexane from unsmoked cigarettes is far less carcinogenic than cigarette smoke condensate (Wynder and Wright, 1957). This demonstrates that the carcinogens in tobacco smoke are largely formed through combustion. These data are compatible with the present data that tobacco chewing plays a lesser part in the formation of cancer of the oral cavity than tobacco smoking.

It has been stated that tobacco could not be a major cause of cancer of the oral cavity because no increase has been noted in males for mouth cancer though there has been a sharp increase in cigarette consumption. U.S. Census data show that, although there has been an increase in cigarette consumption during the past two or three decades,

Fig. 8.—Consumption of tobacco during the twentieth century. (From Haenszel and Shimkin, 1956.)

the total number of smokers has not increased very much, and, in fact, for cigar and pipe smokers there has been a marked drop (Haenszel and Shimkin, 1956) (Fig. 8). In other words, the principal change has been for cigar and pipe smokers to become cigarette smokers. In view of the fact that cigar and pipe smoking involves greater risk for cancer of the mouth than cigarette smoking, we would not expect an increase in cancer of the oral cavity. On the other hand, we would anticipate a slight increase in women because they never smoked cigars and pipes, but are now beginning to have an increased cigarette consumption, which should increase their risk of developing cancer of the mouth.

In a separate report a study of environmental factors of cancer of the mouth in India is presented (Wynder, 1957). The results of this study are in line with those recently reported by Sanghvi and his associates (1955) in that they show cancer of the mouth to be significantly related to bidi smoking and betel-nut chewing. The association of the latter seems to be limited chiefly to cancer of the lip, gum, and buccal mucosa. We attempted to determine whether tobacco was a necessary ingredient of the betel-nut quid among patients with mouth cancer. This was difficult to determine, because there were very few patients with mouth cancer who chewed betel-nut quid without tobacco and were at the same time non-smokers. There is a suggestion, however, based primarily upon female data, that the person of mouth cancer than the person using one that does not contain tobacco.

Alcohol

Alcohol has a marked influence on the development of cancer of the mouth. As in previous studies on larynx cancer, we were unable to effect a simple separation of

tobacco and alcohol effects, since there were few heavy drinkers who are not at the same time heavy smokers. However, it was possible to obtain some estimate of the separate effects of each factor by a rather complex analysis (Wynder, Bross, and Feldman, 1957). The effect of alcohol on mouth cancer occurs primarily, though not exclusively, in patients who are heavy whisky drinkers. One can only speculate on how alcohol increases the risk of oral cavity cancer. This could be due to a direct effect of the alcohol on the tissues. It could be due to a decrease of protective saliva from the mucosa, which would tend to make it more susceptible to the effect of tobacco. A third possibility is an indirect action due to nutritional deficiencies. Though we were unable to determine significant nutritional differences between study and control groups, it is generally accepted that a majority of people who drink heavily will none the less have certain nutritional deficiencies. In reviewing the literature we were surprised at the lack of detailed studies in this respect. However, available data suggest that alcoholics have deficiencies in ascorbic acid, thiamine, riboflavin, and, upon liver involvement, also vitamin A (Jellinek and Jolliffe, 1940).

The elucidation of the mechanism of the alcohol effect would seem to be a problem for laboratory investigation.

Plummer-Vinson's Syndrome

It is interesting to speculate how nutritional deficiencies associated with alcoholism may tie in with the nutritional deficiencies of Plummer-Vinson disease. In a separate investigation we have demonstrated that Plummer-Vinson disease in Sweden is responsible in large part for the relatively high rate of cancer of the mouth in Swedish women (Wynder, Hultberg, *et al.*, 1957). In addition to a chronic iron-deficiency state, Plummer-Vinson disease probably also involves other nutritional deficiencies, notably vitamins C and B. Future laboratory studies in Sweden and in the United States may determine what common basis there may be in nutritional deficiencies of alcoholism and Plummer-Vinson disease, and from the possible finding of a common denominator much may be learned about some of the intrinsic factors that regulate the formation of cancer of the oral cavity.

Dental Conditions

Dental hygiene and dental irritation have often been stressed as important factors in cancer of the mouth. There is some evidence for this in the present study, though these factors do not appear to be major ones. It is possible that in the isolated case a specific irritation may add to the development of a cancer already initiated, which is compatible with laboratory experiments. The most interesting finding about dental conditions is that edentia occurs more commonly among the study cases than among the controls and more commonly among women than among men. It may be theorized that the same type of deficiency which leads to a loosening of the teeth, perhaps through atrophic changes in the gums and mucous membrane, also promotes cancer of the mouth. In studies on Plummer-Vinson disease we had previously emphasized the marked degree of early edentia. It is of interest in that respect that we found a relationship of pregnancy to edentia, particularly among the study cases. This may indicate that some deficiencies promoted by pregnancy may be the same ones which promote edentia and neoplastic changes in the mucous membranes. Deficiencies commonly associated with pregnancy involve especially calcium and iron, but undoubtedly must involve other minerals and vitamins.

Syphilis

Syphilis was shown to be of some importance in the development of cancer of the lip and of the anterior two-thirds of the tongue. It cannot be established whether this relationship is due to syphilitic glossitis or to arsenical therapy, which most of these patients have received. At any rate, with the modern methods for control of syphilis through its early treatment with antibiotics, this factor will be less important.

Other Factors

Other factors of significance in the development of cancer of the lip include excessive exposure to sunlight, a finding in line with the general geographical distribution of cancer of the lip.

A few occupations seemed to influence the development of certain types of cancer, particularly those of cancer of the tonsil and pharynx, which showed a suggested relationship to the type of exposures that confront plumbers and metal workers. It is of interest that the general occupation of metal workers had been under previous suspicion in cancer of the lung. All of these patients, however, were also smokers. There were no single occupations so outstandingly frequent among the study group as to cause particular concern or to be of special academic interest. However, it would be of value to investigate causes of death within these industries to determine whether the present data can thus be confirmed.

Incidence Pattern

We stated, when introducing this report, that variables significant in a given statistical study will gain causative importance if these variables can account for the incidence pattern of a given cancer. We have summarized the incidence variations among different population groups and compared these with the extent of exposure of these groups to variables found to be of statistical significance. In general, there is a close agreement between the degree of exposure of these variables and the incidence of cancer in a given population group.

1. The greater prevalence of male over female cases of cancer of the mouth is consistent with the heavier consumption of tobacco and alcohol among the male population.

2. The fact that cancer of the oral cavity in males has not increased and perhaps has even decreased in some areas is consistent with the fact that the relative risk of mouth cancer is greater for cigar and pipe than for cigarette smokers. During the past decade, although there has been a slight increase in the total number of smokers, there has been a decrease in the number of people smoking cigars and pipes. In view of this fact, we should not expect an increase in mouth cancer as has occurred in lung cancer, a type of cancer predominantly related to cigarette smoking.

3. A small increase of cancer of the oral cavity in women should be expected, because women to-day smoke more cigarettes than in the past and they have never smoked any cigars and pipes. This increase, however, should be small, because there are relatively few women in the cancer age who have smoked extensively for 20 years. Incidence data, of course, are furthermore influenced by some other factors, as suggested by this study and by improved therapy, which makes an exact comparison difficult. However, the present incidence of mouth cancer in men and women is certainly not inconsistent with the relative exposure to different tobacco types and to alcohol.

4. The greater prevalence of cancer of the oral cavity among Catholic men than among Jewish men at the Memorial Center is consistent with the finding that there are three times as many heavy alcohol drinkers among the former.

5. The relatively high rate of cancer of the oral cavity in Swedish women is consistent with the prevalence of Plummer-Vinson disease among this group.

6. The relatively high rate of lip cancer in southern countries is consistent with the greater exposure to sunlight as compared with northern areas.

7. The high frequency of cancer of the mouth in India is consistent with the high rate of bidi smoking and betel-nut chewing.

In addition to the above factors, syphilis and a few occupations influence the rates of cancer of the mouth, particularly for specific sites, but do not seem to have a major influence on the overall incidence.

Preventive Measures: A Summation

The main objective of this communication is to consider possible preventive measures which might effect substantial reduction in the incidence of oral cancer. From this point of view those environmental factors are of special importance which involve a sizable proportion of the general population and which are susceptible to control, either directly or indirectly.

From the point of view of preventive medicine, the main question is whether this study revealed any factors which are susceptible to control and whose control could effect a marked reduction in the nation-wide incidence of oral cancer.

In order to make any prediction of the effect of control of a given factor or factors, it is necessary to make some assumptions. However, if one makes several predictions, each based on somewhat different assumptions, and if these predictions are in general agreement, one can have greater confidence in the prediction. If we assume that control measures are fully efficient and hence the risks for individuals now exposed to an agent would be reduced to the risks of the individuals with little exposure to the agent, we can use the data in this study to predict the potential reduction in incidence rates. Thus, if tobacco and alcohol effects were eliminated by fully effective control measures we would predict that about four out of five male cases of oral cancer could be avoided. If we assume that the inherent susceptibility of males and females to oral cancer is about the same, then if tobacco and alcohol effects were absent the male rates would diminish to the female rates. For example, in New York State (exclusive of New York City) the 1951-3 incidence rates for oral cancer were 15.1 (per 100,000) in men and 4.0 in women. (These data from New York City were supplied to us by Dr. Morton Levin through personal communication.) This would suggest that three out of four male cases of oral cancer are preventable. In view of the fact, as shown by this study, that at least some of the female cases are also related to tobacco and alcohol, the actual lowering of incidence rates that can be achieved should be even more pronounced. We derived a partial check on the assumption of similar inherent susceptibilities of males and females by further analysis of the basic data presented here. While the check is a crude one, we can say that the data seem compatible with this assumption. The Swedish data suggest that, if anything, women may be inherently somewhat more susceptible (Wynder, Hultberg, *et al.*, 1957).

These estimates are, of course, too optimistic, since we would not expect to develop full effective control measures with respect to tobacco and alcohol. Yet, even if the measures were only half effective, there should be a sizable reduction in the incidence of oral cancer in American males.

The question remains, what specific control measures are feasible? From a hypothetical point of view, the individual should reduce or moderate his consumption of tobacco and alcohol. Here it must be emphasized that there is a distinct difference in the use of the term "moderation" as it applies to tobacco and alcohol consumption. Most people will agree that the person who consumes seven or more drinks daily is an excessive drinker, and it is primarily this kind of drinker who carries an increased risk of cancer of the mouth. On the other hand, the person who smokes 20 cigarettes a day or the one who smokes three or four cigars or five or six pipes a day is usually considered a moderate smoker. Yet from the point of view of cancer risk this does not represent smoking in moderation. Only the smoker consuming fewer than 10 cigarettes a day or the equivalent in cigars and pipes has a relatively low risk of cancer of the upper alimentary or respiratory tract. From a practical point of view, voluntary restriction of consumption does not work out effectively. Hypothetically, prohibition of the agents might be a control measure, but past experience with prohibition indicates that this approach is not feasible.

The most promising field in respect to tobacco at present appears to be further research to identify the carcinogens in tobacco smoke and to reduce the exposure to the carcinogens by effective filtration or modification of the tobacco in cigarettes, pipes, and cigars. If safer tobacco products can be developed—and current laboratory results are encouraging—then these can be substituted for present products. Such modifications might reduce the incidence of oral cancer and also the incidence of lung and larynx cancer and other cancers related to smoking. Another measure which can be begun now would be the health education of students in high school. One preventive measure, in conjunction with alcohol effects, would be improved nutrition, particularly with respect to possible supplements of iron and vitamins B and C.

These recommendations apply primarily to oral cancer in countries such as the United States. Preventive measures have to be tailored to the particular situation, and therefore the emphasis in other countries might be somewhat different. In Sweden, for example, current preventive measures in respect to dietary supplements are already achieving a reduction in Plummer-Vinson disease, and, we believe, will eventually reduce the incidence of oral cancer in women from Northern Sweden. In India, moderation in the use of bidis and betel-nut chewing should lead to a great reduction in oral cancer. In the warmer regions of the globe protection against excessive exposure to sunlight, particularly among fair-skinned people, represents a preventive measure for lip cancer.

From the point of view of preventive medicine we can avoid many of the semantic tangles and arguments that have hampered the study of environmental agents in cancer. The important question is not whether an agent is "associated with," "increases the risk of," "causes," "initiates," or "promotes"

Fig. 9.—Aetiological factors in cancer of the oral cavity.

as this study indicates, there may be many factors operating (Fig. 9). Even if a given factor accounts for a few cases, this is surely no reason to ignore factors which account for the majority of the cases. The viewpoint of preventive medicine enables us to maintain some perspective and to keep us from focusing all of our attention on a handful of highly interesting but very rare case histories.

Finally, we would like to make clear the spirit in which these predictions and recommendations are made. We cannot claim that some assertions are absolutely correct, since they have not been subjected to the final test of experience. Until control measures actually reduce the incidence of disease, we can only employ indirect arguments. The final proof of epidemiological data, however, the reduction of disease, cannot be accomplished until proper control measures have been instituted.

The goal we expect to attain demands that we give this problem our fullest attention. If our conclusions are correct, then perhaps much of the suffering and death from oral cancer can be avoided. We do not believe, as stated at the onset of this discussion, that the development of practical control measures must await a complete understanding of the pathogenesis of a given disease. This holds

as true to-day as it did during the days of Snow. In this concept lies the practical significance of epidemiological research and preventive medicine.

SEROLOGICAL EVIDENCE OF INFECTION WITH SENDAI VIRUS IN ENGLAND

BY

P. S. GARDNER, M.B., M.R.C.S., Dip. Bact.

Central Public Health Laboratory, Colindale, London

The first description of Sendai virus as a possible cause of human disease was given by Sano *et al.* (1953), who investigated an outbreak of pneumonitis among newborn infants in a hospital at Sendai, Japan. Twelve out of 17 patients died. The onset was acute, with pyrexia, cyanosis, and marked dyspnoea. X-ray examination showed opacities in the lung fields of some cases, but there were few physical signs in the chest. Jaundice developed in a few cases. From five of the fatal cases, Kuroya *et al.* (1953) isolated a virus by the intranasal inoculation of mice with lung extracts and adapted it to grow in fertile hens' eggs. These workers also reported that a pyrexial disease with pneumonitis occurred in a human volunteer aged 8 years who had been inoculated intranasally with the virus and from whom it was subsequently re-isolated. Later the virus was found to have the property of agglutinating the red-blood cells of a fowl. Haemagglutination-inhibiting antibodies were found in the residents of the town of Sendai but were not present in residents of three other districts. The properties of this virus were also investigated in Japan by Fukumi *et al.* (1954).

In the course of a serological survey of sera from a variety of illnesses in the U.S.A., Jensen *et al.* (1955) found evidence of infection with Sendai virus in two patients; one had suffered from an atypical pneumonia and the other from a nondescript respiratory illness of two to three days' duration. No virus was isolated by these workers. They suggested that the virus might be termed influenza D.

Serological evidence of infection with Sendai virus was detected in this country in 1956 (Bruce White, Gardner, and Hope-Simpson, 1957), during the investigation of an outbreak of respiratory disease in a hospital for the chronic sick. Additional serological evidence of infection has been found in England in a number of other patients, details of which are the subject of this report.

Materials and Methods

For this investigation use was made of all suitably paired sera sent to this laboratory during 1956 from patients suffering

from respiratory disease. Only paired samples of serum consisting of one taken during the acute stage and one taken about ten days later during convalescence were judged suitable for examination by complement-fixation tests (C.F.T.).

The Sendai and mumps virus particle antigens were prepared as described by Bruce White *et al.* (1957), having been made from the same virus strains.

A total of 872 pairs of sera were examined for complement-fixing antibodies to Sendai and mumps virus particle antigen. These consisted of 615 pairs of sera examined for the routine diagnosis of respiratory disease and 257 sera collected at various Royal Air Force stations during a survey of respiratory illness. The R.A.F. sera were examined only for antibodies fixing complement with the antigens of influenza A and B, adenovirus, Sendai, and mumps (virus particle antigens); the remaining sera were tested with antigens of *Rickettsia burneti* and the viruses of influenza C and psittacosis, as well as the antigens used for the R.A.F. sera. A *Streptococcus M.G.* agglutination test for the detection of atypical pneumonia was carried out on the sera of cases sent to this laboratory for routine testing.

Case Reports

Serological evidence of recent infection with Sendai virus, as denoted by a fourfold rise in the titre of complement-fixing antibodies to Sendai virus, was found in 23 cases (4 children and 19 adults): the convalescent titres ranged from 1/8 to 1/64. The salient features of the histories of these cases are summarized in the accompanying Table.

Summary of Clinical History of Patients Suspected of Being Infected with Sendai Virus

Case No.	Age and Sex	Date of Onset	Respiratory Illnesses			History of Mumps
			With Pneumonia	Without Pneumonia	Laryngeal Symptoms	
1	79 M	19/1/56	+	—	—	N.K.
2	59 F	20/1/56	+	—	—	N.K.
3	79 M	3/2/56	—	+	—	N.K.
4	87 F	13/2/56	+	—	—	N.K.
5	90 F	13/2/56	—	+	—	N.K.
6	Ad. M	11/2/56	—	+	—	N.K.
7	21 M	9/2/56	—	+	—	N.K.
8	18 F	14/2/56	—	+	—	N.K.
9	20 M	14/2/56	—	+	—	N.K.
10	20 M	16/2/56	—	+	—	N.K.
11	34 M	21/2/56	—	+	—	N.K.
12	50 M	23/1/56	—	+	—	—
13*	2 M	11/4/56	—	+	—	—
14	8 F	28/5/56	+	—	+	—
15	6 M	27/9/56	—	—	+	—
16	8 F	2/10/56	—	—	+	—
17	49 M	12/11/56	—	+	—	+
18	Ad. F	20/11/56	—	+	—	—
19	51 F	24/11/56	—	+	—	N.K.
20	35 M	Late Nov. 1956	—	+	—	—
21	52 F	5/12/56	+	—	—	N.K.
22	58 M	10/12/56	—	+	—	N.K.
23	51 F	11/12/56	+	—	—	N.K.

Ad. = Adult. N.K. = Not known. + = Predominant feature. — = Minor or absent feature. * This patient also had conjunctivitis and a lymphadenitis.

Cases 1–6 occurred or were associated with an outbreak in a hospital for chronic sick (Bruce White *et al.*, 1957).

Cases 7–11 were single cases which occurred in R.A.F. stations and were not associated as an outbreak. Influenza A was prevalent in these stations at this time.

Cases 12–23 were cases of sporadic disease or family outbreaks in Southern England, from which sera were sent to the laboratory for routine diagnostic tests for respiratory infection. Cases 15 and 16 were brother and sister; Cases 17 and 20 occurred in the same doctor's practice; Case 23 occurred in the same town as the original outbreak in the hospital for the chronic sick. Some members of the families of Cases 6, 17, and 18 had a similar illness but no sera were available for testing.

The most severe illnesses were in those over 50, five of whom had pneumonia. Three of the children showed a predominance of laryngeal symptoms, such as hoarseness, loss of voice, dyspnoea, and stridor. All cases were characterized by an infection of the upper respiratory tract and in

most there were signs of a more general systemic infection. The only evidence available regarding the probable incubation period of this illness was obtained at the hospital for the chronic sick, where the technician (Case 6) was in contact with Cases 2 and 3 on the third day of their illness. If he acquired his infection from Case 3 the probable incubation period would be about five days, if from Case 2 about 19 days.

Discussion

When both Sendai virus and influenza virus A infection were occurring together, as in the R.A.F. and in the hospital for the chronic sick, no clinical differences between the types of infection were apparent. Cases of Sendai virus infection were detected throughout 1956, although the majority occurred at the beginning and the end of the year. The apparent concentration of cases at the beginning of the year may be of no significance, as six cases were from one outbreak occurring in January and February, and five were in R.A.F. personnel from whom the sera were collected only during the five-weeks period February 10 to March 19.

During 1956, 96 of 615 pairs of sera tested, excluding those from the R.A.F., gave fourfold or greater rising titres positive to a variety of virus agents in the routine examination of sera from patients with pyrexia of unknown origin or infection of the respiratory tract. These consisted of 60 positive to influenza A, 16 to adenovirus, 2 to influenza C, 11 to psittacosis, and 5 to *Rickettsia burneti*; there were also two rising titres in the agglutination test with *Streptococcus M.G.* None of these had rising titres to Sendai virus. However, in Case 9, one of the R.A.F. series, there was a diagnostic rise in titres to influenza virus A (the titre for influenza A rising from <1/2 to 1/64 and for Sendai rising from <1/4 to 1/16). This may be regarded as of evidence of a dual infection, or, alternatively, it might be due to an anamnestic response of one of the antibodies. Influenza virus A and Sendai virus infection also occurred about the same time in the hospital for the chronic sick (Bruce White *et al.*, 1957).

From work proceeding at the moment, there appears to be an antigenic relationship between the virus of mumps and Sendai virus. A proportion of patients suffering from mumps, having the usual fourfold or greater rising antibody titre to mumps virus particle antigen, had, in addition, fourfold or greater rising titres to Sendai virus when the paired sera were examined by complement-fixation tests. A proportion of single sera sent to this laboratory having a high titre to mumps virus particle antigen also had a raised titre to Sendai antigen by complement-fixation tests. Until more information has been obtained on this point, all sera suspect of containing Sendai antibodies are being tested with mumps virus particle antigen.

Case 10 shows a fourfold rise to mumps virus particle antigen as well as to Sendai (the antibody titre for Sendai rising from <1/4 to 1/16 and that for mumps from <1/4 to 1/8). Shortage of serum prevented further investigation of this interesting case. The serological findings in this case are open to at least three interpretations. In the first place, it is possible that this was a case of mumps virus infection in which Sendai complement-fixing antibodies were evoked by an anamnestic reaction. Clinically this was unlikely, since the patient had none of the stigmata of mumps. In the second place, the infection may have been with Sendai virus, which provoked a mumps virus particle antibody response of the anamnestic type. A third possibility is that Sendai virus, or some strains of the virus, share an antigenic component with mumps virus, or some strain of mumps virus, with the result that infection with Sendai virus produces antibodies capable of reaction with both viruses in the complement-fixation test. The true explanation is at the moment doubtful, but it is of interest that Chanock (1956), in the U.S.A., found a relationship between his "croup agent" and mumps virus.

Where possible, patients were questioned for a past history of mumps, and this is recorded in the Table. It is worth noting that Case 14 had a definite history of mumps nine

NEWBORN PNEUMONITIS VIRUS (TYPE SENDAI)

EVIDENCE OF INFECTION IN SOUTH-WEST SCOTLAND

BY

R. G. SOMMERVILLE, M.B., Ch.B.

WITH THE TECHNICAL ASSISTANCE OF

H. G. CARSON, F.I.M.L.T.

From the Virus Laboratory of the University Departments of Bacteriology and of Infectious Diseases, Ruchill Hospital, Glasgow

months earlier. She was found to have a raised but unchanging titre of complement-fixing antibodies to mumps virus particle antigen in her two specimens of sera (the titres of Sendai complement-fixing antibodies showed a rise from 1/16 to 1/64, but the corresponding titres of mumps complement-fixing antibodies were 1/32 and 1/32).

In the 23 cases reported here evidence of Sendai infection was found in retrospect and no specimens of throat washings or swabs were available for isolation tests. The failure, so far, to isolate a virus only stresses the importance of obtaining suitable specimens for attempted virus isolation from cases of suspected influenza.

Summary and Conclusion

During 1956 the 872 suitably paired sera from cases of respiratory illness sent to this laboratory for investigation were examined for evidence of complement-fixing antibodies to Sendai virus.

Twenty-three cases of respiratory illness have been described in which a fourfold or greater rise in titre of complement-fixing antibodies to Sendai virus was found.

The illnesses varied from a mild influenza-like malady to a severe pneumonia; cough and laryngeal symptoms were often prominent. Cases were found in both sexes and among all age groups.

Evidence of an antigenic relationship between mumps and Sendai antigens was found. This was illustrated in a proportion of patients suffering from mumps who showed a rise in complement-fixing antibodies to both Sendai and mumps virus particle antigens.

Only one case in the present series gave a rising titre of complement-fixing antibodies to both Sendai and mumps virus particle antigen. The possible cause of this is discussed.

The C.F.T. for Sendai virus infection appears to be reliable, and a diagnosis can be readily made by serological means in cases of respiratory illness. Cross-reactions did not occur with other virus antigens used during the routine investigation of sera for respiratory illness.

Sendai virus or a related virus should be considered as a possible cause of respiratory disease, especially during the winter months.

I wish to acknowledge the help given to me in this series by many persons: Dr. F. O. MacCallum, the director of the Virus Reference Laboratory, for his helpful criticism in preparing this paper; Dr. R. E. Hope-Simpson and his staff at the hospital laboratory, Cirencester; Dr. I. M. Librach, of Ilford Isolation Hospital; Dr. G. P. McKendrick and staff, of St. Ann's Hospital, Tottenham; Dr. J. MacMurray, of the Royal East Sussex Hospital, Hastings; Drs. P. L. Masters and J. A. Davies, of the Paediatric Home Care Service of St. Mary's Hospital; Drs. P. Wormald, G. T. Cook, P. Martin, and F. A. Holden, of the Public Health Laboratories at Cambridge, Guildford, Ipswich, and Peterborough; and the following general practitioners, Drs. R. Southern, J. Shackleton-Bailey, J. C. Inglis, J. Sturridge, and C. Nesbitt-Wood, for supplying sera and case histories. I am also indebted to Drs. B. E. Andrews and J. C. McDonald, and the Director-General of R.A.F. Medical Services for sera and case histories of R.A.F. patients; also to Dr. C. E. D. Taylor for the routine screening of sera from October to December, 1956.

The newborn pneumonitis virus (N.P.V.) (type Sendai) was isolated by Kuroya *et al.* (1953) from the lungs of newborn infants who died during an outbreak of pneumonitis in the wards of the department of paediatrics of the Tohoku University, Japan. The virus was cultured by intranasal inoculation of mice and was subsequently adapted to the allantoic cavity of the embryonated egg. Isolations of N.P.V. were reported about the same time by Misao (personal communication to Kuroya *et al.*) and Ohashi (personal communication to Kuroya *et al.*), from an epidemic of A prime influenza; later Matsuzawa *et al.* (1954) found antibody to the virus in healthy adults in various parts of Japan.

In the U.S.A. Jensen *et al.* (1955) found antibody to N.P.V. by haemagglutination inhibition tests in about 40% of paired sera from a variety of illnesses. These authors observed the highest levels of antibody in the under 18 age group, and in serum from more than 559 varied illnesses they found eight instances of what they considered a significant rise in antibody titre to N.P.V. In only two patients were they able to correlate rising titres of antibody with a clinical illness: one patient was diagnosed as a case of atypical pneumonia; the other case as a mild respiratory illness.

This paper presents evidence for the existence in south-west Scotland of an antigenic stimulus producing antibodies to N.P.V. Antibody was discovered on routine screening of paired serum specimens. Fourfold rising titres were observed in nine instances by complement-fixation tests; clinical details of these are summarized. No attempts were made to isolate the virus.

Methods

The population investigated and the techniques used have been described briefly in a previous paper (Grist, Sommerville, and Carson, 1957). During the winter seasons of 1955 and 1956 the sera were drawn from three sources: paired sera were obtained from 175 adults admitted to the pneumonia wards of Ruchill Hospital, Glasgow; 97 pairs were obtained from infants admitted to the infant pneumonia wards of the same hospital; and 172 serum pairs were provided from cases of upper respiratory illness by general practitioners participating in the scheme for detection of influenza in the community during the course of influenza vaccine trials by the Medical Research Council (1955). In every instance the interval between collection of the serum samples in a pair was more than 7 and usually between 10 and 14 days.

The Sendai strain of N.P.V. was supplied by the World Influenza Centre of the World Health Organization. This virus was passed by the allantoic route in embryonated eggs at the eleventh day of incubation. Allantoic fluids were harvested and pooled 72 hours after incubation with 0.1 ml. of 1/1000 dilution of virus. After titration in "chess-board" experiments the pooled allantoic fluid was used at an

optimal dilution as an antigen in complement-fixation (C.F.) and haemagglutination-inhibition (H.I.) tests. Positive and negative control ferret sera were supplied by the Virus Laboratory of the School of Public Health, University of Michigan.

The C.F. and H.I. techniques employed have both been described by Grist (1955). A small-volume C.F. test with a 90-minute fixation period at 37° C. was used with all adult sera, but infant sera were tested by a small-volume cold-overnight test in view of the relative insensitivity of short fixation with infant sera reported by Grist (1957). In H.I. tests identical techniques were used with adult and infant sera, but owing to shortage of serum C.F. tests only were performed in some instances.

Tests for virus-neutralizing antibody were not performed because of shortage of serum.

Results

The results of C.F. tests on paired sera, using N.P.V. as antigen, are shown in Table I. Failure to fix complement at a dilution of 1/8 or less was observed in 88% of sera, and a small proportion from each group was found to be anti-complementary. Complement fixation at 1/16 or 1/32 and twofold rise or fall in titre were observed in 12 cases, but only fourfold rises were regarded as positive evidence of the relevant antigenic experience. A fourfold rise in titre was found in nine instances—three in the adult pneu-

N.T. = Not tested.

monia and six in the "influenza" group. For comparison the results of H.I. tests are shown in Table II. In this series 78% failed to inhibit haemagglutination at a serum dilution of 1/8 or less, but this proportion is raised to 95% if a dilution of 1/32 or less, as is customary with the influenza viruses, is used as the index of negativity. Only four cases were found with a fourfold rise in titre by H.I., and these also showed a similar rise by C.F. tests. A falling titre by H.I. in the case of one infant was not reflected in the C.F. test.

The main findings in the nine cases which showed a fourfold rise in titre by one or other test are shown in Table III. In contrast to the experience of Japanese investigators all cases in this series were adult. The description "influenza" in the diagnosis column denotes an influenza-like illness of varying severity in a patient drawn from the general-practitioner "influenza" group in Tables I and II. The other cases belong to the group of adult pneumonias.

In general, antibody reacting with N.P.V. appeared between the 5th and 10th days of illness, and the titre increased until the end of the second or third week. Thereafter the level decreased slowly during the third and subsequent weeks.

The appearance of antibody was delayed in two cases—F141 and R574. In these an initial febrile illness was complicated later by acute respiratory symptoms, which in turn were followed by rising titres of antibody reacting with N.P.V. One case (R496) developed a rising antibody titre to influenza during the course of his stay in hospital at a time when the antibody titre to N.P.V. was at its highest level. The influenza antibody response followed a clinical relapse during the convalescent phase of his initial illness. Apart from this case no other evidence of infection with influenza viruses was found in the nine patients under discussion.

Clinical Aspects of Infection with N.P.V.

All patients suffered from an acute respiratory illness which differed in severity from case to case but which presented no distinguishing pattern. All were diagnosed clinically as suffering from either pneumonia or influenza during winter months when both pneumonia and influenza were prevalent. The main features of the illness in each group are summarized in Table IV.

The cases of patients who were admitted to hospital with a diagnosis of pneumonia may be briefly described.

Case R293.—A man aged 69, whose illness began on November 17, 1954, was admitted to hospital five days after the onset of febrile illness. The presenting symptoms were headache, pleural pain, cough, and breathlessness. On admission there was minimal sacral oedema with slight overfilling of neck veins. Chest examination revealed coarse moist sounds at all areas despite

TABLE IV.—Summary of Two Types of Case Showing Antibody Reacting with Newborn Pneumonitis Virus

	Influenza	Pneumonic
No. of cases	5	4
Age (average)	43 years	61 years
Sex	M—3; F—2	M—2; F—2
Duration (average)	3 weeks	6 weeks
Previous history	Normal	1 normal; 1 congestive cardiac failure; 2 chronic bronchitis
Onset abrupt with	Headache; myalgia; fever—not over 101° F. (38.3° C.); malaise	Headache. Fever±. Malaise
Followed by	Nasal catarrh; pharyngitis; cough	Signs of pneumonia with or without congestive cardiac failure
Physical findings	Few	Lobar or bronchopneumonia with or without congestive cardiac failure
Treatment	Antipyretic therapy	Penicillin
Result	Satisfactory	Satisfactory

absence of dullness or diminution of air entry. W.B.C. was 20,600 per c.mm. X-ray examination revealed patchy consolidation in lower lobe of right lung, and a normal heart shadow. Treatment with crystalline penicillin removed fever in 24 hours, and thereafter improvement was rapid despite the development of a few crepitations at the left lung base following an attack of tachycardia on the 12th day of illness. X-ray examination showed chest clear at 15 days. This patient was reputed to have had a coronary thrombosis three years previously which was followed by an episode of congestive cardiac failure, but electrocardiograms during the course of the present illness revealed only "left heart strain and myocardial disease." During the first ten days in hospital antibody reacting with N.P.V. increased from less than 1/8 to 1/32 by C.F. and from less than 1/8 to 1/16 by H.I. tests.

Case R496.—A man aged 75, whose illness began on January 24, 1956, had a history of chronic bronchitis for many years. On admission to hospital three days after the onset of acute exacerbation of bronchitis, he was cyanosed and orthopnoeic and producing large amounts of grey sputum. Auscultation revealed marked bronchospasm with some scattered adventitious sounds. X-ray examination showed patchy consolidation and a normal heart shadow. W.B.C. was 8,000 per c.mm. Treatment with crystalline penicillin and aminophylline produced clinical improvement in three days, but relapse occurred 15 days after admission to hospital with exacerbation of symptoms, fever, and malaise. A second course of treatment with penicillin and aminophylline again produced improvement, and the subsequent recovery was uneventful. Antibody reacting with N.P.V. increased from less than 1/10 to more than 1/160 by C.F. tests between the 4th and 14th days of illness. During the same time a rise in titre from 1/8 to 1/128 occurred by H.I. A specimen obtained at the 42nd day of illness still revealed a C.F. antibody titre of 1/160, although the H.I. titre had fallen to 1/40. Titration of this specimen for antibody to influenza A in parallel with the serum specimen obtained at the 14th day revealed that during this time antibody to influenza A had increased by C.F. tests from less than 1/8 to 1/160. The pooled specimen resulting from serum obtained at the 21st and 28th days of illness, when tested for antibody to influenza A, revealed a C.F. titre of 1/80, and it was therefore concluded that, while the initial illness had produced the rise in titre of antibody reacting with N.P.V., the clinical relapse, occurring at the height of the antibody response to the first agent, had produced antibody to influenza A.

Case R574.—A woman aged 65, whose illness began on March 26, 1956, was admitted to hospital with severe dyspnoea of sudden onset 21 days after a mild influenza-like illness. She was afebrile on admission, but overfilling of neck veins and cyanosis were present. Chest examination revealed inspiratory and expiratory rhonchi and crepitations at all areas. W.B.C. was 12,800 per c.mm. X-ray examination showed cardiac enlargement with bilateral extensive pulmonary congestion, consistent with cardiac failure. A temperature of 101° F. (38.3° C.) which developed 24 hours after admission to hospital was controlled in 72 hours by crystalline penicillin although no pathogenic bacteria were isolated in culture. An E.C.G. revealed myocardial damage. Treatment with penicillin continued for 10 days, and aminophylline was administered frequently during the first few days, after which the patient was digitalized. Subsequent recovery was uneventful. During the first ten days following admission to hospital antibody reacting with N.P.V. increased from less than 1/8 to 1/128 by both C.F. and H.I. tests.

The cases classified as "influenza" were with one exception treated at home by general practitioners and were mild

febrile infections of the upper respiratory tract. Three were female and three male, and the ages ranged from 35 to 52 years. The illness lasted between two and eight weeks and none was fatal. In five cases the onset was abrupt, with headache, myalgia, fever, and malaise rapidly followed by nasal catarrh and pharyngitis. The temperature did not exceed 101° F. (38.3° C.) and quickly settled. An irritable cough developed in two cases. All five had few physical findings within the chest, and none had an x-ray examination. The condition resolved with mild antipyretic therapy.

The sixth patient had a prolonged illness. A basal pneumonia which was treated with penicillin was slow to resolve at first and x-ray examination revealed consolidation of the right middle and lower lung lobes. The patient was detained in hospital, and resolution occurred spontaneously over five weeks.

Discussion

The present studies reveal the presence of a hitherto unrecognized antigenic stimulus in the adult population of south-west Scotland. This is capable of producing antibody reacting with N.P.V. The number of reports in the world literature of infection with this agent is small, and the pattern of illness attributable to it has not been clearly defined. However, all reports are in agreement that the severe illness and high fatality rate in newborn infants originally reported by Kuroya *et al.* (1953) are not seen when the adult is infected. Volunteer experiments in adults by Kuroya *et al.* (1953) suggested that the illness was mild and febrile, affecting the upper respiratory tract and clinically resembling influenza. Collateral confirmatory evidence was supplied by Misao and by Ohashi (personal communications to Kuroya *et al.*) when they isolated viruses antigenically similar to N.V.P. from adults during an influenza epidemic in Japan. One of two adult cases described briefly by Jensen *et al.* (1955) suffered from a mild respiratory illness at a time when influenza B was prevalent, and the second case was described clinically as suffering from an atypical pneumonia.

The present investigation revealed infection with this agent during winter months when influenza viruses A and B were present, but influenza antibody was only once associated with antibody reacting with N.P.V. The incidence of infection with influenza in the population under investigation has already been described (Grist *et al.*, 1957).

In addition our present experience confirms the mild influenza-like nature of the illness in the majority of cases, but adds the possibility of a more severe type affecting persons who have a previous history of chronic bronchitis or heart disease, and who fall within an older age group.

Summary

We examined 444 paired sera by complement-fixation test, and 381 of these pairs by haemagglutination-inhibition test for antibody reacting with newborn pneumonitis virus in the population of south-west Scotland. Evidence was found in adults for the existence of an agent which is capable of producing this antibody. Nine instances were detected of a fourfold rising titre by complement-fixation test, and clinical details recorded from these cases revealed that the infection presented either as a mild influenza-like illness or as pneumonia.

We wish to acknowledge the help of the following general practitioners by whom the general-practice study was carried out: Dr. W. Blair, Dr. W. K. Brown, Dr. W. F. Caldwell, Dr. Alison Clarke, Dr. S. Dunn, and Dr. T. F. Stewart. We are grateful to Dr. T. D. Grant and Dr. M. Thomas for assistance with the investigation of patients admitted to hospital; to Dr. C. H. Andrewes, of the World Influenza Centre, Mill Hill, London, and to Dr. K. E. Jensen, of the University of Michigan, U.S.A., for supplies of seed virus and control serum.

ADDENDUM.—Since this paper was prepared for publication an outbreak of respiratory illness caused by infection with newborn pneumonitis virus in a hospital for the chronic

sick and infirm has been reported by Bruce White *et al.* (*British Medical Journal*, 1957, 1, 381). In this outbreak six patients developed rising titres of antibody, and the clinical illnesses resembled influenza.

AGAMMAGLOBULINAEMIA WITH SPLENOMEGALY

BY

KENNETH M. CITRON, M.D., M.R.C.P.

Senior Medical Registrar, Brompton Hospital, London

Agammaglobulinaemia is a biochemical defect characterized by absence of serum gamma-globulin and is usually associated with deficiency of immunoglobulins, resulting in increased susceptibility to infection. The frequent recurrence of infection, which is the principal clinical feature of this condition, has been accentuated by the use of antibacterial drugs which have enabled these subjects to survive a succession of infections to which they might otherwise have succumbed.

Since agammaglobulinaemia associated with recurrent sepsis was first described by Bruton (1952) over 40 cases have been recorded. In these cases the symptoms and signs of the disorder have usually been those of recurrent infections. The purpose of this paper is to report two cases of agammaglobulinaemia in which enlargement of the spleen and liver and generalized enlargement of lymph nodes were also outstanding clinical features.

Case 1

The patient, a man of 33, had suffered from measles and pertussis in childhood, but apart from this had enjoyed good health until 1942, when at the age of 19 he had pneumonia. Enlarged lymph nodes were palpable in the neck and in both axillae, and the chest radiograph showed enlarged lymph nodes at the hilum of the right lung and shadows in the right lung. Respiratory symptoms recurred four months later and septic tonsils were removed. He remained in poor health and in the subsequent 14 years suffered numerous infections. In 1945 he had gingivitis, laryngitis, and pleurisy, and in 1946 seborrhoeic impetigo, herpes zoster, laryngitis, and pneumonia. In 1946 generalized enlargement of lymph nodes was present, enlarged nodes being palpable in the cervical, epitrochlear, axillary, and inguinal regions on both sides. In 1948 he had mumps and a respiratory infection, and in 1949 furunculosis and several respiratory infections.

In 1950 he was admitted to hospital with pleurisy. A firm spleen was palpable 1 in. (2.5 cm.) below the left costal margin, and the liver was palpable 1 in. (2.5 cm.) below the right costal margin. Generalized enlargement of superficial lymph nodes similar to that found in 1946 was noted and the chest radiograph again revealed right hilar node enlargement. Penicillin was given and respiratory symptoms improved, but jaundice occurred later and lasted three weeks. At this time the level of serum globulin was normal and albumin was raised. Total protein was 8.8 g. per 100 ml. (albumin 6.1 g., globulin 2.7 g.). The thymol turbidity was 4 units (normal). The blood count was normal. Biopsy of an enlarged lymph node showed reactive hyperplasia but no other abnormality.

Between 1950 and 1954 he suffered six acute respiratory infections. In 1954 sarcoidosis was suspected because of respiratory symptoms, hilar node enlargement, lymphadenopathy, hepatosplenomegaly, and a negative Mantoux test. Another enlarged lymph node was removed and showed reactive hyperplasia but no evidence of sarcoidosis or any primary reticuloses. The total serum protein was 8 g. per 100 ml. (albumin 6.4 g., globulin 1.6 g.).

In November, 1955, he had measles for the second time. In December the zinc flocculation test was 5 units (normal). In February, 1956, he had pneumonia and was treated with tetracycline, but pneumonia recurred in May and he was again treated with tetracycline. In May the zinc flocculation test showed only 1.5 units, suggesting that the serum gamma-globulin was low. In June the total serum protein was 6 g. per 100 ml. (albumin 4.6 g., globulin 1.4 g.). In July he had another acute respiratory infection which responded to chlortetracycline.

On admission to hospital in July he was seen to be a lean man with a frequent dry cough. The spleen was palpable 8 cm. below the left costal margin and felt firm. The liver was palpable 6 cm. below the right costal margin. Moderately enlarged firm lymph nodes were palpable in the epitrochlear, axillary, and inguinal regions on both sides. Rales were heard at the bases of both lungs.

Investigations

Paper electrophoresis of serum revealed no detectable gamma-globulin. Total serum protein was 6.39 g. per 100 ml. Electrophoretic analysis on the Tiselius apparatus (Professor N. H. Martin) showed: albumin, 62.8% (4.01 g.); globulins—alpha-1 5.4% (0.34 g.), alpha-2 14.4% (0.94 g.), beta 17.5% (1.12 g.), gamma 0.0% (less than 100 mg. per 100 ml.). Gamma-globulin was present in negligible quantities as determined by immunological techniques—approximately 60 mg. per 100 ml. by both red-cell agglutination and precipitation diffusion methods. Zinc flocculation test, 1 unit; thymol turbidity test, 2 units.

Deficiency of circulating antibodies was demonstrated by the following investigations. His red blood cells were group A, but anti-B isoagglutinins were present in the serum in negligible quantities (titre 1 in 2). His serum failed to agglutinate suspensions of *Salm. typhi* or *Salm. paratyphi A* and *B* in spite of previous T.A.B. inoculation. Mumps complement fixation was negative in spite of a previous history of mumps. The antistreptolysin titre was less than 10 units per ml. The Schick and Dick skin tests were positive. No skin reaction occurred with 100 tuberculin units of P.P.D., or with *Candida albicans* antigen, which gives delayed-type reactions in 95% of healthy adults. The *C. albicans* complement-fixation test was negative.

Another axillary lymph node was removed. Examination of sections stained by haematoxylin and eosin showed diffuse hyperplasia of the reticulo-endothelial elements of the stroma of the node. The germinal follicles were numerous, with considerable variation in size, some follicles being large and hyperplastic. The axillary lymph node removed in 1954 had a similar appearance, and that removed in 1950 was also similar except that stromal hyperplasia was not so intense. Reticulin stains revealed well-marked follicular patterns. Examination of sections stained specially for plasma cells with Unna-Pappenheim methyl-green pyronine stain showed that in the node removed in 1956 transitional plasma cells (Fagraeus, 1948) were plentiful in the germinal follicles and along the sinuses. Mature plasma cells were very sparse, however, in contrast to normal nodes, where large numbers of mature plasma cells can usually be found in the sinuses. The appearance of the node removed in 1954 was similar.

The chest radiograph showed bilateral hilar lymph-node enlargement and shadows at the bases of both lungs.

The E.S.R. was persistently low even during infections (1–4 mm. per hour, Westergren). Red-cell and white-cell counts were normal. During infection normal neutrophil leucocytosis occurred.

MAY 18, 1957

Soon after admission to hospital he became severely ill with pneumonia, but responded to penicillin and streptomycin. However, only one week after stopping these drugs pneumonia recurred and he was given tetracycline. Gamma-globulin, 0.15 g. per kg. body weight, was administered intramuscularly. This was followed by weekly maintenance doses of 0.05 g. per kg. body weight. The serum gamma-globulin, estimated by paper electrophoresis one day and seven days after the second maintenance dose, was 0.5 g. per 100 ml. and 0.2 g. per 100 ml. respectively. Seven days after the tenth injection serum gamma-globulin was 320 mg. per 100 ml. by the precipitation diffusion method and 270–320 mg. by the red-cell agglutination method. During the three months he has been on the treatment he has had some minor infections, but none of them have been severe or have required antibacterial drugs.

Investigation of the Family.—The patient's parents, sister, and five brothers were all well and not unduly susceptible to infection. The father, mother, and sister all had high levels of serum gamma-globulin. Total protein was determined by the Van Slyke method, using tyrosine standard and Folin-Ciocalteu reagent. The globulin fractions were determined by paper electrophoresis. In healthy subjects the total serum globulin was 2.4 g. per 100 ml. (standard deviation 0.30) and the gamma-globulin 0.99 g. per 100 ml. (standard deviation 0.18) by these techniques. The levels (in g. per 100 ml.) were: father—albumin 3.4, globulin 3.8, gamma-globulin 1.9; mother—albumin 3.7, globulin 3.4, gamma-globulin 1.6; sister—albumin 4.3, globulin 3.2, gamma-globulin 1.7. The serum proteins of three brothers and the patients' two sons were normal.

Case 2

This patient was born in 1940, one month prematurely; her birth weight was 5 lb. (2,270 g.). She was well until the age of 2 years, when measles was followed by recurrent bilateral otorrhoea. After whooping-cough at 3 years she had persistent cough and failed to thrive. She first attended hospital in 1951, aged 11 years, with bilateral mucopurulent otorrhoea.

At 12 years she was admitted to hospital with an acute febrile respiratory infection. She was physically underdeveloped, underweight, partially deaf and mentally dull. The spleen was grossly enlarged, its edge being palpable below the umbilicus. The liver edge was palpable 5 cm. below the right costal margin, and lymph nodes were palpable in the neck. The chest radiograph showed shadows at the bases of both lungs. In spite of this acute febrile respiratory infection there was no leucocytosis, the total leucocyte count being 5,000 per c.mm. (neutrophils 53%, lymphocytes 41%). There was no anaemia, and iliac crest bone marrow was reported as normal. The infection responded to penicillin. Thereafter, apart from cough, she remained without symptoms until the age of 14 years, when she was again admitted to hospital with another acute respiratory infection. The spleen was even larger, its edge being palpable in the left iliac fossa. The chest radiograph showed shadows in the lingula and left lower lobe. There was no leucocytosis; total count 6,000 (neutrophils 60%, lymphocytes 36%). The pulmonary infection was controlled with antibiotics, but persistence of cough, sputum, and some radiological shadows suggested the presence of bronchiectasis.

Because of its large size the spleen was removed, although the cause of the splenomegaly was obscure. At laparotomy the liver was slightly enlarged, but of normal consistency, and a biopsy was taken. About the splenic and hepatic vessels there were several enlarged lymph nodes, which were removed.

In a microscopical section of the spleen there was a relative increase in the amount of splenic pulp with reduction in the number of Malpighian bodies. In the pulp most of the sinuses were widely dilated and lined by cells which were more pleomorphic than is usually seen in a normal spleen. Germinal follicles were sparse and of varying size. No cells of the plasma-cell series, either mature or trans-

sitional, were demonstrated by Unna-Pappenheim stains. The lymph node from the splenic hilum consisted chiefly of diffuse sheets of lymphocytes with only an occasional germinal follicle, which again varied considerably in size. There was diffuse hyperplasia of the reticulo-endothelial elements of the stroma. Reticulin stains confirmed the sparseness of germinal follicles. No cells of the plasma-cell series were demonstrated by Unna-Pappenheim stains. There was no significant change in the liver cells.

After the operation, paper electrophoresis of the serum showed absence of gamma-globulin. Total serum protein was 5.4 g. per 100 ml. (albumin 4.2 g., globulin 1.2 g.).

Eighteen months after splenectomy the patient developed severe pneumococcal meningitis. A leucocytosis was now present; total leucocytes, 40,000 (neutrophils 88%, lymphocytes 8%). She responded well to antibacterial therapy. Paper electrophoresis of serum again showed no gamma-globulin. Two months later the patient developed another respiratory infection, which responded poorly to penicillin.

In 1955 (aged 15 years) she was admitted to Brompton Hospital. The liver edge was palpable 5 cm. below the right costal margin, and moderately enlarged firm lymph nodes were palpable in neck and axillae. Total serum protein was 5.7 g. per 100 ml. (albumin 4.2 g., globulin 1.5 g.). No gamma-globulin was detected by paper electrophoresis of serum. Thymol turbidity and zinc flocculation tests showed only 1 unit.

Deficiency of normal circulating antibodies was shown by deficiency of beta-agglutinins in her group A blood (the anti-B titre varied between 0 and 1 in 8). Her serum failed to agglutinate suspensions of *Salm. typhi*, *Salm. paratyphi A* and *B*, *Br. abortus*, and *Br. melitensis*. The Schick reaction was positive in spite of previous diphtheria toxoid. The Dick test was positive. The reaction to 100 tuberculin units was negative. *C. albicans* reaction was also negative.

Leucocytes were 26,000 per c.mm. (neutrophils 71%, lymphocytes 19%). Cultures of sputum yielded pneumococci, haemolytic streptococci, and coagulase-positive staphylococci. Penicillin improved respiratory symptoms and cleared pathogens from the sputum, but prompt clinical and bacteriological relapse occurred on stopping penicillin. The patient developed a fulminating *H. influenzae* meningitis, which, in spite of the administration of gamma-globulin and antibiotics, proved fatal. Post-mortem examination was refused.

Investigation of the Family.—Her parents and sister were well and were not unduly susceptible to infection. Her mother's serum globulin was raised—albumin 3.3 g., globulin 3.2 g. per 100 ml. The increase of globulin was distributed evenly throughout the alpha-2, beta, and gamma fractions. The serum protein of her father and sister showed no abnormality.

Discussion

Agammaglobulinaemia may occur as an isolated defect of the serum, the other electrophoretic components of globulin and albumin being present in normal quantity. This abnormality may be associated with a variety of clinical features on the basis of which cases may be divided into two broad groups, congenital and acquired.

In congenital agammaglobulinaemia increased susceptibility to infection occurs in infancy or childhood, exclusively in males; and its occasional occurrence in brothers and other males in the family suggests that the defect is genetically determined and probably transmitted as a sex-linked recessive trait (Janeway *et al.*, 1953). In this condition the deficiency of gamma-globulin is permanent, and it should be distinguished from cases of agammaglobulinaemia of limited duration occurring in infants of either sex in whom it is thought that the passively transferred gamma-globulin from the mother is not replaced by the infant's own gamma-globulin owing to a delay in the assumption of normal gamma-globulin synthesis (Good and Mazzitello, 1956).

Acquired agammaglobulinaemia may occur in either sex at any age. It may be secondary to disorders of the

reticulo-endothelial system, and has been found in association with malignant lymphoma (Arends *et al.*, 1954), chronic lymphatic leukaemia (Brem and Morton, 1953; Jim and Reinhard, 1956), myelomatosis (Zinneman *et al.*, 1954), and histoplasmosis (Seltzer *et al.*, 1955). There are other cases in which the disease is acquired but no cause for the gamma-globulin deficiency can be found, and these are referred to as the acquired idiopathic type (Good and Mazzitello, 1956).

Agammaglobulinaemia may occur not as an isolated defect, but in association with a general hypoproteinaemia, such as occurs in a variety of conditions, including nephrosis.

The term agammaglobulinaemia implies absence of gamma-globulin as detected by electrophoresis of serum. However, the use of more delicate immunological techniques for the detection of gamma-globulin may reveal small quantities of gamma-globulin where electrophoresis fails to demonstrate any. Strictly speaking, therefore, these are cases of hypogammaglobulinaemia. Moreover, immunoglobulins may occasionally occur in serum which is apparently deficient in gamma-globulin, and, probably because of this, agammaglobulinaemia is not always associated with increased susceptibility to infection (Martin, 1954).

The two cases described here have the features of the acquired idiopathic type of agammaglobulinaemia, in that there was good health before onset of symptoms of recurrent infection and also absence of any primary disorder to which the development of agammaglobulinaemia might be attributed. Moreover, in Case 1 the normal zinc flocculation, thymol turbidity, and total globulin levels in the early stages of the disease are strong circumstantial evidence that gamma-globulin was present in appreciable quantities at the time, so that the agammaglobulinaemia must have developed later.

Gross enlargement of the spleen was a striking clinical feature of both cases. In Case 2 enlargement of the spleen was present before severe infections had occurred, and the spleen was observed to increase in size during the next three years until splenectomy. In Case 1 enlargement of the spleen was noted eight years after the onset of the disease with symptoms of infection and enlarged lymph nodes, and the spleen increased in size over the next six years. The liver was enlarged in both patients. Generalized enlargement of lymph nodes was present in both patients, including hilar nodes in Case 1 and intra-abdominal nodes in Case 2.

Among 45 cases of agammaglobulinaemia reported in the literature there are six cases in which the spleen was enlarged (Rohn *et al.*, 1954; Grant and Wallace, 1954; Rosecan *et al.*, 1955; Collins and Dudley, 1955; Young *et al.*, 1955; Good and Mazzitello, 1956). All six were of the acquired idiopathic type; three were in males and three in females, their ages ranging between 17 and 53 years.

In these cases the microscopical appearance of the reticulo-endothelial tissue showed similar features to those described here. Of four cases in which the spleen was examined there was reticulum-cell hyperplasia of variable degree in all four. Germinal follicles were sparse in two. Lymph nodes were examined in two and showed reticulum-cell hyperplasia in both. In the present cases there was diffuse hyperplasia of the reticulo-endothelial elements of the stroma of all lymph nodes examined, and also of the spleen in Case 2. Germinal follicles were sparse in the lymph node and spleen in Case 2, in contrast to Case 1, in which the numbers of germinal follicles were consistently within normal limits in three separate biopsies taken over the course of six years.

The most striking variation from normal, present uniformly in all histological material from both Case 1 and Case 2, was the virtual absence of mature plasma cells. Absence of plasma cells has been noted previously in cases of agammaglobulinaemia (Good and Mazzitello, 1956). Plasma cells are known to be concerned with the production of gamma-globulin and circulating antibodies (Sundberg, 1955), and agammaglobulinaemia has been attributed to absence of these cells. Although there was severe deficiency of

mature plasma cells in both cases, they differed in that transitional plasma cells were plentiful in the germinal follicles and sinuses of Case 1, whilst in Case 2 no cells of the plasma-cell series were present in the sparse germinal follicles or in the sinuses. It may be, therefore, that the deficiency of mature plasma cells present in both cases resulted from a disturbance acting at different stages of development of the plasma cells.

Among the relations of these patients deficient in gamma-globulin there were healthy individuals of both sexes with hypergammaglobulinaemia. Abnormally high serum gamma-globulin occurred in the father, mother, and sister of Case 1, and the mother of Case 2 had a raised total globulin level. Similar findings were reported by Young *et al.* (1955), who found hypergammaglobulinaemia in the healthy mother and brother of an adult male patient with acquired idiopathic agammaglobulinaemia. This evidence suggests that the abnormalities of globulin production in these families might depend upon genetic factors and that some cases of acquired idiopathic agammaglobulinaemia are genetically determined like the congenital variety, but differ from it in the late onset of symptoms and the occurrence in females as well as males.

No neutrophil leucocytosis occurred in response to infection in Case 2 until after splenectomy, when neutrophils increased readily in infection. Among the six cases of agammaglobulinaemia with splenomegaly detailed above, three had neutropenia and neutrophilia did not occur in infections. Three cases had an acquired haemolytic anaemia, in two of which the spleen was removed, with relief of the anaemia in both. The relief of haemolytic anaemia and neutropenia by splenectomy suggests that these disturbances were due to destruction of erythrocytes or leucocytes by the enlarged spleen and not to an immunological mechanism, since circulating antibodies were deficient or absent in these patients.

The E.S.R. determined in Case 1 on 11 separate occasions, usually during infection, was 5 mm. per hour or less (Westergren), except on one occasion. In Case 2 the E.S.R. was moderately raised during infection except in the last few weeks before death, when in spite of much pulmonary infection the E.S.R. was 3 mm. per hour or less. Persistently low E.S.R. readings during infection have been noted in some other cases of agammaglobulinaemia (Elphinstone *et al.*, 1956).

It is concluded that agammaglobulinaemia of the acquired idiopathic type may be associated with generalized hyperplasia of the reticulo-endothelial system and should be considered in the diagnosis of enlargement of the spleen and lymph nodes of obscure origin, particularly in the presence of recurrent infection.

Summary

Attention is drawn to the association of acquired idiopathic agammaglobulinaemia with enlargement of the spleen and lymph nodes. Two cases are described and six similar ones in the literature are reviewed. The principal histological features are diffuse reticulo-endothelial hyperplasia and deficiency of plasma cells. Haemolytic anaemia and neutropenia may occur. In some cases increase in the serum globulin of healthy relatives has been found.

I thank Dr. Lynne Reid for her advice about the histology; Drs. F. P. Lee Lander, J. G. Scadding, S. D. V. Weller, and N. Wynn-Williams for permission to publish their cases; and Professor N. H. Martin for his advice. Case 1 has been included in a therapeutic trial organized by the Medical Research Council, who also supplied the gamma-globulin.

ADDENDUM.—Since this paper was submitted another patient with hypogammaglobulinaemia, whose mother had increased serum gamma-globulin, has been investigated. The patient was a girl of 14 years who during the past

year had suffered from 14 attacks of acute pulmonary infection. Previously she had been well. Her serum gamma-globulin was only 0.2–0.3 g. per 100 ml. Her mother was quite well, but had a marked increase in serum gamma-globulin (2 g. per 100 ml.). The serum proteins of the patient's father and sister were normal. This observation adds further support to the suggestion that in some cases of acquired idiopathic agammaglobulinaemia (hypogammaglobulinaemia) the abnormality of gamma-globulin production is genetically determined.

AGAMMAGLOBULINAEMIA

REPORT OF TWO ADULT CASES

BY

W. T. COOKE, M.D., F.R.C.P.

W. WEINER, M.D.

AND

N. K. SHINTON, M.B., M.R.C.P.

From the Birmingham United Hospitals

The clinical and laboratory findings in patients with deficiencies or absence of gamma-globulin in their serum have been described only in the past few years. Most of the cases have been in children (Bruton, 1952; Fried and Henley, 1954; Elphinstone *et al.*, 1956), but a number of examples of the condition have been recorded where the deficiency has not appeared until adult life (Grant and Wallace, 1954; Wall and Saslaw, 1955).

The purpose of this paper is to record the findings in two further adult female patients in whom this deficiency was present.

Case 1

A single woman, born in 1907, was perfectly well until 1933, when she had a chronic cough for a few months. In 1937 she had her first attack of pneumonia, two more attacks following in 1943. She was admitted to hospital in 1949 for investigation of diarrhoea of one year's duration, and was found to have a mild degree of steatorrhoea (4–8 g. of faecal fat on a 50-g. daily fat intake). Her blood count showed: red cells, 4,460,000 per c.mm.; haemoglobin, 9.9 g. per 100 ml.; M.C.V., 96 cubic microns; M.C.H.C., 25%; white cells, 7,400 per c.mm., with normal differential; and serum proteins: albumin, 4 g. per 100 ml.; globulin, 1.2 g. with gamma-globulin 0.04 g. (alcohol precipitation method—G. Thomas, 1954, unpublished observation). The serum

bilirubin, alkaline phosphatase, cholesterol, empirical tests of liver function, and pancreatic enzymes were normal. Chest radiographs showed no abnormality.

Over the next two years she had pneumonia on four further occasions and her diarrhoea increased. In 1951 she complained of severe attacks of abdominal pain, on account of which an exploratory laparotomy was performed by Mr. B. N. Brooke. A swollen pink pancreas was seen, but no other abnormality.

For the next three years she continued to have recurrent attacks of pneumonia and constant diarrhoea of up to 10 stools a day, and in 1954 she was readmitted to hospital. Estimations of faecal fat then showed an excretion of 10–20 g. a day. The serum amylase fluctuated between 183 and 370 units per 100 ml., with one period of a week during which it rose steadily to 670 units per 100 ml. On admission serum electrolytes showed: sodium 146 mEq, potassium 2.9 mEq, chloride 106 mEq per 100 ml. The blood count, serum proteins, bilirubin, alkaline phosphatase, cholesterol, and empirical tests of liver function showed no significant change from 1949. Gamma-globulin was estimated at 0.05 g. per 100 ml. by alcohol precipitation method and 0.1 g. per 100 ml. by paper electrophoresis (Dr. Hardwick), but none was shown by the Tiselius method (Dr. Kekwick). Serum tested by the immunochemical method (Gell, 1955) for gamma-globulin showed that some was present in amounts approximating to 10% of that in the normal control serum. A routine blood grouping at this time showed absence of iso-agglutinins. She was treated with a high-protein and low-fat diet and pancreatin, 12 g. daily with meals. Her diarrhoea improved on this regime, though she continued to excrete 10–20 g. of fat daily. She was discharged relatively well after two months in hospital.

During the past 18 months the patient has had one further attack of acute bronchitis, which subsided within a week in response to antibiotic therapy. In order to raise her gamma-globulin level before the winter 1 litre of fresh plasma was transfused in October, 1955. The last estimation of gamma-globulin, in July, 1956, by paper electrophoresis, showed it to be 0.3 g. per 100 ml.

Case 2

A single woman born in 1916 was well until the age of 20, when she began to suffer with severe nasal catarrh and repeated "colds" each winter. In 1947, at the age of 31, she had her first attack of pneumonia, followed by further attacks in 1948 and 1949, when she was admitted to hospital for drainage of an empyema. In 1950 and 1951 she had further attacks of pneumonia, and in 1952 she was admitted to another hospital, where she underwent a resection of her right middle lobe for bronchiectasis. This, however, did not prevent her from having a further attack of pneumonia in 1953. In 1954 she had another attack, and later in that year (October) was admitted to hospital for investigation and treatment of her chronic nasal catarrh by Mr. Stirk Adams. A routine blood grouping disclosed at this stage an abnormality in her iso-agglutinins which suggested an absence of gamma-globulin.

Examination of the serum proteins showed albumin 4.1 g. and globulin 1 g. per 100 ml. No gamma-globulin was revealed by the alcohol precipitation method, but paper electrophoresis showed 0.3 g. per 100 ml. The immunochemical method showed the presence of gamma-globulin in quantities below that present in normal control serum. Blood counts, serum bilirubin, alkaline phosphatase, and empirical tests of liver function were within normal limits. Shortly before her intended discharge she again developed pneumonia, which responded to penicillin, but two days after discontinuation of the therapy she had a second attack and, whilst convalescing, a third.

During this period the white blood cells rose from a normal level of 7,000 to 19,000 per c.mm., with 12,000 polymorphs per c.mm. No alterations in the levels of the serum proteins were detected. As no gamma-globulin was available at this

time it was decided to raise the level of her serum gamma-globulin by the transfusion of fresh plasma, 300 ml. being administered every three days until a total of 3 litres had been given. This resulted in a rise of gamma-globulin to 0.6 g. per 100 ml. as assessed by paper electrophoresis, but it gradually fell over the next 14 days to 0.3 g. per 100 ml., at which level it seemed to be relatively stationary. She was therefore given a further boosting transfusion of 600 ml. of plasma and discharged. Before the winter of 1955 1 litre of fresh plasma was transfused, which again raised the gamma-globulin level from 0.3 to 0.6 g. per 100 ml. Apart from one short attack of pneumonia aborted by antibiotic therapy during the summer of 1956, the patient has remained well.

Examination of blood from all her living relatives by paper electrophoresis and blood-grouping techniques failed to show any evidence of a deficiency in gamma-globulin and there was no history of recurrent infections.

Diagnosis

The condition, although attracting much attention, is rarely found with the present methods for detection. Nearly all cases, however, including the two reported above, have a history of recurrent infection, pneumonia being particularly frequent.

The deficiency of total gamma-globulin may be readily picked up by paper electrophoresis or by using the alcohol precipitation method, but techniques for detecting important partial deficiencies have not yet been developed. The immunochemical method is one such improvement which may allow the detection of some of the many protein fractions necessary for protection against infection.

The simple procedure of blood grouping, performed with care, will in most cases produce a result indicating an abnormality in the protein moiety of the serum that should invite further investigation. The pattern obtained in both of the above cases was more or less identical. The first case grouped by cell grouping as group O, but at first no alpha- or beta-agglutinins were identified in the serum, a finding usually associated with group AB. Further investigation of the serum at different temperatures (4° C., 20° C., and 37° C.) against A and B cells showed that at 4° C. group A cells were agglutinated up to a titre of 2, whereas group B cells showed hardly any agglutination at all. In spite of the fact that several high-titre group O sera did not agglutinate the patient's cells, it was thought necessary to exclude a possible subgroup of B, analogous to A2 or A3. Grouping-serum of moderate potency was incubated at room temperature for two hours with an equal volume of packed cells from the patient and with control group O cells, no difference being found. Interestingly enough, an indirect Coombs test performed with the serum from the patient against group A and group B cells at low temperature gave a weakly positive result against A cells only. Investigation for the presence of other immune antibodies gave a negative result, using a fairly large number of test cells. Later, when the serum contained some gamma-globulin, the abnormal grouping results had rectified themselves somewhat, and both group A and group B cells were now agglutinated at room temperature to a titre of 4, and, if anything, group B cells showed better agglutination than group A cells.

The diagnosis in the second patient was, as pointed out, actually suggested by a routine blood grouping. Again the cells grouped regularly, group A this time, and one would have expected the serum to contain beta-agglutinins. However, neither group A nor group B cells were agglutinated at either 22° C. or 4° C. To exclude a low-grade B antigen absorption experiments were performed with completely negative results. To exclude the possibility of a "blocking" anti-B antibody giving no reaction in saline media an indirect Coombs test was performed, using group B cells. Also trypsinized cells and cells suspended in albumin were used. A uniformly negative result was obtained. About six weeks later, when the patient had had treatment for some time, a little activity was demonstrated, but this only to a

titre of 2. From the findings obtained in both patients and others (Janeway *et al.*, 1953; Grant and Wallace, 1954; Sanford *et al.*, 1954; Wall and Saslaw, 1955; Kuhns *et al.*, 1956) it would appear that careful blood groupings might in all cases of group O, A, or B give an indication of agglutinin abnormality which should invite further investigation. Group AB patients would in this respect be at a disadvantage, as no iso-agglutinins are normally present in their serum.

Treatment

Once the condition is detected the use of antibiotics will control most infections, but it may also be necessary to raise the plasma gamma-globulin level. If fractionated gamma-globulin is not available in adequate amounts, this can be done temporarily by the transfusion of fresh plasma. Both of the above cases appeared to derive benefit from this form of treatment.

Discussion

The absence of gamma-globulin in the serum of young children has been ascribed to a hereditary defect resulting from a sex-linked recessive characteristic (Janeway *et al.*, 1953; Gitlin, 1954; Good, 1954). It is less likely, however, that such a concept holds good where the condition is first detected in adult life, such as the two cases reported here. In neither patient was there evidence of any unusual or recurrent illness in infancy and childhood. The familial occurrence of the condition was sought for in Case 2, but was not detected. In neither case was there any evidence of liver dysfunction, and, with the exception of the gamma-globulin, the other serum proteins were normal on all occasions, findings which support the view that gamma-globulin is not formed by the liver.

It is of interest that three further cases at least (Sanford *et al.*, 1954; Saslaw and Wall, 1954; Good 1954) have been reported somewhat similar to Case 1 in having a sprue-like syndrome. Some diminution in gamma-globulin, usually in conjunction with a general diminution of serum proteins, has been noted in a number of our patients with steatorrhoea due to varied causes, but in Case 1 the recurrent respiratory infection preceded the symptoms of steatorrhoea by at least 10 years, and it seems more likely that the pancreatitis and steatorrhoea were secondary to the agammaglobulinaemia.

The condition of agammaglobulinaemia in the two patients reported here would appear to be phasic, and it may well be that the administration of fresh plasma is adequate to tide them over any temporary crisis.

Summary

Two further cases of agammaglobulinaemia are described; both had recurrent attacks of pneumonia and one also had recurrent pancreatitis and steatorrhoea. The method of diagnosis, with particular reference to the blood-group screening test, is discussed. Transfusion of fresh plasma is recommended as a means of combating recurrent acute infection in these cases.

ACUTE IMMEDIATE REACTIONS TO PENICILLIN

BY

G. W. LEWIS, M.B., Ch.B.

General Practitioner, Leeds

Severe reactions, often fatal, occurring immediately after the administration of penicillin continue to be reported in this and other countries. The now extensive literature was reviewed by Calvert and Smith (1955). Cases have since been reported by Winton and Nora (1955), Dubberley (1955), Wright (1955), Bhattacharya (1955), Tidswell (1955), and Bell (1956).

Many of the reactions described are typically anaphylactic in type. In others vasomotor collapse may not be a prominent feature and bronchiolar spasm and angio-neurotic oedema do not occur, the main reaction being one of acute emotional upset. This type of reaction occurs usually within seconds of an injection of procaine penicillin, often after several injections of a course have been given without ill effect, and in a number of instances further injections of the same material have been given without incident. Batchelor *et al.* (1951) believed this type of reaction to be due to accidental intravascular injection of emboli consisting of agglomerations of crystals.

Angor animi and cacogeusia have been described as features of both this and the anaphylactic type of reaction.

Penethamate hydriodide ("neo-penil," "estopen") has earned a particularly bad reputation for producing severe and dangerous reactions, possibly on account of an inherent toxicity of this compound rather than on account of its penicillin content (Welch *et al.*, 1953).

The reaction potentiality of the very slowly absorbed repository penicillins is uncertain, but Anderson (1954) described a severe and protracted reaction following a single injection of benzathine penicillin.

The following comments were made in the *British Medical Journal* (1955b): "The frequency of accidental intravenous injection as a factor is still uncertain and calls for closer investigation. . . . More exact information is needed on the relative degrees of danger associated with soluble and procaine penicillin, and on whether sensitivity to procaine itself is a factor."

Since nearly all injections of penicillin given in hospital are administered by the nursing staff it was thought that more intimate information on these problems might be obtained from general practitioners, as they have to administer most of their injections themselves. Therefore the College of General Practitioners made an appeal to all members to supply information on any acute immediate reactions to penicillin seen by them. In order to define "immediate reaction" the arbitrary figure of one occurring within 15 minutes of the injection was adopted. The case reports which follow were obtained in this way. Cases 3 and 4 (Lewis, 1953, 1954) and Case 2 (Singh, 1955) have been described elsewhere. The cases have been divided into three groups.

Group 1

Case 1

A middle-aged medical practitioner described his own experience. There was no personal or family history of allergy. After an appendicectomy in 1949 he had a chest infection for which he was given twice-daily injections of

500,000 units of crystalline penicillin. On the third day he developed pyrexia and irritation of toes and groins in the same distribution as he had had a fungus infection whilst serving in the Western Desert. On ceasing the penicillin treatment his temperature fell to normal and the irritation subsided. In 1951 he had an acute sinusitis which was treated with daily injections of 300,000 units of procaine penicillin for four days without any ill-effect.

In September, 1954, he developed a very painful boil inside his nostril. A colleague gave him an injection of 1,000,000 units of crystalline penicillin followed immediately by 900,000 units of procaine penicillin in aqueous suspension. His experiences are best told in his own words: "About 15 minutes after the injection I felt nauseated and shortly afterwards became very red in the face. This was followed by swelling of the upper lip, and I felt so ill that I decided to drive to the local hospital. During the drive I had a feeling of constriction in the chest and a conviction of impending doom. I could feel that my heart rate was greatly accelerated and irregular. Having reached the hospital, I staggered in, dimly remembering being led to a side-ward, and then lost consciousness. I vaguely remember being looked at by a sister several times and by one of my colleagues, but regained full consciousness only after two hours, feeling very weak, itching as though I had a thousand fleas, and with a stiff, swollen upper lip. I was told that my pulse had been very fast, thready, and irregular. I was given promethazine hydrochloride ("phenegan") and spent the rest of the day in bed in a sleepy state, possibly due to the promethazine hydrochloride. The next day, though feeling weak and a little itchy, I was able to carry on with my work. One week later, whilst on holiday, the severe itching returned, with large urticarial weals all over my body."

Case 2

A medical practitioner aged 53 had received many previous injections of penicillin. On the last occasion, following an injection of procaine penicillin, he developed slight and transient swelling of the face. In January, 1955, having decided to give himself a further course of penicillin, he took two tablets of mepyramine maleate about five minutes before an injection of procaine penicillin in aqueous suspension which he administered to himself. Immediately after the injection he developed dryness of the throat and redness of the eyes, followed by a choking sensation, loss of sphincter control, and unconsciousness. He was given 0.5 ml. of a solution of adrenaline, 1 in 1,000, by an attendant.

When seen a few minutes later he was unconscious, incontinent, and sweating profusely. His breathing was laboured and stertorous and his pulse was impalpable. As he had already been given adrenaline, nikethamide was injected. After about two minutes he regained consciousness and complained of a burning sensation in the epigastrium and severe buzzing in the ears. He was given 30 min. (1.8 ml.) of aromatic spirit of ammonia but again lapsed into unconsciousness, with an impalpable pulse, profuse sweating, and dyspnoea with laryngeal stridor. A further injection of nikethamide and 1 ml. of adrenophedrine was given. He regained consciousness in about two minutes, again complained of a burning sensation in the epigastrium, and was shivering violently. The shivering continued for half an hour. When seen one hour later he had slight swelling of the upper lip, slight puffiness of the face, and complained that his whole body was aching. Next morning he seemed in perfect health, but 24 hours later he again developed aching of the whole body, which persisted for quite a long time.

Group 2

Case 3

A woman aged 34, with no personal or family history of allergy, had received courses of penicillin three and a half years and one year previously without incident. In September, 1953, she had acute otitis media, and 1,000,000 units

of crystalline penicillin was injected into the buttock. One minute later she suddenly lost consciousness. Her pulse was rapid, feeble, and irregular, but there was no evidence of cyanosis or respiratory embarrassment. She recovered consciousness in half a minute and repeatedly stated that she was dying. During the next 15 minutes her pulse became stronger and slower but was still irregular and she continued to feel very weak and ill. She then quite suddenly developed a severe colic, felt deep in the pelvis, with exacerbations and remissions each lasting about 10 seconds. These pains were described as "like labour pains, not a bellyache." This colic remained severe for half an hour, then ceased suddenly, and a few minutes later she seemed to be normal and had a strong regular pulse. An adrenaline injection was prepared but was not used. Twenty-four hours after the attack she began to menstruate, 10 days before her period was due. She had never previously had the slightest menstrual irregularity and had never suffered from dysmenorrhoea. Fifteen days later an intracutaneous injection of 4,000 units of crystalline penicillin produced neither an immediate nor a late reaction.

Case 4

A robust man aged 38 with no personal or family history of allergy had received a seven-day course of penicillin injections 20 months previously. A few days after the termination of this course he developed a rash which cleared quickly. In October, 1954, he developed a large carbuncle in his back with considerable surrounding cellulitis. Streptomycin was injected for two days with no improvement, so treatment was changed to daily injections of 900,000 units of procaine penicillin in aqueous suspension. After four days of this treatment without incident the cellulitis had resolved and the core was separating. For the next three days he received only local treatment, but the local condition deteriorated and daily injection of 900,000 units of procaine penicillin was resumed.

Four hours after the second injection of the resumed course he felt faint for a minute or two. Next day he received a similar injection into the buttock. Within seconds he lapsed into semi-consciousness with a rapid, irregular pulse and a conviction of impending doom. There was no cyanosis, respiratory embarrassment, or overfilling of neck veins. He was able to answer simple direct questions throughout. After about one minute he complained of severe throbbing in his back, indicating the tip of his fourth lumbar spine as the exact spot, and of paralysis from that level downwards. He could not feel the chair beneath him but could raise both feet just clear of the ground with difficulty. His arms felt numb and heavy. His pulse was still irregular, rate 160 a minute. About three minutes from the onset of the attack his legs felt a bit better and the throbbing in his back had ceased, but he then developed crippling substernal pain and complained of "pounding of the heart." His pulse was still irregular, rate 140. About six minutes from the onset of the attack he felt much better; the palpitation had ceased and sensation had returned to his body and legs. He had a feeling of coldness from the waist downwards and of tingling in the arms and fingers. These sensations passed quickly and 10 minutes later he seemed normal and cheerful. His pulse was regular, rate 80. He was given a card to place in his wallet stating that he had suffered a severe reaction to penicillin.

Case 5

A man aged 50 had had one injection of penicillin, probably crystalline, four years previously without incident. He was given an intramuscular injection of 500,000 units of crystalline penicillin for an acute bronchitis of three days' duration. Within two minutes of the injection he collapsed. His pulse was weak, rapid, and irregular, and the skin pale and cold. Within a further two minutes he showed signs of reviving, and the injections of adrenaline and nikethamide which had been prepared were not given. When able to

speak he said he felt very weak and was sure he was dying. He experienced a vague pain in the right leg as he was reviving. The chest infection was short-lived, but his recovery from the effects of the reaction was protracted. One month after the attack he still felt so weak that he was unable to walk more than about 50 yards (45 m.). Three months later he was in excellent health.

Case 6

A man aged 60 who had no personal or family history of allergy and who had never previously had penicillin by mouth or by injection was given a course of penicillin injections for a carbuncle. The course consisted of daily injections of 600,000 units of procaine penicillin in aqueous suspension. Five injections were given without incident. About half a minute after his sixth injection he turned pale and said he felt sick and queer, and that he was about to die. His breathing became rapid and shallow and his pulse impalpable. He next complained of a severe throbbing headache and then lost consciousness. He remained unconscious for about two minutes. As he was recovering he complained of severe substernal pain, but after lying recumbent for a while this eased off and in 15 minutes he had recovered sufficiently to go home. On examining the syringe used for the injection it was noted that the dregs were slightly blood-stained.

The practitioner recording this case reports that over a period of five years he has discarded a syringe of procaine penicillin on three occasions because traction on the plunger had withdrawn blood.

Case 7

A married woman aged 35 was given daily intramuscular injections of 600,000 units of procaine penicillin in aqueous suspension for chronic sinus infection and bronchitis. So far as could be ascertained she had not previously had penicillin by injection but had applied penicillin cream for an infected dermatitis four years previously. The injections were given by the district nurse, the first four without incident. Immediately after the fifth injection the patient collapsed, with greyish pallor and feeble pulse. When seen about half an hour later she had recovered considerably but was still very frightened. Following the attack her personality changed; previously jolly and active, she became depressed and anxious. Her menses were diminished and she suffered from hot flushes. She was now sensitive to all forms of penicillin and also to chloramphenicol and sulphonamides. She had improved somewhat one year later, when she left the district, but was still far from being her old self.

Case 8

A woman aged 54 was a chronic invalid with a history of rheumatoid arthritis, paroxysmal tachycardia, asthma, bronchiectasis, and emotional instability. She is believed to have had injections of penicillin on previous occasions. In October, 1955, it was decided to give her a course consisting of 500,000 units of penethamate hydriodide plus 1 g. of streptomycin sulphate daily on account of an acute flare-up of her bronchiectasis. When both preparations had been mixed in one syringe, the syringe used was filled to capacity, rendering it impossible to withdraw the plunger before injection, and the full injection was given into the buttock. This was followed immediately by exclamations of fear and by dizziness, confusion with partial loss of consciousness, and a complaint of pain up the back of the neck. There was no evidence of collapse, and recovery was complete within about 15 minutes without treatment. Intradermal injections of penethamate hydriodide and of streptomycin sulphate a few days later produced no reaction and she was subsequently given five daily injections of 600,000 units of procaine penicillin in aqueous suspension without ill effect.

The practitioner recording this case believes that the reaction was due to accidental intravascular injection of some of the material.

Group 3

Case 9

A guardsman aged 21 who had had a boil on one of his fingers for several days was prescribed a course of penicillin injections. There was no personal or family history of allergy. Three years previously he had been given a course of penicillin injections with no ill-effect. An injection of 600,000 units of procaine penicillin in aqueous suspension was given by an experienced orderly. Within seconds he complained of feeling queer and collapsed. When seen, almost immediately, he was shocked, with cold sweating hands, impalpable radial pulse, regular apex beat of 120, dyspnoea with rapid deep breaths, and bouts of intense shivering; he complained of "pins-and-needles" in, and inability to move, his lower limbs. There was no withdrawal of the feet or movement of the great toes on plantar stimulation. He was restless and very anxious. He remained conscious throughout. Within a few minutes he was given 1 ml. of 1 in 1,000 adrenaline solution. After about 30 seconds his dyspnoea ceased and he began to feel better, but one minute later all his symptoms reappeared in full. A further 1 ml. of the adrenaline solution was given and again he improved, this time permanently. The whole episode lasted about five minutes. Later that day he felt quite well.

The practitioner who treated this case mentions that he has since given penicillin injections himself whenever possible and has been surprised to find how easily blood is aspirated into the syringe occasionally.

Case 10

A healthy woman aged 55 gave no history of allergy. She had received several previous courses of penicillin injections without incident. In August, 1955, on account of an abscess, a course of injections of procaine penicillin in aqueous suspension was given, the dose being one injection of 600,000 units daily. The first three injections were given without incident. During the fourth the plunger was withdrawn and about a quarter of the dose injected before it was realized that a trace of blood had entered the syringe. The needle was withdrawn a little before completing the injection. Within a few seconds she felt dizzy and became confused and obviously frightened, calling for her husband and child in anguish and complaining of failing vision. The pulse and colour remained good and none of the classical signs of shock were present. Five minims (0.3 ml.) of adrenaline solution 1 in 1,000 was injected and in about 10 minutes she had recovered completely. Ten days later an intradermal injection of procaine penicillin produced a slight red flare.

Case 11

A man aged 56 gave no personal or family history of allergy and had not had penicillin previously in any form. He had an excision of caecum and ascending colon performed in February, 1956, on account of chronic infection with an abscess cavity extending into the substance of the iliacus as far as the periosteum. For six days before and six days after operation 900,000 units of procaine penicillin in aqueous suspension was injected daily without incident. Six days after the last injection he developed a pyrexia, and it was decided to give him a further course of procaine penicillin. Immediately after the first injection of 900,000 units, given into the left buttock, he complained of severe stabbing pain across the buttocks and extending up the back of the spine to the occiput, and that his head felt "muffled and numb." He had a feeling of impending death, but this passed quickly. There was no clouding of consciousness or any evidence of circulatory collapse. He recovered his composure within about half a minute and felt much better, but his left arm and leg seemed "numb and bloodless." This passed quickly, and within 15 minutes he felt normal. The attack was attributed to accidental intravascular injection. Four further daily injections of 900,000 units of procaine penicillin were given without incident. Three months after the attack his head still felt a bit numb and his legs were still weak.

Case 12

A middle-aged woman who had suffered from bilateral bronchiectasis for many years had received numerous courses of penicillin injections during acute exacerbations. The earlier courses consisted of various preparations of soluble penicillin, but for the past eight years a course had consisted of five daily injections of 900,000 units of procaine penicillin in aqueous suspension. In October, 1953, immediately after the last of five daily injections, she became unconscious, with stertorous breathing and Jacksonian movements of the left side of the body. Both pupils were widely dilated and her pulse was weak, rapid, and irregular. She recovered consciousness after about five minutes and had a premonition of death; the pulse became more irregular and she lapsed into unconsciousness again. The pulse slowly became more regular, and in a further 20 minutes she had recovered sufficiently to be taken home by car.

Discussion

There seems little doubt that many of the acute reactions described in the literature after the administration of penicillin have been anaphylactic. This is suggested by the following facts: crystalline penicillin has been given intravenously in very large doses without incident (Janowitz *et al.*, 1948; Whipple, 1951); there is usually a history of previous penicillin therapy and often of a mild reaction following one of the preceding doses; some but by no means all patients can be shown, by means of cutaneous and intradermal tests, to be sensitized following the reaction; the clinical picture of an acute reaction bears a close resemblance to those following anaphylactic reactions to foreign sera and proteins; and the pathological findings in fatal cases of acute reactions to penicillin (Harpman, 1952; Curphey, 1953; Rosenthal, 1954) are essentially similar to those resulting from serum and foreign protein anaphylaxis (Vance and Strassmann, 1942). Most of the fatalities with penicillin have been attributed to profound circulatory failure or to asphyxia due to intense bronchospasm.

The sensitizing agent usually incriminated is injected crystalline or procaine penicillin; but sensitization, and even severe reactions, may occur after oral administration or topical application. Severe reactions have been reported after the use of penicillin tablets (Welch *et al.*, 1953; Bell, 1956), lozenges (Mayer *et al.*, 1953; Calvert and Smith, 1955), "aerosol" (Leibowitz and Schwartz, 1950; Blanton and Blanton, 1953), ophthalmic ointment (Carter and Cope, 1954), and after instillation into the sinuses (Everett, 1951; Weiss, 1953) and application to a wound (Irwin *et al.*, 1951). It has been claimed that penicillin O is antigenically different from penicillin G (Volini *et al.*, 1950), but this has been disproved (Siegal, 1951; Feinberg *et al.*, 1953). The simultaneous administration of an antihistamine has been shown to be without significant protective value (Mathews *et al.*, 1955); and the danger of relying on the simultaneous administration of either adrenaline or cortisone in sensitized individuals is illustrated by the fatal cases of Pick and Patterson (1953) and Winton and Nora (1955).

Waldrott (1953) has suggested that a major factor in the production of anaphylaxis in man is accidental intravenous injection or introduction into a vein by back-seepage. From his experience with foreign proteins he emphasized that, except in highly sensitized individuals, intravenous injection produces a much more rapid and profound anaphylactic reaction than does local injection. Rosenthal (1954) failed to find any evidence of penetration of a vein by the needle in the course of necropsy on six cases of acute reaction to penicillin, but in a case before the Westminster coroner (*British Medical Journal*, 1955a) in which a woman aged 72 died within five minutes of an injection of 500,000 units of crystalline penicillin, the pathologist reported that a vein in the arm showed evidence of having been transfixed by the needle. It is thus probable that both the type and the severity of the anaphylactic type of reaction to penicillin

may depend on whether any of the material has reached the blood stream directly as well as on the degree of sensitization of the patient.

Everything that has been said of crystalline penicillin applies equally to procaine penicillin, but in the case of the latter it is necessary to consider whether all or part of the reaction might not be due to the procaine moiety. Provided procaine is absorbed slowly, large doses can be given without producing central effects, but the toxicity of procaine is enormously increased if rapidly injected intravenously. Martin (1928) described acute toxic reactions to procaine as being of two types. One is characterized by clonic convulsions due to irritation of nerve centres, and may be followed by respiratory paralysis. The other is characterized by an abrupt fall in blood pressure, also probably due to central irritation, in which the patient becomes cold, clammy, and dazed. Buff (1950) described a syndrome due to procaine toxicity which is characterized by tachycardia, tremor, irregular respiration, blurring of vision, sweating, paraesthesiae, dilated pupils, and intense anxiety with angor amini—a symptom-complex which is very reminiscent of some of the acute reactions described following injections of procaine penicillin. State and Wangenstein (1946) found that intravenous injection of procaine at a rate in excess of 8 mg. a minute caused flushing, dizziness, and generalized numbness.

Commercial preparations of procaine penicillin contain 32–40% by weight of procaine base (Batchelor *et al.*, 1951) and an injection of 600,000 units of procaine penicillin will contain about 240 mg. of procaine base (Goodman and Gilman, 1955). The accidental intravascular injection of all or part of this dose within a period of, say, half to one minute would be expected to produce an immediate reaction on the basis of the known toxic effects of procaine without there being any need to invoke the phenomena of sensitization, hypersensitivity, or idiosyncrasy. Such a toxic reaction might well resemble an anaphylactic reaction in many of its features. If, however, there were smooth-muscle spasm, or if the attack were accompanied or followed by urticaria or angioneurotic oedema, none of which is a manifestation of procaine toxicity, the reaction might be a mixed one, some of the symptoms being due to procaine toxicity and some to the intravascular injection of penicillin in a slightly sensitized individual.

In those instances of acute reaction to procaine penicillin in which subsequent injections of the same material have been given without incident, as in Case 11 of this series and in five of the eight cases reported by Batchelor *et al.* (1951), it is probable that the reaction was due to the procaine moiety gaining direct access to the blood stream, but the danger of assuming that any reaction following injection of procaine penicillin is due to its procaine content alone is borne out by the experience of Thomson (1952). His patient developed a severe immediate reaction after an injection of procaine penicillin. On the assumption that the reaction was due to procaine hypersensitivity this patient was given an injection of crystalline penicillin five weeks later and died in profound shock within 15 minutes.

It is believed that the diverse pattern of acute immediate reactions to injected preparations of penicillin is due in part to variation in the degree of sensitization of the patient, and in part to direct entry of injected material into the vascular system. In the present series there was direct evidence of intravascular injection in three instances. It is suggested that the reaction in the cases placed in group 1 was due to intramuscular injection of penicillin in sensitized individuals, in group 3 to rapid intravascular injection of procaine, and in group 2 to intravascular injection of penicillin in slightly sensitized individuals. Of the cases placed in group 2, the preparation used in Cases 3 and 5 was crystalline penicillin, whereas in Cases 4, 6, and 7 the preparation was procaine penicillin, and the reaction in these may have been due, in part, to the procaine moiety. In Case 8 the reaction followed an injection of penethamate hydriodide and may have been due to the known toxicity of this compound, since

subsequent injections of procaine penicillin were given without incident. Alternatively, the reaction may have been due to the streptomycin administered at the same time.

Precautions

The following precautions are suggested as a means of minimizing the incidence and severity of acute reactions to penicillin preparations.

1. *Reduction of Incidence of Sensitization.*—Topical application of penicillin in the form of cream, ointment, lozenges, chewing-gum, tulle gras, aerosol, etc., is of very doubtful value and probably should be abandoned. Oral and parenteral administration should be confined to cases in which there is a clear indication.

2. *Careful History-taking.*—Inquiry should be made concerning any personal or family history of allergy, and details obtained of any previous treatment with penicillin—parenteral, oral, or topical. An effort should be made to elicit any evidence of a reaction following previous administration of penicillin, a point being made of inquiring about any reaction experienced within 10 days, as late reactions might not have been interpreted as being due to the penicillin. Even a mild reaction such as irritation or a mild pyrexia is significant.

3. *Handling of the Suspicious Case.*—In the allergic individual, one who has experienced a mild reaction previously, and those who have received many previous courses of penicillin it may be wise to carry out dermal and intradermal tests where feasible, using solutions of crystalline penicillin. A positive reaction would indicate the need to exercise extreme caution; a negative reaction means absolutely nothing. In all suspicious cases the technique suggested by Waldbott (1953) of injecting a small amount of the preparation and then waiting 45 seconds with the needle *in situ* before giving the rest of the dose has much to recommend it. Alternatively, it may be possible to give a preliminary test dose by mouth as suggested by Schiller (1953), since any reactions to penicillin by this route are likely to be less acute than when it is given parenterally. The patient should be kept under observation for 20 minutes after the injection, and a solution of adrenaline should be at hand ready for immediate use. Several writers have suggested that the arm or leg should be used for the injection in preference to the buttock, so that a tourniquet can be applied immediately should a reaction occur.

4. *Spacing of Injections.*—The interval between individual injections of a course should never exceed 10 days, the time required for sensitization to become established.

5. *Technique of Injection.*—A wide-bore needle, not smaller than a No. 1 serum needle, should be used for both crystalline and procaine penicillin so that blood will be readily aspirated if the needle penetrates a vein. To the same end, the syringe should never be filled to capacity. After insertion of the needle, traction should be applied to the plunger and should be prolonged in the case of procaine penicillin, as it is difficult to recognize the entry of a small amount of blood and the blood takes time to reach the side of the syringe on account of the viscosity of the suspension. The patient should be recumbent or sitting on a chair in such a way that there will be little or no movement during the process of injection; and should the position of the needle change, even slightly, during the injection, this should be halted and traction again applied to the plunger to ensure that the needle is still outside a vein. The injection should be given slowly and without applying more than light pressure on the plunger. Not infrequently there is considerable resistance when beginning an injection of procaine penicillin, due to blockage of the needle by an agglomeration of crystals. In this event it is probable that the preceding traction on the plunger could not have produced blood even if the needle had been in a vein. The needle should be withdrawn, the block cleared by pressure on the plunger, and the needle reinserted. After completion of the injection, pressure should be applied to the injection site for a few seconds to prevent

oozing, but the injection area should not be massaged for fear of producing back-seepage of the injected material into a punctured vessel.

All nurses, and other personnel who may be required to give penicillin injections, should receive instruction on the minutiae of the injection technique.

6. *Precaution Against Repetition.*—All patients who have suffered an acute immediate reaction from the administration of penicillin should be given a card or disk indicating this fact, and this should be carried in the wallet or handbag.

Treatment

The fact that so many of the patients in this series recovered rapidly without treatment suggests that the claims made for this or that treatment may be unjustified, recovery occurring in spite of treatment rather than because of it. However, since it is impossible to forecast the train of events and there is a danger that severe bronchospasm may occur rapidly, it is best to regard every acute reaction as an anaphylactic one so far as immediate treatment is concerned. At the first sign of an acute reaction 0.5 ml. of a solution of adrenaline 1 in 1,000 should be injected intramuscularly. This should be repeated as required or injection of the solution continued at the rate of 0.1 ml. a minute until the attack shows signs of terminating. An intravenous antihistamine such as diphenhydramine hydrochloride in a dose of 50–100 mg., or of promethazine hydrochloride in a dose of 25–50 mg., may also have some value, but they tend to produce a state of drowsiness lasting several hours. Positive-pressure oxygen should be administered where indicated and if available, and in cases where recovery is delayed intravenous hydrocortisone has been found to be valuable.

Those patients who experience weakness and malaise for a considerable time after the reaction, such as Cases 5, 7, and 11 in this series and one of the cases described by Bell (1956), may benefit from the administration of neostigmine, as did three of the patients described by Winston and Nora (1955). Acute reactions believed to be due to procaine toxicity in which there is evidence of gross central stimulation, such as generalized convulsions, might be expected to benefit from the administration of an intravenous barbiturate.

Summary

Twelve instances, from general practice, of acute immediate reactions following injection of preparations of penicillin are recorded.

The nature of these reactions and their possible modes of production are discussed. It is suggested that they may be produced in one of three ways: (1) intramuscular injection of penicillin in sensitized individuals; (2) accidental intravascular injection or back-seepage in sensitized individuals; or (3) accidental rapid intravascular injection of procaine penicillin suspensions.

A scheme for minimizing the incidence and severity of these reactions is outlined and suggestions are made for treatment.

I am indebted to Drs. C. A. Brockbank, S. D. Singh, A. C. Caftanach, A. A. Fullerton, A. R. Montgomery, J. Macdonald, A. Gilston, and L. S. Calvert for allowing me to quote their case reports, to the other practitioners who sent reports on penicillin reactions which did not quite fall within the arbitrary definition of immediate reactions, and to the College of General Practitioners and the *Practitioner* for publishing my request for case histories.

CHLORAMPHENICOL IN TREATMENT OF ACUTE RESPIRATORY INFECTION

BY

A. H. IOANNIDIS, M.B., Ch.B.

Clinical Assistant

AND

J. McC. MURDOCH, F.R.F.P.S., M.R.C.P.Ed.

Senior Medical Registrar

From the Royal Infirmary, Edinburgh, and the Department of Therapeutics, University of Edinburgh

During recent years medical teaching in this country has tended to limit the use of chloramphenicol primarily to the treatment of the typhoid group of infections in view of its alleged toxic effects on the haemopoietic system; it has been suggested that respiratory infections are more appropriately treated with other chemotherapeutic agents. The view is now generally held, however, that the micro-organisms commonly invading the human respiratory tract are of a mixed type. Of these, probably the most important in the United Kingdom are the *Haemophilus influenzae* and the pneumococcus (*Lancet*, 1955). The former organism is highly sensitive to chloramphenicol both *in vitro* (Fairbrother, 1956) and *in vivo* (May, 1953a, 1953b, 1954; Elmes, Knox, and Fletcher, 1955; Franklin and Garrod, 1953). Cohen and Schwartz (1950) believed chloramphenicol to be the antibiotic of choice in acute respiratory infections of undetermined origin, in the absence of an influenza epidemic or a "common cold."

Tunbridge (1953) points out that in infections usually of mixed origin it is advisable to use a chemotherapeutic agent which is effective against both Gram-negative and Gram-positive organisms, as well as against some virus infections. Penicillin alone is not always effective, as it has a limited action against Gram-negative organisms, especially *H. influenzae* (Stuart-Harris *et al.*, 1953), and May and Oswald (1956) have suggested that a combination of penicillin and streptomycin gives prompt and complete remission of exacerbation in the early stages of chronic bronchitis.

In our view, however, there are several possible objections to this combination of antibiotics in such cases. Firstly, in the absence of absolute negative evidence of a tuberculous basis for the bronchitis, the use of streptomycin carries the risk, albeit small, of inducing resistance in the causative tubercle bacilli, even with a relatively small total dose (Medical Research Council, 1948). Secondly, it seems irrational to subject a severely ill patient to frequent and possibly painful injections where simple oral therapy could be used. Thirdly, as Zinnemann (1953) has shown, chloramphenicol was the only one of five antibiotics capable of inhibiting 100% of strains of *H. influenzae* tested at the comparatively low concentrations obtained with the usual recommended therapeutic doses; it would therefore seem that this organism cannot always be eradicated by such a combination. Finally, there is no doubt that many staphylococcal infections, especially those seen in hospital, are due to penicillin-resistant strains (Barber and Burston, 1955).

As Hausmann and Karlish (1956) have suggested, staphylococcal infections are responsible for a considerable number of cases of pneumonia failing to respond to penicillin, and such infections are likely to present a major problem in the future. In a series of 17 cases of penicillin-resistant staphylococcal empyemata reported by Brownrigg (1955) chloramphenicol was found to be the most effective drug. De Vries and Pritchard (1955) isolated *Staphylococcus pyogenes* from 87 post-mortem specimens. Of these, 100% were sensitive to chloramphenicol, and 88% were resistant to penicillin, 48% being resistant also to the tetracyclines. Rantz and Rantz (1956), studying the resistance pattern of 242 strains of *Staphylococcus aureus*, showed 81.8% to be penicillin-resistant, 51.7% streptomycin-resistant, 52.5% tetracycline-resistant, and only 5.8% chloramphenicol-resistant.

It would seem, therefore, that oral antibiotic therapy is preferable in the treatment of acute respiratory infections, and the choice lies between chloramphenicol and the tetracyclines. For short-term therapy we elected to use the former antibiotic, in the belief that the tetracyclines were better reserved for the long-term treatment of more chronic advanced cases of bronchial infection, and there is some evidence (Helm *et al.*, 1956) that stopping such treatment and restarting after a short interval may encourage the development of resistant strains of *H. influenzae*.

We report here our observations and results of treatment with chloramphenicol in 80 consecutive admissions to the Royal Infirmary, Edinburgh, all of whom were suffering from acute and severe respiratory infection, either *per se* or complicating other conditions. This is a report of experience only and is in no way a controlled trial.

Materials and Methods

The 80 patients selected for treatment were consecutive admissions to the hospital during the period June 10, 1956, to February 7, 1957. There were 63 males and 17 females, whose ages ranged from 34 to 79 years, and all were suffering from acute respiratory infection, characterized by fever, dyspnoea, and cough with the production of a purulent or mucopurulent sputum. Of these, 54 were suffering primarily from respiratory disease with an acute exacerbation. The remaining 26 had an acute respiratory infection complicating another condition. Out of the total number, 24 patients had received previous treatment with penicillin alone, 6 with penicillin combined with streptomycin, and a further 6 with

spiramycin. None of these 36 patients had shown a favourable response to such treatment, given in adequate total dosage by modern standards. Details of these patients are shown in Table I.

TABLE I.—Patients' Main Disease and Previous Antibiotic Treatment, if Any

Main Disease Complicated by Respiratory Infection	No. of Cases		Previous Antibiotics		
	Male	Female	Penicillin	Penicillin and Streptomycin	Spiramycin
Chronic bronchitis— empyema	29	12	17	5	6
Bronchiectasis	6	—	1	—	—
Bronchial asthma	3	4	2	—	—
Pulmonary embolism	5	—	—	—	—

Observations made in all cases before, during, and after treatment included assessment of general physical state, degree of fever, character, quantity and bacteriology of the sputum, and full peripheral blood counts.

The treatment consisted of chloramphenicol, 2 g. daily (500 mg. six-hourly) to a total of 10 g.—that is, five days' treatment. Careful observations on possible side-effects such as glossitis, skin rashes, sore throat, and alteration in the character and frequency of the stools were also made during treatment.

Pre-treatment sputum cultures on blood-agar medium showed the predominant organism to be *H. influenzae* in 15 cases, pneumococcus in 24 cases, *Staph. pyogenes* in 19 cases, and no predominant growth from mixed organisms in 22 cases. These figures are summarized in Table II. Of the

19 cultures yielding a predominant growth of *Staph. pyogenes*, only two were found to be fully sensitive by routine laboratory methods—that is, to penicillin, streptomycin, chloramphenicol, and the tetracyclines. Seventeen were resistant to penicillin, seven to streptomycin, and eight to the tetracyclines. All were sensitive to chloramphenicol and five to this antibiotic alone.

Results

The results of treatment are shown in Table III. The general condition of 77 patients was regarded as improved at the end of the fifth day of treatment in that they were afebrile and free from respiratory symptoms and signs. Of these, 73 remained free from symptoms, continuing to be

without sputum for periods varying from one to eight months after treatment. Relapse occurred in three patients within seven days of stopping therapy: return of fever and productive cough with infected sputum. One patient, although subjectively improved, had a mucopurulent sputum at the end of treatment, while three patients were totally unaffected.

As to the control of infection, the assessment of the change in purulence of the sputum before and after treatment is shown in the Chart. The bacteriological results are shown in Table IV. Forty-eight patients had no sputum at the end of treatment. Twenty-five produced mucoid sputum from which no growth of organisms was obtained on culture. Of the seven patients considered either to have been unaffected by treatment or to have relapsed within one week, mixed organisms were cultured from the sputum in four—*H. influenzae* in one, and pneumococcus in two.

It is noteworthy that in none of the 19 patients whose sputa grew *Staph. pyogenes* before treatment could any growth of organisms be obtained on culture thereafter.

No. of cases	Side-effects				No Side-effects
	Blood Disorders	Diarrhoea	Skin Rash	Dry Mouth	
Percentage	0	1	1	3	75
	6.25				93.75

Side-effects (See Table V).—Seventy-five patients (93.75%) in this series were completely free from any side-effects attributed to chloramphenicol. Of the remaining five (6.25%), one had slight transient diarrhoea for 24 hours, which did not necessitate stopping the drug. Three developed a dry mouth, detected only by direct questioning, and one of them had in fact a mild "black tongue." The fifth patient exhibited a slight erythematous rash over the arms and hands during treatment, although this may have been caused by concomitant phenobarbitone medication. No evidence of bone-marrow depression as a result of therapy was elicited by comparative blood counts before and after treatment in all cases.

Discussion

In deciding to employ chloramphenicol in this series, we were well aware of the serious objections which have been raised against its use. Probably as a result of the negligible incidence of reported side-effects, chloramphenicol was extensively and often indiscriminately prescribed prior to 1952, by which time a number of blood dyscrasias, including aplastic anaemia, thrombocytopenia, and neutropenia had been reported. All of these were surveyed by the Food and Drug Administration of the United States of America in 1952 (Lewis *et al.*, 1952). As a result, a policy of restraint in its use was advocated thereafter. Since then exhaustive work, both experimental and clinical, has been carried out

in an endeavour to elucidate the questions raised by such reactions. These have been admirably posed by Parker (1955-6) as follows: What is their true significance? Are they purely coincidental? Are they a toxic reaction to the nitrobenzene radical? Are they related to the total dosage of the drug? Are they precipitated by previous or concomitant medication?

Research workers now seem to be in a little doubt about the cause of the abnormal bone-marrow finding in experimental animals after the administration of large doses of chloramphenicol. They seem to agree that the earlier reports on the marrow findings (Radomski and Nelson, 1953; Rigdon *et al.*, 1954) are mainly, if not wholly, due to malnutrition of the animals resulting from the administration of chloramphenicol (Nelson and Radomski, 1954; Weston *et al.*, 1954; Saslaw *et al.*, 1954-5; Radomski *et al.*, 1955; Reutner *et al.*, 1955; Rigdon *et al.*, 1955; Reutner *et al.*, 1955-6). This malnutrition was shown to be due to the marked anorexia induced by chloramphenicol, noted earlier by Gruhitz *et al.* (1949).

Following the earlier reports attributing blood dyscrasias to chloramphenicol administration, a nation-wide survey was carried out by Lewis *et al.* (1952) in the U.S.A., which produced no definite clinical evidence incriminating chloramphenicol in this respect. Welch *et al.* (1954), in a similar survey two years later, emphasized that "it cannot be stated categorically that chloramphenicol actually caused the blood dyscrasias which developed following its use." In the United Kingdom Hodgkinson (1954) surveyed 31 blood dyscrasias attributed to chloramphenicol from 20 centres, 28 of which were classified as aplastic anaemia. Seventeen of these patients had received concomitant treatment with other drugs, including sulphonamide (12), pyribenzamine (2), and streptomycin (1), each of which has been reported to be associated with the occurrence of aplastic anaemia. In 24 cases the dosage was over four times that employed by us, and the average was more than double that calculated to be the maximum necessary to control most infections.

In an endeavour to determine whether or not early blood or bone-marrow depression occurred in a controlled group of 43 children receiving antibiotics—75% of whom had chloramphenicol for 10 days—Doyle *et al.* (1953-4) found by serial examinations no change in the normal pre-treatment marrow or peripheral blood findings either during treatment or three months thereafter. Among others, Bercovitz (1953-4) also reported no abnormal blood findings in 67 patients with ulcerative colitis treated intermittently with chloramphenicol for long periods. In our series of 80 patients there was no significant clinical or laboratory evidence of blood disorders as a result of chloramphenicol administration.

Accordingly, we feel that the risks incurred by giving chloramphenicol in short courses of 10 g. are negligible or, at most, no more than with any potent drug. It is worth recalling that following early reports of serious sulphonamide toxicity, such as that of Sutcliffe *et al.* (1943), a restricted total dosage has been in use for many years. Even penicillin administration carries the risk of anaphylactic reactions in susceptible individuals, amounting to 100 to 200 acute reactions in a single year (Welch *et al.*, 1954), and three deaths have recently been attributed to this cause (Andersen, 1955-6).

As has been stated already, the tetracyclines should be reserved for the long-term treatment of more chronic advanced cases of bronchial infection, rather than for short-term treatment of acute episodes. There is already some evidence that repeated short courses of tetracyclines may encourage the development of resistant strains of *H. influenzae* (Helm *et al.*, 1956). Moreover, the high incidence of tetracycline-resistant staphylococci may be attributed to repeated or prolonged exposure, or to hospital infection (Brownrigg, 1955; de Vries and Pritchard, 1955; Barber and Burston, 1955; Rantz and Rantz, 1956; May and Oswald, 1956). We would also hesitate to use the tetracyclines in such cases as diabetic ketosis aggravated by bronchial infection or

mitral stenosis with cardiac failure attributable to bronchial infection, where any diarrhoea caused by these drugs would be detrimental to the underlying disease.

Summary and Conclusion

Eighty patients with acute respiratory infection of mixed bacterial origin either *per se* or complicating other conditions were treated with chloramphenicol, 2 g. daily for five days. Clinical improvement resulted in 77, three being totally unaffected. Relapse occurred in three patients within one week. The infection was controlled in 73 patients for periods varying from one to eight months after treatment.

Seventy-five patients were quite free from side-effects; dry mouth was observed in three, a mild skin rash in one, and slight transient diarrhoea in one. No blood dyscrasias of any kind were detected.

The potential toxicity of chloramphenicol has been overstressed. If it is given in short courses of 10 g. over five days to patients with acute and severe respiratory infections a satisfactory and prompt response is obtained, with a very low failure and relapse rate, and with negligible toxicity. Chloramphenicol has therefore a definite place in the treatment of such cases, but should not be employed in prolonged dosage or for trivial infections. It may well be that the avoidance of its extensive use in recent years has had the advantage of enabling us to deal effectively with organisms now frequently resistant to the other antibiotics more commonly employed.

We are grateful to Professor D. M. Dunlop for helpful advice and criticism on the preparation of this paper, and for allowing us to study the patients under his care. We also thank Dr. J. H. Bowie and the staff of the bacteriology department of the Royal Infirmary, Edinburgh, for carrying out the sputum cultures and sensitivity tests.

Elizabeth Garrett Anderson Hospital, London

The work described below is a controlled trial of oral treatment of trichomonas vaginitis, using the oral product aminitrozole (2-acetyl-5-nitrothiazole, "tritheon"). During the course of the trial, attempts have been made to culture the *Trichomonas vaginalis*, using the simplified trypticase serum medium of Kupferberg.

Literature

Cuckler, Kupferberg, and Millman (1955) showed that aminitrozole administered orally is effective against trichomonas infection *in vitro* and *in vivo*. It was shown to have a therapeutic effect in experimental vaginal trichomoniasis in monkeys and mice. It is also effective against amoebae and against schistosomiasis. Aminitrozole was well tolerated in six species of animal for extended periods when administered by various routes. In some cases in dogs, brown urine was produced, and this has also been noted in humans.

Perl, Guttmacher, and Raggazoni (1956) treated a series of 174 cases of trichomonas vaginitis with aminitrozole and a cure was obtained in 35%. Out of 48 husbands of infected women, trichomonads were found in the semen of 28 (58%). Of these, 16 who brought further seminal specimens after treatment with aminitrozole were cured after one course of treatment, while a further two were cured after two courses of treatment. The remaining 10 defaulted. In the female trichomonas infection was found to be heaviest one week before and one week after menstruation. When husband and wife both received treatment the percentage of cures was increased.

Plentl, Gray, Neslen, and Dalali (1956) treated a series of cases of trichomonas vaginitis, using aminitrozole in a dose of 150 mg. three times a day. Severe side-effects were noted, including nausea, abdominal pain, anorexia, and dark urine. When the dose was reduced to 100 mg. three times a day, using enteric-coated tablets, side-effects were minimal. Eradication of trichomonas was achieved in 35% and clinical improvement in 67%.

Kupferberg, Johnson, and Sprince (1948) gave a detailed description of the method of preparing a simplified trypticase serum medium for the culture of *Trichomonas vaginalis*. Kean and Day (1954), using this medium for the diagnosis of trichomonas infection, found that culture was more reliable than the hanging drop method for the diagnosis of infection. In 500 consecutive patients examined from a gynaecological clinic the hanging drop was positive in 12.2%, while culture was positive in 18%. They concluded that culture of the organism was essential for diagnosis.

Present Investigation

This investigation was planned with two main objects. The first was to test the effectiveness of aminitrozole for the oral treatment of trichomonas infection. During the course of the trial the second object was to test the use of the simplified trypticase serum medium for the culture of *Trichomonas vaginalis*.

Cases of trichomonas vaginitis were divided alternately into two groups—treated and control. The treated group received aminitrozole 100 mg. three times daily by mouth for ten days, and "aci-jel" vaginal jelly inserted night and morning for three weeks. The control group received aci-jel only, night and morning for three weeks. (Aci-jel is a buffered vaginal jelly with a pH of 4, containing acetic acid, boric acid, oxyquinoline sulphate, ricinoleic acid, and glycerin in a vegetable-gum base.)

In all cases the aim was to take smears at the first visit and after two, four, and six weeks. Treated cases which were negative at six weeks were re-examined at 12 and 24 weeks. Control cases which remained positive after four weeks were given treatment and thus transferred to the treated group. Treated cases positive after six weeks and those which relapsed were given further treatment, some patients receiving three courses in all. Cases regarded as failures with oral treatment were removed from the trial and given local treatment with acetarsol or other forms of medication; in a few cases local symptoms were so persistently severe that it was necessary to institute this after only one course of oral treatment.

The husbands of eight of the patients were examined at St. Paul's Hospital through the kind co-operation of Mr. D. Innes Williams.

Diagnosis

In the early stages of the trial all swabs were submitted to examination of a hanging-drop preparation and to culture using a simplified trypticase serum medium containing antibiotics and prepared as follows: (1) Maltose, 1 g.; (2) bacto agar, 1 g.; (3) distilled water, 400 ml. Heat in autoclave at 10-lb. (0.7 kg. per square cm.) pressure for 10 minutes, dissolve agar. Filter through coarse paper (Reeve Angel). (4) Trypticase (B.B.L.), 20 g.; (5) cysteine hydrochloride, 1.5 g.; (6) 0.5% methylene blue, 0.48 ml.; (7) distilled water to make 600 ml. Adjust pH to 6 with 5N NaOH. Make up to 950 ml. volume with distilled water. Tube in 9.5-ml. amounts. Autoclave at 15-lb. (1.05 kg. per square cm.) pressure for 15 minutes and cool to room temperature. Add 0.5 ml. of sterile serum 100%, which has been adjusted to pH 6. Add 250 units of penicillin and 1 mg. of streptomycin per ml. of medium. (In practice 5-ml. aliquots had been found satisfactory.)

In the early stages of the trial a swab of the vaginal secretion was rotated in 1-2 ml. of saline, brought at once to the laboratory, and immediately examined. Several drops of the suspension were then inoculated into bijou bottles containing 5 ml. of the culture medium. The bottles were incubated at 37° C. and the cultures examined after 48 and 96 hours. As the results were unsatisfactory the technique was modified, the swab being placed immediately into the culture medium to avoid the addition of saline and ensure a heavy inoculum.

The temperature of the incubator was next tested and found to vary by several degrees on different shelves. Stabilization at 37° C. was attained, but the results remained unconvincing.

About 40% of those preparations which revealed large numbers of trichomonads in the hanging drop were still positive after 48 hours' cultivation, but in most instances the numbers were much reduced, motility was sluggish, and disintegrating forms were visible. If the wet preparation showed only a few trichomonads, survival after 48 hours was infrequent, and after 96 hours rare. The impression gained was that the medium encouraged the protozoa to survive for a limited period but did not promote their growth.

On only one occasion was a positive culture obtained from a negative hanging-drop preparation, although several of these strongly suggested a trichomonas infection. Lately it was felt that thorough examination of a hanging-drop preparation was the far more reliable guide to the presence of trichomonads and culturing was discontinued.

The results obtained from 113 swabs examined directly, after 48 and 96 hours' culture, are shown in Table I. These results were disappointing, and compared very unfavourably with those reported by American workers using a similar medium.

TABLE I

	Hanging Drop Positive (77)		Hanging Drop Negative (36)	
	Positive	Negative	Positive	Negative
48-hour culture ..	30	47	1	35
96- " " ..	10	67	0	36

Results

A total of 60 women were enrolled in the trial, consisting initially of 34 treated cases and 26 controls; 9 in the treated group and 5 in the control group defaulted and did not attend for further treatment. The results in the remainder are shown in Table II.

TABLE II
Treated Group (25)

Cured of trichomonas vaginitis ..	5
" " but monilia infection appeared ..	1
Still positive after treatment ..	11
Relapsed after one negative swab or more ..	6
Underwent hysterectomy, cured of trichomonas vaginitis ..	1
Toxic symptoms; did not take tablets ..	1

Control Group (21)

Remained positive, treated ..	17
Dilatation and curettage, and cauterization of cervix, cured ..	1
Symptomatic improvement ..	2
Other treatment given ..	1

Controls Treated with Aminitrozole (17)

Persistently positive ..	12
Relapse ..	2
Defaulted ..	1
Recent cases not followed up ..	2

Twelve of the 25 treated patients had one course of aminitrozole, six had two courses, and seven had three courses. Of the five cured of trichomonas vaginitis, four had one course of aminitrozole and one had two courses.

Eight of the treated controls had one course of aminitrozole, four had two courses, and two had three courses.

Thus of 37 patients (23 treated and 14 treated controls) who received treatment with aminitrozole and aci-jel, six were cured of trichomonas vaginitis.

Husbands Examined by Prostatic Smear (St. Paul's Hospital).—Eight husbands were examined: five were negative, two were positive, and one had pus but no trichomonads. The two men with positive smears were both treated and the smears became negative; the wife of one was treated but relapsed after 18 weeks; the wife of the other was cured after treatment with aminitrozole. In the man with pus only, this disappeared after treatment with aminitrozole, and his wife was cured by a further course of aminitrozole.

Summary and Conclusions

Aminitrozole (2-acetyl-5-nitrothiazole, "tritheon") has been recommended for the oral treatment of trichomonas vaginitis.

The results of a controlled trial of oral treatment are presented.

Attempts to culture *Trichomonas vaginalis*, using a simplified trypticase serum medium, have proved unsuccessful; careful examination of a hanging-drop preparation has proved the best method of diagnosis.

The main conclusion of this work has been that aminitrozole with a buffered acid vaginal jelly ("aci-jel") cannot be recommended for the treatment of trichomonas vaginitis. Only 6 out of 37 patients treated

were cured, and in fact the results have proved so disappointing that it has been reluctantly decided to abandon the trial.

Further work might show whether aminotroazole is effective in eliminating trichomonads in the female urinary tract and in the male, but the results so far suggest that it is not suitable alone for vaginal infections. There may be a place for it in conjunction with an effective trichomonicide, used locally in the vagina, especially in chronic cases, but its use without such treatment does not give sufficiently good results to make it a practical method.

We acknowledge our indebtedness to Ortho Pharmaceutical Limited for their generous support of this investigation. This has included help with the technical side and supplies of tritheon, aci-jel, and materials for the culture medium. This help has been given without prejudice to any results that might be obtained. We also thank Mr. D. Innes Williams and the staff of St. Paul's Hospital. Miss Landau, Miss Mocatta, and Miss Hurter kindly allowed us to treat patients under their care.

SENSITIVITY TO FOLIC ACID

BY

I. CHANARIN, M.D., D.C.P.

Registrar

Registrar

AND

D. L. MOLLIN,* M.B.

Lecturer

Department of Pathology, Postgraduate Medical School of London, W.12

Folic acid (pteroylglutamic acid) has been extensively used since 1945 not only for the treatment of certain megaloblastic anaemias but also as an ingredient of numerous vitamin preparations. In spite of this wide use the only report of sensitivity to this drug is that of Mitchell, Vilter, and Vilter (1949). Their patient, a woman aged 35, reacted on two occasions to folic acid. On the first occasion she developed a pruritic rash which disappeared on withdrawal of the drug; on the second occasion an anaphylactoid reaction followed an intravenous dose. Subsequent skin tests confirmed that she was sensitive to folic acid. She was known also to be sensitive to phenobarbitone, various foods, wool, soaps, and face-powder.

The purpose of this paper is to report an example of sensitivity to folic acid arising in a previously healthy subject. The results of intradermal tests with folic acid and closely related compounds are also described.

Case Report

A healthy male doctor aged 35 was given, for experimental purposes, 3 mg. of folic acid as a solution of the sodium salt by mouth without untoward reaction. The material was absorbed normally, for the serum folic-acid concentrations, measured with *Streptococcus faecalis* R assay (Jukes, 1955), rose from 0 to 40 m μ g. per ml. in the first four hours after the dose.

*In receipt of a grant from the Medical Research Council.

Six weeks later the same subject was given four 5-mg. tablets of folic acid by mouth. Forty minutes after taking the tablets he complained of general malaise, aching pain in the lower thoracic region, and respiratory difficulty with restricted inspiration. This was followed 20 minutes later by itching of the palms of the hands and soles of the feet. Pruritus then became generalized; it was worse at the flexures, and was associated with a generalized erythematous rash, most pronounced on the thighs and forearms. The reactions disappeared within three hours of taking the folic acid.

Investigations.—Intradermal tests were carried out by injecting 0.1 ml. of the test solutions into the skin on the front of the forearm. A test solution of folic acid was included in each set of tests together with a distilled-water control. Positive reactions with weal, red flare, and itching were obvious in 10 to 15 minutes after the injection; they reached a peak in about 20 minutes and disappeared in 45 to 60 minutes. The substances tested, the concentrations of test solutions, and the results are given in the Table.

Two different samples of commercially available folic acid (pteroylglutamic acid) gave positive reactions after intradermal injection in concentrations of 5 μ g. per ml. or more, as did similar concentrations of a crystalline preparation of folic acid of high (97%) purity kindly supplied by Dr. William L. Williams, of Lederle Laboratories Inc. Similar reactions followed the intradermal injection of the same concentrations of aminopterin (4-aminopteroylglutamic acid). On the other hand, no reactions followed the intradermal injection of the following solutions: two preparations of folic acid ("leucovorin," N¹⁰-formyltetrahydropteroylglutamic acid), N¹⁰-formyltetrahydropteroylglutamic acid; anhydroleucovorin; a folic acid conjugate "teropterin"; and amethopterin (4-amino-N¹⁰-methylpteroylglutamic acid).

Free antibody was tested for by a precipitation method using a constant antibody optimal-proportions technique (Dean and Webb, 1926) and also by adsorbing folic acid to tanned red cells and testing the ability of the patient's serum to agglutinate these cells (Boyden, 1951). No antibodies were demonstrated by either method.

Six months after the development of sensitivity the blood count was: red cells, 5,300,000 per c.mm.; haemoglobin, 15.4 g. per 100 ml.; packed cell volume, 46%; white cells, 8,000 per c.mm. There were no abnormalities in the stained film.

Discussion

The results of skin tests in our patient show that while he was sensitive to folic acid (pteroylglutamic acid) and its analogue aminopterin (4-aminopteroylglutamic acid), he did not react to folinic acid, anhydroleucovorin, N¹⁰-formyltetrahydropteroylglutamic acid, and amethopterin, which are related compounds with substituents in the 5 and 10 positions (see Table).

None of the compounds we used was absolutely pure; the purest folic acid obtainable contained about 3% impurities, and the aminopterin and related compounds contained traces of folic acid as well as other chemical contaminants.

Results of Intradermal Tests with Folic Acid and Related Compounds

A CASE OF CONJOINED TWINS

BY

T. WILSON RODDIE, M.B., B.A.O., M.R.C.O.G.

Senior Lecturer in Obstetrics and Gynaecology, University of Malaya, Singapore

Conjoined twins are rare and may at times offer serious difficulties to delivery. The following case seems of sufficient interest to merit publication, as the monsters were delivered intact vaginally. Frequently some form of mutilating operation is necessary before vaginal delivery can be effected, or a caesarean section may have to be done.

Case Report

A Cantonese woman aged 30 was admitted in labour to the Kangang Kerbau Hospital in the thirty-second week of her eighth pregnancy. All seven previous confinements had been normal and had resulted in live births.

On examination she was anaemic, her face and hands were puffy, and there was clinical oedema of her feet and ankles. The abdomen was the size of a full-term pregnancy and rather tense.

There seemed to be definite hydramnios and the uterus was contracting. The possibility of a multiple pregnancy was considered, though no foetal heart sounds could be heard with certainty. Her blood pressure was 160/100 mm. Hg. The urine contained a trace of albumin. Vaginal examination revealed a bulging bag of membranes, a cervix practically fully dilated, and something other than a head presenting—probably

Photograph of the omphalopagus.

feet. A straight x-ray film of her abdomen showed twin foetuses both presenting by the breech. However, the fact that the two heads were on the same level and facing each other suggested the possibility of some form of foetal union.

By this time the patient was beginning to bear down and the membranes ruptured spontaneously. A large quantity of dark-coloured liquor amnii drained away and two feet presented at the vulva. It was decided to attempt delivery and she was anaesthetized. Vaginal examination now confirmed that the twins were joined together, and there did not seem to be any second sac, as the other pair of lower limbs and feet were felt at the cervix. These were brought down easily, and with traction on the four limbs the bodies descended parallel to each other through the dilated cervix and vagina. The legs and trunks were now lifted well forward over the symphysis pubis, allowing the posterior head to engage in the pelvis and be born with the anterior head following quickly afterwards. Both foetuses were fresh, and the one whose head was delivered last made feeble attempts to breathe. A single placenta, with velamentous insertion of two cords at opposite sides, was expressed a few minutes after delivery of the monster. There was no excessive blood loss, and episiotomy performed during the delivery was repaired with catgut. The puerperium was uneventful.

It was therefore of some importance that a positive reaction was obtained with both folic acid and aminopterin at equal concentrations of 5 μ g. per ml. and that at greater dilutions the reactions became doubtful with both substances. The patient reacted to the aminopterin *per se* and not to traces of folic acid which might have been present as a contaminant.

The formation of specific antibodies against folic acid by the subject studied indicates that this substance functioned in him either as an antigen or, more probably, as a haptene or antigenic determinant in a larger complex. An essential criterion of antigenicity is that the compound in question is "foreign" to the subject. These observations therefore suggest that pteroylglutamic acid was not normally present in the tissues of our "patient." As he remained perfectly well, however, and was not anaemic the requirement of his tissue cells for "folic acid" on this hypothesis must have been supplied by substances other than pteroylglutamic acid.

It has been recognized for some time that pteroylglutamic acid is itself unlikely to play a part in tissue metabolism. Recent work suggests that N¹⁰-formyltetrahydropteroylglutamic acid or a closely related compound is the physiologically active member of this group of substances (Greenberg, 1954). N¹⁰-formyltetrahydropteroylglutamic acid is itself highly unstable and probably exists in the liver in a bound stable form (Greenberg, 1954). Under aerobic conditions it is rapidly oxidized to N¹⁰-formylpteroylglutamic acid, and this in turn, under alkaline conditions, is converted to pteroylglutamic acid. Under anaerobic conditions, on the other hand, N¹⁰-formyltetrahydropteroylglutamic acid is converted to N⁵-formyltetrahydropteroylglutamic acid (folinic acid).

The isolation of folic or folinic acid from foodstuffs does not necessarily imply that this was the form in which this substance was originally present. It is possible that the absence of sensitivity reactions in our subject after meals is due to the fact that pteroylglutamic acid is not absorbed from food as such, and not that too little is absorbed to produce these reactions.

Summary

A subject is described who was found to have become sensitive to folic acid six weeks after taking an oral dose.

Intradermal tests showed that he was sensitive to folic acid and aminopterin, but not to folinic acid (leucovorin), anhydroleucovorin, N¹⁰-formyltetrahydropteroylglutamic acid, a folic acid conjugate (teropterin), or to amethopterin.

We thank Professor J. V. Dacie for advice and encouragement; and Dr. William L. Williams, of Lederle Laboratories Inc., for supplying the pure specimen of pteroylglutamic acid used in the study and also for the anhydroleucovorin, folinic acid (leucovorin), and teropterin.

A Society of Indexers has been formed in London, its principal objects being to improve the standard of indexing and secure some uniformity in its technique, to set up a panel of indexers, and to publish papers and notes on the subject. It is believed to be the first society of its kind in the world. The chairman, Mr. A. R. HEWITT (librarian of the Institute of Commonwealth Studies), is son of a former librarian of the Royal Society of Medicine. Among those elected to the council of the society was Miss D. F. ATKINS, librarian of the Postgraduate Medical School of London. Further information may be obtained from the hon. secretary, Mr. G. NORMAN KNIGHT, 4, Fitzroy Street, London, W.1.

Examination of the twins showed them to be well formed and symmetrical (see photograph). Both had normal female external genital organs. The combined weight was 4 lb. 10 oz. (2,100 g.). They were joined by a bridge of skin-covered soft tissue at a level just below the xiphoid processes. Both infants showed exomphalos and there appeared to be a large common liver. The monster can be classed as an omphalopagus (Hirst and Piersol, 1892). The specimen is being preserved.

Comment

The incidence of conjoined twins is difficult to ascertain. Aird (1954) suggests that the greater frequency of case reports is "due to the increasing accessibility of very large populations in Asia and Africa, to the greater possibility of the successful birth of conjoined twins in improved modern obstetrical circumstances," and, of course, to the greater possibility of successful surgical separation should they be born alive.

From the clinical aspect it is interesting to note how most standard textbooks agree that double monsters can be delivered spontaneously in many cases. They also agree that when the monsters give rise to dystocia dangerous and complicated operations are often needed to effect delivery. Many cases, of course, come into premature labour when the foetuses are small and vaginal delivery is thus possible. In general, delivery is easier by the breech, and Munro Kerr and Chassar Moir (1949) advise version if the heads are presenting. The advantage of breech extraction is that destructive operations, if they become necessary, can be more easily carried out. An interesting case of a thoracopagus delivered through the vaginal route in a very unusual fashion, the foetuses being extracted one after the other in cephalic presentation, has been described by Morrone (1954).

As regards the diagnosis, the association between hydramnios and foetal abnormality is so frequent that the latter should be suspected whenever hydramnios occurs. Careful abdominal palpation and internal examination, if the dilatation of the cervix is adequate, are important. Radiography is valuable, and in the case described suggested the possibility of conjoined twins, as the two heads were at the same level, faced each other, and the thoracic cages of the foetuses were together. However, if the union be very flexible the two heads may well be at different levels, as in a case described by Rawlings and Warwick (1951).

My thanks are due to Professor B. H. Sheares for permission to publish this case report, and to Mr. Austin Bennett for the photograph of the monster.

A considerable range of lecture courses are now offered to Cambridge medical students during the Long Vacation. These cover not only the preclinical and transitional periods of medical studies but also provide opportunities for continuing a general education in the arts. For the preclinical student there is a course in pharmacology as well as the usual lectures and demonstrations in anatomy and physiology. Practical experience in the department of pathology may be arranged, and formal instruction in biochemistry is also available. For the student who has passed in anatomy and physiology, the Medical School offers a course of instruction in elementary clinical methods at Addenbrooke's Hospital, and there is also an introductory course in psychology. The Faculty of Modern Languages under the Pressland Bequest provides an elementary course of 24 lectures in German, Russian, and Italian for science and medical students. More advanced courses are also available in some of these languages. A special series of lectures in English literature and poetry for students in scientific faculties is arranged by the Faculty of English.—*Cambridge University Reporter*, March 8.

Medical Memoranda

Lichen Urticatus as an Allergic Manifestation of Pregnancy

It has been noted (Urbach and Gottlieb, 1946) that, in general, pregnancy has an influence which tends to diminish a pre-existing allergy, and this can be frequently observed in cases of asthma and hay-fever. Various theories have been postulated to explain this (Ahlmarm, 1944; Zondek and Bromberg, 1945a, 1945b).

There are, however, certain conditions of an allergic nature which can be actually brought about by the pregnant state. During pregnancy the skin can show a definite hypersensitivity to substances originating in the foetus and also to the placental protein (Urbach and Gottlieb, 1946), and in some women various dermatoses of pregnancy can result, due, it is believed, to the production of an abnormal amount of endogenous allergens from the foetus or placenta. It is assumed that, normally, specific antibodies are produced in the pregnant woman as a reaction to this foetal or placental protein (Seegal and Loeb, 1943). The assumed presence of such specific antibodies has been used to explain (Freund, 1909) the good results achieved with systematic injections of the serum of pregnant women in the treatment of the dermatoses of pregnancy, a form of treatment used with success in America. The presence of these antibodies in the injected serum effectively neutralizes the increased supply of antigen which presumably causes the condition.

Lichen urticatus is one of the ways in which an allergic manifestation of pregnancy can show itself; the following three cases illustrate this.

CASE REPORTS

Case 1.—A primigravida aged 22, blood group O, Rh positive, developed, seven days before delivery, a typical papular urticarial rash covering the entire body, which was extremely itchy and caused great discomfort. Both the rash and the irritation were completely unresponsive to phenindamine or diphenhydramine in full dosage. In an attempt to afford her relief a subcutaneous injection of adrenaline was given without any effect. Within 24 hours of the normal delivery of the baby (full term) there was definite relief from the irritation, and the lichen urticatus began to fade, but took nearly two weeks to disappear completely. There was no personal or family history of allergy or allergic response to any drugs excepting that her mother suffered with migraine.

Case 2.—A primigravida aged 23, blood group A, Rh positive, began to develop, when 33 weeks pregnant, a typical lichen urticatus with irritation, covering the body and upper parts of the arms and legs. She was given full doses of mepyramine maleate and mepyramine maleate cream to apply locally. In four to five days the rash disappeared, whereupon she stopped the treatment. The irritation and resulting distress returned within 12 hours, and two days later the papular urticaria had reappeared. Recourse was had once more to mepyramine maleate tablets and cream, but this time with no relief. Within a few hours of the normal delivery of the baby (full term) the pruritus had gone, and the rash began to fade within 24-48 hours, the final traces taking nearly three weeks to completely disappear. There was no personal history of allergy or allergic response to any drugs, but the family history showed that the mother had asthma.

Case 3.—A primigravida aged 23, blood group O, Rh positive, developed, about the fourth month of pregnancy, lichen urticatus with pruritus covering the body, especially the front of the chest. No treatment, except calamine lotion locally, was given, and the rash persisted throughout the remainder of the pregnancy. Within 24 hours of the normal delivery of the baby (full term), the rash and

irritation had completely disappeared. There was a definite history of allergy in this patient, when as a young girl she suffered with severe asthma.

COMMENT

Not infrequently pregnant women exhibit urticaria, but in most cases it can be related to an external cause, the removal of which brings about the disappearance of the rash, sometimes accelerated by the use of antihistamines. In the three cases described above, lichen urticatus was due to the foetus or placenta only, and persisted until the cause was removed with the expulsion of the child and placenta. In all three cases relief from irritation occurred soon after, and the papular urticaria began to fade as quickly, finally disappearing when the last traces of the antigenic substances were removed from the blood.

Range of Movement of Testicle

One of the peculiarities of present habits of thought in our profession is that matters of demonstrable fact are treated as matters of opinion. Anatomy is essentially concerned with matters of fact, yet I have found in a number of instances that assertions of the inaccuracy of generally accepted anatomical teaching are treated as if they had to do with religion or politics—subjects in which opinions incapable of proof are held on grounds of habit or emotion. An instance is that of the range of movements of the testicle. It is common knowledge that in all children and many adults the testicles can move upwards out of the scrotum over the pubic bone. The anatomists have not described any cavity into which they could go, and in consequence the strange idea has arisen that the cremaster dragged them into the inguinal canal. I say the idea was strange, since the normal testicle is far too big to go into the normal external ring at any age; and to bring it into the canal the cremaster would need a contractility totally unlike that possessed by similar muscle elsewhere.

What actually happens can easily be demonstrated at an operation for inguinal hernia on a child, if the testicle is pushed upwards out of the scrotum and held there by an assistant pressing from below while the surgeon cautiously dissects down on it. The fascia of Scarpa is first defined, and when it is opened the testicle will be found lying in an extremely loose areolar space between it and the external oblique. (Incidentally the nature of tissue which permits such extreme mobility would be an interesting study.)

I described this upward prolongation of the scrotal cavity as the "superficial inguinal pouch" (Browne, 1938) and suggested that much bad treatment and inaccurate prognoses in cases of maldevelopment of the testicle could be avoided if it were understood. My statement produced an annotation and many letters disagreeing with it; but no one then or since suggested examining the human body to see who was right. I do not think that in sciences such as physics or chemistry a similar question would be left similarly in the air; it would be promptly settled one way or the other.

An interesting and important paper by Mr. John Baty (1956) illustrates the persistence of the anatomical error and throws a light on the significance of this upward extension of the scrotum. He states that it is well known that in small boys the testicle may temporarily disappear up the inguinal canal or into the abdominal cavity; actually, as I have said, this is not a well-known fact but a widespread delusion. The purpose of his paper, however, is to describe a painful spasm of the cremaster dragging the testicle upwards and jamming it against the pubic bone. This spasm is apt to occur in mental stress, and it seems to me quite possible that it is an involuntary atavistic reflex to withdraw

the organ into the pouch away from possible danger; and that if this withdrawal could be completed the spasm would not occur. It is a common observation that the testicle tends to withdraw upwards in extreme cold; and, although the prudery so marked in our country and profession makes it difficult to obtain information, it does the same in certain males during sexual excitement.

The illustrations show a normal male in whom, as is not uncommon, the early range of movement has been retained. They show the remarkable nature of the belief that a testicle of that size could pass through the external ring.

FIG. 1.—Testicles in usual position at bottom of scrotum.

FIG. 2.—Right testicle pushed up out of scrotum into the superficial inguinal pouch.

This particular question raises a much larger one—that of the mechanism of distribution of knowledge throughout the profession. How long will it take for this piece of knowledge to get into the anatomy books, from thence to the students, and finally be applied to the benefit of the general population? We are all so conditioned by our medical education to reciting the orthodox anatomy by rote as gospel that surgeons are very unwilling to move without the authority of the professors. The professors, apart from the loss of face involved in admitting that they have been reproducing errors and omissions for generations, must all move together or not at all, since otherwise one of them might fail the students of another in an examination for reproducing what they had been taught. From my experience in several other cases, notably the pointing out of the dangerous vessel in tonsillectomy (Browne, 1928), I anticipate that it will take many years and be done gently in stages. The first stage probably will be a statement that, though the retracting testicle usually goes into the inguinal canal, in certain cases it goes into the recess I have described.

DISSECTING MANUAL

A Manual of Human Anatomy. By J. T. Aitken, M.D., G. Causey, M.B., F.R.C.S., J. Joseph, M.D., M.R.C.O.G., and J. Z. Young, M.A., F.R.S. Vol. I: Thorax and Upper Limb. (Pp. 161+viii; illustrated. 14s.) Vol. II: Head and Neck. (Pp. 179+viii; illustrated. 16s.) Vol. IV: Lower Limb. (Pp. 117+viii; illustrated. 12s. 6d.) Edinburgh and London: E. and S. Livingstone, Ltd. 1956.

Three volumes of a new dissecting manual have just been published, the authors being four anatomists of the London group of medical schools. They have set out to present to the preclinical student a method of dissection and a guide to the amount of knowledge of the topography of the human body that will be expected from him in the second professional examination. They have endeavoured to link together structure and function, and stress the importance of practical exercises in osteology and surface anatomy, instructions being given for the conduct of such classes. The fact that this new manual has been written draws attention once more to the concern felt by many teachers about the overcrowding of the preclinical course and to the fact that some measure of pruning is desirable—nay, even imperative. What form such pruning should take is a matter of extreme difficulty to decide, and it will only be through study of how books such as the present one serve the students' and teachers' needs that progress in the solution of this problem can be made.

The work is well written in an easy, pleasant style, the dissection of each part being divided into regions centering around important landmarks, such as the joints in the limbs and the major viscera elsewhere. In each section dissecting instructions are first given and are then followed by structural details. Description of the unimportant branches of arteries and the precise attachments of muscles have been omitted with benefit to the text. It is doubtful, however, if information about the ossification times of each part of the skeleton should be retained. The ossification of certain bones should be emphasized, but for the remainder it is an unprofitable exercise in memory. The importance of the lymphatic system is stressed by including a chapter on the regional lymphatics of each part. Too often this clinically important system is not properly appreciated by the student, since it is not demonstrable by him to any extent in the cadaver. The notes on osteology and surface anatomy for small tutorial classes form a useful guide for teachers, most of whom will, however, modify them according to their own ideas of the importance of this method of instruction, including more physical examination of the normal living body with appropriate radiological study. The illustrations are simple, clear line drawings with a judicious use of colour and with the minimum of reference pointers. There are a very few which seem of dubious value—for example, Fig. 17, Vol. I—and there is the occasional error—for example, Fig. 7, Vol. IV—which will no doubt be corrected in any future edition.

This dissecting manual deserves the serious consideration of anatomists who are conscious of the changing plan of anatomy in the preclinical curriculum, and it should go a considerable distance towards relieving the burden upon our students of an overloaded curriculum.

J. S. BAXTER.

OCULAR AND CEREBROSPINAL FLUIDS

Physiology of the Ocular and Cerebrospinal Fluids. By Hugh Davson, D.Sc. (Pp. 388+viii; illustrated. 65s.) London: J. and A. Churchill Ltd. 1956.

The advancing stream of scientific research is becoming more and more a series of rivulets extending in diverse directions and isolated completely from one another. Any attempt to bring these individual channels of research together is very welcome, and, although no startlingly new concept emerges from this comparative study of aqueous humour and cerebro-

spinal fluid, it does bring to light the similarity of the fundamental processes in their formation. In both fluids certain electrolytes are present in higher concentrations than in the plasma, and both can be considered secretions in the sense that they involve the performance of osmotic work and the utilization of metabolic energy, and both fluids are continuously being formed and drained away.

The morphological aspects of intraocular and cerebrospinal fluids are described first, and then follow chapters on their chemical composition and the exchange of substances between them and the blood. The properties of the blood-aqueous and blood-cerebrospinal-fluid barriers and the changes which take place when these barriers are disrupted are discussed, as are the principles governing the maintenance of the fluid pressures in the two systems. The author is rightly critical of much of the earlier work on chemical composition of the fluids, and points out many of the errors which may influence the results. For example, plasma concentrations of substances such as glucose may vary widely, and it is essential to attain reasonably stable levels before comparative measurements of aqueous and plasma concentrations can be made. Isolated measurements of substances in aqueous or cerebrospinal fluid are likewise of little value unless the concentration in the plasma is known. The importance of the vitreous body in modifying the kinetics of the penetration of substances into the aqueous is fully recognized. The author does not hesitate to express his personal views and theories, so that the book is never dull and should prove a useful stimulant to future work in these fields. The bibliography is extensive and up to date. A brief summary of the main conclusions at the end of each chapter would be helpful to the general reader. The book is well printed and bound and adequately illustrated. It brings together a mass of material from a wide range of specialist journals, and, while its main value will be to physiologists, clinical ophthalmologists and neurologists will find in it much to interest them.

E. S. PERKINS.

SQUINT

Strabismus: Diagnosis and Treatment. By Beulah Cushman, M.S., M.D. (Pp. 208; illustrated. 45s.) London: Henry Kimpton. 1956.

This book on strabismus has arisen from a series of notes on the objective examination of the extrinsic ocular muscles which were prepared originally for postgraduate students of the Northwestern University. It considers in detail the various forms of ocular muscle imbalance, and it emphasizes the importance of an accurate assessment of this imbalance, not only in the primary position but also in the six cardinal positions. It stresses the need for an understanding of any secondary deviation or secondary contracture of the ocular muscles, in addition to a knowledge of the paretic muscles, in order to plan the surgical approach to the problem in the best possible way. It is doubtful, however, if the ability to achieve a binocular result in each individual case is considered in its true perspective, and it is inaccurate to state that in all cases of strabismus it is usual to find some type of binocular fixation at the angle of squint. Furthermore, there is a tendency to regard a binocular result as the outcome of correct objective examination methods and of correct surgical technique, whereas in reality a detailed objective examination will not necessarily determine whether a binocular result is possible or not, and a correct surgical technique is unlikely to produce ultimate binocularity in cases showing no fundamental binocular ideas pre-operatively. There is an elaborate account of the screen cover test incorporating the use of prisms, and this is a very important objective method of examination which has not been stressed sufficiently in recent years. There should be a place, however, for a description of the simple cover test, using a target for fixation and the hand for a cover, as a preliminary to the prism screen test. It is doubtful if prolonged occlusion should be stressed as the ideal method of eliciting a minor degree of muscle imbalance in preference to such tests as the Hess screen test.

This is an interesting book because it presents against a personal background a detailed account of the methods used in a series of 62 cases of strabismus and of the results following treatment, but it is not comprehensive, and it is likely to appeal more to the experienced ophthalmic surgeon than to the ophthalmologist in training.

KENNETH WYBAR.

THE EFFICIENT USE OF STEAM

Principles and Methods of Sterilization. By John J. Perkins, M.S. (Pp. 340+xi; illustrated. 60s.) Springfield, Illinois: Charles C. Thomas. Oxford: Blackwell Scientific Publications. 1956.

The author is Director of Research in the American Sterilizer Co., and his book replaces that by the late W. B. Underwood of the same firm. Underwood's book plainly exposed the pitfalls in steam sterilization 23 years ago. Perkins teaches the same lessons with equal clarity, and embodies in his text the great advances in the design of sterilizing equipment which have since been achieved. It has been stated recently that 90% of surgical autoclaves in this country are inefficient, and in seeking to remedy this state of affairs no better guide can be found than this book. American practice in this field is admittedly far ahead of that in most other countries, and our own surgeons and theatre sisters are likely to break the Tenth Commandment repeatedly when they read of such things as the automatic washer-sterilizer for instruments and a rapid instrument sterilizer employing steam at very high pressure for only three minutes. Another novelty to us is the "carboxyclave," in which heat-sensitive materials can be sterilized with ethylene oxide ("carboxide" is the mixture of this gas with CO₂ used to eliminate explosion risk). There is also an automatic "glove conditioner": gloves are autoclaved at full pressure, but should be allowed to "rest" for one to two days thereafter to regain their tensile strength. The use of metal drums is firmly discouraged. Syringes, having passed through a mechanical cleaner in which stacked rings hold 32 each, are sterilized by dry heat; autoclaving is said to be an alternative only if they are disassembled.

Although the efficient use of steam is the principal theme, there are also chapters on a central department for the supply of all sterilized equipment; on disinfection by boiling water (for the benefit of those not so generously endowed); on chemical disinfection (with emphasis on formalin as the most efficient reagent); on water sterilizers, the use of dry heat, the preparation of parenteral solutions and of infant feeds; and on sterilization indicators, chemical and microbiological. There are admirable illustrations, and some eye-opening graphs of performance under varying and sometimes bad conditions. The history and theory of the subject as well as its practice are dealt with, and each chapter includes a useful list of references.

L. P. GARROD.

AIR POLLUTION

Air Pollution Handbook. Edited by Paul L. Magill, Francis R. Holden, Ph.D., and Charles Ackley. Editorial Consultant: Frederick G. Sawyer, Ph.D. (14 sections plus 24-page index. \$12.50; £5 12s. 6d.) London: McGraw-Hill Book Company. 1956.

The editors of this book say that it "brings together in readily available form useful information on the major aspects of the problem of air pollution." So handsomely does it justify this modest assertion that it must surely become an indispensable reference book for anyone working in this field. It is authoritative and comprehensive. In 14 well-documented sections it deals with most aspects of air pollution, including chemistry, physics, epidemiology, meteorology, city planning, chemical engineering, plant damage, hazards to livestock, experimental techniques, sampling and analytical methods, and legislation. Emphasis is properly placed throughout on the abatement of air pollution. The section on epidemiology by Dr. Phair, of the University of Cincinnati, is a thoughtful essay in very general terms which puts this great problem in perspective

and shows how little is known and how much remains to be learnt. It is disappointing to find that lung cancer is barely mentioned. There are 349 references in the section on analytical methods, and it is an indication of the complexity of the analyst's task that, despite this vast amount of published work, we are still without a satisfactory method for the determination of free sulphuric acid in London air. Dr. Siiverman's section on experimental test methods is invaluable; he deals with exposure-chamber design and the generation of gas, vapour, and particle concentrations in sufficient detail to satisfy most research workers.

There are serious air-pollution problems in the U.S.A. which are not encountered in Britain, but the American origin of this book in no way detracts from its value in this country: its scope is international. It suffers from a defect, largely unavoidable, which is common to works of such large scope and detail: it quotes no work later than 1954, and much has been done since then. But it will be a very long time before this book is out of date.

P. J. LAWTHOR

MALARIA DIAGNOSIS

The Microscopic Diagnosis of Human Malaria. Part II. A Morphological Study of the Erythrocytic Parasites. By John W. Field and P. G. Shute. Illustrated by Yap Loy Fong. (Pp. 251. No price.) Kuala Lumpur: Institute for Medical Research, Federation of Malaya. 1956.

After seeing the first volume of this work, expectations with regard to the second were set at a very high level. It is a pleasure to report that, for once, such expectations have been more than realized. The highest praise is due to the authors and publishers for a fine production. The contents include a short account of the history of the microscopic diagnosis of malaria and a provocative and stimulating discussion on the parasite in relation to the erythrocyte (the problem of "in" or "on" is neatly suspended). Full descriptions of all four human *Plasmodia* follow, covering synonyms, host and habitat, and geographical distribution; the schizogonic cycle, including notes on incubation and prepatent periods, erythrocyte invasion, and parasite anatomy; parasites in the peripheral blood, distribution in the host, and cultivation *in vitro*. Gametogony is equally fully described. There is also much important information regarding blood examination, degrees of parasitaemia, and morphological variation of parasites. One interesting section deals with doubtful species and "sub-species." A chapter on methods of examination deals with diagnosis during life and after death. With regard to the latter point the authors have attempted with only moderate success the almost impossible task of discussing in a few pages everything from pathological processes to necropsy findings.

The triumph of this book lies in its final sixty-odd coloured and tone plates illustrating the parasites in all stages and in all circumstances—in smears, blood vessels, and phagocytes. Most of these beautifully drawn and reproduced plates possess the added virtue of having been prepared "in the course of the day-by-day routine of the Malaria Research Division of the Institute" and of coming from Asian patients naturally infected in Malaya. Each is accompanied by a full description on the facing page, which sensibly includes, where relevant, a short clinical account of the patient from whom the blood was taken. These pictures should be displayed in every teaching institution concerned with medicine in the tropics.

B. G. MAEGRAITH.

This year's edition of the *British Journal Photographic Almanac* contains the usual sections, brought up to date, on technical data and new apparatus. Among the signed articles are two that may be of special interest in hospital photographic departments—namely, "Replenishing the Developer," by K. M. Hornsby, and "The Use of Filters in Colour Photography," by G. W. Ashton. A large section is now devoted to flash photography. All told, this well-known almanac is well up to standard, and will be of great interest to amateur as well as professional photographers. It is published by H. Greenwood and Co. for 8s. 6d.

SATURDAY MAY 18 1957

POLIO VACCINATION IN SUMMER

If sufficient vaccine is available to inoculate children against poliomyelitis throughout the summer, doctors will have the anxious task of advising parents on whether it is advisable for their children to have it. Precise data on the risks, if any, of inoculating when the incidence of the disease is high or rising are still rather scanty. Moreover, if there are any risks they need to be set against the possible benefits of inoculation; but these too are hard to define in Great Britain. The vaccine used here differs from the American and Canadian vaccines; it has been given to only relatively few children; and last summer, when its prophylactic efficacy was first measured in the field, the incidence of the disease was low. While the Medical Research Council has not yet published the epidemiological evidence it has gathered on the protection conferred by the British vaccine administered last year, its study of the vaccine's antigenic activity, recently reported in this *Journal*,¹ showed that it was able to produce an antibody response to all three types of poliomyelitis virus in a high proportion of children. The results were similar to those obtained in America and better than some obtained elsewhere; and reports from the U.S.A. encourage the hope that their vaccine (apart from the faulty batch) has not been found to provoke the disease.

The observation that an injection might provoke attacks of paralytic poliomyelitis was first (somewhat debatably) reported by M. De Teyssien, of Bordeaux, in 1921.² Sporadic observations followed until in 1950 several investigators³⁻⁶ in Great Britain and Australia reported series of cases which confirmed the facts, first, that inoculation with diphtheria and pertussis antigens can sometimes provoke an attack

of paralytic poliomyelitis, and secondly that the site of paralysis is related to the site of inoculation. Workers in the U.S.A. came to the same conclusion.⁷⁻⁹ A recent contribution from a Medical Research Council Committee¹⁰ agrees with previous reports in finding that the risk does not extend beyond a month after the inoculation. The nature of the prophylactic to some extent determines the risk, which was found to be greatest with alum-precipitated diphtheria-pertussis vaccine and absent with smallpox vaccine. In none of these investigations was the effect of inoculation with the poliomyelitis vaccine studied, and the first observations on it were discussed in the report of the American field trials in 1954 issued by the Vaccine Evaluation Centre of the University of Michigan.¹¹ This stated that there was "no evidence of disproportionate frequency of paralytic poliomyelitis in vaccinated or inoculated children up to four weeks after the completion of vaccinations, nor was there any indication of selective localization of paralysis when present." A later report from the Surgeon-General of the U.S. Public Health Service¹² on these 1954 trials added two contraindications to the injection of poliomyelitis vaccine when the incidence of the disease is high. The first of these is the presence of minor illness, "especially fever, sore throat, or gastrointestinal upset," when the patient is due to be inoculated, and the second is the occurrence of a case of poliomyelitis in the household immediately before the proposed injection.

In 1955-6 a severe outbreak of poliomyelitis occurred among U.S. naval personnel and their dependants in Hawaii. To combat it the authorities boldly decided to carry out an immediate large-scale campaign of inoculation, and they were on the alert to detect any signs of a provoking effect.¹³ The outbreak resulted in 53 cases, including 2 deaths. Thirty-seven of these cases were considered suitable to include in the investigation of whether or not the vaccine had a provoking effect. No such provocation could be found. Among 25 of these patients, who went down with the disease when the incidence was rising rapidly, were 13 vaccinated within 30 days and 8 unvaccinated. The 13 vaccinated cases comprised 7 paralytic and 6 non-paralytic, while the 8 unvaccinated comprised 4 paralytic and 4 non-paralytic. As the authors say, the similarity of these figures does not suggest a provoking effect. A fortnight ago another important contribution appeared in the U.S.A. in the form of a preliminary report on the large outbreak of poliomyelitis in Chicago in 1956.¹⁴ During the year 1,111 confirmed cases were reported, of which 75% were paralytic. The attack rate for the city was 29.2 cases per 100,000

population, but non-whites were affected much worse than whites, having an attack rate of 108.1 against 13.5 for the whites. Of the paralytic cases, 221 had been inoculated within 0 to 30 days of the onset of the disease. For 42 of these the data are incomplete, so 179 are left on which to base conclusions. The distribution of paralysis in these cases does not show any significant relationship to site of inoculation. Looking back on the outbreak as a whole, the authors recommend administering Salk vaccine when the incidence of poliomyelitis is rising in a community that has not previously prepared itself—presumably by earlier vaccination—for, they say, "the possible benefits are greater than the possible provocative effects."

On the whole, therefore, the evidence, sparse though it is and in addition a somewhat unsure basis from which to generalize about British conditions, suggests that the advantages of continuing the inoculations through the poliomyelitis season outweigh the disadvantages. A joint committee of the Central and Scottish Health Services Councils has gathered information from many countries overseas with experience of the vaccine, and recommends that vaccination "need not in general be suspended" during the summer season of higher incidence (see p. 1178). The Ministry of Health is consequently going to continue issuing supplies when they are available. American opinion seems to be that, if the vaccine does have a provoking effect, the risk is most effectively offset by giving the vaccine in areas where the incidence of the disease is rising fast or already high. Some theoretical justification for believing any provoking effect to be slight or absent may be drawn from Bodian's experiments on monkeys,¹⁵ by which he showed that the degree of irritation produced locally was related to the severity of paralysis: and the poliomyelitis vaccine, in comparison with some other vaccines, is relatively non-irritant.

ORAL CANCER

When, many years ago, a senior surgeon at one of the London teaching hospitals was asked whether pipe-smoking or syphilis was the most important factor in the production of cancer of the tongue, he replied that he could not give a direct answer, but that the wise man should certainly avoid the combination of the two. At that time it was widely believed that syphilis, pipe-smoking, and alcohol might all contribute in varying degrees to the production of the various cancers of the buccal cavity. The evidence was based mainly on impressions and failed to convince critical reviewers,¹ and only recently, with the re-

awakening of interest in the possible carcinogenic effect of social habits, has any extensive body of facts been collected. In 1953 D. A. Sadowsky and colleagues² reported the results of a detailed analysis of the smoking habits of over 2,500 white male patients attending hospitals in four American cities, including 571 men who suffered from cancer of the lip, 132 with cancer of the tongue, 85 with cancer of the pharynx, and 348 with cancer in other parts of the buccal cavity. Prevalence rates for their diseases in the different categories of smokers were estimated on the assumption that the smoking habits of the patients with diseases other than cancer were representative of the population at large, and it was found that: first, the rates for cancer of the lip were significantly higher among pipe smokers than among non-smokers; secondly, the rates for cancer of the tongue and other parts of the oral cavity were significantly higher among both pipe smokers and cigar smokers; and, thirdly, the rates for cancer of the pharynx were not significantly raised with any type of smoking. These results were in sharp contrast to those which had been obtained for cancer of the lung, in which an increased prevalence was confined to persons who smoked cigarettes.

In Bombay, where cancer of the buccal cavity is one of the most important forms but where the relative proportions arising from different sites within the mouth are entirely different from those in the U.S.A., L. D. Sanghvi and colleagues³ found that smoking was associated with cancer of the oropharynx and tonsils, that the combination of smoking and chewing betel and tobacco was associated with cancer of the base of the tongue and of the hypopharynx, and that chewing—but not smoking—was associated with cancer of the mucosa and anterior part of the buccal cavity. In this part of India tobacco is smoked in the form of hand-rolled "bidis," which differ in many ways from the cigars and cigarettes which are smoked in Europe and North America.

The preliminary results of a more thorough inquiry by Drs. E. L. Wynder and I. J. Bross, of the Sloan-Kettering Institute, New York, are now reported in the opening pages of the *Journal* this week. They studied 543 male and 116 female patients with cancer of the oral cavity and compared their histories with the histories given by 207 male and 246 female patients suffering from other conditions who were selected to be of the same age, religion, hospital status, and socio-economic background as the patients with

cancer. In addition to the tobacco history, inquiries were also made into the consumption of alcohol, the incidence of syphilis, the extent of exposure to sunlight, the state of the teeth, and the extent of possible past nutritional deficiencies. The results for smoking are in general conformity with those of the earlier American study, in that Wynder and Bross find a close association between cancer of all parts of the oral cavity and pipe smoking, a somewhat less marked association with cigar smoking, and a relatively weak association with cigarette smoking. On the other hand, the association with cigarette smoking is distinct, whereas in the earlier study² it was inappreciable. Wynder and Bross use the data to estimate the risk associated with the different methods of smoking—a procedure which has proved to be justified in relation to cancer of the lung. They conclude that the average risk of oral cancer among men who smoke cigars or pipes is somewhat greater than that for men smoking 35 or more cigarettes a day and four times greater than the risk for non-smokers. Similar data for alcohol consumption are more difficult to interpret owing to the tendency for heavy drinking and smoking to be found together in the same individual. The authors have, however, been able to make some estimate of the separate effects of each factor, and they conclude that the risk among heavy whisky drinkers may be as much as 15 times the risk to which men are exposed who drink only occasionally. In this case it is striking that, in contrast to the findings with tobacco, there is little increase in risk with more moderate consumption, and the authors suggest as one possibility that alcohol may exert an indirect action through association with nutritional deficiency, or that, by decreasing the amount of saliva, it might sensitize the mucosa to other external agents. In the classification used heavy whisky drinking is defined as the consumption of seven or more "shots" a day, so that it would certainly not be surprising if nutritional deficiencies were observed. What may be surprising to British readers is that 12% of the "control" patients admitted they had a daily consumption equivalent to this amount of alcohol in one or other forms. Not all types of oral cancer were equally associated with alcohol; for patients with cancer of the lip the association was slight or non-existent, while it was most marked for patients with cancer of the pharynx, floor of the mouth, or tonsil.

A history of syphilis or a positive serum test was found more often among the cancer cases than among the controls, but the excess was significant only for cancer of the lip or of the anterior two-thirds of the tongue. Other positive associations were also noted (particularly with regard to edentia), but the findings

were not altogether self-consistent and it will be necessary to await the detailed publication of the full results—and probably further studies of more cases—before they can be properly assessed.

Of particular interest is the contrast presented in the present paper between the findings in cancer of the lung, intrinsic and extrinsic larynx,⁴ and oral cavity. These go far to account for the paradox that, while cancers of all parts of the respiratory system are related to smoking, the mortality attributed to the individual sites has variously fallen, remained almost stationary, and, in one case, risen dramatically. Between 1935 and 1955, for example, crude annual death rates from cancer of the buccal cavity among men in England and Wales fell from 145 to 66 per million; during the same period the mortality from cancer of the larynx (intrinsic and extrinsic) decreased from 45 to 32 per million, but the mortality from cancer of the lung increased from 131 to 693 per million. These differences, it would now seem, may be explained by the almost complete change in habit from pipe smoking to cigarette smoking, accompanied by the reduction in the amount of spirit drinking and in the prevalence of syphilis. But though this appears to be a reasonable explanation the evidence is far from complete. It is, for example, unknown why tobacco smoked in different ways should affect such different parts of the respiratory system. To some extent the differences may be explained by the individual differences in the extent of inhaling, but it may also be that the physical state of the smoke particles on entering the mouth depends on the method of smoking and so affects the ease with which they are distributed throughout the respiratory system.

ELIMINATION OF STRONTIUM

Man but not fish is cunningly designed to retain calcium. Our renal tubules reabsorb most of the calcium from the glomerular filtrate, whereas the fish's kidney is largely a haemopoietic organ and excretes an ultrafiltrate. Since man clears in the kidney only about 2 ml. of plasma per minute¹ and the gut can do little if any better, most of the calcium circulating in the plasma is available for exchange with bone. It can be shown by means of radioactive tracers that the reaction $\text{Ca (plasma)} \rightarrow \text{Ca (bone)}$ is exceedingly rapid, so rapid that the total plasma must be cleared many times over in the course of an hour. Strontium, another alkaline earth, is chemically

like and widely distributed with calcium in nature, so that all natural sources of calcium in the diet contain strontium in amounts from about 0.1–1%. In human bone strontium is present to about 70–170 p.p.m. of ash,² which indicates that there is some discrimination by the body between calcium and strontium. In fact calcium is about twice as readily absorbed, and the kidney excretes it twice as readily.³ The mammary gland also differentiates between the two, so that milk is relatively poor in strontium.⁴

Radioactive strontium, especially the isotope strontium-90, is produced in some abundance in nuclear fission. It is considered to be the most hazardous of all fission products and as a result of the testing of nuclear weapons is now widely detectable in the soil and in plant and animal material. It would be desirable therefore to prevent its further uptake into man or to facilitate its removal if present in dangerous amounts. However, because the bone has such a great affinity for calcium and its analogues, the removal of strontium presents formidable difficulties. Some success has been announced from Boston.⁵ About one-third of recently injected strontium could be removed from the body of experimental dogs by means of an artificial kidney or by means of a cation-exchange column included in the circulation. Similarly, reports from Saclay⁶ show that cation-exchange resins fed to rats immediately after an oral dose of strontium result in a retention within the body of only about one-third of the amount retained by untreated control animals. Both these experimental essays make use of the favourable conditions immediately following the administration of the strontium, when it is still in circulation or held loosely by bone. As time elapses the element is held much more tenaciously.

LABORATORY CONTROL OF ANTI-COAGULANT THERAPY

Anticoagulant therapy with coumarin and allied drugs has been in general clinical use for over ten years. The generally accepted laboratory method of control has been the one-stage "prothrombin" test first introduced by A. J. Quick in 1935,⁷ who discussed certain features of it in this *Journal* two years ago.⁸ In 1951 P. A. Owren and K. Aas described a new method for the control of therapy with these drugs.⁹ The method of Owren and Aas has been called the prothrombin and proconvertin determination, sometimes abbreviated to the "P. and P." method. Most clinicians and pathologists responsible for the control of anticoagulant therapy have become familiar with the use of the one-stage test of Quick and have found it, in general, reliable, provided a brain extract is used as the source of thromboplastin. Because of this, the P. and P. method has not yet come into general use in Great Britain. Moreover, the preparation of the reagents is somewhat more complicated technically. But the method has been used at several centres particularly interested in these problems, and R. Biggs and W. Trillwood comment that the con-

trol is more sensitive, trends towards overdosage are more obvious, and the correct dose can be decided two or three days earlier than by the more usual method.¹⁰

The coumarin drugs interfere with the thromboplastin mechanism responsible for the conversion of prothrombin to thrombin and also cause some depression of prothrombin itself. The interference with the tissue thromboplastin system is by lowering the concentration of a coagulation factor called factor VII (proconvertin). In Quick's one-stage test a brain extract is added to the plasma and the plasma-brain mixture recalcified by the addition of calcium chloride, the clotting time being recorded. In addition to prothrombin and factor VII other components of the clotting mechanism may cause prolongation of the one-stage test as recorded in Quick's method. A further plasma coagulation component called factor V is responsible together with factor VII and brain extract for the conversion of prothrombin to thrombin in the tissue thromboplastin mechanism. The concentration of fibrinogen may also be of importance in causing prolongation of the one-stage test. In the P. and P. method as described by Owren and Aas steps have been taken to control the concentration of factor V and fibrinogen in the test system. A preparation rich in factor V and fibrinogen is obtained by the Seitz filtration of ox plasma. The Seitz filtration is carried out through paper pads with a specified content of asbestos under certain detailed conditions. This Seitz filtration removes the prothrombin and proconvertin (or factor VII) from the plasma, leaving the factor V and fibrinogen. A large amount of this plasma can be prepared and stored frozen at -20°C . in amounts suitable for daily use. To carry out the assay, the test plasma is diluted 1 in 10; 0.2 ml. of the ox plasma free of prothrombin-factor VII is mixed with 0.2 ml. of the diluted test plasma and 0.2 ml. of thromboplastin. This is then recalcified in the usual way and the clotting time recorded. The result on the test plasma is then compared with the results obtained from dilutions of a normal plasma in a similar system and the concentration read from a suitable dilution curve. In this test system the brain extract, factor V, fibrinogen, and calcium are all present in excess in standard amounts and the variable is the concentration of prothrombin and factor VII, which thereby is measured. It is probable that in Quick's technique the main factor controlling the prolongation of the one-stage test is the depression of factor VII, and the concentration of prothrombin itself is probably less significant in such a test system. In the P. and P. method, in which the test plasma is used at considerably greater dilution in the final test system, it may be that such a system is sensitive not only to the changes in factor VII but also to some extent to the changes in prothrombin concentration itself.

This newer method may well have advantages, but obviously it is not so simple as that described by Quick. The technique entails collection of the ox plasma and its preparation by Seitz filtration. Some British laboratories have modified the method in so far as they use adsorption by barium sulphate for the removal of prothrombin and factor VII from the ox plasma, finding this to be more constant in its action than Seitz filtration. When

it is decided to introduce the newer technique, it is wise not to abandon the older, standard method before the newer system has been given adequate trial in the individual laboratory.

DECLINE OF ACUTE RHEUMATISM

Rheumatic fever and rheumatic heart disease have for long been major causes of death in children and young adults, and even in 1955, of all the deaths at ages between 1 and 30 years, probably some 4% were due to acute rheumatic fever or to its late cardiac sequelae.¹ There is, however, clear evidence that the toll of acute rheumatism is declining. R. A. N. Hitchens² has recently reviewed the records of the clinic for acute rheumatism that was established by the school health service in Cardiff in 1929. He examined all the original case records in an endeavour to secure uniformity of diagnosis, and found that in the period 1931 to 1950 there were altogether 407 children who could be diagnosed as having had acute rheumatism with carditis and 341 who had had acute rheumatism without carditis. Inception rates were calculated by relating the number of children falling ill with a first attack of acute rheumatism in any year to the mid-year school population. Prevalence rates were based in the same way on the number of children known to have, or to have had, the disease in the particular year or earlier. During the first few years of the clinic's work the rates fluctuated somewhat, and the prevalence rate even increased, doubtless owing to increasing completeness of ascertainment. But from about 1935 onward there was a steady decline both in incidence and in prevalence. For example, the incidence of new cases with carditis and with a defined date of onset was 0.86 per 1,000 in the quinquennium 1931-5; it fell to 0.44, 0.35, and 0.29 in the three succeeding quinquennia. Prevalence rates fell from about 5.2 per 1,000 in 1935 to 2.3 per 1,000 in 1950.

This well-documented study by Hitchens has a precision that was necessarily lacking from most earlier reports of the decline of the disease, because these reports had to be based largely on mortality statistics. In 1949 J. Knowelden,³ reviewing the Registrar-General's figures, showed that mortality from rheumatic heart disease in children had declined between 1921 and 1938. J. A. Glover,⁴ in 1930, showed that the decline had been in progress since the beginning of the century, and A. Newsholme,⁵ in 1895, claimed that a decline had in fact started around 1875. Similar reports came from the United States^{6,7} and from Scandinavia.⁸

The decline is evidently real enough, but whether it is due to some decline in the pathogenic abilities of the haemolytic streptococcus—now accepted as an essential agent in the genesis of the disease—or to some improve-

ment in the resistance of the host is quite unknown. Hitchens makes the point that the decline in acute rheumatism was checked in the early 1930's, to be resumed again around 1935, and that this check coincided with a period of industrial depression, but his records do not really go back far enough to justify much argument on this point: the high prevalence of rheumatism in the early 1930's might have been associated simply with a widespread epidemic of streptococcal infection which was only partly reflected in the scarlet fever notifications. That the streptococcus is now less virulent than it was seems undoubted: among children under 15 years of age the death rate from scarlet fever has, in fact, decreased more than a thousand-fold since about 1860,¹ and the major decline occurred long before the advent of antitoxin or chemotherapy. Toxic scarlet fever is now extremely rare. In contrast, there is little evidence that streptococci are much less prevalent in the community now than they were. Equally there is no doubt that standards of living have improved. Hitchens discusses the various factors included in "standard of living" and suggests that the most relevant may be "quality of maternal care." But this is a very indefinite concept, and we still need to know just what it is that makes some children respond to a streptococcal infection by developing rheumatic fever. Until we know this we are unlikely to explain the fact that fewer children develop rheumatic fever to-day than previously.

IVAR THE BONELESS

In *A History of the English-speaking Peoples* Sir Winston Churchill tells how Ragnar Lodbrok the Viking was taken prisoner by King Ella, of Northumbria, cast into a snake-pit, and sang his death-song foretelling the vengeance his four sons would take. "The little pigs would grunt now if they knew how it fares with the old boar." The son destined to keep his father's promise by killing King Ella was Ivar the Boneless, a great warrior of command and guile, the master-mind behind the Scandinavian invasion of England in the last quarter of the ninth century. Dr. Knut Hatteland, who has undertaken an investigation of the incidence of osteogenesis imperfecta in three families in the north of Norway, has now traced the ancestry of Ivar the Boneless.²

He was the oldest son of Ragnar Lodbrok by his second wife, who was reared in great poverty in Norway. Lodbrok took her to Denmark, and on proposing to share a bed with her he was asked to bide awhile to meet her fancies. Disobliging, he paid the forfeit of having a first-born son, Ivar, with cartilages where bones should have been. He could not walk on his legs, and he was carried around on shields or bars. Yet his stature was such that he dwarfed all his contemporaries, and his wisdom was such that "it is doubtful if anyone has ever been wiser than he." In battle he was always in the van, determining its issue. His arms were so strong that his bow was more powerful and his arrows heavier than those of his companions, bending his bow as if it were an elm branch and twanging his bowstring to an

unheard-of pitch. After subjecting King Edmund of East Anglia to martyrdom, Ivar suddenly quitted England for ever. Laden with loot and seemingly invincible, he settled in Dublin and died there peacefully two years later. Of his bloodthirsty past and pious end, Churchill has written: "Thus it may be that he had the best of both worlds." Dr. Hatteland claims that Ivar's is the earliest-known record of osteogenesis imperfecta in the Scandinavian countries. He can find no record of this disease in any of Ivar's descendants. The sagas built up around Ivar are richer in poetic flights of the imagination than in sober descriptions of his physical handicap, so Dr. Hatteland has found it difficult to weigh the evidence for and against the diagnosis of osteogenesis imperfecta and possible alternative diagnoses. Any scrutiny of Ivar's bones is now out of the question, since William the Conqueror is said to have dug up his grave and burnt its contents in a great bonfire.

TREATMENT OF HEPATIC FAILURE

The treatment of cardiac, respiratory, and renal failure is based on a reasonably accurate knowledge of underlying physiological and biochemical processes. It is only recently that a similar approach has been made to the problem of hepatic failure.¹ Ascites and hepatic coma are the most important manifestations of the failing liver, and can often be treated very satisfactorily if the way in which they arise is properly appreciated. The development of ascites depends on a combination of portal hypertension and hypoalbuminaemia, and is associated with retention of sodium. Recognition of the sodium retention has led to a rational form of therapy, similar to that used in cardiac failure; it is based on bed rest, rigid salt restriction, and mercurial diuretics.² Intake of protein should be kept as high as possible unless there are signs of hepatic coma, and paracentesis should be avoided, except in the initial stages, since it drains off a considerable amount of protein. After a period of several weeks fluid no longer accumulates in the peritoneal cavity, and the albumin level in the serum rises. At this point it may be possible to allow a higher intake of sodium.

Hepatic coma is believed to be due to a failure in synthesis of urea, with subsequent intoxication by ammonia and other nitrogenous compounds. The most rational treatment therefore is to restrict the intake of protein, and as little as 20 g. a day can be tolerated for long periods.³ Carbohydrate should be given in large quantities, if necessary intravenously, to ensure an adequate intake of calories. A short course of chlor-tetracycline or neomycin is recommended to destroy nitrogen-forming bacteria in the gut. Unfortunately no specific drug is yet known for the treatment of hepatic failure comparable, for example, to digitalis. Glutamic acid is occasionally successful, but does not influence the

course of the more severe forms of hepatic necrosis.⁴ More recently an encouraging report has appeared on arginine, an amino-acid which plays a part in the formation of urea from ammonia.⁵ It is given intravenously, 25 g. of L-arginine hydrochloride being dissolved in 500 ml. of 10% dextrose; the dose can be repeated if necessary. More than half the fifteen patients studied, including two with severe viral hepatitis, responded favourably, but the course of liver failure is so unpredictable that larger numbers will have to be treated before conclusions are justified.

It is important to avoid the various precipitating factors of hepatic failure, since it is difficult to estimate the functional capacity of the damaged liver. Nitrogenous intoxication can be produced by ammonium compounds, amino-acids such as methionine,⁶ ion-exchange resins, and acetazolamide. Bleeding from oesophageal varices provides another source of protein which may be dangerous. For this reason control of bleeding by the Sengstaken tube, followed by gastric lavage, mild aperients, and high enemata has been recommended. Anaemia must be corrected, if necessary by blood transfusions, though these may increase ascites because of their high salt content. Morphine should be given sparingly, and the short-acting barbiturates are probably safer. Even minor surgical procedures are poorly tolerated, and it cannot be too strongly emphasized that porta-systemic anastomoses in patients with severe portal hypertension should be avoided until every effort has been made to ensure adequate liver function by conservative medical treatment.

SCOTLAND'S HEALTH IN 1956

About 70,000 people were occupied wholly or partly in running the Health Service in Scotland during 1956, 55,700 of them on whole-time work.¹ Medical men and women comprised only 10% of the whole-time workers, since they numbered 5,570. This was an increase of 68 over the previous year's total. In round figures, there were 1,400 dentists, 29,300 nurses and midwives, 2,800 pharmacists, 900 opticians, 2,300 medical auxiliaries, 4,300 administrative and clerical staff, and 23,000 ancillary and domestic staff. This great team between them succeeded in continuing to improve Scotland's health, especially the health of the children. At 28.6 per thousand live births, the infant mortality rate was below 30 for the first time. For schoolchildren aged 5-14 the main cause of death among the 343 deaths registered was accident (40%), and the second was malignant disease (11%).

Deaths from respiratory tuberculosis numbered 714 and non-respiratory tuberculosis 85, giving rates of 14 and 2 per 100,000 population. Only eight years ago, in 1948, these rates were 66 and 9 respectively. The proportion of "safe" milk sold in Scotland is now higher than anywhere else in the United Kingdom; 99.5% comes from cows which have passed the tuberculin test, and almost all the remaining 0.5% is pasteurized.

CONCEPTS OF SCHIZOPHRENIA*

BY

E. STENGEL, M.D., M.R.C.P.

*Consultant Psychiatrist, United Sheffield Hospitals;
Professor of Psychiatry, University of Sheffield*

Eugen Bleuler, the great Swiss psychiatrist, was born on April 30, 1857. During the next few months psychiatrists all over the world will hear and talk a great deal about schizophrenia. These discussions will reach their climax in September, when the International Congress of Psychiatry will meet at Zurich for the Bleuler centenary. I should like to make a small contribution to this world-wide discussion by speaking about concepts of schizophrenia, especially those of Bleuler, who coined the term.

Everyone who has attended meetings or clinical conferences on schizophrenia must on occasion have had the uneasy feeling that not all of the participants were talking about the same thing, and that, in fact, their concepts of schizophrenia differed considerably. The inconclusiveness of many a discussion among psychiatrists is partly due to their insufficient awareness of these differences. It therefore appears profitable to re-examine the concept of schizophrenia from its inception and to see what has become of it since it was first advanced.

It is often taken for granted that with the term, which caught on almost immediately, Bleuler's concept of the schizophrenias, too, was generally accepted. Such an assumption is unjustified. This is not surprising if Bleuler's concept is viewed in its proper historical perspective and in its relationship to other notions concerning this mental disorder or group of mental disorders.

Kraepelin and Dementia Praecox

The majority of textbooks give the impression that the Kraepelinian conception of dementia praecox (Kraepelin, 1919), which was based on symptoms and outcomes supposedly common to a large majority of cases, had reigned supreme from 1896, until it was superseded by that of schizophrenia which did justice to the frequent absence of deterioration and to the onset of the illness in various age groups. This is historically not quite correct.

When Bleuler first proposed the term "schizophrenia" in 1908, Kraepelin's concept of dementia praecox as a clinical entity was still highly controversial. It was opposed by a number of leading psychiatrists. Adolf Meyer had published his objections against it well before Bleuler. Meyer never accepted the notion of a disease entity. Kraepelin soon became aware of the shortcomings of the term "dementia praecox," which had been coined by Morel (1860). He conceded that a certain number of cases did not deteriorate and even recovered, and that the illness did not always start in young age. Bleuler himself did not regard his stronger emphasis on those two facts as his main contribution. On the contrary, he disclaimed any merit on that account. Referring to the concept of dementia praecox, he said in his monograph (Bleuler, 1911), almost angrily: "Peculiarly enough, one of the objections which even now can be heard frequently, especially abroad, is that we are dealing neither with dementia nor with precocity. Considering that Kraepelin defined his concept so clearly, and expressly referred to recoveries and to later onsets, this can be called a gross misunderstanding: those critics concentrate on the name, but they really reject the concept." Bleuler

endeavoured to gain recognition for it, though in a modified and less rigid form (the main title of his monograph was "Dementia Praecox," with a subtitle: "The Group of the Schizophrenias"). It cannot even be said that the widening of the area of schizophrenic manifestations was Bleuler's special contribution. Kraepelin's clinical concept of dementia praecox was for a certain period of its evolution quite as wide as Bleuler's. In what respect, then, did his concept differ from that of Kraepelin; and how much of Bleuler's contribution has stood the test of time?

Adolf Meyer and Eugen Bleuler

Bleuler and the other members of the Zurich school, among whom Jung was prominent, were profoundly influenced by Freud, whom Bleuler credited with having inspired his work. It is often forgotten that Kraepelin, Freud, and Bleuler were contemporaries, born in three consecutive years. The concept of schizophrenia presented by Bleuler in his monograph in 1911 was really a joint creation of those three men.

There is another historical fact which is insufficiently known, although it may explain the comparative indifference with which Bleuler's concept was received in the English-speaking countries. Adolf Meyer's theories of reaction types and habit deterioration, implying a rejection of Kraepelin, preceded Bleuler's concept; Meyer (1906) stated his views in a symposium on dementia praecox at the Annual Meeting of the British Medical Association at Toronto in 1906. His address contained in a nutshell practically the whole of his teachings. This article was known to Bleuler. Meyer's intervention in the discussion of dementia praecox several years before Bleuler had completed his work of modernizing Kraepelin was decisive for American psychiatry. Bleuler's monograph was translated into English only a few years ago, when Meyer's influence was already on the wane.

Bleuler's Hierarchy of Symptoms

Bleuler's clinical concept of schizophrenia is basically Kraepelinian, but with a greater emphasis on the variety of manifestations and developments. Compared with Kraepelin, Bleuler was much less pessimistic about the outcome, but nevertheless was more so than present-day psychiatrists. These differences concerning prognosis are not fundamental. They have obviously been largely due to the longer follow-up periods studied by successive generations of psychiatrists. Bleuler postulated some underlying structural cause. Some such working hypothesis has always been adopted by most clinical psychiatrists and underlies modern research into the experimental psychoses produced by drugs.

Bleuler distinguished basic, or primary, from accessory, or secondary, symptoms. The former were the disturbances of association and of affectivity as well as the patient's tendency to replace reality by fantasy which was responsible for the various manifestations of autism. Hallucinations, delusions, and all the other manifestations of schizophrenia were regarded as secondary.

Bleuler therefore, unlike Kraepelin, proposed a hierarchy of symptoms, of which the basic ones were supposed to be directly caused by the hypothetical organic process, while the secondary symptoms were regarded "partly as distorted mental functions, partly as the result of more or less unsuccessful, or even successful, attempts at adaptation to the primary disturbance." Here we meet already the concept of adaptation which has played a considerable part in more recent theories of schizophrenia. In differentiating primary and secondary symptoms, Bleuler was influenced by Freud, who, it seems, had been impressed by Hughlings Jackson's distinction between negative and positive symptoms.

Jung's "Complexes"

In the primary symptoms of disturbance of association, emotionally charged largely repressed groups of ideas, which Jung had called complexes, were regarded to be of particu-

lar importance. In his monograph on the psychology of dementia praecox, which appeared three years before Bleuler's book on schizophrenia, Jung (1909) had described the ways in which complexes became isolated in hysteria and schizophrenia and how they interfered with the normal processes of thinking. Any idea could become the nucleus of a complex, which may be transient and short-lived. Jung's and Bleuler's use of the term differed from its later use in psycho-analysis, where it was reserved for a very small number of emotionally charged ideas of great dynamic power and representing basic and universal tendencies. This difference illustrates the gradual replacement of association psychology by a more specifically Freudian dynamic psychopathology. Jung and Bleuler were not only concerned with the formal aspects of the formation and isolation of complexes in schizophrenia; they also studied their contents in relation to the individual's history along Freudian lines.

Bleuler made it clear that the assumption of an underlying organic process was not an essential premise to his concept of schizophrenia. He said: "It is not unthinkable that the symptoms may be caused psychologically, and that they may develop from slight quantitative deviations from the normal; in the same way as in some individuals the predisposition to hysterical symptoms is so great that they tend to react hysterically to the ordinary difficulties of life, while the average person does so only as the result of an exceptionally severe psychic trauma." However, Bleuler did not pursue this hypothesis further, as he favoured that of an organic cause.

Alternatives to Bleuler's View

What were the alternatives to Bleuler's concept of schizophrenia? One, of course, was strict adherence to Kraepelin, a course taken by many clinicians all over the world. Another alternative was Adolf Meyer's hypothesis of reaction types and habit deterioration, which was widely accepted in the United States and in this country. Meyer lacked Bleuler's clarity of thinking and he failed to formulate auxiliary hypotheses. Many psychiatrists found it difficult to understand how faulty habits in childhood should lead to schizophrenic symptoms and even to personality disintegration. Meyer did not expressly address himself to the question why this sequence of events should take place in some individuals and not in others. His aetiological theory, which most psychiatrists classified as psychogenic, is remarkable in that it did not undergo any noticeable change since it was first advanced 50 years ago. Its great value lay in the emphasis on the individual and his environment and their interaction. In his theory of the aetiological importance of current life situations he introduced an infinite number of changeable variables and discouraged discrimination between environmental factors of different pathogenic significance. His approach, though productive of therapeutic optimism, had the fundamental weakness of paying too little attention to the unknown.

The psycho-analytical theories of schizophrenia have developed almost independently of Bleuler's work. He refused to think in terms of mental energy. "We possess," he said, "no means of measuring psychic energy and therefore we are quite unable to discuss dynamic theories." For this reason he had no use for Janet's (1903) "abaissement du niveau mental" and similar notions, nor did he follow Freud, who thought in terms of mental forces. In Bleuler's concept of ambivalence the idea of conflict so fundamental to psycho-analysis did not enter. In fact, this word was hardly mentioned in his writings. There is another term which is conspicuous by its absence in his work—namely, that of regression, which one could almost call the alpha and omega of the psycho-analytical theory of schizophrenia; this mental disorder is viewed as a regression to one of the earliest phases of mental development. However, it is still highly problematical why such a regression should take place in some individuals. Most psycho-analysts seem to imply some kind of very early psychological influence still un-

known. The valuable psycho-analytical contribution to schizophrenia will come to fruition only when it is considered together with the knowledge of other factors, some of which will probably be non-psychological. Such a view is more in keeping with Freudian principles than a purely psychogenic hypothesis (Stengel, 1956).

There is yet another aspect of regression in relation to schizophrenia—that is, the anthropological; Storch (1924) described the similarities between schizophrenic and archaic-primitive modes of thinking and behaviour. This aspect, which has been neglected for some time, will no doubt come to the fore again with the increasing interest in the social and anthropological problems of schizophrenia.

Schizophrenia in the Melting-pot

What is the status of Bleuler's concept to-day? In 1951 Manfred Bleuler presented a balance-sheet of his father's work. His review, which was based on an unrivalled knowledge of the literature, was a sober statement free from filial sentimentality. Manfred Bleuler saw the most important recent development in this field not in the growth of the physical methods of treatment but in the shattering of the classical notions concerning schizophrenia. Every one of them had become questionable, although none of them had been finally refuted. The whole problem was in a state of fermentation to-day. What yesterday appeared to be generally accepted and established was to-day to some at best a precarious working hypothesis, to others a dogma to be fought, and to others again a fairy tale from a remote past. This applied to questions such as those of disease entity, of aetiology, of the influence of heredity and environment, etc. In his view the following facts stood out from the welter of theories and observations. (1) Even if a disease process—that is, an impersonal catastrophe—should play an essential part in the schizophrenic development, it did so in its relationship to the development of a personality. (2) All the observations which previously were regarded as indicative of an underlying somatic illness—that is, Bleuler's primary or basic symptoms—could nowadays be just as well or even better explained as secondary—that is, as results of the schizophrenic mental disorder with its profound emotional fluctuations and its abnormal behaviour. This also applied to all findings concerning abnormal physiological functions in schizophrenia. He regarded the effects of the somatic therapies as theoretically inconclusive. Manfred Bleuler concluded that we had tried to answer the wrong questions, especially in examining heredity and environment as independent factors and in insisting on the artificial antithesis of organic versus psychogenic aetiology. Manfred Bleuler's appraisal of the present state of the theory of schizophrenia is both correct and fair.

In addition to the psycho-analytical approach there are a variety of concepts which derive from current biological, sociological, or philosophical trends. The following are representative modern views on schizophrenia.

Hoskins (1946) expressed the view that this psychosis represented an end-result of a general failure of adaptation arising from a defective evolution of the maturing process. Manifestations of this failure were defective somatic and psychic homeostasis, defective empathy, and final disintegration of the personality. The accessory symptomatology of the psychosis constituted secondary adaptations to the difficulties arising out of the primary defect. These are Bleuler's ideas expressed in the language of adaptation theory.

Norman Cameron (1944) regards inadequate empathy as the primary defect. He formulated his theory of schizophrenia thus: "social disarticulation resulting from the cumulative replacement of communication by private fantasy, in persons who have been unable to establish themselves firmly in their cultural pattern, because of failure to develop adequate role-taking skills." This formulation does not go beyond Bleuler and Meyer, but a new approach was

*A Maudsley Bequest Lecture delivered on November 12, 1956.

adumbrated when Cameron expressed the view that the study of interpersonal relations and their changes in schizophrenia must also include the social fields within which all human organisms operate. This and similar ideas have recently led to interesting researches into the ecology of schizophrenia.

Harry Stack Sullivan (1940) also stressed, almost exclusively, the social aspects in the aetiology and symptomatology of schizophrenia. To him psychiatry was the study of disturbed interpersonal relations. He distinguished dementia praecox, which he regarded as an organic process, from a variety of schizophrenic personality developments arising from situations of panic and resulting in a throw-back to the interpersonal relations of earliest childhood. Sullivan combined Freudian, Meyerian, and sociological concepts with a philosophy of his own. He spoke of "a collapse of the individual-world synthesis" and of "the resort to a wild compensatory programme leading to schizophrenia." He regarded personalities and mental disorders as abstractions: "There are only degrees of developments and vicissitudes of the communal existence of the person with others."

Current Continental Trends

I should like to make some brief comments on concepts of schizophrenia prevailing on the European Continent. Bleuler's hierarchy of symptoms and the psychological theories underlying it were not generally accepted, though most of his clinical observations were incorporated into European psychiatry.

A new and important aspect was introduced with the differentiation of process schizophrenia and defect schizophrenia, an attempt which has never quite succeeded. Another modification of Bleuler's clinical system was the distinction between a nuclear and a marginal group of schizophrenias, which again has not found general acceptance. Similar proposals of a differentiation within, or even a dissolution of, the clinical entity of schizophrenia have been made repeatedly. The concept of the schizoid personality, which was launched by Bleuler and elaborated by Kretschmer, was an addition of fundamental significance from both the clinical and the theoretical point of view.

The most important trend in Continental psychiatry since Kraepelin and Bleuler has been the phenomenological orientation which has cultivated a careful study of the subjective psychological experiences in mental illness. From the clinical point of view, it has aimed at establishing diagnostic and prognostic criteria based on differences of subjective experiences. This school of thought has created a vocabulary of its own which makes translation into other languages difficult. Their standard work is Jaspers's *Allgemeine Psychopathologie*, which appeared in 1913, only two years after Bleuler's monograph. It is an amazing fact that psychiatry is still living on the capital investments made by a few brilliant men before the first world war. This is especially true for the concepts of schizophrenia. Jaspers has found a successor in Ludwig Binswanger (1946), who, like Bleuler and Meyer, is a Swiss psychiatrist. He is the father of "existential analysis," which, he maintains, owes a great deal to Jaspers and Freud. He tries to establish in what kind of subjective world, or worlds, the schizophrenic lives and thus to understand his mode of existence and its changes. He regards his method as fundamentally descriptive. He claims that even in advanced schizophrenia the human mind has at its disposal definite principles of organization and structure. According to Binswanger this kind of analysis enables the psychiatrist to communicate with his patients more closely than other methods and to help them by psychotherapy which has to be based on careful study of the individual case.

This approach is not as remote from current trends as it may appear. It has something in common with the theories of Cameron and Sullivan, whose ideological background, is, of course, different from Binswanger's. While he speaks of "being in the world" and "existence," they talk of interpersonal relations and empathy, but fundamentally they

mean something very similar. The need for establishing contact with the schizophrenic on his own ground for the purpose of treatment has been repeatedly stressed by psychoanalysts; they have no doubt that the schizophrenic's world is fundamentally that of the infant, while Binswanger would allow himself to be guided mainly by his patients' experiences. Also, the emphasis on "object relations," which started as a controversial issue in psycho-analysis, is bound to lead to a closer study of the social field of which the individual is a part. But existential analysis in its present form has great limitations. While it may be a method of getting closer to certain types of patient and thus gaining a full insight into some aspects of delusions and abnormal behaviour, it is difficult to see how it can advance knowledge of the aetiology of a condition such as schizophrenia. There is a growing awareness among those interested in this approach that it requires to be integrated with other methods.

Conclusions

This review demonstrates the divergences of the concepts concerning this vast group of mental disorders. Psychiatry has in this field not progressed beyond working hypotheses, of which Bleuler's hypothesis can be regarded as the one which was the most comprehensive when it was first advanced, and which even now, if brought up to date, poses more relevant questions than any other. It is often believed that attempts at clarification of concepts are futile in the present state of knowledge but to-day, when there is so much therapeutic and experimental activity, it is more than ever important for psychiatrists to look after their tools of communication. It cannot even be said that, although we are using different concepts of schizophrenia, we know a schizophrenic when we see one.

There are many indications that differences of theoretical concepts, however vaguely held, are frequently responsible for diagnostic disagreements. The uncertainty about the effects of various treatments would be less general if there was a closer understanding among psychiatrists about the conditions they are treating. Similar difficulties exist in experimental psychiatry. The important question of the relationship of the "model psychoses" experimentally produced by drugs to mental illness cannot be answered without reference to concepts such as those discussed here. Some psychiatrists take it for granted that they are dealing with experimental schizophrenia, but this has been contested by others.

There is a tendency among research workers to get away from current concepts of mental illness altogether and to concern themselves with fundamental phenomena, but some of these workers seem to be unaware that they are doing this, and they continue to talk and to write in terms of current clinical concepts to which they pay scant regard. Such a state of affairs is apt to reduce the value of many interesting observations. These are only some of the reasons why careful attention to concepts is essential for progress in psychiatry.

MEDICAL RESEARCH AND ANIMAL WELFARE RESPONSIBILITY OF THE EXPERIMENTAL WORKER

[FROM A SPECIAL CORRESPONDENT]

The old controversy on vivisection is regrettably still with us, and anything that can manifestly integrate scientific inquiry and animal welfare is a blow to this particular folly. Such was a symposium on "Humane Technique in the Laboratory," organized by the Universities Federation for Animal Welfare and held at Birkbeck College, London, on May 8. Professor P. B. MEDAWAR, F.R.S., took the chair.

Considerate Experimentation

Introducing the symposium, Major C. W. HUME, secretary-general of the Universities Federation for Animal Welfare, drew attention to the two separate aspects of humane-ness towards laboratory animals: good husbandry, which needs no defence, and considerate experimentation, which is the aim of all normal workers. It was the latter aspect with which the symposium was especially concerned. Improvements in technique could be effected in three ways. Sentient animals could be replaced by non-sentient animals, by biological systems of a lower order, or by non-biological systems. Reduction in the number of animals required for a given test could be brought about by choosing the most suitable species or strain, regulating the environment appropriately, and applying statistical methods to observations so as to make them yield the maximum information. Lastly, refinements designed to reduce or eliminate pain from experimental procedures should always be pursued.

The use of laboratory animals in this country was put in perspective by a discussion on logistics by Dr. W. LANE-PETTER, director of the Medical Research Council's Laboratory Animals Bureau. Enough information had been collected by the Bureau to show not only how many animals were used, for what purposes, in what sort of laboratories, where they came from, how they fell short of ideal quality, and what had to be done to improve matters, but also to indicate future trends in demand and how they could be anticipated. This information was useful in ensuring that the biologist continued to be supplied with adequate experimental material. It also showed where efforts to improve conditions should be directed to produce the most effect.

The criteria of a humane technique were considered by Miss PHYLLIS G. CROFT, Ph.D., research fellow of U.F.A.W. Dr. Croft insisted that the necessity for a potentially painful procedure must be established in every case. Care must also be taken to rid the experiment of as much of its element of discomfort as possible by expert handling and management, good design, suitable anaesthesia and manipulation, and, finally, euthanasia. The presence and degree of pain in animals were hard to define, but it was possible to assess them by analogy with human experience and by physiological and other evidence.

Dr. W. M. S. RUSSELL, D.Phil., also a U.F.A.W. research fellow, developed the theme introduced by the first speaker, of taking the animal pain or discomfort out of biological inquiry. His three "R's"—replacement, reduction, and refinement—formed a neat classification of the next nine papers.

Alternatives to Animals

The replacement of sentient animals by micro-organisms was well illustrated by Mr. G. SYKES, M.Sc., head of the microbiology division of the standards department of Boots. There were many similarities between animal and bacterial nutrition, he said. Given a suitable choice of organism and of assay, these similarities could be exploited by various techniques. Assays of vitamins and amino-acids were among those susceptible to this treatment. Similarities, however, were particular, not general, and care was neces-

sary in relating microbiological assays with clinical findings—a warning that applied to every investigation on a substitute, whether inanimate, living but non-sentient, or higher laboratory animal.

Another type of lowly substitute for experimental animals, tissue culture, was discussed by Dr. F. K. SANDERS, D.Phil., director of the M.R.C. virus research group at the London School of Hygiene and Tropical Medicine. In a sense the use of a tissue culture was not so much replacement of a higher animal by a lower organism or a chemical system as the selection of a relevant and immortalized fraction of the higher animal. Dr. Sanders showed, from his own experience in virus research, that tissue culture could be made to yield in appropriate cases information both of a precision and of a kind unobtainable when whole animals are used.

Dr. W. GREY WALTER, Sc.D., of the Burden Neurological Institute, Bristol, going a stage further, showed the possibilities of machines in working out problems normally presented to animals or parts of animals. There was nothing new in using forks for fingers or abaci for mental arithmetic, but developments of electronic apparatus in recent years had enormously enlarged the field of replacement of biological systems by physical ones, he said. Moreover, the use of machines might even present advantages, because the components of a mechanical system could be accurately enumerated and specified.

Control of Variance

When animals are being used for quantitative estimations there is obviously a great advantage in ensuring that the individual animals show a maximum degree of uniformity: the less variation between individuals, the fewer animals required for a given degree of precision. There are two main causes of variation in a group of animals—namely, genetical and environmental. The genetical aspects were dealt with by Dr. LANE-PETTER, who discussed the relationship between variations due to genetical and environmental causes. They were not simply additive, nor were they simply complementary. So it came about that a group of animals which, through inbreeding, had been rendered very similar genetically, might because of their increased homozygosity prove extremely labile or sensitive to small changes in the environment. There could, therefore, be great uniformity in the genotype but increased variability in the phenotype. One way of mitigating this disadvantage was to make first-generation crosses between different inbred strains. The result was a group of genetically similar but generally heterozygous animals possessing all the stability which heterozygosity normally confers.

Environmental aspects of variance control were discussed by Dr. M. R. A. CHANCE, of the department of pharmacology, Birmingham University. He drew attention to our considerable ignorance of the profound effect that certain environmental factors can have upon the biological responses of common laboratory animals. Not only was this so in regard to such obvious factors as temperature, amount of light, and type of diet, but such relatively unexpected factors as the number of animals in a cage and the type of cage in which they were confined were also capable of producing variable responses in certain types of bio-assay. In a further contribution to the symposium Dr. CHANCE emphasized the importance of taking note of the animals' innate behaviour pattern. Details of day-to-day management, which might be arranged or altered to suit human convenience, could be profoundly disturbing to the animal, and this might be reflected in an increased variability of the group. On the other hand, a little trouble taken in training animals to co-operate, so to speak, in the test for which they were being used might remove a substantial element of variability and effectively increase their uniformity.

Technical Handling

Miss CROFT discussed aspects of anaesthesia. For much experimental work it was necessary to sedate or anaesthetize

the experimental animal, and much depended on the actual technique involved in bringing about a state of anaesthesia. Technique, indeed, was just as important as pharmacological knowledge. Recognition of the state of anaesthesia of the experimental animal was, of course, of supreme importance. This was especially so if relaxant drugs were being used because of the risk of the effect of the anaesthetic wearing off while the relaxant was still acting.

In a final paper Dr. RUSSELL showed how refinement in methods of research with animals could contribute substantially to a humane approach. It was a commonplace for research workers attempting to design original experiments to discover that their first thoughts were unnecessarily complicated or likely to be inconclusive. Further thought might lead to a more clear-cut, crisp design, or, put in other words, to a more elegant experiment. Elegance, in this sense, embraced not only scientific suitability but also humane considerations.

A Significant Occasion

To devote a whole symposium, a whole day's meeting, to the consideration of humane technique in the laboratory may appear to some people to be an extravagant waste of scientific time. This point of view might be supportable if it were shown that animal suffering was incapable of interfering with scientific investigations or observations, and also if it were considered to be beneath human consideration in any event. The fact is, however, that suffering or pain is in most cases to be avoided for purely scientific reasons because it is an undesirable cause of variability, and in all cases because we have an obligation of humanity towards our experimental animals. So far, therefore, from being irrelevant, a symposium of this nature is a landmark comparable to those other occasions when British scientists have demonstrated their awareness of humane obligations; such as, for example, in 1870, when the British Association appointed a committee to consider the subject of physiological experimentation, or when, in 1927, the British Medical Association held a conference on animal experimentation. Such occasions give the lie to those opponents to the use of experimental animals who would endeavour to stop this method of inquiry and, in so doing, bring medical research to an end.

POLIOMYELITIS VACCINATION TO CONTINUE DURING THE SUMMER

The following statement on poliomyelitis vaccination has been received from the Ministry of Health. The Joint Committee mentioned in the statement is a committee of the Central and Scottish Health Services Councils.

Among the questions which the Joint Committee on Poliomyelitis Vaccine, under the chairmanship of Lord Cohen, has considered was whether it was necessary to suspend poliomyelitis vaccination during the summer months. It will be recalled that last year vaccinations were stopped at the end of June. This was because of the lack of knowledge of the possible danger of provoking poliomyelitis by vaccination.

The Committee sought detailed information from the directors-general of the Public Health Services of Australia, Canada, Denmark, the Federal Republic of Germany, South Africa, and the United States on the wide-scale use of poliomyelitis vaccine at various periods of the year. The experience in this country following the vaccinations done in May and June last year was also reviewed. Information was provided by the surgeon-general of the United States Public Health Service on the experience following administration of poliomyelitis vaccine in all seasons. In Canada no case of provocation poliomyelitis has been reported, and in Australia provocation poliomyelitis has not been encountered in well over one million injections. From this and other information received from the countries which had used poliomyelitis vaccine there seemed to be unanimity on

the absence of provocation poliomyelitis following poliomyelitis vaccination. In Great Britain nearly 400,000 injections of poliomyelitis vaccine were given in May and June last year, and here again no evidence was found that vaccination provoked paralysis. In none of the three cases of paralytic poliomyelitis which occurred in vaccinated children in May, June, and July, which were reported to the Ministry, did there seem to be evidence of the attack having occurred by reason of the use of the vaccine.

After consideration of this information the Committee recommended that poliomyelitis vaccine need not in general be suspended during the period when the disease was prevalent on the ground that the disease might be provoked by the use of the vaccine, as no evidence of provocation existed. Accordingly, distribution of vaccine to local health authorities will continue throughout the year as supplies become available, but it will be for medical officers of health to determine, in the light of local conditions, whether to suspend vaccinations in their area or not.

ELECTRONICS IN MEDICINE

[FROM A SPECIAL CORRESPONDENT]

It is fashionable to refer to the present period as the electronic age. But few people, professional or lay, are aware of the impact this relatively new field is having on their work or of the pace at which it is developing. During the last two weeks nearly 200 firms have been showing their latest products at Olympia, at the Instruments, Electronics, and Automation Exhibition. The relevance of many of these instruments to medicine, and particularly for the bench worker, is attested by the fact that one of the seven conferences held in connexion with the exhibition was entitled "Medical Day." At it Professor J. ROTBLAT (St. Bartholomew's Hospital Medical School) spoke on instrumentation in medicine, Dr. D. G. MELROSE (Postgraduate Medical School of London) on the artificial heart-lung, and Mr. N. VEALL (Guy's Hospital) and Mr. E. W. PULSFORD (Atomic Energy Authority) on electronic instruments for clinical tests with radioactive isotopes.

On visiting the exhibition one was impressed at once by the number and variety of instruments available in all fields—from the balance which will weigh with an accuracy of one microgram to remote-control manipulators designed to handle with safety large quantities of radioactive material.

A great many firms displayed "automatic chemists," which in general consist of an apparatus capable of titrating an acid or basic solution to a pre-selected end-point and recording the result on a chart. Although some of the less complicated models are reasonably priced (down to £200) and would be very useful in routine laboratory work, they will certainly not replace the chemist. In addition an automatic apparatus for pipetting and mixing liquids from a number of different reservoirs was demonstrated. This too could be very useful in hospital dispensaries; once the vessels were filled with the appropriate solutions a technician could accurately dispense a large number of identical prescriptions in a short time.

There were also a number of displays of more direct clinical interest. The newest version of the artificial heart-lung machine originally developed by Melrose at the Postgraduate Medical School of London was on show. Essentially the pumping action is produced by means of an undulating metal plate squeezing a plastic tube which leads directly from the vascular bed. Valve action is obtained by two sets of smaller metal plates which clamp the tube shut. Three such tubes are synchronized by means of cams to reproduce the complete heart cycle. The lung consists of a rotating "perspex" cylinder containing a number of perspex disks within the lumen and into which oxygen can be admitted. The cylinder is maintained at a slight angle to the horizontal, and the blood, which enters through the upper end, flows down the cylinder under gravity and is picked up by the moving perspex disks and exposed to the oxygen. Although no figures were available, there is little doubt that

this design produces a minimum of red-cell destruction. The apparatus has now been used successfully for a number of years.

Another ingenious instrument is the apparatus developed at the Middlesex Hospital for the continuous measurement of the diastolic and systolic blood pressure. The pressure is measured in a finger. A piezo-electric crystal on the finger responds to variations in the digital pulse, and the output from the crystal is then used to control the pressure in an occlusion cuff surrounding the finger; hence a continuous recording is obtained.

A fully automatic blood-cell counter aroused considerable interest. The instrument used the wide-track scanning principle with a stationary beam and moving specimen. The compensation for "edge effect" was made by successively scanning the field with two slits of different size, the count of the smaller being subtracted from that of the larger. This technique makes the count independent of the upper size of the cell, the size distribution, or cell shape. The actual time taken for a cell count is approximately one minute; assuming an error due to dilution and chamber-filling of $\pm 3\%$, the total error in the count would be $\pm 4\%$. At the present time the cost of the instrument (£650) makes its purchase by other than a hospital or large clinic impracticable.

A bench version of the famous Histokine was displayed. This instrument automatically goes through the entire cycle of tissue fixation, dehydration, washing, staining, and setting in wax or "celloidin," thus eliminating much of the tedium involved in routine histological preparations. Once set in motion no further attention by the operator is required. The instrument is readily adaptable to a number of chemical processes.

PRESENT STATUS OF GLUCAGON

ANNUAL LECTURE TO SOCIETY FOR ENDOCRINOLOGY

The existence of a hyperglycaemic factor in extracts of the pancreas has been suspected ever since Banting and Best first isolated insulin. Although much work has been done in this field in the past 35 years, the position is still far from clear, and Professor C. DE DUVE, of Louvain University, delivering the annual lecture to the Society for Endocrinology on May 8, chose as his subject "The Present Status of Glucagon." He reminded his audience that five years earlier he had been able to say, "Glucagon is the long-sought hormone of the α cells and acts as an antagonist to insulin." Now the position was less satisfactory.

Relationship to Insulin

Professor DE DUVE examined the evidence concerning three most important aspects of glucagon: its mode of action, site of formation, and hormonal status. Did glucagon act antagonistically to or synergistically with insulin? In the intact animal the overall effect was that of antagonism. If insulin were injected, a normal blood-sugar level could be maintained by infusion of glucagon without any significant change in muscle and liver glycogen or in the excretion of urea. On the liver, glucagon exerted a catabolic effect on carbohydrate, fat, and protein metabolism opposed to that of insulin. This fact was illustrated by an experiment in which the effect of insulin and glucagon was separately studied on the incorporation of ^{14}C into glycogen, carbon dioxide, fatty acids, and cholesterol by liver slices incubated in media containing ^{14}C -labelled glucose and fructose.

Peripherally the action of glucagon was less clear. Some experiments suggested an anti-insulin action at the periphery, but others failed to show this; while a third group of experiments had shown an insulin-like effect on the isolated rat diaphragm. Professor DE DUVE suggested that since the crystalline preparations of glucagon used in recent years were not prepared by a method involving specific inactivation

of insulin, as were earlier preparations, they might have been contaminated with insulin. If so, this would explain the insulin-like activity noted in some experiments. However, if glucagon were a hormone, the peripheral effects were probably of only secondary importance, since the liver, through which the hormone would first have to pass, contained a very powerful glucagon-destroying system. Thus he envisaged glucagon as a specific corrector of insulin, suppressing or reversing the effects of insulin on the liver, but with little peripheral action.

An essential tool in the search for the site of glucagon biosynthesis is an adequate bioassay procedure, and here the lecturer emphasized the need for adequate statistical control. The most straightforward technique employed the intact animal, but to compare even two samples of glucagon 300 rabbits would be needed to make the assay statistically sound, he said. With the liver-slice assay only two animals were needed, but there were difficulties due to a potentiating effect of traces of insulin, the insulin inhibiting the inactivation of glucagon by the liver slices.

Professor DE DUVE said he thought the evidence for the α -cell origin of glucagon was overwhelming, citing the high concentration of glucagon found in foetal pancreas and in the pancreas of certain species of birds which contain a high proportion of α cells. There was also a good histological correlation between the distribution of the α cells and glucagon concentration within the pancreas of the dog. In the pancreas of the dog the proportion of islet tissue, insulin, and glucagon increased from the head of the pancreas to the tail. In addition the head (processus uncinatus) contained very low amounts of glucagon relatively to its insulin content, and it had been recently shown that the islets in this part of the pancreas were essentially lacking in α cells. In the guinea-pig too, where cobalt caused reversible injury to the α cells, there was a good correlation between this α -cell damage and loss of glucagon.

Is Glucagon a Hormone?

Whether or not glucagon is a hormone had not been finally settled, although the indications that it is were very strong. Glucagon was a peptide of molecular weight 4,500. It exerted powerful specific effects on various metabolic processes in the liver at very low concentrations of the order of 10^{-8} molar, distant from its site of production. There was also other, albeit rather indirect, evidence to support a hormonal status. For instance, diabetic animals with α cells had larger insulin requirements than those without; and synthalin A and some other compounds which caused cell damage limited to the α cells also provoked hypoglycaemia. Bornstein, Reid, and Young had obtained evidence for the presence of a hyperglycaemic factor in the pancreaticoduodenal veins of cats treated with growth hormone, but Best and his colleagues, who repeated this observation on dogs, found that if the blood were injected into an ergotamine-treated animal the effect was inhibited. This would seem to preclude glucagon being the hyperglycaemic factor involved in this instance. In spite of this, the other evidence would seem to justify Professor DE DUVE's closing verdict on glucagon, "If not a hormone it jolly well ought to be."

The current issue of the *Mouse News Letter* (No. 16) includes information from some 30 laboratories from all over the world on the strains of mice they maintain. A *Collected News* number is available from the Laboratory Animals Bureau, and includes all reports of inbred strains, substrain symbols, mutant genes and linkages, up to *Mouse News Letter* No. 15. The next issue of the *Mouse News Letter* (July, 1957) is a consolidated number which will include information on all stocks of inbred strains, other strains, and mutants held by regular contributors to the *News Letter*. Inquiries about the *Mouse News Letter* should be sent to the Director, Laboratory Animals Bureau, M.R.C. Laboratories, Holly Hill, London, N.W.3.

Correspondence

Because of heavy pressure on our space, correspondents are asked to keep their letters short.

Radiological Hazards

SIR,—A committee was set up last year by the Secretary of State for Scotland and the Minister of Health "to review the present practice in diagnostic radiology and the radiotherapy of non-malignant conditions, with the object of considering the hazards involved." This review was recommended by the Medical Research Council in their report on "The Hazard to Man of Nuclear and Allied Radiations," for they found that medical radiology is in fact the chief source of the extra radiation to which we are now exposed. They emphasized the genetic damage which might be caused by irradiation of the gonads, and it is this damage with which our committee is chiefly concerned. Its importance is difficult to assess, but it means that we must not neglect even very small sources of radiation.

Since I fear that our inquiries are bound to add to the work of busy people I hope you will allow me to describe the investigations which we have in mind. Our first requirement is a more accurate estimate of the amount of gonadal radiation over the whole population, for the genetic hazard depends ultimately on the total rather than on the individual dose, and we must know the present figure if we are to keep in touch with future developments. To obtain such a base-line we need a survey of the total number and type of x-ray examinations carried out within a given period, followed by estimations of the gonadal dose in a representative sample.

We have already sent out detailed questionnaires to make a census of all medical and dental procedures involving x rays and radioactive substances, and a similar more limited inquiry will be made six months hence to take care of any seasonal fluctuations which might affect the result. To measure the probable dose to the gonads in different radiological procedures we are asking a number of hospital physicists to make a detailed investigation in a sample group of about 100 hospitals. This will enlarge the excellent surveys which have been carried out already in particular departments, and when it is finished we shall have a figure for the total gonadal radiation in this country which should be at least more accurate than any former estimates, here or elsewhere.

We are told that any exposure of the gonads may induce some mutations and that all mutations are more likely to be harmful than beneficial. But medical radiology must not be unduly hampered; the possible harm to the race must be set against the certain benefit to the individual. We must aim, however, at reducing all unnecessary exposure of the gonads, and with this in view the committee has formed small specialist groups which are to consider individual procedures in different clinical fields and to suggest measures for improving their safety.

In seeking through your columns to put this information before the profession as a whole, my committee hopes to enlist the interest of all those whose work touches on the use of x rays and radioactive substances. We are fully aware of the inconvenience and extra work we are causing, and we have learnt with regret of occasional failures in our arrangements for giving notice of the survey. But we believe that the final result will justify what we are doing. We live in a period when a rise in the level of man-made radiation cannot be ruled out and ought not to go undetected. It is disturbing to think that medical radiology may be causing unnecessary exposure of the gonads and that it may cause more if we take no steps to measure the present level. We hope that all doctors and dentists will co-operate with us in our work.—I am, etc.,

Cambridge.

ADRIAN.

Danger of Iso-immunization from Intramuscular Blood Injections

SIR,—A recent case has illustrated the danger of iso-immunization to a blood-group antigen (in this case Rhesus D) from the intramuscular injection of donor blood. Blood was being matched for a male patient prior to operation for partial gastrectomy and the patient was found to be group B Rhesus D-negative (d). Since there was no history of previous blood transfusion and repeated transfusions were unlikely, group B Rhesus (D)-positive blood was matched as well as group B Rhesus-negative blood (cde). The latter was compatible, but the former incompatible by the indirect anti-globulin (Coombs) technique. Subsequent investigation showed that there was anti-D present in the patient's serum in the incomplete form detectable by the albumin and by the indirect anti-globulin technique.

The behaviour of the anti-D suggested that it was an immune type of antibody, but there was no history of a previous blood transfusion. Detailed investigations subsequently have failed to reveal any previous transfusion of blood, but 27 years ago the patient did receive two intramuscular injections, each of 10 ml. of malarial blood, for treatment of general paralysis of the insane.

While intramuscular injections of donor blood are probably not now given on a large scale, the danger of blood group iso-immunization should be kept in mind. The writers have in fact encountered a case of severe haemolytic disease of the newborn in a first pregnancy in a Rhesus-negative woman who had never received a transfusion of blood, but had previously been treated with intramuscular injections of her husband's blood (Rh D-positive).—We are, etc.,

Glasgow.

IAIN A. COOK.
JOHN WALLACE.

SIR,—The recent correspondence in the *Journal* on "The Hurt Brain" draws attention to the fact that, though most venereologists and psychiatrists use penicillin alone or with other drugs for the treatment of neurosyphilis, there are still some who also use malaria therapy for selected cases.

A recent case seen by one of us developed a severe haemolytic anaemia of idiopathic acquired type during malaria therapy. During the serological investigation of the acquired haemolytic anaemia the patient's serum was found to contain the immune Rhesus antibody anti-D active at 37° C. in saline and albumin. The only history of exposure to red-cell antigens was the intramuscular injection of malarial blood some three weeks previous. A sample of blood from the donor of the malarial blood was obtained and this grouped as O, CDe/CDe. In view of the absence of transfusion history and in the fact that the anti-D gave the characteristics of an immune antibody, we feel the source of the immunization was the malarial blood.

The literature contains few references to immunization by intramuscular injection of blood, and the only proved cases known to us were reported by Thomson and Walsh¹ and van Loghem.² Subsequent inquiries of users of malarial blood leads us to believe that the possibility of immunization by intramuscular injection is not fully appreciated.—We are, etc.,

Doncaster.
Sheffield.

Women's Footwear

SIR,—A few weeks ago, as I left a lecture in the West End on Eastern colour prints and went into the darkness of the streets, I was faced with a series of such brilliantly lighted windows that for a moment I thought I was still in the lecture hall. I looked again and thought that these were a series of magnificent modern paintings. This was not the case. I looked again more closely and thought I was looking at a museum of ladies' shoes. Even this was not the case. I looked even more intently at a window and saw
